Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Doroła Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: An End-to-End Deep Learning System for Recommending Healthy Recipes Based on Food Images

Authors: Ledion Lico, Indrit Enesi, Sai Jawahar Reddy Meka

PAGE 1 – 7

Paper 2: An Automatic Framework for Number Plate Detection using OCR and Deep Learning Approach

Authors: Yash Shambharkar, Shailaja Salagrama, Kanhaiya Sharma, Om Mishra, Deepak Parashar

PAGE 8 – 14

Paper 3: Convolution Neural Networks for Phishing Detection

Authors: Arun D. Kulkarni

PAGE 15 – 19

Paper 4: A Radial Basis Network-based Early Warning Algorithm for Physical Injuries in Marathon Athletes

Authors: Ruisheng Jiao, Juan Luo

PAGE 20 – 27

Paper 5: Classification of Hand Movements Based on EMG Signals using Topological Features

Authors: Jianyang Li, Lei Yang, Yunan He, Osamu Fukuda

PAGE 28 – 36

Paper 6: Research on Automatic Intrusion Detection Method of Software-Defined Security Services in Cloud Environment

Authors: Xingjie Huang, Jing Li, Jinmeng Zhao, Beibei Su, Zixian Dong, Jing Zhang

PAGE 37 – 43

Paper 7: Experimental Analysis of WebHDFS API Throughput

Authors: Yordan Kalmukov, Milko Marinov

PAGE 44 – 50

Paper 8: Gradually Generative Adversarial Networks Method for Imbalanced Datasets

Authors: Muhammad Misdram, Muljono, Purwanto, Edi Noersasongko

PAGE 51 – 58

Paper 9: Human Fall Detection for Smart Home Caring using Yolo Networks

Authors: Bo LUO

PAGE 59 – 68

Paper 10: Investigation of You Only Look Once Networks for Vision-based Small Object Detection

Authors: Li YANG

PAGE 69 – 82

Paper 11: A Novel Data Aggregation Method for Underwater Wireless Sensor Networks using Ant Colony Optimization Algorithm

Authors: Lianchao Zhang, Jianwei Qi, Hao Wu

PAGE 83 – 93

Paper 12: A New Machine Learning-based Hybrid Intrusion Detection System and Intelligent Routing Algorithm for MPLS Network

Authors: Mohammad Azmi Ridwan, Nurul Asyikin Mohamed Radzi, Kaiyisah Hanis Mohd Azmi, Fairuz Abdullah, Wan Sifi Halimatul Munirah Wan Ahmad

PAGE 94 – 107

Paper 13: Plant Disease Classification and Adversarial Attack based CL-CondenseNetV2 and WT-MI-FGSM

Authors: Yong Li, Yufang Lu

PAGE 108 – 115

Paper 14: EMOCASH: An Intelligent Virtual-Agent Based Multiplayer Online Serious Game for Promoting Money and Emotion Recognition Skills in Egyptian Children with Autism

Authors: Hussein Karam Hussein Abd El-Sattar

PAGE 116 – 129

Paper 15: Adaptive Balance Optimizer: A New Adaptive Metaheuristic and its Application in Solving Optimization Problem in Finance

Authors: Purba Daru Kusuma, Ashri Dinimaharawati

PAGE 130 – 142

Paper 16: Improved Speaker Recognition for Degraded Human Voice using Modified-MFCC and LPC with CNN

Authors: Amit Moondra, Poonam Chahal

PAGE 143 – 151

Paper 17: Customer Segmentation of Personal Credit using Recency, Frequency, Monetary (RFM) and K-means on Financial Industry

Authors: Hafidh Rizkyanto, Ford Lumban Gaol

PAGE 152 – 162

Paper 18: Challenges of Digital Twin Technologies Integration in Modular Construction: A Case from a Manufacturer's Perspective

Authors: Laith Jamal Aldabbas

PAGE 163 – 167

Paper 19: SuffixAligner: A Python-based Aligner for Long Noisy Reads

Authors: Zeinab Rabea, Sara El-Metwally, Samir Elmougy, M. Z. Rashad

PAGE 168 – 172

Paper 20: Scrum: A Systematic Literature Review

Authors: Adrielle Cristina Sassa, Isabela Alves de Almeida, Tábata Nakagomi Fernandes Pereira, Milena Silva de Oliveira

PAGE 173 – 181

Paper 21: Artificial Intelligence Based Modelling for Predicting CO2 Emission for Climate Change Mitigation in Saudi Arabia

Authors: Sultan Alamri, Shahnawaz Khan

PAGE 182 – 189

Paper 22: Implementation of Revised Heuristic Knowledge in Average-based Interval for Fuzzy Time Series Forecasting of Tuberculosis Cases in Sabah

Authors: Suriana Lasaraiya, Suzelawati Zenian, Risman Mat Hasim, Azmirul Ashaari

PAGE 190 – 196

Paper 23: Event Feature Pre-training Model Based on Public Opinion Evolution

Authors: WANG Nan, TAN Shu-Ru, XIE Xiao-Lan, LI Hai-Rong, JIANG Jia-Hui

PAGE 197 – 206

Paper 24: A Novel Network Intrusion Detection System Based on Semi-Supervised Approach for IoT

Authors: Durga Bhavani A, Neha Mangla

PAGE 207 – 216

Paper 25: Iris Recognition Through Edge Detection Methods: Application in Flight Simulator User Identification

Authors: Sundas Naqeeb Khan, Samra Urooj Khan, Onyeka Josephine Nwobodo, Krzysztof Adam. Cyran

PAGE 217 – 229

Paper 26: Personalized Music Recommendation Based on Interest and Emotion: A Comparison of Multiple Algorithms

Authors: Xiuli Yan

PAGE 230 – 235

Paper 27: Research on Customer Retention Prediction Model of VOD Platform Based on Machine Learning

Authors: Quansheng Zhao, Zhijie Zhao, Liu Yang, Lan Hong, Wu Han

PAGE 236 – 244

Paper 28: Development of Computer Vision-enabled Augmented Reality Games to Increase Motivation for Sports

Authors: Bauyrzhan Doskarayev, Nurlan Omarov, Bakhytzhhan Omarov, Zhuldyz Ismagulova, Zhadra Kozhamkulova, Elmira Nurlybaeva, Galiya Kasimova

PAGE 245 – 252

Paper 29: Opposition Learning Based Improved Bee Colony Optimization (OLIBCO) Algorithm for Data Clustering

Authors: Srikanta Kumar Sahoo, Priyabrata Pattanaik, Mihir Narayan Mohanty, Dilip Kumar Mishra

PAGE 253 – 261

Paper 30: Fuzzy Rank-Based Ensemble Model for Accurate Diagnosis of Osteoporosis in Knee Radiographs

Authors: Saumya Kumar, Puneet Goswami, Shivani Batra

PAGE 262 – 270

Paper 31: A Novel Deep CNN-RNN Approach for Real-time Impulsive Sound Detection to Detect Dangerous Events

Authors: Nurzhigit Smailov, Zhandos Dosbayev, Nurzhan Omarov, Bibigul Sadykova, Maigul Zhekambayeva, Dusmat Zhamangarin, Assem Ayapbergenova

PAGE 271 – 280

Paper 32: Reversible De-identification of Specific Regions in Biomedical Images and Secured Storage by Randomized Joint Encryption

Authors: Prabhavathi K, Anandaraju M. B

PAGE 281 – 293

Paper 33: Texture Analytics for Accurate Person Recognition: A Multimodal Approach

Authors: Suchetha N V, Sharmila Kumari M

PAGE 294 – 299

Paper 34: Deep Learning Models for Crime Intention Detection Using Object Detection

Authors: Abdirahman Osman Hashi, Abdullahi Ahmed Abdirahman, Mohamed Abdirahman Elmi, Octavio Ernest Romo Rodriguez

PAGE 300 – 306

Paper 35: Hand Gesture Recognition Based on Various Deep Learning YOLO Models

Authors: Soukaina Chraa Mesbahi, Mohamed Adnane Mahraz, Jamal Riffi, Hamid Tairi

PAGE 307 – 319

Paper 36: Optimized Image Authentication Algorithm using Redundant Wavelet Transform Based Sift Descriptors and Complex Zernike Moments

Authors: Pooja Vijayakumaran Kallath, Kondaka Lakshmisudha

PAGE 320 – 326

Paper 37: Anchor-free Proposal Generation Network for Efficient Object Detection

Authors: Hoanh Nguyen

PAGE 327 – 335

Paper 38: Detecting Fraud Transaction using Ripper Algorithm Combines with Ensemble Learning Model

Authors: Vo Hoang Khang, Cao Tung Anh, Nguyen Dinh Thuan

PAGE 336 – 345

Paper 39: A Single-valued Pentagonal Neutrosophic Geometric Programming Approach to Optimize Decision Maker's Satisfaction Level

Authors: Satyabrata Nath, Purnendu Das, Pradip Debnath

An End-to-End Deep Learning System for Recommending Healthy Recipes Based on Food Images

Ledion Lico¹, Indrit Enesi², Sai Jawahar Reddy Meka³

Goergen Institute for Data Science, University of Rochester, New York, USA^{1,3}

Electronic and Telecommunication Department, Polytechnic University of Tirana, Tirana, Albania²

Abstract—Healthy food leads to healthy living and it is a major issue in our days. Nutri-Score is a nutrition label that can be calculated from the nutritional values of a food and helps evaluating the healthiness of it. Nevertheless, we don't always have the nutritional values of the food, so it is not always easy identifying this label. In the same way, it is not easy finding the healthier option to a favorite food. In this paper an end-to end deep learning system is proposed to identify the Nutri-Score label and recommend similar but healthier recipes based on food images. A new dataset of images is extracted from the Recipe 1M and labeled with the Nutri-Score value calculated for each image. Pretrained models Resnet50, Resnet101, EfficientNetB2 and DensNet121 are tuned based on this dataset. The embeddings from the last convolutional layer of the input image are used to find its most similar neighbor based on KNN algorithm. The proposed system suggests recipes with the lowest Nutri-Score similar to the inputted image. Implementations show that the Resnet50 provides highest prediction accuracy.

Keywords—Deep learning; nutri-score; new dataset; healthy food; accuracy

I. INTRODUCTION

Nutritional food plays an important role in human health. There is an expression from nutritionists “We are what we eat”. Nutri-Score is a nutrition label that converts the nutritional value of products into a simple code of five colored letters (A-E), where A is the healthier food [1]. Each product is awarded a score based on a scientific algorithm. It takes into account the negative nutrients with a high energy value, large amount of sugar, saturated fats, salt and the positive ones with fibers, proteins, fruits, vegetables, nuts, rapeseed oil, walnut oil and olive oil. A set of 50718 food images is extracted from the Recipe 1M dataset [2]. For every image of this dataset the nutri-score value is calculated using Nutri-Score system and the dataset is labeled with labels A, B, C, D, E where A is the healthier food with lowest nutritional value [3].

A new end-to-end deep learning neural network (DNN) architecture is proposed as a combination of existing deep learning systems with k-nearest neighbors (KNN) algorithm. Its input is a food image and the output of the system is a set of recipes and their respective images classified with labels suggesting the user the closest foods regarding the input one. The DNNs considered are Resnet50 -Residual Network with 50 layers (ResNet50) [4], Resnet101-Residual Network with 101layers (ResNet101) [5], EfficientNetB2 [6] and Densely

Connected Convolutional Networks with 121 layers (DenseNet121) [7]. These systems are pre-trained using ImageNet dataset. The systems are then tuned using the new labeled dataset with 50718 labeled images. The embeddings of the last convolutional layer are inputted to the KNN classifier to train it. Whenever a user inputs a food image to the proposed system, the embeddings for this new image are obtained to find its nearest neighbors. The k-neighbors with the lowest Nutri-score and the corresponding recipes will be returned to the user. The accuracy for the four DNNs is calculated yielding that the combination of ResNet50 with KNN algorithm is the most accurate one regarding the new food dataset. Based on our internet searches this is the only algorithm that proposes to the user a healthy recipe only from food images.

A novel approach for recommending healthy recipes based on food images using a combination of deep learning and k-nearest neighbors' algorithm is proposed. The proposed method can help people make healthier food choices by providing personalized recommendations that take into account the nutritional value of different food products. Moreover, the experiments show that the combination of ResNet50 with KNN algorithm is the most accurate approach for this task. The paper introduces a new and innovative approach for recommending healthy recipes. Based on the experimental results it is shown that the proposed approach is effective and accurate.

The paper is organized as: Related works are treated in Section II. Section III describes the Nutri-Score evaluation system; Deep Neural Networks are described in Section IV; the new dataset is described in Section V; methodology is described in Section VI; experimental results in Section VII; conclusions and future work closes the paper with Section IX.

II. RELATED WORK

Several datasets and approaches have been developed in the recent years to address the topic. The [8] introduced a novel method to automatically recognize dishes pictures using Random Forests which allowed them to mine for parts simultaneously for all classes and to share knowledge among them. They also introduced the Food-101 visual classification dataset of 101 food categories, with 101k images. Im2Calories was introduced in [9] in which a classifier was trained on food images taken from 23 different restaurant and used to predict which food are present on the plate and the compute the corresponding calories. The system first performs a food

segmentation followed by a volume estimation. This is obtained by combining two Convolutional Neural Networks (CNNs) for the meal detection and food recognition, with a food image segmentation technique and Google's Places API used to recognize the restaurant. A bigger dataset was introduced in [10]. The dataset contained 720 639 training, 155 036 validation and 154 045 test recipes, containing a title, a list of ingredients, a list of cooking instructions and (optionally) an image. The [11] in collaboration with Facebook research introduced a recipe generation system that takes a food image as an input and outputs a sequence of cooking instructions, which are generated by means of an instruction decoder that takes as input two embeddings. The first one represents visual features extracted from an image, while the second one encodes the ingredients extracted from the image. A transformer-based instruction decoder is used to generate the cooking instructions. The [12] proposed RecipeNet, a system that returns to the user the recipe based on the inputted image. They use the embeddings obtained from the final convolutional layer of ResNet-50, ResNet-101, and DenseNet-121, then use K-NN to return the most similar images and recipes. Although, they don't take Nutri-Score into account when tuning the system and they cannot return the healthiest image. On the other hand they don't compare the models based on this classification task.

III. NUTRI-SCORE

Nutri-Score is a system for categorizing foods based on their nutritional value [1][13]. It guides consumers towards healthier food choices preventing the wide range of nutrition-chronic diseases. It was selected from French government from March 2017 to be displayed on products. It relies on the computation of nutrient profiling system from the United Kingdom Food Standard Agency [14]. Its output is: five classification letters corresponding to five colored labels from A to E, where A is the healthiest food and E is the detrimental one. Calculation of the score is based on the quantity of seven nutrient components found on 100g of food, which are high content of fruits and vegetables, fibers, and proteins (based on a rule of 2019 are added and the healthy oils) for a preferable score, while high content of sugar, saturated fatty acids, sodium yields a detrimental score. Special rules are added for "cheese", "added fats" and beverages. The system doesn't take in consideration the degree of food processing, vitamins, antioxidants, fiber type of additives. The calculation consists of three steps. In the first step the nutritional score of the food is assessed.

Ingredients which affect negatively the Nutri-Score compounding the Total_N_Score value are: high energy density per 100 (g of l), high sugar content, high content of saturated fatty acids and high salt content. Ingredients which affect positively the Nutri-Score results compounding the Total_P_Score value are content of fruits, vegetables, nuts and legumes; fiber content; protein content; content rapeseed, walnut and olive oil.

$$\text{Nutritional_Score} = \text{Total_N_Score} - \text{Total_P_Score} \quad (1)$$

In the second step, the Rayner's score is calculated for all the products in the same way, except cheese, vegetable, animal

fats, oils, and drinks. In the third step, the two scores are used to classify the food in one of five levels of the Nutri-Score system.

Based on the Nutri-Score evaluation system algorithm, 0 – 10 points are assigned for energy value and ingredients which should be limited in diet; 0 - 5 points for beneficial ingredients. To determine the value of a product and its corresponding letter, the sum of points for beneficial ingredients subtracts the sum of points for nonhealthy ingredients, the final score varies from -15 to +40 and with corresponding letters from A to E, where the lower the score the better nutritional food.

Nutri-Score is easily computable by industrial and public stakeholders; it encourages the food industry to improve the nutritional quality of the food supply.

IV. DEEP NEURAL NETWORKS

Deep Learning is a subset of machine learning that automates part of the feature extraction step of the process, thus eliminating some of the manual human intervention and also enables the usage of big data sets [15]. It consists of processing nodes arranged in layers. The system processes data between input and output layers to solve or predict specific task. The neural network needs to learn all the time solving specific tasks in a more qualified way or providing better results. When new data are inputted, the system learns how to act according to new situation [16]. Deep neural networks use layers of nodes to create high level functions from datasets. Different types of neural networks are distinguished between them from working principles, action of schemas and application areas.

Convolutional Neural Networks (CNN) implements convolution in its structure. It reduces the memory using weight sharing and the number of network parameters avoiding the over-fitting problem. Shared weight as well as space or time down sampling implemented in CNN, provide a certain amount of translation, scaling, and distortion invariances [17][18].

Deep Neural Networks are widely used and with great impact in the computer vision field. They solve different problems like image and face recognition, object detection, image classification etc.

A. ResNet-50 and ResNet-101

The template is designed so that author affiliations are not repeated each time for multiple authors of the same affiliation. Please keep your affiliations as succinct as possible (for example, do not differentiate among departments of the same organization). This template was designed for two affiliations.

ResNet50 is a Residual Neural Network of type Convolutional Neural Networks (CNN) with 50 layers. It has very good results in image classification. Number of layers is very important in Deep Learning. Additional layers can improve solution of complex problems or having better results. But it also increases the risk of saturation of accuracy levels which may slowly degrade after some point. The performance of the system may be decreased in training as well as in testing [19].

To increase the accuracy, ResNet uses residual blocks. It introduces the concepts of “skip connections”, which add outputs from previous layers to the outputs of stacked layers, enabling the model to learn the identity function. Residual blocks make possible facilitation of in learning the identity function, minimizing so the percentage error [20].

The first ResNet architecture was ResNet-34, using shortcut connections to turn a plain network into a residual one. Comparing with VGG neural networks, ResNets have fewer filters and less complexity. Layers have the same number of features for the same output feature map size. To preserve time complexity per layer, number of filters is doubled when the feature map size is halved. The VGG plain network is improved with “skip connections” or “shortcuts”. Identity shortcuts are used directly if input and output dimension are the same. Otherwise, extra zeros are padded to increase the dimensions of shortcuts or the projection shortcut is used to match the dimensions [20][21]. ResNet-50 is based on the ResNet-34 model, but the building blocks are modified in a bottleneck design using a stack of three layers. Each block of two layers in ResNet-34 is converted in a three layers bottleneck block yielding ResNet-50 architecture. It has much higher accuracy than Resnet-34 [22]. ResNet-101 or ResNet-152 residual networks use more three layers blocks than ResNet-50.

B. EfficientNet-B2

Scaling up the ConvNets is one of visible ways to achieve better accuracy. For example, ResNets scale from Resnet-50 to ResNet-152 by using more layers. It is possible to scale the models by scaling one or more of dimensions like width, depth, and resolution. EfficientNet models carefully balance network width, depth, and resolution to get better performance. Using new type of scaling method called compound coefficient, EfficientNet models uniformly scale across all the dimensions of width, depth, and resolution [23]. This provides added benefit over ResNet models in terms of accuracy and size of model. These models start with a baseline network designed using neural architecture search and use this new scaling method to obtain the family of models called EfficientNets. Unlike traditional methods which scale network width, depth, and resolution arbitrarily, EfficientNet family of models is formed by scaling these factors uniformly with a set of fixed scaling coefficients. Out of several versions available, we choose to use EfficientNet-B2 keeping in mind the memory and space constraints. This model is comparable in performance but more efficient than ResNet-50.

C. DenseNet

It is shown in practice that residual connections especially short connections between layers help convolutional networks be deeper, more accurate and efficient to train. DenseNets introduces connection between each layer to every other layer of the network in a feed-forward fashion. ConvNets with L layers have L connections one between each layer and its subsequent layer whereas DenseNets have $(L(L+1) / 2)$ direct connections. All previous layers' feature-maps are used as inputs into each layer, and its own feature-maps are used as inputs into all subsequent layers. DenseNets alleviate the vanishing-gradient problem, improve feature propagation, and

promote feature reuse. We use DenseNet121, the base model of DenseNet family keeping in mind space, computation and memory constraints [24].

D. K-Nearest Neighbors Classifier Algorithm

K Nearest Neighbors Algorithm is a supervised machine learning algorithm used to classify data. It a simple algorithm, easy to implement, its time execution increases significantly when data size increases. It finds the K smallest distances between the current data and the dataset, the output is the most frequent label in those K data. Usually, KNN algorithm is used for recommender systems, when the dataset size is not significantly high [25].

V. NEW DATASET

The images are extracted from the Recipe 1M dataset. There is a portion of the dataset that contains nutritional information. Also, it is populated with some data gotten from the web for the recipes without information. The Nutri-Score value is calculated for these recipes.

Each recipe is linked to several images. a new dataset of 50718 images with the respective nutri-score values is created.

In Fig. 1, the distribution of classes presented. It is seen that there is a little imbalance between classes, with class E being the minority class. The images are converted to 256x256 dimensions, normalized and augmented them. Next the dataset is split in a training and validation set with 90%-10% proportion in a stratified way to keep the ratios.

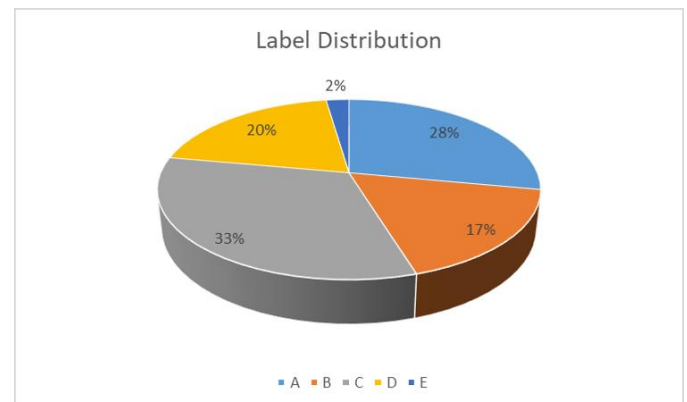

Fig. 1. Class distribution of the dataset.

VI. METHODOLOGY

Four deep learning neural networks, Resnet50, Resnet101, EfficientNetB2 and Densenet121, are considered for the healthy recipes system, which are pretrained using the ImageNet dataset.

The new dataset with 50718 labeled images from the Nutri-Score system is used to tune these pre-trained models. The deep learning pipeline is shown in Fig. 2.

The systems are evaluated and compared in terms of accuracy and loss. Cross-entropy loss and SGD optimizer are used for Resnet 50 and Resnet101 and Adam optimizer is used for EfficientNetB2 and DenseNet121. Servers equipped with GPU, are used for the training. Implementations are done using

Pytorch framework. Tensorboard was used for recording the models' loss and accuracies as well as for visualization.

Embeddings from the last convolutional layer are inputted to the KNN classifier to get the nearest neighbors with the lowest Nutri-Score value.

In our case, we need to return the nearest neighbors for the inputted image and it is returned based on the distance between the embeddings. KNN will evaluate the nearest neighbors based on the Minkowski distance, as it is a general form of Euclidean distance, as shown in equation 2:

$$d(x, y) = \left(\sum_{i=1}^n |x_i - y_i|^p \right)^{\frac{1}{p}} \quad (2)$$

KNN is a classifier that predicts the class of an element as the majority class among its K nearest neighbors.

The healthiest nearest neighbors for the input image are returned to the user together with the corresponding recipes.

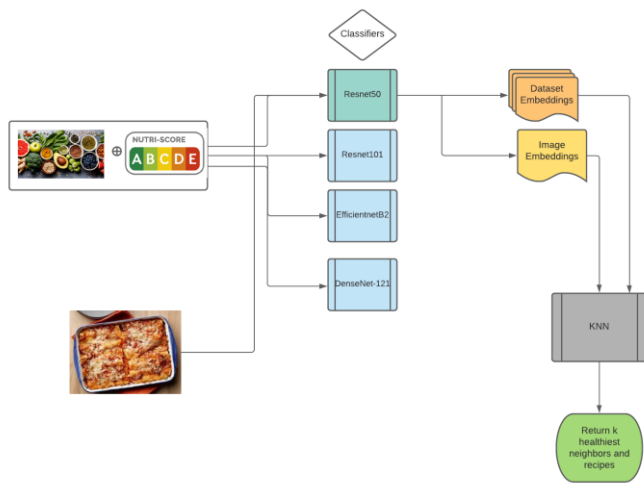

Fig. 2. Deep learning pipeline.

VII. EXPERIMENTAL RESULTS

A. Results from Deep Learning Neural Network Models

The new dataset was created and labeled. The training and test dataset loaders were created and were ready for the modelling part.

At first the pre-trained models on ImageNet are downloaded and the convolutional

Layers are frozen. An initial train is performed getting the best accuracy around 70%. Then the convolutional layers are unfrozen and full training of the networks is performed.

The learning rate scheduler decays the learning rate by a factor of 0.1 every 7 epochs. The SGD optimizer is used for the Resnet50 and Resnet101 models and Adam optimizer is used for Densenet121 and EfficientNetB2. Models are trained for 100 epochs and the best model is selected. Fig. 3 shows the comparison of classification models.

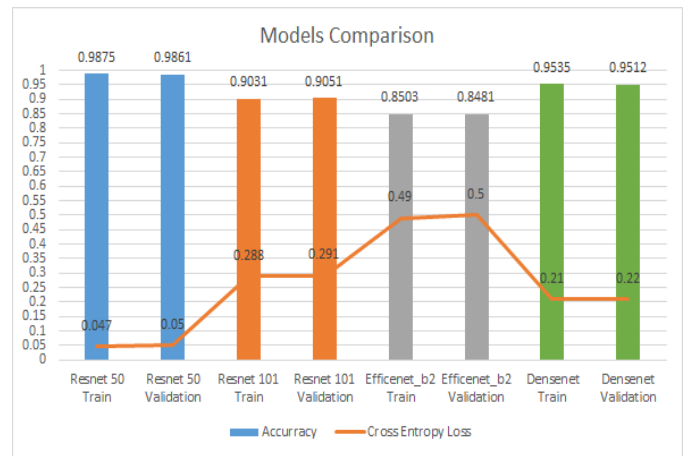

Fig. 3. Classification models comparison.

From the chart, it is shown that Resnet50 and Densenet121 are the best models giving respectively 98.61% and 95.12% of accuracy. Resnet 101 produced 90.51% of accuracy and performed poorer than Resnet50. This fact is explained that Resnet101 is a bigger model and our new dataset is relatively small. EfficientNetB2 is the worst performer with only 84.81%. Attempts are done for executions of EfficientNetB3 and EfficientNetB4 but we did not have the computational resources available to train these models so executions are limited ourselves to EfficientNetB2. To analyze the accuracy for every class, the confusion matrix for the two best models is printed, as shown in Fig. 4 and 5.

The results show that the model performs very well for minority classes also. Augmentation helped to deal with the imbalance. After defining best model, the next step is to get the embeddings and train a KNN model based on them.

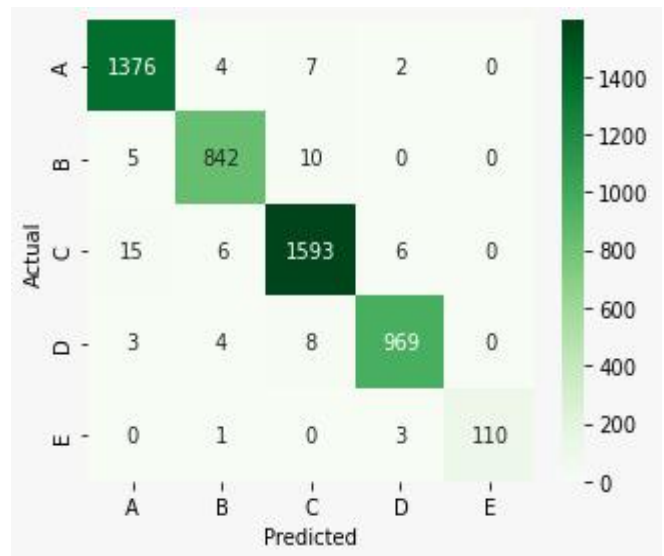

Fig. 4. Confusion matrix for resnet50.

Fig. 5. Confusion matrix for densenet121.

B. Results from KNN Model

Since Resnet50 performed better than other models for the new labeled dataset, embeddings from the last convolutional layer of the Resnet 50 model are extracted.

The images based on the Euclidean distance between the embeddings in Tensorboard are plotted. The results are shown in Fig. 5.

As it can be seen from the plot images closer to the D label are also labelled with D, but some C-values in the surroundings exists. These images are the interested ones images they are similar but healthier. The number of neighbors to the KNN classifier is set to 24. The proposed system returns 24 similar food images according to the inputted one. This number is tunable and can be changed by the user.

Results of the experiment are shown in Fig. 6.

Fig. 6. Sample image input and its 24 outputs images recommended by the system.

As it is seen from the results, the images are similar to each other, and the class labels are very similar. Our main aim is to return the images and recipes with the lowest nutri-score value. The user might input the number of healthy recipes that he wants to get and the system will generate them. It is seen from the sample that the output is C-labelled has two B-labeled neighbors that are similar but healthier. These two images and the corresponding recipes will be returned to the user if he puts the recipe limit to two. According to the same logic, the first three neighbors will be returned for sample image and if the user inputs the recipe limit to three. As an example, we are generating the recipe for the second neighbor of the sample 2 image. The obtained recipe is shown in Fig. 7.

Recipe : Slow Cooker Fruit, Nuts, and Spice Oatmeal :

- Ingredient 1: (quantity:2 cup: 'oats')
- Ingredient 2: (quantity:2 cup: 'cranberries, dried, sweetened'),
- Ingredient 4: (quantity 2 tablespoons: 'salt, table'),
- Ingredient 5: (1/2 cup: 'nuts, almonds'),
- Ingredient 6: (1/2 cup: 'nuts, pecans'),
- Ingredient 7: (3 cup : 'water, bottled, generic'),
- Ingredient 8: (1 cup: 'milk, fluid, 1% fat, without added vitamin a and vitamin d'),
- Ingredient 9: (1 tablespoon: 'spices, cinnamon, ground'),
- Ingredient 10: (1 teaspoon: 'pumpkin, raw'),
- Ingredient 11: (2 teaspoon: 'butter, without salt'],

Instructions : 'Combine the oats, apple, cranberries, almonds, pecans, water, milk, cinnamon, pumpkin pie spice, and butter in a slow cooker. Cook on Low overnight or 8 hours.'

Fig. 7. Recipe for the second neighbor of sample 2 image , A-labeled.

It will be an A-class meal which is very healthy and it is similar to what is actually requested by sample 2 image. The proposed model is able to return the best and healthiest recipes for the input image. The user may decide the number of recipes that he wants to return.

User has also the possibility to set the maximum Nutri-score threshold that he can accept and the system will limit the result accordingly.

VIII. DISCUSSION OF RESULTS

In this paper, a deep learning-based approach for food image retrieval and recipe recommendation is presented. Results show that ResNet50 and DenseNet121 achieved the highest accuracies among the models evaluated. This is consistent with previous studies that have reported the superior performance of these models in image classification tasks [26][27]. Results also highlight the importance of transfer learning, as pre-trained models on ImageNet were used as a starting point for our models, which significantly improved their performance.

One important aspect of the proposed approach is the use of data augmentation to deal with the imbalanced dataset. This

allowed us to achieve high accuracies not only for the majority classes, but also for the minority classes. Data augmentation has been shown to be an effective technique to improve the performance of deep learning models, especially when dealing with limited datasets [28].

The use of KNN for food image retrieval and recipe recommendation is not a novel idea. However, the approach differs from previous studies in that we use the embeddings extracted from the last convolutional layer of the ResNet50 model as the feature vectors for KNN. This approach has been shown to be effective in several image retrieval tasks [29][30][31] and the obtained results confirm its effectiveness for food image retrieval as well.

One limitation of our study is the relatively small size of the dataset, which may affect the generalizability of our results. Moreover, our dataset contains only Western-style dishes, which may limit the applicability of our approach to other cuisines. Future studies should focus on collecting larger and more diverse datasets to improve the performance and generalizability of our approach.

The proposed approach provides a promising solution for food image retrieval and recipe recommendation. The high accuracies achieved by our models, especially for the minority classes, demonstrate the effectiveness of the approach. The use of KNN with embeddings extracted from deep learning models provides a fast and efficient way to retrieve similar food images and recommend healthy recipes. It has the potential to be useful for various applications, such as food logging, dietary analysis, and personalized meal planning.

IX. CONCLUSIONS AND FUTURE WORK

In this paper, an end-to-end deep learning neural network model is developed that recommends healthy meals to the users based on the imputed food images. A new dataset with 50718 records is created by extracting food images from Recipe 1M dataset and labeling them with the Nutri-Score value.

This dataset can be expanded even more in the future and can be used for healthy food classification tasks. Deep learning models ResNet50, ResNet101, EfficientNetB2 and DensNet121 are compared on the new dataset. Experimental results show that Resnet50 gives the maximum accuracy of 98.61 followed by Densnet121 with 95.12%. Embeddings from the last convolutional layer are inputted to the KNN model providing the user the healthiest recipes of food similar to the input image but healthier in nutritional values.

The results demonstrate the feasibility of using deep learning neural networks for recommending healthy meals based on food images. The new dataset created in this paper provides a valuable resource for future research in healthy food classification. The comparison of various deep learning models on this dataset highlights the importance of selecting an appropriate model architecture for the task at hand.

However, there are still some limitations that need to be addressed in future work.

Firstly, the dataset used in this study is relatively small and limited to Nutri-Score values. Expanding the dataset with

additional labels and nutritional information could further improve the performance of the model. Secondly, the proposed model is limited to recommending healthy meals based solely on food images, which may not be sufficient for some users. Future work could consider incorporating additional user information, such as dietary preferences and restrictions, to further personalize the recommendations.

Abstract—The use of automatic number plate detection devices in safety, commercial, and security has increased over the past few years. Number plate detection using computer vision is used to provide fast and accurate detection and recognition. Lately, many computerized approaches have been developed for the identification of vehicle registration details based on license plate numbers using either Deep Learning (DL) methodologies. In the proposed framework, we used Optical Character Recognition (OCR) and a deep learning-based new approach for automatic number plate detection and recognition. A deep learning approach trains the model to recognize the vehicle. The vehicle registration plate area is cropped adequately from the image, and a Convolution Neural Network (CNN) uses OCR to identify numbers and letters. The Jetson TX2 NVIDIA target served as the model's training data source, and its performance has been tested on a public dataset from Kaggle database. We obtained the highest accuracy of 96.23%. The proposed system could recognize vehicle license plate numbers on real-world images. The system can be implemented at security checkpoint entrances in highly restricted areas such as military areas or areas surrounding high-level government agencies.

Keywords—Number plate detection; recognition; deep learning; OCR; image classification

I. INTRODUCTION

Automatic number plate Detection is also known as license plate detection or vehicle registration plate detection. It uses image processing technology to extract the registration plate from digital images or video [1]. Afterward, the information stored can be used to find various new models, some of which could be transaction gateways or traffic violation systems. Taking the context of a real-life problem into consideration, in practical applications, researchers have to deal with a variety of challenges, such as registration plate type, textual font, registration plate color and font, registration plate location, and environmental conditions such as lighting and weather. License plates become challenging to recognize. License plate formats vary from country to country: Different colors, languages, and fonts. Some plates have a different colored border than the background surrounding the plate, and some have a plain background, which indirectly adds challenges to capturing and recognizing car plates [2]. Variations in environmental conditions, such as lighting and image background, also affect the license plate recognition rate. Several studies have been proposed earlier.

YOLO is a unified model for object recognition [1]. This model can be built and trained directly on full frames. In contrast to classifier-based approaches, YOLO is introduced

with a loss function that directly corresponds to recognition performance, and the entire model is prepared together. Fast YOLO is the fastest general-purpose object detector in the literature, and YOLO advances state of art in real-time object detection. YOLO also generalizes to new domains, making it ideal for applications that rely on fast and robust object detection. Authors discuss the detection of a registration plate for a person who does not wear a helmet in [3]. The two-wheeler operator must have a helmet for his safety. In this study, they proposed a real-time detection of number plates using YOLO, for which they deployed the CNN layer. The accuracy of the model was 95.5%.

In [4], they DL method was proposed for vehicle detection using R-CNN and faster R-CNN, in which they tested and trained their model. The model has three steps: data acquisition, CNN design, and R-CNN. The mean average precision (map) values from faster R-CNN and R-CNN were approximately 0.73, 0.76, and 0.64, and 0.65, respectively. Another one had an overall accuracy of 94.98%. [5], proposed a deep learning model using an Image AI library for training. The model consists of four steps: video acquisition, detection of a vehicle, registration plate detection, and then registration plate character recognition. The model's accuracy was 96% for plate localization and 90% for character recognition was 90%. In [6], firstly, they made the image acquisition, after which they used pre-processing techniques like RGB to grayscale conversion, noise removal, and image banalization. For registration plate extraction, used Sobel's edge detection [7]. After that, the characters are segmented using the CNN layer for character recognition. The model had an overall accuracy of 95%. In [8] they proposed a highly accurate trained model for both registration plate detection and recognition [9]. The whole model was prepared by sharing a convolution layer with the above features. The proposed system had an accuracy of 94% for a jointly trained model. In [10], a framework for character detection using a differentiable binary process is presented. In [11], a framework requires text extraction from an input digital image in which the image has been processed and filtered thoroughly. They used the CV2 OpenCV library in Python for pre-processing and Tesseract for character recognition. Real-time plate detection was performed on a Bangla dataset [12]. For character recognition, the proposed model employed a CNN layer. The dataset used had a sample size of 5500, and the accuracy of successful recognition was 90.90% in a real-time study. In [13-14], YOLO is used for object detection. They trained and fine-tuned the CNN layer for each stage, then did the segmentation part. The SSIG dataset, which contained 2000 frames from 101 videos, was

used. The system had an accuracy of 93.53% with 47 frames per second. In [15], [18] a kernel that was partially restricted was focused on with the help of direct blind deconvolution and denoising with CNN on a real-time blur image that was acquired from a traffic surveillance system used a neural network that was trained on artificial data. They used deep learning mode [19]-[28], which includes image acquisition, plate detection, segmentation, and character recognition. The data set was the Turkish vehicle license plate dataset, which consists of real-world images obtained from a security surveillance camera. Unlike other countries, India, with a population of 1 billion, has a unique need for ANPRs. ANPR's primary uses are highway monitoring, parking lot management, and neighborhood law enforcement safety. Existing literature says that in India, within every four minutes, one person dies, and surprisingly, most of them are because of over-speeding. ANPR monitors the average speed of vehicles, and vehicle owner information can identify vehicles violating the traffic rules. In this case, e-challans can be automatically generated for the penalized plate owner. This helps maintain law and order, which in turn minimizes traffic fatalities. ANPR provides the best solution for giving parking management. Vehicles with registered license plates are automatically allowed into the parking area, but unregistered vehicles will be charged at check-in and check-out. According to the study, approximately 200,000 cars are stolen annually in India. This number can be reduced by taking appropriate measures and using this model to track vehicles. This allows law enforcement agencies to determine when, where, and through which route the stolen vehicle is stolen, if vehicle is stolen. This allows us to bring justice to such a powerhouse quickly. The main objectives of the proposed system are as follows. (1) To understand ANPR and apply it to a license plate recognition system. (2) To improve the performance of the number plate detection system using OCR and DL approach. (3) The proposed system efficiently used for detection and recognition of vehicle number plate.

The study is organized as follows: Section I provide the literature review on problem formulation and various existing methodologies; Section II describes the proposed procedures. Following that, in Section III, the results are analyzed and discussed. Section IV explains the conclusion and future scope.

II. PROPOSED METHOD

Fig. 1 depicts the proposed framework of number plate detection in four essential parts: a dataset, license plate detection, segmentation, and OCR. Modern rural, urban, and national highway networks have proliferated in recent decades. This created the need to monitor and manage traffic on the road efficiently. The primary goal of this study is to train a model to recognize and identify license plates from their images correctly. Different countries have different characteristics of license plates, such as their number system, colors, sign language, style (font), and size of a license plate, so further research is needed.

Deep learning (DL) is a branch of Machine Learning (ML), and ML is a subset of Artificial Intelligence (AI)

that mimics the way humans acquire certain kinds of knowledge. Deep learning is a critical component of data science, including statistics and predictive models. It benefits data scientists who must collect, analyze, and interpret large amounts of data. Deep Learning makes this process faster and easier. At its simplest, DL can be thought of as a way to automate predictive analytics. While traditional ML algorithms are linear, DL algorithms are built up in increasing complexity and abstraction layers. A shallow CNN quickly scans the test image and eliminates most sample windows. In the proposed approach, authors have used four layers to predict number plates. In the first layer, the number plate detection work is done; in the second and third layers, region extraction is calculated; and in the last layer, OCR is used. The automatic framework for number plate detection using OCR and deep learning architectures is shown in Fig. 2.

A. Dataset

The desired unit where deep learning problems fail is a need for a public dataset. As we know that, the wrong data sets can produce inaccurate or incorrect results. So, we need to ensure that there are no similarities between the content of a dataset other than its essential characteristics. Because India is a large country, hence need to consider all the contexts and ensure that the given dataset is well-balanced without favoring or disfavoring any entity, such as vehicle type or license plate layout. Firstly, the vehicle types present on the streets of a typical Indian city are cars, two-wheelers, buses, trucks, and pickups. So, every type of vehicle has its own format for displaying the registration plate. For example, most cars have one line of plates, but some people prefer a layout with two lines of plates. Registration plates belonging to Indians can be single-row or double-row and most two- and three-wheeler registration plates are two lines, but their layout differs. The font on both sides is also different, with some 3-wheeler auto rickshaw uses paint rather than printing the number plate. So here we found the basic first step in license plate recognition is to collect a database. In the proposed work dataset is downloaded from the Kaggle website, which includes license plates with significant variations in registration numbers collected by kaggle.com. Total of 4326 were trained on our model to identify the number plate and had used deep learning strategies as you can see in the Table I. It represents us the type of vehicle that were been trained as you can see the dataset is not biased as all type of vehicle are been taken into account.

B. Preprocessing

When images are acquired at this stage and passed to the algorithm for further testing and prediction, Image pre-processing is one of the crucial stages for any computer vision system. So, the main objective of this image pre-processing is to recognize the image and collect information regarding the image, which can be used in further processing [7]. Image pre-processing changes the operation performed on a non-figurative object. The primary goal is to improve image information to extract the necessary information from that image. Fig. 3 shows sample images from the custom dataset for experimental work.

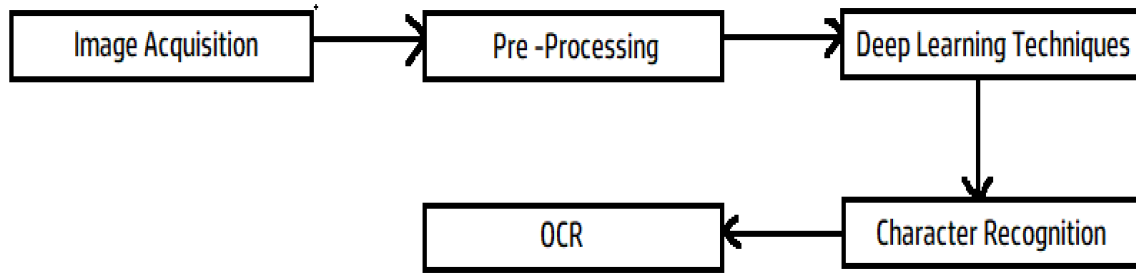

Fig. 1. The block diagram of proposed methodology.

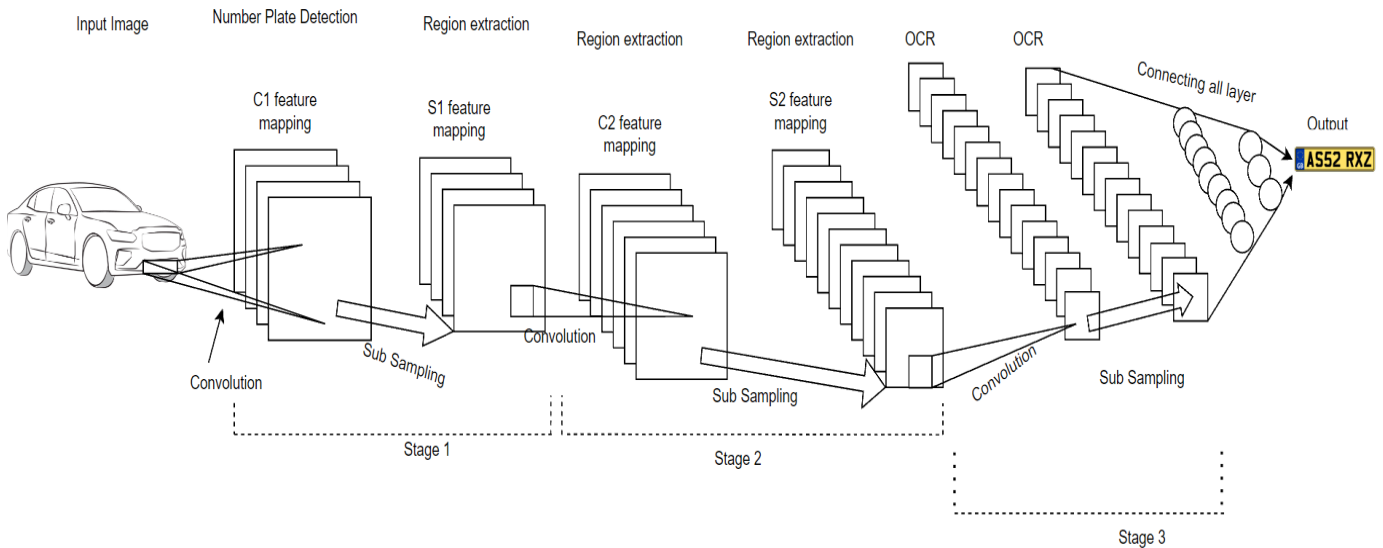

Fig. 2. An automatic framework for number plate detection using OCR and deep learning architecture.

C. Number Plate Detection

Most countries around the world have registration plates that are shaped like a rectangle. Moreover, the registration plate comes in different shapes and layouts in India. Sometimes it is seen that a two-wheeler uses a trapezoidal plate. In terms of size, the average size of the plate varies by vehicle, with the average size for cars being 500×120 mm and for motorcycles being 200×100 mm [11]. Three-wheeled vehicles such as an auto rickshaw have tiny plate painted mainly by a painter. Taking all the points into context, we put all the registration plates into a rectangular box. As shown in Fig. 2, the image of the car with the highlighted number plate is in the green-colored rectangular box. Fig. 4 shows the detection of registration plat.

The result uses a thresh holding algorithm on the number plate, and because of this thresh holding method, the plates are being segmented at a higher level. These thresholds help us recognize the character correctly.

D. Charactor Recognition

As discussed earlier, the main issue with character recognition is that there are many types and categories of the font used in the plate. So, the best way to train our desired model is to check for letters and digits to cover different typefaces, including those used in painted panels. Here, we used OCR for character recognition. The recognized and segmented character can be trained with our custom-built dataset for training and testing purposes.

A corresponding file was created for training and testing with a valid dataset of 4326 images. So, after all the model training, we figured out that our model is about 95% accurate at the detection range of the license plate and fails only when the license plate is a little smaller in size as compared to the standard plate size or when similar plates are present in the tested image.

Fig. 3. Sample images from the custom dataset for experimental work.

Now let's check how the OCR works. The attributes are extracted from the sample image. These features can be preferred as follows: (1) Distance to the wall (DTW): The calculation for such is based on active pixels. They are the highest intensity value possible, depending on the image format. For example, in an 8-bit grayscale format, the maximum level is 255; to calculate that, it is divided into 12 regions (4 rows x 3 columns). And the activated pixel is calculated concerning the horizontal and vertical areas within each region. (2) Cross-Time Feature (CTF): This feature includes the six widest white-to-black and black-to-white transitions across the character horizontally and vertically. The six widest shifts are computed for every row and column of character candidates. These intersections are sorted, and the first three rows and columns with the highest and lowest changes are saved along with their positions. (3) Active Region Ratio (ARR): The region is divided into four rows and three columns, respectively, and the area of active pixels is chosen as a critical feature for the block. (4) Height to Width Ratio (HWR): When talking about HWR, alphanumeric symbols for

any language have been bifurcated into three types, namely, those with more extensive and equivalent height and width. Table I depicted describes the count of vehicle.

The positive score represents the character, and the negative score represents the non-character symbol within the plate. Optical character recognition has been around for the last 80 years. However, large technology companies initially were the primary developers of products that recognized optical [18] characters. Advances in machine learning and deep learning have enabled individual researchers to develop algorithms and techniques that can more accurately identify handwritten manuscripts. We also see more and more researchers using - convolutional neural networks (CNNs) to recognize handwritten and machine-printed characters. This is since CNN-based architectures are well suited for recognition tasks where the input is an image. CNN's were initially used for object detection tasks in images. ImageNet Large Scale Visual Recognition Challenge (ILSVRC) is commonly used CNN-based architectures for visual recognition tasks.

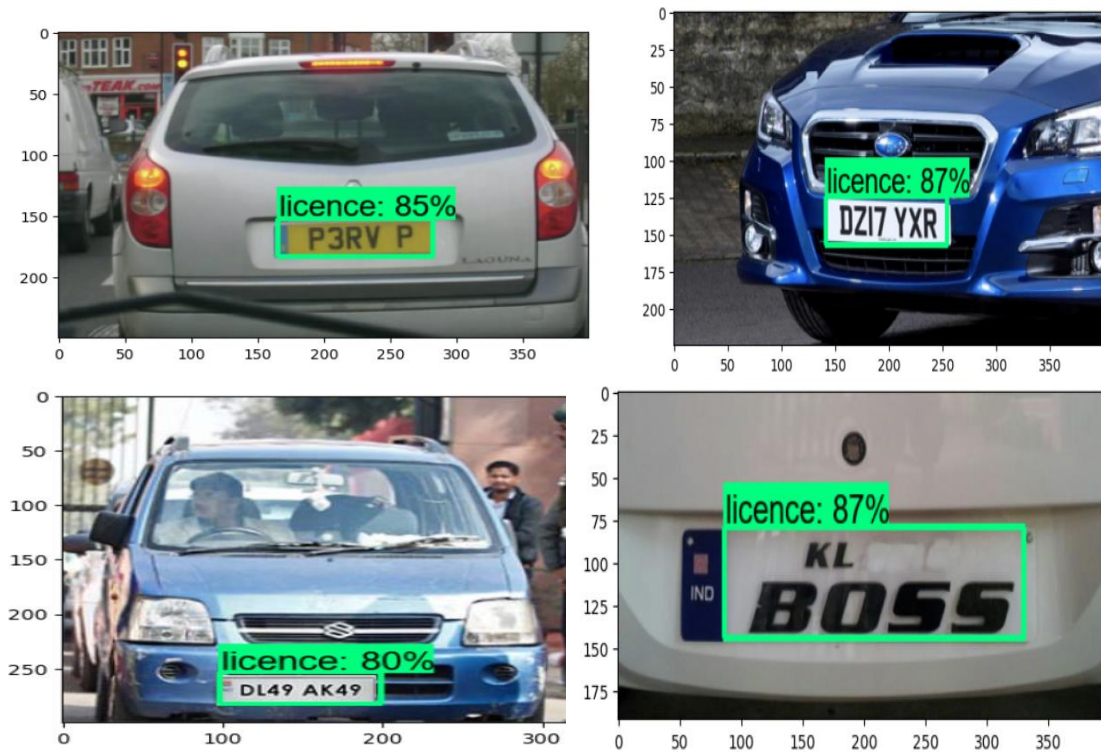

Fig. 4. Detection of registration plate in rectangular boxes.

TABLE I. DESCRIBES THE COUNT OF VEHICLE

Type of vehicle	Type of license plate	Font of license plate
Two Wheeler (300)	Printed (375)	Single line (273)
		Multiline (102)
Three Wheeler (637)	Painted (125)	Single line (89)
		Multiline (36)
Car (2963)	Printed (2957)	Single line (61)
		Multiline (96)
Truck & pickup (426)	Painted (480)	Single line (86)
		Multiline (394)
	Printed (6)	Single line (2873)
		Multiline (84)
	Painted (82)	Single line (2)
		Multiline (4)
	Painted (344)	Single line (80)
		Multiline (2)
		Multiline (284)

TABLE II. EXISTING METHOD FOR REGISTRATION PLATE DETECTION & RECOGNITION

Actual Registration plate	Predicted Registration Plate	Mismatched Recognition	Accuracy
P3RV P	P3RV P	0	900%
KL BOSS	KL 8OSS	1	84%
DL49 AK49	DL49 AK49	0	89%
DZI7 YXR	DZI7 YXR	0	85%
Mh 14 Gn 9239	Mh il Gn 9239	2	80%

III. RESULT AND DISCUSSION

The proposed system evaluates the car image from a given dataset. The most crucial factor in solving deep learning problems has an accurate dataset that is unbiased, because of which it produces inaccurate or skewed outcomes. It is necessary to ensure no similarities between the items in the dataset other than the characteristic of interest. After that, we came to the training part of the data set. We considered 4326 sample images and trained the model to detect the license plate. The results of OCR based approach are shown in Fig. 5. The captured registration plate is processed for letter segmentation. Separated characters are recognized using OCR (Optical Character Recognition). After which, the essences extracted from the registration plate are stored in an Excel spreadsheet. Table II shows the sample test cases on the real-time dataset.

Fig. 5. Results of OCR approach to detect number plate.

TABLE III. COMPARISON WITH EXISTING METHDOS FOR NUMBER PLATE DETECTION AND RECOGNITION

Method/Ref.	Accuracy (%)	
	Detection	Recognition
YOLO, Response surface methodology (RSM) [5]	97 %	90 %
CNN, TensorFlow [16]	96.36%	93%
YOLO, CNN, Edge Detection [6]	94%	91%
RGB Scaling, CNN[9]	97%	94%
YOLO v3	91%	91%
Deep CNN [20]	98.1%	88.1%
Deep CNN, Fast RCNN [18]	99%	91%
RCNN, SVM, ANN [17]	94.4%	96%
RANSAC, SVM [16]	91.4%	91.4
RESNET, RCNN [3]	94.98%	92%
Proposed Method	100% (Vehicle Detection) 95% (License Plate Detection)	96.23%

The Table II clearly shows that a minimum of 80% accurate result can be obtained; in some cases, even 100% accurate prediction is achieved. Table III compares the proposed method’s performance and existing literature. It can be concluding from the Table III that the proposed method performs far better than the existing method.

IV. CONCLUSION

This study shows that in the presence of anomalies, the performance of deep learning techniques is relatively better and beneficial in the process of ANPR as per India’s conditions. Authors represented the entire end-to-end ANPR and noticed multiple lines of LP, non-uniform padding, plate shapes, fonts, and non-uniform font sizes. This presented a complete end-to-end pipeline for ANPR. For LPD, we proposed a model that works well in India and also introduced an alternate method for CR networks suitable for the Indian situation. Our LPD model achieved 96.23% accuracy with a detection threshold of 0.5, which only dropped because it has a 98% accuracy rate for small license plates on cars and buses and a total loss of less than 10% with a learning rate of 92%. The proposed network

showed a high average accuracy of 94.9%, including multiline panels, and predicted 93.7% of the characters with a higher confidence level than 90%. ANPR can identify vehicle owners, vehicle model identification, traffic voltage and control, and vehicle location tracking. This model can be further extended as a multilingual ANPR to automatically identify the language of the characters based on the training data.

Convolution Neural Networks for Phishing Detection

Arun D. Kulkarni

Computer Science Department
The University of Texas at Tyler
Tyler, TX, 75799, USA

Abstract—Phishing is one of the significant threats in cyber security. Phishing is a form of social engineering that uses e-mails with malicious websites to solicitate personal information. Phishing e-mails are growing in alarming number. In this paper we propose a novel machine learning approach to classify phishing websites using Convolution Neural Networks (CNNs) that use URL based features. CNNs consist of a stack of convolution, pooling layers, and a fully connected layer. CNNs accept images as input and perform feature extraction and classification. Many CNN models are available today. To avoid vanishing gradient problem, recent CNNs use entropy loss function with Rectified Linear Units (ReLU). To use a CNN, we convert feature vectors into images. To evaluate our approach, we use a dataset consists of 1,353 real world URLs that were classified into three categories-legitimate, suspicious, and phishing. The images representing feature vectors are classified using a simple CNN. We developed MATLAB scripts to convert vectors into images and to implement a simple CNN model. The classification accuracy obtained was 86.5 percent.

Keywords—Classification; convolution neural networks; machine learning; phishing URLs

I. INTRODUCTION

Convolution Neural Networks (CNNs) present a tool that enables the computer to learn from image samples, extract internal representations, and classify images. Study into CNN has increased in recent years as the computing power is being available. CNNs have several advantages such as they do not require any feature extraction technique. CNNs extract features through convolution and pooling. Through unique layer designs CNNs can extract higher order statistics and non-linear correlations. Today, many CNN models are available in practice that can be executed efficiently with recent advantages in hardware like Graphical Processing Units (GPUs). CNNs need image data as an input. Conventional Machine Learning (ML) techniques require samples in the form of a feature vector for classification. The purpose of feature extraction to reduce data by measuring certain features or properties that distinguish input samples. Samples belonging to the same categories form clusters in the feature space. The classification problem essentially reduces to partitioning the feature space. When classes overlap in the feature space classifiers such Naïve Bayes classifier makes decisions based on posterior probabilities. Commonly used parametric and non-parametric classification techniques in ML include decision trees, neural networks, minimum distance classifier, Support Vector Machine (SVM), Naïve Bayes classifier, etc. For these conventional ML techniques, input is presented in the table form and each sample is represented by a feature vector, whereas for CNN models, data is presented in the form of an

image. To take advantage of CNNs one-dimensional feature vectors can be converted into two-dimensional images. A lot of data such as genomics, transcriptomic, methylation, mutation, text, spoken words, financial and banking are in non-image form and ML techniques used in these fields. Sharma et al. [1] have suggested a methodology to transform non-image data to image data. They have suggested a method to map a vector consisting of gene expression values to a feature matrix. In their method the location of a feature in the feature matrix depends upon similarity between feature values. In this paper, we suggest a new approach to map a feature vector to a feature matrix or the output image. In our approach, we divide the output image into regions and the gray value of each region is determined by a value in the feature vector. Each region in the output image represents a value in the feature vector. The number of regions in the output image is the same as the dimension of the feature vector. We have considered the problem of classification of Uniform Resource Locators (URLs) using a Deep Convolution Neural Network (DCNN). URL represents documents and other resources on the World Wide Web (WWW). Malicious web sites present a serious threat to cybersecurity. Malicious websites host unsolicited contents such as spam, phishing, viruses, etc. Many Machine Learning (ML) algorithms have been used to classify malicious URLs into classes such as legitimate, suspicious, or phishing. Common types of attacks using a malicious URL include Driven-by download, phishing, and spam. URLs consist of two components the protocol identifier and resource name. These two components are separated by a colon and two forward slashes. The common method to detect malicious URLs is the black-list method, which is database compiled over the period. ML approaches for URL classification use a set of URLs as training data and develop a model. To develop a model, one needs to extract features from URLs. In the present study, we have used a dataset consists of features 1,353 real world URLs that were classified into three categories-legitimate, suspicious, and phishing. The dataset contains ten attributes. The three classes: phishing, suspicious, and legitimate are denoted by -1, 0, and 1 respectively. We have converted the feature vectors into images that were stored in three folders. The folder names are the same as the class names. We developed a MATLAB script to map feature vectors into images, to implement a simple convolution neural network to classify URLs. The outline of the paper is as follows. The related work is provided in Section II. The proposed approach is described in Section III and implementation and results are provided in Section IV. Section V presents the conclusions and the future work.

II. RELATED WORK

This paper deals with phishing detection using convolution neural networks (CNN). CNN models are a part of artificial intelligence (AI). AI includes any technique that enables computers to mimic human behavior and reproduce or excel over human decision making to solve complex tasks independently or with minimum human intervention [2]. AI research deals with reasoning, knowledge representation, natural language processing. AI includes machine learning (ML) algorithms, Artificial Neural Networks (ANN), and deep learning networks. Machine learning evolved from pattern recognition and computational learning theory [3]. ANN models are biologically inspired. They learn from training samples and have used in pattern recognition since 1950s. Many ANN models with learning algorithms such as multilayer perceptron, backpropagation, Boltzmann machine, Hopfield net, neo cognition model etc. are available in practice [4,5,6,7]. Deep learning is a form of machine learning that enables computers to understand the world in terms of hierarchy of concepts. Convolution Neural Networks (CNNs) are special type of networks for processing data that have a known grid like structure [8]. DNNs discover in large datasets using the backpropagation algorithm [9]. CNNs are feedforward networks in that information flow takes place in one direction only, from their input to output [10]. CNN architectures in general consist of convolution and pooling layers that grouped in modules followed by fully connected layers. CNNs evolve into deep convolution neural networks (DCNN). DCNNs proven to be one of the best learning algorithms for understanding image contents and shown exemplary performance in image segmentation, detection, and retrieval tasks [11]. Recent developments in DCNN were possible because of availability of large data sets and graphical processing units (GPUs). With the ability of new programming framework, availability of data, and accessibility to GPUs many analytical models are developed [12]. DCNNs use gradient decent backpropagation algorithm. The use of Sigmoid activation functions leads to saturation resulting into slow convergence of gradient decent algorithm. The problem becomes sever as we go away from the output layers to hidden layers. The compound effect of saturation at multiple layers is known as vanishing gradient [13]. To avoid the vanishing gradient problem, DCNNs often use entropy loss functions with Rectified Linear Units (ReLU) in the output layer. Another issue with DCNNs is overfitting. Various regularization techniques such as dropout or bagging are used to overcome this problem [14].

Phishing URLs is one of significant threats in the world today. Commonly used technique for phishing URLs detection is blacklisting. Blacklists include sender blacklists and link blacklists. The effectiveness of using blacklists depends on update of databases that maintain blacklists. Phishing emails are sent from an Internet disguised as an email from a legitimate, trustworthy source. Many researchers have worked on phishing email detection. Gilehan and Taylor [15] used syntactic features for phishing detection. They presented the

comparison of sentence syntactic similarity and the difference in subjects and objects of target verbs between phishing emails and legitimate emails. Fang et al. [16] suggested a framework to detect phishing emails based on improved recurrent convolution neural networks (RCNN) with multilevel vectors and attention mechanism. In their approach to extract features they divide each email into multiple levels, the character and word level of the email header as well as the character and word level of the email body. Rashid et al. [17] propose an efficient machine learning based phishing detection technique. They first extract lexical, host and word vector features and using the principal component analysis to reduce the number of features and use the SVM model for classification. They use five principal components and obtain the efficiency of 95.66 percent. Machine learning techniques for phishing extract features that distinguish legitimates from phishing websites. Features are extracted from various sources such as URLs, page content, search engine, digital certificate, web traffic etc. Software based approaches are classified into machine learning based, blacklist based, and visual similarity based [18].

Zhang et al. [19] proposed a page content-based technique. Huang et al. [20] proposed an approach that is based on URL features. They have used 23 features from URL and used the SVM. The two classifier values are fed into the fusion model. Abdelhamid et al, [21] built a system for detecting phishing URLs based on associative classification. Hadi et al. [22] proposed an approach for detecting malicious URLs using only visible features from social networks. Kulkarni and Brown [23] have classified phishing URLs using machine learning techniques such as SVM, decision tree, Naïve based classifier, and ANN. Sahoo et al. [24] provide a comprehensive survey and structural understanding of malicious URL detection techniques using machine learning. Yang et al. [25] have proposed a spam filtering method based on multi-model fusion. During pre-processing they separate text and image data from an email. The text dataset to train Long-Short Term Memory (LSTM) and image datasets are used to train a CNN model. CNN architecture allows dealing with images effectively. CNN architecture employs a collection of neighborhood pixels as opposed to individual use of features by ML models [1]. Chiramdasu, et al. [26] explore the various ways of detecting malicious links from the host-based and lexical features of the URL to protect users from being subjected to identity theft attacks. We have used a CNN model for classification of URLs into three classes legitimate, suspicious and phishing. We used features that are extracted from URLs. To use CNN, we first converted feature vectors to images that were classified by the CNN model.

III. METHODOLOGY

In this paper, we propose a framework for classification of phishing URLs. In our approach we use the features that are extracted from URLs. Often phishing emails contain URLs of malicious websites. We use a simple DCNN to classify URLs from their feature vectors. The framework for the proposed approach is shown in Fig. 1. The second step in our approach converts the feature vectors into 2-D image matrices.

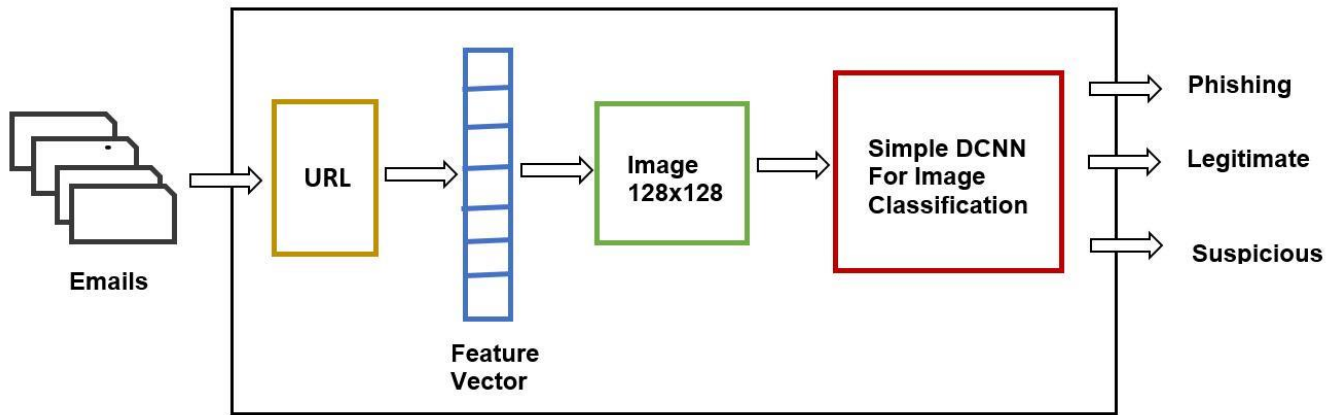

Fig. 1. Framework for phishing URL detection.

In our method we first normalize the values between 0 and 255 and create gray value regions based on the features in the feature vector, 0 corresponds to black and 255 corresponds to white. In between values are mapped to corresponding gray values. Fig. 2 shows the feature vector consists for four features and the output image. The gray values represent numeric values in the feature vector. There are four regions in the image, and each represents a feature value and the image represents the feature vectors. All feature vectors in the dataset are converted to the corresponding images. We created a datastore containing three folders one for each class. The labels of the folders are the same as the class labels. The images were of the size of 128 rows and 128 columns. The images were split into two datasets-training and testing datasets by randomly chosen images. The DCNN was trained with the training set images and was tested with images in the test dataset. Conventional neural networks with the backpropagation learning algorithms have been used for classifying feature vectors. Conventional neural networks during the learning phase use the mean squared error at the output layer and is propagated backwards to hidden layer to update the weights. That causes vanishing gradient problem. We use a simplified model of a DCNN as shown in Fig. 3.

Fig. 2. Mapping a feature vector to an image.

The model consists of the input layer, convolution layer, batch normalization layer, ReLU layer, max pooling layer, fully connected layer, SoftMax layer, and classification layer. We can specify the input image size at the input layer. There are three convolution layers. The batch normalization layers normalize the activations and gradients propagating through the network, which makes the training an easier optimization problem. The batch normalization layers are followed by an ReLU layers. The max pooling layer is used to downsize the network and extract features. The fully connected, SoftMax and classifier layers map the feature vector to class labels. The output of the SoftMax layer consists of positive numbers that sum one that are used as class probabilities. To classify URLs, we have used three classes: phishing, legitimate, and suspicious.

IV. IMPLEMENTATION AND RESULTS

We used a dataset consists of 1,353 real word URLs that are classified into three categories a) phishing, b) legitimate, and c) suspicious. The dataset used in this paper is downloaded from University of California at Irvine (UCI) Machine Learning Repository [27]. The data set consists of ten features that are extracted from each URL. The features include URL of the anchor, Request URL, Server Form Handler (SFH), URL Length, Having “@” character, Prefix/Suffix, IP address, Sub Domain, Web Traffic, and Domain Age. These features are represented by numeric values such as -1, 0, and 1. We transformed each feature vector into a gray image by mapping numeric values in the feature vector to gray value regions. The images are classified using a DCNN model shown in Fig. 3. The image size for the input layer was set to 128x128. We used a 3x3 filter size and 8, 16, and 32 filters in the first, second, and third convolution layers, respectively. We used a 2x2 region size for the max pool layer. The number of units in the output layer was set to three as there three classes in the dataset.

We developed a MATLAB script to convert feature vectors into images. Three folders were created for three classes. The folder names are the same as the class names-phishing, legitimate, and suspicious. The output images were stored in the respective class folders. The images were classified by the simple DCNN. The total number of tuples in the data set is 1353 that represents 702 phishing, 548, legitimate, and 103

suspicious URLs. The samples were split into two datasets- the training and testing datasets. Randomly chosen seventy percent samples were used for training and thirty percent were used for validation. Fig. 4 shows randomly chose sixteen images from the training datasets. The classified images with class labels are shown in Fig. 5. The DCNN was trained using the training set data. Fig. 6 shows the accuracy and error curves with respect to epochs. The validation accuracy obtained was 85.47 percent in eight epochs.

Fig. 5. Classified output images.

V. CONCLUSIONS

In this paper, we suggested a new approach to map non-image data to two-dimensional images so that data in the feature vectors form can be classified using CNN models. We mapped values in the feature vector to regions with different gray shades that are determined by feature values. We developed MATLAB script to convert feature vectors to images and classify them using a simple CNN model. The model was trained to classify real life URLs into three classes legitimate, suspicious, and phishing. We used randomly chosen seventy percent samples for training and thirty percent for testing. We obtained an accuracy of 85.56 percent. There are many ways to improve classification accuracy. In our method we used rectangular regions to map values in the feature vectors to corresponding gray regions in the output image. It is possible to use more complex shapes to define the regions. It is also possible to define shapes in the output image as a function of feature values. Furthermore, we can use DCNN models with a greater number of layers such as Alex Net, Res-Net, etc. to classify images obtained from the feature dataset. Our future work includes classifying data with DCNNs and testing the models with big datasets. In the present data set attributes consists of only three discrete values -1, 0, and 1. We plan to test the algorithm for features with multiple discrete values and explore complex shapes for mapping feature vectors to images and evaluate the suggested algorithm by comparing it with other machine learning algorithms.

A Radial Basis Network-based Early Warning Algorithm for Physical Injuries in Marathon Athletes

Ruisheng Jiao¹, Juan Luo^{2*}

College of Physical Education, Chizhou University, Chizhou, China¹

College of Foreign Languages, Chizhou University, Chizhou, China²

Abstract—For marathon runners, a single injury may affect their lifelong athletic career, so their injury management is very important. The current injury management for marathon runners has a certain lag, and the current injury warning is mainly based on manual teams, which is costly and poorly automated. To solve these problems, the study proposes a marathon athlete physical injury warning algorithm based on inertia weight adjustment optimized radial basis network. Particle swarm optimization technology has also been incorporated into early warning algorithms. Finally, an athlete injury and disease early warning model is constructed based on the algorithm. The results of performance tests show that the algorithm has a minimum fitness function value of 0.13, which is significantly lower than the current algorithm used for comparison. In the test with real data, the MAPE of the proposed algorithm was as low as 7.598% and the agreement of the hazard score results with the expert human assessment reached 100%. The results of the study indicate the practicality of the algorithm to assist work teams and perform early warning of physical injuries in athletes. However, the high number of iterations required is a limitation awaiting resolution.

Keywords—Radial basis neural network; exponentially decreasing inertia weights; early warning algorithm; sports injury; marathon; particle swarm; model building

I. INTRODUCTION

Marathon is one of the most popular athletic events. For marathoners, injury management and prevention are of the utmost importance. A single serious injury can end an athlete's career. However, there is a certain lag in the current injury management of marathon athletes. In addition, marathoner injury management is currently mainly through human analysis and decision making, which is costly and less automated [1]. To solve these problems, an early warning algorithm for physical injuries of marathon runners is proposed. The research gap of this study is focused on injury prevention for athletes. There are few studies focused on automation and algorithm applications, and there is still a large research gap in this field. Radial basis function neural networks have excellent approximation and global optimization capabilities, and are an effective tool for solving early warning problems [2]. Currently, there are few studies on the application of radial basis function networks in athlete injury prevention. This research can enrich these fields. To address the problem of balancing global and local search performance in radial basis networks, the Exponential Decreasing Inertia Weight (EDIW) strategy is introduced into radial basis networks. The physical injury warning algorithm for marathon runners is constructed

based on the radial basis network optimized by EDIW, and it is hoped that this study will bring meaningful results for injury management and warning of marathon runners.

This article has a total of V parts. The second part is related works, which reviews the research achievements in relevant fields in recent years, laying a foundation for this research. The third part is methods, which introduces the design idea of the algorithm and the construction process of the model. The fourth part is the experimental results, which show the performance of the proposed algorithm in the experiment. The fifth part is the conclusion, which summarizes the results of this study.

II. RELATED WORKS

Radial basis function neural network is a type of feedforward neural network that has superior performance and has been widely used in the prediction and warning fields. Zijie N led a team to build a mobile platform control system integrated with two Radial basis function neural networks, one for identifying the system's state and the other for predicting the mobile platform's deviation angle based on existing data [3]. The experimental results showed that the application of this algorithm during longitudinal driving reduced the correction time by 1.4 seconds and the overshoot angle by 7.4 degrees compared to traditional control algorithms. Additionally, Wang H and their research team proposed a robot fault-tolerant control model based on Radial basis function neural network prediction, which estimated external disturbances using an RBFNN and automatically handled hazardous factors employing trajectory tracking techniques [4]. The experimental results showed that this RBFNN model could predict external disturbances with an accuracy rate of over 70% and effectively mitigate their impact using tracking and vibration elimination techniques. Furthermore, Lian X and other researchers proposed a sliding mode controller based on an adaptive Radial basis function neural network that introduced a track modeling approach with 12 degrees of freedom [5]. Through performance testing and comparative analysis, the algorithm was found to perform high-precision satellite capture and release tasks. Current Radial basis function neural network research tends to focus on practical applications, with limited research investigating performance optimizations of RBFNN itself. This study addresses its own performance limitations to some extent by optimizing RBFNN prior to its use in practical applications.

Injury management and prevention in athletes has long been an important research topic in the field of sports. Ye and

Di studied injury and fatigue in a large number of winter Olympic athletes and continuously monitored their psychological status for injury prevention in winter athletes [6]. The results of the study showed that there was a significant correlation between the adequacy of athletes' preparation activities and the rationality of training programs and athletes' injuries. Wang and his research partner developed a mutual information sports injury warning model based on an attribute parsimony algorithm, which was designed for youth athletics [7]. Simulation experiments found that the model was able to warn youth track and field athletes of injuries with 80% correctness, but the model suffered from a local optimal solution. Bahr led his team to explore the characteristics of athletes' injuries and diseases based on epidemiological research methods, and they reached consensus on a set of recommendations for the latest sports injury and disease research and proposed an athlete epidemiological research report list extension [8]. The study provided a systematic understanding of the causes of injury and disease in athletes and developed protective measures accordingly. Li used data fusion techniques to analyze and assess potential injury factors in various sports and based on this, developed a dynamic chain model for early warning of risk factors for sports injuries [9]. The study provides a reference for athletes to avoid and reduce injury risk and guarantee normal training and competition, and the authors also applied the research results to tennis training and achieved scientific results. Chia and her research team studied injury prevention in athletes from a social marketing perspective and proposed a strategy to implement athlete injury prevention efforts using a social marketing mix [10]. The team analyzed in detail the useful features of the social marketing mix, including elements such as product, price, and location, and provided high-value recommendations on the corresponding injury prevention programs. According to the analysis results of the literature in the field of athlete injury management, it is found that there is less research on the balance between local and global search capabilities, and the application of radial basis function networks in the field of sports is also relatively lacking. This indicates that there is not much research focused on automation and algorithm applications in this field, and there is still large research space. Therefore, the improved radial basis network is applied to injury warning for marathon runners, hoping to bring practically meaningful research results to these fields.

III. RADIAL BASIS NETWORK-BASED PHYSICAL INJURY WARNING ALGORITHM CONSTRUCTION FOR MARATHON RUNNERS

A. Radial Basis Network Model for EDIW Optimization

Radial basis networks belong to feedforward neural networks and have excellent approximation and global optimization capabilities [11]. In addition, radial basis networks have a simpler structure compared to other feedforward networks and are therefore widely used in approximation, classification, and regression problems [12]. The marathon runner physical injury warning algorithm is based on a special radial basis network, and the topology of this network and its difference from the ordinary radial basis network are shown in Fig. 1.

Fig. 1. Radial basis function network model.

Fig. 1(a) shows the structure of the ordinary radial basis network. Fig. 1(b) shows the adopted special radial basis network, which is based on nonlinear regression and is called generalized regression network. The difference from the ordinary radial basis network is that the hidden layer of the generalized regression network is a two-layer structure, i.e., the mode layer and the summation layer [13]. The mode layer is activated using a radial basis Gaussian function, while the summation layer performs direct and weighted summation of the output values of the mode layer, respectively [14]. This structure allows radial basis networks to optimize the warning effect by eliminating the need to adjust the connection weights and only changing the smooth factor to affect the activation function of the mode layer [15]. Current particle swarm optimized radial basis networks have received attention for their stronger global search capability and computational efficiency, and therefore damage warning algorithms also use particle swarm optimized generalized regression radial basis networks [16]. However, the global search and local exploration capabilities of such optimization networks are often not easily balanced, so how to adjust the inertia weights of the algorithm and achieve the best balance is a key issue for such networks [17]. In this study, an EDIW-based strategy is proposed, and the operational flow of the radial basis network model optimized by this strategy is shown in Fig. 2.

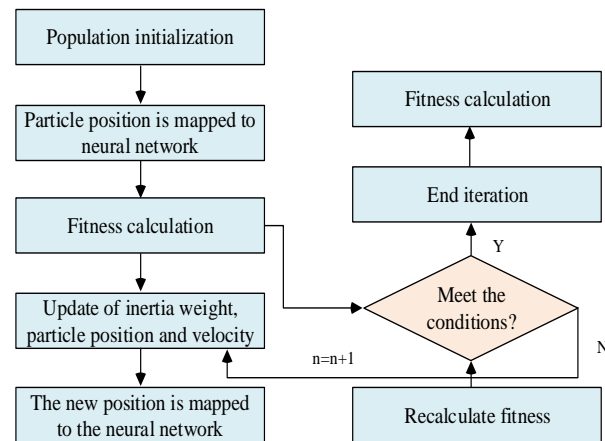

Fig. 2. Operation process of EDIW optimized RBF network model.

In this operational flow, the particle population is first initialized and the positions of the particles are mapped to the radial basis network. After that, the fitness is calculated and the inertia weights and particle positions and velocities are updated, and then the new values are mapped into the radial basis network. The mathematical expression of the EDIW strategy is shown in Eq. (1).

$$\omega(n) = \frac{n(\omega(\max) - \omega(\min))}{N} \quad (1)$$

In Eq. (1), n is the number of iterations of the neural network, and N is the maximum number of iterations. $\omega(\max)$ and $\omega(\min)$ are the maximum and minimum initial inertia weights, respectively. According to the mathematical properties of the EDIW expression, it is a linear function with the decline as shown in Eq. (2).

$$LD = \frac{\omega(\max) - \omega(\min)}{N} \quad (2)$$

The LD in Eq. (2) is the weight reduction. The inertia weights have two main roles for the motion damage warning algorithm, one is to adjust the influence of the historical velocity on the current velocity, and the other is to balance the global detection and local search ability. Therefore, at the beginning of the iteration, the inertia weights should decrease at a faster rate to ensure that the particle swarm can search the region where the feasible solution is located more quickly. At the later stage of the iteration, the inertia weight decreases at a significantly slower rate, thus limiting the step size of particle updates, which allows the particles to increase their ability to search for the optimal solution in the region of feasible solutions. Based on this theory, an EDIW strategy based on control parameters is proposed, as shown in Eq. (3).

$$\omega(n) = \exp\left(-\frac{Con * n}{N}\right) * (\omega(\max) - \omega(\min)) + \omega(\min) \quad (3)$$

In Eq. (3), Con is the control parameter whose value is always greater than 0. The strategy adds this parameter to the normal EDIW and uses it to change the drop in inertia weights. The decrease is affected by the variables Con , $\omega(\max)$ and $\omega(\min)$. Provided that the maximum and minimum initial inertia weights remain unchanged, the decrease in the weights according to the change in Con is shown in Eq. (4).

$$|\Delta\omega(n, Con)| = \frac{\exp\left(-\frac{Con * n}{N}\right) * (\omega(\max) - \omega(\min)) * Con}{N} \quad (4)$$

In Eq. (4), $\Delta\omega(n, Con)$ indicates how much the weight decreases with Con . The drop in weight becomes smaller as the number of iterations goes up. Assuming $n = N$, the expression of $|\Delta\omega(n, Con)|$ becomes Eq. (5).

$$|\Delta\omega(n, Con)| = Con * (\omega(\max) - \omega(\min)) * \exp(-Con) \quad (5)$$

The derivative function analysis of Eq. (5) is shown in Eq. (6).

$$\Delta' = \exp(-Con)(Con - 1) \begin{cases} > 0 & x < 1 \\ = 0 & x = 1 \\ < 0 & x > 1 \end{cases} \quad (6)$$

According to Eq. (6), when the value of the control parameter is greater than 1, the decline of the weights gradually converges to 0 with the increase of the control parameter. The maximum value of the decline is $\frac{1}{e}$, when the value of the control parameter is 1. So far the algorithm has achieved the design of the inertia weights with the number of iterations. The rate of decrease of the inertia weight decreases with the increase of the number of iterations. At the beginning of the iteration, the inertia weights are larger, which leads to the fact that the particles will retain more of the historical velocity. It is easy to see that the output results of the algorithm under this model are greatly influenced by the control parameters, so the values of the control parameters are important to ensure accurate results. Depending on the number of iterations, the selection of the control parameters also needs to satisfy different conditions. When $n = N$, the control parameters must be such that the inertia weights can reach or converge to $\omega(\min)$, and the inertia weights at this time are shown in Eq. (7).

$$\exp(-Con) = \frac{\omega(n) - \omega(\min)}{\omega(\max) - \omega(\min)} \quad (7)$$

In this case, the inertia weights are taken as shown in Table I.

TABLE I. INERTIA WEIGHTS

Con	1	2	3	4	5	6	7	8	9	10
$\omega(\max)$ =0.7	0.3	0.2	0.2	0.2	0.2	0.2	0.2	0.2	0.2	0.2
$\omega(\min)$ =0.2	84	65	33	09	04	01	01	00	00	00
$\omega(\max)$ =0.9	0.4	0.2	0.2	0.2	0.2	0.2	0.2	2.0	0.2	0.2
$\omega(\min)$ =0.2	58	95	34	11	05	02	01	1	00	00
$\omega(\max)$ =0.7	0.4	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3
$\omega(\min)$ =0.3	45	54	20	09	03	01	00	00	00	00
$\omega(\max)$ =0.9	0.5	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3
$\omega(\min)$ =0.3	21	79	29	13	05	02	01	00	00	00
$\omega(\max)$ =0.7	0.5	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4
$\omega(\min)$ =0.4	14	46	19	05	02	00	00	00	00	00

When $0 < n < N$, the control parameters need to be taken in such a way that the weights fall faster and then slower. In

this case, the values of the control parameters can lead to large differences in the drop curves of the inertia weights, and it is necessary to test the drop curves with different parameter values to determine the optimal parameter values.

B. Construction of Injury Influencing Factors Model and Injury Warning Algorithm for Marathon Runners

Most sports injury events in marathon runners are not triggered by a single factor, but by a plural number of influencing factors acting together [18]. Therefore a correct analysis of the influencing factors is the basis of the early warning algorithm. According to the definition of sports injuries, the risk factors that induce this type of injury can be classified as internal and external factors [19]. Internal factors refer to the physical condition of the athlete, including age, muscle strength, injury history, etc. External factors are environmental factors other than the athletes themselves, including terrain, weather, etc. [20]. However, the model of injury influencing factors from internal and external factors only lacks comprehensiveness, so stimulus-triggering factors were added as the third assessment dimension in the influencing factor model. Stimulus-predisposing factors are factors that amplify the likelihood of an athlete's injury while internal and external influences remain unchanged. When an athlete's internal or external influences are abnormal, the athlete is judged to be an injury prone individual [21]. Injury-prone individuals are significantly more likely to be injured in marathon sports than non-injury-prone individuals and require extra attention. When stimulus triggers are present, the likelihood of injury increases and the risk is higher for injury-prone athletes, at which point the algorithm needs to warn the athlete and their team in a timely manner. This study compiled injury-influencing factors for marathon athletes based on the opinions of a panel of professional track and field players and coaches, as well as a large number of actual situations in competition, as shown in Fig. 3.

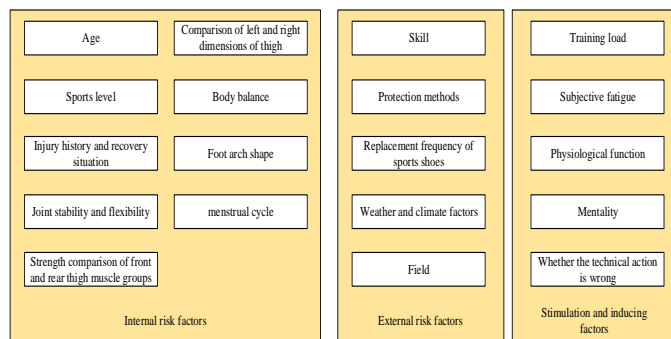

Fig. 3. Influencing factors of injury and disease of marathon athletes.

After importing the injury influencing factors into the radial basis network and training, the early warning algorithm is able to determine the injury risk of marathon runners by the input physical and other related information. The athlete's injury risk is classified as low, medium or high. The algorithm does not warn for low risk. For medium risk, the algorithm issues an alert and indicates the source of the risk to the athlete and his or her team. For high risk, the algorithm issues a warning and strongly advises the athlete not to participate in the competition or to take appropriate measures. The hidden layer activation

function of the radial basis network is a Gaussian function, whose mathematical expression is shown in Eq. (8).

$$f_j(x) = \exp\left(-\frac{\|x - c_j\|^2}{2\sigma_j^2}\right) \quad (8)$$

In Eq. (8), $f_j(x)$ represents the output value of the j hidden layer node. x It is the independent variable and the input to the network. c_j is the center vector of the kernel function of the j hidden layer node. Under this activation function, the output of the radial basis network is shown in Eq. (9).

$$y_j = \sum_{j=1} \omega_j f_j(x) \quad (9)$$

In Eq. (9), y_j is the output of the i th output layer node, and ω_{ij} is the connection weight between the i th and j th hidden nodes. Since the position vector of each particle in the radial basis network is composed of the function center, function width and connection weights, these three elements need to be defined [22]. First an error function needs to be defined, as shown in Eq. (10).

$$M = \frac{\sum_{q=1} E_q^2}{2} \quad (10)$$

In Eq. (10), M is the error function and E_q is the error of the input sample. The definition of the error is shown in Eq. (11).

$$E_q = d_q - \sum_{j=1}^3 \omega_{ij} \exp\left(-\frac{\|x - c_j\|^2}{2\sigma_j^2}\right) \quad (11)$$

Eq. (11) in d_q represents the value of the desired type of sample. The values vary according to the different athlete injury risk levels, 1 and 2 for low risk, 3 and 4 for medium risk, and 5 for high risk. According to the error function, the weights of the radial basis network output cells are shown in Eq. (12).

$$\omega_{ij}(m+1) = \omega_{ij}(m) - \eta \frac{\partial M(m)}{\partial \omega_{ij}} \quad (12)$$

In Eq. (12), $m+1$ is the value after iteration and m represents the current value of the individual variable. η represents the learning efficiency. The radial basis network implicit layer function centers are defined as shown in Eq. (13).

$$c_j(m+1) = c_j(m) - \eta \frac{\partial \eta(m)}{\partial c_j} \quad (13)$$

Eq. (13) in c_j is the center of the function. The width of the function is defined, as shown in Eq. (14).

$$\sigma_j(m+1) = \sigma_j(m) - \eta \frac{\partial M(m)}{\partial \sigma_j} \quad (14)$$

Finally, the fitness function of the radial basis network needs to be defined. The fitness function uses the relative error function between the actual output and the network output, and its mathematical expression is given in Eq. (15).

$$F = \frac{\sum_{r=1}^R \sum_{k=1}^K (y_{rk} - \dot{y}_{rk})}{R} \quad (15)$$

In Eq. (15), y_{rk} represents the first r output value of the k output neuron, and \dot{y}_{rk} is its actual value. R is the sample size and K is the number of output neurons. In the practical application of the physical injury warning algorithm for marathon runners, it is first necessary to initialize the particle population and map its position into the radial basis network. After training, the radial basis network calculates the global extremes of the particles. After updating the weights, the particle fitness is calculated again and iterated continuously. If the population fitness after iteration is better than the last one, the iterated extreme value is used as the new extreme value. Keep iterating until the global extreme value meets the fitness filtering condition to output the prediction result.

IV. PERFORMANCE AND APPLICATION EFFECT TEST OF PHYSICAL INJURY WARNING ALGORITHM FOR MARATHON RUNNERS

The experimental hardware environment is a computer system with I7 processor and 8G memory, and the programming environment is PYTHON, and the experimental procedure is to test the theoretical performance of the early warning algorithm by simulating the environment and test data set, and finally to conduct the practical application test by using the data of real marathon runners' bodies and other related factors. Since the performance of the proposed warning algorithm is greatly influenced by the control parameters, the optimal control parameters need to be confirmed first. The inertia weight variation curves under different control parameters are shown in Fig. 4.

The number of iteration steps of the radial basis network is set to 1000 in Fig. 4, and the maximum and minimum initial weights are 0.7 and 0.2, respectively. Fig. 4 illustrates that smaller control parameters ensure that the inertia weights change slowly at the beginning of the network iteration, allowing the algorithm more space to find the ideal region while larger control parameters enable the algorithm to arrive at the minimum initial weight when it is iterating to the maximum number of iterations. When the control weights are above eight, the inertia weights drop too fast and reach the lower bound at 400 iterations. And when the inertia weight is less than six, the inertia weight decreases too slowly, and the lower bound is still not reached by the maximum number of iterations. In general, when the control parameter ranges from 6 to 8, the inertia weight decreases more satisfactorily. This experiment takes the middle number 7 as the control parameter

of radial base network. After completing the control parameter setting, the simulation performance test of the warning algorithm was started. Firstly, experiments were conducted on the variation of the fitness function curve of the parameters with the number of iterations. In order to compare and determine the differences between the proposed algorithm and the existing algorithms, a normal radial basis network, a particle swarm optimized radial basis network and a linear decreasing inertia weight (LDIW) optimized radial basis network are used here as the comparison algorithms, and the results are shown in Fig. 5.

Fig. 4. Change of inertia weight under different control parameters.

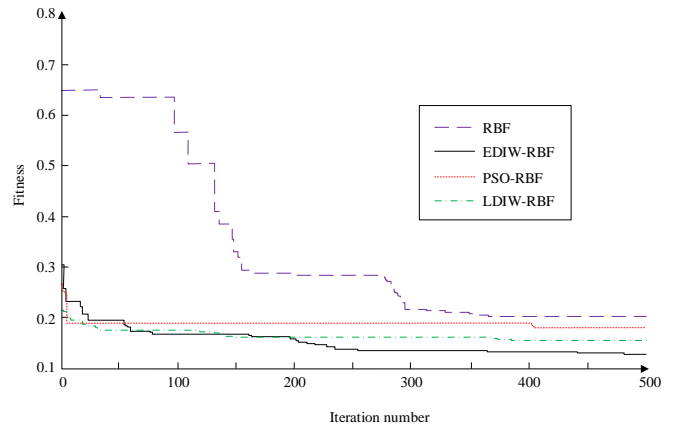

Fig. 5. Change of algorithm fitness function curve.

According to Fig. 5, it can be seen that the radial basis network without any optimization has the slowest convergence rate in terms of fitness, and the fitness that reaches stability after convergence is 0.22, which is greater than the other algorithms. The proposed EDIW optimized radial basis network shows a convergence speed very close to the other two optimized radial basis networks in the experiment and has the smallest fitness function value, which is 0.13. The four algorithms have the highest to lowest fitness function values in order of radial basis networks; particle swarm optimized radial basis networks, LDIW radial basis networks and the proposed

algorithm. The results illustrate that the proposed early warning algorithm has the smallest neural network training error and shows the highest accuracy with negligible differences between the convergence speed and similar optimization algorithms. The next experiment trained the algorithm using time-series data of injury influencing factors of marathon runners, and the output obtained is shown in Fig. 6.

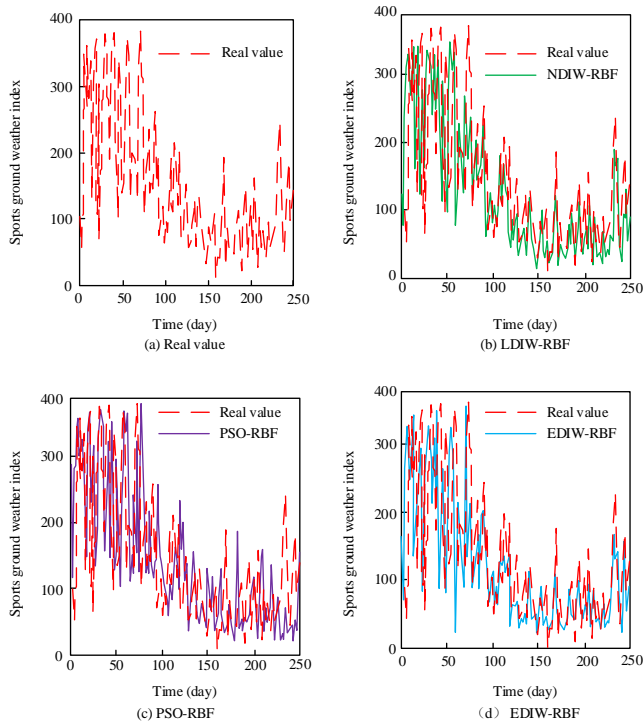

Fig. 6. Output curve of algorithm in training.

In Fig. 6, Fig. 6(a) shows the actual values of the training data; Fig. 6(b) shows the superimposed images of the output of the radial basis network optimized by LDIW and the actual values; Fig. 6(c) shows the superimposed images of the output of the radial basis network optimized by particle swarm and the actual values; Fig. 6(d) shows the superimposed images of the output of the proposed algorithm and the actual values. It can be seen that the weather index of the sports field in this dataset reaches a maximum of 390 and a minimum of 11, showing an overall trend of significant fluctuations followed by a decrease. All three algorithms used in this session are able to restore the trend of the real data, but some errors can still be observed. To further compare the errors in a quantitative and visual way, the error images of the three algorithms in this session were drawn, as shown in Fig. 7.

In Fig. 7, Fig. 7(a) shows the error image of the particle swarm optimized radial basis network; Fig. 7(b) shows the error image of the LDIW optimized radial basis network; and Fig. 7(c) shows the error image of the proposed algorithm. It is not difficult to see that the training errors under all three algorithms show a trend from large to small. Before the 80th iteration, the error values of all three algorithms fluctuate more drastically. Both the radial basis network with particle swarm optimization and the radial basis network with LDIW optimization show an error of more than 250. The maximum

error of the proposed algorithm, on the other hand, is 235, which shows an advantage in terms of the error maximum. After the 80th iteration, the errors of all three algorithms decreased significantly, indicating that the predictive stability of the algorithms for the test data increased with the number of iterations. The mean square error (MSE), root mean square error (RMSE) and mean absolute error (MAE) of the three algorithms in training were tested, and the three metrics of the proposed algorithms were found to be 2.521, 0.129, and 20684, which are the smallest among the three compared algorithms. This represents that the error of the proposed algorithm is the smallest of several algorithms. After completing the network training and related experiments, the actual accuracy of the early warning algorithm was further tested using real data sets, and the test results are shown in Table II.

Fig. 7. Error comparison of different algorithms.

TABLE II. ALGORITHM ERROR TEST RESULTS UNDER REAL DATA

Case number	PSO-RBF	LDIW-RBF	EDIW-RBF	Actual value
1	224.34	223.14	234.75	231.50
2	247.48	245.87	236.61	223.00
3	241.01	250.63	241.11	281.00
4	247.00	248.47	241.75	215.00
5	249.63	246.33	239.07	247.00
Index	\	\	\	\
MAPE (%)	8.796	8.213	7.598*	\
MSE	6.846	5.268	4.996*	\
RMSE	0.011	0.010	0.008*	\

^a Note: "*" indicates that the error of this item is the lowest among the three algorithms.

Table II provides the error performance of the proposed algorithm and the two compared algorithms with the real data set and uses it to evaluate their actual accuracy. The proposed algorithm exhibits an RMSE of 0.008, MSE of 4.996, and

Mean Absolute Percentage Error (MAPE) of 7.598% in this session. The three errors metrics of the proposed algorithm are the lowest among the compared algorithms, which indicates that the actual accuracy of the proposed algorithm is better than the other two algorithms. This result further demonstrates the feasibility of applying the improved EDIW to the particle swarm radial basis function neural network, and its optimization effect is higher than other similar algorithms. Although the proposed algorithm has shown better performance than similar algorithms in predicting injury and illness factors in marathon runners, in reality most injury and illness risk factors management in marathon runners is still implemented by expert teams for human management. This management approach has proven to be effective, but consumes more human resources. Although the proposed algorithm can save labor cost, its consistency with expert team decision making still needs to be proven. Therefore, the experiments were conducted using the same set of athletes and race data, allowing the expert team and the algorithm to be evaluated separately, and the results are shown in Fig. 8.

Fig. 8(a) shows the results of the radial basis network with particle swarm optimization versus expert team decision making. Fig. 8(b) and Fig. 8(c) show the results of LDIW versus the output of the proposed algorithm versus the expert team decision, respectively. Although all three algorithms agree with the expert decision results in terms of the trend of the hazard level for different cases, only the hazard level scoring results of the proposed algorithm agree with the expert assessment by 100%. The agreement between the results of the particle swarm algorithm and the expert assessment is only 20%, while the agreement between the LDIW optimization algorithm and the expert assessment is 80%. This result indicates that the judgment of the radial basis network with particle swarm optimization has been very close to the judgment of experts who have worked in the industry for many years, which represents that compared to other algorithms, the learning effect of the radial basis network with particle swarm optimization is better, following the results of personal judgment by the close person.

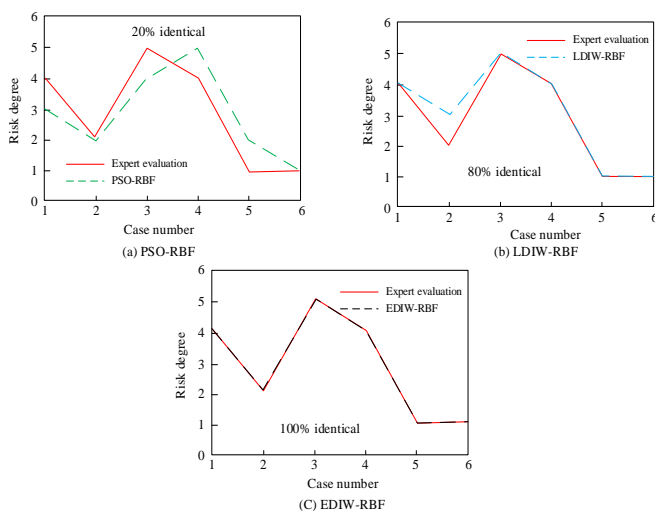

Fig. 8. Comparison between algorithm output and expert evaluation results.

V. CONCLUSION

To address the problems of lag and low automation in modern marathon tele-mobilization injury management, this study proposes a marathon athlete physical injury warning algorithm based on particle swarm radial basis neural network with EDIW optimization. The algorithm utilizes the EDIW strategy to optimize the search process of the neural network to ensure that the algorithm achieves an optimal balance between global search and local search. The minimum fitness function value of the proposed algorithm is 0.13, which is lower than the values of particle swarm radial basis network and LDIW radial basis network. In the training session of the neural network, the MSE, RMSE, and MAE of the proposed algorithm are 2.521, 0.129, and 20684, respectively, with lower errors than other comparative algorithms. In the test with real data, the MAPE of the proposed algorithm is as low as 7.598%, while the MAPEs of the LDIW radial basis network and the particle swarm radial basis network used as comparisons are both above 8.1%. In the comparison with the expert group's assessment, only the hazard score results of the proposed algorithm reached 100% agreement with the expert assessment. The experimental results demonstrate the practicality of this injury warning algorithm and its ability to enhance the automation of injury management for marathon runners. Although the construction of this algorithm has been successful, there are obvious limitations. Only when the number of iterations is high enough, the negative impact of parameter initialization of the proposed algorithm is small. However, this will lead to a large amount of computation, which leads to a high overhead of algorithm operation. In the case of a low budget, this algorithm may be difficult to apply to reality. How to reduce the computational complexity of the algorithm while ensuring performance is the focus of future research. In this regard, based on global optimization algorithms, using algorithmic search to find the most appropriate initial value, thereby reducing the amount of computation, is a promising direction.

Abstract—Hand movement classification based on Electromyography (EMG) signals has been extensively investigated in the past decades as a promising approach used for controlling upper prosthetics or robotics. Topological data analysis is a relatively new and increasingly popular tool in data science that uses mathematical techniques from topology to analyze and understand complex data sets. This paper proposes a method for classifying hand movements based on EMG signals using topological features crafted with the tools of TDA. The main findings of this work on hand movement EMG classification are as follows: (1) topological features are effective in classifying EMG signals and outperform other time domain features tested in the experiments; (2) the 0-th Betti numbers are more effective than the 1-st Betti numbers; (3) Betti amplitude is a more stable and powerful feature than other topological features discussed in this paper. Additionally, Betti curves were used to visualize topological patterns for hand movement EMG.

Keywords—EMG classification; persistent homology; topological features; betti curve

I. INTRODUCTION

Electromyography (EMG) is a bioelectrical signal generated by muscle cells, providing valuable information about muscle activity that can be used to recognize hand movements [1]. Over the past few decades, various techniques have been developed to discriminate hand movements from EMG signals [2], [3], [4], [5], and most follow a unified analysis pipeline that involves preprocessing, feature extraction, and classification. Feature extraction involves transforming raw data into a feature vector that is later fed into a classifier. The dimension of the feature vector is usually much smaller than the raw data, which helps to reduce redundant data and prevent learning from the curse of dimensionality [6], thus accelerating learning speed and generalization steps. Therefore, choosing the right features has a significant impact on classification performance.

Previous studies have evaluated the ability of various EMG features to recognize hand movements, which can be categorized into time and frequency domains. Time-domain features analyze EMG signals over time, and common ones include mean absolute value (MAV) and root mean square (RMS) [7]. Frequency-domain analysis involves measurements that describe specific aspects of the signal's frequency spectrum, with mean frequency and median frequency being two useful features [8]. In addition, there are also end-to-end learning models that try to learn a feature representation of raw signals instead of using hand-crafted features [9], [10]. These models map the initial input to the final outputs directly, making it difficult to classify features into a particular domain.

In this work, we introduce a new type of feature for hand movement classification called topological features. The primary method used in this study to extract topological features falls in the field of topological data analysis (TDA). TDA is an approach that extracts topological features and describes the geometric shapes of datasets using techniques from topology [11], [12], [13]. Topological invariants are flexible and independent of metrics and coordinates, which allows us to compare EMG data collected from various wearing manners of EMG sensors. Additionally, topological invariants characterize the overall features of datasets, making topology-based solutions less sensitive to noise and enabling the identification of EMG signal shapes despite countless deformations [14]. For a point set in a Euclidean space, we can obtain a filtration of simplicial complexes as the spatial scale changes. The filtration of simplicial complexes provides a multi-scale perspective to understand data. The most common constructions of the filtration of simplicial complexes are the Vietoris-Rips complex and the Čech complex [15], [16]. Persistent homology is proposed to measure the topological features of data that persist across all scales. Since topological features are detected over a wide range of spatial scales, it is more likely to find true patterns of shape behind the data rather than noise.

TDA has found applications across diverse fields, such as material science [17], [18], biomolecules [19], [20], oncology [21], sensor networks [22], and data science [23]. Numerous TDA-based methods have been proposed for time series analysis [24], [25], [26]. For example, Pereira and de Mello developed a time series clustering approach using topological features computed by persistent homology [27]. Khasawneh and Munch tracked the stability of stochastic dynamical systems with TDA [28]. Gidea and Katz detected market crashes with financial time series analysis using topological features [29]. Emrani et al. applied TDA for wheeze detection in breathing sounds [30]. TDA has also been employed in ECG signal analysis, with Ignacio et al. identifying Atrial Fibrillation using topological features [31] and Dlugas detecting arrhythmias with topological methods [32].

This study presents a novel and effective method for visualizing and recognizing hand movement EMG signals and provides guidance for selecting hyper-parameters. The main innovations of this work are as follows. First, our approach does not rely on a specific embedding dimension and delay to transform time series signals into point clouds for analysis. Instead, we explored various combinations of embedding dimensions and delays to determine the optimal values and understand the relationship between classification accuracy

and the embedding parameters. Secondly, a wide range of topological features (Wasserstein amplitude, Betti amplitude, landscape amplitude, and persistent entropy) were considered from the perspective of entropy and amplitude to classify EMG signals. The topological features derived from different dimensions of homology groups were considered separately and jointly. Finally, we pioneered the use of Betti curves to visualize the topological structure of EMG signals. Betti amplitude can be used as a metric to evaluate the difficulty in distinguishing two hand movements using EMG signals.

To the best of our knowledge, this is the first work that employs topological features for classifying hand movements based on EMG signals. Our experimental results show that the proposed topological features achieve higher accuracy than other time-domain features for EMG signal classification. The main contributions of this study are: (1) The information conveyed by the 0-th Betti numbers is found to be more effective than that conveyed by the 1-st Betti numbers in classifying EMG signals. Combining the 0-th and 1-st Betti numbers does not result in higher classification accuracy, but instead yields a lower accuracy than using only the 0-th Betti numbers. (2) Among the four topological features explored, Betti amplitude, which is the L_2 -metric between Betti curves, is stable and effective in classifying EMG signals, with its accuracy almost unaffected by the embedding dimension and embedding delay. (3) Inspired by the effectiveness of the 0-th Betti numbers in classifying EMG signals, we visualized EMG signals of 53 types of hand movements using 0-th Betti curves and clearly observed differences in the topological structure.

The rest of this paper is organized as follows: Section II introduces the general approach for classifying EMG signals using topological features, along with related concepts and tools. Section III delves into the experimental aspects, addressing topics such as hyperparameter selection, topological feature selection, and the effectiveness of topological features. Finally, Section IV summarizes the study and highlights potential directions for future research.

II. METHODS

This section will begin with a review of the fundamental concepts and methods of TDA that are relevant to this work. It will cover the concepts of simplex, simplicial complex, and persistent homology. Additionally, it will introduce the notion of a persistence diagram, which is one type of representation used in persistent homology. The latter part of this section will focus on the pipeline used to classify EMG signals. The pipeline involves transforming the time-series EMG signal into a metric space, followed by converting the metric space into a topological space. From this topological space, topological features are extracted and fed into classifiers.

A. Homology and Persistent Homology

The triangle is known to be one of the simplest geometric shapes in the plane, and we can combine triangles into a more complex shape. The simplex can be viewed as a generalization of the notion of the triangle in any dimension. Specifically, a p -simplex is a p -dimensional polytope which is the convex hull of its $p + 1$ geometrically independent vertices in the Euclidean space \mathbb{R}^n . For example, a 0-simplex is a point, a

1-simplex is a line segment, a 2-simplex is a triangle, a 3-simplex means a tetrahedron, etc. A simplicial complex K in the Euclidean space is a collection of simplices such that (1) each face of a simplex of K is a simplex; (2) the intersection of any two simplices of K is either empty or a common face of them. Simplicial complexes provide discrete representations for topological spaces.

Homology is one of the essential topological invariants for describing the intrinsic properties of spaces. In this work, we focus on the simplicial homology on simplicial complexes. Let K be a simplicial complex. Let \mathbb{F} be a field. Denote $C_p(K; \mathbb{F})$ the \mathbb{F} -linear space generated by the p -simplices of K . Then $C_*(K; \mathbb{F})$ is a chain complex with the boundary operator $\partial_p : C_p(K; \mathbb{F}) \rightarrow C_{p-1}(K; \mathbb{F})$ given by

$$\partial_p[v_0, v_1, \dots, v_p] = \sum_{i=0}^p (-1)^i [v_0, \dots, \hat{v}_i, \dots, v_p], \quad p \geq 1$$

for any simplex $[v_0, v_1, \dots, v_p]$ of K , where \hat{v}_i means omission of the term v_i . For $p = 0$, we denote $\partial_0 = 0$. Then the p -th homology group of K is defined by

$$H_p(K; \mathbb{F}) := \frac{\ker \partial_p}{\text{Im } \partial_{p+1}}, \quad p \geq 0.$$

The homology groups reflect the topological features of simplicial complexes. The 0-dimensional homology group detects the connected components of simplicial complexes, the 1-dimensional homology group detects the loops while higher dimensional homology groups detect higher dimensional voids or cavities. In essence, homology detects “holes” in a simplicial complex. Betti number, defined by $\beta_p = \dim H_p(K; \mathbb{F})$ is the usual topological invariant to describe the information of “holes”. The advantage of using Betti number to represent the topology pattern of data is that it is more intrinsic and more resistant to noise.

Persistent homology is the central method to detect the topological features and describe the geometric shapes of high-dimensional data in topological data analysis. The persistence is intended to focus on the multi-scale information of data sets. We build the persistent homology on data sets by a filtration of simplicial complexes. Given a collection of points in Euclidean space \mathbb{R}^n , the Vietoris-Rips complex \mathcal{R}_ϵ is the abstract simplicial complex whose p -simplices are the sets of $p + 1$ points which are pairwise within distance ϵ [15]. The Vietoris-Rips complex is the most frequently used filtration of complexes constructed from a point set. Let K be a simplicial complex equipped with a real-valued function $f : K \rightarrow \mathbb{R}$. Then we have a filtration of simplicial complex $\{K_\epsilon\}_\epsilon$ given by $K_\epsilon = \{\sigma \in K | f(\sigma) \leq \epsilon\}$. The (a, b) -persistent homology of K with respect to f is defined by

$$H_p^{a,b}(K; \mathbb{F}) := \text{Im}(H_p^a(K; \mathbb{F}) \rightarrow H_p^b(K; \mathbb{F})), \quad p \geq 0.$$

The (a, b) -persistent Betti number is given by $\beta_p^{a,b} = \dim H_p^{a,b}(K; \mathbb{F})$. There are two typical representations of persistent Betti numbers, the barcode, and the persistence diagram. The barcode and the persistence provide the visualization of the persistent homology. See Fig. 1 as an example. Consider a collection of points in a Euclidean plane \mathbb{R}^n . We obtain a filtration of simplicial complexes as the parameter ϵ grows. When $\epsilon = 0$, the Vietoris-Rips complex \mathcal{R}_0 is the

Fig. 1. A nested sequence of simplicial complexes as the radius increases.

simplicial complex of discrete points. By setting the sample points as the circle center and setting the scale parameter ϵ as the radius of a circle, the filtration of simplicial complexes can be constructed as follows: if two circles have an intersection, then add a line segment between the two points ($\epsilon = 1$). If three circles have intersections with each other, then add a triangle among the three points ($\epsilon = 2$). Thus simplices are added to the complex step by step, which generates a nested sequence of simplicial complexes as the radius increases. As the scale parameter grows, some generators come into existence at some parameters while some generators disappear at some parameters. The parameter that a generator α appear is called the birth time of α , and the parameter that α disappears is called the death time. The (birth, death) pairs are plotted in a diagram called persistence diagram. Persistence diagram provides a concise description of the topological changes over all scale parameters.

B. Topological Features

Although persistence diagrams are useful descriptors of data, they may not be suitable as input data for most machine learning models due to the absence of a natural linear structure. However, this limitation has been addressed through vectorizing persistence diagrams or using kernel methods. In this study, we extract four types of topological features by vectorizing persistence diagrams. These features have been successfully employed in other work for time series analysis. The four features can be categorized into two groups: entropy and amplitude. Entropy refers to persistent entropy, while amplitude includes Wasserstein amplitude, landscape amplitude, and Betti amplitude. The followings are the details of the topological features.

- (a) *Persistent entropy*: Persistent entropy is defined as the Shannon entropy of the persistence diagram. In general,

the lower the persistent entropy is, the simpler the shape of the data will be. Let D be a persistence diagram and $\alpha = (b_\alpha, d_\alpha)$ be a point in the diagram. Then, the persistent entropy of D is defined as:

$$E(D) := - \sum_{\alpha \in D} p_\alpha \log p_\alpha \quad (1)$$

where

$$p_\alpha = \frac{d_\alpha - b_\alpha}{\sum_{\alpha \in D} (d_\alpha - b_\alpha)} \quad (2)$$

- (b) *Amplitude*: The main idea behind amplitude is to partition a diagram into sub-diagrams based on homology dimension, and use a metric to measure the distance of each sub-diagram (or the derivative of each sub-diagram) with respect to the diagonal diagram. The diagonal diagram consists of only the diagonal line. Wasserstein amplitude computes the p -Wasserstein distance between sub-diagrams and the diagonal diagram, and it is defined as:

$$A_w = \frac{\sqrt{2}}{2} \sum_{\alpha \in D} ((d_\alpha - b_\alpha)^p)^{\frac{1}{p}} \quad (3)$$

Landscape amplitude computes the L_p distance between persistence landscapes derived from sub-diagrams and the persistence landscape derived from the diagonal diagram. Betti amplitude, on the other hand, computes the L_p distance between Betti curves derived from sub-diagrams and Betti curve derived from the diagonal diagram. Persistence landscapes and Betti curves are two other representations of topological signatures. In this study, we only consider the case of $p = 2$.

C. Time Delay Embedding

To compute persistent homology and extract topological features from the 1-dimensional time series EMG signals, they must first be represented in the form of a point cloud. This can be achieved using the method of time delay embedding, also known as Taken's embedding. Given a 1-dimensional time series $X(t)$, its time delay embedding can be described as a sequence of vectors in the following form:

$$X_i = [X(t_i), X(t_i + \tau), \dots, X(t_i + (d-1)\tau)] \in \mathbb{R}^d \quad (4)$$

where d is the embedding dimension and τ is the time delay. Each vector is treated as a point in a d -dimensional Euclidean space, and all vectors together constitute a point cloud. There are two main parameters that need to be set in time delay embedding: embedding dimension and time delay. The embedding dimension determines the dimension of the Euclidean space. A higher dimension means more information is embedded in one single point, but it is harder to find patterns from these points in a higher space. The embedding delay determines how long a term of memory is embedded in one single point. A longer term of memory means longer memory, but the resulting data points lose the short-term memory and local features. The selection of embedding dimension and delay determines the topology of the embedded point clouds and thus affects the classification results.

In most cases, EMG signals are collected from multiple electrodes, making them multivariate time series. To apply time delay embedding on multivariate signals, it is applied to each channel separately, and each channel of an EMG sequence corresponds to a point cloud. In our proposed method, we use the same embedding dimension and time delay for all channels. Considering a window of an n -channel EMG signal with the shape of $(m \times n)$, where m is the length of the window, we obtain n point clouds.

III. EXPERIMENTS

A. Dataset and Preprocessing Policy

The EMG dataset employed in our experiments is a publicly accessible dataset called NinaPro DB5 [33], which records muscle activity using two Thalmic Myo armbands. Each Myo armband is equipped with 8 electrodes, yielding a total of 16 channels of EMG signals collected. The dataset comprises 6 repetitions of 53 distinct movements (including rest) performed by 10 intact subjects. The Thalmic Myo already incorporates a 50 Hz notch filter, eliminating the need for additional filtering [34].

Before feeding the EMG signals into classification models, data preprocessing is necessary. To compare the results of our proposed method with other benchmarks, we must maintain consistency in data preprocessing. Thus, we followed the exact procedure outlined in [34]. This process involves dividing each detected repetition into 200-sample windows with an overlap of 100 samples. Subsequently, each window is labeled with its corresponding movement number. For training and testing dataset splitting, repetitions 1, 3, 4, and 6 were used for training, while repetitions 2 and 5 were designated for validation. Classification was performed on all 53 movements (including

rest). It is important to note that the rest movement's sample size is significantly larger than that of other movements, so it was reduced to avoid dataset imbalance. Python served as the programming language for conducting the experiment. We employed various Python packages, including Risper [35] for computing persistent homology and scikit-learn for building classifiers.

B. Selecting the Best Embedding Delay and Dimension

As outlined in Section II-C, we employed time delay embedding to transform time-series EMG signals into point clouds in Euclidean space. Time delay embedding involves two primary parameters: embedding dimension and delay. The selection of these parameters defines the topology of the embedded point clouds, which in turn influences the classification accuracy. To determine the optimal values for embedding dimension and delay in EMG classification, we generated point clouds for each channel by applying the same dimension and delay parameters, ranging from 2 to 10 and 1 to 9, respectively.

Subsequently, we calculated persistent homology on these point clouds and extracted persistence diagrams. The 0-th and 1-st Betti numbers were utilized to detect the number of connected components and the number of independent loops of simplicial complexes. This approach was chosen as computing higher-dimensional Betti numbers can be highly complex. Persistent entropy was then extracted as a feature descriptor from the persistence diagram. For a single channel, persistent entropy is a 2-dimensional vector in a plane, with coordinates corresponding to the 0 and 1-dimensional homology groups. As illustrated in Fig. 2, the two hypotheses being compared are labeled as H_0 and H_1 . The dataset used in this experiment contained recordings from 16 channels. When persistent entropy was computed for each channel, both H_0 and H_1 were produced, each 16-dimensional. Concatenating H_0 and H_1 resulted in a single 32-dimensional feature vector.

The EMG data was classified using persistent entropy of H_0 , H_1 , and their concatenation. Each feature was input into a random forest classifier separately. The classifiers' performance was then evaluated to identify which feature yielded the best results. Fig. 2 displays the classification outcomes. The heatmap reveals the following findings: (1) The persistent entropy of H_1 does not contribute any valuable information for EMG signal classification and exhibits poor performance. (2) Concatenating H_0 and H_1 does not significantly enhance classification accuracy. The highest classification accuracy achieved in our experiment was 71.86%, obtained with an embedding delay of 1 and a dimension of 6.

The optimal combination of embedding delay and dimension discovered in our previous experiment using persistent entropy and the random forest classifier may not be entirely convincing. Moreover, while the highest accuracy was attained at dimension 6, it is unclear whether this dimension is significantly better than dimensions 5 or 4, as the classification accuracies are only marginally different. To gain further insight into the effect of embedding delay and dimension on classification performance, we conducted a second experiment. Similar to the first experiment, we transformed the raw time-series data into point clouds for each channel using dimension

Fig. 2. Accuracy heatmap for various combinations of embedding delay and dimension.

and delay parameters selected from the range of 2 to 10 and 1 to 9, respectively, and computed persistent homology on these point clouds. We then extracted four types of topological features, namely persistent entropy, Wasserstein amplitude, landscape amplitude, and Betti amplitude. For each type of feature, we considered both H_0 , H_1 , and their concatenation. These features were then fed into both SVM and random forest classifiers for further analysis.

To explore the impact of embedding dimension on classification accuracy, we first calculated the mean accuracy for each embedding dimension across all delays and plotted the mean accuracy curve in Fig. 3. In the legend of the first subfigure, “entropy_h0_rf” denotes using persistent entropy of H_0 with a random forest classifier, while “entropy_rf” denotes using the concatenation of persistent entropy of H_0 and H_1 with a random forest classifier.

The figure reveals that: (1) The topological features of H_1 provide no meaningful information for EMG signal classification and perform poorly, consistent with the conclusion of the first experiment. The classification accuracy using the topological features of H_0 does not show a decreasing trend with any classifier, and even continues to increase beyond a dimension of 10 in the case of persistent entropy and Wasserstein amplitude. (2) Concatenating topological features of H_0 and H_1 generally does not result in a positive effect. The accuracy curve initially exhibits a rising trend, reaches a peak, and then declines. This occurs because H_1 carries less information and negatively impacts the concatenation of H_0 and H_1 . (3) Classification using Betti amplitude of H_0 proves effective and stable across all dimensions, while landscape amplitude is not a useful feature, as the landscape amplitude of H_0 , H_1 , and their concatenation did not yield acceptable accuracy.

To examine the effect of embedding delay on classification accuracy, we calculated the mean accuracy for each delay across all dimensions and plotted the results in Fig. 4. Our analysis reveals that: (1) For EMG signals, the classification accuracy using any topological feature (except landscape amplitude, which is not effective) of H_0 remains stable across all delays, indicating that embedding delay has only a minor influence on EMG signal classification. (2) When using the concatenation of topological features of H_0 and H_1 , accuracy decreases as delays increase. This can be attributed to the limited usefulness of the information carried by H_1 , which

can negatively impact H_0 . However, classification using Betti amplitude of H_0 remains stable across all delays.

Fig. 3 shows that the accuracy using topological features of H_0 has a trend of increasing even beyond a dimension of 10. To further investigate this trend, we examined dimensions ranging from 2 to 20, with an embedding delay of 1, as delay has only a minor influence on classification results. The classification results, shown in Fig. 5, reveal that: (1) Betti amplitude remains stable even at higher dimensions, without any significant decrease in accuracy. (2) For persistent entropy and Wasserstein amplitude, the increasing trend becomes less pronounced after dimension 10, and their accuracy converges to a maximum value around dimension 12. (3) The highest classification accuracy achieved is 73.93%, using Betti amplitude of H_0 at an embedding dimension of 3 and an embedding delay of 1 with SVM.

In summary, choosing the appropriate delay and dimension in time delay embedding and using Betti amplitude of H_0 as a topological feature can significantly enhance the accuracy of EMG signal classification. The main findings of the experiments are as follows:

- As the embedding dimension increases, the accuracy improves, eventually converging to a specific value. Delay has only minor effects on movement classification accuracy, so it can be simply set to 1. An exception is the case of Betti amplitude, where the classification model using Betti amplitude is robust to changes in dimension and delay. The optimal choices for delay and dimension for Betti amplitude are 1 and 3, respectively.
- H_0 contains more meaningful information than H_1 for EMG hand movement classification, regardless of the topological feature used. Combining the topological features of H_0 and H_1 has negative effects on H_0 and does not enhance accuracy.
- Betti amplitude of H_0 is the most effective and stable topological feature for classifying EMG signals, as it is robust to changes in dimension and delay and achieves the highest accuracy. Persistent entropy and Wasserstein amplitude are also good choices but require appropriate selection of embedding dimension and delay. Landscape amplitude is not an effective feature for EMG classification.

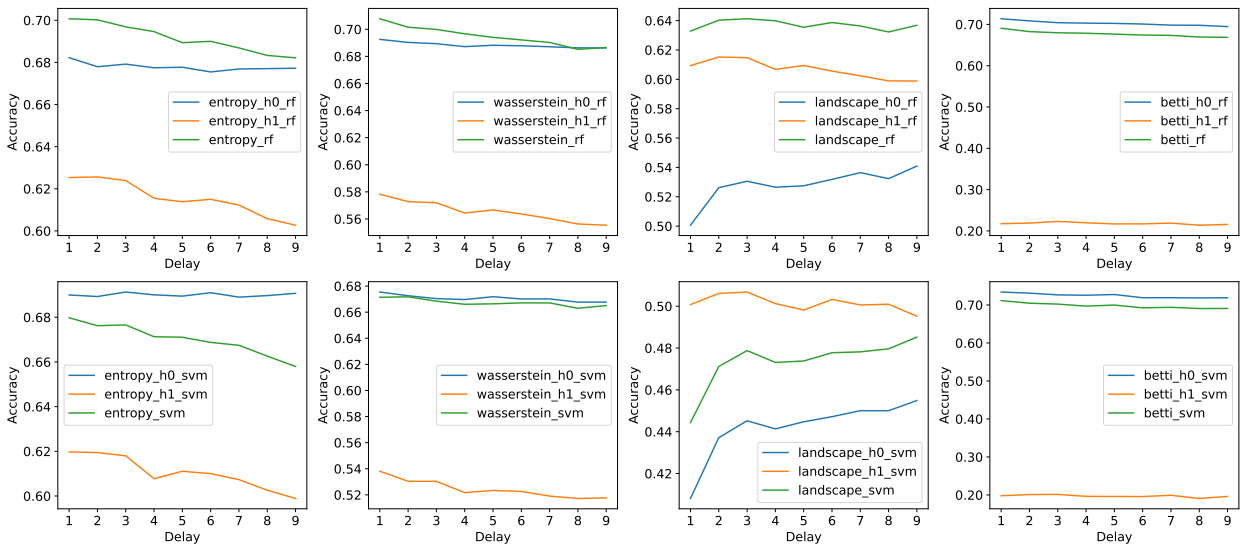

Fig. 4. The mean of the accuracy in each embedding delay across all dimensions.

Fig. 5. The classification accuracy with embedding dimensions ranged from 2 to 20.

TABLE I. CLASSIFICATION ACCURACY USING TOPOLOGICAL FEATURES AND OTHER TIME DOMAIN FEATURES

Features		Classifier	Mean accuracy	Peak accuracy	
Topological features	Persistent entropy	SVM	73.02	73.12	
	Wasserstein amplitude		70.49	70.76	
	Landscape amplitude		56.32	56.51	
	Betti amplitude		73.50	73.93	
Time domain features	RMS (Root mean square)		70.36	70.63	
	TD (Time Domain Statistics)		68.19	68.48	
Topological features	Persistent entropy		Random forest	71.51	71.69
	Wasserstein amplitude			71.69	72.07
	Landscape amplitude	64.35		64.57	
	Betti amplitude	71.37		71.77	
Time domain features	RMS (Root mean square)	71.26		71.60	
	TD (Time Domain Statistics)	69.85		70.19	

Fig. 6. Betti curves of one sample randomly selected from each of three types of hand movements, respectively.

C. Compare to Other Time-domain Features

To evaluate the performance of topological features relative to other feature types, we conducted an additional experiment using two time-domain features: Root Mean Square (RMS) and Time Domain Statistics (TS). RMS computes the root-mean-square value for each channel and constructs a 16-dimensional feature vector. In contrast, TS incorporates the mean absolute value, number of zeros, number of slope changes, and waveform length calculated from each channel [36]. We separately fed these two feature types, as well as the topological features with embedding delay and dimension determined based on the findings from previous experiments, into Support Vector Machines (SVM) and Random Forest for movement classification. We repeated the training process 10 times and recorded the classification accuracies. The mean and peak accuracy are displayed in Table I. Our results indicate that topological features, with the exception of landscape amplitude, outperform RMS and TS. Notably, the SVM model employing persistent entropy or Betti amplitude achieved a high accuracy of over 73%.

D. Visualize EMG Signals using Betti Curves

As previously mentioned, Betti amplitude is recognized for its robustness to changes in dimension and delay, and it has demonstrated the highest classification accuracy among other topological and time-domain features. This suggests that Betti amplitude may be better equipped to reveal the topology of EMG signals. However, Betti curve encodes even more topological information than Betti amplitude, as Betti ampli-

tude calculates only the L_2 distance between Betti curves. As a result, Betti curve can effectively differentiate topological patterns of distinct hand movements. This has inspired us to employ Betti curve for visualizing the topological patterns of various hand movements. For instance, we have plotted Betti curves of randomly selected samples from three types of hand movements in Fig. 6. It is important to note that only the 0-th Betti number, which counts the connected components in the topological space, is displayed in the figure, as we have demonstrated that only the information of H_0 is effective in classifying EMG signals. The figure clearly illustrates the distinct patterns of Betti curves in each channel for different hand movements.

To gain a broader understanding of the topological patterns for a specific type of hand movement, we calculated the average Betti curve by taking the arithmetic mean of Betti curves from all samples within that particular type of hand movement. This offers a more accurate representation of the general topological patterns for a given movement. By visualizing the average Betti curves of various hand movements in a single figure, we can easily observe the clear differences in topological patterns among different movements. This is demonstrated in Fig. 7, where the curve labeled “0” represents the “rest” movement, which is the fastest curve that drops to 0. This suggests that the topological space of “rest” has minimal topological complexity. Defining a distance metric on the average Betti curve could potentially aid in measuring the difficulty of discriminating a movement from EMG signals.

Fig. 7. The average Betti curves calculated for each of the 53 hand movements based on all training samples.

IV. CONCLUSIONS

The goal of this study was to determine whether topological features could enhance the accuracy of EMG signal classification for hand movements and contribute a methodology to the analysis of bio-electrical signals. The main findings of this study are as follows: (1) Topological features can effectively classify EMG signals, achieving the highest classification accuracy of 73.93%, outperforming the other tested time-domain features by nearly 2% in the experiment. (2) Topological features of H_0 prove more effective than those of H_1 . In general, higher embedding dimensions lead to increased accuracy, while embedding delay has a smaller impact on classification accuracy. (3) Among the four tested topological features, Betti amplitude is the most stable, and we have introduced Betti curves for visualizing the shape of hand movement EMG signals. Future research will explore whether these findings can be applied to other types of bio-electrical signals.

Research on Automatic Intrusion Detection Method of Software-Defined Security Services in Cloud Environment

Xingjie Huang*, Jing Li, Jinmeng Zhao, Beibei Su, Zixian Dong, Jing Zhang
State Grid Information and Telecommunication Branch, Beijing, 100053, China

Abstract—In a cloud environment, software defined security services are highly vulnerable to malicious virus attacks. In response to software security issues, this project plans to use machine learning technology to achieve automated detection of software security services in a cloud environment. Firstly, study the intrusion characteristics of software defined security services in cloud environments based on piecewise sample regression, and establish their statistical feature quantities. Then, using the method of decision statistical analysis, achieve its fixed identification. Finally, the intrusion characteristics of software defined security services in the cloud environment are studied and compared with the data in the cloud environment to obtain its power spectral density. On this basis, machine learning methods are used to extract features from software security services in the cloud environment, in order to achieve the goal of automatic extraction and optimization of software security services in the cloud environment. Through simulation experiments, the credibility of the proposed algorithm for software defined security services in the cloud environment was verified, and the attack characteristics of software defined security services in the cloud environment were effectively patched.

I. INTRODUCTION

Software Defined Network (SDN) is a new network innovation architecture first proposed by the Clean-Slate research group of Stanford University in the United States. Its design idea is to separate the data layer from the control layer, in which the control layer is a programmable central controller, which can obtain global network information, status, etc., which is convenient for operators and researchers to manage and configure the network, and can deploy customized new protocols. The data layer includes routers, switches and other packet forwarding devices, which focus on providing simple data forwarding functions and can quickly process matching packets to meet the growing needs of users in the network. SDN has a wide range of application scenarios, such as big data analysis, cloud computing, Internet of Things, and car networking. However, like traditional networks, the new features brought by SDN architecture are also threatened by cyber-attacks [1].

Network intrusion detection technology refers to identifying and filtering abnormal traffic in the network through effective technical means, which is the basic method to ensure network security. Identifying abnormal traffic in time

and accurately can effectively reduce the impact of malicious attacks on the network and users [2]. At present, machine learning algorithm has attracted much attention in the field of network security, and intrusion detection technology based on machine learning has become a hot spot for researchers [3,4]. The study [5] proposes an intrusion detection system model by using different machine learning algorithms for different application scenarios. Autoencoder (AE) shows the advantages of the algorithm based on unsupervised learning in the task of feature extraction, feature reduction and classification, which promotes the progress of network attack traffic detection. The combination of automatic encoder and one-class support vector machine (OCSVM) algorithm can improve the anomaly detection rate and effectively reduce the training time of OCSVM algorithm, thus improving the performance of intrusion detection system. Therefore, it is of great theoretical and application value to study machine learning SDN intrusion detection technology based on automatic encoder and one-class support vector machine. Effectively detect the intrusion data of software-defined security service in cloud environment, and combine the statistical feature analysis and feature extraction methods of software-defined security service intrusion in cloud environment to fix the features and collect samples of software-defined security service intrusion in cloud environment. In research [6], an intrusion feature extraction method of software-defined security services in cloud environment based on blind balanced scheduling is proposed. Combined with the backtracking control method of intrusion nodes, the intrusion feature extraction of software-defined security services in cloud environment is realized, which improves the intrusion detection ability, but the optimization control ability of this method is not good, and the real-time performance of intrusion detection is not good. In study [7], an intrusion feature extraction method of software-defined security services in cloud environment based on spectral peak correlation search is proposed, which combines the autonomous positioning technology of intrusion nodes to realize intrusion feature extraction of software-defined security services in cloud environment, but the active optimization ability of this method is not strong. The most important feature of software-defined network is that it can program the network behavior, but the original software-defined network architecture is only limited to the programmability of the control plane, and the function of its forwarding plane is still limited by the fixed function hardware supported by the equipment provider. P4 can instantiate customized pipelines and stateful objects, support the implementation of complex

workflows, user-defined protocols and finite state machines, and use P4 switch to realize a reliable attack detection system to protect edge node resources from malicious network attacks, thus maximizing network utilization and effectively ensuring service quality [8].

Aiming at the above problems, this paper proposes a software-defined security service intrusion detection method in cloud environment based on machine learning algorithm. The statistical feature quantity of software-defined security service intrusion characteristics in cloud environment is constructed by using piecewise sample regression analysis method, and the intrusion characteristics of software-defined security service in cloud environment are fixed and identified by combining decision statistical analysis method. Combined with the feature fusion analysis method of classified intrusion samples, a big data distribution model of software-defined security service intrusion features in cloud environment is constructed, and the power spectral density feature quantity of software-defined security service intrusion features in cloud environment is extracted. The machine learning algorithm is used to adaptively optimize the extraction process of software-defined security service intrusion features in cloud environment, so as to realize automatic extraction and optimization of software-defined security service intrusion features in cloud environment. Finally, the simulation experiment analysis shows the superior performance of this method in improving the intrusion feature extraction ability of software-defined security services in cloud environment [9].

II. SOFTWARE-DEFINED SECURITY NETWORK INTRUSION NODE DISTRIBUTION MODEL AND INFORMATION SAMPLING

A. Cloud Software Defined Security Network Intrusion Distribution Structure Model

The data forwarding layer is located at the bottom of SDN architecture, and contains thousands of interconnected switches, which are responsible for forwarding data packets. If the switch is damaged, the message flowing through the switch will not be forwarded normally. In addition, the switch is the direct entrance for end users to access the network, and attackers can attack the switch by simply connecting to the switch port. Man-in-the-middle attack is a typical network intrusion method. Its main principle is to insert a proxy node between the source node and the target node, intercept the communication data, and tamper with the communication data without being discovered. The specific attack methods of man-in-the-middle attack include session hijacking, DNS spoofing and port mirroring. Man-in-the-middle attack between controller and switch is an ideal way to attack SDN network [10]. It can intercept and tamper with the forwarding rules of messages sent to switch, so as to control network forwarding. After that, attackers can carry out further attacks, such as black hole attacks. In addition, there may be no direct physical connection between the controller and the switch, that is, the data packet from the switch to the controller may pass through several other switches, so in the man-in-the-middle attack, all the switches and hosts directly connected to it on the communication path can easily be converted into proxy nodes. In order to realize the optimization of intrusion feature extraction of software-defined security service in cloud

environment, it is necessary to construct a distributed sensor model of software-defined security network in cloud environment under intrusion. Combined with the distributed design method of directed graph, blind forensics and intrusion node location are carried out for intrusion feature extraction of software-defined security service in cloud environment. Combined with feature distributed sampling technology [5], the intrusion node distribution model of software-defined security network nodes in cloud environment is constructed by using packet forwarding control technology, as shown in Fig. 1.

Fig. 1. Intrusion node distribution model of software-defined security network in cloud environment.

In the software-defined secure network node distribution model in the cloud environment shown in Fig. 1, when new data traffic in the network enters the OpenFlow switch for the first time, the OpenFlow switch will generate and process a Packet_In message to the control plane. By looking at the Packet_In message, the control plane will install the flow rules (dropping, forwarding and enqueueing) into the flow table and then send them to the OpenFlow switch. There is no authentication mechanism in this communication process if there is an incorrect traffic flow in the network [10].

Data plane refers to the interconnection infrastructure composed of hardware or software-based devices, which have basic packet forwarding functions, and these functions manage the received packets according to the flow rules set by the controller through the southbound interface. Each rule entry in the flow table consists of three fields: operation, counter and mode. The mode field defines the flow mode, and the flow mode is basically a collection of field values in the packet header. When a packet is received, the switch will search for a rule matching the field in its flow table. Once the switch matches such a rule, the counter of the rule will be incremented and the operation corresponding to the specific rule will be executed. Otherwise, the switch will inform the controller to ask for help or directly discard the packet.

The control plane is an independent and logically centralized server, also called the controller, which is used to handle the flow table installation of forwarding rules and monitor the status of data plane devices and links to integrate the global network view. Its main purpose is to manage the distributed forwarding devices of data plane in the network and provide operators with a simpler API, namely the northbound interface. SDN controller communicates with the switch through southbound API, such as OpenFlow protocol, and has a global view of the whole network topology. The originally

designed OpenFlow protocol promotes the decoupling of control plane and data plane. OpenFlow provides a southbound interface for the controller to establish a secure communication channel to manage forwarding device rules and receive status updates. These rules are the operations (such as forwarding, flooding and dropping) of the data packet determined according to the header information of the data packet (such as Ethernet /IP address and TCP/UDP port). The status includes the information discovered by the link layer, and the data packet and byte counters related to the flow table, which are used to support the global network view on the control plane [11].

The application plane is composed of a group of network applications, which provides users with quick response and various business requirements, such as network virtualization, topology discovery, traffic monitoring, security, load balancing and so on. The application communicates with the controller through the northbound API, such as RESTAPI, and the control layer provides the abstraction of physical network resources for the application layer, which enables the user to give the SDN controller other functions through the application and change the data flow rules without reconfiguring all the physical switches, so as to better manage and control the network behavior.

Under the network structure of SDN, equipment suppliers can focus on designing forwarding equipment for efficiently processing data packets, and network operators can easily test and deploy customized network management applications from a higher abstract level [12].

B. Software-defined Security Service Intrusion Information Sampling

Construct a node distribution model for extracting intrusion characteristics of software-defined security services in cloud environment, and use a binary directed graph to represent $G = (V, E)$, and the node's intrusion location is $\eta_n \in \Omega_\eta, n = 1, 2, \dots, N$. Construct a packet link forwarding protocol for network intrusion, and design a node directed graph model for network intrusion, and obtain a link forwarding control protocol for software-defined security services intrusion in cloud environment, which is expressed in the following form:

$$E(p) = [0, 0, \dots, 0, \underbrace{\frac{\gamma_{th} \sigma^2}{h_i [G - (n - k - 1) \gamma_{th}]}}_{i-1}, \dots, \frac{\gamma_{th} \sigma^2}{h_i [G - (n - k - 1) \gamma_{th}]}]^T \quad (1)$$

Set $f(p_i) = \frac{-L_i}{2} \log(1 + p_i)$, by calculating the cross-correlation coefficient between different categories of the hidden layer, according to the priority $E = E_1 \cup E_2 \cup E_3$ of connecting to the software-defined security service intrusion node in the cloud environment, and combining with the correlation detection method, obtain the statistical probability

distribution statistics of the software-defined security service intrusion neighbor node in the cloud environment as follows:

$$Vt(k) = \left\{ a_{s+t} \dots a_{t+1} a_t \dots a_1 \mid \overline{a_{s+t} \dots a_{t+1}} = k, a_i \in \{0, 1\}, 0 \leq k < 2^s \right\} \quad (2)$$

Assume $a_1, a_2 \in V$, $b_1, b_2 \in V'$, for Sink nodes $EHs(j)$ and $EHt(k)$ with software-defined security service intrusion feature distribution in the cloud environment, learn quickly and generalize the method, and get the associated feature quantity of intrusion feature detection as follows:

$$T_{l1} = \sqrt{F_{p1}^2 + F_{q1}^2} \quad (3)$$

According to the number of hidden layers of the structure, the feature validity of node intrusion is analyzed, and the reliability evaluation model of intrusion feature detection is

$F_{il} = \frac{1}{P_{il}}$, thus the feature link distribution model of software-defined security service intrusion nodes in cloud environment is constructed. The hidden layer and the output layer form a complete feature chain, which is expressed as $W(p) = G_T p^2 - Cp + \alpha T$, which $W(p)$ is a quadratic function of the software-defined security service intrusion feature link set SD in cloud environment. Combined with the decision statistical analysis method, the intrusion feature of software-defined security service in cloud environment is fixed and sample identified, which improves the effectiveness of feature extraction.

C. Information Sampling of Intrusion Characteristics

A big data distribution model of software-defined security service intrusion characteristics in the cloud environment is constructed by combining the classified intrusion sample feature fusion analysis method, and the power spectral density of software-defined security service intrusion characteristics in the cloud environment is extracted, and the statistics of blind forensics judgment of software-defined security service intrusion characteristics in the cloud environment are obtained as follows:

$$\mu(n) = \begin{cases} \beta_1 [1 - \exp(-\alpha_1 |e_{MCMA}(n)|^2)], & E[(|e(n)|^2)] > K \\ \beta_2 [1 - \exp(-\alpha_2 |e_{MCMA}(n)|^2)], & \dots \end{cases} \quad (4)$$

Wherein, K is the decision threshold for successful attack $\alpha_1 > 0$, $\alpha_2 > 0$, λ_{max} is the intrusion decision thresholds for software-defined security network in cloud

environment, $0 < \beta_1 < \frac{1}{\lambda_{max}}$, $0 < \beta_2 < \frac{1}{\lambda_{max}}$. When the root mean square error of one-step attack in each variable set is

satisfied as $MSE = E[(|e(n)|^2)] > K$, take smaller α_2

and β_2 to sample the characteristic information of intrusion characteristics. The fuzzy decision algorithm for sampling the characteristic information of intrusion characteristics is described as follows:

```

ROUTE_2      (Route       $u = u_{s+1} \dots u_{t+1} u_t \dots u_1 0$ 
 $v = v_{s+t} \dots v_{t+1} u_t \dots u_1 0$ )
{
 $x = u_{s+1} \dots u_{t+1}$ ,  $y = v_{s+t} \dots v_{t+1}$ ,  $I(x, y) = \emptyset$ ;
For each  $e_i$ , if ( $u_i \neq v_i$ )  $I(x, y) = I(x, y) + e_i$ ;
While ( $I(x, y) \neq \emptyset$ )  $e_i = \text{firstselect}(I(x, y))$ ; //
Set the success probability of feature extraction.

 $y = y_{n-1} y_{n-2} \dots y_0$  //

Forwarding control protocol for variable sets form  $x$  to
 $x + e_i$ ;  $x = x + e_i$ ;  $I(x, y) = I(x, y) - e_i$ ;
}

```

According to the above algorithm design process, an intrusion detection system ML-SDNIDS based on machine learning is designed under the SDN network architecture. The overall architecture is mainly divided into two parts: the control plane and the data plane. The control plane is mainly responsible for the feature processing of the data set, the algorithm training of the intrusion detection model, the creation of the flow table and the centralized management of the data plane. The data plane is composed of multiple P4 switches connected with each other, and is mainly responsible for malicious traffic detection and packet forwarding decision. The control plane uses the existing IDS data set in the network, inputs the data set into the feature extraction module, and then the feature extraction module processes the data packet to effectively select the original features. Then the feature mapping module selects the features with strong correlation, and maps different features to the automatic encoder network. The automatic encoder calculates the root mean square error (RMSE) between the new data and the fitting data, and then uses OCSVM classification algorithm to classify the RMSE to realize anomaly detection.

III. OPTIMIZATION OF INTRUSION DETECTION FOR SOFTWARE-DEFINED SECURITY SERVICES

A. Fixed Handling of Intrusion Characteristics of Software-defined Security Services

Intrusion detection system mainly includes three modules: information collection, data analysis and emergency response. The information collection module is the foundation of the whole system, which mainly collects host log information, network segment protocol datagram information and user behavior status. The data analysis module is the core module of

the whole system, which mainly uses some means such as statistics, pattern matching and anomaly detection algorithm to quickly analyze the data collected in the information collection stage and judge whether there is abnormal behavior in network activities. The emergency response module is to take corresponding protection measures in time to prevent further damage when intrusion is detected in the previous stage.

The control plane uses the existing IDS data set in the network, inputs the data set into the feature extraction module, then the feature extraction module processes the data packet, selects the effective features of the original features, then the feature mapping module selects the features with strong correlation, maps different features to the automatic encoder network, and the automatic encoder calculates the root mean square error (RMSE) between the new data and the fitting data. Then, RMSE is classified by OCSVM classification algorithm to realize anomaly detection, and the intrusion features of software-defined security services in cloud environment are fixed and optimized. This paper proposes an intrusion detection method of software-defined security services in cloud environment based on machine learning algorithm. The statistical analysis model is adopted to construct the feature spatial distribution structure model of software-defined security service intrusion characteristics in cloud environment, and the nonlinear time series of software-defined security service intrusion characteristics in cloud environment is obtained as follows:

$$x_i(t) = x_i^1(t) + x_i^2(t) + x_i^3(t) \quad (5)$$

Wherein,

$$x_i^1(t) = \sum_{k=1}^p \varphi_{k0} x_i(t-k) - \sum_{k=1}^q \theta_{k0} \varepsilon_i(t-k) + \varepsilon_i(t) \quad (6)$$

$$x_i^2(t) = \sum_{k=1}^p \sum_{l=1}^2 \varphi_{kl} [w_{i1}^l, \dots, w_{im}^l] [x_1(t-k), \dots, x_n(t-k)]^T \quad (7)$$

$$x_i^3(t) = - \sum_{k=1}^q \sum_{l=1}^2 \theta_{kl} [w_{i1}^l, \dots, w_{im}^l] [\varepsilon_1(t-k), \dots, \varepsilon_n(t-k)]^T \quad (8)$$

When the intruder attacks the target network, combining with the piecewise linear test method, the statistical characteristics of software-defined security service intrusion detection in cloud environment are obtained as follows:

$$DS = \{(x_0, t_0), (x_1, t_1), \dots, (x_i, t_i), \dots\} \quad (9)$$

Combining machine learning and genetic evolution methods, the feature set of software-defined security service intrusion features in cloud environment is automatically clustered, and the fuzzy fit degree of software-defined security service intrusion feature detection in cloud environment is obtained as follows:

$$\begin{aligned}
O(LOF_k(p)) &= O(\text{Ird}_k(p)) + O(N_{k-\text{dist}(p)}) \\
&\quad + O(\text{Ird}_k(o_i \in N_{k-\text{dist}(p)})) \\
&= O(m * n)
\end{aligned} \quad (10)$$

In the spatial distribution area of software-defined security service intrusion characteristics in cloud environment, the adaptive scheduling of software-defined security service intrusion characteristics in cloud environment is carried out by combining genetic evolution and statistical feature analysis methods.

B. Automatic Extraction and Optimization of Intrusion Characteristics of Software-defined Security Services in Cloud Environment

Combined with the decision statistical analysis method, the intrusion features of software-defined security services in cloud environment are fixed and identified, and the process of extracting intrusion features of software-defined security services in cloud environment is adaptively optimized by machine learning algorithm to realize automatic extraction and optimization of intrusion features of software-defined security services in cloud environment. The implementation steps are described as follows:

Step 1: Constructing a nonlinear feature sequence distribution set $k, k = 1, 2 \dots, p$ and an information weighting coefficient $w_{i1}^l, \dots, w_{in}^l$ of software-defined security service intrusion features in a cloud environment, and performing node initialization operation to meet the requirements.

Step 2: Calculate the spectral density of the cluster head node of the software-defined security service intrusion feature chain in the cloud environment, and calculate the formula of information sampling time delay in the storage space of the software-defined security service intrusion feature in the cloud

$$\tau^*(p) = \frac{\theta(p.d, q.d)}{1 + \alpha \cdot \delta(p.l, q.l)}$$

environment. construct the first route detection protocol under network intrusion.

Step 3: Machine learning algorithm is used for optimization control, and the coverage point set of intrusion feature distribution is obtained.

Step 4: Reconstruct the intrusion characteristics of software-defined security services in cloud environment in the dimension distributed feature space, and get the structural mapping output of the feature chain.

$$\Omega_i(t) = \frac{\gamma_{th} \sigma^2}{h_i [G - (N(l) - 1) \gamma_{th}]}$$

Step 5: Using the fuzzy optimization control method, the iterative formula of intrusion feature extraction is

$$p_i(l+1) = \min(p_{max}, \Omega_i(l+1))$$

. If the software defines the security service intrusion feature storage spectrum

component gain value $h_i \neq h_{min}(l)$ and $\Omega_i(l) > 0$ in the cloud environment, the partial derivative of intrusion feature location output is obtained:

$$\frac{\partial u_i}{\partial p_i} = \frac{G h_i}{\sum_{j \neq i} h_j p_j + \sigma^2} \left(\frac{1}{1 + \gamma_i} - \beta_{c_1} \right) \tag{11}$$

Step 6: According to the improved machine learning algorithm, the adaptive iteration is carried out until the convergence criterion is met, the coverage of intrusion feature distribution of software-defined security services in cloud environment is calculated, and the intrusion feature is extracted according to the coverage, and the end is over.

The implementation process of extracting and fixing intrusion features of software-defined security services in cloud environment is shown in Fig. 2.

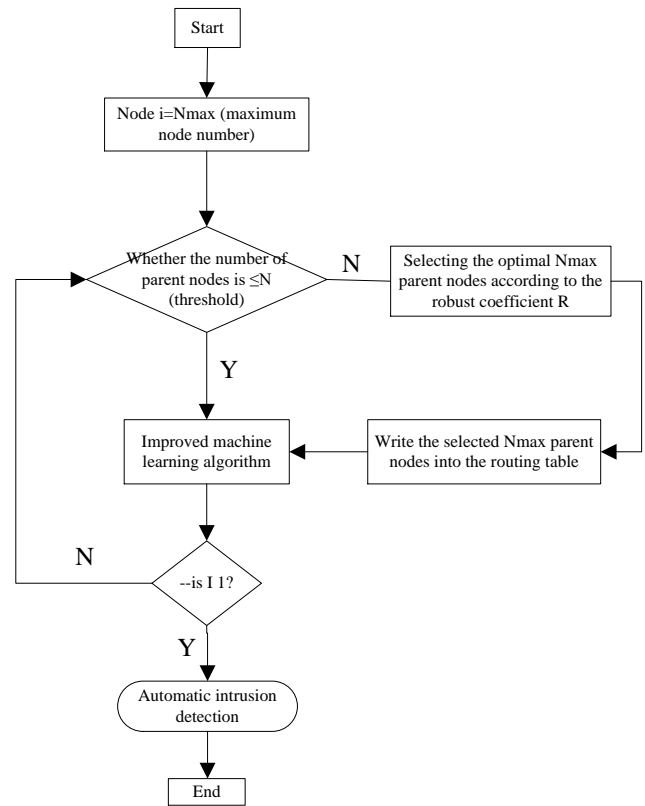

Fig. 2. Flow chart of network intrusion detection implementation.

IV. SIMULATION EXPERIMENT ANALYSIS

In Matlab 7 simulation environment, the simulation experiment of automatic extraction of intrusion characteristics of software-defined security services in cloud environment is carried out. Four P4 switches and four terminal hosts are adopted. The four switches are connected with each other to form a data forwarding plane, switch s1 is connected with hosts h1 and h2, and switch s2 is connected with hosts h3 and h4, and the hosts can communicate with each other. The configuration file describes in detail the network information configuration of each host (such as IP address, MAC address and default gateway), the configuration file path of P4 switch, and the connection path between the host and the switch. CIC-IDS2018 data set is dedicated to the analysis, testing and evaluation of network-based intrusion detection systems. The

data set is generated based on the creation of a user information file, which contains abstract expressions of events and user behaviors browsed by users in the network. The data set contains seven different attack scenarios: Brute-force, Heartbleed, Botnet, DenialofService(DoS), Distributed Denialofservice (DDOS), Webattacks and Infiltration of Modern WorkFrominside. The basic attack facility includes 50 computers as attack nodes, and the attack target includes 420 computers and 30 servers. The final data set includes the captured network traffic and system logs of each machine, and 80 features extracted from the captured traffic using CICFlowMeter-V3. The running environment of ML-SDNIDS is shown in Fig. 3.

```

- MyIngress.ipv4_lpm: hdr.ipv4.dstAddr=['10.0.3.3', 32] => MyIngress.ipv4_forward(dstAddr=08:00:00:00:02:00, port=2)
- MyIngress.ipv4_lpm: hdr.ipv4.dstAddr=['10.0.4.4', 32] => MyIngress.ipv4_forward(dstAddr=08:00:00:00:02:00, port=2)
```

Fig. 3. ML-SDNIDS operating environment.

The fundamental frequency of software-defined security service intrusion feature collection in cloud environment is 20KHz, the coverage range of software-defined security service intrusion feature in cloud environment is 200*400, the spectral feature detection of software-defined security service intrusion feature in cloud environment is set to 12, the normalized termination frequency of information collection is 0.68Hz, and the modulation frequency of intrusion information detection varies between [120Hz and 1024Hz]. The intrusion characteristics of software-defined security services in cloud environment are extracted with signal-to-noise ratios of -5dB, 5dB and 20dB, respectively. CIC-IDS2018 data set is used. Due to the limited experimental environment, some data sets in CIC-IDS2018 total data set are selected for this test. The statistical information is as follows, including the total number of samples, the number of normal samples and the number of abnormal samples in each sub-data set. According to the above simulation environment and parameter settings, the intrusion characteristics of software-defined security services in cloud environment are extracted, and the original intrusion data collection is shown in Fig. 4.

Taking the data collected in Fig. 4 as input, the intrusion feature extraction of software-defined security service in cloud environment is carried out, and the extraction result is shown in Fig. 5.

From the analysis of Fig. 5, it is known that the intrusion feature extraction of software-defined security services in cloud environment by this method has strong detection ability for the distribution of intrusion areas. The accuracy of different methods for intrusion feature extraction of software-defined

security services in cloud environment is tested, and the comparison results are shown in Table I. From the analysis of Table I, it is known that the intrusion feature extraction of software-defined security services in cloud environment by this method has high accuracy and good detection performance.

TABLE I. COMPARISON OF DETECTION PERFORMANCE

Iterations	The method in this paper	Neural network detection	Block matching detection
200	0.914	0.846	0.826
400	0.955	0.889	0.892
600	0.992	0.923	0.926
800	1	0.944	0.965

V. CONCLUSIONS

In this paper, the intrusion data of software-defined security service in cloud environment is effectively detected, combined with the statistical feature analysis and feature extraction method of software-defined security service intrusion in cloud environment, the feature fixation and sample collection of software-defined security service intrusion in cloud environment are carried out, and the software-defined security service intrusion forensics in cloud environment is realized according to the sample categories of software-defined security service intrusion in cloud environment. In this paper, an intrusion detection method of software-defined security service in cloud environment based on machine learning algorithm is proposed. The statistical feature quantity of software-defined security service intrusion characteristics in cloud environment is constructed by piecewise sample regression analysis method, and the intrusion characteristics of software-defined security service in cloud environment are fixed and sample identified by combining decision statistical analysis method. Combined with the feature fusion analysis method of classified intrusion samples, a big data distribution model of software-defined security service intrusion features in cloud environment is constructed, and the power spectral density feature quantity of software-defined security service intrusion features in cloud environment is extracted. The machine learning algorithm is used to adaptively optimize the extraction process of software-defined security service intrusion features in cloud environment, so as to realize automatic extraction and optimization of software-defined security service intrusion features in cloud environment. The research shows that this method has high accuracy in extracting intrusion features of software-defined security services in cloud environment, good reliability in network intrusion detection and strong ability in fixing intrusion features.

Finally, under the software-defined network structure, the control plane realized the intrusion detection model based on the combination of automatic encoder and support vector machine, and the data plane realized the intrusion detection system based on machine learning with P4 programming language. Feature extraction is carried out on the data plane, and the packet features are classified in the matching action

pipeline, and finally the decision classification of the packet is realized in the export pipeline. The final experimental results show that, in most cases, the accuracy of attack detection is higher than that of ninety-seven percent. Although the packet processing delay is increased by about five times, its efficiency is still millisecond.

ACKNOWLEDGMENT

The study was supported by Science and Technology Project of The State Grid Information and Telecommunication Branch "Research and design of key technologies for security intelligent detection and automation arrangement in a heterogeneous cloud environment" (NO. 529939220003).

Experimental Analysis of WebHDFS API Throughput

Yordan Kalmukov, Milko Marinov

Department of Computer Systems and Technologies, University of Ruse, Ruse, Bulgaria

Abstract—Data analysis is very important for the success of any business today. It helps to optimize business processes, analyze users' behavior, demands etc. There are powerful data analytics tools, such as the ones of the Hadoop ecosystem, but they require multiple high-performance servers to run and high-qualified experts to install, configure and support them. In most cases, small companies and start-ups could not afford such expenses. However, they can use them as web services, on demand, and pay much lower fees per request. To do that, companies should somehow share their data with an existing, already deployed, Hadoop cluster. The most common way of uploading their files to the Hadoop's Distributed File System (HDFS) is through the WebHDFS API (Application Programming Interface) that allows remote access to HDFS. For that reason, the API's throughput is very important for the efficient integration of a company's data to the Hadoop cluster. This paper performs a series of experimental analyses aiming to determine the WebHDFS API's throughput, if it is a bottleneck in integration of a company's data to existing Hadoop infrastructure and to detect all possible factors that influence the speed of data transmission between the clients' software and the Hadoop' file system.

Keywords—WebHDFS API; throughput analysis; data analytical tools; Hadoop Distributed File System (HDFS)

I. INTRODUCTION

Data analysis is a key point for success of any business organization. It allows companies to extract knowledge from the data they gather, to optimize their business processes and operations, to predict future failovers and to determine the right moment of maintenance. In general, users and clients are source of enormous amount of data. Companies can use these data to analyze users' behavior [1] and anticipate their demands. So, the analysis of any type of data can provide a significant competitive advantage of the company over rival businesses.

However, data analysis is a complex, time-consuming and computationally intensive task. Data analytics tools are usually either expensive or requires multiple high performance servers to run together with highly qualified IT experts to install and support them. This, of course, is not affordable for small and especially start-up companies. Fortunately, they can still use big data analysis tools, like the ones provided by the Hadoop's ecosystem, by hiring them as services "on demand". The "on demand" business model is a modern trend for hiring web-based (cloud-based) services and paying per request, rather than buying own expensive software and hardware. It provides maximum scalability and flexibility. According to it, computing resources are always available on the Internet and a company can use as many resources as it needs at the moment, while paying as much as it consumes.

Using remote data analytics services however, requires that the company share its data with the service provider [2]. In case big data analytics tools, being provided, are part of the Hadoop ecosystem, they will read the data from the "Hadoop Distributed File System" (HDFS). Although there are several ways to copy data to remote HDFS [3], the most preferable one is through the WebHDFS Application Programming Interface (API). It allows third-party applications to connect to remote HDFS file system and write/read files to/from it. As we are considering big data analysis, the amount of data being transferred is supposed to be large enough, so the WebHDFS API's throughput plays an important role in integration of a company's data to the Hadoop service provider. Other ways of data integration are reviewed in [4],[5],[6],[7],[8] and [9].

The aim of this work is to perform a series of experimental analyses to determine the WebHDFS API's throughput; if it is a bottleneck in integration of a company's data to existing Hadoop infrastructure; and to detect all possible external factors that influences the speed of data transmission between the clients' software and the WebHDFS API of existing Hadoop cluster.

The paper is structured as follows: Section II reviews some previous work done by other researchers. Section III describes the experimental system's architecture and the experimental setup in details. Section IV analyzes and discusses obtained experimental results. Finally, Section V ends the article with a conclusion, outlining and summarizing all key observations authors noticed during the experimental analysis.

II. RELATED WORK

HDFS allows management of large volumes of data using commodity items. This reinforces the need to provide robust data protection to facilitate file sharing in Hadoop, as well as having a trusted mechanism to verify the authenticity of shared files. This is the focus of [10], where the authors' attention is directed to improving the security of HDFS using a blockchain-enabled approach (hereafter referred to as BlockHDFS). User connects to the WebHDFS REST API, through which all data retrieval and modifications are implemented. In BlockHDFS, the blockchain is responsible for storing the file metadata. The costs incurred in storing HDFS file metadata on the blockchain are twofold. First, the WebHDFS API must read a file's metadata from HDFS as a hash value. Second, additional operations are required to store the metadata in the blockchain. However, since the metadata size is typically small, such overhead will neither introduce high latency for HDFS operations nor require a large amount of disk space for blockchain storage. The paper proposes a new approach to introduce blockchain (and more specifically, Hyperledger) to improve the security of the HDFS ecosystem.

Paper [11] discusses one of the most significant challenges of next-generation big data federation platforms, namely the access control in Hadoop systems. The paper critically analyzes and explores security limitations in Hadoop systems and presents a tool called “Big Data federation access broker” to address eight major Hadoop security limitations. To validate the performance of the broker, authors have conducted a set of experimental studies on a real Hadoop cluster. They made a comparison between read and write operations, performed through WebHDFS, in two cases - without using any security measures (pure WebHDFS access) and when using the authors' proposed broker model for accessing the big data. Performance analysis of operations executed over WebHDFS with files of various sizes was done as well.

Authors of [12] discuss the design of a data transfer service, called Stargate, to address the challenges of large data transfers over a WAN. Stargate implements a content-addressable protocol and multi-layered caching to cope with these challenges. It uses a novel approach that localizes computation, cache, and transfers to achieve efficient data access in cluster computing. Stargate is evaluated experimentally by comparing its performance with two widely used Hadoop data access methods - DistCP and WebHDFS. DistCP is a built-in Hadoop data delivery tool. DistCP preorders data, while WebHDFS provides data access on-demand. The elapsed times of three Hadoop benchmarks that have different I/O workloads were compared to evaluate efficiency. Experiments show that Stargate over WAN has comparable performance to HDFS running on a LAN. It also has lower overhead than WebHDFS, which is widely used for remote access to data from Hadoop clusters.

Apache Spark uses a cluster of compute-optimized servers on which the execution modules run, and a cluster of servers, optimized for performing storage operations and hosting the HDFS data. However, the network transfer from the data warehouse to the computing cluster becomes a serious obstacle for big data processing. Near-data processing (NDP) is a concept that aims to ease the network load in such cases by offloading some of the computing tasks to the storage cluster. Rachuri et al. present an architecture and basic principles of implementation of an NDP system for Spark [13]. HDFS can be configured to add redundancy by copying the same blocks of files across multiple data nodes to improve fault tolerance. It also provides an API - WebHDFS. In the proposed implementation, the authors take advantage of the replication factor to increase the number of data nodes that can perform operations related to offloading the computational tasks and intercept the WebHDFS communication between the client and the data node to perform NDP operations. Simulation results and experiments conducted on the developed prototype show that SparkNDP can help reduce the execution time of Spark queries compared to both - the default approach of not directing any tasks to the repository, and the direct NDP approach to offloading all tasks to the repository.

High Performance Computing (HPC) and Big Data are two trends that are starting to converge. In this process, aspects of hardware architectures, system support, and programming paradigms are revisited from both perspectives. The authors of [14] present their experience on this path of convergence. They

propose a framework through which some of the programming problems, arising from such integration, are solved. An integrated environment has been developed that integrates: (1) COMPS, a programming environment for developing and running parallel applications for distributed infrastructures; (2) Lemonade, a data mining and analysis tool; and (3) HDFS, the most widely used distributed file system for big data. In order to implement the integration between COMPS and HDFS, aspects of the available techniques for communication between external applications, in particular those written in Java and Python, and HDFS are considered. HDFS provides interfaces through a direct Java API, a command-line interface (CLI), a REST API (WebHDFS), and a C API (libhdfs). The proposed solution provides processing of large data transfers, with access to low-level functions.

WebHDFS allows users to connect to HDFS from outside the Hadoop cluster, which is especially useful when an external application needs to load data into or out of HDFS or work with the data stored in HDFS. WebHDFS also supports (for all HDFS users) operations such as reading files, writing to files, creating directories, changing access permissions, renaming, etc. The WebHDFS API is used for two functions in [15]: 1) after server-side processing is complete, this data is stored in HDFS via the WebHDFS API; and 2) when the created final data for visualization in raw text format is requested by clients, the data is passed to them via the WebHDFS API.

A system architecture combining the “IP multimedia subsystem (IMS)” platform and the Hadoop system used in the distributed storage of the IMS service resources is proposed in [16]. The result is a manageable Hadoop-based data center for telecommunication service providers. Interoperability between different systems is achieved through RESTful web services. The WebHDFS API is used to allow services to interact with HDFS, while the Oozie Web Services API is used for the compute service. The conducted tests prove the availability, scalability, and reliability of the proposed system. Experimental results show that system performance is improved, especially in terms of disk space utilization and system throughput.

Although HDFS works well with medium-sized and large files, its performance seriously degrades in case of multiple very small files. To overcome this shortcoming, the authors of [17] propose a system to improve the performance of HDFS using a distributed full-text search system. By indexing each file's metadata, such as name, size, date, and description, files can be quickly accessed through efficient metadata searches. Additionally, by consolidating many small files into one large file to be stored with better space and I/O efficiency, the negative performance impacts caused by directly storing each small file separately are avoided.

HDFS is a widely used open-source scalable and reliable file management system designed as a general-purpose distributed file storage solution. WebHDFS is a service for accessing data stored and maintained in HDFS. It runs on all nodes in the Hadoop cluster and provides a REST interface for data access. Unlike other file systems or data transfer tools, WebHDFS detects the layout of data blocks stored in HDFS. Using this block information, clients can directly access the

HDFS node (data node) on which the data is stored. This not only reduces data access latency, but also provides load balancing of data access requests. This motivated the authors of [18],[19],[20] to investigate the performance of HDFS in remote data access.

III. EXPERIMENTAL SETUP

To study the throughput of the WebHDFS API, a testing client must be developed to access the interface in both read and write modes. The client, for the current experiment, has been implemented in the php programming language. It uses the open source library PHP-Hadoop-HDFS [21], implemented and maintained by Aleksandr Kuzmenko. It is a wrapping library that does not do any specific data processing, but just composes the necessary HTTP requests to access the WebHDFS API. The access itself is done through the cURL (client URL library) library [22], distributed together with the php interpreter. The WebHDFS API could be accessed without PHP-Hadoop-HDFS library, but it facilitates the access, since the library frees the programmer from having to know the WebHDFS API itself. Instead, the programmer should only know the methods that the library implements and their input arguments. The architecture of the experimental system is presented on Fig. 1.

When performing the experiments, several key parameters should be monitored: total time; upload speed; download speed; bytes uploaded; bytes downloaded; and response HTTP code. Fortunately, all of these, together with many more parameters, are measured by the cURL library itself.

The throughput of the WebHDFS API is not the only limitation factor. The network speed is important as well, even more important. Even if the API itself allows the transfer of hundreds of megabytes per second, if the user's Internet speed is slow, then the API's throughput does not matter at all. Therefore, experiments should be performed from different type of computer networks:

1) *Internet*- This is the most important experiment, as this is the most realistic scenario for accessing the Hadoop cluster. Most likely, the greatest limitation factor will be the Internet connection speed.

2) *Corporate LAN of the service provider*: This experiment is important in case of a large company, having multiple offices, maintaining its own Hadoop infrastructure and MAN network between the different locations. Experiments could be done at multiple network speeds - 1 gbit/s and 100 mbit/s seem to be the most realistic speeds for a company's MAN.

Although writing to HDFS is more important than reading, both operations will be tested. Writing is more important since company's data should be saved to HDFS, before being analyzed by the Hadoop's data analytical tools. So, the data flow direction in general will be from the company to the Hadoop cluster. However, reading is also useful.

Experiments have been conducted with small, medium-sized and large files which are generated with the Windows' fsutil application. They contain only zeros (i.e. no meaningful information). Since we are making performance experiments, the content of the files does not matter at all, but their exact size does. It is important that their size can be precisely controlled.

The Hadoop cluster consists of 1 name node (2 x Intel Xeon Silver 4110, 32 total threads, 64 GB RAM) and 9 data nodes (Intel Xeon E-2124, 16 GB RAM). Servers are connected through 24 Port Gigabit switch HPE OfficeConnect 1820.

The experimental application, developed in php, runs on a laptop computer (Intel i7-7500U, 12 GB RAM) for all experiments in all types of networks. Using the same laptop for all experiments is intentionally done in order to ignore the influence of the client's hardware.

The access from the client to the WebHDFS API is done through the:

- 1) *Internet* – the access is done from a laptop computer, connected to a home router. According to the subscription, the guaranteed Internet speed is 80 mbit/s.
- 2) *University of Ruse's campus network* – the access is done from the same laptop, connected to any point of the university's campus-wide 100 mbit/s network.
- 3) *1 gbit/s cluster's switch* – the laptop is connected directly to the 1-gigabit switch of the Hadoop cluster.

IV. EXPERIMENTAL RESULTS

A. Writing Data to HDFS

As previously mentioned, when integrating a company’s data to an existing Hadoop cluster, writing/saving files to WebHDFS is the most important operation. So, it is tested with priority.

Experiments started with small to medium-sized files from 10 to 100 MB, with a step of 10MB. Results are presented on Fig. 2. They show almost constant write speed when WebHDFS is accessed from the Internet and the university’s campus-wide 100 mb/s network. The transfer speed almost reaches the network’s capacity – with the 80 mbit/s Internet connection, the achieved speed is around 60 mbit/s, while within the 100 mbit/s campus-wide LAN, we achieve sustainable transfer of 85 mbit/s.

When the laptop is connected directly to the cluster’s gigabit switch, the writing speed is times higher and is increasing with the increase of the file size.

Since the API supports high-speed data transfer, we decided to go further and experiment with medium-sized files, from 100 to 300 MB with step of 50 MB, and large files from 500 to 1500 MB with step of 500 MB. Results are shown on Fig. 3 and 4 respectively. For larger files, upload speed becomes constant (about 800 mb/s) for the gigabit network as well. That proves the WebHDFS API supports very high writing speeds and could not be considered as bottleneck in the integration architecture. Most probably, the API just saves the incoming data to the HDFS file system without applying any complex processing on them.

As known from everyday usage of computer network and different types of file transfer, copying single large files is much more efficient than copying multiple smaller files. There are objective reasons for that, including metadata overheads. So, it is worth testing how much slower uploading multiple smaller files will be in respect to a single large file, having the same total size.

Three experiments have been performed with single large files of 100 MB, 200 MB and 300 MB, and 10 x 10 MB, 20 x 10 MB and 30 x 10 MB. The size of the single large file exactly matches the total sum of bytes of the respective many 10 MB files. Results are presented on Fig. 5. Expectedly, uploading a single large file is faster than uploading many smaller files, having the same total size as the large one.

Fig. 2. Write speed to HDFS via the WebHDFS API with relatively small file sizes - from 10 MB to 100 MB.

Fig. 3. Write speed to HDFS via the WebHDFS API. File sizes from 100 MB to 300 MB. Write speed is constant, independent on the file size.

Fig. 4. Write speed to HDFS via the WebHDFS API. File sizes from 500 MB to 1500 MB. Write speed is still constant, although files have got very large.

Fig. 5. Time to write data (single large file or multiple small files) to HDFS via the WebHDFS API.

B. Reading Data from HDFS

Although reading data from HDFS is less important operation when integrating a company’s data to existing Hadoop cluster, a series of experiments will be done by using the files, already uploaded to the HDFS through the WebHDFS API. The same client is used, as in the previous experiments for writing data, and runs on the same laptop computer as well. Results are shown on Fig. 6 (for files 10 to 100 MB), Fig. 7 (for files 100 to 300 MB) and Fig. 8 (for files 500 to 1500 MB).

Fig. 6. Read speed from HDFS via the WebHDFS API with relatively small file sizes - from 10 MB to 100 MB.

Fig. 7. Read speed from HDFS via the WebHDFS API. File sizes from 100 MB to 300 MB. On high-speed networks, read/download speed is decreasing with increasing the file size.

Fig. 8. Read speed from HDFS via the WebHDFS API. File sizes from 500 MB to 1500 MB. Read/download speed is decreasing with increasing the file size on all networks.

In contrast to the constant writing speed however, the reading (download) speed rapidly falls with increasing the file size – significantly noticeable for the high-speed 1 gbit/s connection. The initial suspicion/assumption was this decrease of the reading speed is related to the higher number of packets that the large files consist of. There is a sense in that – since larger files contains many more packets, more time may be

required to reconstruct the file from the higher number of packets. To test if the assumption is correct, the experiments have been repeated with measuring not just the total time, but transferring time and file saving time separately.

Results show that the transferring time, without the time needed to save the file within the local file system is commensurate with the total time. And time needed to reconstruct and save the file is actually very small and does not depend on the file size. So, the assumption is wrong. Since the communication between the client and the WebHDFS API is handled by the cURL library, distributed with the PHP interpreter, then the cause of the reading speed decrease could be either the cURL library itself or the API. To determine where the problem is, the WebHDFS API should be accessed in another way. It could be accessed directly through a browser, but it is not very convenient. Other tools like Postman or Rester are not very suitable as well, since they do not measure times. The cURL library however is not developed specially for PHP, but it is an open source project ported to almost any programming language. It is provided as a built-in application in Unix/Linux/macOS and could be downloaded as external stand-alone application for Windows.

We take the HTTP queries, generated by the PHP-Hadoop-HDFS library and run them from the cURL applications for MacOS and Windows. Results show that files are downloading (read) from HDFS with very high speed almost reaching the maximum throughput capacity of the relevant type of network, regardless of the file size. So, the causer of the read speed decrease in our experiments is determined to be the cURL library, distributed with the PHP interpreter. Further experiments will be done with different versions of PHP and its accompanying cURL library.

Another interesting and unexpected result occurred when reading files from WebHDFS over the Internet. The utilized home Internet subscription plan is guaranteeing speed of 80 mbit/s. However, reading was done at speeds up to 175 mbit/s. The connection between the home computer and the Internet Service Provider (ISP) is actually higher than the guaranteed 80mbit/s. Apparently, the ISP also has a high-speed connection to the university's network, where the Hadoop cluster is located. So, the access to the servers from the home computer is done in a kind of MAN network with speeds significantly higher than guaranteed Internet connection. Interestingly, this is not the case when writing data to WebHDFS. When writing (uploading) files, they are transferred at a speed no higher than the guaranteed Internet connection. This, however, is a specific case study related to the specific ISP and should not be considered as an essential part of the results of the experiments.

V. CONCLUSIONS

Since WebHDFS is the most preferable way for remote access of the distributed file system HDFS, it is important to know its capabilities, performance and throughput.

After performing dozens of experiments and additional analyses, the results could be summarized in the following conclusions:

1) WebHDFS API allows data exchange with the Hadoop Distributed File System (HDFS) at very high speeds, and in general it is not the limitation factor, but the speed of the network itself. In a 1 gbit/s network, we achieve data transfer rates of around 800 mbit/s. On slower networks, the network capacity is almost entirely compressed.

2) The speed of writing (uploading) files through the WebHDFS API does not depend on the size of the files, but remains constant and it is only limited by the network capacity.

3) In contrast to the constant write speed, the reading (download) speed through the WebHDFS API decreases rapidly as the file size increases.

4) However, the reason for the decreasing read speed is not in the WebHDFS API itself, but in the implementation of the cURL library, distributed together with the PHP interpreter. When accessing the API in alternative ways, the read speed remains constant and comparable to the write speed.

5) When reading files from the WebHDFS API by using PHP and cURL, it is mandatory that the PHP interpreter is configured to use a larger amount of RAM memory than the size of the files being read. This is expected since the data transfer happens in multiple small network packets, but in order to reconstruct the file from them, they must be stored and arranged in a common buffer (located within the RAM memory).

6) When writing files through the WebHDFS API, the amount of RAM memory that the PHP interpreter can work with is not of such importance because the data is read from the local file system in chunks, which are typically much smaller than the default memory limit of 128 MB. In this case, the buffer size is important on the receiving side – i.e. on the server where the WebHDFS API is running. This size is managed by Cloudera Manager and is large enough.

7) In relation to the above-mentioned, it has been observed that files larger than 2GB cannot be reliably written to HDFS via the WebHDFS API. For all of our attempts to upload a file larger than 2 GB, the server did not return any HTTP response, although in some cases the files were actually stored in HDFS. The fact that files of 1.99 GB were always reliably saved, but 2.0 GB were not, suggests that the reason might be a WebHDFS setting, maybe the server-side buffer in question or something else. Further analysis could help to determine the exact cause.

8) A large number of small files are transferred more slowly than a single large file of the same total size. This observation is absolutely expected given the fact that with many small files, many separate HTTP requests are made, each of which has time to resolve the domain to an IP address, time to connect, time to make and receive the request, etc.

The WebHDFS API allows data exchange with HDFS at very high speeds, so it could not be considered as a bottleneck in the integration of a company's data to an existing Hadoop cluster. However, by default, it does not perform any user access control by itself, so additional means should be designed and implemented, or integrated, to control user access

and guarantee data isolation (no third-party company should be able to access data of another company).

Abstract—Imbalanced dataset can cause obstacles to classification and result in a decrease in classification performance. There are several methods that can be used to deal the data imbalances, such as methods based on SMOTE and Generative Adversarial Networks (GAN). These methods are used for overcoming data oversampling so that the amount of minority data can increase and it can reach a balance with the majority data. In this research, the selected dataset is classified as a small imbalanced dataset of less than 200 records. The proposed method is the Gradually Generative Adversarial Network (GradGAN) model which aims to handle data imbalances gradually. The stages of the GradGAN model are adding the original minority dataset gradually so that it will create new minority datasets until a balance of data is created. Based on the algorithm flow described, the minority data is multiplied by the value of the variable that has been determined repeatedly to produce new balanced minority data. The test results on the classification of datasets from the GradGAN model produce an accuracy value of 8.3% when compare to that without GradGAN.

Keywords—Classification; imbalance; GAN model; GradGAN model; significant oversampling

I. INTRODUCTION

The data mining solving on classification is a research topic that still needs contribution [1]. Because every use the dataset often result in data imbalances which can reduce the performance both of images and classification accuracy [2], [3]. In research on data imbalance, many methods have been offered but the method's robustness has not been satisfactory. This phenomenon is shown by existence of several data classification results that are less than [4], [5]. There are several cases of imbalanced data, for example, in the medical field, regarding disease prediction [6] and hepatitis diseases detection [7]. Imbalanced data classification is a vital problem [8], and the key is to create a flexible and correct method of classifying minority and majority data. This raises an urgent need for a better solution to the data imbalance problem so that the classification process can be more optimal.

The sampling method can be carried out at the preprocessing stage, for example, in the case of missing values, which has less significant impact on machine learning outcomes [9]. In the majority class, the use of under-sampling technique is relatively easier to do to balance the data [10]. Whereas in the minority class, the over-sampling method that commonly uses Synthetic Informative Minority Over-Sampling (SMOTE) algorithm to find synthetic data, is currently effective [11], [12]. Another over-sampling method

for dealing with synthetic data is Borderline-SMOTE [13]. There is a drawback of the SMOTE algorithm, namely there is no consideration of neighboring information from minority class samples, resulting in over generation. The Modified Fuzzy-Neighbor Weighted Algorithm has also been proposed, the classification results are also better [14]. Although existing classification methods have been able to overcome data imbalances, a new approach is still needed to overcome the challenges of the problem of heavy imbalanced data flows [15]. The online ensemble learning algorithm has also been used for unbalanced data streams [16]. Recently, a relatively new method has been developed to overcome over-sampling techniques for imbalanced data, namely the Generative Adversarial Network (GAN) method; the goal is to overcome the difficulties of minority data samples to be more balanced with the majority data [4], [17]. Initially, the GAN model was implemented in deep learning machines, namely about human faces, adopting images so as to produce better images [18]. Another implementation of GAN, is that it models complex real-world image data and normalizes data imbalances [19]. There are several developments of GAN models, including Triple Generative Adversarial Nets (TripleGANs) [20], and Senti Generative Adversarial Networks (SentiGAN) [21]. The development of GANs is not only for deep learning but also addressing imbalances of machine learning in data mining. For example, to classify public data of Bank Marketing, Credit, and Lending Club from the UCI repository, the GAN model and the random forest method produce several sub-classes of sample data and these sub-classes will be combined with the original dataset to form a new minority dataset [4]. Generative Adversarial Networks (GAN) model is also used to create new text from the scarcity of the Dialectal Arabic dataset which generates annotations (notes or comments) with automatic generation [21].

Learning methods that are commonly used and have good performance are Naïve Bayes (NB), k-Nearest Neighbour (k-NN), Support Vector Machine (SVM), and Decision Tree (D-Tree). NB has the advantage that it is simple and works well in the real world. The weakness is that the dataset to be tested must be in numerical form [22], [23]. K-NN has advantages, which are effective and robust against noisy training data [24]. SVM has the advantage of being able to generalize and is known to produce high accuracy values but is less than optimal when applied to imbalanced data [25]. Meanwhile, the drawback is that it is difficult to implement in large cases and is developed for two-class problems [26]. The D-Tree method has the advantage of a simpler and more straightforward, specific, and flexible way of making decisions, while the

weaknesses are frequent overlap and difficulty in designing a more optimal one [27]. The random forest ensemble applied to predict heart disease produces a better accuracy value than the other methods [28]; besides that, it is applied to the classification of Sarcastic Tweet, resulting in the highest accuracy [22].

Based on the above explanation, to overcome the heavy flow of imbalanced data, this research proposes a Gradually Generative Adversarial Network (GradGAN) model. The GradGAN model works to handle oversampling data with a resampling technique, namely adding minority data gradually. This technique is expected to be optimally applied to all dataset sizes. In future research, the GradGAN model can be developed and relied upon to deal with data imbalance problems. To test the quality of the data resulting from the

GradGAN model, data can be classified by using the NB, SVM, k-NN, D-Tree and RF methods because they are common methods and have good classification performance. The dataset used in this research is a small imbalanced dataset that is taken from the UCI repository.

II. RELATED WORK

So far, the obstacle faced by researchers in handling datasets in machine learning and deep learning applications is data imbalance. The reason is because the data imbalance makes the performance of the machine not optimal. In fact, the results of research on classification show that classification performance is less significant. There are several methods in research to handle the classification and imbalance of datasets.

The development model in this research refers to the literature research in Table I. The GAN model used in this paper is developed into a Balancing GAN (BAGAN). The BAGAN model requires a large amount of data to function properly [2]. In order to achieve automatic balancing, Piece-Wise Incremental Data Re-Balancing (PWIDB) is combined with the Racing Algorithm (RA) technique and incremental iterative balancing techniques. According to [3], PWIDB outperforms other balancing techniques. The GAN model serves to overcome data imbalance and handle minority data samples. Several data samples based on a random forest model were broken down into sub-sections and then combined with the original data to form new minority data. The most ideal selected dataset is large size. The advantage in classification has produced good AUC and F1 [4]. The Radial-Based Under sampling method is proposed to handle imbalanced data to get good results, by combining the NB, SVM, and k-NN classification [5]. The Synthetic Informative Minority Oversampling (SMOTE) Technique method is used to balance training data by creating artificial minority data. The test results of the Naive Bayes, SVM-RBF, C4.5, and RIPPER classification methods produce the best accuracy with a value of 89.5%, 90% precision, 89.4% recall, 89.5% F-score and 83.5% Kappa [6]. In this paper, the problem to be solved is to classify the hepatitis dataset that is not balanced.

To increase the accuracy of the k-NN method due to the influence of data imbalance, an Adaptive-Condensed NN (Ada-CNN) method has been developed and then the accuracy value can reach a maximum [10]. In this paper, it is explained that to improve accuracy, it must balance the data, the method used is SMOTE. To find higher accuracy, data has been tested by the common classification methods, namely SVM, Random Forest, KNN, Naive Bayes, and Decision Tree. Then the general classification methods are compared with the proposed method using a voting multiclassifier; the results are better than the general method [11]. To overcome the lack of ROC values due to imbalance data, this research used the SMOTE method. In order to know the ROC value, the NB and D-Tree methods are used for data classification [12]. To overcome the decline in classification performance due to imbalanced data, this paper applies a Generative Adversarial Network (GAN) model. The workflow begins with creating artificial data so that minority sub-data are formed. Furthermore, from some of the minority sub-data, they are formed together to form a new minority data. Classification algorithm used is the Random Forest (RF) method [17]. Generative Adversarial Network (GAN) model was first proposed by Goodfellow et al. [18]. Invoked as a model to bridge between supervised and unsupervised learning in 2014, it has been hailed as the most exciting ideas in machine learning in the last ten years. To overcome imbalances level in classification, object detection and pixels in segmentation, this paper applies the Generative Adversarial Neural Networks (GANs) model [19]. The GAN model is promising in its application in handling image forms, but there are weaknesses between the generator and discriminator which are not optimal and cannot control the resulting sample. To overcome this problem, research is applied using a generator, discriminator and classifier called the triple Generatif Adversarial Net (Triple-GAN), which has produced a good classification [20]. The GAN model

collaborated with sentimental to form sentimental GAN (SentiGAN) has been succeeded in text creation domain. The modified SentiGAN utility will amplify a small data set and produce a variety of high-quality sentences in different Arabic dialects obtained from the MADAR data set. And it can produce a higher number of sentences than the original data, and this method can reduce vocabulary and only use common words. Even though there are slight deficiencies in the resulting text, the key features detected can help the classification remain strong. So the Generator process is not only effective and consistent but can also improve classification when used from the original dataset and the resulting dataset from the model process [21]. To find the accuracy value of the 14 datasets, in this paper, the classification methods used include Naive Bayes (NB), SVM, D-Tree, and k-NN. And from the test results, the NB method has produced the best accuracy value [22]. To overcome class imbalance, in this paper, the algorithm chosen is SMOTE. Meanwhile, the NB method is used for classification. The test results have resulted in an accuracy value of 88.5%, more significant than the R algorithm of 87.5% [23]. To overcome the imbalance problem, the popular SMOTE algorithm is used while the k-NN method is chosen for classification. Imbalanced data test results produce lower accuracy, while data that is balanced has greater accuracy [24]. The case of credit assessment can not be just any method that can be applied because it can hinder the assessment work itself. A good method to use is the SVM method in collaboration with Least Squares SVM (LS-SVM), It is shown from the test results with eight data set that it produces better performance when compared to other methods such as D-Tree and k-NN. But, in this research, SVM is also supported by meta-heuristics to be better [25]. Another research on the treatment of breast cancer uses several classification methods, the best results is the SVM method with an accuracy of 80.4% [26]. In implementing the algorithm, it is very vulnerable to the existence of data, and sometimes it is found that the data is imbalanced. To overcome that case, in this research has utilized decline tree with the D-Tree and Random Forest (FR) methods for the data balance process. The test results show that all classifications are strongly influenced by the balance of the data to achieve maximum results [27]. Detecting heart disease with feature selection and Random Forest Ensemble methods, the resulting accuracy is better by 99% [28]. Comparison of SVM, k-NN, Maximum Entropy and Random Forest methods for classification, the best accuracy value is Random Forest [22]. The GAN model can be applied in several cases to handle dataset imbalances. For example, in the field of financial anti-fraud with smaller data samples, the GAN model can be collaborated with the Long Short-Term Memory (LSTM) network algorithm so that the problem of data imbalance can be taken seriously [28]. Both of these models will share roles to process data in a time sequence completed by the Long Short-Term Memory network, while the GAN is to distribute selected real data which will produce data that is similar to the original data [23]. In this research, the SMOTE algorithm was used to overcome data imbalance, while the best method was chosen to classify, namely NB, D-Tree and RF, for example in the case of breast disease prediction [24]. The class with a small number of observations is called the minority class, while the class with the largest number of observations is called the

majority class. In this paper, to handle data imbalance, the SMOTE and Borderline-SMOTE algorithms were selected, while to measure the accuracy value, they relied on the Safe Level Graph [13]. In the end, the GAN model will produce data similar to the original [23]. In this paper, to overcome data imbalances, the SMOTE algorithm is used, while for classification, the method chosen is D-Tree [26]. The preprocessing process is a step for preparing the dataset to be tested. The new original dataset is usually still not perfect, there are still deficiencies, for example an empty record is found, it is necessary to handle imputation to perfect the dataset. The goal of imputation is to keep the number of datasets ideal. There are several imputation methods to choose from, including Zero, Mean/Median, k-NN, Multivariate Imputation with Chained Equations (MICE), Deep Learning (Datawig) [26].

In the previous research, the GAN model algorithm can be described in Eq. (1), and the algorithm flow [4], [18] as follows:

- Collect m noise samples $\{z(1).....z(m)\}$ from the noise chamber $P_g(z)$.
- Collect m data samples $\{x(1).....x(m)\}$ from the $P_{data}(x)$ data set.
- Update the discriminator by promoting a random gradient. The specific formula is as follows:

$$\Delta\theta \frac{1}{m} = \sum_{i=1}^m \left[\log D^{(i)} + \log \left(1 - D \left(G \left(Z^{(i)} \right) \right) \right) \right] \quad (1)$$

The next step:

- Group m noise samples $\{z(1)....z(m)\}$ from the noise space $P_g(z)$.
- Refine the generator by reducing the random gradient. The specific formula is as Eq. (2):

$$\Delta\theta \frac{1}{m} = \sum_{i=1}^m \log \left(1 - D \left(G \left(Z^{(i)} \right) \right) \right) \quad (2)$$

The GAN flow diagram can be described as Fig. 1.

Fig. 1. GAN algorithm flowchart.

The first GAN produces two sub-models namely Generator G (generative model) and Discriminator D (discriminative model). In the initial algorithm, the generative model G based on available noise generates some data. Then Discriminator D will assess whether the data obtained is in the form of real data or data generated by the generative model G. The purpose of the generative model G is to make the resulting data as close as possible to the actual data and cannot be easily identified by

the discriminatory model D. The purpose of the discriminator the discriminative model D is to distinguish between real data and data generated by the generative model G [4].

III. PROPOSED METHODOLOGY

The steps of the research methodology process are carried out, starting from the dataset collection stage to the process stage of producing the expected output from the research. In this research, there are several steps as follows.

A. Data Collection

The selected dataset are Hepatitis, Immunotherapy, and Echocardiogram medical data, all of are taken from the UCI repository, where all of them are datasets with a relatively small number of less than 200 records and are not balanced [11].

B. Pre-Processing

The preprocessing process is a step for preparing the dataset to be tested. The new original dataset is usually still not perfect, and there are still deficiencies; for example, if an empty record is found, it is necessary to handle imputation to perfect the dataset. The goal of imputation is to keep the sum of the datasets perfect. There are several imputation methods to choose from; and in this research the imputation method used was the k-NN method. [26].

C. Proposed Model GradGAN

The GradGAN method is a development and modification of the GAN model. The working pattern of the Gradually Generative Adversarial Network (GradGAN) model is to overcome imbalanced data gradually until it gets balance. The process in GradGAN will involve a generator function to generate random datasets which will create majority and minority data from random samples of the original random dataset. And the discriminator that functions knows that the majority data are original data from the generator results. In this research, the main concern is minority data. Minority data will be processed with the GradGAN model to produce a new minority data sample. The next step is that the minority data will be multiplied by the variable value gradually so that new minority values will be created until a balance value is formed with the original majority data. Then classification is carried out where the new minority data serves as test data and the original majority data as training data. This GradGAN model is a new discovery model and has never been used by other researchers in dealing with imbalanced data. Following is a Fig. 2 of a flowchart and its explanation.

The process in GradGAN will involve a generator function to generate random datasets, which will create majority and minority data from random samples of the original random dataset. Moreover, the discriminator that functions knows that the majority and minority data are original data from the generator results. In this research, the main concern is minority data. Minority data will be processed with the GradGAN model to produce minority data samples. The next step is that the minority data will be multiplied by a variable value gradually so that new minority values will create until a balance value forms with the original or original majority data. Then the two data, namely the new minority data, serve as test

data and the original majority data as training data for classification. This GradGAN model is a new discovery model and has never been used by other researchers in dealing with imbalanced data.

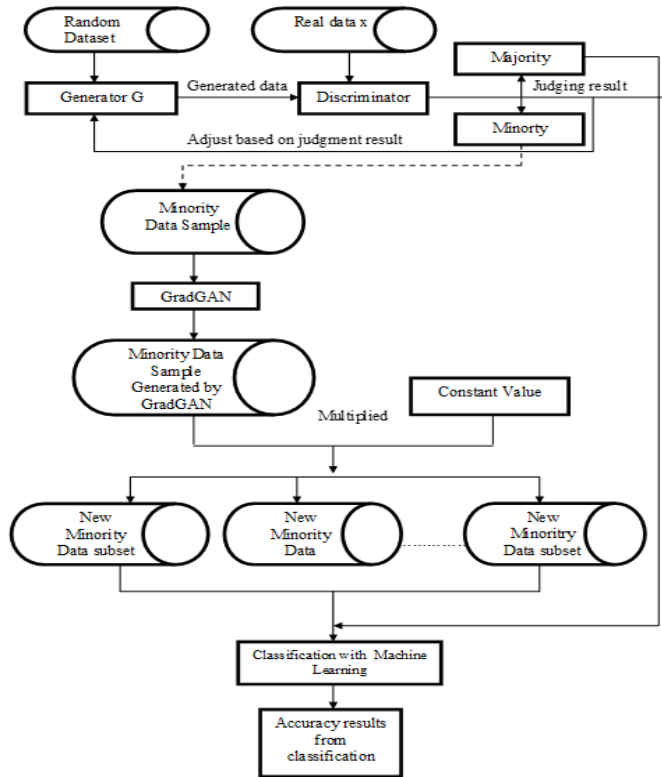

Fig. 2. Flowchart of the GradGAN algorithm.

Based on the above explanation, the GadGRAN model can be explained by calculating the equations in detail as follows:

- A sample set of x random datasets ($d^{(1)} \dots d^{(x)}$) with a total dataset of the $Dx^{(d)}$ variable will be generated to produce a total of majority and minority data.
- Determine the sample set x majority data class ($a^{(1)} \dots a^{(x)}$) with the number of the $Mx^{(a)}$ variable.
- Determine the sample set x minority data class ($i^{(1)} \dots i^{(x)}$) with the number of the $Mx^{(i)}$ variable.

In this research, the primary concern of data oversampling is to resample minority data with the $Mx(i)$ variable multiplied by a variable value to add minority data called new minority data. The goal is to create new minority data so that there is a balance with the original majority data. A mathematical formula can calculate with the following Eq. (3).

- Determine the sample x new minority data that is close to the balance ($i2^{(1)} \dots i2^{(x)}$) with the amount of data the $Mx(i2)$ variable.
- Determine the sample x variable value ($k^{(1)} \dots k^{(x)}$) with the value of the $Kx(k)$ variable.

- Calculate the number of new minority data using Eq. (3) or it can be written with Eq. (4).

$$Mx(i2) = Mx(i) (\sum_{k=0}^x Kx(k)) \quad (3)$$

$$Mx(i2) = \{(Mx(i)) (Kx(k))\} \quad (4)$$

The $Mx(i2)$ variable describes the number of new minority data, which results from the calculation of the constant the $Kx(k)$ variable multiplied by the number of original minority data in the $Mx(i)$ variable. This calculation is carried out in stages until there is a balance between the number of the $Mx(i2)$ and $Mx(a)$ variables' original majority data.

The GradGAN model, which has been described mathematically, can be described in the form of a Pseudo-code algorithm as follows:

1. Start
2. Input minority dataset $Mx(i)$;
3. Input Dataset majority $Mx(a)$;
4. Initialize $Mx(i2) = 0$;
5. Initialize $Kx(k) = 1$;
6. Compute the new minority value $Mx(i2) = (Mx(i)) * Kx(k)$
7. Is the value of $Mx(a) \geq Mx(i2)$ then
8. $Kx(k) = Kx(k) + 1$;
9. Goto 5
10. Else
11. Print $Mx(i2)$
12. Classification process
13. End

In the process of the algorithm for measuring balance, the $Kx(k)$ variable is multiplied by the minority data $Mx(i)$ on gradually, where $Kx(k)$ is variable value (1, 2, ..., k). $Mx(i2)$ or new minority data is the product of multiplying the original minority $Mx(i)$ with $Kx(k)$ variable, where k variable represents the number of variable values. In the next process, the minority data will be multiplied by a variable value gradually to create another new minority data until it finds data that is close to class balance.

This algorithm can be applied to all imbalanced data of all types of data sizes. In this research has been tested on three imbalanced datasets, which have different attributes and number of records. All data can be implemented well in this algorithm and produce a significant average accuracy value. The limitations of this algorithm cannot be applied to imbalanced datasets with missing values or with empty attributes.

IV. RESULTS AND DISCUSSION

The dataset is described and shown in Table II. In the description of the Hepatitis dataset, there are two classes representing death, "Die" and life, "live" In the Echocardiogram dataset, there are two classes representing death, "Dead" and life, "Alive". In the Immunotherapy dataset, there are two classes represented "No" and "Yes"; the purpose is to assist treatment. Treatments can be stopped if a positive "Yes" or a negative "No" is treated.

TABLE II. ORIGINAL DATASET DESCRIPTION

Dataset	Number of records	Number of features	Imbalanced ratio	Minority class	Majority class	Number of classes
Hepatitis	155	20	80 : 20	“Die”	“Live”	2
Echocardiogram	131	13	70 : 30	“Alive”	“Dead”	2
Immunotherapy	90	8	80 : 20	“No”	“Yes”	2

Fig. 3 compares the majority class and the minority class between the original dataset and the dataset that has been processed with the GradGAN model in stages with the final value. In the original dataset, the imbalance can obtain from the training data, which describes the majority class, and the test data, which describes the minority class. Furthermore, the GradGAN model functions to gradually increase the number of minority class data to become new minority data that is close to balance. By generating the original data, the calculation results can be seen in Fig. 3.

The three datasets in the GradGAN model to achieve balance can be seen in the comparison of the majority and the minority as follows: hepatitis dataset 124: 124, echocardiogram 107: 96, immunotherapy 71: 57.

In Fig. 3, the data balance stage process has been carried out. It starts from balancing the original data to form majority and minority data. Then the next process is applying the Gradually Generative Adversarial Network (GradGAN) model, balancing the original data gradually, forming a comparison of the original majority data with the new minority data gradually. Each comparison of the datasets formed by majority and minority data will be carried out with a classification experiment. The majority of the experimental results resulted in increase in the accuracy value of each dataset in the five classification methods. The result is shown in Table III.

Fig. 3. Comparison chart of majority class and minority class original data and GradGan model.

In Table III, the results of the experimental accuracy of the two datasets are the original dataset and the dataset that already has the influence of the Gradually Generative Adversarial Network (GradGAN) model. First, the lowest classification

value for the original dataset is 66%, obtained from the hepatitis dataset, while the highest is 83% from the echocardiogram dataset. Second, is the classification of the dataset that has been balanced with the GradGAN model. Classification produces an accuracy value of at least 68% and a maximum of 94%. Of the three original datasets and datasets that already have influence of the GradGAN model that It has been tested on five classification methods, and there is an average increase in accuracy of approximately 8,3%.

TABLE III. THE RESULTS OF CALCULATING THE ACCURACY VALUE OF THE DATASET

Dataset Name	Methods	Accuracy Values (%)		
		(a)	(b)	(c)
Original Datasets	NB	73	75	73
	SVM	81	79	81
	D-Tree	66	82	81
	k-NN	77	65	75
	RF	79	83	82
GradGAN Model Influence Dataset	NB	80	85	69
	SVM	84	84	70
	D-Tree	84	87	94
	k-NN	71	71	75
	RF	88	89	93

Abbreviations:(a)Hepatitis;(b)Echocardiogram;(c)Immunotherapy

A description of the dataset is a way to find out the character of the data. From the description of the selected datasets in this research, it can be seen that there is an imbalance in data. The evidence of data imbalance is an unequal comparison between the majority class and the minority class. An imbalance will affect the resulting accuracy value in the classification. To overcome the imbalance of the dataset in this research, a new innovation was developed from the GAN model, namely the GradGAN model. The flow of the GradGAN algorithm is shown in Fig. 2. The generation process starts from a random dataset and a discriminator to find out the original dataset so as to form an imbalanced majority and minority data. The goal of the GradGAN model is to form some new, larger minority data gradually. In this research, to increase the number of minority data gradually, by multiplying the number of variables (1, 2, ... k) that has been determined. So that it will produce several data sets which eventually form new minority data that are balanced or close to balance, as shown in the Fig. 3. The dataset that will be tested is the original imbalanced dataset and the balanced dataset using the five selected classification methods. The results of the classification accuracy can be seen in Table III. Experiments from three balanced datasets have been carried out to prove that the GRadGAN model has good classification performance by producing a better increase in accuracy values. Table IV shows a collection of classification results from the original dataset and the GradGAN model influence dataset. The results show that a balanced dataset has a significant increase in accuracy values, namely hepatitis by 88%, echocardiogram 89%, and immunotherapy 94%. The increased accuracy of the

original dataset and the GradGAN model for each dataset, namely hepatitis 7%, echocardiogram 6% and immunotherapy 12% with an average increase in accuracy of 8.3%. Hypothesis analysis can be described in that, the influence of the GradGAN model can increase the accuracy value significantly and in the future it can be applied to data other than the data that has been tested.

TABLE IV. THE INCREASE IN THE RESULTS OF THE ACCURACY VALUE ON THE ORIGINAL DATASET AND THE GRADGAN MODEL

Datasets	(a)	(b)	(c)
Hepatitis	81%	88%	7%
Echocardiogram	83%	89%	6%
Immunotherapy	82%	94%	12%
Average Accuracy Improvement	82%	90,3%	8,3%

Abbreviations:(a)Originaldatasets;(b)GradGANmodel;(c)Accuracy improvement

V. CONCLUSION

Based on the results of the research discussion above, it can be concluded that the dataset is getting closer to being balanced and the results are getting better. In this research, accuracy values were generated from the classification of three datasets, both of original and influence datasets from the GradGAN model. Experimental results involving five classification methods and three datasets, the application of the GradGAN model resulted in an increase in the accuracy value of 8,3%, compared to the original dataset. Thus the hypothesis can be concluded that the GradGAN model is very influential in the process of handling imbalanced datasets. Evidence of increased accuracy from imbalanced datasets and balanced datasets resulting from the resampling process of the GradGAN model is shown in Table IV. This means that by applying the GradGAN method the accuracy results are superior to those without GradGAN. In this research, the model was only tested on small imbalanced datasets, but other trials need to be carried out on large imbalanced datasets.

Human Fall Detection for Smart Home Caring using Yolo Networks

Bo LUO¹

Engineering Training Center, Chongqing Kechuang Vocational College
Yongchuan 402160, Chongqing, China

Abstract—In order to help the elderly and limit the incidence of falls that result in injuries, effective fall detection in smart home applications is a challenging topic. Many techniques have been created employing both vision and non-vision-based technologies. Many researchers have been drawn to the vision-based technique amongst them because of its viability and application. However, there is still room for improvement in the effectiveness of fall detection given the poor accuracy rate and high computational cost issues with current vision-based techniques. This study introduces a new dataset for posture and fall detection, whose photo images were gathered from Internet resources and data augmentation. It employs YOLO networks for fall detection purpose. Furthermore, different YOLO networks are implemented on our dataset to address the most accurate and effective model. Based on assessment parameters including accuracy, F1 score, recall, and mAP, the performance of the various YOLOv5n, s and YOLOv6s versions are compared. As experimental results showed, the YOLOv5s performed better than other.

Keywords—YOLO; computer vision; fall detection; smart home; caring

I. INTRODUCTION

In recent years, improvements in information and communication technologies (ICTs) and the innovations that followed them have significantly altered people's lives and given rise to elegant surroundings, cities, and societies. By observing our environments and making decisions to produce desired results, technologies like artificial intelligence (AI) and the Internet of Things (IoT) improve our quality of life. As the foundation of cities and societies, houses play a crucial role in developing smart living. They are anticipated to be major enablers of smart cities and societies [1]. Life expectancy is rising, and fertility is significantly declining in the modern world due to several socioeconomic causes [2]. An automated home-based solution to lessen the pressure on staffed health services and give frequent insight into fall risk would be an alluring alternative strategy [3] as more senior people struggle to preserve their independence and live in their own homes. At the same time, healthcare difficulties are becoming more and more significant due to the rise in the number of senior people worldwide. Elderly individuals who live alone must use human motion capture technology to address these problems. Also, by observing an elder's posture, it is possible to track how healthy they are, and if high-risk postures, such as falling over, are noticed, a warning may be sent. In addition to increasing the effectiveness of posture recognition, these systems will lighten the workload on human resources [4]. Due to considerations

including shifting viewing angles, body occlusion, and significant variations in human posture, figuring out how to recognize human posture is extremely difficult [5].

The three basic categories are sensor-based, vision-based, and radio-based HAR [5]. Sensor-based types rely on information gathered by sensors to identify human activity. For instance, a light sensor's activation can signal movement in a certain region or activity. Vision-based types rely on picture and video data formats to identify human activity. As an illustration, motions in smart home recordings imply doing specific tasks like cooking or strolling. Radio-based technology relies on the information and characteristics of signals to detect human activity. Wearable motion sensors that track the movement of body parts might detect particular behaviors like sitting or walking [6].

Systems for recognizing gestures and actions based on video analysis have been thoroughly investigated. Since vision-based data are less expensive and simpler to gather than sensor-based data, the most recent research has been on vision-based HAR. Thus, this study only partially covers the vision-based HAR investigations; it only includes a limited and representative sample. HAR is used in many applications, including surveillance systems, behavior analysis, gesture recognition, patient monitoring systems, and ambient assisted living (AAL). Recent research has focused on fall detection rather than fall risk prediction [7].

Falls are a common occurrence in the course of human growth. Falls happen when kids learn to stand, walk, climb, run, and engage in other activities. In a similar vein, falls also grow more common as we age. Though most falls are minor mishaps, as people age, falls become far more common and serious. It frequently underestimates falls' effect on people and society since they are just a natural part of life [8] [9]. Worldwide, falls are a significant health and financial problem. While falls inflict a high cost on healthcare systems in terms of in-patient and long-term care, they can also have indirect psychological impacts, such as reducing or avoiding physical activity out of fear of falling, in addition to the immediate direct medical repercussions. From an economic standpoint, it is obvious that any additional demand on the health system has a direct financial cost to society; nevertheless, lost productivity also has a hidden cost that is frequently disregarded. It should be no surprise that fall detection research and innovation have been sparked by the frequency and effects of falls, the risk of mortality, healthcare expenditures, and lost social and economic output [8].

The HAR problem has long been addressed using machine learning (ML) techniques, including random forest (RF), Bayesian networks, Markov models, and support vector machines (SVM). Traditional ML algorithms have demonstrated impressive performance in tightly regulated settings with little input data. However, they could be more efficient and take a lot of time to produce since they need several pre-processing stages and appropriate hand-crafted characteristics. External feature use also results in subpar incremental learning or unsupervised learning results. Due to its remarkable performance in several study domains, including object detection and identification, picture classification, and natural language processing (NLP), deep learning has attracted much community attention in recent years. Deep learning significantly decreases the effort required to select the best features compared to typical machine learning algorithms. The deep learning framework has also been effective with unsupervised learning and reinforcement learning. As a result, more and more newly released HAR frameworks are through deep learning [7].

Deep learning, particularly the convolutional neural network (CNN), which is modeled after the hierarchical processing of the human visual cortex, has had great success in the last few years when it comes to classifying images. CNN is a useful feature extraction and classification technique because it can automatically learn discriminative features from training data [10]. One or more of CNN's exciting application areas include speech recognition, object detection, video processing, object classification and segmentation, and natural language processing [11].

The two primary kinds of target detection algorithms based on CNN are two-stage detection algorithms, which divide target detection into two steps: finding and recognizing. The traditional technique, known as the Region-Convolutional Neural Network (R-CNN), performs poorly and cannot keep up with real-time demands. Fast regions with CNN (Fast R-CNN) and faster regions with CNN (Faster R-CNN) are offered because of further advancements based on R-CNN, although they still need to satisfy people's demands for real-time performance. The other is a one-stage detection technique, which combines target placement and recognition into a single phase for optimization. Single-shot multi-box detector (SSD) and YOLO series models are classic examples of this method [12].

In this paper, different versions of YOLO networks are investigated for fall detection which is utilized in smart home application for elderly caring. This investigation intends to address the most of less memory space usage and highest accuracy detection rate in fall detection.

The format of this essay is as follows: The background is offered in Section II, the technique is described in Section III, along with the training and testing procedure, the discussion and analysis of the findings are found in Section IV, and the conclusion and future work are found in Section V.

II. RELATED WORKS

Several recent deep learning-based approaches have been reported to improve the accuracy of fall detection recognition.

In this section, we will have a brief overview of several methods of this type.

The suggested approach establishes a framework for fall protection research. In contrast to providing raw data to the cloud for real-time prediction of fall occurrences, [13] offered a framework for fall detection through LSTM networks that utilized edge devices like a laptop for computation. The suggested system used the open-source Apache Flink streaming engine, a low-cost MetaMotionR sensor from MblentLab, and three-axis accelerometer raw data. The architecture has been trained and tested using a portion of the public MobiAct dataset. The created system found that the waist was the ideal location for placing sensors. With a 95.8% accuracy rate, the suggested framework can forecast autumn occurrences from current fall data. Performance can be improved by using many sensors and data streams.

The study [14] has presented a fall detection system design with health monitoring features. Utilizing low-power enabled low-power wide-area network (LPWAN) technology, the system combined Edge computing, Fog computing, and a compression method to transport data. This reduced the latency of the system. LSTM and RNN networks have been developed on the edge computer to identify falls from the incoming data. Raw data is delivered to the cloud via these edge gateways for online analysis, along with real-time notifications and alarms. The suggested architecture extends battery life and allows operation in regions with weak network access. Using the suggested approach and the MobiAct dataset, fall event predictions have been made with an average accuracy of 95% and a precision of 90%. The system performance may be increased by making a few adjustments and combining various techniques.

To more reliably and speedily identify fall behavior, [15] provides a fall detection approach based on a video in a complicated environment. The following is the paper's primary contribution: First, a YOLOv3 network model for the detection method is suggested. Second, the Pascal VOC data set format creates the human fall detection data set. Next, a self-built data set is used to train and test the network model on a GPU server. The experimental data demonstrates that the algorithm's mAP is 0.83 and its AP of down is 0.97, which are better than other conventional algorithms and have a strong resilience and detection impact.

In [16], a noise-tolerant FDS is shown operating with missing values in the data. This study seeks to use DL techniques for wearable sensor-based fall detection when faced with difficulty identifying missing values in data. On the SisFall and UP-Fall datasets, two public accessible datasets, the suggested method applies RNN with an underlying stack of BiLSTM blocks. When a value in the sensor data disappears, BiLSTMs can quickly obtain the long-range context thanks to their innate capacity to store long-term dependencies from both the past and the future. This explains why BiLSTM is a good fit for our noise-tolerant fall detection system that uses sequential sensor data. On the benchmark datasets for SisFall and UP-Fall Detection, the system outperforms the current state of the art with the accuracy, sensitivity, and specificity values of 97.21%, 97.41%, 96.38%, and 91.45%, respectively.

Due to its ability to maintain long-term dependencies from the past and future, the results show that BiLSTM is an appropriate model option to manage missing variables for wearable fall detection systems.

Based on the Fast Pose Estimation approach, [17] suggests a revolutionary human fall detection solution. The method employs 1Dimensional Convolutional Neural Network (1D-CNN) and Time-Distributed Convolutional Long Short-Term Memory (TD-CNN-LSTM) models to categorize retrieved data from picture frames accurately. As a result, the suggested approach effectively contributes to accurate human fall detection by employing the Fast Pose Estimation technique. The original URFD films were subjected to rotation, brightness, horizontal flip, and gamma correction augmentation procedures for dataset preparation. The result was an improved version of the URFD dataset. This resulted in a total of 560 movies, comprising 240 videos of falls and 320 videos of daily activities, which were then used to evaluate the produced models.

III. METHODOLOGY

A. YOLO based Networks

Basically, YOLO is a pre-trained object detector that is trained to recognize everyday objects like tables, chairs, cars, phones [18]. To create a model that can detect human falls, we used different versions of yolo, among which the yolov5s model obtained better results.

1) *YOLO v5 network*: The YOLO v5 target detection model, which avoids the recomputation of candidate areas in the two-stage series and has high identification precision and quick inference, is the most representative target detection model in the one-stage series. The four primary model structures of the YOLO v5 architecture are YOLO v5l, YOLO v5x, YOLO v5m, and YOLO v5s [19], with decreasing order of network complexity. The YOLO v5n model, which has just 1.9 MB parameters and the same model depth as the YOLO v5s model but a network width half that of the YOLO v5s, was later developed to adapt the solution to mobile devices.

The backbone, neck, and head are the three fundamental parts of the YOLO v5 basic architecture. Fig. 1(a) to 1(d) show the module composition for the basic design. A CNN, which creates visual characteristics by combining many fine-grained pictures, is one of the Backbone structures. Convolution operations such as 2D convolution, 2D regularization, and SiLU activation are carried out by the conv module, which serves as the architecture's fundamental convolution unit [20].

2) *YOLO v6 Network*: The second autonomous detector used in this investigation is the single-stage object detection framework for industrial applications, YOLOv6, the most recent member of the YOLO family. Although this model does not belong to the official YOLO series, it reportedly exceeds YOLOv5 in terms of detection precision and inference speed, making it more effective for industrial applications. YOLOv6 includes many improvements in the Backbone, Neck, Head blocks and also training strategies. For instance, the Neck and Backbone in YOLOv6 have been redesigned by using Rep-

PAN and EfficientRep structures, respectively, based on the idea of hardware-aware neural network. EfficientRep Backbone can make use of hardware computing power, such as GPU, and it also has strong representation capabilities. Rep-Pan Neck, is more accurate and faster than PANet and SPP. YOLOv6 Head is decoupled by adding a layer between the network and the final Head, which in turn improves the performance during the training process [21]. The architecture of YOLOv6 is shown in Fig. 2.

B. Dataset

A bespoke fall detection dataset containing two directory pictures and labels was made using photographs gathered from various sources. The study's classifications refer to sitting, walking, and falling. Two subdirectories—Training (333 photos) and Val (111 images)—are included in the images directory and are utilized for different purposes. Here, we have text files with labels for that specific image in this directory. The Labels directory has two subdirectories, train and Val. Our dataset is shown in various cases in Fig. 3.

The 333 photos from the dataset were increased to 1092 images utilizing Roboflow to enhance our model. A maximum of three enhanced versions of each image were created by randomly applying blur (up to 1 px), noise (up to 5% px), brightness (between -40% and +40%), exposure (between -35% and +35%), rotation hue (between -50° and +50°), and exposure (between -35% and +35%).

The dataset related to validation consists of three sets, including one main dataset and two other sets obtained by applying preprocessing and augmentations. In one of our preprocessing suites: resizing (stretched to 416x640), automatic contrast adjustment (using adaptive equalization), grayscale (applied) and increments: brightness (between -40% and +40%), exposure (between -21% and +21%) and in another set of pre-processing: resizing (stretched to 640x480), automatic contrast adjustment (using adaptive equalization), and gain: brightness (between -40% and +40%), exposure (between -21% and +21%), 90° rotate (clockwise, counterclockwise) we used. Examples of augmented images are shown in Fig. 3. Lastly, the labeled pictures are divided into a training (70%) and validation set (30%).

C. Google Colab

We used Google Colab, which provides free access to powerful GPUs. All training and testing tasks are performed using a 12GB NVIDIA Tesla T4 GPU. Our model was trained for 20 epochs with batch size of 16, image size of 640 and with YOLOv5 default adjustment for other hyper parameters. Fig. 4 shows the Google Colab's details for our model implementation.

D. Training and Testing

It is usually a good idea to start with a model that has already been trained on very big datasets and then use its weights to train an object detector. Even if the trained weights do not have the items needed for this experiment, this is OK. Transfer learning is the name for this process. In order to speed up network learning, beginning weights from a pre-trained model are utilized, which comprises weights from the COCO

dataset. Additionally advantageous is the fact that fewer data will be needed. [18].

Our total dataset consists of 1425 images, 75% of which are used for training, 25% for validation. 75% of training includes 1092 images, 25% of validation includes 333 images.

IV. EXPERIMENTAL RESULTS AND PERFORMANCE ANALYSIS

In this section, we introduce the experimental results and model performance analysis, and show the training outcomes with using pretraining weights and compare the three models of YOLO.

A. Experimental Results

We trained our model with YOLOv5n, YOLOv5s, YOLOv6 which are different versions of YOLO model, YOLOv5s performed better. Some examples of model predictions for new and unseen images are shown in Fig. 5, and label 0 for falling, label 1 for walking, and label 2 for sitting.

B. Model Evaluation

The gathered experimental data were compared in this work using various assessment criteria, including accuracy, recall, and mean average precision (mAP). The true positive rate, or TPR, is a statistic used to assess the likelihood that items from the real world would be correctly identified. When a model produces no false negatives, which indicates that there are no bounding boxes that are not recognized but ought to be detected, it has a high recall. Eq. (1) provides the mathematical form for the recall.

$$R = \frac{TP}{TP+FN} = \frac{TP}{\text{Total Ground Truths}} \quad (1)$$

The real positive and false negative are denoted in the equation above by the letters TP and TN, respectively. Eq. (2) defines *precision* as the percentage of correctly anticipated positives, often known as the positive predictive value. The accurate model creates no false positives (FP) and only detects important things.

$$P = \frac{TP}{TP+FP} = \frac{TP}{\text{Total Predictions}} \quad (2)$$

According to Eq. (3), AP is the area under the PR curve, and mAP is the average of all AP values across various classes and categories (3).

$$mAP = \frac{1}{n} \sum_{i=1}^n AP_i \quad (3)$$

where n is the number of classes [22].

We YOLOv5n, YOLOv5s, and we taught YOLOv6s. In Fig. 6 and 7, we have shown the confusion matrix, F1 confidence and Precision-Recall curves, respectively. In addition, we have included the parameters of each model for better evaluation.

Table I show the performance results for different Yolo based models. These models are YOLOv5n, YOLOv5s and YOLOv6s. As shown in the Table, YOLOv5s presents better results compared to other models.

YOLOv5s model obtained better results.

V. PERFORMANCE COMPARISON

This section presents performance comparison of different human fall detection methods. These methods involve OpenPose + LSTM [23], OpenPose + CNN [24], OpenPose + three thresholds [25] and the proposed method. In order to conduct fair comparison, these methods are experimented in current dataset and evaluated the performance using the procedure stated in [26]. Table II shows the performance comparison for existing methods.

TABLE II. PERFORMANCE COMPARISON BETWEEN METHODS

Model	OpenPose + LSTM	OpenPose + CNN	OpenPose + three thresholds	our proposed method
Accuracy	0.936	0.917	0.924	0.948

As shown in Table II, our proposed method presents better results compared to other existing methods in terms of the accuracy rate.

VI. CONCLUSION

This study investigated the advantages of data augmentation for the human posture dataset, and a dataset consisting of 1092 images for training and 374 images for testing was created from three classes, i.e. falling, walking and sitting. The performance of different YOLOv5 and YOLOv6 kinds was compared in the second stage based on accuracy, recall, and mAP. Based on the results, YOLOv5s outperformed other fall detection algorithms and had the greatest mAP @ 0.5, 0.948 and mAP @ 0.5: 0.95, which was 0.588. Finally, the proposed method is compared to other existing methods to demonstrate the outperformed method. The proposed method in this study is sensitive to the camera field of view for elderly fall detection that can be effectively influenced on accuracy rate in real applications. For future works, may employ other sensors combine with vision-based sensors to improve accuracy rate detection.

Investigation of You Only Look Once Networks for Vision-based Small Object Detection

Li YANG¹

Department of Electronic Information Engineering, Leshan Vocational and Technical College
Leshan 614099, Sichuan, China

Abstract—Small object detection is a challenging issue in computer vision-based algorithms. Although various methods have been investigated for common objects including person, car and others, small object are not addressed in this issue. Therefore, it is necessary to conduct more researches on them. This paper is focused on small object detection especially jewellery as current object detection methods suffer from low accuracy in this domain. This paper introduces a new dataset whose images were taken by a web camera from a jewellery store and data augmentation procedure. It comprises three classes, namely, ring, earrings, and pendant. In view of the small target of jewellery and the real-time detection, this study adopted the You Only Look Once (Yolo) algorithms. Different Yolo based model including eight versions are implemented and train them using our dataset to address most effective one. Evaluation criteria, including accuracy, F1 score, recall, and mAP, are used to evaluate the performance of the various YOLOv5, YOLOv6, and YOLOv7 versions. According to the experimental findings, utilizing YOLOv6 is significantly superior to YOLOv7 and marginally superior to YOLOv5.

Keywords—YOLOv7; YOLOv6; YOLOv5; computer vision; jewellery detection; small object detection; real-time detection

I. INTRODUCTION

Target detection techniques based on deep learning have recently received much attention because of their strong generalizability, which has coincided with the growth of deep-learning theory and improved computer performance [1]. Convolutional neural networks dominate deep learning (CNN). Using the input picture as training data, the convolution network may successfully learn the key characteristics of the recognised item. Repeated training steadily boosts the training model's performance to provide accurate target detection outcomes [2].

Whether or not candidate areas are formed, the current popular object detection methods may be classified into two-stage algorithms and one-stage detection techniques. The RCNN [3], SPP (Space Pyramid Pooling)-Net [4], Fast-RCNN [5], Faster-RCNN [6], Mask-RCNN [7], and other algorithms are examples of the former. The latter primarily consists of the YOLO algorithm (YOLOv1 [8], YOLOv2 [9], YOLOv3 [10], YOLOv4 [11], YOLOv5 [12], etc.) and the SSD [13] algorithm. While two-stage algorithms may achieve high accuracy, the lengthy detection time makes it challenging to meet the real-time requirement in common object identification applications. The one-step detection method has taken centre stage in the study of object detection due to its benefits of high precision and quick speed. Early object identification systems,

such as YOLOv1, YOLOv2, etc., often had a network topology that consisted of a fully-connected layer on top of many convolution layers. The model's capacity to recognize several scales was significantly constrained by only calculating the feature map of a set size. In this case, the algorithm's detection accuracy for tiny objects could be more optimal [14].

Tiny/small object recognition is a difficult topic in computer vision, and several solutions have been put out to deal with it. Tiny/small object identification techniques have a long history that dates back to the early 2000s, a time when classic feature-based techniques were widely used. Later, with the development of deep learning, researchers started looking at object detection techniques based on deep neural networks. Faster R-CNN, YOLO, SSD, and RetinaNet, among other well-known object detection frameworks, were first developed for identifying large objects, but they have now been upgraded to handle small/tiny objects. With techniques like Yolo, EfficientDet, and Sparse R-CNN reaching cutting-edge performance on tiny/small object identification benchmarks, there has been tremendous research advancement in this field recently. By altering network topologies and incorporating and enhancing additional datasets, researchers attempt to enhance the outcomes for tiny object identification. Another clear answer to this problem is to improve the input image resolution, although it increases processing time [15].

In this paper, we introduce a new dataset whose images were taken by a web camera. The main objective of this study is to address an effective method to deal with small object detection challenge with generated dataset. In order to generate the dataset, data augmentation and YOLO are used to detect jewellery object as one of popular small objects. The reason to use Yolo based object detection in this study, because of their high efficiency in terms of accuracy rate and low computation complexity in object detection. In view of the small target of jewellery and the real-time detection, we chose YOLOv7 [16], YOLOv6 [17] and YOLOv5 models and compare their results.

In summary, this paper has the following contributions:

- 1) Generating a new dataset for tiny objects: We gathered about 2,500 photos from a webcam which includes three categories of jewellery (earrings, ring and pendant) and then augmented them to about 6,500 images.
- 2) Generating new Yolo-based model on different versions of YOLOv7, YOLOv6 and YOLOv5 algorithms.

3) Conducting extensive evaluations and analysis for the generated models and presented comprehensive performance comparison on the methods.

The rest of this paper consists as follows; Section II presents the background of the study. Section III discusses the research methodology. The results and analysis are presented in Section IV. Finally, his paper concludes in Section V.

II. BACKGROUND

In 2015, researcher Joseph Redmon and colleagues introduced YOLO algorithm. The YOLO series outperforms preceding versions in terms of speed and the ability to find tiny things [18]. It just takes one iteration of the algorithm to spread over a picture for the YOLO to detect things in real time [19]. In this study, various YOLO model iterations were used for both training and testing.

A. YOLOv5

A number of object recognition architectures that have already been trained using the MS COCO dataset are available in YOLOv5, which was released in 2020. Because of its quick speed and great accuracy, it is one of the most well-known detection algorithms. The photos are divided into a grid system by YOLOv5, and each grid cell is in charge of identifying items inside its own area. When several objects are present, this method offers a particular benefit.

The YOLOv5 is a deep learning-based platform available in five distinct iterations, ranging in size from the tiny YOLOv5 nano version, designed for mobile and embedded devices, to the gigantic YOLOv5x large version [18, 20, 22].

The author did not publish a detailed paper, but only launched a repository on Github and updated improvements there. Fig. 1 illustrates the backbone, neck, and head of the YOLOv5 architecture, which may be understood by analyzing its structural code [18, 21, 23]: Cross Stage Partial Networks (CSP) and the focal structure make up the backbone. The focus structure down samples the input data dimension while the

original data is kept. The model's capacity for learning is enhanced, and its memory use is decreased, thanks to the CSP Network's ability to extract important information.

The neck part combines the acquired characteristics and transmits them to the prediction layer using Feature Pyramid Networks (FPN) and the Path Aggregation Network (PAN). The FPN up samples the high-level feature data via top-to-bottom communication and prediction fusion. The underlying pyramid, PAN, communicates important positioning properties top-to-bottom, aiding in the distinguishing of similar objects of various scales and sizes.

The final output vectors, consisting of bounding boxes, class probabilities, and object scores, are provided by the output layer's head by applying anchor boxes to the features. Including the focus and CSP layers is the primary change in YOLOv5. The focusing layer decreases layers, parameters, FLOPS, and CUDA memory to increase forward and reverse speeds. The backbone layer's CSP layer tries to extract specific data and carry out more extensive activities. In YOLOv5, the meshing ideas from the original YOLO algorithm have been retained [18].

B. YOLOv6

The single-stage object detection framework for industrial applications, MT-YOLOv6 (created by the Meituan firm, hence the prefix "MT"), has a hardware-friendly, effective design and excellent performance [24].

Numerous upgrades to the Backbone, Neck, and Head blocks as well as training methods are included in YOLOv6. For instance, utilizing Rep-PAN and EfficientRep structures, respectively, the Neck and Backbone in YOLOv6 have been redesigned in accordance with the notion of a hardware-aware neural network. Strong representational capabilities are combined with hardware computational capability, such as GPU, in the EfficientRep Backbone. Rep-Pan Neck outperforms PANet and SPP in terms of accuracy and speed.

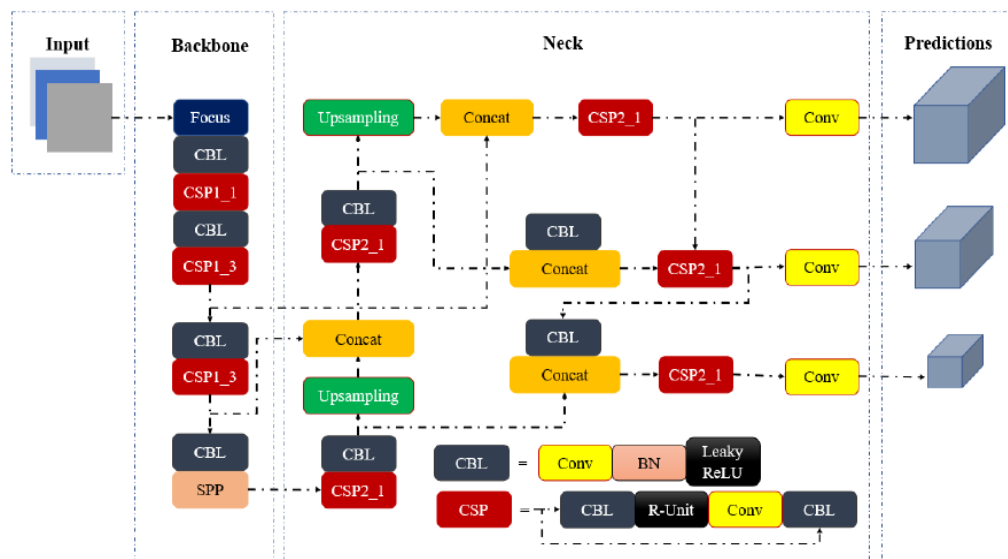

Fig. 1. Network structure of YOLOv5 [18].

Fig. 3. Network structure of YOLOv7 [30].

In [32] YOLOv5 network modifications were made for aerial small target detection. By utilizing the first effective channel attention module, they altered the backbone, and the channel attention pyramid approach was suggested. Consequently, the module for identifying large items was removed in order to improve the identification of tiny things, and a detect layer was introduced to look for smaller objects. Finally, transposed convolution was used to produce upsampling rather than the already used closest neighbor interpolation. With the suggested technique, the mAP for the VEDAI dataset was 6.9%, for the xView dataset it was 6.7%, for the DOTA dataset it was 2.7%, and for the Arirang dataset it was around 2.4% for the small car class.

To address the problem of detecting small fish [33] presented a YOLOv5-based model. It tries to address the issues of inaccurate location and insufficient information for detecting underwater targets. First, they proposed combining the attention mechanisms CA and C3 structure to increase the network's ability to retrieve crucial information. Next, they suggested expanding the YOLOv5's three detection layers to four in order to address the issue of numerous, intensive detection tasks. Finally, in order to improve convergence time and lessen erroneous regression findings, GIOU loss was used in place of EIOU loss. The experimental findings demonstrated that the revised algorithm affected various indicators differently; mAP@0.50 achieved 94.9%, which was more accurate. The detection effect was 24.6 percent greater, and

there were 248 picture detections overall—49 more than with YOLOv5. Performance for target detection was enhanced. Poor underwater fish swarm detection, tiny target location, few pixels, and low accuracy issues are all resolved.

In [31] some generic work for detecting tiny objects was done. They showed that one of the reasons for the poor average accuracy for small objects is the need for more representation of small things in training data. This is especially true for today's most advanced object detectors, which require a large enough training set of objects to guarantee that the predicted anchors match. They suggested two ways to improve the initial MS COCO database in order to resolve the problem. They first demonstrated how oversampling photos with small items during training may easily enhance performance on small objects. Second, they recommended an improved method based on pasting microscopic items. Compared to the state-of-the-art achieved by Mask R-CNN on MS COCO, their trials showed a 9.7% relative improvement, for instance, segmentation and a 7.1% relative improvement for object detection for tiny objects. The collection of augmentation techniques that have been suggested provides a trade-off between the accuracy of predictions for small and big objects.

In [34], their technique produced counting dense flocks of hemp ducks using positive detection findings. To improve the network structure of the YOLOv7 algorithm, three CBAM modules were added to the backbone network. SE-YOLOv7 and ECA-YOLOv7 were introduced for comparison studies

along with an updated YOLOv7 algorithm that includes an attention mechanism. As a consequence of the experimental findings, CBAM-YOLOv7 was shown to have greater accuracy, as well as somewhat enhanced recall, mAP@0.5, and mAP@0.5:0.95 values. There was no change in the computational demand, and the FLOPS only slightly increased by 0.02 G. They also provided two labelling methods: whole-body labelling and head-only tagging, taking into consideration the overlap problem with hemp duck labelling frames. The full-body frame labelling approach showed a greater detection effect, whereas the head-only labelling method resulted in the loss of a significant amount of feature information.

2) *Jewellery detection*: Although there are not many articles available for jewellery recognition work, especially jewellery in store, some similar works can be mentioned.

Images of jewellery have been categorized using a machine-learning method [35]. They employed various methods. The first method takes advantage of the characteristics of AlexNet's support vector machine and support vector machine extracted from the input pictures. The Inception-v3 model is used in the second technique to carry out the same task. The results of the experiments showed that both techniques worked well, although Inception-v3 had a 0.9% higher success rate. In order to improve consistency, the Inception-v3 was then used to train the dataset from scratch. SVM has a 98.30% accuracy rating compared to 99.19% for Inception-v3.

In [36], the author focuses on picture recognition methods for automatically classifying stone-grinding flaws. After that, the stone quality is classified using the computed pertinent image attributes. A binary decision tree-based technique that uses decision thresholds modified from a training dataset does classification. In the end, the accuracy and time complexity of the proposed method are compared with more than twenty cutting-edge machine learning algorithms, and the results are competitive: on the D1 dataset, the best accuracy was reached among all tested algorithms; on the D2 dataset, 7% poorer prediction than the best algorithm was achieved. In addition, the algorithm consistently outperformed all others in all tests.

A novel technique for counting pearls was presented in [37]. The model is composed of an approach to counting and object detection. After a thorough investigation, they examine the key performance metrics of nine object detection algorithms. The results demonstrate that pearl identification can be accomplished using Faster R-CNN with ResNet152, which was pretrained on the pearl dataset, and only needs 15.8 ms of inference time with a counter following the initial loading of the model. Additionally, performance for precise counting and pearl recognition of natural or artificial light is promising. Additionally, the network obtained 100% accuracy in counting pearls and a recall/AR@100 (medium) of 95% for pearl identification.

In [38], they generated a model for automated coin identification and recognition. In contrast to image processing techniques, which focus on the extraction of color, shape, and edge information, the majority of coin identification systems

now in use are based on the physical characteristics of the coins. They have suggested a deep learning strategy for the recognition and detection of Indian coinage. AlexNet, a convolutional neural network that has already been trained, is trained using features including textures, colors, and forms. More than 1600 photos were used to train the model. They used a pre-assembled collection of photos to train AlexNet in their trials, which proved that there was sufficient training data. Results obtained demonstrated that the suggested technique outperformed more established methods.

III. METHODOLOGY

YOLO was developed as a pre-trained object detector that can identify common items, including tables, chairs, automobiles, phones, and more [39]. We suggest a detection approach based on YOLO techniques to create a model that could recognize jewellery. Also useful in real-time applications are our models.

A. Dataset

Our dataset consists of three various categories of jewellery (earrings, ring and pendant). The dataset includes images taken from our webcam. We collected our photos from a jewelry store webcam that was fixed in place. Fig. 4 shows some examples of our dataset. The dataset contains different image sizes including small target objects, which is more challenging to detect.

We selected photos of different types of shapes, sizes, resolutions, angles and different numbers of samples in each image. Using Roboflow, the 2456 photos from the dataset were increased to roughly 6500 images in order to improve our model. The following random processing steps were applied to each image: horizontal flip, rotation (between -15° and $+15^\circ$), saturation (between -20% and $+20\%$), exposure (between -10% and $+10\%$), and brightness (between -20% and $+20\%$). A maximum of three enhanced versions were produced for each image. In Fig. 5, examples of enhanced pictures are displayed. A training set (93%), a validation set (6%), and a test set (1%), each comprised of the labelled images, are then created.

B. Google Colab

Utilizing Google Colab, which offers free usage of powerful GPUs, was helpful. A 12GB NVIDIA Tesla T4 GPU, shown in greater detail in Fig. 6, is used for all training and testing workloads. Our whole model was trained with an image size of 640 pixels and 50 training iterations. Other hyperparameters were adjusted using the YOLO default settings.

C. Transfer Learning

It is always a good idea to begin the training process for an object detector with a model that has already been built using weights from extremely sizable datasets. Even if the training weights do not have the test items, this is OK. Transfer learning refers to this procedure. In order to help the network learn more quickly, a pre-trained model that uses weights from the COCO dataset as its initial weights is employed. Additionally advantageous is the fact that fewer data will be needed [39].

IV. RESULTS AND ANALYSIS

In this section, we introduce the experiment's details, and then we show the training results using pretraining weights.

A. Model Evaluation

In the proposed study, the gathered experimental findings were compared using a variety of assessment metrics, including accuracy, recall, F1-score, confusion matrix, and mean average precision (mAP). The true positive rate, or TPR, indicates how probable it is that things from the real world will be correctly identified. When a model produces no false negatives, which indicates that there are no bounding boxes that are not recognized but ought to be detected, it has a high recall. Eq. (1) provides the mathematical model for the recall [18]:

$$R = \frac{TP}{TP+FN} = \frac{TP}{\text{Total Ground Truths}} \quad (1)$$

The real positive and false negative are denoted in the equation above by the letters TP and FN, respectively. Eq. (2) defines precision as the percentage of correctly anticipated positives, often known as the positive predictive value. The exact model creates no false positives and only detects important things (FP) [18].

$$P = \frac{TP}{TP+FP} = \frac{TP}{\text{Total Predictions}} \quad (2)$$

The F-1 score, as stated in Eq., is the harmonic mean of the accuracy and recall scores (3).

$$F - 1 = 2 * \frac{P * R}{P + R} \quad (3)$$

Eq. (4) defines AP as the area under the PR curve and defines mAP as the average of all AP values across all classes/categories.

$$mAP = \frac{1}{n} \sum_{i=1}^n AP_i \quad (4)$$

where n is the number of classes [18].

We trained YOLOv5n, YOLOv5s, YOLOv5m, YOLOv6t, YOLOv6n, YOLOv6s, YOLOv7tiny and YOLOv7. In Fig. 7 and 8, we have shown F1-confidence and precision-recall curves respectfully. Correspondingly, the results of validation's mAP, recall and precision are shown in Table 1. In addition, we put the training time and parameter values of each model for better evaluation.

B. Model Losses

The results of loss functions of models are shown in Fig. 9 to 11:

C. Analysis

We trained our model with YOLOv5n, YOLOv5s, YOLOv5m, YOLOv6n, YOLOv6t, YOLOv6s, YOLOv7tiny and YOLOv7. Fig. 12 to 14 provide examples of model predictions for the fresh and undiscovered images. Although YOLOv7 is the newest version and was launched in July 2022, it is allegedly better at object recognition than YOLOv5 and YOLOv6. All models that were trained on our jewellery dataset showed promising performance. However, we explored first YOLOv6 and next YOLOv5 are performing better than YOLOv7, and both YOLOv7tiny and YOLOv7 training accuracies were far worse on our dataset.

Due to their recent publication, the poor accuracies of the current YOLO versions may have resulted from insufficient experimentation, tweaking, and correction [40].

As shown by the results, the smallest model YOLOv5n achieved mAP@0.5 of 0.865 and the largest model, YOLOv7 achieved mAP@0.5 of 0.60. YOLOv6s model almost outperformed all other models and YOLOv6n is in second place. The worst result is for YOLOv7tiny except for training time which is the lowest with 2.393 hours. In the next place, the YOLOv7 has the worst performance. Due to the number of their parameters, YOLOv7 took the longest, clocking in at 4.518 hours. The detection speed of the model decreases as the number of parameters increases.

Another problem that should be investigated is that in all YOLOv5 models, the number of undetected objects is higher. It is feasible that expanding the dataset will boost the model's precision.

D. Additional Analysis

We analyzed two other cases. One is to change the Augmentation strategy and the second is to train with more epochs. We augmented our images as described in Section III A with RoboFlow. We also know that there are techniques to augment data in the structure of YOLO algorithms. For further investigation, we once removed all data augmentation techniques in the YOLOv5s and YOLOv6s algorithms. And next time we only removed the mosaic and mixup techniques. The difference in accuracy and speed between the original models with the modified models is shown in Table II. Interestingly, we noticed that when we remove the three data augmentation, results in YOLOv5s increases slightly and in YOLOv6s is almost equal. But in both models the training time decreases by a large margin.

Finally, to evaluate training more epochs, we trained the YOLOv6s algorithm with 100 epochs, the results compared to 50 epochs are in shown Table III. It shows that training with more epochs is slightly better. Fig. 12to 14 show the experimental results for Yolov5, 6 and 7.

V. CONCLUSION

In this work firstly a dataset consisting of 6k images of three classes, i.e., earrings, ring and pendant was created. Our photos were taken from a webcam fixed in a jewellery store. It has been tried that the photos be in different lighting conditions and angles as well as with different qualities. We have also used the benefits of data augmentation for our dataset. The performance of several YOLOv5, YOLOv6, and YOLOv7 variations was then compared based on the algorithm's accuracy, recall, mAP, and training time. YOLOv6s outperformed other algorithms for identifying jewellery, achieving the greatest mAP@0.5, of 0.917, and mAP@0.5:0.95, of 0.6, according to the results. The fastest algorithm was YOLOv7tiny with 2.393 hours of training time for 50 epochs. Also, we analyzed the model's augmentation techniques and training with more epochs. The proposed method in this study has advantages compared to other existing

methods because of high accuracy rate and low computation complexity. For future study, the results of the work show that we have reached good accuracy, but there is more work to be done, especially for the YOLOv7 algorithms, which can be compensated for by further optimization and investigation and the execution of more epochs. Another direction for future study on tiny/small object detection is to explore the use of attention mechanisms in deep neural networks. The use of attention mechanisms and generative models could help improve the performance of tiny/small object detection models and lead to better results on real-world applications.

Abstract—Underwater Wireless Sensor Networks (UWSNs) have a wide range of applications for monitoring the ocean and exploring the offshore environment. Sensor nodes are typically dispersed throughout the area of interest at different depths in these networks. Sensor nodes on the seabed must use a routing protocol in order to communicate with surface-level nodes. The suitability assessment considers network resources, application requirements, and environmental factors. By combining these factors, a platform for resource-aware routing strategies can be created that meet the needs of different applications in dynamic environments. Numerous challenges and problems are associated with UWSNs, including the lack of battery power, instability of topologies, a limited bandwidth, long propagation times, and interference from the ocean. These problems can be addressed through the design of routing protocols. The routing protocol facilitates the transfer of data between source and destination nodes. Data aggregation and UWSN protocols are widely used to achieve better outcomes. This paper describes an energy-aware algorithm for data aggregation in UWSNs that uses the improved ACO (Ant Colony Optimization) algorithm to maximize the packet delivery ratio, improve the network lifetime, decrease end-to-end delay, and use less energy.

Keywords—UWSNs; routing; data aggregation; energy efficiency; ant colony optimization algorithm

I. INTRODUCTION

During the past few years, wireless and emerging technologies have experienced significant advancements, especially the Internet of Things (IoT) [1, 2], Wireless Sensor Networks (WSNs) [3], artificial intelligence [4, 5], machine learning [6-8], smart grids [9], Blockchain [10], 5G connectivity [11, 12], and cloud computing [13], all of which have proven to be beneficial to society in a number of ways. Underwater WSNs (UWSNs) allow devices to receive, process, and communicate embedded in water for monitoring and exploration at different depths [14]. These devices are equipped with sensors that send information to a surface station after being received from the underwater environment [15]. The data are then processed based on the requirements of the application. The creation of UWSNs has been inspired by several factors, including the study of geological processes on the ocean's surface, the identification of mines, predicting and visualizing climate change, the analysis of the human impact on marine ecosystems, the discovery of areas containing

underwater oil, the prevention of accidents, the tracking of mammals, fish, and other microorganisms, as well as the protection of water borders against invaders [16-18].

Sensor networks used for underwater communications differ from those used for wired communications. Underwater networks must be able to withstand extreme pressure and temperature changes. They also require specialized communication protocols to account for the longer transmission times and greater signal loss associated with underwater transmission. Additionally, acoustic waves are used for underwater communications, as radio waves cannot propagate through water. As a first point, energy consumption varies concerning the sort of application. Underwater networks must also be designed to be energy-efficient to ensure long-term operation. The second characteristic of such networks is that they typically work towards shared objectives rather than representing specific individuals. Maximizing throughput instead of ensuring relative fairness between nodes is the goal. Thirdly, the number of hops, link distance, and reliability are correlated in these networks. Several short hops rather than a single long hop are used in underwater networks; hence multi-hop data delivery uses less energy than single-hop data delivery. The end-to-end reliability of packet routing is, however, affected by many hops, especially when the environment is harsh underwater. As a final factor, individual companies using inexpensive equipment typically install these networks, so strict interoperability is unnecessary [19]. The subsurface environment may complicate UWSN design. Host conditions pose significant challenges in terms of node movement and 3D topology. Some underwater applications, such as detection and rescue missions, require ad hoc deployment, which is often unplanned and needs networks to be deployed in short timeframes [20].

UWSNs have attracted researchers' attention thanks to their wide range of applications in several sectors. Monitoring environmental conditions, oil and gas extraction under the sea, surveillance of military operations, smart farming, and communication are some of the many applications of UWSN [21]. UWSNs suffer from several significant issues, including highly energy-consuming, insufficient processing power of nodes, and short-term lifespans in routing protocols [22]. Therefore, it is a research challenge to reduce energy

*Corresponding Author.

consumption and processing in UWSNs to extend their lifetimes. There are two main types of data aggregation in UWSNs: unstructured and structured [23]. The amorphous category has no predefined structure for data gathering, so local information is utilized to aggregate data. Structured data aggregation networks have a defined structure. Structured data aggregation is classified into two categories: flat and hierarchical. A flat structure has objects that contribute to sensing and perform similar functions. Hierarchical approaches typically organize sensor nodes logically and enable them to communicate securely. There are three primary methods of implementing hierarchical structures: centralized, clustered, and tree-based [24].

The ACO algorithm for aggregating data from UWSNs is improved in this work. The first step is a description of network and optimization models. Second, an enhanced ACO algorithm is presented based on improvements to heuristic information, pheromone update procedures, and evaporation parameters. To improve the heuristic data of the conventional ACO algorithm, we provide heuristic information that considers distance and remaining energy. Also, the suggested adaptive scheme for the evaporation parameter enables the algorithm to perform a global search and reach a higher convergence rate. The article is organized as follows. In the second part, previous techniques are discussed. The proposed technique is thoroughly explained in Section III. Section IV presents the simulation results. The paper's fifth and final section offers some ideas for future research.

II. RELATED WORK

As scientists construct UWSNs, they are challenged by significant mobility, propagation delays, limited bandwidth, and restricted battery and memory capacities. Tran and Oh [25] proposed a clustering approach that overcomes the UWSN's limitations. It is divided into four stages: the initiation stage, cluster head selection stage, clustering stage, and data aggregation stage. Efforts are being made to reduce the network's energy consumption, increase throughput, minimize data redundancy, and guarantee data accuracy.

UWSN sensor nodes continually lose power while performing underwater monitoring tasks. With limited replacement options for underwater sensor nodes, energy saving is key to increasing their lifespans. Data aggregation and clustering are potentially energy-saving techniques. An improved data aggregation method for cluster-based UWSNs is presented by Goyal, et al. [26], which employs a TDMA transmission schedule to eliminate collisions between clusters and an efficient sleep-wake-up algorithm to aggregate the sensed data, and by combining data aggregation, scheduling, and fusion, well-known existing protocols are improved to minimize energy consumption. Compared to existing protocols, the proposed scheme performs better concerning energy consumption, delay, and packet delivery rate than existing approaches.

A similarity function-based data aggregation with a Semaphore process is used by Ruby and Jeyachidra [27] to reduce energy consumption in UWSNs. A Date Palm Tree approach is used to cluster sensor nodes. Data aggregation nodes use Minkowski distance to check if readings collected from cluster members are similar. Data aggregators and cluster heads implement the Semaphore concept to ensure optimal network performance and reduce energy consumption. Packets can be moved from the data aggregators to the cluster heads through the message queue. Similarity measures in the proposed algorithm would lead to an improvement in link quality, redundancy, data delay, and energy consumption.

Krishnaswamy and Manvi [28] propose a palm tree-based approach for data aggregation and routing in UWASN. Petioles, rachis, leaflets, and spines make up the structure of palm trees. The sink node is connected to the junction of petioles. The proposed scheme creates fronds and leaflets by connecting them through spines. Several factors are taken into account when selecting master center nodes at the petiole junction, such as interconnection, petiole angle, Euclidean distance, and residual energy. The third step involves the identification of local centers at either end of the leaflet and linking them to the master centers via mobile agents. As for the fourth step, local aggregation considers leaflet nodes at local centers and carries them to a connected master center. Simulations are performed under various UWASN situations to assess the effectiveness of the scheme.

Wan, et al. [29] present an energy-efficient adaptive clustering routing protocol for UWSNs. Using a hierarchical network structure, the algorithm determines the size of the competition radius based on the distance between cluster heads and the base station. By avoiding early death, cluster heads can avoid excess competition radius and excessive energy burden. Based on the nodes' residual energy and transmission paths' energy loss, the algorithm can select the cluster head with the largest residual energy. This will optimize network energy consumption. To balance energy, routing rules are determined by residual energy levels to select between a single-hop routing node that is more energy-efficient and a multi-hop routing node that is more energy-efficient. According to simulation experiments, the proposed algorithm results in significant energy savings to the AFP protocol and DEBCR algorithm.

IoT-enabled depth base routing (IDBR) was proposed by Farooq, et al. [30] in order to maximize energy efficiency. MATLAB simulation was used to compare the IDBR with the standard DBR protocol. Both methods (IDBR and DBR) are analyzed based on delay, base station utilization, network lifetime, and energy consumption, alive nodes. Based on simulations, it is found that IDBR is 27.7% more energy efficient than DBR and improves network stability. IDBR also utilizes surface sinks more than DBR since sinks are used as relays, forwarding data to the base station directly, which gives field nodes more power. It increases the accessibility and security of the sensed data while improving the network's lifetime.

III. PROPOSED METHOD

The proposed method for data aggregation problems in UWSNs usually has a high delay, or they do not consider this problem. This section proposes a technique through the ACO algorithm to solve this problem, reduce energy consumption, and extend the underwater network's lifespan. The ACO algorithm always chooses the routes with the least number of hops to route data packets between sources and sink nodes.

A. Network Model

According to the suggested network model, all sensor nodes are dispersed over a three-dimensional space with fixed sensor placements, and the base station knows their locations. Since they are close, all sensors can send and receive data to and from the base station. The proposed model represents the

network as a graph $G=(V, E)$, where V is the set of nodes and E is the links between nodes, as seen in Fig. 1. In the model, sensors receive data from other sensors, integrate it with their data, create a packet without considering the amount of data received, and then send the packet. The problem is planned by a routing plan to deliver integrated packets from the sensors to the base station to reduce the energy consumption of the sensors, increase the network lifetime, and reduce the end-to-end delay. One solution is to use multi-hop communication by integrating the associated data. The problem is modeled as a graph with sensors representing the graph nodes. A maximum sensing range is considered for each node, which adjusts its neighborhood group and routing table. Each source node senses the sensing area regularly and sends data to the next node to receive from the base station.

Fig. 1. The proposed network model.

B. Optimization Models

1) *Attenuation model*: Attenuation results from the conversion of sound energy to heat, and the energy absorbed by the water is accounted for according to the signal frequency. The Throb model [31] has the simplest equations for calculating attenuation based on signal frequency. The Throb equation is Eq. (1), where f is the signal frequency in kHz.

$$\alpha = 0.11 \times \frac{f^2}{1+f^2} + 44 \times \frac{f^2}{4100+f^2} + 2.75 \times 10^{-4} \times f^2 + 0.003 \quad (1)$$

2) *Transmission loss model*: The loss of transmission (no connection between the transmitter and the receiver) occurs because of the reduction in the sound intensity on the route (communication link) between the transmitter and the receiver. It depends on the range of the nodes and the signal attenuation. The transmission loss is defined and calculated by Eq. (2) and Eq. (3), where SS is the spherical distribution factor in the three-dimensional environment calculated as follows:

$$TL = SS + \alpha \times 10^{-3} \quad (2)$$

$$SS = 20 \times \log r \quad (3)$$

α is the attenuation coefficient, calculated by Eq. 1, and r is the communication area of the nodes in meters.

3) *Signal-to-noise ratio (SNR) model*: Generally, SNR is a criterion that indicates the proportion of the desired signal versus noise in the network. SNR is defined such that a higher ratio means that the amount of signal is more significant than the noise. In wireless sensor networks underwater, the SNR of the signal transmitted by a node is defined as the sum of the source level, transmission loss (TL), noise level (NL), and directional index (DI) of the signal transmission. This ratio is defined as follows:

$$SNR = SL + TL + NL + DI \quad (4)$$

SL depends on the Transmission Power (P_t) and Transmission Power Intensity (I_t), defined as follows:

$$SL = 10 \times \log\left(\frac{I_t}{0.067 \times 10^{-18}}\right) \quad (5)$$

The I_t of an underwater signal is calculated as follows according to the P_t :

$$I_t = \left(\frac{P_t}{2 \times \pi \times 1m \times d}\right) \quad (6)$$

Where I_t unit is m^2 because this ratio is estimated for a signal within a one-meter distance of the source node for shallow water, and d is the distance in meters between the nodes. TL is estimated using Eq. (2), and the considered DL is zero because of assuming that the receiver and transmitter of the signals (hydrophones) are distributed in an appropriate direction. NL in an underwater wireless sensor network is the sum of disturbance noises, the ships transportation noise, sound noise, and thermal noise, calculated by the following equation:

$$N(F) = N_t(f) + N_s(f) + N_w(f) + N_{th}(f) \quad (7)$$

In which the values of $N_t(f)$, $N_s(f)$, $N_w(f)$, and $N_{th}(f)$ are estimated as follows:

$$10 \log N_t(f) = 17 - 30 \log(f) \quad (8)$$

$$10 \log N_s(f) = 40 + 20(s - 0.5) + 26 \log(f) \quad (9)$$

$$10 \log N_w(f) = 40 + 7.5\sqrt{w} + 20 \log(f) - 40 \log(f + 0.4) \quad (10)$$

$$10 \log N_{th}(f) = -15 + 20 \log(f) \quad (11)$$

S in Eq. (9) is the transportation factor, in Eq. (10), wind speed ranges from 0 to 1, and f in all of the above equations is the frequency in kHz.

4) *Delay model*: The suggested technique uses a propagation delay model to calculate delay using Eq. (12). Underwater propagation delay depends on the underwater sound speed and distance between the nodes.

$$t_p = \frac{d}{c} \quad (12)$$

Eq. (12)'s terms d and c represent the distance between two nodes and the sound speed (m/s), respectively. Sound speed for underwater acoustic communications is calculated using Eq. (13). A sound wave can be mechanical energy transferred by the source node. This wave can be propagated from one

particle to another one through the ocean proportional to the sound speed.

$$C = 1449 + 4.6T + 0.055T^2 - 5.304 \times 10^{-2}T^2 + 2.374 \times 10^{-4}T^3 + \quad (13)$$

In Eq. (13), T stands for temperature, D for depth, and S is the saltness of water (parts per 1000). Since the sea depth varies between 0 and 1500 meters, the water temperature and saltness reduce with sound speed.

5) *Energy consumption model for UWSN*: Usage of energy in an underwater channel for data transmission between two nodes with These equations are used to calculate distance d :

$$E(d) = E_t(d) + E_r(d) \quad (14)$$

$$E_t(d) = l(E_{elec} + E_{amp}) + P_t \times \frac{l}{h \times B(d)} \quad (15)$$

$$E_r(d) = l(E_{elec} + E_{DA}) + P_r \times \frac{l}{h \times B(d)} \quad (16)$$

In the above equations, P_t and P_r are transmission and reception powers to transfer and receive energy E_t and E_r , l is the size of the data packet, $B(d)$ is the existing bandwidth, and h are bandwidth efficiency (bps/Hz), calculated by applying Eq. (17):

$$h = \log_2(1 + SNR) \quad (17)$$

E_{elec} is the required energy to process one bit of the packet (data package), E_{amp} is the amount of energy consumed. These are the values they follow: $E_{elec} = 50nJ/bit$ and $E_{amp} = 10pJ \times bit^{-1} \times m^{-2}$. Moreover, E_{DA} in Eq. (16) is the required energy for data aggregation. In the proposed method, data aggregation is performed by each parent node. The energy consumption of this process is estimated using Eq. (18), where l is the length of the transmitted packet, EDa is the consumed energy for data aggregation, and n is the count of the aggregator node's children.

$$E_{DA} = l \times E_{Da} \times n \quad (18)$$

6) *Lifetime model*: The network lifetime is calculated by applying Eq. (19), where $e_{initial}$ The initial energy of the system. e_{total} The sum of the required energy for data transmission and reception is estimated using Eq. (14).

$$Lifetime = \frac{e_{initial}}{e_{total}} \quad (19)$$

7) *The objective function*: According to the models discussed in the previous sections, all parameters should be optimized to achieve the desired result. Therefore, the objective function used in this paper is a multi-objective optimization function given by Eq. (20), where E is the consumed energy, L is the lifetime, D is the end-to-end delay, α is attenuation, and TL is the transmission loss rate. W_1 , W_2 , W_3 , W_4 , and W_5 are the mentioned function coefficients used for the normalization of the results. These coefficients are between 0 and 1, and $W_1 + W_2 + W_3 + W_4 + W_5 = 1$.

$$Fitness = W_1 \times E + W_2 \times L + W_3 \times D + W_4 \times \alpha + W_5 \times TL \quad (20)$$

C. The Proposed Method

The proposed method uses the ACO algorithm to create the aggregation tree, and one ant is considered for each node. First, each creates a route through the heuristic function and pheromone set. The route is stored as a solution. The proposed procedural steps are as follows.

1) *Solution generation by ants*: This step generates a primary population, initialises parameters, and the ants present a solution.

- Step 1-1: Generating primary population

The number of nodes in a network and the primary ant population are related; additionally, each ant has an array with the IDs of the nodes on the route to the destination. Fig. 2(a) shows three arrays of the response. The last index shows the base station, and the first index of each array shows the source node. Fig. 2(b) displays the generated tree for the solutions.

Fig. 2. Ant solutions.

- Step 1-2: The parameters initialization

In this step, the parameters should be set based on the problem. Thus, the correct values for the primary pheromone of the route and the heuristic function should be defined.

- The heuristic function definition: various functions can be used for the heuristic function in this problem. This function is proportional to the cost of the links. In the proposed method, the inverse Euclidean, a node's distance from the following node, is considered the heuristic function. Hence, an $n \times n$ matrix is generated to save the distance between the nodes. The heuristic function is shown in η that η_{ij} is the reverse distance between the i^{th} and j^{th} nodes.
- Pheromone definition: the amount of the pheromone between the i^{th} and j^{th} nodes shows the amount of the route goodness based on the ants' experience in the previous round. When the ants reach their destination, the pheromone is updated. In this paper, the primary pheromone for each route is the reverse Euclidian, the distance from the base station to the next node. An $n \times n$ matrix is created to save the primary pheromone in each route.

- Step 1-3: Solution generation by the ants

The ants are the answer generator routines that generate the answer by random movement on the graph $G = (V, E)$. The ants should consider the policies and the limitations of the problem when moving on the graph. They search for a route to the base station to generate a solution. The probability of selecting the next step is computed by Eq. (21). The definitions related to Eq. (21) are presented in Table I. One of the nodes is selected randomly after calculating the probability of each node selection as the next step. The roulette wheel sampling method (a random selection method of a discrete distribution) is used for this aim. The ants continue their step-by-step movement until the ant reaches the base station. Each ant's solution includes a generated route from the source node to the base station that is saved in an array with the length of the route.

$$P_{i \rightarrow j}^k = P_{ij}^k \begin{cases} \frac{(\tau_{ij})^\alpha \times (\eta_{ij})^\beta}{\sum_{u \in N_i^k} (\tau_{iu})^\alpha \times (\eta_{iu})^\beta} & j \in N_i^k \\ 0 & j \notin N_i^k \end{cases} \quad (21)$$

- Step 1-4: The obtained solution evaluation

The generated answer by each ant is evaluated in this step. At first, to determine the distance between the nodes, Eq. (22) is used.

$$d = d + \text{distance}(n(i) + (n(i+1))) \quad (22)$$

In Eq. (22), $n(i)$ is the source node, $n(i+1)$ is the next node, and d shows the total distance between the source node and the base station. The entire route distance is calculated step-by-step and saved in d . Then the energy consumption, delay, lifetime, attenuation, and SNR of each route are computed based on the equations in the mentioned models.

2) *Pheromone update*: This step includes adding the pheromone and its evaporation. The goal of adding a pheromone is to increase the amount of the pheromone related to the optimal solutions performed after each repetition of the algorithm. The pheromones are evaporated in each round. Pheromone evaporation helps the ants to forget previously learned unacceptable solutions.

- Step 2-1: Adding pheromone

Shedding pheromone is performed in this step based on the obtained solutions from the ant colony optimization algorithm. Some pheromone is added to each edge from the i^{th} to j^{th} node passed by the k^{th} ant proportional to the cost of the k^{th} ant solution using Eq. (23). Q is a constant considered 1. Less cost of the key leads to adding more pheromones to the route.

$$\tau_{ij} = \tau_{ij} + Q / \text{ant}(k). \text{cost} \quad (23)$$

- Step 2-2: Pheromone evaporation

The route's pheromone is evaporated proportional to Eq. (24), in which ρ is the evaporation rate with the value of 0.05.

$$\tau_{ij} = (1 - \rho) \times \tau_{ij} \quad (24)$$

IV. EXPERIMENTAL RESULTS

MATLAB is used for the implementation and data analysis of the proposed method because this simulator is used in many types of research because of its high ability for mathematical calculations, high capability to show the results, high efficiency, and high data volume. Simulation parameters and the used variables of the planned method are presented in Table II.

Three scenarios show the proposed method's efficiency rather than the previous ones. End-to-end delay and the energy consumption of the proposed technique are compared with the previously proposed techniques in the first and second scenarios. The idea of using multiple sinks is identified in the third scenario, and its performance is compared with the methods that use only one sink. The first scenario has been performed based on the data of [32], and the parameters of this paper are shown in Table III. In this scenario, as shown in Fig. 3 to 6, the proposed method delay outperforms the Clustered-based Multipath Shortest-distance Energy efficient Routing protocol (CMSE2R), and the genetic algorithm regarding network lifetime, energy consumption, end-to-end delay, and packet delivery rate.

The second scenario has been performed based on the data of [33], and the parameters of this paper are shown in Table IV. In this scenario, as displayed in Fig. 7, the proposed method performs well regarding end-to-end delay compared to Depth Base Routing (DBR). The third scenario has been performed based on the data of [34], and the parameters of this paper are shown in Table V. Fig. 8 and 9 show that the planned method performs better in terms of energy consumption and delay than Firefly mating optimization inspired Routing Protocol (FFRP) and Particle Swarm Optimization (PSO) algorithm. The simulation findings demonstrate that the suggested method needs low energy compared with the previous methods, and its end-to-end delay

is less than the previously proposed methods. A new idea is proposed and implemented to improve this method in which multiple sinks are used for data gathering instead of one sink. Also, the network lifetime improves in addition to the energy and delay reduction.

Considerations for the subsurface environment should be taken into account when evaluating UWSNs. The host conditions pose major challenges in terms of continuous node movement and 3D topology. Additionally, some underwater applications, including detection or rescue missions, are often ad hoc in nature, requiring both rapid deployment of networks and no advance planning. The routing protocol should be able to determine the location of the nodes in such circumstances without requiring any prior knowledge of the network. Furthermore, the network should be able to reconfigure itself under dynamic conditions so that the communication environment can be optimized. A significant consideration in the selection of a system is the relationship between the communication range and data rate and the specific conditions. Even when configured for higher data rates, a deep-water system may not be suitable for shallow water.

In practice, manufacturers' specifications of maximum data rates are mostly useful for establishing the upper performance bounds, which are not always achievable under specific conditions. Well-funded users have purchased multiple systems and tested them in specific environments in order to determine whether they are suitable for their needs. There is a need for an international effort to standardize the tests for acoustic communications, but this is not as simple as it sounds since private organizations or even government organizations that conduct comprehensive tests do not generally publish the results of their studies. Additionally, there is a lack of global standards for acoustic communication systems, which makes it difficult to compare the performance of different systems. Without a unified set of standards, it is difficult to determine which system is best suited for a particular application.

TABLE I. DEFINITIONS OF VARIABLES IN EQ. (21)

Parameters	Definition
P_{ij}^k	Probability of choosing node j as the next step by ant k
(τ_{ij})	The pheromone flow rate from node i to node j
(η_{ij})	The reverse of the distance between nod i to node j
N_i	The set of nodes
α	The controlling parameter for the relative effect of the amount of pheromone
β	The controlling parameter for the relative effect of the amount of heuristic function

TABLE II. SIMULATION PARAMETERS

Parameters	Description	Value
A(m×n×z)	Sensing area	100*100 – 500*500
N	Number of nodes	100-500
MaxIT	Max iteration	100-1000
L	Packet length	2-10 byte
$E_{initial}$	Initial energy	0.25 – 5 j
α	Ant colony constant	1
ρ	Pheromone evaporation rate	0.006
τ	Initial pheromones	1
Q	Ant colony constant	1
β	Ant colony constant	1

TABLE III. PARAMETERS FOR THE FIRST SCENARIO

Parameters	Values
No. of Nodes	300
Network Size	1500m x 1500m
Initial Energy	70 J
Simulation time	1000 sec
Data Packet size	64 bytes
Transmission range	100 m to 150 m
MAC Protocol (Shin & Kim, 2008)	802.11-DYNAV
The surface sink distance difference	100 m
Energy consumption for receiving	0.75w
Energy consumption for idle listening	8mw
Energy consumption for transmitting	2w

Fig. 3. Energy consumption comparison.

Fig. 4. Network lifetime comparison.

Fig. 5. End-to-end delay comparison.

Fig. 6. Packet delivery rate comparison.

TABLE IV. PARAMETERS FOR THE SECOND SCENARIO

Parameters	Values
Data Packet size	512 bytes
Network Size	3000m x 3000m
No. of Nodes	30-150
Range (Transmitter/Receiver) of nodes	100m
Simulation time	70 sec

Fig. 7. Energy consumption comparison.

TABLE V. PARAMETERS FOR THE THIRD SCENARIO

Parameters	Values
Initial Energy	100 j
Network Size	1000m x 1000m
No. of Nodes	300
Data Packet size	30 bytes
Range (Transmitter/Receiver) of nodes	150m
Simulation time	130 sec

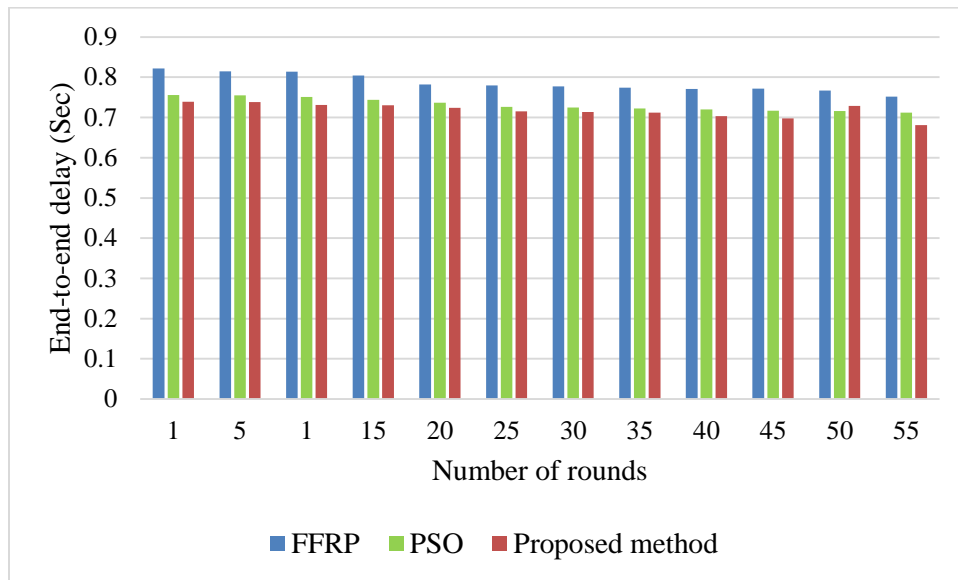

Fig. 8. End-to-end delay comparison.

Fig. 9. Energy consumption comparison.

V. CONCLUSION

In order to mitigate the issue of excessive energy consumption in UWSNs, this work developed an energy-efficient data aggregation technique with the modified ACO algorithm. The paper made the following contributions. The heuristic information was enhanced using the distance factor and the residual energy of nodes. This research also included an improved adaptive technique for updating the evaporation parameter for the pheromone update mechanism, which can increase the algorithm's global search capacity and convergence rate. As a third point, this paper proposes ant searches. Simulation findings regarding packet delivery rate, end-to-end latency, network lifetime, and energy consumption demonstrate that the suggested technique surpasses existing ones. To achieve effective data aggregation, the aggregator must wait until the data is collected from various sensors and

transmit them to the sink without any collisions or delays. In order to accomplish this, effective scheduling techniques are required. Therefore, in the future work we will develop a scheduling technique that will allow for the effective aggregation of data from the sensors. As the aggregated data is transmitted to the sink without delay or loss of quality, it considers both spatial and temporal co-relationships among the data. For energy balanced networks, the mobility of sensor nodes should also be taken into consideration in an intra- and inter-cluster data aggregation process.

Abstract—Machine Learning (ML) is seen as a promising application that offers autonomous learning and provides optimized solutions to complex problems. The current Multiprotocol Label Switching (MPLS)-based communication system is packed with exponentially increasing applications and different Quality-of-Services (QoS) requirements. As the network is getting complex and congested, it will become challenging to satisfy the QoS requirements in the MPLS network. This study proposes a hybrid ML-based intrusion detection system (ML-IDS) and ML-based intelligent routing algorithm (ML-RA) for MPLS network. The research is divided into three parts, which are (1) dataset development, (2) algorithm development, and (3) algorithm performance evaluation. The dataset development for both algorithms is carried out via simulations in Graphical Network Simulator 3 (GNS3). The datasets are then fed into MATLAB to train ML classifiers and regression models to classify the incoming traffic as normal or attack and predict traffic delays for all available routes, respectively. Only the normal traffic predicted by the ML-IDS algorithm will be allowed to enter the network domain, and the route with the fastest delay predicted by the ML-RA is assigned for routing. The ML-based routing algorithm is compared to the conventional routing algorithm, Routing Information Protocol version 2 (RIPv2). From the performance evaluations, the ML-RA shows 100 percent accuracy in predicting the fastest route in the network. During network congestion, the proposed ML outperforms the RIPv2 in terms of delay and throughput on average by 57.61 percent and 46.57 percent, respectively.

Keywords—Machine learning; intrusion detection system; routing algorithm; quality of service; communication system

I. INTRODUCTION

Multi-protocol label switching (MPLS) routing technique for telecommunication networks was invented in the late 1990s as a more efficient alternative to the traditional Internet Protocol (IP) routing [1]. In contrast to traditional network protocols, which route data packets according to the source-to-destination (S2D) addresses, MPLS routes traffic from one node to another according to predefined labels in the packet header. These labels may contain information related to quality of service (QoS) such as traffic latency, jitter, packet loss and downtime, which allows network traffic to be prioritized according to its importance. One of the most noteworthy advantages of MPLS is its independence from any

protocol or transport medium. It supports IP-based, Ethernet-based, asynchronous transfer mode (ATM), and frame relay transmission [1]. Other benefits of MPLS include [1]: 1) providing good QoS performance for latency-insensitive applications such as video and mission-critical data; 2) allowing data and voice applications to coexist on the same network; 3) allows the pre-programming of different types of data with distinct priorities and service classes; and 4) offers network scalability to users.

However, as the number of applications and users grows exponentially, conventional MPLS networks are likely to become more complicated and require stringent QoS regulations to ensure network reliability, delay tolerance, and throughput. Routing assignment (RA) algorithms used in conventional networks are typically based on the shortest path with fixed rules. They may not give the optimal QoS, particularly in a complicated network architecture. While standards and algorithms have been developed to increase the efficiency of the existing networks, it is anticipated that conventional approaches would be unable to meet growing demand while maintaining QoS. Additionally, the networks are facing threats from cyber attackers that take advantage of network vulnerabilities, resulting in extensive network disruption and significant damage to an organization's reputation. These challenges emphasize the critical importance of intelligent routing techniques and network security protection, such as that provided by network intrusion detection systems (IDSs).

An IDS monitors network traffic for signals of hostile activity by building a predictive model that can discriminate between attack and normal network flows. However, despite decades of advancements, existing IDSs continue to face detection accuracy challenges by reducing the false alarm rates and the identification of unknown threats [2]. Additionally, the fixed rules of IDS systems are vulnerable to threats including Denial-of-Service (DoS) and brute force [3]. To safeguard the network from such vulnerabilities, researchers all around the world have created cutting-edge IDS with the integration of machine learning (ML) algorithms. ML is capable of rapidly identifying patterns in a variety of data and solving complex, multi-dimensional problems with little to no human intervention. Since intrusion detection is a

classification problem, ML can be one of the promising candidates for IDS in the network. A Learning-based system is used in ML-based IDS to identify possible attack classes based on the behavior of an incoming packet. These ML-based IDSs offer various advantages over conventional systems, including lower computational loads and greater flexibility, as well as the ability to detect novel attacks and capture the complex features of attack behavior [4].

This research addresses several issues in MPLS networks, including improving network QoS and enhancing network security using ML algorithms. This work proposes a hybrid supervised ML-based IDS and ML-based RA algorithm (herewith will be referred to as ML-IDS and ML-RA, respectively) that is trained using an ML-IDS dataset generated using a simple data extraction method. The proposed ML-IDS is a security intrusion classification algorithm that analyses the incoming traffic patterns and network conditions and then classifies the traffic as legitimate or potentially intrusive. Afterwards, the ML-RA intelligently computes a route that is predicted to provide the best QoS requirements under any network condition. In short, the main contributions of this research work are as follows: 1) we proposed an ML-IDS algorithm that uses a simple data extraction method from the network to train the classifier without compromising the accuracy; 2) we developed an ML-RA algorithm that predicts the QoS parameters and performs path computing for the incoming traffic with various priorities in different traffic conditions; and 3) we introduce the first hybrid ML-IDS and routing algorithm (RA) that enhances network security and QoS.

This paper is organized as follows. Section II provides the literature review. The formulated ML-IDS and ML-RA methodology is presented in Section III. The discussion on the findings in the evaluation of the proposed strategy is presented in Section IV. Finally, Section V refocuses on the purpose of the research and draws conclusions for this study.

II. LITERATURE REVIEW

A. Routing Strategies in the Literature

One of the networking fundamentals responsible for selecting a path for packet transmission is network traffic routing. With proper network routing management, it is possible to achieve a QoS-compliant and cost-effective route, especially through the implementation of ML in network routing. However, ML-based traffic routing is often challenging because of various constraints including complex and dynamic topologies, diverse traffic, and unique QoS requirements. In routing optimization problems, traffic and route matrices can be used to describe the input and output of ML algorithms [5]. To predict or select a path for incoming traffic, ML algorithms must learn the correlation between traffic inputs and link conditions. The recent applications of ML in routing can be divided into five routing objectives, which are discussed as follows:

1) *Routing by predicting network parameters:* In today's network operations and administration, it is critical to predict network parameters such as path or connection quality, delay, throughput, optical signal to noise ratio (OSNR), and

incoming traffic. ML aims to improve overall network performance by learning from past data or the environment. For example, Alvizu et al. [6] trained an artificial neural network (ANN) using a public dataset from Milan to forecast the traffic load and variation and calculate the best resource allocation via dynamic optical routing in software defined networks (SDNs), thereby reducing energy consumption. In contrast, Choudhury et al. [7] introduced a hybrid machine learning (ML) model based on the Gaussian process (GP) method to forecast traffic volume for each traffic engineering tunnel over time, followed by forecasting the optical performance of new wavelengths in a multi-vendor environment.

2) *Routing for QoS improvement:* By controlling the network's delay, jitter, bandwidth, and packet loss ratio, a good QoS can be attained. However, with the explosion of traffic volume in the network, it can be challenging to fulfil the QoS specifications for each incoming traffic. Due to the network's complexity, conventional algorithms to improve the QoS parameters may be impractical. To meet the QoS requirements, researchers are continuously developing and refining unique solutions, such as ML-based algorithms, to maximize throughput while minimizing latency.

Nakayama et al. [8] proposed a routing scheme using the Markov Chain Monte Carlo algorithm to reduce the worst-case end-to-end delay of all the front-haul flows of the centralized radio access network (C-RAN) and ensure that all flows meet the latency requirements. The proposed solution successfully reduces all flow's latency, demonstrating that the ML-based approach can address the CRAN's queuing delay problem. Additionally, Stampa [9] proposed a deep RL agent that can optimize routing in accordance with a predefined target metric, such as the delay requirement in SDN. The deep RL model automatically adapts to the current traffic conditions and proposes a customized configuration that minimizes network delay. The suggested deep RL agents were able to reliably calculate total traffic intensities, and the average delay is less than the benchmark of 100,000 randomly created routes.

3) *Low computation routing scheme:* Incorporating ML in the network may lead to high computational load, especially when dealing with high dimensional input features or when using deep learning (DL)-based algorithms. With that, several works proposed a low computational routing scheme. For example, Hendriks et al. [10] proposed Q2-RA, which is hybrid of Q-routing and Multi-Agent Reinforcement Learning (MARL) RAs. In the algorithm, ad-hoc wireless nodes decide on a route by selecting the neighbor with the best Q-value as the next-hop destination. Although this algorithm has an additional modified reward function to meet the QoS criterion, it is comparable to Q-routing. Only training traffic is provided throughout the learning process to obtain the Q-values on the available path until it converged inside a predetermined threshold. The transmission of data traffic then starts once the rate of sending learning traffic has drastically lowered. The

suggested Q2-RA performs better than the ad hoc on-demand distance vector method with QoS awareness and is more flexible to network condition changes.

Martin et al. [11] proposed a classifier that was trained using labelled Risk Weighted Assets (RWA) configurations and solved using inductive logic programming (ILP). The classifier can offer online network setup for newly arriving traffic matrices once it has been trained. In response to rapidly changing traffic patterns, it can dynamically adapt and reconfigure the network because of the quick computation of RWA configurations. Instead of calculating ILP for every incoming traffic, the network will remember prior ILP solutions and allocate a path in accordance with the historical data. As compared to the ILP method, this approach reduces computational time by up to 93%.

4) *Congestion-control routing*: Congestion is one of the main concerns for network providers as it can degrade the overall network performance. Through congestion control, network stability, fair resource allocation, and a reasonable packet loss ratio are all made possible [12]. In conventional routing protocols, previous network abnormalities, such as network congestion, are not learned. As network traffic keeps growing, the network is put under a lot of strain, which creates problems with resource management and allocation that affect traffic QoS. Given that the majority of networks are still using outdated routing systems, this congestion problem is getting more critical [13]. Additionally, routing systems were created for fixed networks that determine the shortest paths using distance vectors or link costs. Eventually, the network will experience excessive traffic load, which will severely degrade network performance. The conventional RAs frequently commit the same routing mistake when this condition recurs, leading to an unmanageable rise in delay and packet error rate. This is where the predictive ML models come in to attempt to overcome the congestion issue.

Due to the inflexibility of route selection in circuit-switched networks, their total routing performance is usually constrained. This issue is highlighted by the least loaded (LL) routing protocol, one of the network's routing protocols. Because of the excessive capacity consumption under conditions of heavy load, this routing protocol may result in subpar performance and overall inefficiency [5]. To assist the LL routing performance, a novel online-based supervised Naive Bayes (NB) classifier is proposed in [14]. The classifier forecasts the likelihood of future circuit blocking between node pairs. When a service is provided or denied, the network snapshot is stored as historical information to determine the best route for new service connections. The proposed solution outperforms the least-load and short-path conventional routing protocols in terms of the minimum number of extra hops, lowest blocking probability, and least amount of network capacity overconsumption.

Another example of congestion control is demonstrated by Tang et al. [13]. The authors proposed a real-time DL-based intelligent network traffic control method based on deep convolutional NN (deep CNN) with uniquely characterized

input and output to represent the wireless mesh network backbone. The performance of the proposed scheme is compared with Open Shortest Path First (OSPF), Intermediate System to Intermediate System (IS-IS), and Routing Information Protocol (RIP). The simulation results showed that the DL-based routing scheme is superior to other routing protocols, as 98.7% of congestion cases are avoided.

5) *Load-balancing routing*: The bursty nature of SDN packet traffic creates a network load imbalance. Yao et al. [15] proposed a pair of ML-aided load balance routing schemes that take queue utilization (QU) into account to address this issue. The aim is to improve load-balance routing by reducing the packet loss ratio and improving the worst throughput. To deal with network congestion caused by a sudden traffic burst, ANN algorithms predict the QU for the next time slot. The predicted value is used to guide intelligent routing decisions. When compared to the shortest path approach, the proposed scheme improves packet loss ratio and throughput while increasing delay by 20%.

The next-generation wireless network (NGWN) is a network service and operation interface that can support multiple standards such as 5G, Wi-Fi, and cognitive radio networks. However, the volume of traffic in the current communication infrastructure is expanding rapidly that the router's speed may not be sufficient to keep pace. Additionally, the NGWN's real-time load balance request cannot be satisfied and served by using conventional routing schemes that are solely based on standard rules and have limited computing capacity [16]. To anticipate the network queue state, which is one of the measures for making wise routing decisions, Yao et al. [16] suggested a load balancing routing based on NN. The proposed algorithm is compared to shortest path-based algorithms such as Bellman-Ford (BF) and Queue-Utilization BF (QUBF), in terms of throughput and delay. According to the results, the proposed technique reached the highest throughput while incurring a 20% delay over the BF approach. The proposed algorithm also can predict the next-hop path with the smallest buffer and thus improve load balancing.

B. Challenges in Routing

From the literature review, recent related works on ML-based RA have proven to route the traffic effectively. Almost all related works from literature successfully overcome the limitations of conventional routing protocols. Despite ML's superiority in routing in communication networks, there are still some challenges to consider, discussed as follows.

1) *Trade-off between accuracy and computational load*: The trade-off between accuracy and computational load in ML-based RA using classical ML and DL is similar to the issue discussed for ML-based IDS. This trade-off must be considered because ML routing decisions need to be swift and in real-time to avoid processing delay. Unlike the proposed ML-RA in the literature which used DL-based classifiers, our work aims to use ML-based regressions including DT-regressions and LR by Gibbs Sampling (LRgs) to predict the delay in all available routes. DT and LRgs are well-known for

their simplicity and interpretability, but they are prone to overfitting. To address this issue, we will train, test, and evaluate our proposed ML-RA under various network and traffic conditions.

2) *Lack of congestion and link failure scenario for routing*: The majority of associated studies in the literature test the effect of their proposed ML-based routing scheme under congested network condition, as evident from the studies in [13], [17]–[22]. Only a few research, such as [23], develop ML-based RA that considered both congestion and link or node failures. Therefore, our proposed ML-RA considers both congestion and link failure scenarios.

3) *Traffic modelling for performance evaluation*: As the network becomes more complex and congested with traffic of varying priorities, it is critical that the ML-based routing mechanism can deliver traffic while meeting QoS requirements. However, most related works only consider single traffic type for routing, which may not be feasible to resemble real-world traffic with different priorities. There has been little research into ML-based routing for traffic with varying QoS requirements. For example, in [24], the Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) traffic are considered, which correspond to voice over Internet Protocol (VoIP) and video traffic. While

the authors [10] used three traffic priorities; high, medium and low priority, they did not explicitly specify the traffic types. Our proposed ML-RA will consider three traffic types which are expedited forwarding (EF), assured forwarding (AF), and best-effort (BE) traffic, which correspond to VoIP, close-circuit television (CCTV), and data transfer, respectively. It is expected that our proposed ML-RA can successfully route all traffic within their QoS requirements.

4) *Quality datasets for training*: When generating traffic in the network simulator, it is crucial that the traffic pattern is not random or static as demonstrated in [9], [11], [14], [17], [18], [22], to preserve the quality of the dataset used to train the ML algorithms. To improve the quality of the dataset, the traffic packets can be modified to resemble legitimate traffic properties, such as the standardized data rates and size. In this work, the ML-RA dataset is constructed using EF, AF, and BE traffic following the standard of VoIP, CCTV, and file transfers. More details on the traffic properties will be elaborated in Section III. In addition, the traffic is also modelled using the typical EF, AF, and BE traffic mixture ratios of 20:40:40 for [25].

Table I summarizes the discussed ML works in routing with their advantages and shortcomings.

TABLE I. SUMMARY OF RECENT ML-BASED RAS WITH THEIR ADVANTAGES AND SHORTCOMINGS

Authors	Routing Objectives	Description	Issues of Conventional Routing Protocol	ML Method	Advantages	Shortcomings
Yao et al. [15]	Load balancing	Proposed a pair of ML-assisted load-balancing RAs that consider QU, to improve load-balance routing by packet loss ratio reduction and improving the worst throughput	High computational complexity for QoS RA	DL	Improved global realignment and more efficient network optimization	<ul style="list-style-type: none">• High computational load• Only considers two traffic patterns (Steady and congest)
Yao et al. [16]	Load balancing	Proposed NN-based load-balancing RA to predict network queue status to make intelligent routing decisions	Traditional RAs cannot always serve the NGWN effectively	DL	Enhance the bit error rate, throughput, and delay	<ul style="list-style-type: none">• High computational load• Do not consider link failure• Do not consider different traffic priorities
Fadulullah et al. [23]	Predicting network parameters	Proposed a value iteration architecture-based deep RL routing approach, which includes the network node's adjacency matrix as learning parameters. The method can forecast the next node until the destination is reached	High computational cost to address RWA problems	DL	Ensures more stable network performance in the event of network topology changes	<ul style="list-style-type: none">• High computational load• Do not consider different traffic priorities
Murudkar et al. [18]	Predicting network parameters	Proposed a User Specific-Optimal Capacity Shortest Path RL routing in 5G networks is to establish the resource-based optimum-capacity shortest route for a user between S2D pairs	Challenging spectrum resource optimization	RL	Quickly determine the shortest route with the highest capacity	<ul style="list-style-type: none">• Only constant bit rate traffic in the simulations• Do not consider different traffic priorities• Do not consider node failures condition
Salani et al. [17]	Predicting network parameters	Proposed an integration of RF-based estimation for routing and spectrum assignment for quality of things	Inaccessible of perfect transmission knowledge to train the ML model	RF	Saves up to 30% on spectrum occupation.	<ul style="list-style-type: none">• Traffics in the simulations are generated randomly• Do not consider different traffic priorities• Do not consider link failure

Vashishth et al. [22]	Low computation routing scheme	Proposed cascade learning, an ensemble-based ML that combines LR and NN classifiers. Using the ML-based Probabilistic Routing Protocol and the History of Encounters and Transitivity (MLProph) as input, the logistic algorithm will generate two probabilities: delivered or not delivered	Context-free routing protocols suffer from high network overhead ratio and congestion	Ensemble LR and DL	Enhance message delivery probability, network overhead ratio, average hop count, and message drop rate.	<ul style="list-style-type: none"> Data generated is based on a flooding-based routing protocol to train the ML algorithms Do not consider different traffic priorities Do not consider node failures condition
Vashishth et al. [21]	Low computation routing scheme	Proposed a routing approach based on the Gaussian mixture (GM) model classifier in the Opportunistic Internet of Things (OppIoT) that increases message delivery probability	Fixed S2D path is non-existent, making routing very challenging	GM	Increase message delivery probability, the average hop count, the number of dropped packets, and the network overhead ratio	<ul style="list-style-type: none"> Delay is not one of the performance parameters Do not consider node failures
Hendriks et al. [10]	Low computation routing scheme	Proposed a hybrid of Q-routing and MARL RA. Ad-hoc wireless nodes use the algorithm to make routing decisions by selecting the neighbor with the best Q-value as the next hop	Traditional RAs have a high overhead load to be used in an ad hoc environment	RL	Outperforms well-known ad-hoc RAs in dynamic environments with QoS constraints	<ul style="list-style-type: none"> Do not consider node failures or congestion
Li et al. [14]	Congestion-control routing	Proposed an online-based supervised NB classifier for performance improvement. The classifier predicts the likelihood of future circuit blocking and uses the data to select routes for future service connections	Fixed route oriented significantly limits the routing performance and flexibility	NB	Saves ~ 90% of the time for the learning process, significantly speeding up simulation studies.	<ul style="list-style-type: none"> Traffic in the simulations is generated randomly Do not consider different traffic priorities
Tang et al. [13]	Congestion-control routing	Proposed a real-time DL-based intelligent network traffic control based on DCNN for a wireless mesh backbone	OSPF for training the ML-RA, which lacks the necessary intelligence to handle newly occurring situations	DL	Avoid 98.7% of congestion cases	<ul style="list-style-type: none"> High computational load Do not consider different traffic priorities Do not consider link failure scenario
Pasca et al. [20]	QoS improvement	Proposed an application-aware multipath flow routing framework integrating ML in SDN for traffic classification. The algorithm assigns paths based on QoS requirements of available parameters e.g., bandwidth and delay	Traditional static routing is slow to respond to network changes and slow to converge	NB, DT, Bayesian Network and SVM	Provide better routing configuration effectively reduces the network delay	<ul style="list-style-type: none"> Do not consider link failure Do not improve on delay
Nakayama et al. [8]	QoS improvement	Proposed a routing scheme based on the Markov Chain Monte Carlo algorithm to decrease the worst-case end-to-end delay of all CRAN front-haul flows and ensure that all flows fulfill the latency requirements	The current QoS-aware routing scheme ignores frame-level queuing delay.	Markov Chain Monte Carlo	All flows have a delay that is less than the threshold and meets the requirements.	<ul style="list-style-type: none"> Do not consider node failures or congestion Different class traffic is considered but did not mention explicitly
Stampa et al. [9]	QoS improvement	The authors designed and tested a deep RL agent in SDN that could significantly improve routing based on delay requirements	Limited routing optimization capabilities	Deep RL	Achieves improved delay when compared to the non-DRL agent routing scheme	<ul style="list-style-type: none"> Data samples used are 100,000 gravity generated traffic matrix Do not consider different traffic priorities Do not consider link failure and congestion
Mao et al. [19]	QoS improvement	Proposed Tensor-based Deep Belief Architectures (TDBA), in which traffic patterns from the edge router are fed into TDBA to build a path to all edge routers	Conventional routing cannot cope with the complex environment	DL	Achieves zero packet loss rate	<ul style="list-style-type: none"> High computational load Do not consider different traffic priorities Do not consider link failure condition

Alvizu et al. [6]	Predicting network parameters	Trained an ANN for forecasting the traffic load and variation and calculate the best resource allocation in SDN	Over-provisioning yields inefficiency and high operational costs	DL	The proposed scheme yields an optimality gap above 3%	<ul style="list-style-type: none"> • Training using a public dataset • Do not consider link failure

III. DEVELOPMENT OF THE HYBRID ML-IDS AND ML-RA

The ML-IDS dataset development is carried out via Graphical Network Simulator 3 (GNS3) by varying the network inputs. The normal incoming traffic is generated via the OSTINATO traffic generator, while the attack traffic is generated via Low Orbit Ion Cannon (LOIC). The output of the simulations in GNS3 for the ML-IDS algorithm will be the actual normal or attack label, while the output for ML-RA is the actual delay for all available routes between a S2D pair. All inputs and outputs are extracted via Wireshark and tabulated in a CSV file to build the ML-IDS and ML-RA datasets.

For ML-IDS, since it is a classification-based algorithm, the dataset is fed into MATLAB to train several ML classifiers. In contrast, ML-RA is a regression-based algorithm, and the ML-RA dataset is fed to train ML regression models. Both datasets are split into 70% training dataset and 30% testing dataset for performance evaluation during the algorithm development phase.

To further improve the performance of the ML models, the hyperparameters are optimized iteratively in MATLAB until the performance, i.e., error rate, converges to a constant value. Then, all the ML models are further tested using new data. The new data consists of new input features but without the actual output label. It is up to the ML models to provide predictions on the new data. The model which provides the most promising performance such as accuracy, precision, and F-measure are chosen for the proposed ML-IDS and ML-RA. Finally, both ML-IDS and ML-RA are cascaded together to build a new hybrid algorithm to enhance network security and improve network delay and throughput.

The simulation setup, the proposed algorithm, system parameters, and simulation scenarios are discussed in detail as follows.

A. The Simulation Setup

The network environment for the hybrid ML-IDS and ML-RA in the MPLS network system is depicted in Fig. 1. The network consists of eight edge routers, R1, R2, R5, R6, R7, R8, R9, and R10, which can be used as ingress or egress label edge routers (LER). Concurrently, R3 and R4 are normal label switch routers (LSRs) in the MPLS domain. All edge routers are linked to various types of traffic, such as VoIP, CCTV, and file transfers. The network is built in four ring topologies: 1) R1, R2, R3, R4, R5, and R6 form the main ring; 2) R1, R4, R5, R7, and R8 form the second ring and serve as node protection for R4; 3) R2, R3, and R9 form the third ring; and 4) the final ring is made up of R3, R6, and R10. The third and fourth rings protect the links between R2-R3 and R3-R6, respectively. In this network environment, all links are active, and the conventional RA and proposed ML-RA must compute the route for all traffic.

GNS3 is used to build the network for simulation, data collection, and performance analysis. OSTINATO and LOIC are used to generate normal and attack traffic, respectively. All edge routers are connected to either a Virtual PC (VPC), Windows virtual machine (VM), or OSTINATO traffic generator. The VPC is placed in the edge routers for traffic monitoring while the VM is used to mimic an actual Window's PC in the network for file transfers, generate DoS traffic and for traffic monitoring. Note that generated traffic can be sent using several streams simultaneously using different protocols at different rates.

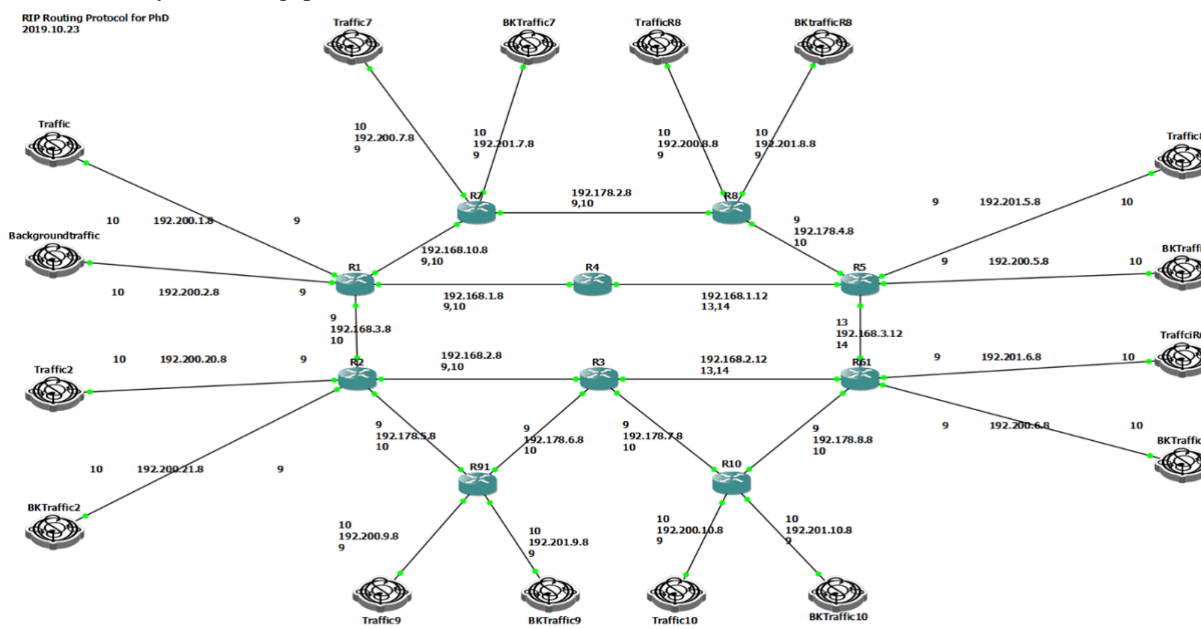

Fig. 1. Network environment in GNS3.

To launch a DoS attack, the LOIC tool is first installed in Window's VM in GNS3. After configuring the virtual Ethernet port of the VM, the IP address of the client or server is entered in the network as the DoS attack target, followed by the DoS method and packet flooding speed. The LOIC will flood the route leading to the targeted client. Once the DoS attack began, all network Virtual Private Clouds (VPCs) lost connectivity to the targeted client, while all clients connected to the route that links to the target client are also affected by the DoS attack. This scenario illustrated the severe damage of a DoS attack in the network domain as the attack affects not only the victim but also the devices linked to it.

B. Hybrid Supervised ML-IDS and ML-RA

This section discusses how ML-IDS and ML-RA are cascaded together to form complete ML-based security and QoS enhancement algorithms. Fig. 2 shows the framework of the proposed hybrid ML-IDS and ML-RA. The ML-IDS is incorporated at every ingress router that is R1, R2, R5, R6, R7, R8, R9, and R10, while the rest of the routers only focus on forwarding the traffic as computed by the ML-RA. ML-IDS is a classifier-based supervised ML that will predict the incoming traffic as normal or attack. In contrast, ML-RA, is a regression-based supervised ML that predicts the delay of all possible routes between the S2D pair.

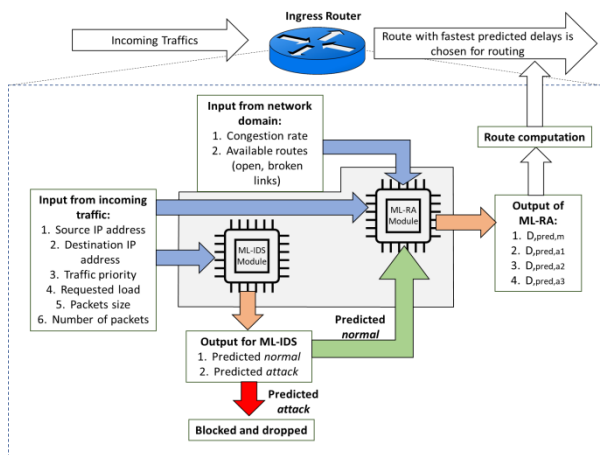

Fig. 2. Framework for the hybrid ML-IDS and ML-RA.

As incoming packets enter the ingress router, network information such as S2D IP address, traffic priority, requested load, packet size, number of packets, and data rates are fed into the ML-IDS. Additional network domain information, such as congestion rate and available routes, is required as inputs for the ML-RA. The output for the ML-IDS will classify the incoming traffic. If it is predicted as attack traffic, the ML-IDS will block and drop the traffic from entering the MPLS network. However, if it is predicted as normal by ML-IDS, the traffic will feed into the ML-RA module for route computation. To build the ML-IDS, the dataset constructed from the data generated using LOIC and OSTINATO is

tabulated in a CSV file format. The ML-IDS dataset is later fed into the Classification Learner App (CLA) in MATLAB, which trains model to classify data using supervised ML. This application allows users to import datasets, select features, specify validation schemes, train models, and assess results. Automated training of the ML algorithms allows users to select the models with the best classification model types. These automated training features ease the model development and evaluation process by eliminating the trial-and-error process to choose the best ML classifiers.

After importing the dataset into the CLA, the data is ready to be trained by a series of ML algorithms, and the best performing algorithm will be chosen for the proposed ML-IDS. The overall process to develop the proposed ML-IDS is as shown in Fig. 3. The dataset is split into a training dataset and test dataset with a split ratio of 70:30 [26]. However, the split ratio must be carefully adjusted to avoid over-fitting or under-fitting. A trial-and-error basis is generally adopted until the accuracy saturates.

The dataset of ML-RA is built in GNS3, covering the incoming traffic and network information from the MPLS domain. Simulations are conducted in GNS3 using different traffic parameters in the OSTINATO traffic generator for EF, AF, and BE traffic. For congestion, another OSTINATO traffic generator is run in GNS3 by bursting continuous packets. Broken links are simulated by simply closing the link in GNS3. The available routes in the network are performed by using RIPv2 routing protocol. RIPv2 was chosen due to ease of configurations in the Cisco emulator in GNS3 and because RIPv2 utilizes shortest-path routing scheme regardless of network conditions.

At first, a random S2D pair is chosen. Then, by using trace IP route in the Cisco Command Line Interface (CLI), GNS3 will show the main route computed by the RIPv2. Then, the main route is purposely closed to allow the RIPv2 to recompute to other available routes. The process is repeated until there are no more alternatives for S2D pair. For this research, the alternative routes are already trained by the ML-RA using the RIPv2 routing protocol. The advantage of this method is that ML-RA algorithm no longer needs to manually compute alternative routes in the network when a sudden surge of traffic in the network occurs. The ML-RA algorithm is trained so that it will predict the QoS parameters on all available routes and quickly assign a path for the traffic in any incoming packets and network conditions. For each S2D pair, different EF, AF, and BE traffic configurations, and network conditions are run in the simulations for several iterations to improve the ML-RA training rate. Since the delay and throughput of each iteration are not always precisely constant due to processing delay and limitation of the simulation platform, training it with several iterations will allow the ML-RA to foresee the patterns and trends in the network.

Fig. 3. Flowchart for the development of ML-IDS.

There are a total of 21 features for the ML-RA dataset. The first five input features are the information of the incoming traffic while the rest are on network conditions. To simplify the dataset, network congestion and broken links share the same column, where the value “0” denotes zero congestions, value “20” denotes congestions, while “100” denotes a broken or closed link. The data extracted from the simulations is up to half-a-million of iterations for all possible S2D pairs with different traffic and network conditions.

The ML-RA dataset is then fed into MATLAB's Regression Learner App (RLA) to create a regression model that predicts the delay for each route in the network. The RLA eases the ML development work by suggesting several regression models that fit the ML-RA dataset. For this case, the linear and tree-based regressions algorithms, including medium tree, course tree, and fine tree are suggested by the RLA. All the regression's algorithm is then compared with

their prediction speed, training time and RMSE. The best one among all will be chosen as the ML model for the ML-RA. Delay in this context is defined as the total time taken from the moment the first packets enter the MPLS domain to the time the last packets are received at the receiver end. The predicted delay by the ML-RA for the main route, Alternative Route 1 (ALT1), Alternative Route 2 (ALT2), and Alternative Route 3 (ALT3) are denoted as $D_{pred,m}$, $D_{pred,a1}$, $D_{pred,a2}$ and $D_{pred,a3}$, respectively. The predicted delays by the ML-RA will be used for route computation. The flowchart for the route computation is as shown in Fig. 4. The route computation for each traffic will be based on four network conditions, namely, all routes available, one or two routes down, three routes down, and all routes down based on the predicted delay. If the route is not available either due to broken links for node failures, the ML-RA will predict a value of “∞” to the route, indicating that the predicted delay is too high and should be avoided.

Fig. 4. Route computation flowchart for the proposed ML-based hybrid IDS and intelligent routing algorithm.

As shown in Fig. 4, when all routes are available, the ML-RA module will rank each of the predicted delays from lowest to highest. Then the route with the lowest predicted delays will be chosen for the traffic, starting with EF, followed by AF and BE traffic. In the event where all routes are down, ML-RA will drop all the packets until a route is back to available. One of the advantages of ML-RA is that from the predicted delay alone is already sufficient to understand the network conditions. For instance, when the link is congested, the predicted delay will be high. While, when the link is down or node failure, the predicted delay is “∞”. This eases the route computation works to choose the best route for the traffic without processing too much network information.

C. System Parameters

The design parameters for ML-IDS are shown in Table II. Note that the traffic generated by both OSTINATO and LOIC traffic generators in GNS3 follows the IEEE 802.3 standard, where the packet length is between 64 to 1520 [27]. The OSTINATO traffic generator is limited to only 20 Mbps for normal traffic, while LOIC generates attack traffic up to 40 Mbps, with up to 40,000 packets per second. However, due to limited computing storage, the number of packets per session is capped at 20,000 packets per session.

The design parameters for the ML-RA are as shown in Table III. The traffic in the network comprises of EF, AF, BE, and congested traffic. The requested load begins at 20% with an increment of 10% up to 100% according to the traffic mixture ratio of 20:40:40 for EF, AF, and BE, respectively. Our finding shows that the maximum network capacity in GNS3 is at 20 Mbps. With that, at 100% requested load, the throughput for EF, AF and BE is 4 Mbps, 8 Mbps, and 8 Mbps, respectively. The packet length for EF traffic is fixed at 160 bytes, following the Cisco bandwidth calculator [28]. Due to the limited computational storage of the GNS3 VM and ease of data extraction, the packet size for AF and BE traffic is fixed at 500 bytes. However, for congestion traffic, the length of the packet is set at random between 60 to 1550 bytes with the number of packets up to 20,000 packets per session using the “random” feature in OSTINATO.

D. Simulation Scenarios for Performance Study

Four S2D pairs are chosen for ML-RA validations: R6 to R2, R2 to R5, R10 to R7, and R5 to R3. These S2D pairs were selected because there are one main route and three alternative routes; namely ALT1, ALT2, and ALT3 available and it involves almost the entire link in the network, which is suitable for performance study. It is worth mentioning that there are also other S2D pairs available. However, because the four pairs with all the available routes already involve the entire links and LSRs in the network, it is deemed sufficient.

For ease of explanation on the routing, each of the routes in the network is given a unique LSP ID, as shown in Fig. 5. For instance, the route between R1 to R4 is LSP 1. For routes with more than one hop, for example, the route between R1 to R6 is denoted as LSP 1.2.3, which represents a total of three links. The main and alternative routes computed by the RIPv2 routing protocol for R6 to R2, R2 to R5, R10 to R7, and R5 to R3 are tabulated in Table IV. When the network is not

congested, the shortest path offers the best QoS parameters. RIPv2 will always compute the shortest path, which in this case, is the main route between an S2D pair regardless of network congestion. The downside is, when there is a sudden change in the network, RIPv2 may not be able to perform at its peak. When the main route is broken, the RIPv2 will recompute the next best route, which is the ALT1 and so forth.

To force the traffic to choose another alternative route, traffic engineering is configured via CLI in the Cisco router’s Internetwork Operating System. A sample case study is demonstrated in this paper, in which the main route for an S2D pair is congested, with one network route is down. The purpose of this sample study is to investigate how the proposed ML-RA can compute the path for different network conditions. The accuracy of the ML-RA is considered good when it can avoid congested routes and broken links. As a result, it is expected that the ML-RA will offer better QoS performance compared to RIPv2 that only considers the shortest path. The objective of ML-RA is to predict and compute the best routes in the network, regardless of the network conditions. The simulation details in GNS3 for ML-RA performance study are summarized in Table V for R6 to R2, R2 to R5, R10 to R7, and R5 to R3. The performance study focuses on the accuracy of the ML-RA to choose the route with the predicted best QoS. Then, the delay and throughput for the route are computed by the ML-RA and compared with RIPv2.

TABLE II. DESIGN PARAMETERS FOR THE PROPOSED ML-IDS

Design Parameter	Description
Packet length	60 bytes < Packet length < 1520 bytes
Number of packets	Up to 20,000 packets per session
Data rates	Up to 40 Mbps
Packets per second	Up to 40,000 packets per second for DoS attack
ML-based classifier	GBT, RF, DT, DL, FLM, LR, and GLM
Dataset	Proposed ML-IDS dataset and CICIDS-2018
Actual traffic type	The actual traffic from the dataset’s label (normal or attack)

TABLE III. DESIGN PARAMETERS FOR THE PROPOSED ML-RA

Design Parameter	Description
Traffic Priority	EF, AF and BE
Requested Load	20%, $\Delta \pm 10\%$ up to 100%
Packet Length	Background traffic (60 bytes to 1550 bytes), EF (160 bytes), and AF and BE (500 bytes)
Number of Packets	Up to 20,000 packets per session
Data Rates	Up to 20 Mbps for 100% load
Congestion Rates	Fixed at 20 Mbps
ML-based Regressions	Linear Model Regressions, Medium Tree Regressions, Fine Tree Regressions, and Course Tree Regressions
Dataset	Proposed ML-RA dataset
Routes	Main route, ALT1, ALT2, ALT3
Delay	Actual delay of the traffic from simulation during the training phase

Fig. 5. Network environment with LSP ID.

TABLE IV. MAIN AND ALTERNATIVE ROUTES BY RIPV2 ROUTING PROTOCOL

Source router	Destination router	Main route (LSP)	ALT1 (LSP)	ALT2 (LSP)	ALT3 (LSP)
R6	R2	4.5	13.12.11.10	3.2.1.6	3.9.8.7.6
R2	R5	6.1.2	6.7.8.9	5.4.3	10.11.12.13.3
R10	R7	12.5.6.7	12.11.10.6.7	13.3.9.8	13.3.2.1.7
R5	R3	3.4	3.13.12	2.1.6.5	9.8.7.6.5

IV. RESULTS AND DISCUSSION

This section will discuss the results of the proposed system, along with some of its limitations and the future direction of the hybrid ML-IDS and ML-RA system.

A. Simulation Results

Delay is an essential parameter in evaluating the performance of ML-RA, especially for EF and AF traffic, as they require stringent delay requirements. There is no strict timing delay requirement for BE traffic. However, for comparison purposes, the delay for BE traffic is compared in different network conditions and different routing protocols and measured via the analysis tool in GNS3's Wireshark. Provided that it is within the delay standards, the lower the delay, the better the performance of ML-RA.

The next performance matrix evaluated is throughput, which is defined as the amount of data transferred between a S2D router to show the performance between ML-RA and RIPv2 RA [29]. AF and BE traffic require high amount of throughput compared to the EF traffic. It is also expected that the higher the congestion rate and the number of hop count for selected LSP will lower the throughput performance. Similar to delay, throughput is also measured via the analysis tool in GNS3's Wireshark.

Delay and throughput performance parameters are chosen for benchmarking purposes. This is because one of the problem statements is that the shortest path in the network will not provide the best QoS especially when the network resources are limited. The delay comparison between ML-RA and RIPv2 will show which RA performs the best with

different traffic and network conditions. The delay performance parameter is also helpful to evaluate the accuracy of the ML-RA to predict the fastest route in the network.

TABLE V. SIMULATION DETAILS FOR ML-RA PERFORMANCE STUDY

Source router	Destination router	Main route (LSP)
R6	R2	LSP 4.5 is congested and LSP 3 is closed
R2	R5	LSP 6.1.2 is congested and LSP 3 is closed
R10	R7	LSP 12.5.6.7 is congested and LSP 3 is closed
R5	R3	LSP 3.4 is congested and LSP 6 is closed

When the traffic reaches a receiver beyond the standard delay requirements, it is considered as packet loss. This shows that the delay parameter alone is sufficient to describe how the traffic is being forwarded in the network. Conversely, the throughput performance parameter is chosen to verify the capacity rate of the traffic to reach the destination. Having higher throughput proves that the route computed by the RA offers better quality for the incoming traffic. For the performance simulation, a total of four S2D pairs are chosen, which are R6 to R2, R2 to R5, R10 to R7, and R5 to R3 as summarized in Table V.

The sample case studies the performance of ML-RA when the main route is congested, and one of the routes to reach the destination router is down. With that, for all the S2D pairs, there are only two routes available, which are the congested main route and ALT1. Based on the traffic and network conditions, the routes computed by ML-RA for R6 to R2, R2 to R5, R10 to R7, and R5 to R3 are as shown in Table VI. The computed route for this case for all S2D pairs is the ALT1. The result is as expected where ML-RA accurately rerouted the traffic to the normal ALT1 as the main route is congested. As has been explained, since RIPv2 always chooses the shortest path regardless of network congestion, RIPv2 still computed the main route for routing. In terms of delay, it is expected that as the load increases, the delay also increases due to a higher number of packets being forwarded to the destination. The delay comparisons between ML-RA and RIPv2 for all S2D pairs are shown in Fig. 6. The lower the delay of the ML-RA compared to RIPv2, the better the performance of the algorithm.

In Fig. 6, the solid line represents the delay for the route computed by ML-RA, while the dotted line represents the delay for RIPv2. The delay for both routes computed by ML-RA and RIPv2 increase as the offered load for all traffic increases from 20% to 100%. However, the delay for ML-RA is lower compared to RIPv2 for all traffic types. This is because ML-RA rerouted the traffic immediately via the ALT1. The results prove that, although the ALT1 comprises of a higher number of hops, the delays are lower compared to the congested main route with a lesser number of hops. For instance, the delay for R6 to R2, as shown in Fig. 6(a), even though the main route comprises of only one hop, but since the main route is congested, the delay for ALT1 which comprises of three hops contributes to a lower delay.

Fig. 6. Delay for the sample case.

TABLE VI. SIMULATION DETAILS FOR ML-RA PERFORMANCE STUDY

Source router	Destination router	Predicted fastest route by ML-RA
R6	R2	LSP 13.12.11.10
R2	R5	LSP 6.7.8.9
R10	R7	LSP 12.11.10.6.7
R5	R3	LSP 3.13.12

However, from 20% to 40% offered load for R6 to R2 S2D pair, the delay for BE traffic for both ML-RA and RIPv2 are almost in-line with each other as shown in Fig. 6(a). This is because the ratio of the number of hops between ALT1 and main route is almost triple, and the traffic from 20% to 40% offered load is too small to notice any delay difference. Nonetheless, beyond 40% offered load, the delay difference is more significant. At 100% offered load, the delay for BE traffic reduces from 1.2974 s to 0.6228 s for the route computed by ML-RA. While in Fig. 6(b) to 6(d), even though the difference in terms of number of hops between the main route and ALT1 is only by one additional hop, there is also a significant delay difference between the route computed by ML-RA and RIPv2. Since RIPv2 only computes the shortest available path in the network, the main route is chosen even though it will result in a higher delay. The delay comparison between ML-RA and RIPv2 for EF traffic for all pairs is not as significant as AF and BE traffic. This is because the data size and data rate for EF traffic are smaller compared to AF and BE.

The throughput is shown in Fig. 7. As opposed to delay, the higher the throughput offered by the ML-RA compared to RIPv2, the better the performance of the algorithm. Since the design parameters for the traffic is set at 20:40:40 traffic mixture ratio for EF, AF, and BE traffic, respectively, both AF and BE should theoretically have the same amount of throughput. However, due to the simulators' computation load, slight throughput fluctuation is expected. The throughput for all four S2D pairs shows a similar trend, which increases with increasing offered load from 20% to 100% for all traffic. However, since ML-RA successfully rerouted the traffic to the ALT1 for all four pairs, the throughput offered by the routes computed by ML-RA is higher compared to RIPv2.

For R6 to R2 S2D, the throughput for AF and BE traffic is almost in-line to each other from 20% to 60% offered load, as shown in Fig. 7. This is because the delay differences for both ML-RA and RIPv2 are not significant enough to produce a higher throughput difference. While for the rest of the S2D pairs where the number of hops difference between the congested main route and ALT1 is just addition by one, the delay difference between ML-RA and RIPv2 is even more significant which correlates to higher throughput difference.

The throughput and delay improvements for all S2D pairs are as shown in Table VII. In terms of throughput, the improvements for EF, AF, and BE traffic are up to 75.0%, 57.1%, and 57.1%, respectively. While in terms of delay, the improvements are up to 50.0%, 44.4%, and 44.4%, respectively. The results prove the superiority of ML-RA to predict and compute the fastest route in the network. For all S2D pairs, ML-RA learned from historical data that for this network condition, the fastest route would be ALT1. As a result, ML-RA intelligently computes ALT1 as the preferred route in the future when given the similar network condition.

From the results, the ML-RA is proven to be able to predict the route with the lowest delay and highest throughput, outperforming the RIPv2. ML-RA avoided the closed and congested routes and accurately computed the other faster alternative routes. Even when all routes are congested, ML-RA accurately predicts the fastest route in the network. Even though the route computed by ML-RA is the same as RIPv2, the goal of predicting the fastest path is met and maintained. Although only four S2D pairs are considered, the main and alternative routes cover the entire network, and almost all the LSRs in the network are involved. Thus, the ML-RA is expected to perform similarly for other S2D pairs.

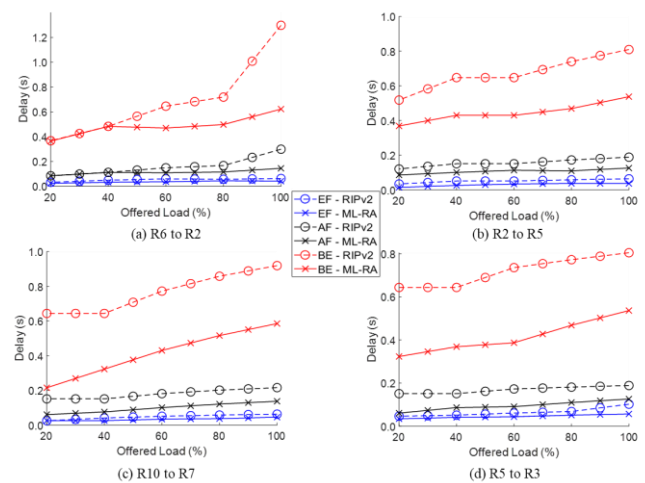

Fig. 7. Throughput for the sample case.

TABLE VII. THROUGHPUT AND DELAY IMPROVEMENT BY ML-RA

Source	Destination	Delay improvement (%)			Throughput improvement (%)		
		EF	AF	BE	EF	AF	BE
R6	R2	50.0	44.4	44.4	33.3	51.3	52.0
R2	R5	42.8	33.3	33.6	75.0	50.0	50.0
R10	R7	27.7	36.3	36.3	38.4	57.1	57.1
R5	R3	44.4	33.3	33.3	22.2	50.0	50.0

B. Limitations and Future Work of the Hybrid ML-IDS and ML-RA System

From the performance evaluations of the proposed ML-IDS and ML-RA, the system shows 100% accuracy in predicting the fastest route, as well as shows better performance against the RIPv2 in terms of delay and throughput. Despite the great performance of the proposed system, there may be several limitations that can be further improved in future research. For example, the proposed system relies on simulation data generated in GNS3 for dataset development. Note that the dataset was constructed using EF, AF, and BE traffic following the standard of VoIP, CCTV, and file transfers. However, this dataset may not accurately reflect the traffic patterns and network behavior of real-world environments. Thus, it may be advantageous to validate the performance of the system with real-world traffic data to confirm its practicality and effectiveness. Additional research on the influence of the parameters for the dataset on the performance of the system may also be investigated. The system's performance could also be assessed against different datasets in addition to evaluating its performance and scalability on larger and more complicated networks. Moreover, other ML techniques such as deep learning or reinforcement learning could be integrated to improve the accuracy and resilience of the proposed system. It is also advantageous to validate with real-world traffic data to confirm its practicality and effectiveness. Finally, the proposed system's implementation in a real-world environment could be performed to evaluate its applicability and feasibility in practical scenarios.

V. CONCLUSION

This study develops a hybrid ML-IDS and ML-RA algorithm to enhance the MPLS network's resiliency and improve traffic QoS. The proposed ML-IDS is a classification-based ML algorithm that learns the traffic pattern at the ingress router. Based on historical data, ML-IDS predicts and classifies the incoming traffic as normal or attack. The predicted attack traffic will be denied access to the network domain and discarded. While the predicted normal traffic will be queued according to their priority. This study prioritizes EF, AF, and BE traffic, which correspond to VoIP, CCTV, and data transfers, all having unique delay and bandwidth requirements. The GNS3 network setup is used for simulation and data collection. In particular, the LOIC traffic generator is used in the setup to simulate a DoS attack, while the OSTINATO traffic generator is used to generate the EF, AF, and BE traffic. Another OSTINATO traffic generator is used to burst background traffic in the network to simulate network congestion. The data in the network is collected as datasets. The output label for the ML-IDS and ML-RA datasets is the actual traffic type (normal or attack) and the actual delay for all available routes for all S2D pairs. The datasets are fed into MATLAB, which is then used to train classifiers for the ML-IDS algorithm and regressions for the ML-RA algorithm. For the performance evaluation, the ML-RA algorithm is compared to RIPv2. From the performance evaluations, the ML-RA shows 100% accuracy in predicting the fastest route in the network. During network congestion, the proposed ML outperforms the RIPv2

in terms of delay and throughput on average by 57.61% and 46.57%, respectively.

Plant Disease Classification and Adversarial Attack based CL-CondenseNetV2 and WT-MI-FGSM

Yong Li¹, Yufang Lu^{2*}

School of Information Science and Engineering, Guilin University of Technology
Guilin, China

Abstract—In recent years, deep learning has been increasingly used to the detection of pests and diseases. Unfortunately, deep neural networks are particularly vulnerable when attacked by adversarial examples. Hence it is vital to explore the creation of intensely aggressive adversarial examples to increase neural network robustness. This paper proposes a wavelet transform and histogram equalization-based adversarial attack algorithm: WT-MI-FGSM. In order to verify the performance of the WT-MI-FGSM, we propose a plant pests and diseases identification method based on the coordinate attention mechanism and CondenseNetV2: CL-CondenseNetV2. The accuracy of CL-CondenseNetV2 on the PlantVillage dataset is 99.45%, which indicates that the improved CondenseNetV2 model has a more significant classification performance. In adversarial sample experiments using WT-MI-FGSM and CL-CondenseNetV2, experimental results show that when CL-CondenseNetV2 is attacked by the adversarial algorithm WT-MI-FGSM, the error rate reaches 89.8%, with a higher attack success rate than existing adversarial attack algorithms. In addition, the accuracy of CL-CondenseNetV2 is improved to 99.71% by adding the adversarial samples generated by WT-MI-FGSM to the training set and performing adversarial training. The experiments demonstrate that the adversarial examples caused by WT-MI-FGSM can improve the model's performance.

I. INTRODUCTION

A country's agricultural sector is vital to its economic growth, with the potential to both stimulate and directly impact the national economy's development or stagnation. The stability of agriculture is intrinsically linked to social stability and national self-sufficiency; therefore, it is crucial to achieve the steady and sustainable development of agriculture. To achieve sustainable development in the agricultural field, we must first perform well in the prevention and control of crop diseases and insect pests, guarantee that the prevention and control measures are scientific and safe, successfully control diseases and insect pests, and promote eco-logical development in the agricultural field in a benevolent and sustainable direction [1].

Since the advent of deep learning, deep learning-based picture identification has been a popular topic in the image recognition community, finding widespread application in areas such as facial recognition, transportation, and healthcare. The most traditional network models are GoogLeNet, VggNet, and ResNet [2]-[4]. In recent years, the agricultural sector has also made extensive use of deep learning. Progress has been

made in the identification of plant diseases and pests as a result of the extensive research undertaken by scientists. Based on the AlexNet network, LV and others use batch normalization, PRelu activation function, etc. to improve network convergence and avoid over-fitting. They also combine extended convolution and multi-scale convolution to improve network feature extraction ability, demonstrating that the algorithm of feature enhancement can effectively improve the network's feature extraction ability and recognition accuracy [5]. Pandian et al. utilized image enhancement technology based on image processing and deep learning to improve the crop disease data set. Additionally, they expanded and improved the data set with the antagonistic generating network and neural pattern transfer using migration learning technology. Using this method, the experimental findings show that the improved data set can reach higher precision [6]. Durmus used tomato photos from the PlantVillage dataset to train numerous deep neural networks, and the accuracy of networks such as SqueezeNet significantly improved due to this [7-8]. Using plant images in the visible spectrum, Lily proposed a straightforward and reliable method for diagnosing plant diseases [9]. In his research work, Kaur proposed the DAG-ResNet model and utilized it to discover a number of tomato illnesses [10]. The accuracy was 98.8%. ALVARE et al. integrate FasterR-CNN, SSD, RFCN, VggNet, ResNet, and other feature extractors to obtain a notable recognition and classification effect [11]. Wenliang Tang used conditional convolution, channel attention module, and knowledge distillation to improve the model [12]. The accuracy was 97.6%. Agriculture diseases and pests have a high degree of similarity, a more dispersed and intricate distribution, a greater difficulty in classification, and a greater need for classification networks. Based on the classic CondenseNetV2 model, this work introduces CL-CondenseNetV2, a method for identifying agriculture diseases and pests that combines the coordinate attention mechanism and CondenseNetV2. The model incorporates a flexible and lightweight coordinate attention mechanism and embeds the position information into the channel attention in order to detect and identify the target area with greater precision. As a result of these enhancements, the CL-CondenseNetV2 model now has an identification accuracy of 99.45%, allowing for highly precise detection of agricultural diseases and pests.

Although deep neural networks perform well in most classification tasks, they are vulnerable when faced with adversarial samples. Adversarial samples are a class of samples formed by intentionally adding subtle perturbations to a dataset, which can induce the network model to misclassify

*Corresponding Author

and threaten the model's safety. However, on the other hand, for model designers, adversarial samples can be used as an effective tool to evaluate the security and robustness of the model. They can effectively improve the correctness and security of the model classification through adversarial training. Adversarial attack algorithms can be classified into two categories according to the mainstream classification methods: black-box attack and white-box attack, and white-box attack algorithms include FGSM, DeepFool, C&W, etc. [13]-[15]. Black-box attack algorithms currently have single-pixel and local search attack algorithms, etc. [16].

However, there are fewer examples of improving the classification success of the model by adding adversarial examples for adversarial training. This paper proposes a new DNN called CL-CondenseNetV2 that adds a coordinate attention module to CondenseNetV2. A significant number of comparative studies have shown that our network model performs well. In addition, this paper introduces wavelet variation and histogram equalization in the image domain based on the MI-FGSM algorithm to propose a new adversarial attack algorithm WT-MI-FGSM. The adversarial examples generated by this algorithm can be used to train CL-CondenseNetV2. Training with adversarial examples will help us to improve the accuracy of the classification of plant diseases and the security and robustness of the model.

II. ADVERSARIAL ATTACK ALGORITHM

FGSM, a white-box attack technique built on the production of adversarial example gradients, is the most widely used adversarial assault algorithm today. By iteratively computing the gradient, Alexey et al introduced I-FGSM, which significantly enhances the fit of the adversarial sample to the model [17]. After introducing the momentum factor based on I-FGSM, Dong et al suggested the MI-FGSM approach, which greatly increased the success rate of black-box assaults and successfully enhanced the migrability of the generated adversarial samples [18]. The MI-FGSM algorithm function is shown in (1) and (2).

$$g_{t+1} = \mu \cdot g_t + \frac{\nabla_{x_t^{adv}} J(x_t^{adv}, y)}{\|\nabla_{x_t^{adv}} J(x_t^{adv}, y)\|_1} \quad (1)$$

$$x_{t+1}^{adv} = Clip_{x_t}^{\varepsilon} x_t^{adv} + \alpha \cdot sign(g_{t+1}) \quad (2)$$

In the formula, $sign()$ is a symbolic function, and $\nabla_x J(x, y)$ represents a gradient. ε is the size of the neighborhood. x_{t+1}^{adv} is the adversarial example generated by iterating $t+1$ times. t represents the number of iterations. The step length can be obtained by $\alpha = \varepsilon/T$. It ensures that the adversarial examples generated are in the neighborhood of x . Where μ is the decay factor of the momentum term, and g_{t+1} denotes the cumulative gradient iteration $t+1$ times. The role of the $Clip$ function is to constrain the adversarial examples within the ε -neighborhood of the original image x to satisfy the Infinite norm constraint.

In this study, wavelet transform and histogram equalization are successfully integrated with MI-FGSM to create the WT-MI-FGSM, a more effective adversarial attack algorithm. The overall flow of WT-MI-FGSM is shown in Fig. 1 below. By means of an adversarial attack algorithm, the original example is utilized to produce an adversarial example. First, the wavelet transform and histogram equalization are performed on the origin example to obtain a $224 \times 224 \times 3$ image. The loss function is then computed using the acquired images as input into the model. Iteratively updating the example along the gradient of the loss function is followed by the addition of perturbations. If the requirements are unmet, the iteration will continue until it succeeds. Finally, output confrontational examples. The WT-MI-FGSM algorithm function is shown in (3). Where D is the image enhancement function. It includes wavelet transform and histogram equalization.

$$g_{t+1} = \mu \cdot g_t + \frac{\nabla_{x_t^{adv}} J(D(x_t^{adv}), y)}{\|\nabla_{x_t^{adv}} J(D(x_t^{adv}), y)\|_1} \quad (3)$$

Fig. 1. WT-MI-FGSM attack concrete steps.

III. CL-CONDENSENETV2 MODEL DESIGN

A. CondenseNetV2

Huang Gao's team proposed DenseNet and CondenseNet in 2017, and DenseNet establishes a dense connection mechanism that allows each layer in the network to be directly connected to its preceding layer in the same block to achieve feature reuse, which enables DenseNet to reduce the total number of parameters and improve efficiency significantly [19]. CondenseNet introduces a full-dense connection and pruning mechanism based on DenseNet [20]. The full-dense connection enables the network to establish a dense connection between different blocks while combining with average pooling to achieve stitching between feature maps of various sizes, thus gaining more robust feature reuse. CondenseNet can achieve

almost the same accuracy as DenseNet with just 1/10 the training time thanks to the pruning mechanism, which enables the network to prune the irrelevant weights during the training phase and reduce network redundancy.

Nevertheless, features in DenseNet and CondenseNet will remain the same once they are formed, drastically ignoring the potential value of some features. CondenseNetV2, a powerful yet lightweight neural network based on CondenseNet, was suggested by Gao Huang in 2021 [21]. CondenseNetV2 introduces a sparse feature reactivation mechanism that enables the network to learn to choose a few potentially redundant features. The efficiency of the deep network's feature reuse is increased by concurrently cropping and updating these redundant features to make them better suited to feature learning. CondenseNetV2 achieves better performance than DenseNet and CondenseNet at a low computational cost, and achieves excellent performance on image classification and detection tasks. Table I shows the CondenseNetV2 network structure.

TABLE I. CONDENSENETV2 NETWORK STRUCTURE

B. Introduction of Coordinate Attention Mechanism

Attention Mechanism is a unique structure within a machine learning model that is used to automatically calculate and learn the contribution of input data to output data. Common modules for attention mechanisms include SE, CBAM, etc. SE is only concerned with the weighting of channels [22]. Despite the fact that CBAM simultaneously considers the weight allocation of channels and spaces, redundant convolution pooling operations result in the loss of

some useful information [23]. Coordinate Attention (CA) mechanism is an attention mechanism that can embed position information into channel attention introduced in this paper [24]. In comparison to SE, CBAM, and other attention mechanisms, this attention mechanism is not only capable of capturing cross-channel information, but also direction perception and position perception information, in addition to being lightweight and flexible. Coordinate attention operations consist of coordinate information embedding and coordinate attention generation. Coordinate attention module is shown in Fig. 2.

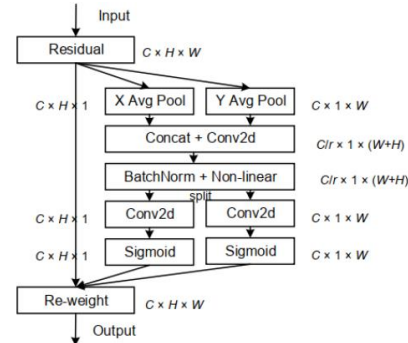

Fig. 2. Coordinate attention module.

1) *Coordinate information embedding*: Channel attention frequently employs two-dimensional global pooling to encode global spatial information, but this operation typically makes it challenging to save target location data. In order to prevent this, the Coordinate attention mechanism decomposes the two-dimensional pooling of channel attention into two one-dimensional feature coding processes and collects features along two spatial directions. Equation (4) and formula (5) represent the horizontal and vertical coordinate coding operations of input x .

$$z_c^h(h) = \frac{1}{W} \sum_{0 \leq i \leq W} x_c(h, i) \quad (4)$$

$$z_c^w(w) = \frac{1}{H} \sum_{0 \leq j \leq H} x_c(j, w) \quad (5)$$

Where x_c denotes the c th channel component of the input data, h and w respectively reflect the data's height and width. These two coding operations allow the attention module to capture the long-term dependency along one spatial direction and to store precise location information along the other spatial direction, thereby assisting the network in more precisely identifying the target information of pests and diseases on crops.

2) *Coordinate attention generation*: In order to make full use of the global receptive field obtained through the embedding operation of coordinate information and encode the accurate position information, first embed the coordinate information into the obtained features for concatenate operation, and then send them into the convolution module with the shared convolution core of 1×1, reduce its dimension to the original C/r , and then send the feature map F_1 after

batch normalization into the nonlinear activation function to obtain the feature map f in the form of $1 \times (W + H) \times C/r$. Equation (6) is shown below.

$$f = \delta \left(F_1 \left(\left[z^h, z^w \right] \right) \right) \quad (6)$$

Where $[\cdot, \cdot]$ is the splicing operation along the spatial dimension, δ is the nonlinear activation function, F_1 is the convolution change function, and f is the intermediate feature map that encodes the spatial information in the horizontal and vertical directions.

After the above operations, f is decomposed into f^h and f^w along the spatial dimension, and 1×1 convolution and nonlinear activation operations are performed on them to obtain the attention weights g^h and g^w of the feature map in the horizontal and vertical coordinate directions respectively. Equation (7) and (8) are as follows.

$$g^h = \sigma \left(F_h \left(f^h \right) \right) \quad (7)$$

$$g^w = \sigma \left(F_w \left(f^w \right) \right) \quad (8)$$

Where σ is the sigmoid activation function, F^h and F^w represent the convolution change function of the characteristic components f^h and f^w , respectively.

Finally, expand g^h and g^w , calculate the coordinate attention mask by matrix multiplication, and act on the input to get the output Y of the attention module:

$$y_c(i, j) = x_c(i, j) \times g_c^h(i) \times g_c^w(j) \quad (9)$$

C. CL-CondenseNetV2

The above coordinate attention is added to the CondenseNetV2 network to obtain the basic structure of CL-CondenseNetV2 as shown in Fig. 3. In each layer of the proposed network, LGC is first used to select important features for feature learning, and after obtaining new features, the SFR module is used to reactivate the previous features. On this basis, we added the coordinate attention module. The coordinate attention module improves the recognition accuracy of the model by making the network model lightweight while enabling the model to locate and identify the target region more accurately. Since plant disease features are distributed in different positions on the front of leaves, the classification network needs to accurately pay attention to the spatial location of disease features. Therefore, coordinate attention can significantly improve the recognition accuracy of plant diseases

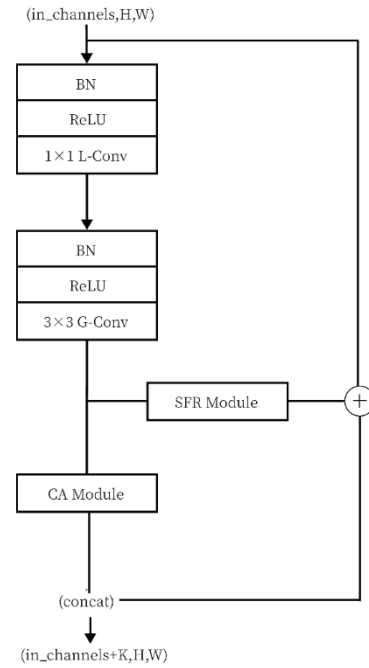

Fig. 3. CL-CondenseNetV2 structure.

IV. PREPARATION FOR THE EXPERIMENT

A. Experimental Environment

The experiment's environment setting is as follows: The graphics card is an NVIDIA GeForce RTX 3060, and the Windows 64-bit system CPU is an 8-core, 16-thread AMD Rayon R7-5800H processor. The memory is DDR4 16G, and the hard drive storage is 512G SSD. The software environment consists of Anaconda 4.10.3 and CUDA 11.6. The model is built and trained using the Python programming language and PyTorch framework.

B. Parameter Setting

In the model training parameter settings, the training batch size is set to 16, the test batch size to 8, and the number of iterations to 50 rounds (Epochs). The employed optimizer is SGD (Stochastic Gradient Descent) [25]. The rate of learning is set at 0.001. Adopting the learning rate exponential decay approach. Gamma has been adjusted to 0.9. Loss is represented by the SoftMax cross-entropy loss function. The definition of the function is:

$$L = - \sum_{k=1}^n \sum_{i=1}^C t_{ki} \lg y_{ki} \quad (10)$$

Where, n is the pixel of the picture; t_{ki} is the probability that pixel k belongs to the category i ; y_{ki} is the probability of predicting the pixel k as the category i for the classification network.

C. Data Set

The data set utilized in this experiment is PlantVillage, which consists of tens of thousands of photos of healthy and diseased plants annotated by plant pathologists and is available for free download at www.PlantVillage.org. All photographs in the PlantVillage database were captured at experimental research stations affiliated with American institutions (Pennsylvania, Florida, Cornell, etc.). The data set consists of 54303 health and disease images split into 38 categories, and it is still growing [26]. The image and caption of several plants pest data sets are depicted in Fig. 4.

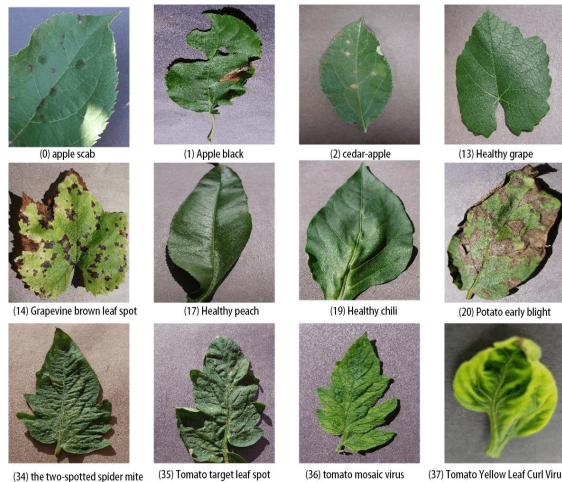

Fig. 4. Examples of images and labels of some crop pest data sets.

D. Data Preprocessing

By using a data enhancement approach, this work also increases the dataset. First, the data image is separated into a training set and a test set with an 8:2 ratio, and then the training set's data image is expanded to 81454 images to serve as the expanded training set. The resolution of the data image is finally rebuilt to 256×256 resolution, and the image is then standardized using the mean and standard deviation. Not only can data preparation imitate the actual agricultural setting and increase the diversity of training samples, but it can also improve the model's robustness and prevent overfitting.

E. Transfer Learning

In the realm of artificial intelligence, there exists a method known as "transfer learning". First, acquire knowledge in the source domain, and then apply it to the target domain, so that the target domain can achieve superior learning outcomes [27]. We can use this technique to reduce the number of training samples required by the model, eliminate the time-consuming and inefficient "ab initio" training process, accelerate network model training, and improve their overall learning efficiency. It has found widespread application in the field of image classification.

The improved model employs the model fine-tuned transfer learning method, employs the CondenseNetV2 pre-training model trained on the ImageNet large open dataset, and combines the transfer learning fine-tuning method to apply its parameters to the CL-CondenseNetV2 model, and uses it to identify plants diseases and pests.

F. Performance Metrics

For each of the experiments examined in this study, the evaluation metrics Accuracy, Precision, Recall, and Specificity are used to assess how well the network performed in identifying the test pictures. The evaluation metrics are calculated using the following equation.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

$$Precision = \frac{TP}{TP + FP} \quad (12)$$

$$Recall = \frac{TP}{TP + FN} \quad (13)$$

$$Specificity = \frac{TN}{TN + FP} \quad (14)$$

Where TP is the true case, FP is the false positive case, FN is the false negative case, and TN is the true negative case. Accuracy is the percentage of samples that the model properly recognizes and categorizes to the total samples, which is often used to evaluate the overall accuracy of the model. Precision is the ratio of true cases to the number of positive cases classified by the model; Recall is the ratio of true cases to all positive cases; Specificity is the ratio of true negative cases to all negative cases.

V. PREPARATION FOR THE EXPERIMENT OF CLASSIFICATION

A. Experiment of Classification

1) Comparison of experimental effects between CL-CondenseNetV2 and CondenseNetV2: The original CondenseNetV2 and CL-CondenseNetV2 are trained on the extended dataset to evaluate how well the improved approach of this model works. Fig. 5 and 6 depict a comparison of the accuracy curve and loss value curve of the original network and the modified network, while Table II depicts a comparison of the accuracy and loss value results.

Fig. 5. Comparison of accuracy curves between CL- CondenseNetV2 and CondenseNetV2.

Fig. 6. Comparison of loss curve between CondenseNetV2 and CL-CondenseNetV2.

TABLE II. ACCURACY AND LOSS OF CL- CONDENSENETV2 AND CONDENSENETV2

Algorithms	Acc (%)	Pre (%)	Recall (%)	Spe (%)	Params (M)	Loss
CL-CondenseNetV2	99.45	98.85	98.17	99.89	6.1	0.0259
CondenseNetV2	99.07	96.69	97.03	99.22	6.1	0.0389

As can be shown in Fig. 5 and 6, the CL-CondenseNetV2 suggested in this study is superior than the CondenseNetV2 network model when it comes to the classification and recognition of pictures, as well as the recognition of crop diseases and insect pests. The accuracy and speed of CL-CondenseNetV2's accuracy convergence are faster than those of the original network, and the loss value curve is more consistently steady. According to Table I, the recognition rate of the original network is 99.07 percent, whereas the upgraded network model enhances the recognition rate of crop diseases and pests by 0.38 percent, demonstrating the viability of the improved model CL-CondenseNetV2.

2) *Comparison of experimental effects between CL-CondenseNetV2 and other models:* To further validate the benefits of the CL-CondenseNetV2 network model, employ three traditional networks, Vgg16, ResNet18, and ResNet50, to train on the improved data set and conduct comparative experiments with CL-CondenseNetV2 in the same experimental environment, using the same training parameters and training timeframes. Fig. 7 and 8 depict a comparison between the accuracy curve and the loss value curve.

Fig. 7 demonstrates that the CL-CondenseNetV2 network model maintains certain advantages. CL-CondenseNetV2's accuracy curve converges more rapidly during training, is more stable, and can essentially maintain its accuracy advantage over Vgg16, ResNet18, and ResNet50.

Fig. 8 shows that the CondenseNetV2 loss value curve has fallen greatly and rapidly, and that the loss value curve is more steady than those of Vgg16, ResNet18, and ResNet50, indicating that the network is more robust. This demonstrates that the CL-CondenseNetV2 network model is preferable. Table III displays a comparison of the experimental outcomes of each model.

Fig. 7. Comparison of accuracy curves of each model.

Fig. 8. Comparison of loss curve of each model.

TABLE III. ACCURACY AND LOSS OF EACH MODEL

Algorithms	Acc (%)	Pre (%)	Recall (%)	Spe (%)	Params (M)	Loss
CL-CondenseNetV2	99.45	98.85	98.17	99.89	6.1	0.0259
ResNet18	98.35	96.48	93.57	99.38	11.2	0.0573
ResNet50	98.37	95.37	95.52	99.85	23.5	0.0527
Vgg16	98.21	96.18	96.65	99.34	134.4	0.0596

Table III shows that under the same experimental conditions, CL-CondenseNetV2 achieved the highest accuracy of 99.45, the lowest loss value of 0.0259, and the least parameters of 6.1M, which were superior to Vgg16, ResNet18, and ResNet50. The accuracy of CL-CondenseNetV2 is 1.08 percentage points higher than the highest of the remaining deep learning models, ResNet50, while the number of parameters is 17.4M less than that of ResNet50. When compared to Vgg16, whose parameters is as high as 134.4M, the reductions are even more significant. CL-CondenseNetV2 outperforms other methods when taking into consideration both the network model's parameters and the recognition accuracy, indicating that the enhanced model may be put to better use in the detection of plant diseases and pests.

B. Experiment of Adversarial Example

1) *Preparation for the experiment:* To fairly validate the performance of the WT-MI-FGSM proposed in this paper, the experimental preparation for the adversarial attack experiments is approximately the same as when a model such as CL-CondenseNetV2 is trained. The experiments use the PlantVillage dataset. This experiment utilized smaller perturbations to make them more difficult to identify rather than setting the hyperparameters as the norm in the momentum method. Using small perturbations can increase the attack algorithm's success rate when compared to other adversarial attack methods. The maximum perturbation $\epsilon = 0.3$; the number of iterations $T = 10$; the step size $\alpha = 0.03$; and the fading factor $\mu = 1.0$. Controlled studies employing the white-box attack techniques of I-FGSM, MI-FGSM, and FGSM, respectively, were also carried out to further confirm the efficacy of the performance of WT-MI-FGSM.

2) *Experimental results:* This experiment contrasts four white-box adversarial attack algorithms—WT-MI-FGSM, I-FGSM, MI-FGSM, and FGSM—attack Vgg16, ResNet50, ResNet18, CondenseNetV2, and CL-CondenseNetV2, and generates both adversarial and original cases, as illustrated in Fig. 9. According to the experimental findings, all five models are susceptible to adversarial assaults, and all four of these attacks have a high success rate. The attacked models' recognition accuracy was lowered by roughly 91%. It is important to note that the differences between the original instances and the adversarial examples produced by the WT-MI-FGSM given in this research are negligible and challenging for the human eye to detect. The adversarial examples and original examples generated by the experiment are shown in Fig. 9.

Fig. 9. Adversarial examples generated by various algorithms.

The recognition rate of each model reduces dramatically when attacked by the adversarial attack algorithm, as seen in Table IV. Vgg16 has the fastest drop when attacked by the WT-MI-FGSM algorithm proposed in this research, with a recognition rate of 0.6%, followed by ResNet18 and ResNet50,

with a recognition rate of 2.8% and 3.1%. And closely followed by CondenseNetV2, with a recognition rate of 5.3%. CL-CondenseNetV2 still has the greatest recognition rate after receiving the attack, with 10.2%. In addition, Table IV compares the performance of WT-MI-FGSM with other traditional adversarial attack algorithms. The success percentages of FGSM, I-FGSM, and MI-FGSM after CL-CondenseNetV2 received assaults from each algorithm are 85.9%, 86.5%, and 87.3%, respectively. They are all less than 89.8% of WT-MI-FGSM. WT-MI-FGSM outperforms MI-FGSM, which has the highest attack success rate among classic attack algorithms, by 1.9%. It is observed that the proposed adversarial attack algorithm WT-MI-FGSM has the best performance in this paper.

TABLE IV. ACCURACY AND LOSS OF EACH MODEL

Algorithms	ResNet 18	ResNet 50	Vgg1 6	CondenseNet V2	CL-CondenseNet V2
FGSM	88.5%	88.2%	92.1%	86.1%	85.9%
I-FGSM	89.8%	89.3%	92.4%	87.4%	86.5%
MI-FGSM	91.2%	90.1%	93.2%	89.1%	87.3%
WT-MI-FGSM	97.2%	96.9%	99.4%	94.7%	89.8%

Adversarial examples can increase model accuracy and robustness. The adversarial examples generated by WT-MI-FGSM are added to the training set, and the individual models are adversarial trained. Table V shows the accuracy of each model after training. CL-CondenseNetV2 has an accuracy of 99.71%, which is 0.26% greater than without adversarial training. Other models' accuracy has also increased. The experimental results show that adversarial examples generated by WT-MI-FGSM can improve model performance.

TABLE V. THE EXPERIMENT OF ADVERSARIAL TRAINING

Models	mAP (%)	mAP(%) (Slow)	mAP(%) (Medium)	mAP(%) (Fast)
CL-CondenseNetV2	99.71	99.07	99.97	99.57
CondenseNetV2	99.38	97.29	99.88	97.93
ResNet18	98.69	93.76	99.67	96.79
ResNet50	98.73	95.75	99.85	95.78
Vgg16	98.63	94.56	99.57	96.85

C. Discussion

To further verify that the CL-CondenseNetV2 model which is added to adversarial examples has a higher recognition rate of plant diseases and pests, it is compared with the DAG-ResNet model in literature [10] and the CondConvSENet detection model in literature [12]. The experimental results are shown in the Table VI.

TABLE VI. EXPERIMENTAL RESULTS

Models	Acc (%)
CL-CondenseNetV2 (Add adversarial examples)	99.71
CL-CondenseNetV2	99.45
DAG-ResNet	98.80
CondConvSENet	97.60

As can be seen from the table, the recognition rate of the CL-CondenseNetV2 model is higher than that of other models, while the classification recognition rate of the CL-CondenseNetV2 model after adding counter samples is far higher than that of other models. The feasibility and necessity of adding adversarial samples in model training are illustrated.

VI. CONCLUSIONS

In this paper, the proposed CL-CondenseNetV2 based on CA attention and CondenseNetV2 effectively improves the network's attention to feature space and enhances the accuracy of identifying agricultural diseases and pests. CL-CondenseNetV2 obtains 99.45% recognition accuracy in comparative studies with many models, outperforming classic CondenseNetV2, ResNet18, ResNet50, and Vgg16. This paper proposes a new adversarial attack algorithm WT-MI-FGSM based on MI-FGSM with the introduction of wavelet transform and histogram equalization. The comparison experiments use different adversarial attack algorithms against various models. The experimental results reveal that WT-MI-FGSM has a greater attack success rate than FGSM, I-FGSM, and MI-FGSM when compared to conventional adversarial attack methods, and the perturbations are too small to be recognized by human eyes. Furthermore, the adversarial samples generated by WT-MI-FGSM are added to the training set. After adversarial training, the recognition rate of CL-CondenseNetV2 may reach 99.71%, which is 0.26% higher than the accuracy rate without adversarial training, effectively increasing the model recognition's accuracy and robustness. Adversarial training is an efficient method for increasing the model's robustness. However, it has drawbacks such as sluggish training speed and overfitting when trained on tiny data sets. As a result, enhancing the performance of adversarial training will be the main focus of future study.

EMOCASH: An Intelligent Virtual-Agent Based Multiplayer Online Serious Game for Promoting Money and Emotion Recognition Skills in Egyptian Children with Autism

Hussein Karam Hussein Abd El-Sattar

Department of Mathematics & Computer Science, Ain Shams University, Faculty of Science,
Abbassia 11566, Cairo, Egypt

Abstract—Autism, often known as "autism spectrum disorders (ASD)," is one of the most common developmental disabilities that affect how people learn, behave, communicate, and interact with others. Two crucial everyday tasks that people with ASD typically struggle with are managing finances and recognizing emotions. As the online gaming sector grows and develops, the question of why this type of media can't be used as a useful educational tool for those with ASD arises. This paper discusses this issue via a novel virtual agent-based multiplayer online serious game referred to as "EMOCASH," which aims to improve these important tasks for Egyptian children with ASD and achieve transfer of acquired knowledge to real-world situations via a 3D virtual shop scenario that was designed using the Autism ASPECTSS™ Design Index. EMOCASH served as an instrument for investigating the following research question: What role does technology play in the education of those with ASD? Numerous sub-questions that were related to the primary question were also addressed. A variety of usability metrics were used to assess effectiveness, efficiency and satisfaction aspects.

Keywords—Autism; virtual agents; serious games; digital technology; AI; online gaming; usability and accessibility

I. INTRODUCTION

Individuals with ASD frequently experience difficulties in daily living skills, including conceptual, social, or practical skills. The importance of daily living skills for people with ASD is especially important since they have a direct impact on the growth of abilities like self-determination and autonomy [1]. Numerous studies have used technological interventions to enhance the daily living (DL) skills for individuals with learning disabilities, including housekeeping [2], first aid training [3], money management skills [4]–[7], learning math subject [8], raise awareness about the effects of littering in [9] and diabetes in [10]. Scholars discovered that people with ASD commonly suffer from mindreading, or theory of mind (ToM) skills [11]–[14], and anthropomorphism, which is the extension of ToM to non-human agents [15]–[16]. ToM refers to our ability to observe the mental states (intentions, emotions, knowledge, and beliefs) of other people. Previous work [17]–[21] reported that autistic people's ToM skills are less developed when they mind-read human beings than when they mind-read non-human agents having anthropomorphic traits, such as animals and cartoons. For instance, the authors of [21]

demonstrate how anthropomorphizing faces—that is, placing them on objects like vehicles—can help people with ASD better recognize emotions. We carried out a study by expanding this idea to assist Egyptian children with ASD in practicing handling money, recognizing emotions, and teaching them how to behave properly in a shopping center using a collaborative authentic learning environment (CALE) instead of the conventional on-screen display apps. The app shows autistic children the potential everyday activities that could happen when a child goes shopping. Contrary to prior approaches, the learning environment was designed using the Autism ASPECTSS™ Design Index [22], [23] to adapt to the needs of all types of users. Moreover, the scenario supports multiplayer, which is more engaging and motivating than single-player training games. We expand on these foundations. The paper is organized as follows: the problem statement, the research questions that were raised, and the purpose of this paper are presented in Section II. Section III discusses previous studies connected to both money management and emotion recognition for people with ASD. Some theoretical background is summarized in Section IV. Section V introduces the methodology used. The development processes of the proposed system, including system architecture, design, and implementation used to develop the system, are presented in Section VI. The clinical characteristics and practices of the participants are listed in Section VII. Section VIII describes the different usability metrics used to assess the effectiveness, efficiency, and user satisfaction of the produced application, along with a comparison with existing techniques. Section IX concludes the paper and highlights future work.

II. OBJECTIVES AND RESEARCH QUESTIONS

While transitioning from adolescence to maturity, everyone must take a huge and difficult step. Because of their impairment symptoms, people with ASD typically have significant problems carrying out basic daily tasks on their own. Traditional intervention techniques, including the Picture Exchange Communication System (PECS) [24], social skills classes, narrative, role-playing, and so on, are costly, time-consuming, staff intensive, boring for patients due to exercise repetition, and usually have long waiting lists, rendering them ineffective. Internet-driven rapid advancements in ICT, such as serious games (SGs), VR, AR, virtual agents, AI, and robot,

among others [25]-[30] have opened creative and promising scenarios for therapists to improve DL skills for individuals with ASD. However, studies on how using authentic learning environments and engaging in online games affect learning outcomes for those with ASD are noticeably lacking. Taking into account the importance of user-built environment interaction for autistic persons, this paper addressed these issues using an innovative virtual agent-based multiplayer online SG called "EMOCASH," which served as an instrument for investigating the following research questions: (1) Is it possible to employ agent technology to create intelligent agents that can be included in online games for persons with ASD? (2) What advantages do online games provide for people with ASD? (3) How can we improve the appeal and motivation of education for those with ASD? (4) Which learning environments are most effective for this purpose? (5) What aspects of game elements are taken into consideration when using online gaming to educate autistic people? Concerning the first and second questions, the usability of virtual agent technology via online gaming for people with ASD is investigated in this paper using CALE. Online gaming enhances user experience, encourages immersion, social interaction and competitiveness, reduces autism symptoms, and promotes the satisfaction of working independently. When playing an online game, there is no eye contact or facial expression required, which can help reduce anxiety and any other unusual behaviors. Online games give people with ASD the opportunity to interact with their peers in a safe and less stressful learning environment that does not require regular face-to-face interaction; as a result, they can build communication skills that promote friendships and socializing (For instance, please refers to [31]-[34]). Regarding the third and fourth questions, we employed the Autism ASPECTSS™ Design Index [22] to accommodate specific autistic needs as a design development tool to support environments conducive to learning for those with ASD. The concepts of authentic learning [35]-[36] and authentic design thinking [37]-[38] were also used. In the methodology section, numerous key game elements will be examined together with relevant information on each one's usefulness for our developed game in response to the fifth question.

III. RELATED WORK

The use of serious games (SGs) to teach DL skills to persons with ASD has been proposed in a number of studies. These studies were categorized into four categories: conceptual (e.g., money, science, etc.), practical (e.g., use of money, travel and transportation, etc.), social (e.g., emotions, communication, etc.), and general skills. According to [30], the percentage degree of studies targeted at all of those learning categories is given as follows: conceptual skills (25.53%), practical skills (8.51%), social skills (36.17%) and general skills (29.79%). Furthermore, 1.06 percent of research papers were devoted to discussing money management techniques for those with ASD, demonstrating the pressing need for more studies in this field. Different DL skills such as money management skills [4]-[7], emotion recognition [39]-[45], among others have been successfully improved using SGs in special-needs education. However, those methods would not fit with the Egyptian lifestyle, currency and language. As an illustration, Caria et al.

[5] designed a single-player Web-based game that assists people with ASD in acquiring skills to help them understand the notion of Euro currency and its usage in real life in comparison to Bangladeshi Taka currency [7]. The authors in [45] conducted an intervention program using animated vehicles with real emotional faces to improve emotion recognition for Chinese children with ASD compared with Western children in [21]. Additionally, the vast majority of earlier studies concentrated on a single player in a two-dimensional gaming environment, whereas there is a notable lack of research on the development of collaboration skills through multiplayer online games in three dimensions, which support emotions and social interaction among participants and are more engaging and motivating than a single player. One more significant issue is that designated learning environments need to take sensory issues into consideration in order to meet learners' demands. This paper considers all these issues by applying the Autism ASPECTSS™ Design Index [22] as a design development tool for the EMOCASH game's environment. ASPECTSS™ is an abbreviation for: Acoustics, Spatial Sequencing, Escape Space, Compartmentalization, Transitions, Sensory Zoning, and Safety.

IV. BACKGROUND AND FUNDAMENTAL CONCEPTS

A. Serious Games

Serious games (SGs) are a form of education and entertainment that is designed to educate as well as amuse. Unlike games that are just played for fun, games intended for learning are labeled "serious" [46]-[47]. The key concept of serious gaming is the implementation of gaming elements, attributes, mechanisms and flow states to engage learners toward achieving real-life goals.

B. Activity Theory

Activity Theory (AT) is a theoretical framework for examining how people behave in a certain setting. According to AT, the essence of an activity is the interaction between a subject (a human doer) and an object (the item being done). Activity systems [48]-[49], a model of which is shown as a triangle (see Fig. 1). Simply, activity theory is all about 'who is doing what, why, and how' [49].

Fig. 1. Structure of activity theory.

C. Virtual Learning Environment and Virtual Agents

The term "Virtual Learning Environment" (VLE) refers to a design environment for teaching and learning. There are several types of VLE, such as single-user, multi-user, and collaborative VLE (CVLE) [50]. Each one of them has a unique avatar that the user may use to engage freely in the digital world. Avatars might take the form of a cartoon character, an entirely abstract shape, or a human-like image. The avatar in our system is a 3D representation of a rabbit with real faces grafted onto it. A software system that is embedded in a particular environment and has the capacity to behave autonomously there in order to achieve its design goals is known as a virtual agent, also known as an intelligent virtual agent (IVA) [51]. IVAs should be autonomous, proactive, reactive, and socially capable. There are several AI agents, so an environment for the IVA design work has to be created, which is called the PEAS (Performance Measure, Environment, Actuator, and Sensor) system [52]. The PEAS System is used to classify similar agents together. An agent's success is assessed using performance metrics; an actuator is a part of the agent that releases the action's output into the environment; and sensors are the receptive parts of an agent that takes in data. The qualities of the environment influence an agent's behavior [53]. Different types of intelligent agent programs based on their degree of perceived intelligence and capability are used in AI, namely: reflex agents, model-based agents, goal-based agents, utility-based agents, and learning agents [52]. Each kind of agent program combines particular components in particular ways to generate actions. The EMOCASH game uses reflex agents where the agent function is based on condition-action rules as demonstrated in Fig. 2.

Fig. 2. Schematic diagram of reflex agents program.

V. METHODOLOGY

A. Methodology Workflow

According to contemporary conceptions of effective learning, learning is most successful when it is proactive, reactive, social, experiential, problem-based, and offers quick feedback [48]-[49]. Learner achievements and engagement, as well as active learning, are the two major elements of effective learning. One of the most significant elements influencing learner achievements, success and outcomes is the learning environment [53]. According to the sensory definition of autism [54] the problem of the sensory environment and its relationship to autistic behaviour appears to be the key to designing for autism. This description serves as the foundation for the Autism ASPECTSS™ Design Index [22], [23] which we employed in our methodology as a design development tool for the EMOCASH game's environment. For active learning,

learning environment should be authentic with authentic tasks. Learning in the real-world is authentic learning. To support learners' engagement towards the 21st century skills, the concepts of authentic learning and authentic design thinking [35]-[38], should be employed in educational contexts. In order to engage learners in 21st-century skills, service providers must consider the following five dimensions of 21st-century skills, which were in-depth examined in [37]: cognitive, metacognitive, social-cultural, productivity, and technological. Design thinking (DT) shows a variety of characteristics when used in educational contexts, according to [37] in chapter 9. These characteristics include: 1) DT comes out of social processes where ideas are being formed, clarified, and refined. Collaboration is an important foundation for DT in educational settings; 2) DT involves knowledge creation and is more closely characterized by an iterative and non-linear process that contains five phases (Empathize, Define, Ideate, Prototype, and test), as illustrated in Fig. 3; and 3) DT doesn't have well-defined and well-ordered design stages. Instead, ideas go forth and backward through social interactions until they are wholly embraced by the team. Training individuals with ASD necessitates repeating tasks, which might reduce participants' motivation and interest. To maximize the training outcomes while maintaining the participants' motivation, our methodology takes into consideration the idea of authentic design thinking, game elements' diversity, game attributes, and task activities and introduces an activity system as a framework to embed intelligent agents in SGs' development, as shown in Fig. 4.

Fig. 3. Design thinking (DT) cycle.

Fig. 4. Learning as an activity system.

As demonstrated in Fig. 4, this system effectively combines learning and technology while also capturing real-world learning environments, which is essential for 21st-century skills [37]. Task activities are the activities and interactions designed to keep the learner engaged and learning in the game's environment. In our approach, the task activities are used as the building blocks of the SG design, and the learning objectives are defined according to the kind of tasks, their number, and difficulty. We now respond to the research question listed in section II: How can we improve the appeal and motivation of education for those with ASD? Authenticity and sensory design aspects [22], [54] should be addressed throughout the design phase of the specified learning

environment. This produces the answer to this question. When the word "authentic" is added to the term design thinking, it transforms into a creative process that aids service providers in coming up with meaningful approaches to their issues by giving them the chance to experiment, develop and prototype models, gather feedback, and redesign instructional materials to improve their learners' learning and performance. Therefore, the finest resource is your expert judgment and relevant stakeholders. As shown in Fig. 5, the methodology workflow is iteratively developed and built from the study of the core design components of an authentic learning environment [35]-[36] and authentic design thinking [37]-[38], as well as the following rules and recommendations that are directly gathered from relevant stakeholders in the area of special needs education using a multi-stage process known as participatory design or a similar user-centered design (UCD) [55]. UCD is defined as a philosophy that places the learners at the center of the design process, taking into account their characteristics, needs, skills, desires, behavior, etc.

Fig. 5. Methodology workflow.

- Learner-centered: The interests and desires of your learners need to always be your starting point. What, for example, are their interests and needs? What engages them?
- Based on your learner needs, determine a possible goal or outcome. Link the outcome to anything in real life to highlight relevance and authenticity (e.g., shopping in the supermarket, in our case).
- Divide the skills your learners will learn in order to accomplish the outcome.
- Assess your learners both before and after teaching: How do they now perform in these skills? What do they now know? What new skills do they now have? This issue was addressed in our case through usability testing in terms of learnability rate.
- Community-driven design: Individuals struggle to address the entire system; a multidisciplinary group of people with a range of expertise is required to find a solution. We employed the idea of participatory design

[55] to satisfy the needs and preferences of the learners in order to accomplish this goal.

- Give the AMT model some attention: Provide learners with the opportunity to concentrate on the three learning goals of acquisition, meaning-making, and transfer (AMT), as shown in Fig. 6.

Fig. 6. The AMT model.

B. Pedagogical Agents

To facilitate and improve the learning process, virtual characters, or artificial agents, are commonly used in computer games via a VLE. These individuals, also known as "pedagogical agents," may serve in a range of roles, including that of teachers, subject-matter experts, mentors, motivators, or companions [56]. Pedagogical agents are computer agents designed and built to support education by enhancing learners' capacity for spontaneous recall and information retention. It has often an animated persona that responds to the action of the learner [57]. Numerous pedagogical agents have been created and assessed by scholars from different perspectives [58]-[60]. We used anthropomorphic agents—3D models of rabbits with real faces superimposed on them—to construct the pedagogical agents for the EMOCASH game. Additionally, we made an effort to make the rabbit's form larger in order to grab the child's attention. Similar findings have been made by [17]-[19], who claim that autistic individuals' ToM skills are less developed when they read the minds of humans than when they read the minds of non-human agents with anthropomorphic traits like animals. The EMOCASH game may be played by many users using a CALE, and users can interact with one another via their pedagogical agents (see Fig. 7).

Fig. 7. An illustration of a CALE with pedagogical agents.

C. EMOCASH Gameplay

Gameplay defines how the learner and the game interact with each other; it simply means playing the game. EMOCASH gameplay is briefly discussed below:

- The psychologist describes the therapy process. To start the game, each participant has to log in.
- Game Acts: It is defined as the highest-level element in the EMOCASH game which is divided into many

parts, including the registration page, login screen, play mode, evaluation mechanism to allow tracking of players' progress, etc. Six distinct types of 3D mini-game engines, each with a different level of difficulty, are included in the play mode. Participants must register the first time they play the game. Each participant's results and learning progress are tracked in the assessment file folder.

- **Scenes:** The gameplay takes place in acts, where each act is divided into scenes. Scenes take place in one or more scenarios with different levels of difficulty.
- **Therapeutic game challenge:** The essence of the gameplay is the challenges-actions relationship (what challenges the game has and what actions the player can take to achieve the goals).
- **Currency recognition mini-game:** This mini-game attempts to help autistic children recognize the several primary Egyptian cash denominations and their corresponding values as a tutorial via two engines. The first engine that will be shown is an animated book (GameBook) that has all the major Egyptian cash denominations. The participants' task is to open each page, see and freely move the provided cash notes in all directions in accordance with the six DOFs as depicted in Fig. 8(a). The second engine's job is to put together an image of the currency note (e.g., a one, five, ten, twenty, etc.) from a variable number of pieces that are spread out across a table surface in random placements. The puzzle's final appearance after being properly solved is depicted by a target image in the upper portion of the screen. The task requires the participants to piece together the required image using the materials they have collected, as illustrated in Fig. 8(b). By the time the session is over, the participants will have two levels of easy quizzes that gradually get harder. For instance, we ask the participant to choose one of four currency notes that are displayed on the screen.

Fig. 8. (a) An animated game book containing all Egyptian currency denominations (b) Puzzle game.

- **Emotion Recognition mini-game:** With the use of numerous settings for purchasing (such as being a customer) and selling (such as being a cashier) inside a 3D virtual shop environment, this game enables autistic children to reinforce some facial expressions used when shopping. For instance, if you need to buy something but don't have enough money, you'll feel "sad"; alternatively, you'll feel "happy." When asking for assistance when shopping, the same feelings will manifest as depicted in Fig. 9. To engage participants and confirm that they were able to understand the required activities, the game start-up user interface

featured a tutorial for an animated human cartoon face with distinct emotions incorporating visual and audio stimuli (see Fig. 10).

(a) A snapshot of some players asking for some assistance

(b) The message indicates that the player received a favorable response (a happy feeling)

(c) A snapshot of some players asking for some assistance

(d) The message indicates that the player received an unfavorable response (a sad feeling)

Fig. 9. Snapshots of recognizing some human facial emotions in various contexts while shopping.

Fig. 10. A Screenshot for an animated designed human cartoon faces with different emotions.

- **3D virtual shop scenario:** This mini-game aims to teach the process of shopping to autistic children by achieving the transfer of acquired knowledge to a real-world scenario, such as shopping in the supermarket. The scenario employs a (CALE) with a simplified navigation and interaction interface that encourages emotions and interactions among participants, who can play alone or with their instructors. For agent movement in a virtual world, the A* (A-Star) path-finding search algorithm is used [61] (see Fig. 11). It addresses the problem of finding a shortest path from any coordinate in the game world to another.

Fig. 11. The A* (A-star) algorithm in action.

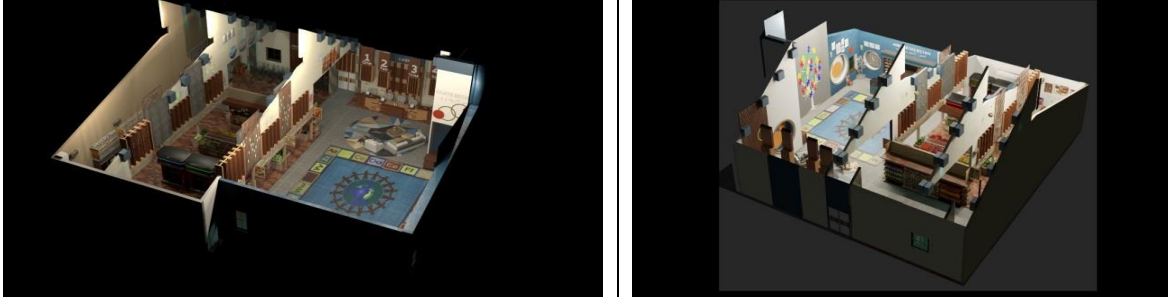

- By the end, feedback sessions are planned and the results are analyzed.

D. Game Elements and Attributes

The parts that make up a game and give learners an engaging experience are known as game elements. Every game element must have attributes that may be utilized to affect how

they are used when developing SGs. Scholars [5], [62]-[64] have reported that incorporating game elements into teaching methods for people with ASD can improve their learning abilities. For instance, the authors of [62] consider game elements as intrinsic and extrinsic factors to increase a learner's motivation. The majority of previous research did not explicitly identify the game elements or specifically state or offer information on the games' elements they employed while creating their solutions. Even when they did, they didn't provide adequate information on the efficiency of the particular game elements. We now respond to the research question listed in section II: What aspects of game elements are taken into consideration when using online gaming to educate autistic people? The EMOCASH game offers a variety of useful game elements with relevant information on each one's effectiveness, as indicated in Table I.

TABLE I. EMOCASH'S GAME DESIGN ELEMENTS FOR LEARNING

Game Elements	Description
Game World/Environment	<p>It is a virtual environment where players go while playing the game. As illustrated below, the gaming environment in the EMOCASH game is created as a 3D virtual shop scenario based on the principle of authentic learning with authentic tasks, like grocery shopping, for teaching the shopping process to autistic children. It was designed in accordance with the Autism ASPECTSS™ Design Index [22], [23], [54] to take into account the specific needs of autistic people and facilitate the learning process for those populations.</p> 
Clear Goals	When people are aware of their responsibilities, the goals are crystal clear. Giving meaningful challenges and establishing clear norms are closely tied to setting clear goals. Clear objectives improve attention. To hold players' attention and make sure they will be able to understand the necessary tasks, the primary objectives and rules of each mini-game are given at the beginning of the introduction to the entire EMOCASH game.
Challenges	Challenges are game tasks or exercises that require effort to perform. In the EMOCASH game, there are a lot of tasks for each mini-game to be completed. Once achieved, some rewards are provided.
Rewards	A reward is a component of the game that gives the players satisfaction and inspires them to work harder. Extrinsic rewards, such as points, badges, and leader boards, are available through EMOCASH, as well as intrinsic rewards, which are given for successfully completing each mini-game throughout the entire game in exchange for resources (such as earning virtual currency with a numeric value) and reputation (such as a certain number of stars).
Best Moments	It is a fun feature that motivates the participants during the game. The virtual gained items from the prize gallery are stored in an inventory which can be reached by clicking on the "prizes customization" button on the main screen to enable the participants to experience a personalized training by meeting their curiosity and virtually using the items (e.g., wearing a glass) through a variety of customization options.
Status	The status is a categorization of participants based on their scores. In EMOCASH, the motivation is based on the aim of participants to reach a high status by earning more virtual currency and gaining more stars. The rating number of stars shows great achievements. The higher the star's number rating is, the better its status.
Leader boards	A visual representation of the participant's progression with respect to others. The leader boards exploit social emotions such as feelings of "fame" and "status" while allowing comparison between participants and enhancing competition among them.
Competition	Competition modes are: single-player competition against the game environment; competition between two or more players; cooperation of two or more players against the game environment; and team-based competition. The EMOCASH game supports the first two modes.
Points	Game points are like grades in the educational system. It is a numerical representation of the player's performance in achieving goals. Points are assigned to each activity as a function of the number of goals reached and the time needed to be finished. Each mini-game mode assigns different points to participants. Points can be divided into levels, and levels can be presented with badges.
Badges	Badges are virtual goods that have a visual representation. They are awarded to participants after completing certain challenges or reaching certain achievements. In the EMOCASH game, we used it to represent participants' status or reputation.
Levels	Levels can have different meanings in games. Levels can refer to the rating of the participant based on his/her score or can be related to the difficulty of the game. The EMOCASH game supports both. In terms of difficulty, each mini-game has two levels of difficulty, namely basic and advanced, where the level of complexity increases very gradually in order to keep the participants motivated and to provide them with a continuous challenge (see figures below).

	  
Flow state	To feel the fun, users have to be in the channel of flow state. The flow theory is widely accepted to be one of the fundamental models for improving the game experience. When an individual experiences flow, they are said to be in a "flow state."
Feedback	For generating the flow it is important that activities provide immediate and clear feedback which can be provided with the help of visual and audio elements. As a demonstration, the figure below shows the feedback provided for money comparison and counting mini-game scenarios.
Progress bar	A progress bar was utilized to graphically represent the proportion of completed tasks in order to display the participants' progress for each activity. For each activity, a green color will emerge if the exercise is successfully solved, signifying that the participant has given the correct response; otherwise, a red one will be displayed.
Progression	Player growth and development.
Visual Aesthetics	Include visual elements such as the overall look and feel of the game.
Game Mechanics	The procedures and rules of the game.
Story	The series of events that occur as players play the game.
Technology	It is the medium through which the tale will be told, the mechanics will occur, and the visual aesthetics will take place. We used intelligent agent technology through online gaming for the EMOCASH game. Moreover, the learning environment was designed using the Autism ASPECTSS™ Design Index to adapt to the needs of all types of users
Game Fantasy	Refers to the environmental contexts that provide virtual world imagery
Sensation	Multimedia presentation of the virtual world.
Emotions	Games are good for creating emotions among participants. Those emotions can be created through gameplay, storytelling, or socialization. The EMOCASH game is a multi-player SG which supports both emotions and socialization among participants.
Avatars	A visual representation of a player character. The EMOCASH game uses anthropomorphic agents in the form of 3D models of rabbits grafted with real faces.

VI. SYSTEM DEVELOPMENT AND IMPLEMENTATION

A. System Architectural Design

Architectural design defines the interconnection and resource interfaces between system subsystems components and modules in ways suitable for their detailed design and overall configuration management. As training requires repetitive tasks, having a large number of mini-games is quite important to avoid boredom in the long term. Fig. 12 shows a sample architectural design overview of our EMOCASH game architecture, which is composed of six 3D mini-games, each one with two difficulty levels (basic and advanced). The complete navigational system for the EMOCASH game is shown in Fig. 13.

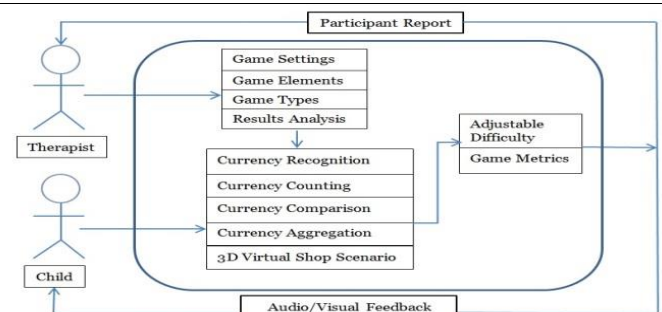

Fig. 12. EMOCASH's system architecture.

Fig. 13. EMOCASH's system navigation scheme.

B. Learning Mechanics-Game Mechanics (LM-GM) Model for EMOCASH Gameplay

This subsection analyzes the relevance of learning mechanics and game mechanics for the EMOCASH gameplay

through the Learning Mechanics-Game Mechanics mapping model (LM-GM) [65]. Several authors have offered definitions of the idea of game mechanics. However, there are no universally agreed-upon definitions of game mechanics, as evidenced by the wealth of literature [66]-[68]. For instance, game mechanics are described as "something that connects the player's actions with the purpose of the game and its main challenges" in a definition offered by [68]. On the other hand, activities or design patterns of mechanics that explicitly support learning but are not playable mechanics are referred to as learning mechanics. Table II displays the analysis of both the learning and game mechanics for the EMOCASH gameplay through the LM-GM model [65], [66], as well as how participants use them and how they were actually implemented.

TABLE II. THE LM-GM MODEL ANALYSIS FOR THE EMOCASH GAMEPLAY

Game Mechanics	Learning Mechanics	Implementation	Usage/Description
Cascading information/ Tutorials	Guidance/ Tutorial	The main goals and regulations of each mini-game are explained at the start of the introduction to the entire EMOCASH game with the help of a brief animation and voice.	Main goals are clearly presented in the game's introduction to keep participants' attention and ensure that they will be able to comprehend the necessary tasks.
Cooperation/ Collaboration	Emotion/ Competition/ Participation	The gaming environment in the EMOCASH game is designed as a 3D virtual shop scenario using the Autism ASPECTSS™ Design Index and is based on the idea of authentic learning with authentic tasks, such as shopping at the supermarket.	Games are good for creating emotions among participants. Those emotions can be created through gameplay, or socialization. Using a CVLE, the EMOCASH game is a multi-player SG which supports both emotions and socialization among participants.
Time pressure	Motivation Action/Task	Count down clocks/Response time	Extrinsic motivation.
Meta-Game Mechanic (Rewards that can be earned during the actual gameplay)/ Collecting (Elements of virtual rewards can be represented by virtual objects, which can be collected by the player)	Motivation/ Rewards/ Incentive	All six types of 3D mini-game engines include this feature.	The player earns virtual currency with a numeric value and some stars for each correct answer and for each mini-game successfully completed in the entire game.
Questions & Answers	Assessment	Once the player finishes practicing the currency recognition mini-game, he or she will have to play two simple and fun quiz games called puzzle and matching games before proceeding to the next task.	All five types of 3D mini-game engines include an activity part with two levels of difficulty, namely, basic and advanced, where the level of complexity increases very gradually in order to keep the participants motivated and provide them with a continuous challenge.
Rewards	Motivation/ Instructional/ Feedback	Extrinsic rewards, such as points, badges, and leader boards, are available through EMOCASH, as well as intrinsic rewards, which are given for successfully completing each mini-game throughout the entire game in exchange for resources (such as earning virtual currency with a numeric value) and reputation (such as a certain number of stars).	Extrinsic and intrinsic rewards are used to keep participants engaged in SGs and keep them happy and satisfied.
Behavioral momentum	Incentive/ Motivation/ Participation	The virtual gained items from the prize gallery are stored in an inventory which can be reached by clicking on the "prizes customization" button on the main screen to enable the participants to experience a personalized training by meeting their curiosity and virtually using the items through a variety of customization options.	It is a fun feature that motivates the participants during the game.
Feedback	Motivation/ Feedback	Points/levels/response time/badges/ emotional sounds/ audio-visual feedback/Progress bar.	Extrinsic rewards that facilitate both motivation and flow state.
Capture (How many points or counters a player has won or captured)	Action/Task Participation	Stars earned and the score of each mini-game completed.	Use information to solve problems. The accomplishment of goals during gaming is represented by stars, which are gathered with each new goal attained. The rating number of

defines how strong they are)			stars shows great achievements.
Challenge	Questions & Answers/ Action/Task /Participation/ Feedback/ Assessment	<ul style="list-style-type: none"> ▪ Challenges in games must match the player's skill level ▪ Games should provide different levels of challenge for different players ▪ The level of challenge should increase as the player progresses through the game 	Challenges are game tasks or exercises that require effort to perform. In the EMOCASH game, there are a lot of tasks for each mini-game to be completed. Once achieved, some rewards are provided. For instance, in the case of a puzzle game, the main challenge is the participant's ability to piece together the required image using the materials they have collected from a variable number of pieces that are spread out across a table surface in random placements.

C. Implementation

Our system is organized in multiple levels and implemented using Unity. Blender software was used to create the learning environment as well as the 3D models of various objects (e.g., rabbits) and import them into Unity. Since different currencies have a range of different coin values, or denominations, we employed the greedy change algorithm [69] in our implementation of the change problem.

VII. METHOD

A. Participants

In this study, we recruited a sample of fourteen distinct autistic children between the ages of seven and fifteen to play the EMOCASH game for at least one and a half hours each week, for a total of seven weeks of open trial. These groups, referred to as "Group #1," received an autism diagnosis from a psychiatrist and a clinical psychologist. Ten children (72%) were boys, while four (28%) were girls. We also invited a group of seven typically developing volunteer children, referred to as "Group#2," who tested the game in order to measure the effectiveness of using the developed application. Ethical approval was granted by the Egyptian General Ethics Standards.

B. Procedure and Materials

The intervention protocol used for participants consists of three different phases: pre-intervention, intervention, and post-intervention phases. During pre-intervention sessions, children completed IQ testing representing verbal and performance IQ taken from the 2nd Wechsler Abbreviated Scale of Intelligence (WASI- II), and parents filled out the Social Responsiveness Scale, 2nd edition (SRS-2) and the Vineland Adaptive Behavior Scales, 2nd edition (VABS-II) to confirm the children's diagnostic status. At the end of the pre-intervention session, participants and their parents were introduced to the EMOCASH game. A seven-week, three-times-per-week EMOCASH training program was part of the participant's intervention procedure. After a 7-week intervention period, participants and their parents participated in the post-intervention assessment. In this phase, a questionnaire is created to assess the expectations and satisfaction of both parents and children playing EMOCASH game.

VIII. EVALUATION, USABILITY TESTING AND RESULTS

A. Usability Testing with Experts

Usability testing is a technique used to assess the effectiveness and satisfaction of a developed application by its users and experts. Four subject-matter experts in different fields were asked to participate; two of them were experts in psychology and psychiatry, while the other two were experts in

game design and teaching, respectively. Furthermore, to identify the usability issues of the developed application in terms of efficiency and satisfaction, it was evaluated not only from the experts' perspective but also with input from people who are not disabled (Group#2). The purpose of these tests serves the function of gathering system feedback. A list of the six mini-games engine's interface and the tasks to be carried out in the EMOCASH game were given to the experts for usability analysis to be sure that it is suitable for use by children with ASD without any issues. Five themes were used to group the perspectives of experts on the EMOCASH gameplay: Effectiveness, usefulness, enjoyment, ease of use, and attitudes toward future usage. Most experts agreed that the proposed game was effective because of the following factors: (1) goals were clearly presented in the game's introduction to the entire EMOCASH game with the help of a brief animation and voice, which improve attention and help with their learning; (2) the presentation of multimedia resources (audio, visual, etc.) is done simultaneously; (3) immediate and clear feedback was given with the help of multimedia resources; (4) clear goals and feedback support concentration, which is one of the learning outcomes; (5) learner activities that use authentic learning closely resemble the real-world situations that professionals encounter while practicing; and (6) promoting practical life skills like money management can enhance a person's autonomy and self-determination. According to experts in the psychology and psychiatric disciplines, the game is useful since it is affordable, promotes self-confidence, may aid with motor skill development, and saves time for the teachers. Experts in game design and teaching fields found that the game is enjoyable because of the following reasons: (1) it attempts to increase both participant concentration and the sense of curiosity in individuals with ASD; (2) it contains audio-visual feedback and both extrinsic (e.g., points, badges, leader boards, etc.) and intrinsic rewards that facilitate motivation and flow state and, as a result, promote players' engagement, learning, and motivational outcomes; and (3) playing online games, which improve the user's experience, immersion, foster social engagement and competition, and reduce autistic symptoms, increases the enjoyment of working independently. In terms of usability, the majority of experts agreed that the game is useful, easy to use, and user-friendly, and that the challenge-skill balance matches the player's skill level. In addition, they reported that the game's mechanics and interface are straightforward, simple to understand, and non-intrusive, allowing for simple access to the game. In terms of attitude, all experts agreed that the game could be objectively used as a teaching tool for treating children with ASD in a cost-effective manner. They also found that the game is enjoyable, fascinating, and beneficial.

B. Evaluation Instrument for User Satisfaction

To evaluate the functionality of the system we have distributed a questionnaire evaluation form to assess expectations and satisfaction among parents and their children. Parents rated their expectations and satisfaction by filling out several questionnaires using a 10-point Likert scale to during pre-intervention and post-intervention measurement. Sample questionnaires are given in Table III.

TABLE III. A SAMPLE ASSESSMENT QUESTIONNAIRE FOR PARENT EXPECTATIONS AND SATISFACTION

Q#1	Parent expectations sample questionnaire	Parent satisfaction sample questionnaire
1	Do you think that this EMOCASH game is educational for your child?	How motivated was your child to play the EMOCASH game?
2	How much do you expect your child's skills will advance after playing the EMOCASH game?	Do you think the EMOCASH game had an effect on your child's performance on the different daily living (DL) tasks/skills?

After finishing the EMOCASH game, participants were also asked to provide their opinions, including what they enjoyed and disliked about it, as well as their favorite game. For this purpose, we utilized the Fun Toolkit [70], to assess participants' satisfaction. Moreover, all experts and ordinary volunteer children answered the System Usability Scale (SUS) questionnaire [71] after playing the game. The SUS questionnaire contains 10 questions about ease of learning, efficiency, ease of memorization, occurrence of execution errors, and level of satisfaction. Each question has a five-point scale varies from one (totally disagree) to five (totally agree). By combining the contributions of the scores of each item, the SUS questionnaire's results were analyzed. The results were positive between experts and ordinary volunteer children regarding their acceptance.

C. Game Data and Usability Metrics

The EMOCASH game's usability was assessed using the game data of each participant. The data for the game is stored in internal structures and contains the participant's score for each game successfully completed. The system creates reports in the assessment file folder when the participant has finished the games, providing the therapist with feedback. In order to test the application with users and to measure the efficiency and effectiveness of the application's use in education, we considered the following usability metrics [72] (see Fig. 14) where,

Fig. 14. Usability metrics.

1) *Success Score*: It refers to whether the user accomplished or didn't finish the required task (Number of completed tasks/Total number of attempts).

2) *Success Rate*. This includes several levels of success: a) Complete success: the user completed the task with no errors and exactly as specified; b) Minor issue success: the user completed the task but encountered a minor issue; c) Major issue success: the user completed the task but encountered a major issue; and d) Failure: the user was unable to complete or finish the required task.

3) *Task Time*: The amount of time it takes the user to complete the task.

4) *Learnability Rate*: it takes into account both how simple a task is for users to perform the first time they use the interface and how many tries it takes for them to get it right. Fig. 15 depicts the learnability rate for the participants' responses using conventional and non-conventional ways after practice with our EMOCASH game. It is clear that after practicing with our game, their performance improved significantly.

Fig. 15. Learnability rate.

D. Results and Discussion

This section describes the findings of the responses collected from experts, parents, and their children. This was done to help children recognize the EMOCASH game as a learning tool and determine which features of the game are more attractive. The results of the collected data show that the game is very useful and the results are given as follows:

- Most of them agreed that the system is helpful, straightforward to use with a user-friendly learning environment, and has simple content with good topic flow.
- Regarding game motivation, most of the participants found the game to be fun to play, especially when applying newly learned information through the 3D virtual store setting, which fosters feelings and sociability among players who can play alone or with their educators.
- Concerning game usability, most of the participants were able to play the game because their preferences were achieved via factors like simple GUI, audio-visual feedback, and both extrinsic and intrinsic rewards. Most experts rated the usability of the EMOCASH game as "excellent"
- The majority of the experts, typical volunteer children, as well as parents and their children with ASD, were satisfied with the EMOCASH game. Experts indicate that the game appears to have outstanding potential and can be objectively used as a teaching aid for assisting individuals with ASD. Parents also reported that seven

weeks of EMOCASH's use significantly improved their children's performance on the different money and emotion recognition tasks.

- The gathered data also explores the beneficial effects of involvement in online gaming as an effective teaching strategy for those with ASD. People with ASD can communicate more easily and participate in the gaming community without having to disclose their handicap by playing online games.

E. Comparisons

According to the taxonomy discussed in [46], [47], Table IV compares our proposed framework (EMOCASH) with other existing frameworks previously discussed during this research. As demonstrated in Table IV, all of the prior research only took into account a single player in a two dimensional gaming world, as opposed to multi-player collaborative games in three dimensions, which support both emotions and social interaction among participants and facilitate collaborative learning, which are more motivating and engaging than a single one. In addition, this research is one of the few that uses authentic learning activities like going

shopping while adhering to the autism ASPECTSS™ Design Index, a set of architectural design guidelines for individuals with autism. The EMOCASH game possesses the following merits that set it apart from previous works: (1) the scenario uses a CALE, which supports multiplayer, which is more engaging and motivating than single-player training games; (2) the sensory environment issues and their relationship to autistic behavior were taken into consideration by applying the Autism ASPECTSS™ Design Index as a design development tool for the EMOCASH game's environment to adapt to the needs of all types of users; (3) it explores the beneficial effects of involvement in online gaming as an effective teaching strategy for those with ASD; (4) our strategy takes into account the wide range of game elements and attributes to enhance training outcomes while keeping participant motivation; (5) the learning mechanics-game mechanics (LM-GM) model idea was used to assess and examine the efficacy of the proposed game in order to keep participants' interest and motivation; and (6) the game was developed using a number of design principles, such as guidelines from the literature, guidance from learning experts and instructors, and feedback from a wide range of stakeholders, including those who are not impaired.

TABLE IV. COMPARISON BETWEEN OUR PROPOSED FRAMEWORK AND THE OTHER EXISTING FRAMEWORKS

Criteria	Sources/References

IX. CONCLUSION AND FUTURE WORK

The number of people with ASD continues to grow worldwide. As a result of the incapacity symptoms, they often experience serious difficulties in performing daily living activities independently. Money management and recognizing emotions are two essential daily living activities that people with ASD generally struggle with. When designing a learning environment for them, care should be taken to take into account any sensory challenges they may have. The problem of the sensory environment and its connection to autistic behavior seems to be the key to designing for autism. There are few studies that look at sensory design issues while developing children's learning environments, and there is a noticeable lack of studies on how using virtual environments and playing online games affects social and relational interactions for persons with ASD. This paper addresses these issues and makes an effort to close this gap using a novel virtual agent-based multiplayer online serious game called "EMOCASH," which aims to enhance these crucial tasks for Egyptian children with ASD and achieve transfer of learned skills to real-world contexts via a 3D virtual shop scenario created using the Autism ASPECTSS™ Design Index. EMOCASH served as an instrumental tool for investigating numerous relevant research questions. A variety of usability metrics, were used to assess effectiveness, efficiency, and satisfaction aspects. This study is one of the few implementing activities related to real-world scenarios, such as shopping in the supermarket for people with autism using intelligent agent technology through online gaming. Our findings indicate that, when compared to non-agent methods, virtual agent technology through online gaming, reinforced by sensory design aspects, may be used as an objectively successful learning technique for individuals with ASD. Our future work will focus on three directions: 1) expanding the number of activities developed and making the application available on various platforms; 2) analyzing the impact on larger populations of autistic children with various categories; and 3) employing Brain-Computer Interface technology as a physiological measuring instrument that retrieves and uses information about an individual's mental state, which is closely related to the ToM and anthropomorphism.

Adaptive Balance Optimizer: A New Adaptive Metaheuristic and its Application in Solving Optimization Problem in Finance

Purba Daru Kusuma, Ashri Dinimaharawati

Computer Engineering, Telkom University, Bandung, Indonesia

Abstract—Adaptability becomes important in developing metaheuristic algorithms, especially in tackling stagnation. Unfortunately, almost all metaheuristics are not equipped with an adaptive approach that makes them change their strategy when stagnation happens during iteration. Based on this consideration, a new metaheuristic, called an adaptive balance optimizer (ABO), is proposed in this paper. ABO's unique strategy focuses on exploitation when improvement happens and switching to exploration during stagnation. ABO also uses a balanced strategy between exploration and exploitation by performing two sequential searches, whatever circumstance it faces. These sequential searches consist of one guided search and one random search. Moreover, ABO also deploys both a strict acceptance approach and a non-strict acceptance approach. In this work, ABO is challenged to solve a set of 23 classic functions as a theoretical optimization problem and a portfolio optimization problem as the use case for the practical optimization problem. In portfolio optimization, ABO should optimize the quantity of ten stocks in the energy and mining sector listed in the IDX30 index. In this evaluation, ABO is competed with five other metaheuristics: marine predator algorithm (MPA), golden search optimizer (GSO), slime mold algorithm (SMA), northern goshawk optimizer (NGO), and zebra optimization algorithm (ZOA). The simulation result shows that ABO is better than MPA, GSO, SMA, NGO, and ZOA in solving 21, 18, 16, 11, and 8, respectively, in solving 23 functions. Meanwhile, ABO becomes the third-best performer in solving the portfolio optimization problem.

Keywords—Optimization; metaheuristic; adaptability; portfolio optimization; IDX30

I. INTRODUCTION

Metaheuristics is a popular method used in various optimization problems. In the cloud system, the genetic algorithm (GA) was modified in service caching and task offloading to improve resource efficiency and user satisfaction [1]. A deep convolutional neural network is enriched with a gorilla troop optimizer (GTO) to improve its capability in diagnosing skin cancer [2]. The whale optimization algorithm (WOA) was used to solve portfolio optimization based on the FTSE100 index [3]. An improved sparrow search algorithm (ISSA) was developed to improve the high-intensity focused ultrasound (HIFU) technology that is used for tumor treatment [4]. A combination of tabu search (TS) and simulated annealing (SA) is used to solve the coupled task scheduling of the heterogeneous multiple automated guided vehicles (AGV) in a manufacturing system [5]. Its popularity comes from two

reasons. The first reason is that there are a huge number of metaheuristics already existing today. The second reason is that metaheuristic uses a stochastic approach to be efficient enough in solving large-scale optimization problems with limited computational resources [6]. Moreover, metaheuristic is also flexible enough to solve various kinds of problems by abstracting the problem. It focuses on the objectives and constraints of these problems. Then, it uses a trial-and-error mechanism to improve the solution through iteration. Meanwhile, this stochastic approach means that all metaheuristics do not guarantee finding the optimal global solution but only the high-quality or quasi-optimal one [7]. Besides, metaheuristic is also challenged with the optimal local issue.

One important consideration in metaheuristics is adaptability. Adaptability is important, especially in facing the circumstance of whether the current search produces a better solution or not. Each metaheuristic was developed based on a strategy for finding a better solution. This new solution is then used for the next iteration for several purposes. In some metaheuristics, new solutions are used to choose the reference for the guided search. Some metaheuristics rank the solutions and then split them into several groups where each group performs its strategy. Some other metaheuristics rank the solutions to eliminate the worst solution or some worst solutions for the next iteration.

Unfortunately, almost all metaheuristics are not adaptive enough. Many metaheuristics do not care about the quality of the new solution relative to the previous solution. The new solution still replaces the current solution, although this new solution is not better than the existing solution. This mechanism can be found in many metaheuristics, such as grey wolf optimizer (GWO) [8], MPA [9], GSO [10], SMA [11], darts game optimizer (DGO) [12], butterfly optimization algorithm (BOA) [13], chameleon swarm algorithm (CSA) [14], tunicate swarm algorithm (TSA) [15], squirrel search optimizer (SSO) [16], coronavirus optimization algorithm (COVIDOA) [17], white shark optimizer (WSO) [18], stochastic paint optimizer (SPO) [19], and so on. In some metaheuristics, a strict-acceptance approach is applied. Through this approach, a new solution is accepted to replace the current solution only if it is better than the current one. This approach can be found in many latest metaheuristics, such as the pelican optimization algorithm (POA) [20], guided pelican algorithm (GPA) [21], total interaction algorithm (TIA) [22], three-on-three optimizer (TOTO) [23], average and

subtraction-based optimizer (ASBO) [24], northern goshawk optimizer (NGO) [25], zebra optimization algorithm (ZOA) [26], coati optimization algorithm (COA) [27], fennec fox optimization (FFO) [28], chef-based optimization algorithm (CBOA) [29], modified honey badger algorithm (MHBA) [30], flower pollination algorithm (FPA) [31], football game based optimizer (FBGO) [32], red fox optimization algorithm (RFO) [33], and so on.

On the other hand, few metaheuristics are adaptive enough when it fails to improve. In KMA [34], the population size increases if stagnation occurs and decreases when improvement occurs. There is a static number of the increasing or decreasing population. The population size can increase until the maximum population size, while the population size can decrease until the minimum population size. In an artificial bee colony (ABC) [35], the bee performs a full random search after it fails to improve for certain periods.

The other consideration is the use case used to evaluate the metaheuristic when it was first introduced. In general, all metaheuristics were tested by using theoretical optimization problems. This theoretical problem consists of a set of mathematical functions. The set of 23 classic functions has been widely used in the first introduction of many metaheuristics, such as in the first introduction of KMA [34]. Other functions are CEC 2015, CEC 2017, and so on. In some studies, the new metaheuristics were also challenged to solve practical problems. Some optimization problems in mechanical engineering are commonly used, such as pressure vessel design problems, speed reducer design problems, welded beam design problems, and tension-compression spring design problems. The power flow optimization problem in the energy sector is also a common use case. Unfortunately, a study that uses optimization problems in the financial sector is rare.

Based on this consideration, especially on the adaptability and use case issues, this work is aimed to develop a new metaheuristic that is adaptive enough to tackle the stagnation problem. This stagnation can be detected, especially when the optimization process fails to improve the quality of the current solution during the iteration.

The main scientific contributions presented in this work are described below:

- 1) A new metaphor-free metaheuristic called as adaptive balance optimizer (ABO) is presented.
- 2) This work presents the adaptive strategy used in ABO, especially in switching between exploration and exploitation.
- 3) The performance of ABO is evaluated by implementing it to solve both theoretical optimization problem (a set of 23 classic functions) and practical optimization problem (portfolio optimization problem).
- 4) The performance of ABO is also competed with five other metaheuristics: MPA, SMA, GSO, NGO, and ZOA.
- 5) The hyper parameter evaluation is performed to evaluate the performance of ABO due to the increase of maximum iteration and population size.

The rest of this paper is organized as follows. The literature review regarding the latest of metaheuristics is performed in

Section II. A detailed description of the adaptive balance optimizer consisting of its main concept, algorithm, and mathematical model is presented in Section III. The evaluation regarding the performance of ABO, especially in solving the set of 23 classic functions, the hyperparameter test, and the portfolio optimization problem, is presented in Section IV. The in-depth analysis of the simulation result, the drawback regarding the theory, limitations, and the algorithm complexity is discussed in Section V. Finally, the conclusion and the potential of future studies and development are summarized in Section VI.

II. RELATED WORKS

Adaptability is one important issue in the development of metaheuristics. Ironically, most of all, metaheuristics were developed without considering this issue. Many metaheuristics focus on developing strategies regarding the exploration and exploitation capability statically. It means most metaheuristics perform the same installed strategy, whether the improvement or stagnation happens.

Many metaheuristics respond to the improvement or stagnation by determining whether the new solution will be accepted to replace the previous solution or not. Some metaheuristics deploy a strict acceptance approach, meaning that a new solution replaces the previous solution only if the improvement occurs. On the other hand, some other metaheuristics deploy a non-strict acceptance approach which means that a new solution will replace the previous solution despite the improvement of stagnation. One distinct approach is introduced by simulated annealing, which uses a stochastic acceptance approach. If the improvement occurs, the new solution will replace the previous one immediately. Otherwise, the new solution may replace the previous solution based on a stochastic calculation. Ironically, metaheuristics that use improvement or stagnation circumstance to decide which strategy will be performed in the next iteration is rare to find.

Fortunately, some metaheuristics perform adaptive strategies in response to improvement or stagnation. KMA uses improvement or stagnation to determine the population size for the next iteration [34]. When the improvement occurs for two successive iterations, the population size decreases to reduce computational consumption. On the other hand, when stagnation occurs in two successive iterations, the population size increases to boost the exploration effort. However, the searches are still the same because whether the improvement or stagnation takes place, there are still three groups of agents where each group performs different searches. Meanwhile, an artificial bee colony (ABC) runs a different approach to make it adaptive. ABC generally performs neighborhood search and roulette wheel selection [35]. Meanwhile, after stagnation takes places for certain periods, full random search is performed without performing strict acceptance approach [35].

This adaptability issue is also not popular in the development of latest metaheuristics. Many metaheuristics, especially those that use a metaphor, focus on exploiting the mechanism of their metaphor as a novelty or contribution. Besides, many latest metaheuristics exploit their capability to outperform other metaheuristics as proof of their superiority.

TABLE I. SUMMARY OF SOME LATEST METAHEURISTICS

No	Metaheuristic	Metaphor	Adaptability	Acceptance Approach	Use Case
1	MHBA [30]	honey badger	no	strict	power flow
2	SPO [19]	paint	no	non strict	23 functions, CEC 2019, 52-bar planar truss structure, 120-bar dome truss structure, 3-bay 15-story frame, 3-bay 24-story frame
3	KMA [34]	komodo	population size decreases when improvement occurs and increases when stagnation occurs	non strict	23 functions
4	COVIDOA [17]	coronavirus	no	non strict	20 functions, CEC 2011
5	SSO [16]	squirrel	no	non strict	power system
6	MPA [9]	marine predator	no	non strict	30 functions, pressure vessel design, welded beam design, tension/compression spring design, operating fan schedule, building energy performance
7	GWO [8]	grey wolf	no	non strict	29 functions, tension/compression spring design, welded beam design, pressure vessel design, optical buffer design
8	BOA [13]	butterfly	no	non strict	30 functions, spring design, welded beam design, gear train design
9	POA [20]	pelican	no	strict	23 functions, pressure vessel design, speed reducer design, welded beam design, tension/compression spring design
10	TIA [22]	-	no	strict	23 functions
11	ASBO [24]	-	no	strict	23 functions
12	NGO [25]	northern goshawk	no	strict	23 functions, CEC 2015, CEC 2019, pressure vessel design, welded beam design, tension/compression spring design, speed reducer design
13	ZOA [26]	zebra	no	strict	23 functions, CEC 2017, tension/compression spring design, welded beam design, speed reducer design, pressure vessel design
14	COA [27]	coati	no	strict	CEC 2011, CEC 2017, pressure vessel design, speed reducer design, welded beam design, tension/compression spring design
15	RFO [33]	red fox	no	strict	22 functions, three bar truss, welded beam design, compression spring, pressure vessel, gear train
16	this work	-	different strategy during improvement and stagnation	strict and non-strict	23 functions, portfolio optimization problem

The other issue concerns the practical use case chosen to evaluate new metaheuristics in their first introduction. Problems in engineering are so popular; whether mechanical, civil, or electrical problems. Meanwhile, studies regarding new metaheuristic that uses problems in finance, are rare to find.

The summarized review of some latest metaheuristics is presented in Table I. There are 15 metaheuristics presented in Table I. Moreover, the proposed metaheuristic is placed in the last row to clarify its position among the existing metaheuristics.

Table I indicates that almost all metaheuristics have not considered adaptability. These metaheuristics perform the same strategy from the beginning of the iteration until the maximum iteration is reached. Some metaheuristics perform a strict acceptance approach to avoid the optimization process going to the worse solution. In comparison, some others still accept a worse solution, hoping it may lead to a better solution. Moreover, the financial sector, still not popular, became a practical use case to evaluate a new metaheuristic when it was first introduced.

Based on this circumstance, this work proposes a new metaheuristic that is adaptive enough when there is no improvement regarding the current solution. Moreover, the

proposed metaheuristic gives equal treatment between two circumstances: improvement succeeds or fails. Besides, the proposed metaheuristic also performs both a strict acceptance approach and a non-strict acceptance approach.

III. PROPOSED MODEL

An adaptive balance optimizer (ABO) is designed as an adaptive metaheuristic that gives balance effort in intensifying the quality of the current solution and being adaptive when the improvement fails. Based on this objective, the reasoning for constructing ABO is as follows. ABO performs multiple searches, as many latest of metaheuristics also perform this approach. ABO performs guided search and random search explicitly. ABO performs different strategies when the improvement fails. ABO accommodates both a strict acceptance approach and a non-strict acceptance approach.

Based on this reasoning, the main concept of ABO is dividing strategy based on the circumstance it faces. There are two possible circumstances. The first circumstance is that the improvement happens. In this first circumstance, the strategy intensifies the exploitation. The second circumstance is that stagnation takes place. In this second circumstance, the strategy is deploying exploration. There are two searches in every circumstance: guided search and random search.

There are two searches performed in the exploitation mode. The first search is a guided search toward and beyond the best global solution. This guided search aims to trace possible better solutions between the corresponding solution and the global best solution. Moreover, this guided search is also designed to trace possible better solutions beyond the global best solution. As known, the global best solution is assumed as the best solution so far. It means that the quality of the best global solution is better than that of the corresponding solution. The probability of finding a better solution will increase when the corresponding solution moves closer to the global best solution. Meanwhile, it is also more probable for the global best solution to find a better solution by avoiding a worse solution. The second search is the limited random search or neighborhood search. In general, as a random search, the corresponding solution traces a new solution around its current solution. However, the search space is reduced as the iteration increases. In the exploitation mode, the strict acceptance approach is deployed in a guided search toward the global best solution and the limited random search. The searches in the exploitation mode are illustrated in Fig. 1.

Fig. 1. Searches when improvement is achieved: (a) guided search toward the global best solution, (b) limited neighborhood search.

There are two searches performed in the exploration mode. The first search is the guided search relative to a randomly selected solution. This search can be viewed as a guided exploration. This search is included in the exploration because it is used a randomly selected solution among the population as the reference. The population is known to be spread within the search space, especially in the early iteration. Moving relative to one of these solutions means the corresponding solution traces any solution within the search space but based on a reference. If the reference quality is better than the quality of the corresponding solution, the corresponding solution moves toward the reference. Otherwise, the corresponding solution avoids this reference. The direction of this movement may push the corresponding solution closer to or away from the best

global solution. This search is performed based on the reasoning that although the global best solution is the best solution, getting closer to the global best solution may push the corresponding solution to the local optimal entrapment. The second search is a full random search. As its name, the corresponding solution moves uniformly within the search space. This search can be viewed as a full exploration. In this exploration mode, the strict acceptance approach is not deployed. It means the new solution replaces the existing solution without considering the quality of this new solution. Moving to the worse solution may be better, which may lead to a better solution, rather than staying in the current solution without any improvement until the iteration ends. These two searches in the exploration mode are illustrated in Fig. 2.

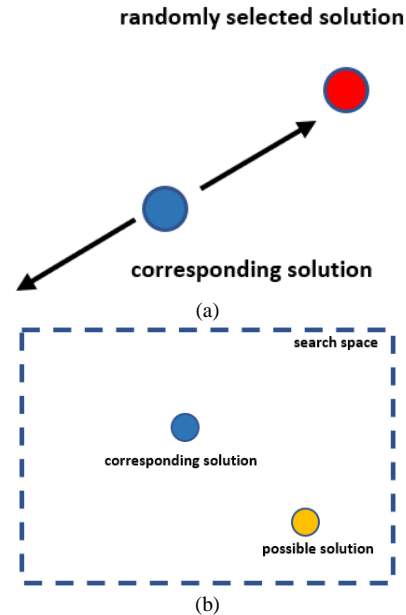

Fig. 2. Searches when improvement fails: (a) guided search relative to a randomly selected solution, (b) full random search.

This ‘two-approach mechanism’ needs a toggle to indicate whether the corresponding solution is in the exploitation or exploration mode. This toggle has two values updated at the end of every iteration. Suppose the corresponding solution fails to improve its quality after performing two sequential searches, whether, in the exploration or exploitation mode, the value of the toggle will be set so that exploration will be performed in the next iteration. Otherwise, the value of the toggle will be set so that exploitation will be performed in the next iteration.

The concept of ABO is then formalized using algorithm 1. As a metaheuristic, ABO consists of two phases: initialization and iteration. Lines 2 to 5 represent the initialization phase, while lines 6 to 25 represent the iteration phase. In the initialization phase, only one loop runs for the entire population. Meanwhile, two loops run in the iteration phase. The outer loop runs from the first iteration to the maximum iteration. The inner loop runs for the entire population. Lines 9 to 12 represent the exploitation mode, while lines 14 to 17 represent the exploration mode. Lines 19 to 23 represent the toggle updating process. g_s denotes the toggle value where 1 indicates the exploitation while 0 indicates the exploration.

Algorithm 1: Adaptive balance optimizer

```

1  begin
2  for all  $s$  in  $S$ 
3    perform full random search using (1)
4    update  $s_b$  using (2)
5  end
6  for  $t = 1$  to  $t_m$ 
7    for all  $s$  in  $S$ 
8      if  $g_s = 1$  then
9        perform first guided search using (3)
10       update  $s$  using (2) and  $s_b$  using (3)
11       perform limited random search using (5)
12       update  $s$  using (2) and  $s_b$  using (3)
13      else
14        perform second guided search using (6) and (7)
15        update  $s_b$  using (3)
16        perform full random search using (1)
17        update  $s_b$  using (3)
18      end if
19      if improvement fail then
20         $g_s = 0$ 
21      else
22         $g_s = 1$ 
23      end if
24    end for
25  end for
26 end
27 output:  $s_b$ 

```

The initialization phase consists of two processes. In the first process, the full random search is performed to generate initial solutions. This full random search is formalized using (1) where s denotes the solution, s_l denotes the lower boundary, s_u denotes the upper boundary, and U denotes the uniform random. The second process is the global best updating process as formalized in (2). In (2), s_b denotes the global best solution and f denotes the objective function.

$$s = U(s_l, s_u) \quad (1)$$

$$s_b' = \begin{cases} s, f(s) < f(s_b) \\ s', else \end{cases} \quad (2)$$

The exploration mode consists of two searches. The guided search toward the global best solution is formalized using (3) while the limited random search is formalized using (5). s_c denotes the solution candidate which is then evaluated using (4) that represents the strict acceptance approach. In (5), it is shown that the local search space gets narrow as the iteration increases.

$$s_c = s + U(0,1) \cdot (s_b - 2s) \quad (3)$$

$$s' = \begin{cases} s_c, f(s_c) < f(s) \\ s, else \end{cases} \quad (4)$$

$$s_c = s + U(-1,1) \cdot \left(1 - \frac{t}{t_m}\right) \cdot \left(\frac{s_u - s_l}{2}\right) \quad (5)$$

The guided search relative to randomly solution is formalized using (6) and (7). s_s denotes the randomly selected solution which is selected uniformly among the population S . Meanwhile, as shown in (7), the corresponding solution moves

toward the reference if the quality of the reference is better than the quality of the corresponding solution. Otherwise, the corresponding solution avoids the reference.

$$s_s = U(S) \quad (6)$$

$$s = \begin{cases} s + U(0,1) \cdot (s - 2s_s), f(s) < f(s_s) \\ s + U(0,1) \cdot (s_s - 2s), else \end{cases} \quad (7)$$

Moreover, the detailed explanation regarding the influence of parameters used in this algorithm is as follows. The solution s plays an important role as autonomous agent performing the searching process. Meanwhile, the population S as the collection of s actualizes the population-based metaheuristics. The greater size of S in general improves the exploration capability although the size is not always linear to the performance quality. The s_b represents the best solution which is the basic form of collective intelligence in the swarm-based metaheuristic. Iteration t control the iterative process which is limited by the maximum iteration t_m . Uniform random U is used for the stochastic process which becomes the foundation of any metaheuristic. The boundaries s_l and s_u are used as the hard constraint in finding the possible solution. The objective function f is used for measurement of the quality of any solution.

IV. SIMULATION AND RESULT

This section presents the simulation and evaluation of ABO in solving optimization problems. This evaluation can be split into three parts. The first part is a simulation regarding the theoretical optimization problem. The second part is a simulation regarding the hyperparameter test. The third part is a simulation regarding the practical optimization problem. In the first and third parts, ABO is benchmarked with five latest metaheuristics: MPA, GSO, SMA, NGO, and ZOA. MPA, GSO, and SMA are metaheuristics that do not deploy a strict acceptance approach. On the other hand, NGOs and ZOA are metaheuristics that deploy a strict acceptance approach. Meanwhile, ABO plays in the middle by deploying a strict acceptance approach and not a strict acceptance approach based on the circumstance it faces.

The first part is the simulation regarding the theoretical optimization problem. In this work, the set of 23 functions is used as the use case. This set of functions is chosen due to its broad and diverse circumstances and challenges. It can be split into three groups: high-dimension unimodal, high-dimension multimodal, and fixed-dimension multimodal functions. A detailed description of these functions is presented in Table II.

In this work, several adjusted parameters are set as follows. In general, the maximum iteration is 50 while the population size is 5. The fishing aggregate device for MPA is set 0.5 that represents balance between exploration within the search space and the guided exploration toward two randomly selected solutions. The z score for SMA is 0.5. The result in solving the high dimension unimodal functions, high dimension multimodal functions, and fixed dimension multimodal functions is presented in Table III, Table IV, and Table V respectively.

TABLE II. DETAIL DESCRIPTION OF 23 FUNCTIONS

No	Function	Model	Dimension	Problem Space	Global Opt.
1	Sphere	$\sum_{i=1}^d x_i^2$	50	[-100, 100]	0
2	Schwefel 2.22	$\sum_{i=1}^d x_i + \prod_{i=1}^d x_i $	50	[-100, 100]	0

Table III indicates that ABO performs well in solving high-dimension unimodal functions. ABO becomes the first best in solving three functions (Sphere, Schwefel 2.22, and Schwefel 2.21), second best in solving three functions (Schwefel 1.2, Rosenbrock, and Quartic), and third best in solving one function (Step). Table III also indicates a significant gap between three metaheuristics (ABO, ZOA, and NGO) and the three others (SMA, MPA, and GSO), where the first group's performance is far better than the second group.

Table IV indicates that ABO performs well in solving high-dimension multimodal functions. ABO becomes the first best in solving two functions (Rastrigin and Ackley), second best in solving three functions (Griewank, Penalized, and Penalized 2), and fourth best in solving one function (Schwefel). Moreover, ABO can find the optimal global solution in solving Rastrigin and Ackley. Meanwhile, ZOA can also find the optimal global solution for these two functions.

The result in Table IV also divides these metaheuristics into two groups. The first group consists of MPA, GSO, and SMA.

On the other hand, the second group consists of NGO, ZOA, and ABO. Metaheuristics in the second group perform better than metaheuristics in the first group, while the performance gap is significant. This circumstance takes place in almost all high-dimension multimodal functions except Schwefel.

Table V indicates fierce competition among these six metaheuristics in solving fixed-dimension multimodal functions. Fortunately, ABO also performs well in solving these functions. Among these ten functions, ABO performs as the second best in six functions (Shekel Foxholes, Kowalik, Branin, Goldstein-Price, Hartman 3, and Hartman 6), third best in one function (Six Hump Camel), fourth best in one function (Shekel 5), and fifth best in two functions (Shekel 7 and Shekel 10). Different from the high-dimension unimodal and high-dimension multimodal functions, fierce competition happens for all metaheuristics in all ten functions. In general, the performance gap among the metaheuristics is narrow.

TABLE VI. CLUSTER BASED SUPERIORITY OF ABO COMPARED TO OTHER METAHEURISTICS

Group	MPA [9]	GSO [10]	SMA [11]	NGO [25]	ZOA [26]
1	6	7	6	5	0
2	6	5	5	4	2
3	9	6	5	2	6
Total	21	18	16	11	8

Table VI summarizes the performance comparison between ABO and the five other metaheuristics. The comparison represents the superiority of ABO compared to other metaheuristics based on the group of functions. This group-based comparison is needed because of the distinct characteristics among the groups of functions. It is assumed that some metaheuristics may be better in a certain group but mediocre in another group. The last row represents the total number of functions where ABO outperforms a metaheuristic.

Table VI indicates that ABO is superior to MPA, GSO, and SMA and still competitive compared with NGO and ZOA. ABO is better than MPA, GSO, SMA, NGO, and ZOA in solving 21, 18, 16, 11, and 8 functions, respectively. Meanwhile, ABO equals NGO in solving two functions and ZOA in solving six functions. It means ABO is worse than NGO in solving ten functions and ZOA in solving nine functions. ABO is superior to MPA in all groups of functions. Meanwhile, ABO is superior to GSO and SMA in solving unimodal and multimodal functions. On the other hand, ABO is still competitive compared to GSO and SMA in solving fixed-dimension multimodal functions. ABO is superior to NGO in solving unimodal and high-dimension multimodal functions but inferior in solving fixed-dimension multimodal functions. Contrary, ABO is superior to ZOA in solving fixed-dimension multimodal functions but inferior in solving high-dimension functions. Based on this summary, ABO has fierce competition with NGO and ZOA, where ABO is better than NGO in high-dimension functions while ABO is better than ZOA in fixed-dimension functions.

The second part of the simulation is regarding the hyper-parameter evaluation. In this work, two parameters are observed. The first parameter is the population size, while the second is the maximum iteration. The set of 23 functions is still used in this evaluation. The result of the population size evaluation is presented in Table VII, while the result of the maximum iteration is presented in Table VIII.

Table VII indicates that the increase in population size does not improve the quality of the solution in almost all functions. The improvement takes place only in three functions. Among these three functions, two functions are high dimension unimodal functions, and one function is a fixed dimension multimodal function. Meanwhile, there are two reasons why the improvement fails. The first reason is that the global optimal or quasi-optimal solution has been achieved. This reason can be found in twelve functions. The second reason is that ABO fails to find the quasi-optimal solution after reaching the maximum iteration. This reason can be found in eight functions.

22	-2.1184	-2.9625	no
23	-2.2307	-3.0198	no

Table VIII indicates that the increase of the maximum iteration does not improve the quality of the solution in almost all functions. The improvement occurs only in one high-dimension unimodal function (Schwefel 1.2). There are twelve functions where the global optimal or quasi-optimal solution has been achieved in the low maximum iteration circumstance so that there is no improvement anymore due to the increase of maximum iteration.

The third part is the evaluation of ABO in solving a practical optimization problem: portfolio optimization. This problem is chosen because most works that introduced new metaheuristics chose problems in mechanical engineering or power flow distribution as their use case. The portfolio optimization problem is an important optimization work in the finance sector. In general, two objectives can be chosen for the portfolio optimization problem. The portfolio optimization problem can be defined as an effort to arrange financial assets (stock, bond, gold, and so on) to maximize the return or control the risk [36].

In this work, the assets are stocks of the energy or mining companies listed in IDX30. IDX30 is a list published by the Indonesian stock exchange that consists of 30 very liquid stocks with high market capitalization and strong fundamentals. There are ten stocks, and the list is presented in Table IX. These stocks have three important attributes: stock index, market price, and year-on-year capital gain. The market price and capital gain are presented in rupiah per share. The information regarding these stocks was obtained on February 22, 2023.

This portfolio optimization is taken based on some scenario. The objective is maximizing the total capital gain which is calculated by accumulating the capital gain of all shares that are held. The quantity of each stock ranges from 200 lots to 1,000 lots where each lot represents 100 shares. The maximum total investment is five billion rupiah. This problem can be seen as a unimodal problem where the dimension is 10.

In this portfolio optimization, ABO is also competed with five metaheuristics like in the first part: MPA, GSO, SMA, NGO, and ZOA. The population size is 10 where the maximum iteration is 30. The result is presented in Table X.

TABLE IX. STOCK INFORMATION

No	Stock Index	Price	Capital Gain
1	ADRO	2,850	530
2	ANTM	2,050	-150
3	BRPT	910	-55
4	ESSA	940	295
5	INCO	6,800	1,860
6	ITMG	35,575	11,600
7	MDKA	4,610	853
8	MEDC	1,060	500
9	PGAS	1,540	135
10	PTBA	3,540	530

Table X indicates that ABO is competitive in solving this portfolio optimization problem, although it is not the best performer. ABO becomes the third best after SMA and NGO. On the other hand, ZOA becomes the worst metaheuristic in solving this portfolio optimization problem, although it is very competitive in solving the set of 23 functions.

TABLE X. PORTFOLIO OPTIMIZATION RESULT

No	Metaheuristic	Total Capital Gain
1	ABO	1,461,870,054
2	ZOA [26]	1,353,039,265
3	NGO [25]	1,478,676,650
4	SMA [11]	1,479,375,445
5	GSO [10]	1,461,377,050
6	MPA [9]	1,377,967,381

V. DISCUSSION

The simulation result shows that ABO is competitive enough as a swarm-based metaheuristic. ABO can find an acceptable solution in both theoretical and practical optimization problems. ABO can find the optimal global solution in solving five functions. ABO is superior to MPA, SMA, and GSO and competitive to NGO and ZOA in solving the set of 23 functions. Meanwhile, ABO becomes the third best in solving the portfolio optimization problem.

Solving the theoretical optimization problem shows that a strict-acceptance approach is important to achieve good performance, especially for high-dimension functions. In these functions, ZOA [26] and NGO [25] are metaheuristics that implement a strict-acceptance approach, while ABO implements both strict-acceptance and non-strict-acceptance approaches. ABO, ZOA, and NGO are the best of the three in solving almost all functions in the big dimension problems, while GSO [10], MPA [9], and SMA [11] do not implement a strict-acceptance approach. This circumstance indicates that metaheuristics implementing a strict-acceptance approach significantly achieves better results than others. On the other hand, circumstance becomes more dynamic in solving fixed-dimension multimodal functions where the gap among metaheuristics is narrow whether these metaheuristics implement a strict-acceptance approach. It means avoiding a worse solution is important in solving high-dimension functions, while this strategy is not important in solving fixed-dimension multimodal functions.

The strict-acceptance approach also does not significantly affect solving the portfolio optimization problem. Table X shows the narrow gap between the best and worst metaheuristics. On the other hand, ZOA as the worst performer is a metaheuristic that adopts a strict-acceptance approach. On the contrary, MPA, as a metaheuristic that does not adopt a strict acceptance approach, becomes the second worst performer. As a metaheuristic that does not adopt a strict-acceptance approach, SMA becomes the best performer. Meanwhile, NGO becomes the second-best performer as a metaheuristic that adopts a strict-acceptance approach.

The simulation result also shows that the competition among latest metaheuristics becomes tougher. It is common for many latest metaheuristics to deploy multiple searches and enrich the guided search with the random search. Many metaheuristics can find the global optimal in several functions and quasi-optimal in many other functions. Meanwhile, many metaheuristics still need help finding the quasi-optimal solution, especially in the low maximum iteration and low population size. This circumstance strengthens the no-free-lunch theory that a metaheuristic cannot solve all problems with superior results.

There are three loops conceptually performed during the iteration. The outer loop is the iteration from the first iteration to the maximum iteration. The intermediate loop is the iteration for the entire population. The inner loop is the iteration for the entire dimension because all dimensions are calculated in every search. Meanwhile, there are two searches performed by every agent in every iterations. Based on this explanation, the algorithm complexity of ABO is presented as $O(2t_{max} \cdot n(X) \cdot n(D))$. This complexity is normal for the population-based metaheuristic. Moreover, this complexity is achieved because ABO does not implement a sorting process in every iteration.

There are limitations regarding this work and its proposed metaheuristics, even though the proposed ABO performs well in solving both theoretical and practical optimization works. In ABO, the adaptability in tackling the local optimal is performed by choosing a non-strict acceptance approach. Meanwhile, this non-strict acceptance approach is implemented in any iteration. It differs from simulated annealing, where accepting a worse solution becomes more difficult as iteration increases. Meanwhile, different metaheuristic, such as tabu search, uses tabu list to restrict the repetition of a similar solution. This circumstance shows that there are various adaptive approaches that can be explored in the future. At the same time, a single metaheuristic such as ABO cannot adopt various adaptive strategies into a single metaheuristic.

This work has presented the use of optimization problem in financial sector, which is the portfolio optimization problem in the introduction of a new metaheuristic. This work also proves that ABO is competitive enough in solving this problem which is an integer-based problem. Meanwhile, there are various kinds of other optimization problems in the financial sector, such as credit risk assessment, investment planning, debtor analysis, and refinancing problems. These problems can also be addressed in future work.

There is also a limitation in choosing a practical optimization problem as a use case to evaluate the performance of the new metaheuristic. This work chooses a portfolio optimization problem as the use case, with its characteristics being integer-based and unimodal. On the other hand, there are various practical optimization problems, whether common or not, in many studies introducing new metaheuristics. These problems can be used for future studies, especially proposing an improved or modified version of ABO.

The future studies can also be performed by implementing ABO to solve various sustainable development goals (SDGs) related issues. SDG has become the global issue and

consideration for developing sustainable society and environment. For example, efficient energy consumption becomes the main and important issue related to climate change, renewable and affordable energy. Besides, optimization plays an important role in the operation of industry, transportation, and many other economic activities.

VI. CONCLUSION

The introduction of a new adaptive metaheuristic, namely adaptive balance optimizer (ABO), has been presented in this paper. This proposed model is designed to make a metaheuristic adaptive, especially when facing optimal local circumstances. This paper also presents the competitiveness of ABO in solving both theoretical and practical optimization problems. ABO is better than MPA, GSO, SMA, NGO, and ZOA in solving 21, 18, 16, 11, and 8 functions, respectively, in solving 23 functions. It means ABO is superior to MPA, GSO, and SMA and still competitive with NGO and ZOA in solving 23 functions. Meanwhile, ABO is still competitive in solving portfolio optimization problems, although ABO is not the best performer in solving this problem.

Adaptability can be used for future studies in metaheuristics. Various strategies have yet to be explored to make metaheuristics more adaptive, especially in tackling the local optimal entrapment. Besides, developing a superior metaheuristic that can solve the optimization problem in the low maximum iteration and low population size becomes challenging too. Moreover, future work can be conducted by addressing several common issues, such as scalability and more practical recent and future use cases. The scalability issue is related to wider boundaries and higher dimensions of the problem. Meanwhile, there are various recent and future optimization problems, such as in the green and blue economy, climate change, renewable energy, and many more.

Abstract—Economical speaker recognition solution from degraded human voice signal is still a challenge. This article is covering results of an experiment which targets to improve feature extraction method for effective speaker identification from degraded human audio signal with the help of data science. Every speaker's audio has identical characteristics. Human ears can easily identify these different audio characteristics and classify speaker from speaker's audio. Mel-Frequency Cepstral Coefficient (MFCC) supports to get same intelligence in machine also. MFCC is extensively used for human voice feature extraction. In our experiment we have effectively used MFCC and Linear Predictive Coding (LPC) for better speaker recognition accuracy. MFCC first outlines frames and then finds cepstral coefficient for each frame. MFCC use human audio signal and convert it in numerical value of audio features, which is used to recognize speaker efficiently by Artificial Intelligence (AI) based speaker recognition system. This article covers how effectively audio features can be extracted from degraded human voice signal. In our experiment we have observed improved Equal Error Rate (EER) and True Match Rate (TMR) due to high sampling rate and low frequency range for mel-scale triangular filter. This article also covers pre-emphasis effects on speaker recognition when high background noise comes with audio signal.

Keywords—Data science; artificial intelligence; MFCC; LPC; CNN; mel-spectrum; speaker recognition

I. INTRODUCTION

In the current world, voice communication is used to exchange thoughts and feelings. Most of the business are on voice communication and build trust over voice phone calls. Humans can easily identify a person from his/her voice over a phone call but in modern world voice answer machine should also need to identify person by his/her voice. Now-a-days lot of medical issues are also diagnosed through human voice. Human generates audio from throat and mouth. Fundamental frequency is original frequency, and it is modulated by vocal code structure and that makes every human voice as unique voice. Human can be identified based on his or her voice.

Human voice is generally identified in two categories, male voice, and female voice. The main difference between male and female voice is pitch and frequency. So, if it is just needed to identify gender from voice, then it's easy to classify by pitch difference. But, to recognize a human from his/her voice then all voice features are to be considered. Every person's voice is

unique and it's based on different voice features like frequency, jitter, amplitude, pitch and spectral power. Male speaker has 0-900 hz as fundamental frequency and female speaker has 0-1500Hz as fundamental frequency. If we consider average frequency, then male average fundamental frequency is 110 hz and female average fundamental frequency is 211 Hz [1].

Vocal cord, teeth, jaw, and tongue are main articulators of vocal trach which modulate fundamental frequency (FO) [2][3]. To begin with the generation of sound, air pressure is produced by the human lungs. This air pressure generates sound with fundamental frequency. Fundamental frequency sound is modulated by the vocal track to create different sound variations.

In Speaker recognition process, first step to identify human voice feature. MFCC is generally use for voice feature extraction from human voice. MFCC mainly consider frequency changes in human voice to define cepstral coefficients. There are various research earlier which have used MFCC for voice feature extraction. N. V. Tahliramani and N. Bhatt [4] discussed that machine can percept human feature as per MFCC in training phase. Similarly Convolutional Neural Network (CNN) is very popular for speaker recognition process [5]. N. Gupta and S. Jain [6] discussed about Siamese network effects with CNN. A. Chowdhury and A. Ross [7] discussed about CNN with degraded human voice. CNN is one of the preferred model with MFCC and Linear Predictive Coding (LPC) when signal is degraded with high noise [7].

MFCC and LPC are used in most of speaker recognition system. In our experiment, we have modified MFCC and evaluate results. In this article our focus to explain frequency impact on feature extraction and overall improvement in speaker recognition system.

The paper is organized as follows: base model for speaker recognition as discussed in Section II which defines all necessary steps for speaker recognition system, Section III discussed about what are different types of noises and how these noises degrade human voice. Then we discussed about how we prepared dataset with different noises in Section IV, and then in Section V we have defined CNN model including detailed description of modified MFCC, LPC and loss function (cosine triplet), then we have discussed experiment results in Section VI.

II. SPEAKER RECOGNITION BASE MODEL

Speaker Recognition (SR) process has three basic steps to identify speaker. These steps are stich together as per below Fig. 1.

- 1) Preprocessing
- 2) Voice Feature Extraction
- 3) Classification

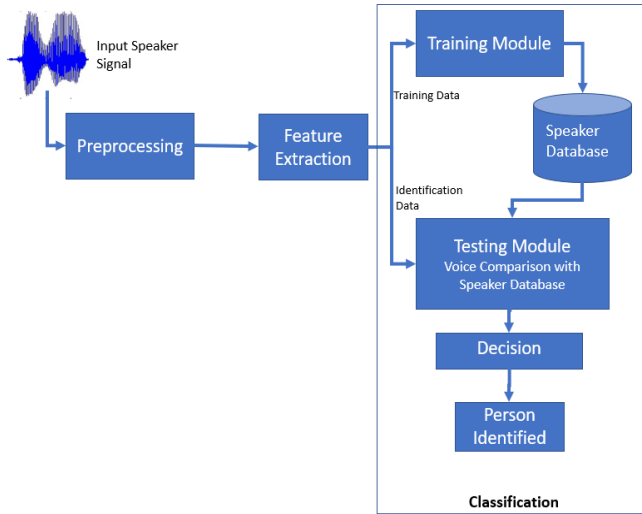

Fig. 1. Speaker recognition process blocks.

Preprocessing is mainly used for cleaning up data. In speaker recognition process preprocessing to remove possible noises from speaker recorded voice. Different types of “Low Pass Filter” (LPF), “Band Stop Filter” (BSF) and “High Pass Filter” (HPF) are used to remove noise from voice sample. Butterworth filter is also used as signal processing filter which is also known as band-stop filter.

Voice feature extraction is used to extract feature from speaker’s audio file. These features are used to classify speaker in next step. Voice features can be extracted by one of the most popular techniques Mel-Frequency Cepstral Coefficient (MFCC) [4][7][8][9][10], Linear Predictive Coding (LPC) [7] is also used for feature extraction. MFCC has its own benefit for feature extraction. For feature extraction, MFCC uses following main steps [4][11][12] to identify cepstral coefficients. MFCC converts voice recording into cepstral coefficient in matrix form which is easy to feed in next classification step. Following steps may be used in combination with LPC or other feature extraction methods also, based on application and source speaker voice.

- Framing & Blocking
- Windowing
- Fast Fourier Transform (FFT)
- Triangular Bandpass Filter (Mel-scale)
- Inverse FFT

These steps are stich together as per below Fig. 2.

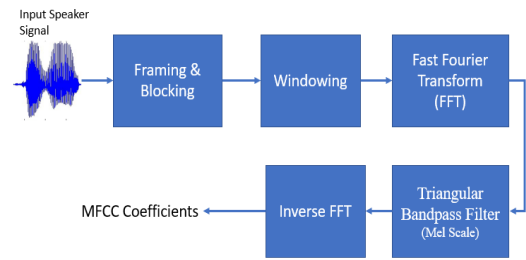

Fig. 2. MFCC processing.

A. Framing

Framing is required to make consistent voice sample. Long voice signal has lot of amplitude and frequency variation which gives lot of inconsistency during voice signal analysis for feature extraction. Short frames solve this issue and generally we create 20 to 40ms short frames for better voice signal analysis [13]. If T is duration of complete voice sample and t is sub frame sample duration, then total number of frames are F.

$$F = \frac{T}{t} * 1000$$

B. Windowing

Windowing is used to increase steadiness between first and end point within the same frame. From framing we get short duration frames, but these frames are generally discontinued because for interworld silence. Humming window makes continuity within same frame. If xi(n) is time domain signal and hi(n) is hamming window, then signal will become with hamming window is

$$xi(n) \text{ after windowing} = xi(n) * hi(n)$$

Where hi(n)

$$hi(n, \alpha) = (1 - \alpha) - \alpha \cos\left(\frac{2\pi n}{N} - 1\right)$$

$$1 \leq n \leq N - 1$$

C. Fast Fourier Transform

When speaker’s voice is recorded by any microphone, that signal is recorded in time domain. Time domain gives limited information about human voice feature. “Fast Fourier Transform” (FFT) converts time domain signal into frequency domain signal. Computation effect of FFT and “Discrete Fourier Transform” (DFT) are equal but Fast Fourier Transform is actually a fast algorithm to conceptualize DFT. DFT is discrete version of FFT. If N represent number of samples in frame, then each sample of that frame needs to be converted in frequency domain. If xi(n) is voice time domain framed signal and Xi(k) is transformed signal as define in below in equation.

$$Xi(k) = xi(n) hi(n) e^{-\frac{j2\pi kn}{N}}$$

$$1 \leq n \leq N \text{ and } 1 \leq k \leq K$$

Where hamming window is h(n), K is length of DFT.

D. Triangular Bandpass Filter: Mel-Scale

Humans perceive different human voice differently and similar intelligence is required in machines also. When human

time domain voice signal converted to frequency domain signal the triangular band-pass filters are used to filter human voice signal. FFT transform time-domain signal into frequency-domain signal and frequency domain signal is passed through from triangular bandpass filter.

At lower frequency range group, humans can understand two separate frequency voice, but at high frequency range group, two separate frequency voice is not recognized by humans. For example, low frequency group 'A' has F1 and F2 frequency voice signal. F1 and F2 has d difference then human can recognize F1 and F2 correctly. Similarly, high frequency group 'B' has F3 and F4 frequency voice signal. F3 and F4 also has d frequency difference then humans face difficulties to recognize it. To add similar intelligence in speaker recognition system, mel-scale is used to convert frequency into mel-scale as per given formula. If mf represents frequency in mel-scale and f in hz then

$$mf = 2595 * \log_{10} \frac{f}{700} + 1$$

The purpose of mel-scale conversion is to change the signals to follow the decrease properties of the mel-scale. At lower frequency it is linear conversion but at high frequency it is more static as per below Fig. 3.

Fig. 3. Mel-scale.

Mel-scale is used to identify the space of the triangular filter bank and also to identify how much filter bank width should be maintained. At the high frequency filter band width should also get wider to maintain frequency variability. Mel-scale based on triangular filter bank makes easy calculation of energies. Once energy is calculated with the help of mel-scale based triangular filter then it's easy to calculate mel-spectrum. Mel-spectrum is used to calculate different cepstral coefficients (generally 20) with the help of Discrete Fourier Transform (DCT).

E. Inverse FFT

Inverse FFT is used to convert back mel-spectrum into to the spatial domain. Initially time domain signal is converted to frequency domain signal and then frequency domain signal is transformed in mel-scale. Then it's necessary to convert back mel-scale signal. When inverse FFT is applied then signal gets converted back to spatial domain. This transformation can be performed either by "Discrete Fourier Transform" (DFT) or Discrete Cousins Transform (DCT). Both DFT and DCT can be used to identify coefficients as DFT and DCT divides a given sequence of finite length data into discrete vector. In

general, DCT is more used to identify coefficient from the specified log mel-spectrum [9]. DCT provides coefficients as output and these coefficients are known as MFCC. If m coefficient is required to calculate (generally 20 or 13 coefficients calculate) and Cn represent MFCC coefficient [9].

$$Cn = \sum_{i=1}^i \log_{10} Xi \cos[m(i - \frac{1}{2}) \pi / i]$$

Where Xi is FFT of the voice signal and m = 0, 1, ... i-1

When an audio signal is converted in matrix data set with the help of MFCC output then this MFCC output works as a input for classifier model. There are multiple models used by different researchers for speaker recognition like "Gaussian Mixture Model" (GMM) [14][15][16][17], "Hidden Markov Model" (HMM) [18], "Support Vector Machine" (SVM) [19][20][21][22], and deep learning based "Convolutional Neural Network" (CNN) [5][6][7][23]. In this article we have used CNN as classification model for speaker recognition.

III. NOISE EFFECTS ON SPEAKER RECOGNITION

Speaker Recognition efficiency is majorly dependent on the speaker's audio quality. If no background noise is included with speaker's voice, then speaker recognition results are quite good as compared to high background noise. When background noise is high then, it degrades the overall human voice signal. Degraded human voice signal is not only difficult to recognize but it also leads to a complicated speaker recognition system. There are multiple methods to eliminate noise from human voice. Some of the articles [1][24][25][26] have used frequency-based filtration logic to eliminate noise.

In speaker recognition process, speaker's voice should be noise free for better recognition. In today's world absolute silence is not possible in public places and lot of background noises are also captured in speaker voice. There are multiple use cases which use speaker recognition as authentication mechanism to identify customer. Background noise coming before and after speaker's voice can be easily eliminated in speaker recognition process but to eliminate background noise coming between two words is a major task in speaker recognition [27]. Type of noise is also important to consider in speaker recognition process.

A. Different Types of Noise

There are different types of noise classifications like colour based noise, white noise, violet noise etc. Noise can also be classified as

1) *Machine based noise*: This type of noise is generated by a machine. When a machine runs then that machine has its own noise like car, bus, large scale process industries machine, train, airplane have their own noises [28]. Machines also contribute to noise generation indirectly, like generation of noise from a home fan due to air friction.

2) *Human generate noise*: When many humans speak at same time with different words then their combined voice resembles as noise. For example, noise in restaurant, in stadium, shopping mall or in street [28].

3) *Nature inspired sound*: When sound is not generated by machine or human and is generated by natural resources then

the noise is considered as nature inspired sound like animal or bird sound, waterfall sound, fire sound, and wind sound. In speaker recognition process, whichever sound comes from the background making disturbance to classify speaker is considered as background noise. When speaker voice comes with waterfall sound or dog bark as a background then it disturbs with human voice signal and makes the speaker recognition process complicated.

B. Signal to Noise Ratio (SNR)

SNR signifies ratio of voice signal power to the noise power. SNR is indirectly proportional to the noise signal power. SNR is low when high noise signal power. If P_s is voice signal power and P_n represent noise signal (background) then SNR is

$$SNR \propto \frac{1}{P_n}$$

$$SNR = \frac{P_s}{P_n}$$

Human voice signal comes from throat and modulated with vocal cord, jaw, teeth and tongue. Human voice is always in changing pattern and it's never constant. As human voice is never constant and dynamic in nature so it's not idle for voice feature analysis. Hence, to regularize this it's required to express voice signal power in logarithmic scale as:

$$P_s(dB) = 10\log_{10} P_s$$

Similarly, noise signal power can also be described in logarithmic scale as

$$P_n(dB) = 10\log_{10} P_n$$

SNR can also be expressed in logarithmic scale. In this article we are considering SNR in decibel(dB).

$$SNR(dB) = 10\log_{10} \left(\frac{P_s}{P_n}\right)$$

OR

$$SNR(dB) = P_s(dB) - P_n(dB)$$

P_n represent noise power (background noise power in SR process) and P_s represent voice signal power without noise. If two separate signals come separately then it's easy to calculate SNR as per above equation. In speaker voice if human voice signal and background noise signal come together then it is hard to separate both signal power. Below equation can be used when both signals come together. When P_x represent human voice signal power with noise [29] and P_n represent noise signal power then SNR is

$$SNR(dB) = 10\log_{10} \left(\frac{P_x - P_n}{P_n}\right)$$

SNR can be positive in value or negative. It's based on voice signal power and noise signal power. When human voice signal is recorded in noisy environment where there is high background noise then there is possibility to have negative SNR. When human voice signal power is greater than noise signal power then SNR will be positive. When noise signal power is greater than human voice signal power then SNR will be negative [29]. For example, when human voice signal is

recorded with continuous high background noise like in mechanical factory or in heavy traffic area then noise power is more than human voice signal power. In this case SNR will be negative. But when background noise is impulsive and only one or two spick comes with human voice signal then SNR will be positive but low in value.

Positive SNR (in dB) when

$$P_s > P_n$$

Negative SNR (in dB) when

$$P_n > P_s$$

IV. DATASET

In our experiment we have created following six different types of datasets with the help of TIMIT dataset and NOISEX-92 noise dataset.

A. TIMIT Dataset

TIMIT dataset provided 630 speakers' voice without any added noise. It is a mixed dataset which contains male and female human voice for ~3sec each. Out of 630 speakers, 462 speakers' voice is in training dataset and 168 speakers' voice are in testing dataset.

B. NOISEX-92 Dataset

This database contains eight different types of noises and we have considered following four noises in our experiment.

- Babble Noise: This noise is generated by many people. For example, many human continuous voices in restaurants or in public place.
- F16 Noise: This noise is generated by F16 fighter aircraft engine.
- Factory Noise: This noise is generated by heavy machines in some process/mechanical factory.
- Car Noise: This noise is generated by car engine.

C. Datasets used in Experiment

a) *Data Set-1 (DS1)*: In this data set we used 630 speakers' voice from TIMIT dataset and babble noise which is generated by many humans in a close room like restaurant or common public place and noise generated by F16 fighter aircraft engine from NOISEX-92 dataset. Below Fig. 4 shows power spectrogram of speaker voice with babble and F16 noise.

Fig. 4. Power spectrogram (babble + F16 noise).

b) *Data Set-2 (DS2)*: In this data set we used 630 speakers' voice from TIMIT dataset, car engine noise and heavy machinery noise which is generated inside the factory from NOISEX-92 dataset. Fig. 5 shows power spectrogram of speaker voice with car and factory noise.

Fig. 5. Power spectrogram (car + factory noise).

c) *Data Set-3 (DS3)*: In this data set we used 630 speakers' voice from TIMIT dataset, babble and car engine noise from NOISEX-92 dataset. Fig. 6 shows power spectrogram of speaker voice with babble and car noise.

Fig. 6. Power spectrogram (babble + car noise).

d) *Data Set-4 (DS4)*: In this data set we used 630 speakers' voice from TIMIT dataset, F16 & factory noise from NOISEX-92 dataset. Fig. 7 shows power spectrogram of speaker voice with F16 and factory noise.

Fig. 7. Power spectrogram (F16 + factory noise).

e) *Data Set-5 (DS5)*: In this data set we used 630 speakers' voice from TIMIT dataset, car and F16 noise from NOISEX-92 dataset. Fig. 8 shows power spectrogram of speaker voice with car and F16 noise.

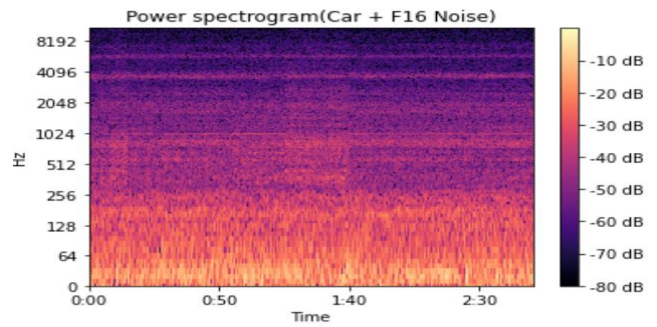

Fig. 8. Power spectrogram (Car + F16 noise).

f) *Data Set-6 (DS6)*: In this data set we used 630 speakers' voice from TIMIT dataset with babble and factory noise from NOISEX-92 dataset. Fig. 9 shows power spectrogram of speaker voice with babble and factory noise.

Fig. 9. Power spectrogram (Babble + factory noise).

In all datasets we have set room size as 3m and added reverberation. Below Table I represents summary of all 6-datasets.

TABLE I. DIFFERENT SIX DATASET SUMMARY

Dataset	Base Voice	Added Noise 1	Added Noise 2
DS1	TIMIT 630 Speakers	Babble	F16
DS2	TIMIT 630 Speakers	Car	Factory
DS3	TIMIT 630 Speakers	Babble	Car
DS4	TIMIT 630 Speakers	F16	Factory
DS5	TIMIT 630 Speakers	Car	F16
DS6	TIMIT 630 Speakers	Babble	Factory

V. PROPOSED CNN MODEL

Any speaker recognition system has two base modules, one is feature extraction module and another is classification module based on extracted feature.

A. Training Phase

In training phase we have used CNN for classification of speaker based on 1D-Triplet-CNN model defined in [7]. Convolutional layers play a key role in a CNN to determine its competency and learning capability. Each convolutional layer deeply learns different "concepts" from the data and hands it over to next convolution layer for further deeper learning in the CNN [30][31]. Speech can be represented in form of two dimensions (MFCC & LPC) but these two dimensions do not

show similarity. Generally, speech signals changes constantly but in short interval of voice it is constant in nature. This short interval of audio frame is called feature frame and it is good for speaker recognition process as it holds independent voice property. These multiple feature frames are useful in CNN for correct speaker recognition. We proposed CNN model with Modified MFCC (M-MFCC) and LPC for feature extraction. Three sets of CNN layers used in training phase as defined in Fig. 10.

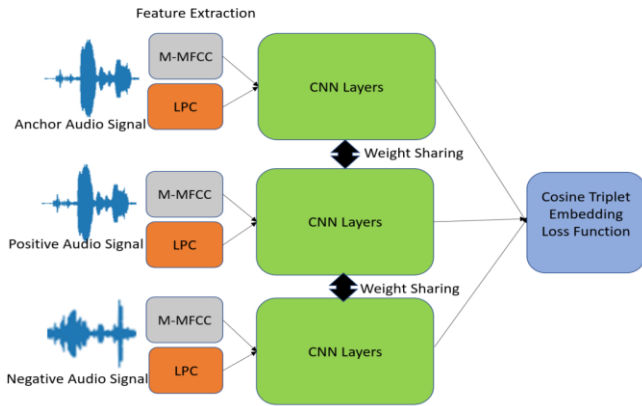

Fig. 10. CNN model training phase.

In training phase, we have used three CNN layers for positive, anchor and negative voice sample. All three CNN layers share weight to learn effectively. Triplet CNN layers are used to learn embedding function $f(x)$.

$$f(x) \in \mathcal{R}^d$$

$f(x)$ represents data sample embedding in d -dimension Euclidean space and x represents data sample. Following are the steps of overall speaker recognition classification model. We have used modified MFCC(M-MFCC) and LPC for feature extraction and then we have combine M-MFCC and LPC output and feed to CNN layers. CNN layers detailed we have defined in sub section D.

B. M-MFCC

We have modified MFCC in three basic steps to make high similarity in anchor and positive sample and dissimilarity in anchor and negative sample.

Step-1: High Sampling Rate

Sampling rate is the key factor to identify voice feature. High sampling rate captures more signal dissimilarity info as compared to low sampling rate. We have increased sampling rate from 22050 to 44100.

Step-2: Frequency Range for mel-scale triangular filter bank

As per Section II, MFCC uses mel-scale triangular bandpass filter. These filters use low and high frequency range to create triangular filter bank. Male speaker has 0-900 Hz as fundamental frequency and female speaker has 0-1500Hz as fundamental frequency. If we consider average frequency, then male average fundamental frequency is 110 Hz and female average fundamental frequency is 211 Hz [1][32]. We observed that most of the male and female voice power comes

up to 2000Hz or less. In this work we have selected the filter bank from 0Hz to 1800/2000Hz then it mostly captures human voice relevant information for speaker recognition process and avoids noise information which in between the words. Optimization of frequency range for triangular bandpass filter gives benefit to filter out background noise and improve mel-scale for small variation.

Step-3: Pre-emphasis Effects

Humans generate sound with fundamental frequency. Vocal track modulates this voice and generates modulated voice. This modulated voice is suppressed by high frequency voice. The objective of pre-emphasis is to compensate high-frequency part that was suppressed during the sound generation by the humans [33][34]. In general, when MFCC coefficient is calculated by different libraries like “python_speech_features” then standard value is 0.97 and when we used same pre-emphasis values then we did not gain much in speaker recognition accuracy. In our experiment, when we optimize pre-emphasis value and make it at 1.00 then we received improvement in results.

C. Linear Predictive Coding

As discussed in [7], when we need to simulate human voice then human throat functioning needs to be understood. Human voice is generated from lungs and filtered at vocal track. Vocal track is nothing but a time varying digital bandpass filter which filters some frequencies. Also, for detail estimation and analysis of human vocal track we generally look all-pole model of filter design. If we consider $H(z)$ as transfer function of vocal track then,

$$H(z) = \frac{G}{1 - \sum_{k=1}^p \alpha_k z^{-k}}$$

Human voice signal is continuous signal so if $S[n]$ is voice acoustics of n th sample and p is past voice sample then n th speech sample can be defined as

$$S[n] = \sum_{k=1}^p \alpha_k S[n-k] + G \cdot u[n]$$

G is gain factor here and $S[n-k]$, $k=1, 2, \dots, p$ are past human voice samples. Excitation of n th voice sample is represented as $u[n]$. α_k represents vocal track filter coefficients. As LPC also aims to identify all zero filters which come from invers vocal track model. If $S'[n]$ represents n th speech sample with conditioned on previous speech sample, then

$$S'[n] = \sum_{k=1}^p \alpha'_k S[n-k]$$

For correct predication of human vocal track filter coefficients, difference between $S[n]$ and $S'[n]$ should be minimum. α_k represents LPC model attribute which is filter coefficient of the Inverse-Vocal Tract filter model.

D. Combine M-MFCC and LPC

MFCC and LPC bring separate feature characteristics and we combine this information to identify similarity between two voice samples [22]. MFCC brings perceptual speech feature where LPC features give information about speaker vocal track for accurate prediction.

In our experiment we combined M-MFCC and LPC coefficients which give unique voice characteristics of a speaker. For every voice sample M-MFCC is one channel and LPC is another channel.

- M-MFCC Channel: Every frame has 40 features. 20 features from MFCC and another 20 features from delta MFCC.
- LPC Channel: Every frame has 40 features. 20 features from LPC and another 20 features from delta LPC

E. CNN Layers

In this experiment we have used 6 different layers as per Fig. 11. Convolutional layer gives learning capacity from different voice features.

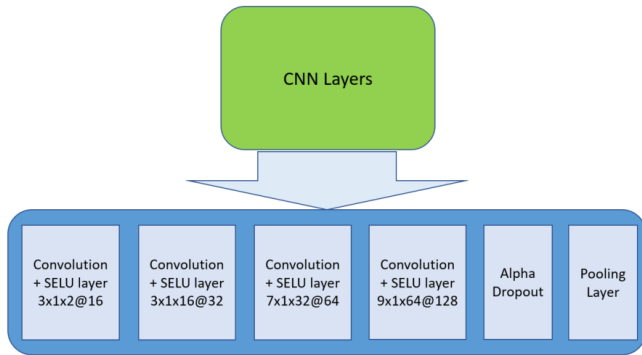

Fig. 11. Different CNN layers.

We have used 4 convolutional layers with SELU nonlinearity, one alpha drop and one pooling layer. Alpha dropout layer works effectively with SELU activation function and it goes hand-in-hand with SELU activation for self-normalization.

- First convolution layer takes 2 channels as input (M-MFCC & LPC) with 16 filters and 3x1 kernel size.
- Second convolution layer takes input from first layer and it has 32 filters with 3x1 kernel size.
- Third convolution layer takes input from 32 neurons and has 64 filters with 7x1 kernel size.
- Final convolution layer takes input from third layer and it has 128 filters with 9x1 kernel size.
- Fifth layer is alpha dropout layer to maintain variance and mean at original input level. We have used dropout rate as 0.2
- Final layer is pooling layer and we have used average pooling.

F. Cosine Triplet Embedding Loss Function

Cosine triplet embedding loss function is used during training phase to calculate loss and make correct model. Ideally Euclidean space between positive and anchor sample should be minimum but Euclidean space between anchor and negative sample should be maximum. Similar to work in [7], if we denote positive sample by Sp, anchor sample by Sa and

negative sample by Sn then cosine triplet embedding loss function.

$$F(Sa, Sp, Sn) = \sum_{a,p,n}^N \cos(f(Sa, Sn)) - \cos(f(Sa, Sp)) + \alpha_{margin}$$

Sa and Sp samples from same speaker and ideally feature distance between Sa and Sp should be zero so cosine of f(Sa,Sp) will be 1. Sa and Sn samples come from different speakers so in other way round ideal distance between Sa and Sn should be maximum so cosine of f(Sa,Sn) will be minimum. This α_{margin} is used to maintain minimum distance between negative and positive voice sample. α_{margin} is adjustable hyper-parameter. And in our experiment, we have considered it at 0.5.

G. Testing Phase

In testing phase also, we have used combined M-MFCC and LPS for feature extraction. CNN layers were trained in training phase with weight sharing together with positive, anchor and negative sample CNN layers. Same trained layers were used in testing phase to test voice samples. as per below Fig. 12.

Fig. 12. CNN model testing phase.

In training we have used cosine triplet embedding loss function as we have trained model with three voice sample positive, anchor and negative audio. In testing phase, we have used cosine similarity as it is needed to validate similarity between two voice samples. Cosine similarity metric is used to compare the extracted embeddings and provide a corresponding match score as defined in Fig. 12. We have given two audio samples in testing phase Audio Sample 1 (AS1) and Audio Sample 2 (AS2). When AS1 and AS2 are from same speaker then ideally cosine similarity should 1 and when AS1 and AS2 are from two different speakers then cosine similarity should be “-1” (negative one).

VI. EXPEREMENT AND RESULT

As defined in section IV, we have created 6 different datasets from TIMIT and NOISEX-92 dataset and performed following six experiments with training and testing model defined in section V. Aim of these experiments was to train model with degraded human voice with one set of noises and

test model with different set of noises. Most of the applications need such kind of functionality to train the model in one set of noises and test in different set of noises. Below Table II sets mapping between experiment ID and corresponding training and testing dataset.

TABLE II. EXPERIMENTS WITH SIX DATASETS

Experiment ID	Training Dataset	Testing Dataset
1	DS1	DS2
2	DS2	DS1
3	DS3	DS4
4	DS4	DS3
5	DS5	DS6
6	DS6	DS5

The tables below show the comparison results for all experiments. We have compared speaker recognition system accuracy in terms of True Match Rate (TMR). TMR has calculated at 10 percent of False Match Rate (FMR). In speaker classification, increased TMR signifies reduction of false prediction (either negative or positive). It is observed that combined MFCC and LPC give significant improvement in TMR as compared to MFCC and it is similar to work in [7]. We got better result with M-MFCC and LPC as defined in Table III.

TABLE III. EXPERIMENTS RESULTS TMR

Exp ID	TMR@FMR=10%				
	Training Dataset	Testing Dataset	MFCC	MFCC & LPC	M-MFCC & LPC
1	DS1	DS2	65.3	80.6	89.1
2	DS2	DS1	66.9	79.7	87.9
3	DS3	DS4	63.8	77.7	83.2
4	DS4	DS3	62.9	69.4	83.4
5	DS5	DS6	60.4	69.4	72.6
6	DS6	DS5	66.6	80	92

We also compare Equal Error Rate (EER) in percentage with all three feature extraction methods. EER represents a point in DET or ROC curve where false rejection rate is equal to false acceptance rate. When both rates (false acceptance and false rejection) are equal then that common value is considered as EER. Low EER represents improved accuracy of speaker recognition system. As per Table IV results, we observed that combined MFCC and LPC gives very significant improvement in EER as compared to MFCC [7] and on top of this we got improvement with M-MFCC and LPC case.

TABLE IV. EXPERIMENTS RESULTS EER

Exp ID	ERR in %				
	Training Dataset	Testing Dataset	MFCC	MFCC & LPC	M-MFCC & LPC
1	DS1	DS2	21.8	12.3	10.5
2	DS2	DS1	20.2	12.5	11.3
3	DS3	DS4	20	12.8	12.1
4	DS4	DS3	22	14.4	12.0
5	DS5	DS6	23.5	14.3	13.8
6	DS6	DS5	18.7	12.5	10.8

VII. CONCLUSION

Different applications require different types of speaker recognition system. Most of the applications are looking for speaker recognition system which should work with no background noise during training, but same system should recognize speaker even with degraded human voice. In our experiment we have used same approach and used speaker voice with most silent background noise (SNR = 10-12dB) and test degraded human voice up to 1dB SNR. In our experiment (As per section V) we observed that high sampling rate, optimized triangular mel-bandpass filter frequency range and optimized pre-emphasis value gives better EER and TMR. Improved EER and TMR are impacting MFCC values for effective speaker recognition process. This can further optimize in future to get better results. In future, triangular mel-bandpass filter frequency range can optimize further to get better results.

AUTHORS' PROFILE

Amit Moondra received the Master of Engineering degree in Communication Engineering from the Birla Institute of Technology and Science, Pilani, India (BITS - Pilani). He has more than 20 years of industrial and research experience with 10+ across countries.

He is currently working in Ericsson Global India Limited as Senior System Manger in Product Development Unit and pursuing his Ph.D. at Manav Rachna International Institute of Research and Studies, India. His research focuses on artificial intelligence, deep learning model in speech area. He is an active member of IEEE.

Poonam Chahal received her Ph.D. in 2017 from YMCA University of Science and Technology, Faridabad India, in the field of Artificial Intelligence. Presently she is working as Professor in Department of Computer Science and Engineering at FET, Manav Rachna International Institute of Research and Studies, Faridabad.

She is actively involved in research activities and is on the reviewing panel of many journals and conferences.

Customer Segmentation of Personal Credit using Recency, Frequency, Monetary (RFM) and K-means on Financial Industry

Hafidh Rizkyanto¹, Ford Lumban Gaol²

Computer Science Department, Bina Nusantara University, Jakarta, Indonesia¹

Doctor of Computer Science Department, Bina Nusantara University, Jakarta, Indonesia²

Abstract—This research focuses on how to build a segmentation model for credit customers to identify the potential for defaulting credit customers based on their transaction history. Currently, there is no segmentation available for this possibility of payment failure. Credit scoring helps in minimizing credit risk when applying for credit. However, using RFM (Recency, Frequency, Monetary) models helps to score each transaction variable of the customer's financial activity. K-means then assists in the process of segmenting the results of the RFM model scoring, which occurs in the middle of the customer's repayment schedule. Challenge is how to decide the variable that can be used in RFM models and how to interpret the clusters that have been formed and the actual implementation of the customer. The Bank can divide the clusters that have possibility of payment failure by their customers so that banks can take preventive actions and as information for the collection system to be able to make payment withdrawals or billing.

Keywords—Credit; credit risk; recency; frequency; monetary; K-means

I. INTRODUCTION

A commercial bank is a business entity that obtains funds from the public in the form of savings, term deposits, and other types of funds. These funds are then distributed to the public as credit with the purpose of improving their standard of living. The financial industry in banking offers various alternative money loans to the public, with the provision of loans in the form of credit to bank customers [1].

Regarding types of businesses, financial service industries that provide funds directly include commercial banks, guarantee companies, and factoring companies [2]. In this research, Bank XYZ, a commercial bank, is used as a case study. There are several types of commercial banks in Indonesia, including state banks, private national banks, foreign banks, joint banks, regional government banks, and commercial banks [3].

As of January 11, 2021, there were 198,986 active credit customers, with a total of 621,968 active and closed credit data for Bank XYZ. For the financial industry in banking, data is an important asset that can be used for corporate strategy. Banks have a large amount of raw data, including transaction data, customer data, and statement data, which require processing to provide decision support information [4]. However, Bank

XYZ, established on July 10, 1970, currently does not have a decision support system that can provide information to credit officers regarding potential customers or customers who may have payment difficulties, which could significantly impact the bank. Therefore, with the implementation of a data processing system, credit handling can be improved by each account officer who monitors the credit of their customers. This will help to reduce errors in the amount and credit payment process, which often results in changes in collectability and poor customer performance, leading to poor credit quality.

In general, data mining functions are divided into two parts: descriptive and predictive. Other functions include classification, association, clustering, sequencing, and forecasting [5]. Data mining techniques can be used to segment credit customers, with clustering as the algorithm used, specifically K-means. The RFM Model is used because it can be adapted to evaluate the value of customers [6] and classify them in different service areas such as finance, telecommunications, and e-commerce [7]. K-means is a non-hierarchical data grouping method that can partition data into two or more groups [8].

The combination of the RFM and K-Means Models can produce optimal segmentation because RFM establishes variables that are closely related to business needs, and K-Means can group them based on the similarities of each customer. The evaluation of the number of segments is determined using the Calinski-Harabasz Index (CH), which gives better results than clustering evaluation methods such as the Elbow method and others [9].

In providing loans, banks face various problems and risks, including the behavior of customers who do not pay their installments on time or delay payment of installments for several months, resulting in bad credit. Therefore, it is essential for banks to evaluate credit risk by focusing on several aspects, including determining the features impacting credit risk and predicting the possibility of default or payment failure [10]. An intelligent processing system is needed to assist banks in selecting prospective customers who will be given loans.

Guangshu Xu, Yuanyuan Li , Jun Wu, Li Shi, Sang-Bing Tsai, Wen-Pin Lin, and Liping Yang,	RFM Model was improved and combine with Algorithm of K-Means.	Quantitative analysis method to make segmentation and platform clusters. Segmenting customers with clear values and purchasing preferences greatly helps platform for effectively allocating marketing resources to specific customer groups and for building healthy long term relationships with customers [15].

III. RESEARCH METHODOLOGY

Clustering can be used to divide all customers into several clusters based on various criteria that are similar to customers. Clustering is employed to group data naturally based on the similarity of data objects and to reduce their similarity with other clusters. Unlike classification, clustering is unsupervised learning and does not require a data training stage. In this study, K-Means and decision tree are used as data mining approaches. The K-Means algorithm can group bank customers based on their similarity in credit payment statements [16].

The method consists of several stages that need to be considered, as shown in Fig. 1.

Fig. 1. The cross-industry standard process (CRISP).

This research suggests customer segmentation using the RFM Model and K-Means algorithm. Many studies have used the K-Means algorithm for the segmentation of customers [17] and traffic management systems [18]. The segmentation of customers and profiling of Recency, Frequency, and Monetary (RFM) method can help understand customer loyalty [19].

Furthermore, customers are assigned to three different variables: Recency, Frequency, and Monetary (RFM). By calculating scores for each instance, an assessment is done where the score ranges from 1 to 5, indicating the lowest and highest variable scores [13].

The evaluation of segmentation will be calculated using the Calinski-Harabasz index. The author in [9] pointed out that the Calinski-Harabasz index is the most reasonable metric to measure how well the number of groups formed by K-Means. Meanwhile, the Elbow method only calculates the error between data points X and centroid C, which will produce sum squared errors (SSE).

1) To calculate CH, the first step is to compute the inter-cluster dispersion or the between-group sum of squares (BGSS). In CH, the inter-cluster dispersion measures the weighted sum of squared distances between the centroid of the cluster and the centroid of the entire dataset (barycenter).

$$BGSS = \sum_{k=1}^K N_k x || C_k - C ||^2 \tag{1}$$

Where, N_k is the number of observations in cluster k , C_k is the center of mass of cluster k , C is the centroid of the barycenter, and K is the number of clusters.

2) The second step involves calculating the intra-cluster dispersion or within-group sum of squares (WGSS). In CH, intra-cluster dispersion measures the sum of the squares of the distances between each observation and the centroid of the same cluster.

$$WGSS_k = \sum_{i=1}^{N_k} || X_{ik} - C_k ||^2 \tag{2}$$

Where, X_{ik} is the observation of the- i in cluster k . Then, add up all the individuals in the group and calculate the sum of squares.

$$WGSS = \sum_{k=1}^K WGSS_k \tag{3}$$

3) The Calinski-Harabasz index is calculated by summing the inter-cluster dispersions and the intra-cluster dispersions for all clusters.

$$CH = \frac{BGSS}{WGSS} x \frac{N - K}{K - 1} \tag{4}$$

N is the number of observations and K is the number of clusters formed. From the equation above, it can be concluded that the greater the value of the Calinski-Harabasz index, the better the grouping is made.

To explain the results of customer segmentation, we can find the score of value and customer type, which can be used as a strategy by the company. For example, this information can be used for marketing or collecting strategies to increase the company's profits, as discussed in [17].

The achievement of the research is the application of customer segmentation in industries related to the banking sector, using the K-Means algorithm based on the score of RFM Credit Payment. The performance of the clustering methods in customer segmentation is shown in Fig. 2.

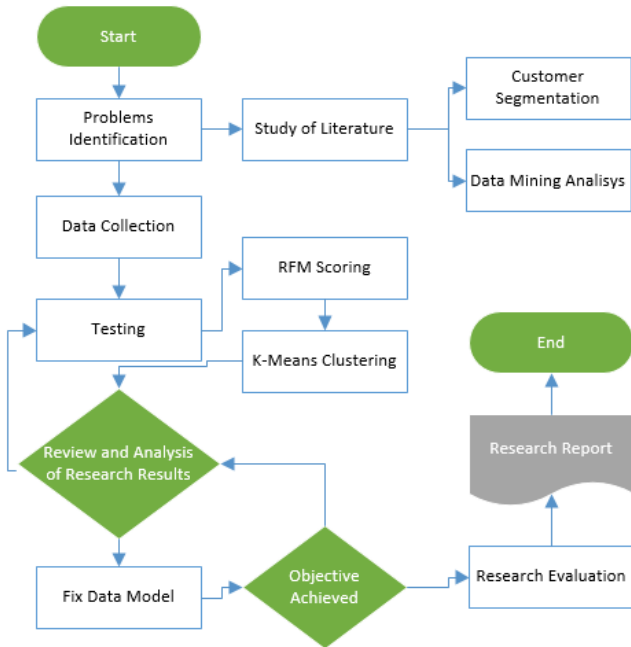

Fig. 2. Research methods.

There are steps to identify variables with good scores that can create better customer segmentation. Each stage of this process uses the Fig. 1 Cross-Industry Standard Process (CRISP), which includes the following details:

4) *Preprocessing*: This stage is the initial stage in the data processing, and it combines data understanding and data preparation. It contains two stages:

a) *Data Cleansing*. This stage is purposed to delete or eliminate variables that are not needed or cannot be used in the grouping process, such as variable names, address details, and dates.

b) *Merging and Generating Variable*. After getting good variables, we can connect each data point and change the variable according to the RFM concept. We take variables that are closely related to the last date, how many transactions, and the accumulated nominal transactions.

- This stage has several steps carried out to produce variables that are feasible for the clustering process. They are:

a) Identification of the quality of each variable using summary statistics. Variables that are not qualified, such as lots of empty data, almost all data values being the same, or the data not being varied, will be removed because they don't significantly affect clustering.

b) Handling empty data on variables. Research shows that using the median or middle value gives better results than

using the mean and k-NN imputation. This research will change each variable's blank value with the median of each variable.

- Modelling**: This stage changes the original value of the RFM variable that is formed into a score according to the concept of the RFM model. The original value changes to 5 bins or 5 score groups. The approach to dividing the original value is based on the frequency, so that an almost equal bin distribution can be formed.
- Modelling Evaluation**. The RFM score variable's results stage will be grouped using K-Means. Calinski-Harabasz (CH) will be used to obtain the most optimal number of clusters. Besides that, the results of plotting all the variables on the clusters formed will also be seen. The results will be tested on test data.
- Deployment**. This final stage interprets the clusters that have been formed and implements the actual customer collectibility process.

IV. RESULT AND DISCUSSION

A. Data Collection

The provided data pertains to credit, savings summaries, and transactions. The customer's personal data is deleted to maintain confidentiality, ensuring that the data processing focuses on transaction variables that will classify the customer's transaction behavior. The data processing process, from start to finish, employs R programming. Table II displays the total observations and variables for each data point.

TABLE II. DATA SOURCE RESEARCH

Data Test	Description	Data Load
Credit	Credit Data	10312 obs. of 24 variables
Saving	Saving Account Data	12373 obs. of 9 variables
Transaction	Transaction / Bank Statement Data	1048575 obs. of 6 variables

B. Model Development

This stage divides into four sub-chapters, they are pre-processing, feature engineering, modeling, and cluster interpretation. Generally, the pre-processing stage involves producing feasible variables for processing in the feature engineering stage. Feature engineering, on the other hand, involves transforming original variables into new ones based on the RFM concept. Meanwhile, the modeling stage involves grouping the previous results using K-Means. At the end of this stage, a detailed description of the formed clusters along with their implementation for collectability will be provided.

1) *Pre-processing*: This stage focuses on eliminating unqualified variables from the modeling process. Each data point will be cleaned, and this stage will remove any variables that cannot be used in the clustering process. Table III shows a list of the savings variables that were deleted because they could not be used.

TABLE III. LIST OF REMOVED VARIABLE SAVING

LIST OF REMOVED VARIABLE SAVINGS				
BRCOD	LOKASI	PDID	AOID	SGBU
SGID	AMBLK	CCCOD	AUTID	CSNO
WARS2	WARS3	TGLOPN	KERJA	SPCL
CTAX	CDATE	AINTR	ATAX	ADATE
INPDAT	INPUID	MNTDAT	MNTUID	AUTDAT
BCCOD	NAMA	ALM1	KPOST	WARS1
INTSPD	DRLIM	SEQNO	SWCIN	CINTR
CONVSW	CONVDT	ACCOLD	ACCNEW	ACSTA
YYMMDD	SEQBAL			

Analyzing this variable produces several important variables that can be used for modeling, as presented in Table IV: "Used Variables in Savings Data".

TABLE IV. USED VARIABLE AFTER DATA CLEANING SAVING

Variable	Description
ACNO	Account Number
LSTRN	Updated Date
MVCRED	Daily Credit Total
MVDBTD	Daily Debet Total
MVCREM	Montly Credit Total
MVDBTM	Montly Debet Total
BLCUR	Balance
BQCUR	Balance For Foreign Exchange
BLPRV	Previous Daily Balance
AVBLM	Previous Monthly Balance
CSSTA	Customer Status

Each data point will undergo data cleaning to remove transaction variables that cannot be used in the clustering process. The list of deleted variables is shown in Table V. The process of analyzing the remaining variables yields several important variables for modeling, which are presented in Table VI as the used variables in transactions data.

TABLE V. LIST OF REMOVED VARIABLE DATA TRANSACTION

TABLE VIII. USED VARIABLES IN LOANS DATA

Variable	Description
CRLIMA	Loan Limit First
CRLIM	Loan Limit
BLCUR	Current Outstanding
MVDEBT	Debet Movement
MVCRED	Credit Movement
MASA	Period Loans (Month)
RATDND	Penalty Rate
CRTNGA	Installment arrears
CRTNGB	Interest arrears
DESCON	End of Month Balanced
JAMIN	Guarantee amount
BICOLL	Collectability
OSATHN	Outstanding early years
CLATHN	Early year limit
PKATHN	Main Balanced early years
BGATHN	Interest early years
DNATHN	Penalty early years
RTATHN	Rate Early Years
PBLATHN	Main month number
BBLATHN	Interest month number
DBLATHN	Penalty month number

The second stage in pre-processing involves merging the data points and generating new variables based on the RFM concept. The loans data is the main data for segmentation in the bill collectability process, and it will be combined with savings and transaction data.

The transaction data is divided into two categories: recipient (debit) and sender (credit). This division is used to gain more insight into the transaction behavior of credit customers. The date-related variables are converted into days, with December 31, 2021, serving as the reference point.

For example, the MMDD variable is converted into days, where smaller values indicate customers who are new to transactions and vice versa. This processing transforms the original variables into variables according to the RFM concept, providing information about novelty, frequency, and total purchases or transactions. Unlike ordinary RFM, this study produces multiple RFM variables to classify credit customer behavior. The results of RFM variable processing are shown in Table IX.

2) *Feature engineering*: This stage focuses on engineering variables that will be used for clustering effectively. Feature engineering involves several stages including identifying the quality of each variable, handling empty data, and changing the original value to the RFM score variable. Table IX presents 64 variables resulting from pre-processing, which help identify the quality of the variables. Additionally, Table X provides a summary of statistics for each variable.

TABLE X. RESULT OF SUMMARY STATISTICS FOR EACH VARIABLE

Variable RFM	Type	Total NA	Mode Value	Total Mode	Total Unique Value	Presentase NA	Presentase Mode	Presentase Value

Table X displays the amount of empty data, most frequent data, and corresponding percentages for each variable. Certain variables are deemed unqualified and are therefore cleaned up using some simple logic, including the following:

- Variables with empty data greater than 70 percent are deleted as they do not provide any useful information or insights.
- Variables with a mode percentage greater than 80 percent are deleted as they do not offer significant insights for grouping. For instance, Fig. 3 shows that the RFM variable will be deleted.

Fig. 3. Removed RFM variable.

After conducting quality identification on the 21 variables, any empty data is changed using the median or middle value of each variable. Table XI lists the variables along with their median values.

TABLE XI. EMPTY VARIABLES RFM WITH THEIR MEDIAN VALUE

Variable	Median
monetary_sender_transaction_desc_taspen	3185000
recency_receiver_transaction_success	28
frequency_receiver_transaction_success	2
monetary_receiver_transaction_success	1136039

In the feature engineering process of this research, the original data is converted into RFM scores. The variable values are sorted into five groups based on the data distribution quantiles. Fig. 4 illustrates the result of dividing the interval from the recency_savings, which denotes the last date of the customer's saving data update.

Fig. 4. Recency_savings variable bin formation interval.

The results of this bin formation will produce the RFM score variable, where the distribution of each score is shown in Fig. 5.

Fig. 5. Distribution of score_recency_tabungan.

The distribution of the Score_recency_saving variable indicates that the smaller the score, the more recently the customer carried out an activity related to savings. A score of 5 means that the customer has sustained long-term activities related to savings, and their distribution is quite small.

Fig. 6. Distribution of score_monetary_monthly_credit.

Fig. 6 shows the distribution of the Score_monetary_monthly_credit variable, where the difference is not significant. Fig. 7 shows the distribution of the Score_monetary_current_balanced variable.

Fig. 7. Distribution of score_monetary_current_balanced.

3) *Modelling*: The modeling process is the final stage in the modeling process. This process involves grouping the RFM score variables using K-Means. First, the data will be randomly divided into two data sets, namely the training data and testing data, each comprising 80% and 20% of the data, respectively. The training data will be used to build a clustering model, which will be tested later using the testing data.

The first step is to remove variables that have a correlation greater than 0.7, as two or more highly correlated variables will not significantly affect the clustering process. Since there are 11 variables that have a high correlation, the clustering process uses 10 score variables.

The development stage of the K-Means model has been completed after testing the number of clusters. Testing the number of k clusters is an important step in the grouping process to obtain a number of clusters that is close to the ideal and can meet the need for customer collectibility.

The Calinski-Harabasz index is used to test how well the number of clusters is formed. Testing is done for the number of clusters ranging from 2 to 25, and the results of the Calinski-Harabasz index for each cluster are shown in Fig. 8.

Fig. 8. Calinski-harabasz index results.

The Calinski-Harabasz (CH) Index can be used to evaluate the clustering model when ground truth labels are not known. It is used to test how well the clustering model has been created using quantities and features inherent to the dataset. The results of the Calinski-Harabasz index in Fig. 8 show that the number of clusters 2 has the highest value, and the larger the number of k clusters used, the smaller the Calinski-Harabasz index value. The CH index is a measurement of how similar an object is to its own cluster (cohesion) compared to other clusters (separation).

In addition to testing the Calinski-Harabasz index, the results of plotting all the variables on the clusters that are formed are also checked. Fig. 9 is a plot of the number of clusters ranging from 2 to 7.

Fig. 9. Cluster plotting results $k < 4$.

Cluster 2 shows a significant difference in the distribution of the two customer groups, indicating that it is quite good at clustering. However, there is a small number of customers who intersect each other.

The same is true for clusters 3 and 4, but they have a larger number of intersecting customers. In contrast, cluster 5 has one customer group whose characteristics are quite similar to the other groups, namely customer group 4, which is mostly similar to customer group 5.

Fig. 10 shows that as the number of clusters increases to 6 and 7, more and more customer groups have overlapping characteristics. This is in line with the results of the Calinski-Harabasz index, where an increasing number of clusters results in a smaller value, indicating that the clustering results performed by K-Means are less optimal.

Fig. 10. Cluster plotting results $k > 4$.

This study chose to use four clusters because K-Means can divide customer groups quite well, with each group having different characteristics. There are some customers whose characteristics intersect with each other but are still understandable. Fig. 11 shows the result of clustering with four clusters.

Fig. 11. Plotting results 4 clusters.

The results of clustering using four clusters show that there are only a few customer data that have intersections with other groups. Therefore, it can be concluded that four clusters are the most optimal number. Fig. 12 shows the result of grouping customers on test data.

Fig. 12. Test data clustering.

This test step used training data and test data, each of which had a composition of 80% and 20%, respectively. The training data was used to build a clustering model, which was then applied to the test data. Clustering results on the test data also provide a good grouping of customers. There are clear differences between clusters, and only a few customers occur in cluster slices, especially in groups 3 and 4, which have more slices than the others.

4) Clustering result interpretation: Fig. 13 shows that the smaller the score, the better it is for the customer who has the most recent activity on their savings. Cluster 3 is the group where most customers carry out updates on savings data, followed by cluster 1. Clusters 2 and 4 are customer groups whose average is not too updated on savings activity, but cluster 2 is less updated than cluster 4. This can be an important record for the collectibility process. Fig. 14 shows a plot between the score_monetary_monthly_credit variable and the clustering results.

Fig. 13. Plotting variabel score_recency_tabungan and cluster.

Fig. 14. Plotting variable score_monetary_monthly_credit and cluster.

This variable measures the average amount of money that comes out of the bank account of a customer each month. The higher the variable score, the higher the amount of money coming out of the customer's account. Cluster 3 is the group of customers who withdraw money from large nominal accounts, followed by cluster 4. Cluster 1 has an average score of 1 and a portion of the score 2. Cluster 2 has most customers in score 1, followed by score 2. Fig. 15 shows a plot of the variable score_monetary_current_balance and the clustering results.

Fig. 15. Plotting variable score_monetary current balance and clusters.

The plotting results show that cluster 3 has the largest current account balance, followed by cluster 1. Meanwhile, cluster 4 has the average account balance, and cluster 2 has the smallest current balance.

The analysis that has been done can be summarized in Table XII, which ranks each variable.

TABLE XII. CONCLUSION OF CLUSTERING RESULTS ANALYSIS

Variable	Analysis
Score_recency_tabungan	The most frequent sequence of activities on savings is cluster 3, 1, 4, 2
Score_monetary_monthly_credit	The order of the most money from the account is cluster 3, 4, 1, 2
Score_monetary_current_balance	The current balance order of lots is clusters 3, 2, 1, 4
Score_frequency_credit	The order of the frequency of cash out is cluster 4, 2, 3, 1

Score_recency_sender_transaction	The sequence of most outgoing transaction updates is cluster 1, 3, 2, 4
Score_monetary_sender_transaction	The order of the most outgoing transactions is cluster 4, 3, 2, 1
Score_monetary_sender_transaction_desc_taspen	The order of the most outgoing transactions for pension funds is cluster 4, 1, 3, 2
Score_recency_receiver_transaction	The most updated sequence of incoming transactions is cluster 3, 1, 2, 4
Score_frequency_receiver_transaction	The order of the most incoming transactions is cluster 3, 1, 4, 2
Score_monetary_receiver_transaction	The order of the largest nominal incoming transactions is 3, 4, 2, 1

Based on the analysis of each score variable in the table above, it can be concluded that there is no dominant cluster that always ranks first, and the results are quite dynamic. The determination of cluster priority uses a point system, with each variable carrying the same weight.

The rule is that the first rank will receive the most points, and the lower the rank, the lower the points will be. Each rank starting from the first rank will receive 5, 3, 2, and 1 point. Table XIII provides detailed results of the point calculations for each score variable in the cluster.

TABLE XIII. CALCULATION OF POINT FOR EACH SCORE CLUSTER VARIABLES

Name of Variables	Point			
	Cluster 1	Cluster 2	Cluster 3	Cluster 4
Score_recency_tabungan	3	1	5	2
Score_monetary_monthly_credit	2	1	5	3
Score_monetary_current_balance	2	3	5	1
Score_frequency_credit	1	3	2	5
Score_recency_sender_transaction	5	2	3	1
Score_monetary_sender_transaction	1	2	3	5
Score_monetary_sender_transaction_desc_taspen	3	1	2	5
Score_recency_receiver_transaction	3	2	5	1
Score_frequency_receiver_transaction	3	1	5	2
Score_monetary_receiver_transaction	1	2	5	3
Total Point	24	18	40	28

Based on the results of the point calculation shown in Table XIII, we can conclude the priority of cluster collectibility, which is as follows:

- Cluster 2 is a group of customers with very low scores in activity, frequency, and nominal transactions of money going out or coming in. Additionally, most customers have very low balances. Therefore, this cluster is the priority in the collectibility process due to the high potential for default.
- Cluster 1 is a group of customers with infrequent activity, the majority of whom have low balances, and the nominal amount and frequency of incoming money are also quite low. Therefore, this customer group is the second priority for the collectibility process because of its high potential for default.
- Cluster 4 is a group of customers with average savings activity, average cash-out transactions, most sufficient balances, and the largest outgoing transactions. Therefore, this group is included in the medium category, meaning that the potential for default is quite small.
- Cluster 3 has many groups of customers with new activities. Most customers have the largest balances, the most updated incoming money activity with the highest frequency, and the largest total nominal value. Therefore, this group is the one with the least potential for default.

V. CONCLUSION

The RFM Model can effectively form the score variable, allowing for an efficient clustering process using K-Means. The resulting cluster interpretation is easy and can provide solutions to problems. By implementing the Calinski-Harabasz index, the number of clusters used can be evaluated. This is an initial step towards determining the optimal number of clusters for the financial industry in banking data. The K-Means clustering results in well-formed groups, with significant customer grouping and no overlap between clusters. The resulting customer grouping can be useful for the financial industry in the process of collecting credit customers.

The next step in this study is to include additional variables, such as credit limits and credit card transactions, to provide payment options. The limitation of this approach is the lack of a Customer Relation Management system, which could provide a better understanding of customer perspectives, describe customer value, and improve the selling or cross-selling of various banking products and programs.

Challenges of Digital Twin Technologies Integration in Modular Construction: A Case from a Manufacturer's Perspective

Laith Jamal Aldabbas 

Al-Ahliyya Amman University, Amman, Jordan

Abstract—Automated models of physical objects are known as Digital twins; letting one to outline, test, array, and monitor and manage robotics in the real world. .CPS (Cyber-physical system) data have to be assembled through real life procedures to form a real-time monitoring cyber model in order to produce Digital Twin. Modification in the cyber model will be shown in real life system to guess or manage. As a result of digital and the progression in ICT, manufacturing and aviation or aerospace industries are now utilizing digital twin. Nonetheless, the uses of DT's in several production firms have not been researched massively. Those studies were sparse in construction, where structures are built without Superstructures, which thus sparked global concern. Herein, DT applications in building/manufacturing sector and in various firms were reviewed first and thereafter aimed on publications concerning DT applications in industry area by organizing a systematic search via Scopus. Notably, the publications were singled out immediately after the assessment of the publications and the study continues to investigate and evaluate the Potentials of digital twins in MIC, Restriction of digital twins in MIC, Impact of digital twins on industry, and Cost of time which should be appropriate for model development. The analysis report however demonstrated that DT is dedicated and thoughtful of in midst of inclusion along other digital technologies. More so, theoretical structure is formed in order to apply DT in module installation in MiC around the circumstances of Hong Kong which happens to be usual city case of high-density. Interestingly, the implementation of Digital twin in Modular Integrated Construction is expected to provide promising potential with significant benefits, such as improved logistics and manufacturing management by employing Digital Twins to track on-site progress during module installation.

Keyword—Digital Twin; DTs; enabling technologies; digital twin model; applications; challenges; literature review

I. INTRODUCTION

Digital twin is subjected to intensive scrutiny. Both the Digital Model and the Digital Shadow identifies an infrastructure relationship between digital and physical components that is either unequal or unidentified [1]. A self-contained digital data structure that is related to a physical system is referred to as a DT. This information would be a "twin" of the raw document that was stored electronically in the physical system and was related to throughout its existence. According to the findings of [2] the term "Digital Twin" has been utilised to signify a variety of different numerical and physical links. Integration can be improved

with the help of a DT by evaluating and reviewing the status of both physical and digital elements simultaneously.

This article examines the most recent developments in digital technology, information technology, and digital twins, as well as the influence such developments have had on the industry. Secondly, it places an emphasis on the integration of Digital Twin technologies with BIM; which is the most recent digital technology that is supported whilst WSN and internet of things was talked about as well. Third, the article discusses the benefits of utilising Digital Twin technology as well as the challenges that must be overcome prior to its widespread adoption in the industrial industry. Implementation of DT in manufacturing area and in various firms was reviewed and aimed on publications concerning DT Implementation in industry area by performing a systematic search via Scopus. As soon as the reviewing publication procedure and evaluation were filtered out, the paper propels in examining and evaluating the potentials of digital twins in MIC, Restriction of digital twins in MIC, Impact of digital twins on industry, and Cost of time which should be appropriate for model development. The findings however unveiled DT to be esteemed with other digital technologies for inclusion.

A. Hong Kong Scenario

Manufacturing is the intended application for the suggested digital twin technology architecture in MIC modules [3]. The implementation of digital twin technologies in manufacturing presents a number of opportunities and advantages [4]. Economic growth and social advancement has been sustained by the construction industries in Hong Kong. It has added about 4.5% of Gross Domestic Product (GDP), 2018 [5]. Yet the industries continue to experience hard challenges, for instance, aging workforce, labour shortage and cost inflation [6]. Thus, it was announced within 2017 and 2018 by Policy Address of Government of Hong Kong Special Administrative Region (HKSAR) for government to welcome and propagate MiC in civil works firms [7,8].

In contrast to normal construction methods, MiC has distinguished its abilities whereby a huge of on-site works is relocated to an industry to produce modules. Building services, architectural works and structural works of modules were partly achieved, thereafter, accompanied by module transportation to construction site for coupling and installation. Thus, many MiC utilized projects has begun so as to propel its notable acceptance in Hong Kong.

B. Research Gaps and Future Motivation

This study is built through the previous literature on digital twins and modular integrated construction. It is important to start the study by examining the literature and finding out the research gaps. On the bases of the literature, the following research gaps have to be addressed.

- 1) Potential of digital twins in MIC.
- 2) Restriction of digital twins in MIC.
- 3) Impact of digital twins on industry.
- 4) Cost of time should be appropriate for model development.

C. Literature Review

Notably, the term "digital twin" (DT) was first defined by NASA in their Technology Roadmap in the year 2010; referred to as an integrated multi-physics, multi-scale, probabilistic simulation of in-built vehicle or framework which utilizes a better suitable real life models, sensor updates, fleet history, etc., to reflect the life of its proportional flying twin [9]. Around 2015, the idea of DT was attuned as composing a generic 'product,' other industries, including manufacturing, industrial engineering, and informatics, began to employ it as part of their business operations. DT thus stands for "design thinking" [10].

Consequently, DT applies to all phases that has to do with product existence and not solely to give out a depiction of the actual product [11][12]. The following is an example of a general definition of DT provided by [13] in the year 2012, and widely acknowledged and utilised Digital twin refers to "an integrated multi-physics, multi-scale, probabilistic simulation of a complex product". This simulation uses the most recent and accurate physical models, sensor readings, and other data to "mirror" the life of the product's "matching twin." A real-time reflection is one of the characteristics that help to define DT, and its definition also sheds light on this characteristic [14]. DT makes it possible for information about the real space to be studied in the physical world in a manner that is accurate and up to date while maintaining a high level of synchronisation and precision. The capability of DT to evolve on its own is also an essential feature of the methodology. In contrast to the actual and virtual worlds, the model used in the virtual environment is susceptible to continuous alterations made in real-time [15].

II. RESEARCH METHODOLOGY

This paper adopts a systematic literature review to highlight opportunities and restrictions in implementing digital twin technology in building projects. The research necessary material used in investigation was gotten via academic search engine database such as Google scholar, science direct, and academia. The analysis focused on the most recent 12 years' worth of publishing, extending from 2010 to 2022. The database allows users to modify the settings for how searches are performed. The search approach had electronic databases of Scopus. The search phrases "digital twin in construction," "semantic web," or "MIC" were used to rectify the

breakthroughs in the scope of research. The initial search suggested that 6890 papers were published on digital twin applications, out of which 4490 were published since 2019. Although much research has been published on digital twins, the authors further confined the search to journal and conference articles only in the "civil engineering domain" via Google scholar, science direct, and academia. More so, with deep investigation of the paper's abstract from the improved search, about 58 manuscripts for the systematic review analysis were realized. Reports were utilized as references from government and non-government organisations to assist the triangulation of the literature that was done in this study.

III. RESEARCH PROGRESSED

A. Examining Current Procedures

The most recent search of manuscripts through Scopus' digital libraries took place in May 2022. In the initial investigation, all papers were subjected to the selection criteria outlined in Section III. A total of 54 publications were called for further examination, after checking the headlines, titles, synopsis, and primary contents of filtered publications, a total of 19 articles were found. All of the publications found in line with DT usage in the civil works industry [16]. The first essay on the subject was published in 2018 the Journal articles and conference papers were evenly distributed among the selected publications. Fig. 1 depicts the disruption in publication timing and format of the recognized publications.

Three of the papers found looked at the use of DT not just during the building phase, however throughout the cycle of the project from inception to operation and maintenance. One of the goals of the DT application is to automate job planning and scheduling. Real-time data collection from a construction site allows for monitoring and appraisal of construction performance [17]. One study generated DT of a type of machinery to reduce production time and cost while other study formed DT as a type of construction tool for simulation to lessen manufacturing time and cost. Fig. 2 shows an outline of the various aims of DT applications spotted in publications.

Fig. 1. Time of publishing and types of articles detected as of May 2022.

Fig. 2. An outline of the prospects for DT application within researched articles.

Fig. 3. Frequency with which DTs are published.

The number of articles with the keyword digital twins is 32 while, integrated modular construction related are nine articles. 15 studies cited "Building Information Modelling (BIM)," with 10 employing DT as an evolutionary representation and five considering the BIM system as DT. Only one article discusses "Wireless Sensor Network" (WSN) in connection with IoT for real-time data transfer. Three publications mentioned "cloud platform" for storing, analysing, processing, and combining data. Three publications reference "machine learning" for self-learning DT. Augmented and Virtual Reality can benefit from Digital Twins since they give immersive aim for viewing historical and real-time data [18]. Fig. 3 illustrates how often Digital twins, Modular construction, blockchain, BIM, IoT/sensor, WSN, cloud platform, machine learning, AR, and VR were referenced.

IV. FINDINGS

A comprehensive study was conducted to identify and synthesize the primary procedures for collecting, transmitting, modeling, integrating data, service for digital twin

technologies (Table I) (Fig. 4). Section 4A discusses the pros and difficulties associated with digital twins.

A. Assessing Digital Twin Applications

1) *Potential of the applications:* Digital twins aid in disaster preparation and asset management. Digital twin models help stakeholders comprehend obstacles and constraints, such as predicting the status of a physical asset, forecasting energy usage while preserving environmental norms, and monitoring structural infrastructure health. AI algorithms and data analytics help digital twin models forecast or back cast. The future status of an asset may be compared to the intended state. Digital twins help stakeholders choose low-carbon, clean-energy designs. Iterative design methods can promote generative design while addressing cost, schedule, and environmental benefits. Real-time data updates monitor construction workers for body segment hazards. Real-time reports on installation activity are needed in dangerous regions like nuclear power plants to protect personnel and limit human intervention. Digital twin models use data like population preferences and material usage priorities for urban planning and design. Using citizen or end-user data, digital twin models could connect people to buildings/cities.

Fig. 4. Bar chart for the findings.

TABLE I. DIGITAL TECHNOLOGY USAGE AND ESTABLISHMENT

Data acquisition	Data transmission	Digital modeling	Data/model integration	Service/objective	Reference
Sensors, RFID	Internet	Geometric model (3D)	Virtual platform	Simulation model	[19]
GIS, BIM data	Internet	CIMs, BIMs	Cloud computing	Controlling and monitoring physical site	[20]
Real-time sensor	Internet	BIMs	Data analysis	Detection of maintenance and operation	[21]
Geospatial dataset	Internet	BIMs	Big data	Simulation for urban	[22]
IOT sensor	Internet	Thermography map	Machine learning algorithm	Renovations for energy planning	[23]

2) *Restriction of digital twins in MIC*: Herein, some of DT challenges cannot be overlooked. According to the literature, data integration is vital to link digital twin to physical assets. Surprisingly, integrating data from different technologies is difficult. DT data is housed in various systems which make it hard to compare with machines, for instance the heterogeneous data source. Data base terminology varies by system and maintaining feedback loops requires data synchronising. Extraction or modification of data reduces quality. DT requires real-time data transfer, which is expensive and time consuming. Digital twin models are subject to digital threats; therefore, data security and privacy is crucial [24]. Digital twins need uniform data transmission and sharing standards. Sensor installation and maintenance rarely concern construction personnel. Construction sensors can be stolen. These devices must save, filter, and match data with BIM models. Construction assets need lifecycle maintenance to survive decades. Construction is complicated and involves many stakeholders. Thus all project members must work together. Multiple stakeholders may impede asset and digital twin model building. Digital twins require experienced builders, money, and high-powered technologies.

3) *Impact of digital twins on industry*: A digital twin assists the production companies to grow its productivity, pliability and capability. They also improve on efficiencies without undermining the involvement of human by utilizing data-driven decision-making. Production system upgraded by digital simulation can be both cost and time-effective. Most institutions reproduce as well as examine every detail of production before it starts [25]. Manufacturers have the tendency to investigate unlike materials, colours and textures preliminary to production along visualization tools. Using a digital twin gives a better blueprint and tool of implementation to construct synthetic scenarios that are useful as tools for training and management continuation. These provide one with clarity to operate machines, systems and processes. Technically, it functions as a communication tool as it enhances the identification of variables one would like to observe. More so, digital twin can foretell about the state of the future of its real life counterpart. It has the ability to bring about what-if scenarios that are dangerous or cost-prohibitive in reality. This system can be perturbed to create unexpected scenarios and examine the system's response and the appropriate mitigation techniques. A digital twin is the only way to do this examination without putting the real asset at risk. Transparency can be improved by making real-time information available and automating the reporting process [26].

4) *Cost of time should be appropriate for model development*: To ensure the viability and acceptance of technology developments in building, the underlying causes must be effectively addressed. Low productivity, bad industrial image, low predictability, structural fragmentation,

and lack of Research and development (R&D) and investment in innovation are some of the industry's issues affecting the construction sector; however investment in DT can help alleviate some of them [27]. Digital twins require experienced builders, money, and high-powered technologies.

Once the DT requirement is acknowledged, the initial building pace of the digital twin is generally achieved already, as these demands serve as the basis for determining which programs should be utilized, what platforms are necessary, how much it would cost, and how difficult the digital twin will be. Time and money can be saved, as no processes have to occur physically for the identification to take place; it is known ahead of time what works and what doesn't. Money can be realized first via time; time is not returnable or stored, and by optimizing the relevant model, money is automatically saved. Obviously, several producing companies have only defined capacity of machine, and every job needs to be scheduled within the scope of the machine. Interestingly, through the use of digital twin, companies like mentioned above can pre-schedule their jobs to perfect the use of money and thus optimise the availability of time to be proportional with the mode; growth as much as possible. Notably, as time turn out to be sole driver, costs are diminished as hourly rates stand the same [28].

V. CONCLUSION

This paper gives the outline of academic publications connected to DT applications within industries, specifically in the building/manufacturing industry. The purpose of this paper is to evaluate the potential and restrictions of Digital twin integration for MiC. Through literature review, a total of 19 articles were found. All of the publications found are connected to the use of DT in the building construction industry. The primary goal of DT is to enable the manufacturing process to be optimized by incorporating seized time-sensitive information for efficient tracking. Additionally, it aims to incorporate flexibility and customization in all production methodologies and variables while maintaining complete authority. In cause of the literature gap findings, we were able to lay emphasis on Potential of digital twins in MIC, Restriction of digital twins in MIC, Impact of digital twins on industry, and Cost of time which should be appropriate for model development.

However, in the future, the applications for digital twins should be thoughtful of upcoming literature review and meta-analysis of publications on DT applications in the manufacturing area through more electronic databases; have collaboration in middle of the stakeholders to guarantee that the appropriate amount of time is spent on model development. Construction industry should primarily emphasize on the education and growth of qualified personnel, particularly for digital twin applications. During the decision-making process, the linked parties should also consider the matter of budget planning as well as to centre on group discussion or meetings with academics and practitioners in the areas of DT and modular building.

ACKNOWLEDGMENT

SuffixAligner: A Python-based Aligner for Long Noisy Reads

Zeinab Rabea^{1*}, Sara El-Metwally^{2*}, Samir Elmougy^{3*}, M. Z. Rashad^{4*}

Computer Science Department, Faculty of Computers and Information, Mansoura University, Mansoura 35516, Egypt

Abstract—Third-generation sequencing technologies have revolutionized genomics research by generating long reads that resolve many computational challenges such as long genomics variations and repeats. Mapping a set of sequencing reads against a reference genome is the first step of many genomic data analysis pipelines. Many mapping/alignment tools are introduced and always made different compromises between the alignment accuracy and the resource usage in terms of memory space and processor speed. SuffixAligner is a python-based aligner for long noisy reads generated from third-generation sequencing machines. SuffixAligner follows the seed extending approach and exploits the nature of the biological alphabet that has a fixed size and a predefined lexical ordering to construct a suffix array for indexing a reference genome. A suffix array is used to efficiently search the indexed reference and locate the exactly matched seeds among the reads and the reference. The matched seeds are arranged into windows/clusters and the ones with the maximum number of seeds are reported as candidates for mapping positions. Using real data sets from third-generation sequencing experiments, we evaluated SuffixAligner against lordFAST, BWA, GEM3, and Minimap2, in which the results showed that SuffixAligner mapped more reads compared to the other compared tools. The source code of SuffixAligner is available at: <https://github.com/ZeinabRabea/SuffixAligner>.

Keywords—Long reads sequencing; reads mapping; suffix array; alignment; seed extending; LF mapping

I. INTRODUCTION

Sequencing machines have generated a flood of biological data known as reads. They have revolutionized over three generations of technologies that play a key role in the data volume, read length and accuracy, sequencing cost, and speed. Third-generation sequencing technologies, such as Pacific Biosciences (PacBio) and Oxford Nanopore, produce a high throughput of longer reads with higher error rates than Illumina sequencing machines' short reads [1]. Reads mapping/alignment is the cornerstone in any sequence analysis pipeline and implies finding the nearly matched locations of each read in the reference genome/transcriptome tolerating the mismatches due to sequencing biases and errors. Since the reads mapping/alignment is a complex and resources intensive process, efficient algorithms and data structures are introduced to complete it reasonably [2-4].

Mapping algorithms utilize two data structures: hash tables and suffix/prefix tries to handle the long reads generated from the third-generation sequencing machines [5]. The seed and extended approach are used in most sequence aligners and rely on extracting a set of matched seeds among the reference and read and index them in a hash table [6]. Then, the seeds are

extended to find the optimal gapless alignment. Examples of tools that utilize hash tables for indexing a set of seeds are [7] Blast [8], NanoBLASTER [9], LAST [10], and Minimap [11, 12]. Suffix tires based algorithms divide the mapping problem into two steps: 1) finding an exact match between the database and the query read using one of the suffixes stored in suffixes tries, and 2) grouping these hits of exact matches to create the final inexact alignment [13].

Genome indexing is the first step in any mapping data analysis framework in which it aims search quickly and efficiently the reference genome for matching patterns (i.e., reads). Many efficient data structures are introduced to build an index for a reference genome, such as suffix arrays [14, 15], hash tables [16], suffix trees [17], and bloom filters [18]. There is no standard procedure for creating the optimal index file; this depends on how the information is organized and how he intends to access it. The second step is the mapping/alignment process that uses the genome indexing to query the reference and search for the reads and align it to nearly matched locations in the genome[19].

In this paper, we introduce SuffixAligner as a long-read aligner that utilizes a modified version of the suffix array construction algorithm for limited-size alphabets such as DNA/RNA and exploits the nature of their corresponding lexicographical ordering. Suffix array is used in the reference indexing stage to compute Burrows–Wheeler transforms. Reads mapping stage follows the seed and extends approach by extracting a set of matched hits called k -mers among reads and the indexed reference. These k -mers are used as seeds to find long stretches of matches extended in both directions of the sequencing read. The regions between the matched seeds among reads and the reference are aligned using dynamic programming approach.

This paper is organized as follows: Section II demonstrates a previously related work, Section III presents the methodology behind the SuffixAligner and describes its three basic stages, Section IV evaluates the SuffixAligner alignment results against four benchmarking alignment tools using two real datasets, and Section V concludes our paper and provides some future insights.

II. LITERATURE REVIEW

Suffix array plays a key role in indexing large-scale genomes and most aligners that dominate the bioinformatics field rely on suffix array and its enhanced versions to complete the mapping/alignment task [20]. It is a list of indexes corresponding to the sorted suffixes of a given sequence in the

lexical order. Its construction algorithm is a resource-expensive process, in which there is always a trade-off between the algorithm running time and its memory usage. Most of the suffix array construction approaches for indexing a reference genome/transcriptome should consider that the sequencing bases have a limited size alphabet (i.e. four letters of DNA/RNA alphabets) and utilize the existing integer-based method for suffix array construction and manipulation [21, 22]. Examples of mapping algorithms that rely on suffix arrays for indexing and searching a reference genome are Bowtie [23], BWA [24], GEM3 [25], and lordFAST [26] (see Table I). The Burrows–Wheeler (BWT) transform is a cornerstone in many alignment/mapping tools developed for short reads and extended to long-read sequencing data. Burrows–Wheeler transform can also be generated from a suffix array and is used to build a compressed and efficient version of a reference genome [27].

TABLE I. DESCRIPTION OF BENCHMARKING ALIGNMENT TOOLS: BWA, GEM3, LORDFAST, AND MINIMAP2

Aligner	Description	Ref
BWA	BWA is based on the FM-index and utilizes the seed-and-extend approach for reads mapping. BWA has three different algorithms: <ul style="list-style-type: none"> • BWA-backtrack (Illumina short sequencing read) • BWA-SW (long reads ranging from 70bp to 1Mbp) • BWA-MEM(long reads ranging from 70bp to 1Mbp) 	[24]
GEM3	GEM3 is based on the FM-index. Best results are produced when the read length up to 1k bases. GEM3 uses a Multithread mode to speed up the running time	[25]
lordFAST	LordFAST is based on the FM-index and utilizes the seed-and-extend approach for reads mapping	[26]
Minimap2	Minimap2 collects the minimizers from the reference and indexes them into a hash table using a locally sensitive hashing technique. It utilizes the seed-and-extend approach for reads mapping. The total length of all reads should not exceed the 2 billion bases	[11, 12]

III. METHOD

SuffixAligner is designated for reads generated by third-generation sequencing machines. It aims to find the ideal location for each read in the indexed reference genome using a suffix array. SuffixAligner has three stages: 1) Finding the matched seeds between the genome and read, 2) Determining the part of the genome with a large number of seeds (identifying a matching window), 3) Using Needleman [28] algorithm to align the regions between the matched seeds (see Fig.1).

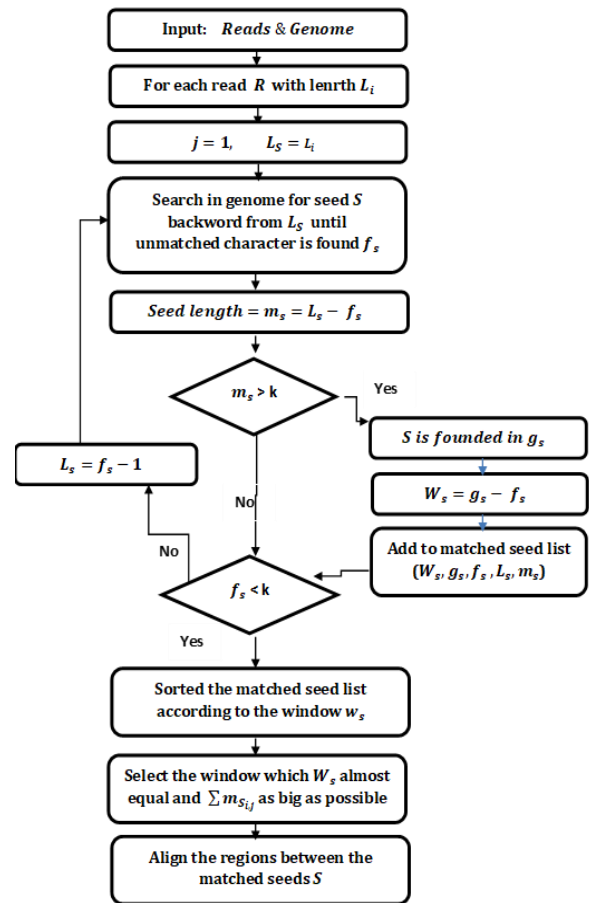

Fig. 1. The SuffixAligner proposed approach for mapping long noisy reads.

The reference genome should be indexed first to compute the matched seeds among reads and the reference genome. In the genome indexing stage, SuffixAligner relies on a suffix array construction algorithm proposed in [29] and exploits the nature of biological sequencing data alphabets such as DNA/RNA as it has limited size letters with a pre-defined lexicographical order. The suffix array is constructed for DNA alphabets incrementally, knowing that there are only four letters with the pre-defined sorted order {A, C, G, T}. Each portion of the suffix array will correspond to the set of indexes starting with one of the DNA alphabets and will be used as a seed to compute the next portion corresponding to the next DNA alphabet in the lexical order. The Burrows–Wheeler transform is constructed from the computed suffix array and represents a compressed version of the indexed reference genome. This paper applies the Last-to-First Mapping (LF-array), a mapping function from the last column of the Burrows–Wheeler Matrix (BWM), to the first column of the BWM. To compute LF-array easily and efficiently, BWT is extracted from the last column of BWM. Also, the first column (F_c) is an alphabetical arrangement of the elements of BWT. Instead of storing the first column of BWM, the frequency of each DNA alphabet in BWT is computed along with its start index in BWT. The LF-array is calculated by adding the rank of each DNA alphabet with its starting index (see Fig. 2). LF-array efficiently searches the reference genome for the exact matches (seeds) extracted from the sequencing reads.

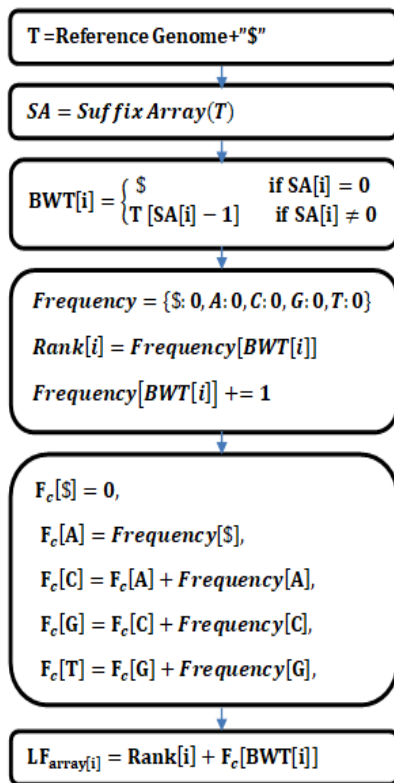

Fig. 2. The Last-to-first mapping (LF-array) computation from the burrows-wheeler transform.

The search starts from the read ending position towards the starting position and stops when mismatches occur. A list of matching seeds between the read and the reference genome, where the seed length of more than 10bp is considered as a valid matched seed. The list contains the starting position f_s of each matched seed in the reference genome g_s , and the ending position l_s and the seed length is m_s which equals $m_s = l_s - f_s$. The starting position of the expected mapping window of each seed is determined by $w_s = g_s - f_s$. The list of matched seeds is sorted according to the window w_s . The optimal window for mapping the read against a reference genome will be chosen according to the total number of matched seeds in the window. The window with the largest number of seeds will be selected. The regions between the matched seeds in the selected window are aligned using a dynamic programming method such as Needleman algorithm.

IV. EXPERIMENTATIONS AND RESULTS

In this paper, we evaluate the four alignment tools: BWA (bwa-0.7.17) [30], GEM3 [25], lordFAST[26], and Minimap2 [11] against our proposed SuffixAligner using real datasets generated by MinION Oxford Nanopore sequencing technology from two different bacterial strains: Flavobacterium columnare and Aeromonas veronii (see Table II).

We measured the quality of alignment by measuring the alignment rate [31]. The alignment rate is calculated by dividing the number of mapped reads by the total number of reads. Samtools [32] analyzed the SAM files and reports the total number of primary and secondary alignments produced by

alignment tools. When a read maps ambiguously to multiple locations, only one of the read alignments is considered as the primary one, and the others are reported as secondary alignments. Supplementary reads are those in which parts of the reads match one location in the genome while other parts match another and often appear in long reads. All the experiments in this work were conducted on a workstation running on Ubuntu Linux with a 3.70 GHz Intel(R) Xeon(R) CPU E5-1620 v2 processor, 64 GB of RAM, and 128 GB SDD hard disk.

TABLE II. CHARACTERISTICS OF THE DATA SET USED EXPERIMENTS

Genome Name	Flavobacterium Columnare	Aeromonas Veronii
Genome Length	3221278	4559061
NCBI	txid996	txid654
Sequencing runs	SRR7449868	SRR7449790
Number Of reads	1142	3994
Number Of Bases	146.1M	644.5M
Max length in reads	62330	53937
Min length in reads	284	279

We evaluated the alignment rate of BWA, GEM3, lordFAST, Minimap2, and SuffixAligner for the real Oxford Nanopore sequencing runs SRR7449868 and SRR7449790. The characteristics of the dataset are shown in Table I. As shown in this table, SuffixAligner has the best Alignment rate. It primary mapped 94% of the total number of reads in the run SRR7449868 of the Flavobacterium columnare reference genome and primary mapped 90% of the total number of reads in the run SRR7449790 of Aeromonas veronii reference genome.

SuffixAligner searches for a one room for every read compared to a reference genome. It considers every read's best mapping position and ignores the other mapping locations. It neglects the secondary and supplementary mapping locations mapped reads (Tables III and IV).

Fig. 3 shows the total number of mapped reads with lengths less than 500bp and greater than 8000bp in the case of the sequencing run SRR7449868. For reads with lengths less than 1000bp, SuffixAligner mapped more reads than other alignment tools; the best results are produced by SuffixAligner, BWA, GEM3, and Minimap2 sequentially. lordFAST ignores reads with lengths less than 1000bp. For reads with lengths greater than 1000bp, SuffixAligner and lordFAST have approximately the same alignment rate then BWA, Minimap2, and GEM3 sequentially.

Fig. 4 shows the total number of mapped reads with lengths less than 500bp and greater than 8000bp in the case of the sequencing run SRR7449790. For reads with lengths less than 1000bp, SuffixAligner mapped more reads than other alignment tools, and the best results are produced by SuffixAligner, BWA, GEM3, and Minimap2 sequentially. lordFAST ignores the reads with lengths less than 1000bp. lordFAST has the best alignment rate with reads lengths between 1000bp and 2000bp, while the SuffixAligner has the best alignment rate with other reads lengths.

TABLE III. EVALUATION OF BWA, GEM3, LORDFAST, MINIMAP2, AND SUFFIXALIGNER ON SEQUENCING RUN SRR7449868 (TOTAL NUMBER OF BASES IS 146.1M)

Metrics Tools	Total	Supplementary	Secondary	Primary	Total mapped		Primary mapped			Primary unmapped		
	#	#	#	#	#	%	#	Bases(kb)	%	#	Bases(Kb)	%
BWA	1325	183	0	1142	1222	92%	1039	4027.29	91%	103	87.88	9%
GEM3	1142	0	0	1142	1004	88%	1004	3999.73	88%	138	115.44	12%
lordFAST	1490	126	222	1142	820	55%	472	3723.04	41%	670	392.13	59%
Minimap2	1518	137	239	1142	1368	90%	992	3998.42	87%	150	116.76	13%
SuffixAligner	1142	0	0	1142	1074	94%	1074	4072.21	94%	68	42.96	6%

TABLE IV. EVALUATION OF BWA, GEM3, LORDFAST, MINIMAP2, AND SUFFIXALIGNER ON SEQUENCING RUN SRR7449790 (TOTAL NUMBER OF BASES IS 644.5M)

Metrics Tools	Total	Supplementary	Secondary	Primary	Total mapped		Primary mapped			Primary unmapped		
	#	#	#	#	#	%	#	Bases(kb)	%	#	Bases(Kb)	%
BWA	1325	183	0	1142	1222	92%	1039	4027.29	91%	103	87.88	9%
GEM3	1142	0	0	1142	1004	88%	1004	3999.73	88%	138	115.44	12%
lordFAST	1490	126	222	1142	820	55%	472	3723.04	41%	670	392.13	59%
Minimap2	1518	137	239	1142	1368	90%	992	3998.42	87%	150	116.76	13%
SuffixAligner	1142	0	0	1142	1074	94%	1074	4072.21	94%	68	42.96	6%

Fig. 3. The total number of mapped reads according to different read lengths in the real sequencing run (i.e., id SRR7449868) with the total number of reads equal to 1142.

Fig. 4. The total number of mapped reads according to different read lengths in the real sequencing run (i.e., id SRR7449790) with total number of reads equal to 3994.

SuffixAligner maps more reads than lordFAST, BWA, GEM3, and Minimap2 and has the best alignment rate. SuffixAligner and lordFAST have approximately the same alignment rate with the longest read lengths. Also, SuffixAligner maps short reads and reads with lengths greater than 8000bp.

V. CONCLUSIONS

In this paper, SuffixAligner is proposed for reads produced by third-generation sequencing machines such as PacBio and Oxford Nanopore. It relies on a specific type of suffix array constructed for the limited-size alphabets, such as the four-size alphabets of genomic data. It has three basic stages: indexing a reference genome using a suffix array, mapping a set of sequencing reads using the seed and extend approach, and

aligning the regions between the matched seeds using a dynamic programming approach. It mapped more reads compared to the other alignment tools and has the best alignment rate accordingly.

SuffixAligner has a long execution running time since it aligns one read at a time. So, as a future work, distributing the computation of mapping reads among different machines to increase the mapping speed and to reduce the memory usage on a single computing node. Also, SuffixAligner may be used to improve the alignment results by mapping only unmapped reads produced by another aligner.

Institute of Industrial Engineering and Management, Federal University of Itajuba (Unifei), Itabira, Brazil⁴

Abstract—This study presents a Systematic Literature Review on an agile project management tool. The study offers a brief comparison between traditional and agile project management methodologies. Their respective concepts and characteristics are laid out to highlight and explain their main differences. The agile methods include quantitative and qualitative data, showing Scrum framework characteristics. This study highlights the importance of project management in function of its emergence as a response to problems encountered during improperly conducted projects. Furthermore, this study provides relevant information for professionals in the Industrial Engineering area and computer science. The results allowed us to conclude that Scrum is an agile framework for empirical-based project development; it was developed in the 1990s by Jeff Sutherland. It is a flexible and adaptable methodology. Scrum research peaked in 2020, and continues to be studied, mainly in the field of computer science. Finally, Brazil is well-positioned in third place for works published.

Keywords—Project management; agile methods; agile manifesto; scrum

I. INTRODUCTION

Project Management (PM), as a practice, has grown rapidly worldwide, and is now globally recognized for its strategic competency for organizations [1]. Projects are employed to revamp business processes, support global customer-focused strategies, and coordinate information and decision-making flows across organizations [2].

PM is a set of management tools that allows a company to develop a set of skills, including individual knowledge and skills, all of which are aimed at controlling non-repetitive, unique and complex events, within a given time frame scenario, with predetermined costs and quality metrics [3].

Many projects are conducted improperly, and consequently, failures can occur. PM is a tool for conducting these projects successfully, without suffering losses. PM tools have been effective in achieving desired results within defined time frames and budgetary limitations within organizations. The author also states that PM is not only used for highly complex and costly large-scale projects [4].

Over the last decades, several design methods have been developed and adopted by project managers [5]. One is the Project Management Body of Knowledge Guide – (PMBOK®), which is the most influential book in the area [2]. The PMBOK® guide consists of standards that identify and conceptualize project management processes, knowledge areas, tools, and techniques [6].

The main PM methodologies can be classified as either traditional (predictive) or agile approaches. Traditional

approaches, for the most part, follow PMBOK® principles, while agile methods are based on the Agile Manifesto, which unites agile method principles and characteristics [7].

The Agile Manifesto was developed amid troubled projects, given dissatisfaction caused by high costs and long scope periods, where software developers needed to restructure project methodologies to focus on programming development and project testing. In 2001, seventeen software professionals, including developers and managers, met in Utah, where the Agile Alliance was created, to create the Agile Manifesto, to make software development lighter, more flexible, and cheaper [8, 9].

Agile project management seeks fast planning with active participation from the whole team and from customer stakeholders at all stages of the project. This is done by fostering an environment of collaboration among the whole team, and by rapidly integrating changes during the project life cycle [8, 10]. Focus and values are what set agile methodologies apart from traditional methodologies. Agile focuses on people, and not on processes or algorithms. Also, less time is spent on documentation, and more on implementation and success [11].

Of the many agile project management methodologies, there are Extreme Programming (XP) created by Beck and Cunningham in 1999 [7, 12]. It is a methodology for projects with requirements that change frequently, for projects that use object-oriented development, for teams comprising up to 12 developers, and for projects that use incremental development [13]. Scrum is another agile project management methodology created by Schwaber and Sutherland in 1990 [14]. It is suitable for companies that conduct product development in environments characterized by uncertainty, self-organization, moderate control, and knowledge transfers [15].

Another important tool is Lean software, which applies principles from the Toyota Production System for software development [16]. The Toyota Production System is a production philosophy created by a Japanese automaker that seeks to eliminate any production processes that do not add product value, or so-called waste [17]. The Kanban methodology, proposed by David J., is defined as a framework for incremental process and system improvements within organizations [18], and seeks to improve processes, teams, and projects. It is useful for companies that are constantly seeking to improve, while also improving productivity and their customer relationships [19].

Scrum is focused on teamwork, to improve communication and enhance cooperation among team members, resulting in increased future productivity. Furthermore, Scrum allows for

short-term problem solving, reduced project risks, greater customer participation throughout processes, and delivers more functional products or services more frequently [20].

Scrum is used in complex projects that cannot predict everything that will happen. This methodology offers a framework, since it is an aggregation of practices that promote visibility, so Scrum practitioners can see all project stages, make corrections, and offer improvements that keep the project moving forward by focusing on achieving the goals [21].

Some of the advantages of using this methodology are adaptability, transparency, continuous feedback, continuous improvement, and motivation [22]. The author in [22] applied Scrum for PM in the naval industry, and concluded that "the responses to problems were more agile, since problems identified in the previous day were discussed the next day in a quick meeting". The author in [11] also proved these advantages by applying this methodology to a tech startup, and by conducting a survey, wherein "most people highlighted visible management, which is a technique whereby controls, as to what is being done, are easily visible to everyone".

In this sense, the general objective of this study is to carry out a Systematic Literature Review on the agile Scrum methodology, which has been studied since the 1990s, and is still one of the main methodologies used in several areas.

This study is structured in five sections. The first section contextualizes the study. The second section presents a brief theoretical framework. The third section details the research methodology used here. The fourth section applies the SLR method. The fifth section analyses the results. The paper finishes with the conclusions, followed by the bibliographic references.

II. METHODOLOGY

A. Systematic Literature Review (SLR)

Literature Review (LR) is a very relevant method for researchers who analyze numerous fields of study [23]. Many articles use more descriptive LR models, and do not follow a systematic approach. One other method that is widely used in exploratory research is Systematic Literature Review (SLR). SLR develops guidelines, since it encompasses searching, selecting, critically evaluating, and creating synopses of primary research results [24]. The authors in [25] and [26] developed structures that contain the main SLR steps, to standardize SLR as a method, and to avoid distortions in the research and data analyses. The author in [27] executed a paper to gather the critical success factors of motivator and demotivator of agile software development.

SLR is a branch of LR, but SLR goes far beyond gathering and discussing important scientific works on a topic of interest. SLR seeks to verify what works, and what does not work, within a given context, using an explicitly presented bibliographic database, so reproducibility is possible. The search and selection parameters for articles, and the reason for the inclusion or exclusion of these parameters, are also explained, along with the limitations that are found in the articles, and in the review itself [28].

One relevant SLR point is its systematic methodology, which allows for necessary critical analysis in carrying out all stages of research. For the purposes of this study, the method applied in the article was based on [29], since it offered a more recent reference, and proposed a structure that fit well with this present study. The proposal consists of three stages, as follows:

- 1) *Planning the Review (The Preparation Stage);*
- 2) *Conducting the Review (The Operational Stage)*
- 3) *Documenting the Review (The Information Stage).*

The first step, i.e., planning the review, consists of two steps:

- a) *specifying the research question; and*
- b) *developing the review protocol.*

In the first step, research questions that are relevant to the subject being studied are defined to guide the next steps. Next, a standard is created to search for documents that will be used to answer the questions from the previous step.

The second step leading to the review is divided into five steps. The first three steps focus on defining the database that will be used to answer the research questions from the previous step. Researchers must apply review protocol (identifying relevant research). Next, the documents that do not address the subject will be excluded (selecting primary studies), and finally, the remaining documents will be studied in-depth, to decide which documents will comprise the SLR database (assessing the quality of the study). In the next steps, all the necessary data and information that will be useful in answering the research questions must be extracted from the documents and synthesized.

Finally, the third step, i.e., documenting the review, uses the information obtained in the previous steps to answer the questions outlined in the first step to complete the SLR.

III. METHOD APPLICATION

The SLR steps, as proposed by [29], will be described here, starting with planning the review.

A. Planning the Review (Preparation Stage)

According to [29] the first SLR stage deals with review planning. The authors mention two initial points that are important for prepping the review stage as: a) Specifying the research question; and b) Developing a research protocol.

The author in [30] was used as a basis for specifying the research questions. The authors propose interesting questions that can be answered using SLR. Thus, the guiding questions from [30], and the questions themselves were elaborated for this study.

Q1. How many Scrum publications are there per year? Q2. Who are the main authors writing on Scrum? Q3. What are the main countries publishing on Scrum? Q4. Who are the main publishers on Scrum? Q5. Which major universities publish on Scrum? Q6. What are the main areas studying Scrum? Q7. What is Scrum's history? Q8. How is Scrum defined? Q9. What are Scrum's principles? Q10. What are the Scrum steps? Q11. What are the Scrum elements? Q12. Is Scrum expensive?

Q13. Is Scrum complex? Q14. How is Scrum scoped? Q15. How are the teams structured? Q16. What is the role of the project manager in Scrum? Q17. What are the advantages of Scrum? Q18. What are the disadvantages of Scrum? Q19. What are the future directions for Scrum?

Table I was created based on the above research questions, creating SLR categories. This categorization was meant to simplify the analyses, by taking the number of questions previously established into account. Furthermore, the categorization will make it easier to describe the results later.

TABLE I. SEARCH CATEGORIES

State of the Arts	Questions	Nature of the Research	Questions
Articles per Year	Q1	General concepts	Q7, Q8, Q9
Top 5 Authors	Q2	Structure	Q10, Q11
Top 5 Countries	Q3	Work Mode	Q12, Q13, Q14
Top 5 Publication Sources	Q4	Time	Q15, Q16
Main Universities	Q5	Advantages and Disadvantages	Q17, Q18
Top 5 areas of Study	Q6	Future Study	Q19

As to the second point pointed out by the authors, which consists of developing a research protocol, the data in this study will be obtained via a systematic search, to obtain bibliographies relevant to the subject in question. The Scopus® database was selected because it stands out given the number of data available, the quality of its resources, and its ease of use. The author in [31] state that the Scopus® database is one of the main sources of data for citations.

A search was performed using the term “Scrum” in the Scopus database. Then filters were applied, like “open access”, “article type document”, “English and Portuguese”. There were no restrictions as to the year or area of study, for possible future comparisons.

After the initial planning, defining the research questions, and forming the data collection for this study, it was preceded to the next SLR stage, which is conducting the review.

B. Conducting the Review (Operational Stage)

This stage seeks to effectively conduct the research, and is an operational stage. The first two points established by [29], are to identify relevant research and to select the main studies. On April 28, 2021, it was made a search in the Scopus® database, as defined in the previous step, to develop these two sub-steps.

The term “Scrum” was searched for in the Scopus® database, searching only the title. 999 articles were returned from the database. Then it was applied filters like “open access”, “article type document”, and “English and Portuguese”, to narrow the search and focus in on the subject of interest. After applying these filters, 77 articles were found.

After applying the filters, it was moved on to the third step, which is evaluating the quality of the articles. This sub-step consists of conducting a more in-depth analysis of the articles,

to identify which articles really contain the characteristics that were seeking in this study. The articles were analyzed by the authors by reading the titles, the abstracts, and the keywords, to exclude any articles that were not relevant to this subject. At the end of this analysis, 50 articles remained for a full reading.

27 articles were excluded from the 77 articles by reading the abstracts and analyzing the theme. “SCRUM” was found to be an abbreviation for certain medical questions, e.g., “Scalp and Cranium Radiation Therapy Using Modulation”, or “Studying Concussions in the Rugby Union using MicroRNAs”, and also for school-related questions, like “School Clinical Rugby Measure”, along with articles that relate scrum to Rugby, and these medical/sports-related works did not fit in this paper, so they were discarded.

After reading the articles, it was found that 9 articles did not include studies addressing Scrum for the following reasons:

- they did not present information about Scrum;
- they were no longer open access; or
- they were not found.

Therefore, they were removed from the analysis. Thus, the SLR focused on 41 articles to answer the research questions. Table II gives a summary of the filters that were used to select the 41 articles in this SLR.

TABLE II. SLR FILTERS

Database	Filter	Results
Scopus	Title: “Scrum”	999 documents
	Open access	≈ 198 documents
	Articles Only	≈ 89 articles
	English and Portuguese	77 articles
	Reading and Analyzing the Titles	50 articles
	Full read and analysis	41 articles

After defining the number of articles that would be included in the SLR, it was moved on to the analysis and extraction phases for the data necessary for answering the research questions detailed in the first stage. This sub-step consisted of the fourth point, as proposed by the SLR authors, i.e., extracting necessary data. Microsoft Excel® was used for the data extraction, and for future quantitative analyzes (Synthesizing the data), which will be presented in the next step of the method. After the analyses, it was moved on to the third SLR stage, which describes the conclusions and evidence.

C. Documenting the Review (Information Stage)

After the review step, the documentation review began, using information obtained from the previous steps to answer the research questions from the first step, and thereby complete the SLR. This stage sought to remove relevant information to answer the aforementioned research questions.

An Excel spreadsheet was developed, wherein the research questions were set in columns, and the selected articles in lines, so the information that might answer the research questions could be record. Furthermore, extra columns were added for

non a priori information. The complete list of articles from the systematic literature review of this article can be found by contacting the authors.

Finally, regarding the results and finishing the SLR, the next section presents these discussions in greater detail.

IV. ANALYZING THE RESULTS

The results analysis for this study focused on analyzing the two pillars of this study, as shown in Table II. The first pillar investigated the State of the Arts, providing information on publications according to year, the main authors, the publishers, the universities, etc. The second pillar focused on investigating the nature of research, by analyzing general concepts, the structure, the way of working, the team, etc. This analysis began with the State of the Arts.

It is worth mentioning that the analyses were based on reading the 41 articles related to Scrum, so the conclusions of this study refer to SLR, and not the extent of the topic in literature.

A. Analysis of the State of the Arts

Regarding the analysis on the State of the Arts, Q1 deals with the number of publications per year on Scrum. It is worth remembering that a time filter was not applied in this analysis, i.e., the data refers to the first and last publications on Scrum. Fig. 1 summarizes this and shows publications dealing with Scrum.

Fig. 1 shows that from the articles considered in the SLR, the first study published on Scrum was in 2010. Over the years the number of works on Scrum has oscillated, and the biggest growth was between 2018 and 2019. 2020 had the most publications, at 12 articles.

Fig. 1. Publications per year.

The next analysis dealt with the main authors on Scrum, responding Q2. The five most published authors in the database selected for this SLR are: Zada, I.; Vogelzang, J.; Shahzad, S.; Gandomani, T. J.; and Admiraal W. F. These authors have their names published in two articles. The other authors have only one published article. Thus, it was noted that no single author focused on the theme, but rather these authors were dispersed.

Regarding the question on the country of publication (Q3), publication sources (Q4), and universities (Q5), for the State of the Arts, it was decided to condense the data into a single table. The results for these three analyzes are shown together in Table III.

TABLE III. TOP 5 COUNTRIES

Top 5 Countries	Number of articles
Pakistan	6
The United States	5
Brazil	4
India	4
Australia	3

Table III shows that the main publishing country in the database was Pakistan, followed by the United States. Brazil was tied for third place along with India, at 4 articles, while Australia appeared last, with 3 articles.

Regarding the publishers (Q4) (Table IV), it was noticed that the number of publications was very close to each other. The International Journal of Advanced Computer Science and Applications came in first, with four publications on Scrum. Second was the International Journal of Advanced Trends in Computer Science and Engineering, with 3 articles. Three publications sources, the Bulletin of Electrical Engineering and Informatics, IFIP Advances in Information and Communication Technology, and Scientific Programming came in third place, with 2 articles each.

TABLE IV. TOP FIVE PUBLICATIONS

Top 5 Publications	Number of articles
International Journal of Advanced Computer Science and Applications	4
International Journal of Advanced Trends in Computer Science and Engineering	3
Bulletin of Electrical Engineering and Informatics	2
IFIP Advances in Information and Communication Technology	2
Scientific Programming	2

The main universities found with publications on the subject in question is presented in Table V. Regarding Q5, it can be seen that the largest number of publications was four papers published by Leiden University. The other universities published 2 articles per year. It is interesting to note that the Federal University of Itajuba was among these main universities with publications on Scrum. The study was from Breno Tavares, Carlos Eduardo Sanches, and Adler de Souza, entitled: Risk management in Scrum projects: A bibliometric study, published in 2017.

TABLE V. MAIN UNIVERSITIES

Main Universities	Number of articles
Leiden University	4
Greijdanus College	2
Federal University of Itajuba	2
University of Melbourne	2
Univerza v Ljubljani	2
Islamic Azad University	2
University of Peshawar	2
Kohat University of Science and Technology KUST	2
Universidad de Ciencias y Humanidades	2
Melbourne Graduate School of Education	2

The last analysis performed for the State of the Arts was identifying the main areas of study that use Scrum (Q6). The main areas of study that use Scrum are: Computer science; Math; Business, Management and Accounting; Engineering; Social Sciences. The main area of study was Computer Science, with 33 publications on Scrum, representing approximately 47% of the top 5 areas of study. This was followed by engineering, at 18 articles on the subject, representing approximately 25% of all publications among the 5 main areas of study. This was followed by Mathematics at 10 articles, Social Sciences at 6 articles, and Business, Management, and Accounting at 3 articles. Some articles were present in more than one area of study, so the total number of articles seems to be greater than the amount studied; however, this is due to the fact that the same article can address multiple areas.

In general, the SLR showed that Scrum was mentioned in literature for the first time in a 2010 in an article called "A teamwork model for understanding an agile team: A case study of a Scrum project [32]. Over time, the area has grown. 2020 had the most publications on the subject, at 12 articles related to Scrum.

Regarding the authors, five main authors had two publications on Scrum, which shows a non-centrality of the topic, considering that most authors had only one publication on the subject. Considering the analyses on the country of origin, Pakistan had the most published articles on the topic, and Brazil ranked third tied with India, with 4 articles on Scrum. Regarding the publication sources, the five main publication sources had similar publication numbers. The International Journal of Advanced Computer Science and Applications had the most publications, at 4 articles. Regarding the universities, the greatest number of publications was four articles by Leiden University, and the rest of results were homogenous, since no university had an expressive number of publications. Federal University of Itajuba was among the universities found in this study.

Finally, regarding the area of study, Computer Science had the most published articles on Scrum. It is interesting to note that this area was also responsible for starting Scrum, and this

trend continues to the present day. This was followed by Engineering, Mathematics, Social Sciences, and Business, Management, and Accounting, respectively.

B. Analysis of the Nature of the Research

Here will be described the observations and studies on the nature of the research, which was also divided into categories, as shown in Table I. First, it was intended to highlight information on the general Scrum concepts.

Questions Q7, Q8, and Q9 sought to understand the history, definitions, and principles of Scrum, respectively.

Regarding its history, the Scrum methodology was first developed in the 1990s, as a project management framework used in business and industry to manage complex projects, especially for software development [33].

Furthermore, [34] states that the term Scrum originates from Rugby (a team sport of intense physical contact), and refers to a powerful team of Rugby players, positioned specifically to win the ball. Scrum provides for ceremonies, roles, and artifacts to monitor progress, to adjust to changing circumstances, and to reflect on product quality.

Scrum was developed in 1993 by Jeffrey Sutherland at the Easel Corporation, to deliver quality software products in small time intervals known as sprints [35].

Regarding the definition of Scrum, according to [36], Scrum is a framework composed of functions performed by team members, artifacts in documentation, delivery standards, and events that consist of essential actions for communication and delivery for a product. The author in [37] add to this, and state that Scrum is an iterative and incremental project management framework. It is a flexible and comprehensive development strategy, wherein a team works as a unit to achieve a common goal, challenging traditional approaches to product development.

For some authors, Scrum is defined as an agile methodology for developing software and information systems with a focus on project management, and on iterative and agile development processes, transparency, visibility, and cooperation among team members and customers [21, 38].

After the conceptual analysis on Scrum, it was able to identify many authors that define Scrum as a methodology or method. However, most authors define Scrum as a framework, and not just as a project management method, constituting the common way of defining Scrum.

Answering the question on Scrum principles (Q9), [33] state that the Scrum framework is based on three main principles, i.e., transparency, inspection, and adaptation. Transparency clearly defines the objectives and gives visibility to the involved processes, while inspection involves frequent reviews to verify team processes, and adaptation refers to adjustments that can be made during the processes to make effective changes to the project when a product does not meet desired requirements. All three pillars are essential so that the staff can learn from their experiences and adapt their activities to meet demands in an ever-changing environment.

Questions Q10 and Q11 sought to detail the Scrum structure, highlighting the main principles and steps. Answering the question on the Scrum stages (Q10), Scrum life cycle begins with the Product Owner's vision, i.e., the vision he/she has in relation to the product he/she wants to create. From this, a list of resource items by priority level is created, called the Product Backlog. Then, the Sprint Planning and the Sprint Backlog are started, which include all the tasks that the team will perform. In the sprint planning, tasks and weights are chosen from Product backlog items. The Sprint backlog is carried out, where tasks are divided for the whole team, and their respective goals are defined for each cycle. Daily meetings last around 15 minutes, and are organized to track project progress. At the end of each sprint cycle, there is a sprint review, where products are inspected by stakeholders, including customers, and the project team, to get feedback and conduct product analysis. Finally, there is the sprint retrospective step, which is carried out before the next sprint that includes the team, and seeks to bring about improvements and better results for the next stage [39, 40]. Fig. 2 shows the Scrum lifecycle by [41].

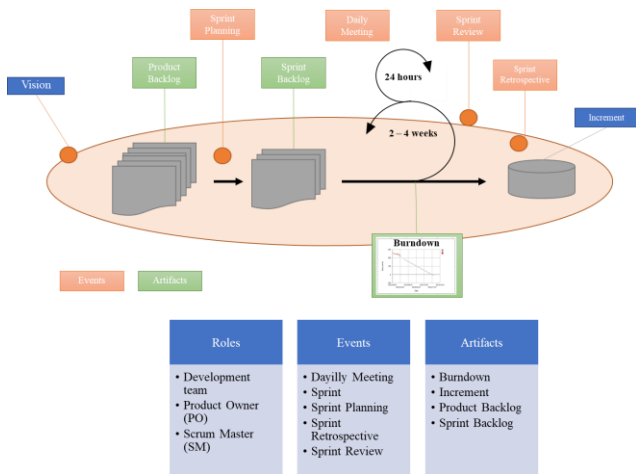

Fig. 2. Scrum lifecycle.

To answer Q11 (What are the Scrum elements?), the Scrum framework includes elements like ceremonies, functions, and artifacts that provide a structure and overview [34]. Scrum framework comprises a Scrum team, roles, and responsibilities, for all members that comprise the team, in addition to events, artifacts, and specific rules that unite all components [42].

The next analysis answered the questions on ways of working with Scrum (Q12, Q13, and Q14). Regarding whether Scrum is expensive (Q12), there are no authors that had made citations on the cost of applying Scrum or values related to it. Thus, it is suggested that future research be carried out on Scrum costs to answer this question.

Regarding the complexity of implementing Scrum (Q13), Scrum adopted by academics and experts used to research or evaluation methods is an easy concept for transference and experience, although some specific particularities need to be adapted [43]. It is also worth mentioning that the Scrum configuration is easy to implement, but its functionality is complex in the team domain [44].

Answering question Q14, on the scope of Scrum, [33] state that Scrum focuses on project management, and is used as a method for dealing with complex projects with imprecise results to minimize risks related to development. Scrum helps resolve uncertainties and respond to changes, providing a set of principles and guidelines to be more productive.

The next questions (Q15 and Q16) focused on the team conceptualization within the framework, and on how the Scrum team composition and the roles of the project manager are defined, respectively. With regard to team composition (Q15), Scrum has three different roles, i.e., a Scrum master, a product owner, and a development team. The Scrum master is responsible for ensuring that the processes run smoothly and that everyone understands and adheres to the Scrum principles. The product owner is responsible for product development focused on customer goals and requirements, and directs the work of the entire team, in addition to defining the product backlog items. The development team comprises professionals from different areas. It is very important that team members work well together, and be focused on the same goal. Another Scrum team characteristic is self-organization. The team has autonomy to make collective decisions, manage their own work, and shift work among themselves, as they see fit [45].

The responsibilities of the traditional project manager (Q16) are divided between three roles in Scrum, i.e., the Scrum master, the product owner, and the development team [46]. The project manager introduces him-/her-self as a Scrum master, and is responsible for the entire project [47].

Questions Q17 and Q18 demonstrate what the SLR authors see to be the main advantages and disadvantages of the Scrum method.

The author in [48] highlights advantages (Q17), as empirical feedback, team self-management, and struggles to build increments of fully tested products in short time frames. Scrum stands out as an agile methodology with the most standardized way of introducing agility, because it is flexible, simple, and a popular agile management method. Furthermore, it facilitates better ways of developing projects, and promoting individual work and teamwork. The Scrum method can generate benefits like increased customer satisfaction, improved communication, increased productivity, reduced production costs, and increased collaboration among everyone involved in the projects, in addition to increasing motivation among the development team [49].

Regarding disadvantages (Q18), the Scrum framework does not formally describe project risk management. Therefore, it is essential that risk management processes be included in the framework according to the project requirements [50]. Another difficulty is linked to large projects, where large numbers of Scrum sprints mean that the development team must manage more complex tasks. The author in [37] also states that one of the weaknesses of Scrum is the strong dependence of the development team on team members.

Finally, Q19 deals with the future directions for Scrum that was addressed by the authors in the SLR. The author in [32] states that future work should focus on identifying and solving problems that may arise during the introduction of agile

development. Another research factor is an extended teamwork model that should be used to study mature agile development teams, to identify and analyze the main challenges encountered by these teams. The flexibility that the Scrum framework offers in terms of compatibility when working together with other agile methodologies for project development is well known, values teamwork, and consequently brings about greater quality, and greater customer satisfaction. One study opportunity would be to analyze the advantages of working with Scrum compared to other agile methods.

Given out analyses for ascertaining the nature of the research topic, the main results are that Scrum was developed as a project management framework in 1993, by Jeffrey Sutherland at the Easel Corporation, and its main objective is to manage complex projects with quality in small time intervals, especially for software development.

Furthermore, the Scrum framework provides for ceremonies, functions, and artifacts, and consists of three main principles, which are transparency, inspection, and adaptation, providing structure and overviews. The purpose of the Scrum scope is to focus on project management, and it is used as a method for dealing with complex projects with inaccurate results, and minimizing risks related to project development.

Scrum's main advantages are flexibility, self-organization, and adaptability. However, disadvantages include informality in risk management processes, the fact that sometimes tasks are too complex for the team, and the fact that all the work is dependent on the development team.

Finally, future directions for Scrum would be studies aimed at improving identifying and solving problems in applying agile concepts, studying mature development teams, studying Scrum frameworks associated with agile methodologies in project development, and analyzing the advantages of working with Scrum relative to other agile methods.

V. CONCLUSIONS

The study conducted a Systematic Review on literature on Scrum to deepen knowledge on the subject, and to obtain a register that could be used to add knowledge for future research. The study was structured following a SLR framework using three stages, i.e., planning the review, conducting the review, and documenting the review.

For the results, it was focused on answering the questions according to the categories into which they were separated, i.e., the State of the Arts, and nature of research. Regarding the State of the Arts, it can conclude that most articles were published in 2020, and the first study found in the database was "A teamwork model for understanding an agile team: A case study of a Scrum project. Regarding the authors, no author had more than two published articles, showing that there is no main author addressing the topic. Moreover, most articles showed an author appearing only once. Regarding the country of publication, Brazil is well-positioned in third place, at two articles published, behind Pakistan in first place. Regarding universities and source of publication, the number of publications was very close, and that there was no main reference. Regarding the publication sources, no single publication had published more than 2 articles.

Finally, regarding the areas of study, more emphasis was given to computer science. It is worth noting that this area gave rise to Scrum, and is still remains at the forefront of research.

The main results from the analyses carried out to ascertain the nature of the research are that the Scrum methodology was developed as a project management framework in 1993, by Jeffrey Sutherland, at the Easel Corporation, and its main objective is to manage complex projects with quality in small time frames, especially for software development.

The Scrum framework provides for ceremonies, functions, and artifacts, and consists of three main principles, which are transparency, inspection, and adaptation. The purpose of the Scrum scope is to focus on project management, and is used as a method for dealing with complex projects with inaccurate results, and to minimize risks related to project development.

Scrum's main advantages are flexibility, self-organization, and adaptability. For future studies on the Scrum framework, authors pointed to improvements in solving problems identified in the applicability of agile development, studying identifying and analyzing problems identified by mature agile teams, and investigating Scrum relative to other agile methods for project management.

Literature points to numerous authors who cite Scrum as a method or methodology for project management. As much as Scrum presents several tools for project development, the term methodology is not the most common term used, as it is based on empiricism. After the analyses in the SLR, we can conclude that Scrum is conceptualized as an agile framework.

This study concluded that Scrum is an agile framework aimed mainly at software development, but can be used in several other areas, e.g., engineering, mathematics, and business, if it is adapted to the context of the specific projects that will be managed.

It was also found that Scrum, as a topic, has grown over the years, and the number of studies has been increasing. Thus, this tool has been consolidated for managing complex projects, which can be better defined as the project is developed. Furthermore, the role of the project manager is more of that of a facilitator, focusing on directing the steps, and eliminating bottlenecks so that the team can develop and self-manage its own work.

It was also concluded that Scrum has some disadvantages, which can be used as themes for developing proposals that could help minimize losses when using the framework. Finally, the results show that future studies still need to greatly develop the Scrum concept, so that Scrum can be increasingly applied within the project management area.

In short, it was able to reach the objectives of this study using a Systematic Literature Review, and by selecting the database for research and analysis, to answer the points defined at the beginning of this study. Studies in literature on Scrum, and the main Scrum concepts, were also detailed here. Finally, this study presents information that could be useful for future studies, as it serves as a simple and direct way of acquiring knowledge about Scrum.

For future studies, the authors suggest that studies deal with financial issues, and complexity when applying Scrum. Another recommendation would be carrying out a new SLR on other agile methods, or conducting a SLR that addressed the most well-known agile methods, offering a comparative analysis to offer the reader a focused approach on each of these methodologies, and what type of project these methodologies would best fit.

Isa Town, Bahrain²

Abstract—Climate change (such as global warming) causes the barrier in the attaining sustainable development goals. Emission of greenhouse gases (primarily carbon dioxide CO₂ emission) are the root cause of global warming. This research analyses and investigates the emission of CO₂ and attempts to develop an optimal model to forecast the CO₂ emission. Several machine learning and statistical modeling techniques have been implemented and evaluated to explore the patterns and trends of CO₂ emissions to develop an optimal model for forecasting future CO₂ emissions. The implemented methods include such as Exponential Smoothing, Transformers, Temporal Convolutional Network (TCN), and neural basis expansion analysis for interpretable time series. The data for training these models have been collected and synthesized from various sources using a web crawler. The performance of these models has been evaluated using various performance measurement metrics such as RMSE, R2 score, MAE, MAPE and OPE. The N-BEATS model demonstrated an overall better performance for forecasting CO₂ emission in Saudi Arabia in comparison to the other models. In addition, this paper also provides recommendations and strategies for mitigating the climate change (by reducing CO₂ emission).

Keywords—Exponential smoothing; transformers; temporal convolutional network; neural basis expansion analysis; climate change

I. INTRODUCTION

The United Nations (UN) has proposed several climate friendly actions for the governments while developing the post-pandemic recovery plans. Governments, all over the globe, are aiming to tackle the climate-crisis for changing the course of carbon dioxide (CO₂) emission trajectory to net-zero, to create a more sustainable and safer future for their citizens. But why there is so much attention given to CO₂ emission? CO₂ is a greenhouse gas. Greenhouse gases traps the heat in the atmosphere and radiates it back in all directions including towards the surface of earth [1]; hence, causing an increase in the global temperature (climate change). There are multiple sources (such as fossil fuels extraction and consumption, wildfires, volcanic eruptions and other similar natural processes, etc.) that generate carbon dioxide. Among these sources, fossil fuels are the major contributing factor of CO₂ emission.

The Kingdom of Saudi Arabia (KSA) presented its first national review report on sustainable development goals (SDGs) to UN High-Level political forum in 2018 [2]. The presented review is the first attempt by the KSA to conduct a comprehensive and systematic review of the status. Climate action is one of the 17 SDGs agenda set by the UN. As the UN member state, Kingdom of Saudi Arabia has adopted the sustainable development goals under its vision 2030. There have been several great initiatives and indicators that has exemplified the enthusiasm of the Kingdom of Saudi Arabia in achieving these goals as indicated from the first voluntary national review report [2][3]. The review suggests that the KSA has made great efforts in numerous areas; however, there are several bottlenecks that place the KSA in a challenging position to achieve its 2030 vision. Based on the review report, the major challenges include data availability, efficient measures and methods for SDG-related statistics collection and dissemination, more effective and better coordination techniques among the non-government and government institutions to avoid effort duplication, enriching and enhancing the existing institutional frameworks, so on and, so forth. Therefore, more profound interventions are essential to move forward. One of the areas of concern among these challenges is emission of greenhouse gases.

Climate change is one of the major hurdles in attaining the sustainable development goals [4][5]. Rapid industrialization and urbanization have given the unexpected economic growth but the world has to pay the price in the shape of climate change. Due to the unprecedented utilization of fossil fuel in energy generation and consumption, the emission of greenhouse gases (primarily CO₂) has increased exponentially. Greenhouse gases gather in the atmosphere, absorb sunlight, and avert the solar radiations to reflect back from the earth surface. Thus, the radiations are entrapped in the atmosphere. The entrapped radiations become the reason to increase the temperature of the plane and thus, causing global warming. This procedure is referred to as greenhouse effect. The gases that cause greenhouse effect include carbon dioxide (CO₂), nitrous oxide (N₂O), chlorofluorocarbons (CFCs), methane (CH₄), and water vapor. Though, among these gases, CO₂ is the primary contributor to greenhouse effect. However, human interventions and activities have increased the CO₂ concentration significantly (by 47%) in the atmosphere in the

past 170 years. This increment in CO₂ concentration would have taken a period of over 20,000 years naturally [6]. Therefore, to mitigate the climate change, an efficient technique is required that can measure the emission of greenhouse gases and can provide an insight for the future emission trends so that an effective climate change mitigation solution can be developed and put into action.

The emission of greenhouse gases does not only causes global warming but also has several other effects such as air pollution, so on and, so forth. The poor quality of air causes various health risks to the citizens. Therefore, there several direct and indirect consequences of GHG emission such as environment deterioration, health deterioration, etc. A research study [7] illustrates that almost 40% of global CO₂ emission is contributed by the electricity generation by combustion of the fossil fuels. However, there are several other natural factors that contribute to GHG emission such as respirations, and volcanic eruptions. Although, the modern industrialization shift has resulted in excessive combustion of the fossil fuels and consumption of natural resources. It also leads to several other major environmental challenges such as climate change, deforestation and water shortage. Effective measurement, analysis and forecasting techniques of GHG emission will guide in identifying the key factors and emission sources that will affect the climate change mitigation policies.

This paper has been organized into six sections. The next discusses the related work in this regard. Section three states the problem statement, research importance and objectives. Section four describes the data and methodologies. It also describes the proposed system framework and the methodologies which have been implemented for developing an effective forecasting model. Section five illustrates the results of different forecasting models, provide performance analysis, and suggest CO₂ emission mitigation strategies. Section six concludes the research paper and provides the future research direction for mitigating climate change.

II. LITERATURE REVIEW

Climate change is one of the most defining global issues of this century. United Nations has listed 17 SDGs in its 2030 agenda. Climate action is one of the sustainable development goals among others such as sustainable cities and communities, affordable and clean energy, responsible consumption and productions, etc. The United Nations 2030 agenda encompasses primarily five pillars such as Planet, People, Peace, Prosperity, and Partnership. The 17 SDGs incorporate these five pillars. As a member state of United Nations, Kingdom of Saudi Arabia (KSA) has adopted sustainable development goals. In the past few years, the KSA has already implemented numerous polices under the Vision 2030, these policies align with the United Nations 2030 agenda. The ongoing 2030 vision has demonstrated progress in several indicators to achieve the sustainable development goals and to become a welcoming economy for visitors, workers and investors. Saudi Arabia has proved its commitment in achieving sustainable development goals and is enthusiastic in recognizing the importance to address these global challenges.

Swift urbanization and unprecedented industrialization have raised the issue of global warming and climate change

around the world. The UN have been setting goals to curb the drastic effects of climate change for its member states. In turn, all the member states have been implementing different policies and taking actions to accomplish their goals for sustainable development. However, due to the high demand of energy for industrialization and urbanization, the ways of energy production and consumptions have not been efficient in lowering the GHG emission levels. As a result, the level of GHG emission have been increasing around the world and causing global warming. The Kingdom of Saudi Arabia is no exception to this. Despite the numerous efforts made by the concerned authorities, the KSA still has to go far to meet its target level of GHG emission. As per the first voluntary national review report [2], the KSA has to cut down its annual carbon dioxide emission as much as 130 million tonnes by 2030.

The Kingdom of Saudi Arabia has placed several policies and strategies to meet its requirement. However, due to the increased power (energy) demand by industrialization and population growth, over 80% of the overall energy demand is fulfilled by using the fossil fuels for energy generation (Amran et al, 2020). Energy generation using fossil fuels is directly linked with CO₂ emission. Thus, an ambitious target for the KSA is to switch to alternative sources of power sources such as nuclear power, green energy [8] or renewable energy sources [9], etc. Climate change does not only cause increment in atmospheric temperature but also accounts of huge financial loses. It has costed around 130 million dollars in 2018 only and almost USD one billion from 1980-2010 (Al-Bassam et al., 2014). Climate's hyper aridity and the sensitive ecosystem place the KSA at a certain climate change risk [10]. In some areas of the KSA, a very high temperature (52°C) has been recorded which is negatively influenced by various human activities and vehicle emission [3].

The government of Saudi Arabia is addressing several challenges for climate change mitigation and adapting measures to restraint the social and diverse economic impacts on the country. Some of these efforts include King Abdulaziz public transport project, conservation measures for water and electricity [11], urban planning scheme [10], research on environment [12], and many more. Although, despite the significant efforts made by the government, per capita CO₂ emission in the Kingdom is still amongst the highest in the world [13]. Therefore, solid strategies, measures and plans are required to put into action for climate change mitigation and economic diversification such as promoting the social responsibilities of corporations for safeguarding the environment.

This research will utilize the data collected from past to analyze the trends and will employ forecasting and/or prediction models in estimating the CO₂ emission (because it is the major constituents amongst GHG). As the future human activities and behavior will have a substantial impact on the accuracy of the estimations, therefore, this research has also attempted to provide the guidelines in developing the effective climate change mitigation pathways and policies. Several machine learning, statistical and mathematical modelling techniques have been employed for the development of an effective forecasting model. As the amount of the GHG

emission data available [14] [15] from all the possible resources is limited, therefore, this research has employed the techniques that perform well under the limited data. Finding an appropriate time series forecasting method has been a significant challenge amongst the community of researchers. Finding a prediction or forecasting technique that can perform well on the known and unknown data is a challenging task. When the historical data available is in low quantity, prediction or forecasting techniques performs well on the training data and produce results with minimal error rate, while on the unseen data the results are usually disastrous [16] [17]. This research has implemented several machine learning, statistical and mathematical modelling techniques for simulating the CO₂ emission in the Kingdom of Saudi Arabia. These findings will play a substantial role in developing the climate change mitigation policies and strategies for Saudi Arabia.

The literature review illustrates that Saudi Arabia has to cut down its annual carbon dioxide emissions by 130 million tonnes by 2030, but it does not provide information on the country's current emissions levels. Several efforts have been made by the Saudi Arabian government to address climate change. However, it has also been observed that there are need for solid strategies, measures, and plans for climate change mitigation and economic diversification. It has also been observed that machine learning, statistical and mathematical modeling techniques have been used for forecasting CO₂ emissions in Saudi Arabia, but it does not provide information on the data sources or the accuracy of the models used.

III. RESEARCH IMPORTANCE AND OBJECTIVES

The GHG emission in Saudi Arabia has increased almost 200% in the past three decades. Per capita GHG emission is the second highest in Saudi Arabia amongst the G20 countries. Kingdom of Saudi Arabia would require to reduce its CO₂ emission below 389 Mt by 2030 as its commitment to UN's sustainable goals and to achieve it vision 2030 goals. Ambient air pollution (a resultant of emission) poses higher health risks (such as stroke, heart disease, lung cancer, and chronic respiratory diseases) in Saudi Arabia as compared to other G20 countries. Kingdom of Saudi Arabia loses almost SAR 859m (~USD 229m) because of extreme weather events and is vulnerable to climate change. The Saudi Arabia has a target to reduce emission equivalent to 130 million tonnes per year. To address and achieve the above targets and issues, an effective estimation technique and guidelines are required which this research study aims to address. This research synthesizes the findings from literature to recognize the opportunities for potential estimate emission reduction and intervention. It implements several machine learning, statistical and mathematical modelling techniques for simulating the emission of greenhouse gases (specifically CO₂) in the Kingdom. It will also aim to address the issue of accuracy in the synthesized data by verifying it from multiple sources as described in the next section. As there is a need for solid strategies, measures, and plans for climate change mitigation and economic diversification, therefore, this research also provides suggested strategies and policies that can be utilized along with the forecasting model to mitigate the climate change.

IV. MATERIALS AND METHODS

This section examines the data collection, and forecasting methodologies used in this paper. This section is organized into three subsections which are dataset, proposed system framework, and forecasting methodologies utilized in this research. The dataset subsection describes the data collection and data pre-processing. The proposed system framework subsection describes the research design, and the forecasting methodologies subsection describes the different forecasting methods implemented in this research study.

A. Dataset

For this research study, CO₂ emission data (as CO₂ is the major greenhouse gas) has been collected available in the public domain. Some major sources of the data that have been considered are World Bank [13], BP [14], and our world in data [15]. This research utilizes the complete emission data obtained from all these sources by converting to one scale and synthesizing it. The figure (see Fig. 1) illustrates the synthesized data.

Fig. 1. Year-wise CO₂ emission in Saudi Arabia.

B. Proposed System Framework

A quantitative analysis has been conducted on the data collected from all the sources to investigate the patterns and trends. This research explores and implements several forecasting techniques such as Exponential Smoothing, Transformers, Temporal Convolutional Network (TCN), neural basis expansion analysis for interpretable time series, and Fast Fourier Transform Forecasting. The following figure (see Fig. 2) illustrates the proposed system framework.

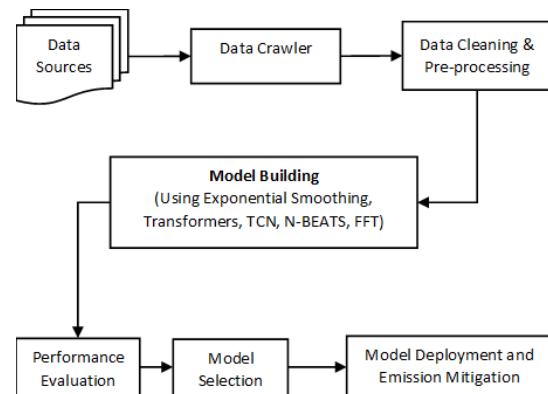

Fig. 2. Proposed system framework.

The study implements an automated data crawler to extract data from various sources [18]. The collected data is processed for any abnormalities and missing values and cleaned. The data is scaled to have the same unit. The next module implements multiple machine learning and statistical modelling techniques. All the developed models are evaluated for their performance. The best performing model is selected as the forecasting model and used to forecast emission by 2030. The findings from the quantitative analysis and literature study have been used in developing the proposed strategies for CO₂ emission mitigation and to achieve sustainable development goals, and Saudi Vision 2030.

C. Model Building

For developing an effective model for predicting CO₂ emission in Saudi Arabia, this research has investigated multiple approaches for forecasting. The forecasting results obtained from some of the approaches like Fast Fourier Transform Forecasting Model (FFT) were discouraging. However, there are several techniques which have performed very well and have promising forecasting results [19] [20]. These techniques include approaches such as Exponential Smoothing, Transformers, Temporal Convolutional Network (TCN), and neural basis expansion analysis for interpretable time series (N-BEATS). This segment analyzes the forecasting techniques implemented in this research paper.

1) *Exponential smoothing*: Exponential smoothing is a statistical forecasting method used for time series analysis and predicting the values of a time-series variable based on its historic data points. Exponential smoothing was first proposed 1950s by three different researchers: Charles C. Holt, Peter W. Winters, and Robert G. Brown [21] [22] [23]. Each of them developed a slightly different version but based on the same fundamental concept. This method is based on the assumption that the time-series pattern can be modeled by a weighted average of the historical observations. In exponential smoothing, usually recent events or observations are granted more weights than the older observations. However, by varying the values of the smoothing parameter, more weight can be shifted to the older observations. The following equation illustrates the exponential smoothing for predicting the future values based on the historical observations:

$$F_{t+1} = \alpha A_t + (1 - \alpha)F_t \quad (1)$$

Where, F_{t+1} is the predicted time-step value for the next step, F_t is the predicted value for the current period and A_t is the actual observation value of the time series at time step t . The term α represents the smoothing parameter, and the values of the parameter varies between 0 and 1 that determines the weight allotted to the current observation. Keeping the α value larger, more weight is shifted to the most recent observations. One of the criteria for applying exponential smoothing is its level of persistence of forecasted values with the historic observations. However, it is not very resistance to the irregularities or sudden changes in the time-series data. The implementation in this paper is based on the simplified version present in [24].

2) *Transformers*: Transformers are a type of neural network having self-attention mechanism [25]. Self-attention allows to process different parts of the input sequence while processing each element. Self-attention computes the attention weight between all the pairs of the input values in the time-series. This mechanism aids in determining the importance of each observation. The transformer implementation for this research study, applies self-attention in two processes. One is to extract the intra-dependencies within the output and within the input vectors which is also known as self-attention. The second is to draw the inter-dependencies within the output and within the input vectors which is also known as encoder-decoder attention. The attention mechanism grants the transformers the ability to grab the long-range dependencies efficiently. The transformer also includes a component called multi-head attention which allows the transformers suitable for parallel processing of the multiple components of the input sequence.

The implementation in this paper is based on [25] [26]. The input chunk length has been set to three and output chunk length has been set to one. The transformer has been trained two encoder and two decoder layers with 128-dimension feedforward neural network. The multi-head number has been set to eight. The rectified linear unit (ReLU) activation function [27] has been used. The model was trained with batch size of 8 and over 200 epochs.

3) *Temporal convolutional network*: Temporal Convolutional Network (TCN) have been designed to process sequences of data. The TCN architecture implemented for this study is based on the TCN architecture proposed in [28]. TCNs are based on convolutional neural network. TCN applies 1-dimensional convolutions along the time dimension of the input data. It enables the neural network to learn the features that are relevant to the temporal structure (such as patterns or trends) of the data. In order to learn long-range dependencies in the input time-series, convolutions skip some of the observations in the input time-series. To learn long-term trends or long-range dependencies in the input time-series, TCNs use dilated convolution [29]. TCNs also resolves the issue of vanishing gradients (which often occurs in deep neural networks) by the use of residual connections. Residual connections are the connections that bypasses one or more convolutional layers and allow information to flow more easily through the network. These features of TCN can grab the complicated temporal relationships amongst the output and input values. The fully connected layers are fed with the output of the convolutional layers to map the learned features to the target output. The convolutional layers are usually followed by dilated convolutional layers to grab long-term dependencies in the time-series data. The final output is a sequence of predicted values for the future time-steps. The entire network is optimized to minimize the forecasting error in contrast to traditional forecasting methods which often require separate steps for feature extraction and model fitting.

The TCN implementation in this research paper is based on the architecture proposed in [28]. The future prediction time-step has been set to one. The kernel size in the convolutional layers has been set to two. Three filters have been used in the convolutional layers. The dilation base has been set to two. The network has been trained over 150 epochs.

4) *Neural basis expansion analysis for interpretable time series*: Neural basis expansion analysis for interpretable time series (N-BEATS) is a machine learning technique that is used for modeling and analyzing time-series data [30]. N-BEATS uncovers the underlying relationships and patterns present in the data. N-BEATS offers two architectures such as generic and interpretable. This research study implements the generic architecture. As the name suggests, N-BEATS utilizes a basis function expansion for time-series representation. The basis function expansion is a linear combination (weighted sum) of a set of basis functions. These basis functions aim to map to the patterns or relationships expected to be present in the time-series data. The coefficients of the basis functions are the weights.

The N-BEATS implementation for this research study is based on the architecture presented in [30]. The future prediction time-step has been set to one. During the training using neural network, the weights are learned. The resulting model is utilized for forecasting future values of the time-series. The weights of the basic functions provide insight about the underlying dynamics of the time-series data. The presence of high weights for certain basic functions indicates the presence of certain periodic patterns in the time-series data. Though, for the implementation in this research study, no such insight has been observed. Neural network is fed with the time-series data to learn the weights of the basic functions. In the training process, neural network learns the weights and produces an approximate time-series that best fit on the given time-series. N-BEATS have the ability to capture complex nonlinear relationships present in the time-series data [31].

V. RESULTS AND DISCUSSION

Time series forecasting problems aims to find a fitting model that can fit the time-stamped historical observations in order to predict the future time-stamped observations of the given data. Traditional approaches have been effective in describing and predicting the time series values such as exponential smoothing and autoregressive integrated moving average (ARIMA). While ARIMA models aspire to depict autocorrelation in the time series data, exponential smoothing targets to characterize seasonality and trend in the time series data. However, sometimes, traditional approaches do not effectively describe and fit the time series, especially when the time series data is more complicated. Therefore, often advanced methods such as transformers, neural basis expansion analysis for time series (N-BEATS) forecasting, and temporal convolutional networks (TCNs), are employed to deal with the complicated time series data. This research utilizes multiple methods such as exponential smoothing, transformers, N-BEATS and TCN for describing and predicting the CO₂ emission values in Saudi Arabia.

Initially, a descriptive analysis of the data has been conducted and the synthesized data is cleaned and pre-processed for any data error. Python has been used for the analysis and modelling. The data preprocessing has been used for converting the data to have same units for carbon emission of each year, finding and handling missing values etc. The forecasting methods discussed in the previous section have been implemented and are fed with the time-series data to learn the weights. In the training process, forecasting models learn the weights and produces an approximate time-series that best fit on the given time-series. The weights are learned by minimizing the variance between the predicted observations and actual observations of the given time-series data. The data is segregated into training and validation data. The figure (see Fig. 3) illustrates training data and validation data.

Fig. 3. Training and validation data.

The training, validation and prediction comparison for all the models implemented in this research study is illustrates in the following figures (see Fig. 4, 5, 6, and 7). The training, validation and prediction comparison for all the models implemented in this research study is illustrates in the following figure. The following figure 4 illustrates the training, validation and prediction of the CO₂ emission using the Exponential Smoothing model. All process has been represented using a different color as depicted via legends. The following Fig. 5 illustrates the training, validation and prediction of the CO₂ emission using the Transformers model.

The above Fig. 7 illustrates the training, validation and prediction of the CO₂ emission using the N-BEATS model.

A. Performance

1) *Mean absolute error*: Mean Absolute Error is also commonly known as MAE is a performance measurement metric which is used to evaluate the performance of a prediction or forecasting models. It measures the average absolute difference of the forecasted data point and the actual data point value, and is expressed in the units of the data. MAE represents the average amount of the errors in the predicted observations, without considering their direction. Therefore, it is capable to handle both positive and negative errors, and it is resistant to the outliers present in the time-series. The formula for calculating MAE is as follows:

$$MAE = (1/t) * \Sigma|a - \hat{y}| \quad (2)$$

Where, t is the total number of data points, v is the actual value and \hat{y} is the predicted value.

2) *Mean absolute percentage error*: Mean Absolute Percentage Error is commonly known as MAPE. It is a performance measurement metric which is used to evaluate the performance of a forecasting model. It calculates the average percentage difference of the actual time series values and the forecasted values. The formula for calculating MAPE is as follows:

$$MAPE = (1/t) * \Sigma|(a - \hat{y})/y| * 100\% \quad (3)$$

Where, t is the total number of time-series data points, a is the actual time-series data-points and \hat{y} is the forecasted time-series data-points.

3) *R2 score*: Coefficient of Determination is also known as R2 Score. It measures the proportion of the variability in the data. The R2 score is calculated as follows:

$$R2 = 1 - (SS_{res} / SS_{tot}) \quad (4)$$

Where, SS_{res} is the sum of the squared residuals, and SS_{tot} is the total sum of squares.

4) *Root mean squared error*: Root Mean Squared Error (commonly referred as RMSE) is a widely used performance metric. It measures the average magnitude of the errors in the predictions, taking into account both the direction and the magnitude of the errors. The formula for calculating RMSE is as follows:

$$RMSE = \text{sqrt}((1/t) * \Sigma(a - \hat{y})^2) \quad (5)$$

Where, t is the total number of points in the time series data, a is the actual value of the time-series step and \hat{y} is the forecasted time-series value.

5) *Overall percentage error*: Overall Percentage Error (OPE) performance metric is used to measure the percentage difference between the actual time-series data values and the forecasted data values, averaged over all the data points. The OPE is expressed as a percentage. The formula for calculating OPE is as follows:

$$OPE = (1/t) * \Sigma(\text{abs}((a - \hat{y})/a) * 100) \quad (6)$$

Where, t is the total number of data points, a is the actual data point of the time-series and \hat{y} is the forecasted data-point.

All the models have been evaluated using the above performance measurement metrics. The following table (see Table I) demonstrates the comparative analysis of the different models. In the present research study, transformer model has performed worse. The study has tried parameter tuning in several ways but the forecasting results could not improve. R2 score achieved is 0.112, MAE score is 55.89, MAPE score is 9.97, RMSE score is 56.10, and OPE score is 9.9. The next model is Exponential Smoothing which has achieved an R2 score of 0.209, an MAE score of 36.87, an MAPE score of 6.43, an RMSE score of 46.90, and an OPE score of 1.413. The TCN and N-BEATS models have performed comparatively well. The R2 score for TCN model is 0.21, MAE score is 14.23, MAPE score is 2.39, RMSE score is 19.58, and OPE score is 0.82. Similarly, the N-BEATS model has achieved an R2 score of 0.7, an MAE score of 14.36, an MAPE score of 2.36, an RMSE score of 19.32, and an OPE score of 0.91.

TABLE I. PERFORMANCE MEASUREMENT FOR VARIOUS FORECASTING MODELS

Performance Metric → Model ↓	R2 Score	MAE	MAPE	RMSE	OPE
Transformers	0.112	55.89	9.97	56.1	9.9
Exponential Smoothing	0.209	36.87	6.43	46.90	1.413
TCN	0.21	14.23	2.39	19.58	0.82
N-BEATS	0.7	14.36	2.36	19.32	0.91

The TCN and N-BEATS model have performed in almost similar fashion; however, the R2 score for N-BEATS model is much higher than the TCN model. A higher value (close to 1) of R2 score and lower values of the other metrics represents a high performing model. As it has been observed based on the performance measurement metrics the overall performance of N-BEATS model for forecasting CO₂ emission in Saudi Arabia is better in comparison to the other models.

However, the main limitation of these results is the limited amount of the sample dataset.

B. Proposed Strategies

Saudi Arabia is one of the top oil producing countries in the world and one of the major carbon dioxide (CO₂) emitters. Therefore, it is crucial to develop effective CO₂ emission mitigation strategies to achieve its vision 2030 goals. This subsection proposes a number of emission mitigation strategies as following:

- Carbon capture and storage: Due to being an oil-based economy, the country has a large number of power plants, refineries, and other industrial process that produces CO₂. Investing and implementing carbon capture and storage technologies will help in capturing CO₂ from various sources and the stored CO₂ can be utilized for enhanced oil recovery or stored in underground geological formations.
- Green hydrogen: The fossil fuels can be replaced by green hydrogen as a cleaner alternative in transportation and industry.

- Promoting renewable energy sources: The kingdom has a vast land area that is not being used for any purpose and has a high potential to harness renewable energy such as wind power and solar energy. The country has already started investing in these sources of energy and plans to generate 58.7 GW of renewable energy by 2030, which will contribute significantly to reducing its CO₂ emissions. Encouraging its residents and citizens to utilize renewable energy sources and providing facilities and availability for energy generation from renewable energy sources such as using solar panels will contribute to reduce CO₂ emission.
- Reforestation and afforestation: Forests are natural CO₂ sequester. Planting trees and creating new forests will aid in mitigating CO₂ emissions.
- Energy efficiency: Improving energy efficiency in buildings, industry, and transportation can significantly reduce CO₂ emissions.
- Carbon Tax: A carbon tax or cap-and-trade system can provide an economic incentive for reducing CO₂ emissions.

By implementing proposed CO₂ emission mitigation strategies, the kingdom can reduce its CO₂ emission and contribute to global efforts to combat climate change.

VI. CONCLUSION

Accomplishing the KSA's goals of vision 2030 require to take actions against climate change. Adopting an apt method for prediction the CO₂ emission will assist in developing the policies for climate change mitigation. Emission analysis from various industries will aid in recognizing the areas of having alarming level of emissions and thus will be to focus the specific industry to put a rein on its emission [32] [33]. Analyzing the emission trends and forecasting the emission levels will provide the future directions of achieving sustainable development goals of the Kingdom as a member state of United Nation. The findings suggest that effective policy measures and technological interventions can help to minimize the negative impacts of climate change on sustainable development goals and achieving the vision 2030. Overall, the paper contributes to the growing body of research on climate change and its implications for sustainable development.

This research has implemented several machine learning and statistical methods include such as Exponential Smoothing, Transformers, Temporal Convolutional Network (TCN), and neural basis expansion analysis for interpretable time series. The data for training these models have been collected and synthesized from various sources using a web crawler. The performance of these models has been evaluated using various performance measurement metrics such as RMSE, R2 score, MAE, MAPE and OPE. The results indicate that the TCN and N-BEATS models perform similarly, with the N-BEATS model achieving a higher R2 score. The N-BEATS model has demonstrated strong predictive power with an R2 score of 0.7, an MAE score of 14.36, an MAPE score of 2.36, an RMSE score of 19.32, and an OPE score of 0.91. Overall, N-BEATS

model, in particular, shows promise for achieving accurate and interpretable predictions. Further research could explore the applicability of these techniques in other domains and investigate approaches for enhancing model performance.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Saudi Electronic University for funding this research work through the project number (8111).

Abstract—Fuzzy time series forecasting is one method used to forecast in certain reality problems. The research on fuzzy time series forecasting has been increased due to its capability in dealing with vagueness and uncertainty. In this paper, we are dealing with implementation of revised heuristic knowledge to basic average-based interval and showing that these models forecast better than the basic one. We suggest three different lengths of interval, size 5, size 10 and size 20 to be used in comparing these models of average-based interval, average-based interval with implementation of heuristic knowledge and, average-based interval with implementation of revised heuristic knowledge. These models applied to forecast the number of tuberculosis cases reported monthly in Sabah starting from January 2012 until December 2019. A few numerical examples are shown as well. The performances of evaluations are shown by comparison on the values obtained by Mean Square error (MSE) and Root Mean Square Error (RMSE).

Keywords—Fuzzy time series; forecasting; length of interval; average-based interval; heuristic knowledge

I. INTRODUCTION

Time series analysis, at the present time has become a very important research object since it has been utilized in large number of fields such as finance, health care, education and environmental. In all these fields, obtaining an accurate picture of the future is an essential requirement and this can only be possible with an appropriate and competent prediction tool. Since the main concern of the time series analysis is to predict the future, it can be considered as an inference problem [1]. We identify that there are three main kinds of inference system (IS) which are utilized in time-series analysis as a prediction tool, i.e Statistical Inference System (SIS), Fuzzy Inference System (FIS) and computational inference system (CIS).

Fuzzy time series (FTS) methods are one of the prediction tool groups based on fuzzy set theory designed for time-series and they take into consideration the dependency structure of time series. In FTS model, time series with crisp observations, by using various fuzzification techniques, is transformed into time series with fuzzy observations called fuzzy time series.

The concept of linguistics variables and their application reasoning was initially introduced by Zadeh [2], [3], [4], [5]. Song and Chissom [6], [7] were the first researchers who

implemented and developed models to forecast in fuzzy time series. Their model is initially used to forecast the number of students enrolled in the University of Alabama from the year 1971 until year 1992. At the same time, they forecast using linear regression technique and compared the results obtained from time series technique. However, their methods require a large amount of computational time since their proposed methods is based on complex matrix operations. Due to limitation on time constraints, Chens [8] simplified the Song and Chissom methods by using simpler arithmetic operations and proved that his methods forecast better than the previous. Chens [9] continues his research, applying the same methods in [8], but he is focusing on high order fuzzy time series, which is more than one fuzzy logical relationship.

Huang [10] has been concerned on dealing with the suitable length of interval. A key point in choosing effective length of intervals is that they should not be too large as there will be no fluctuations in the fuzzy time series or too small as the meaning of fuzzy time series will be diminished. In his research, he proposed distribution- and average-based length in determining the effective length of intervals and proved that average-based length increases forecast accuracy compared to distribution-based length. Meanwhile, Li and Chen [11] proposed a concept of 3-4-5 rules of natural partitions to determine the length of intervals to be used, in their forecasting models.

In 2005, Huang and Yu [12] proposed a type-2 fuzzy time series model for stock index forecasting. They proved that type-2 model is much better for smooth defuzzification process and forecast consistently. Similar work on fuzzy time series can be found in Lee, et al. (2001) [13] and Tsai and Wu (1999) [14]. The other researchers such as Liu (2007) [15], Ozge, et al. (2020) [16] and Lee and Chou (2007) [17] does not specify on how they find the suitable the length of interval in their proposed methods. More research on defining the suitable interval also found in Chen (2014) [18], Wang et.al (2015) [19] as well as Lu et al (2015) [20] in their proposed model.

Ramli and Mohamad (2017) [21] applied the models from [11] in their forecasting models. They used 3-4-5 natural partition rules to find the best length of intervals in their models in forecasting the unemployment rate under different degrees of confidence. The study [22] shows a comparison of

the fuzzy time series methods of Chen, Cheng and Markov Chain model in predicting rainfall in Medan. In their study, Chen's model gives MAPE=8.002%, Markov chain's model gives MAPE=30.12% and Cheng's model gives MAPE=34.5%. According to [23] a model has a very good performance if the MAPE value is below 10% and has a good performance if the MAPE value is between 10% and 20%. Thus, Chen's model forecasting performances was very Good.

Norhayati et al. (2019) [24] proposed that fuzzy time series method is way more accurate compared to geometric brownian motion in forecasting stock prices in Bursa Malaysia. They apply average-based length focusing on trapezoidal membership members in their model Meanwhile, Susilo et al. (2022) [25] applied average-based fuzzy time series markov chain with some modification on partitioning using frequency density in predicting Covid-19 in Central Java, the ideal interval. The average based FTS Markov Chain approach with adjustments to the frequency density partition achieves an accuracy rate of 89.3%, according to the findings of this study. Lasaraiya et. al. (2022) [27] shows that determination of the length of interval by average-based interval gives nearest forecasting value to the actual values compared to forecasting value obtained from determination of length of interval by natural partitions as it shows the smallest percentage error.

This paper will merge Chen's model which is more on determination of suitable length of interval and Huarng's model which is more on choosing the suitable fuzzy logical relationship group (FLRG) in the model. Then, the comparison between the results of Chen's model with basic average-based interval, Huarng's model with average-based interval with implementation of heuristic knowledge and the proposed average-based interval model with implementation of revised heuristic knowledge will be shown. Section II will briefly explain the fuzzy time series background. Section III will be on the general step in the proposed methods. The Section IV presents results and discussion followed by future work and conclusions.

II. FUZZY TIME SERIES

Fuzzy time series concept was proposed by Song and Chissom [6], [7]. It can be used as prediction tools in a real-life problem or cases where historical data are formed in linguistic value. This means that the data in fuzzy time series is linguistic data while the actual data is real number. The definition of fuzzy time series is briefly reviewed below.

Let U be the universe of discourse, where $U = u_1, u_2, \dots, u_n$. A fuzzy set of A_i of U is defined by

$$A_i = \frac{f_{A_i}(u_1)}{u_1} + \frac{f_{A_i}(u_2)}{u_2} + \dots + \frac{f_{A_i}(u_n)}{u_n} \quad (1)$$

where f_{A_i} is the membership function of the fuzzy set A_i , $f_{A_i}: U \rightarrow [0,1]$. u_k is the element of fuzzy set A_i , and $f_{A_i}(u_k)$ is the degree of belongingness of u_k to A_i for $f_{A_i}(u_k) \in [0, 1]$ and $1 \leq k \leq n$.

Definition 1: $Y(t)(t = \dots, 0, 1, 2, \dots)$, is a subset of R . Let $Y(t)$ be the universe of discourse defined by fuzzy set $f_i(t)(i = 1, 2, \dots)$. $F(t)$ is defined as a fuzzy time series on $Y(t)(t = \dots, 0, 1, 2, \dots)$

According to Definition 1, $F(t)$ can be understood as a linguistics variable and $f_i(t)(i = 1, 2, \dots)$ as the possible linguistics values of $F(t)$.

Definition 2: If there exist a fuzzy relationship $R(t - 1, t)$, such that $F(t) = F(t - 1) \times R(t - 1, t)$, where \times is an operator, then $F(t)$ is said to be caused by $F(t - 1)$. The relationship between $F(t)$ and $F(t - 1)$ can be denoted by

$$F(t - 1) \rightarrow F(t) \quad (2)$$

Definition 3: Suppose $F(t - 1) = A_i$ and $F(t) = A_j$, a fuzzy logical relationship (FLR) is defined as $A_i \rightarrow A_j$, where A_i and A_j is on the left- and right-hand side respectively, while the repeated fuzzy logical relationship is removed.

Definition 4: Fuzzy logical relationship can be group together into fuzzy logical relationship group (FLRG) according to the same left-hand sides FLR.

According to Chen's model [8], the repeated fuzzy sets will be removed in the FLRG. For example,

$$\begin{array}{l} A_i \rightarrow A_{j1} \\ A_i \rightarrow A_{j2} \\ \dots \end{array} \rightarrow A_i \rightarrow A_{j1}, A_{j2}, \dots \quad (3)$$

Heuristic knowledge is introduced by [26] and this is used to guide the selection of proper fuzzy set for fuzzy logical relationship group (FLRG) before forecasting step. The definition is as shown below.

Definition 5: In the heuristic models, heuristic functions take fuzzy logical relationship groups and relevant variables as parameters. From these fuzzy logical relationship groups, the heuristic functions use the variables to select proper fuzzy set to establish heuristic fuzzy logical relationship groups.

All fuzzy sets A_1, A_2, \dots, A_n are well ordered. In other word, $A_k \geq A_l$ if $k > l$. Suppose $F(t - 1) = A_j$ and the FLRG for A_j is given by $A_j \rightarrow A_q, A_r, \dots$. Proper fuzzy sets, $A_{p1}, A_{p2}, \dots, A_{pk}$, can be selected by heuristic function $h()$,

$$h(x_1, x_2, \dots; A_q, A_r, \dots) = A_{p1}, A_{p2}, \dots, A_{pk} \quad (4)$$

where x_1, x_2, \dots are heuristic variables; $A_{p1}, A_{p2}, \dots, A_{pk}$ are selected from A_q, A_r, \dots , by the heuristics function. A heuristic fuzzy logical relationship group is obtained below:

$$A_j \rightarrow A_{p1}, A_{p2}, \dots, A_{pk} \quad (5)$$

The heuristic fuzzy logical relationship group is then used to forecast $F(t)$.

III. THE PROPOSED METHOD

Average-based intervals and Average-based intervals with implementation of heuristic knowledge were introduced a few years ago in forecasting the number of students' enrollments in University of Alabama. These models were hugely applied in forecasting in other real-life problems. In this paper, we try to show the Average-based intervals with implementation of revised heuristic knowledge forecast better than the other two models. There are five steps involved in this proposed method. The data as shown in Table I, was obtained from the Hospital of Queen Elizabeth II.

^a Data obtained from Queen Elizabeth II Hospital, Kota Kinabalu, Sabah.

Step 1: Define the universe of discourse, $U = [U_{min} - D_1, U_{max} + D_2]$, where U_{min} and U_{max} are minimum and maximum values in raw data, D_1, D_2 are two real numbers. U will be divided into n equal length of intervals u_1, u_2, \dots, u_n . We applied Chen's method [8] with some modifications in finding the length of intervals. The algorithm in average based interval by [10] to set the suitable length of interval is according to Table II.

TABLE II. BASIS MAPPING TABLE

Range	Basis
0.1 – 1.0	0.1
1.1 - 10	1
11 - 100	10
101 - 1000	100

^b Basis Mapping Table by [10].

Step 2: Fuzzy sets A_i . The linguistics variable is the raw data, A_i as possible linguistics values of the raw data. Each is defined by the intervals u_1, u_2, \dots, u_n .

$$A_1 = 1/u_1 + 0.5/u_2 + 0/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_n$$

$$A_2 = 0.5/u_1 + 1/u_2 + 0.5/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_n$$

$$A_3 = 0/u_1 + 0.5/u_2 + 1/u_3 + 0.5/u_4 + \dots + 0/u_{n-1} + 0/u_n$$

...

$$A_n = 0/u_1 + 0/u_2 + 0/u_3 + 0/u_4 + \dots + 0.5/u_{n-1} + 1/u_n$$

Step 3: Defined fuzzy logical relationship FLR. Repeated FLR will be removed.

Step 4: Group FLR in fuzzy logical relationship group FLRG.

Step 5: Calculated the forecasted output. There are 3 rules involved in Chen's Rule.

- Rule 1: If the fuzzified number of cases of day i is A_i , and there is only one FLR in the FLRG obtained in STEP 4, that is $A_i \rightarrow A_k$, whereby A_k occurs in the interval u_k and the midpoint of u_k is m_k , then the forecast number of cases of day $i + 1$ is m_k .
- Rule 2: If the fuzzified number of cases of day A_i and there is more than one FLR in the FLRG obtained in STEP 4, that is, $A_i \rightarrow A_{k1}, A_i \rightarrow A_{k2}, A_i \rightarrow A_{k3}, \dots, A_i \rightarrow A_{kq}$ whereby $A_{k1}, A_{k2}, A_{k3}, \dots, A_{kq}$ occurs in the intervals $u_{k1}, u_{k2}, u_{k3}, \dots, u_{kq}$ and their midpoint are $m_{k1}, m_{k2}, m_{k3}, \dots, m_{kq}$, the the forecast number of cases of the day $i + 1$ is $\frac{m_{k1} + m_{k2} + m_{k3} + \dots + m_{kq}}{q}$.
- If the fuzzified number of cases of day i is A_i , and there is empty FLR in the FLRG obtained in STEP 4, that is $A_i \rightarrow \emptyset$, whereby A_i occurs in the intervals u_i and the midpoint of u_i is m_i , then the forecast number of cases of the day $i + 1$ is m_i .

IV. RESULTS AND DISCUSSION

According to Section III, there are 5 steps counted. The data used in this study is the number of tuberculosis cases reported monthly in Sabah, period of January 2012 to December 2019 as you can see from Fig. 1. The time series graphic as in Fig. 1 demonstrates that there is no discernible pattern in the number of tuberculosis cases reported. This can be caused by any unexpected factors, such as gender, family background, knowledge, etc., and did not become observation in this study.

Fig. 1. Plot actual number of tuberculosis cases reported in sabah period January 2012 – December 2019.

A. Length of Interval

The first modification was done in determining the length of intervals. According to the data in Table I, $U_{min} = 199$ and $U_{max} = 601$ respectively. We choose $D_1 = 9$ and $D_2 = 9$ respectively. Thus, $U = [199 - 9, 601 + 9] = [190, 610]$. The modifications (b) and (c) are as follows:

- Based on Table II, the length of interval obtained is 10.
- The length of interval is then divided by 2, giving the length of interval is 5.
- The length of interval is then multiplied by 2, giving the length of interval is 20.

Then, the lengths of intervals considered are size 5, size 10 and size 20, and hence list of intervals is shown below. All three sizes applied to the average-based interval model, average-based interval model with implementation of heuristic knowledge and average-based interval model with implementation of revised heuristic knowledge.

TABLE III. THE LENGTH OF INTERVALS AND LIST OF INTERVALS

Length of intervals	Number of intervals	List of intervals
Size 5	84	$u_1 = [190 - 195], u_2 = [195 - 200], \dots, u_{84} = [605 - 610]$
Size 10	42	$u_1 = [190 - 200], u_2 = [200 - 210], \dots, u_{42} = [600 - 610]$
Size 20	21	$u_1 = [190 - 210], u_2 = [210 - 230], \dots, u_{21} = [590 - 610]$

^c. Jupyter Notebook tools under R kernel

B. Fuzzy Logical Relationship (FLR)

Next, is to find FLR. The number of tuberculosis cases reported monthly is to be defined according to intervals as shown in Table III and IV. The same step is repeated for all three models: average-based interval, average-based interval with implementation of heuristic knowledge and proposed average-based interval with implementation of revised heuristic knowledge.

TABLE IV. THE FUZZY SETS, A_i

Length of intervals	Number of intervals	List of intervals
Size 5	84	$A_1 = 1/u_1 + 0.5/u_2 + 0/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{84}$ $A_2 = 0.5/u_1 + 1/u_2 + 0.5/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{84}$ $A_3 = 0/u_1 + 0.5/u_2 + 1/u_3 + 0.5/u_4 + \dots + 0/u_{n-1} + 0/u_{84}$... $A_{84} = 0/u_1 + 0/u_2 + 0/u_3 + 0/u_4 + \dots + 0.5/u_{n-1} + 1/u_{84}$
Size 10	42	$A_1 = 1/u_1 + 0.5/u_2 + 0/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{42}$ $A_2 = 0.5/u_1 + 1/u_2 + 0.5/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{42}$ $A_3 = 0/u_1 + 0.5/u_2 + 1/u_3 + 0.5/u_4 + \dots + 0/u_{n-1} + 0/u_{42}$... $A_{42} = 0/u_1 + 0/u_2 + 0/u_3 + 0/u_4 + \dots + 0.5/u_{n-1} + 1/u_{42}$
Size 20	21	$A_1 = 1/u_1 + 0.5/u_2 + 0/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{21}$ $A_2 = 0.5/u_1 + 1/u_2 + 0.5/u_3 + 0/u_4 + \dots + 0/u_{n-1} + 0/u_{21}$ $A_3 = 0/u_1 + 0.5/u_2 + 1/u_3 + 0.5/u_4 + \dots + 0/u_{n-1} + 0/u_{21}$... $A_{21} = 0/u_1 + 0/u_2 + 0/u_3 + 0/u_4 + \dots + 0.5/u_{n-1} + 1/u_{21}$

^d. Jupyter Notebook tools under R kernel

C. Fuzzy Logical Relationship Group (FLRG)

Group of FLR is defined according to same fuzzy set in left hand side of the FLR. As for example, numerical FLR in the model for size 5 is shown. FLRG for fuzzy set A_{33} is chosen.

1) Average-based interval: FLRG will be grouped according to Definition 3. Refer Fig. 2.

FLRG for item (12) is $A_{33} \rightarrow A_{31}, A_{33}, A_{38}, A_{77}$

FLRG for item (13) is $A_{33} \rightarrow A_{31}, A_{33}, A_{38}, A_{77}$

FLRG for item (27) is $A_{33} \rightarrow A_{31}, A_{33}, A_{38}, A_{77}$

FLRG for item (84) is $A_{33} \rightarrow A_{31}, A_{33}, A_{38}, A_{77}$

```

Fig. 2. The FLRG of A_{33} in Average-Based Intervals for Size 5 is $A_{33} \rightarrow A_{31}, A_{33}, A_{38}, A_{77}$.

2) Average-based intervals with heuristic knowledge according to Definition 5. Let the month $t - 1$ be $F(t - 1)$ and the FLRG for $F(t - 1)$ be $A_j \rightarrow A_q, A_r, \dots$. This study assumes that there is heuristic knowledge showing the increment or decrement in the number of cases reported. The heuristic function is set as $h(x; A_q, A_r, \dots)$ where x is an indicator for number of cases forecasting. Fig. 3 shows the example on fuzzy sets of A_{33} . The heuristic FLRG is shown below.

FLRG for item (12) is $A_{33} \rightarrow A_{31}$

FLRG for item (13) is $A_{33} \rightarrow A_{33}, A_{38}, A_{77}$

FLRG for item (27) is $A_{33} \rightarrow A_{31}$

FLRG for item (84) is $A_{33} \rightarrow A_{33}, A_{38}, A_{77}$

D. Forecasting

The output will be defined according to Step 5. The forecast number of tuberculosis cases with respect to length of intervals size 5, size 10 and size 20 for the three models; average based intervals, average-based intervals with implementation of heuristic knowledge and average-based intervals with implementation of revised heuristic knowledge is shown in Table V, Table VI, and Table VII.

E. Accuracy Validation

The performance for the proposed method is compared based on their value of Mean Square Error (MSE) and Root Mean Square Error (RMSE). The smaller the MSE value, the better the forecast. Meanwhile, RMSE is known to be a good measurement of how accurate the model is in prediction. Lower values of RMSE indicate better fit. Based on Table

VIII, the average-based intervals with implementation of revised heuristic knowledge for size 5 give the smallest MSE = 1309.11 and RMSE = 36.18168 respectively compared to average-based interval and average-based interval with implementation of heuristic knowledge. Based on this MSE and RMSE value, it is concluded that the average-based intervals with implementation of revised heuristic knowledge model increase the accuracy of the forecasting value.

TABLE VIII. THE COMPARISON ON MSE AND RMSE OF EACH SIZE

Models	Length of intervals	MSE	RMSE
Average-based interval	Size 5	2618.065	51.15726
	Size 10	3337.299	57.76936
	Size 20	4392.890	66.2788
Average-based intervals with implementation of heuristic knowledge	Size 5	1436.139	37.89642
	Size 10	1926.855	43.89595
	Size 20	2624.269	51.22762
Average-based intervals with implementation of revised heuristic knowledge	Size 5	1309.114	36.18168
	Size 10	1887.522	43.44562
	Size 20	2289.208	47.84564

V. FUTURE WORK

Overall, this paper shows only the results on training phase of the comparing model and length of interval chosen size 5, size 10 and size 20. Training phase is done for the period of January 2012 until December 2019. Testing phase on the next year 2020 (January-December) can be done as a future work for length of size 5, 10 and 20, limited to list of FLRG obtained from the training phase. The forecasting results will be compared with the actual number of tuberculosis cases.

ACKNOWLEDGMENT

The author would like to thank the main supervisor, Dr. Suzelawati Zenian and co supervisor for their continuous support in this research. Besides, million thanks to Mdm. Nadirah Sulaiman from Clinical Research Centre (CRC), Hospital Queen Elizabeth (HQE) as well as Dr. Roddy Teo from Communicable Disease Unit, Sabah State Health Department for their help throughout this research.

Abstract—The comments in the evolution of network public opinion events not only reflect the attitude of netizens towards the event itself, but also are the key basis for mastering the dynamics of public opinion. According to the comment data in the event evolution process, an event feature vector pre-training model NL2ER-Transformer is constructed to realize the real-time automatic extraction of event features. Firstly, a semi-supervised multi-label curriculum learning model is proposed to generate comment words, event word vectors, event words, and event sentences, so that a public opinion event is mapped into a sequence similar to vectorized natural language. Secondly, based on the Transformer structure, a training method is proposed to simulate the evolution process of events, so that the event vector generation model can learn the evolution law and the characteristics of reversal events. Finally, the event vectors generated by the presented NL2ER-Transformer model are compared with the event vectors generated by the current mainstream models such as XLNet and RoBERTa. This paper tests the pre-trained model NL2ER-Transformer and three pre-trained benchmark models on four downstream classification models. The experimental results show that using the vectors generated by NL2ER-Transformer to train downstream models compared to using the vectors generated by other pre-trained benchmark models to train downstream models, the accuracy, recall, and F1 values are 16.66%, 44.44%, and 19% higher than the best downstream model. At the same time, in the evolutionary capability analysis test, only four events show partial errors. In terms of performance of semi-supervised model, the proposed semi-supervised multi-label curriculum learning model outperforms mainstream models in four indicators by 6%, 23%, 8%, and 15%, respectively.

Keywords—Event vectorization; NL2ER-transformer model; public opinion reversal prediction; evolution of public opinion event; multi label semi supervised learning

I. INTRODUCTION

Network public opinion refers to the public's opinions on an event on the network media. When an event causes heated discussion among netizens and forms a certain scale of network public opinion, this work call it a network public opinion event, hereinafter also referred to as an event. Network public opinion often leads to various public opinion phenomena, such as public opinion reversal, network violence, secondary derived events, etc. Network public opinion prediction from the perspective of public opinion phenomenon recognition is one of the current research directions of public opinion prediction: by analyzing the influencing factors of public opinion phenomena, designing event feature vectors, and

further constructing machine learning classification models to predict various phenomena of public opinion events. This paper focuses on the upstream event pre-training model, while the downstream task takes the prediction of public opinion reversal [1] as an example to verify the model.

This paper maps the public opinion event vector construction problem to the pre-train model based natural language feature vector generation problem. Based on the Transformer structure, we build an event vector generation model NL2ER-Transformer (Natural Language to Event Representation from Transformer) with the ability to predict the event evolution. The generated event vector is more in line with the evolution characteristics of public opinion reversal event. It solves the problem that the current event vectorization models only consider the static subjective characteristics of events and have not learned the dynamic evolution characteristics. The specific contributions of this paper are summarized as follows:

- Combining manually designing features and event evolution analysis, we put forward the concepts of comment word, event word and event sentence. Based on the three concepts, this work transforms an event into a sequence, which is similar to vectorized natural language. This kind of representation form of event can enable the model to better learn the evolution characteristics of the event. In order to obtain comment words automatically, a semi-supervised multi-label curriculum learning model is proposed, which can automatically convert comments into discriminative feature vectors, and then construct event vectors based on them.
- Based on the sequence data proposed in this paper, by the training mode of simulating event evolution, an event vector generation model NL2ER-Transformer with event evolution prediction ability is constructed based on Transformer. It solves the problem that the current event vectorization models only consider the static subjective characteristics of events and have not learned the dynamic evolution characteristics. This paper has carried out several experiments to verify the effectiveness of the model. The experimental results show that using the event vectors constructed by NL2ER-Transformer to train the public opinion reversal prediction model are better than the classifiers trained

by the event vectors constructed by other event vectorization models.

II. RELATED WORK

Feature extraction of event representation vector is the most important step to build a network public opinion prediction model based on machine learning. At present, the feature extraction of event vectors mainly includes three methods: manually designing features, pre-training model and knowledge graph.

A. Manually Designing Features

At first, scholars generated event vectors by manually defining or extracting qualitative and quantitative event features from social media. Research [2] uses 33 artificial features to assign values to public opinion events; study [3] made a secondary improvement on the basis of [2], reducing 33 features to 30 features; author in [4] combines Twitter and Weibo, and proposes some characteristics to analyze public opinion based on their commonalities; researcher in [5] combines time features and proposes new event features for rumor analysis. The manually defined event features are very dependent on expert knowledge which usually can only be obtained by observing the influencing factors of one period or even the whole period of the event. Although the manually defined event features contain some event evolution information and the prediction model based on them can obtain better prediction accuracy, this method requires that the event has evolved for a period of time before the event features are obtained, and it is difficult to determine the event features at the early stage of the event [6][7]. Therefore, the model trained with manually designed event features has poor prediction ability for events with short occurrence time, and the prediction accuracy is not high before the occurrence of public opinion phenomena such as public opinion reversal.

B. Pre-Training Model

With the continuous development of computer hardware technology, people have made great progress in natural language vectorization, from the initial word2vec [8]-[10] to ELMo [8] and GPT [11] with context awareness as the core. With the proposal of Transformer [12] in 2017, natural language vectorization has made amazing progress again, and language transfer models have begun to flourish. At the same time, the vectorization of public opinion events, which is closely related to natural language, has also been correspondingly improved. For example, studies [13] and [14] transform event description information into event vectors based on Transformer structure; Mohammadreza Samadi[15]used RoBERTa[16], XLNET[17], BERT[18] and other transfer learning models to transform events into vectors, and tested them on multiple groups of classification models; SZU Yin Lin[19] and Guillermo Blanco[20] used Bert to transform event information into vectors for subsequent prediction. Such methods are the mainstream methods for vectorization of news events or public opinion events at present, but they only vectorize according to the event description text, and do not consider the dynamic factors of

event evolution, such as public sentiment and attitude in the manually designing features. The method generated event vectors do not have enough information to express the change and development of events and it is difficult to accurately predict the reversal phenomenon in the process of public opinion evolution.

C. Knowledge Graph

As the mainstream method of public opinion research, knowledge graph has also been used by many scholars to construct public opinion event vectors. For example, research [21] proposed a method to construct a knowledge graph of public opinion with online news comments, which is used for the decision-maker master the online public opinion quickly and directly; study [22] constructed an NPOKG based knowledge graph for extracting features of public opinion events; study [23] based on ELECTRA and REDP methods, entity extraction and relationship extraction are performed on public opinion text information respectively. Network public opinion knowledge graphs are constructed for Weibo platform and short video platform, and comparative analysis is conducted on each network public opinion knowledge graph. However, from the experimental results of the research, it can be seen that the knowledge items contained in Internet public opinion are relatively sparse, and a large number of entities extracted through text can only construct a very small number of nodes, so it is not suitable to be used as a vectorization means of public opinion events.

In view of the problems of the above event vectorization methods, on the basis of the influence factors of the reversal event and dynamic temporality of public opinion evolution, this paper maps the public opinion event vector construction problem to the pre-train model based natural language feature vector generation problem. Based on the Transformer structure, we build an event vector generation model NL2ER-Transformer (Natural Language to Event Representation from Transformer) with the ability to predict the event evolution. The generated event vector is more in line with the evolution characteristics of public opinion reversal event. The classifier can accurately predict the events that may be reversed only relying on the information before the event reversal.

III. EVENT VECTORIZATION AND TRAINING METHOD OF SIMULATING EVENT EVOLUTION

In this section, we show the model for event vectorization and training method of simulating event evolution. The model consists of two parts. The first part transforms an abstract event that has occurred for m days into a sequence based on netizens' comments, by defining comment word (automatically obtained through the proposed semi-supervised multi-label curriculum learning model in Section III B), event word vector, event word and event sentence; The second part uses the proposed NL2ER-Transformer model to generate event vector that contain the characteristics of the event itself and the evolution characteristics of the event. The model framework is shown in Fig. 1.

Fig. 1. Model framework.

A. Mapping Public Opinion Event into Sequence Like vectorized Natural Language

Definition 1. Comment word

A comment word is a vector constructed by the corresponding comment text based on the characteristics of it. The specific form is shown in Formula (1).

$$C = [c_1, c_2, \dots, c_7] \quad c_i \in \{0,1\} \quad i \in \{0,7\} \quad (1)$$

We use vector \$C\$ to describe comments and \$c_i\$ is the \$i\$th feature. The value of \$c_i\$ and design criteria will be discussed in Section III.1(a).

Definition 2. Event word vector

The event word vector \$Z_j\$ represents the characteristics of an event on a certain day. The specific construction method is shown in formula (2)-(5).

$$\bar{C} = [\bar{c}_1, \bar{c}_2, \dots, \bar{c}_7] \quad \bar{c}_i \in \{0,1\} (1 \leq i \leq 7) \quad (2)$$

$$Z_j = [z_1, z_2, \dots, z_7] \quad (3)$$

$$\bar{c}_i = \frac{\sum_{t=1}^{k_j} c_i^{(t)}}{k_j} \quad (4)$$

$$z_i = \begin{cases} 1 & \bar{c}_i > \omega \\ 0 & \bar{c}_i \leq \omega \end{cases} \quad (1 \leq i \leq 7, 0 \leq \omega \leq 1) \quad (5)$$

Where \$k_j\$ is the total number of comments collected on \$j\$th day of the event, \$\bar{c}_i (1 \leq i \leq 7)\$ is the average value of the \$i\$th feature of all comments collected on the \$j\$th day, \$\omega\$ is a pre-defined threshold.

Definition 3. Event word

An event word is a decimal value corresponding to the event word vector.

The mapping relationship between an event word vector and an event word is represented by the event word dictionary in Table II. The construction process of a single event word is shown in Fig. 2.

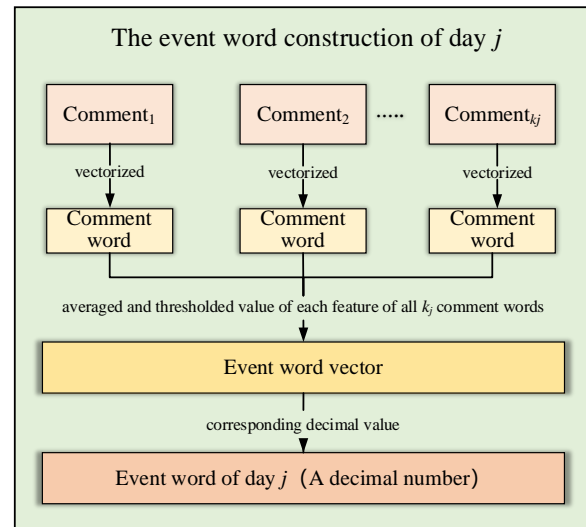

Fig. 2. Construction process of an event word for \$j\$th day.

Definition 4. Event sentence

Event sentence is a data form similar to vectorized natural language data, which is composed of event words according to the chronological order of events. The form of an event sentence is presented in Fig. 3.

Fig. 3. The form of an event sentence.

According to definitions 1 to 4, we can interpret all the comments on the \$j\$ day of an event as comment words one by one, construct the event word vector of that day with the average value of all the comment words of that day, map the event word vector to the event word of that day, and then arrange all the event words in order according to the time sequence of the event, so as to obtain the event sentence from the start of the event to the current time point.

Therefore, a public opinion event is represented as a description sentence (event sentence) with a certain meaning. The event words of each day in the event process constitute the vocabulary in the sentence, while the evolution time point of the public opinion event where the comment is located determines the grammatical order structure of the sentence. The event sentence obtained contains various specific information of the public opinion event from its start to the current time point including event evolution and change information.

1) *Characteristics of comment words and construction of event word dictionary*

a) *Design of features about comment words:* The comments are personal opinions that expressed by netizens on the situation occurred on the day of an event, usually in the form of short text or information combined with pictures and texts. In natural language, the number of words is limited, so each word can be uniquely encoded by constructing a

dictionary, and sentences can be constructed using the codes of words. This paper regards an event as a sentence and the comments as words in the sentence. However, because the different lengths of comment texts are too complicated, and each comment is a unique mind expressed by different people, it is difficult to use comments as words to construct an upper-limited "dictionary" in natural language.

The comments not only reflect the current progress of the event, but also includes the netizens attitudes. It is including the deep excavation, questioning and disclosure of the event. Additionally, in many cases the comments will affect the evolution direction of the event and even reverse public opinion. Based on the important influencing factors of public opinion reversal analyzed in [2][3], this paper designs seven discriminative features for comments, and transforms text comments into comment words at a relatively abstract level. The features and values of a comment word are shown in Table I.

TABLE I. FEATURE DESCRIPTION AND VALUE OF COMMENT WORD

Feature name	Feature description	Value
c_1	Whether the comment is mixed with some kind of social emotion	Yes 1, NO 0
c_2	Whether the comment's inclination is positive	Yes 1, NO 0
c_3	Whether the comment is in a declarative tone	Yes 1, NO 0
c_4	Whether the comment is cyberbullying	Yes 1, NO 0
c_6	Is the comment stereotypical	Yes 1, NO 0
c_7	Whether the comment has agenda setting	Yes 1, NO 0
c_8	Whether there are emoticons and special characters in the comment	Yes 1, NO 0

2) *Event word dictionary and event sentence:* According to the 7-dimensional comment word vector designed in Table I, after averaging and thresholding the comment words, the event word vector can be obtained. An event word dictionary

composed of event word vector and its corresponding decimal value is constructed, which is shown in Table II (all comment words are also derived from this dictionary).

TABLE II. EVENT WORD DICTIONARY

Features of event word vector Decimal value	Whether the comment is mixed with some kind of social emotion	Whether the comment's inclination is positive	Whether the comment is in a declarative tone	Whether the comment is cyberbullying	Is the comment stereotypical	Whether the comment has agenda setting	Whether there are emoticons and special characters in the comment
0	0	0	0	0	0	0	0
1	0	0	0	0	0	0	1
.....
127	1	1	1	1	1	1	1

3) *A model of comment word generation based on semi-supervised multi-Label curriculum learning:* In order to automatically generate the vector representation of a comment

in the NL2ER-Transformer model, this paper designs a semi-supervised multi-label curriculum learning model, the structure is shown in Fig. 4.

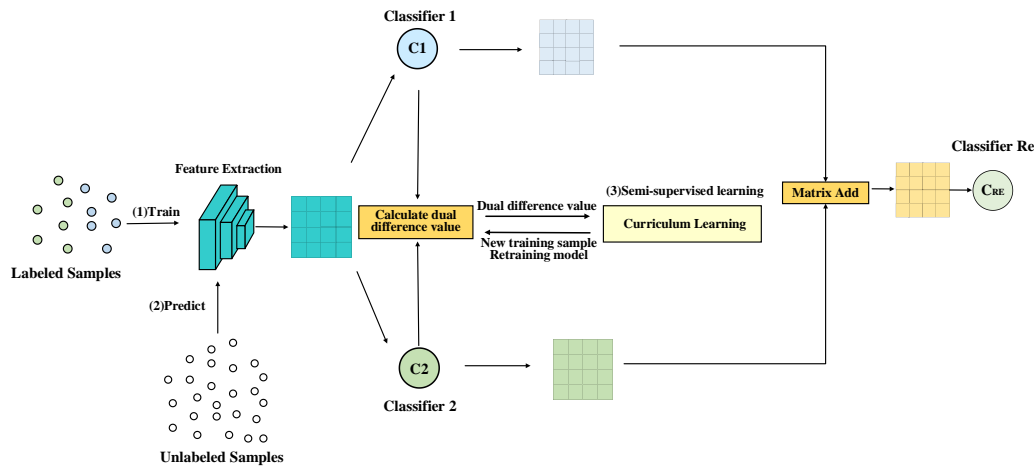

Fig. 4. Structure of the semi-supervised multi-label curriculum learning model.

The model contains four neural networks, one feature extractor $E(\cdot)$, two multi label classifiers $C_1(\cdot), C_2(\cdot)$, and one final classification $Cre(\cdot)$. Specifically, $E(\cdot)$ extracts features from samples; $C_1(\cdot)$ and $C_2(\cdot)$ are used to obtain the label prediction results(i.e., comment words); the label relation is

abstracted by adding $C_2(\cdot)$ and $C_1(\cdot)$, and finally classify the samples through $Cre(\cdot)$. During the curriculum learning, difference of $C_1(\cdot)$ and $C_2(\cdot)$ can be used to screen pseudo labeled samples added to training samples. The part of the semi-supervised curriculum learning is shown in Fig. 5.

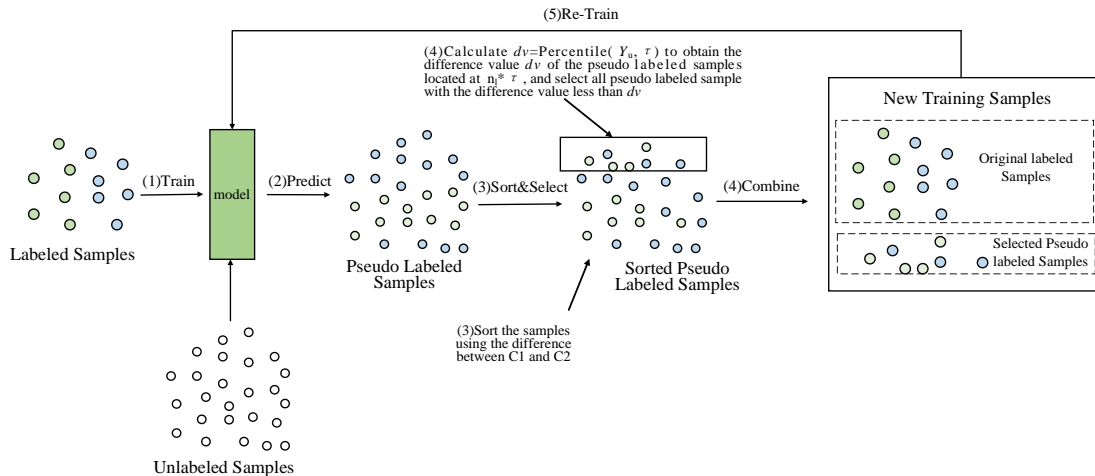

Fig. 5. Training method of the semi-supervised multi-label curriculum learning.

The training method of curriculum learning in Fig. 5 is explained as following, the details are in [26].

- Train the model with labeled comments; (2) Predict all unlabeled comments; (3) Rank pseudo labeled data based on the difference between $C_1(\cdot)$ and $C_2(\cdot)$; (4) Obtain the difference value $dv = \text{Percentile}(Y_u, \tau)$ of the samples ranking at $n_l * \tau$, select the pseudo labeled samples with the difference value less than dv and combine it with the original training set to form a new training set; (5) Re-train the model, and repeat (2) - (5) until all the pseudo labeled data have all the marks. n_l represents the number of labeled samples; $Y_u \in R^{n_l * d_l}$ represents the unlabeled feature matrix and the label matrix.

The adaptive threshold dv is obtained in accordance with the following method: In the training process, all the unlabeled data X_u into the model are put to predict and calculate the

difference df of each sample, and then rank it in ascending order according to the sample difference, after that we obtain sample difference value dv of location in $n_l * \tau$ and select the samples, which df is less than dv . Adding them to the labeled data set X_l , in which $\tau \in [0.2, 0.4, 0.6, 0.8, 1]$, that means after every cycle. It will select 20% or more pseudo labeled samples incorporated into the training set. The specific process of curriculum learning is shown in Fig. 5. The difference $df(x_i)$ is calculated as formula (6).

$$df = \| C_1(\cdot) - C_2(\cdot) \|_2^2 \quad (6)$$

B. Event Vectorization Model based on Transformer

Dynamic evolution is an important information of events. Learning the characteristics of the event evolution, which plays a significant role in predicting public opinion reversal from a developmental perspective. Inspired by training natural language, a training model NL2ER-Transformer is designed to

simulated event evolution based on the event sentence structure mentioned above. The model is based on Transformer structure which is a classic NLP model proposed by Google in 2017 [12]. Transformer uses a self-attention mechanism and does not use the sequential structure of RNN, so that it can be trained in parallel and can have global information. In the model, the event sentence from the start to the i th day of the event is used

as the training **feature**, and the event sentence from the start to the $(i+1)$ th day of event is used as the **label**. This process is similar to text translation: the sentences to be translated are as features, and the corresponding translation results are as labels.

The whole training process of the event based on NL2ER-Transformer is shown in Fig. 6.

Fig. 6. Training method of simulating event evolution.

IV. EXPERIMENTS

This paper verifies the effectiveness of the designed model from three aspects: (1) For the proposed comment word generating model based on semi-supervised multi-label curriculum learning, two multi-label classification benchmark models, Fast Tag [27] and Semantic Auto Encoder (SAE) [28], were selected for comparative experiments. At the same time, in the test data used for the downstream reversal prediction task, 50% of the comment words were automatically generated by the model, further verifying the effectiveness of the model; (2) For the event evolution analysis capability of the proposed NL2ER-Transformer model, we manually represent the event sentence value of each day of the event according to the definition, and then compare it with the event sentence value predicted by the model; (3) For downstream reversal prediction tasks, select different event vectorization baseline models and multiple classification models to verify the effectiveness of event vectors generated by NL2ER-Transformer model.

A. Datasets

We obtained 55 events in 2020-2022 from public opinion monitoring platforms such as Qingbo Index (<https://www.gsdata.cn>) and Zhiwei Shijian (<https://ef.zhiweidata.com/library>), including 26 public opinion reversal events, 29 public opinion non-reversal events, and a

total of 38,091 comments on related events. And according to the assignment rules given above, seven discriminative features of 8041 comments were manually annotated. Data can be obtained from the following link: <https://pan.baidu.com/s/1mEQxLdRyOHZd4T8Rmxz0fg>. Extraction code: xl8m

In the data annotation, for reversal events, from start to the day of reversal, the label is 1 and from the day after reversal to the end of the event, the label is 0; for non-reversal events, from start to the end of the events, the label is 0.

In the training of the comment word generation model, we selected 30472 comments in total, including 10051 manually labeled comments and 20421 pseudo-labeled comments generated by the proposed model. In the construction of the downstream public opinion reversal prediction model, we randomly selected 12 events as the test set (including 6 reversal events and 6 non-reversal events). The 50% of comments used for the test set are pseudo-labeled data generated by the proposed semi-supervised multi-label curriculum learning model), and the remaining 43 events as the training set.

B. Verification of the Comment Word Generation Model based on Semi-Supervised Multi-Label Curriculum Learning

TABLE III. COMPARISON RESULTS

Method	Absolute matching rate	Hamming loss	Accuracy	Precision	Recall	F1 score
FastTag	0.31189	0.14582	0.67537	0.2681	0.26729	0.2282
SAE	0.11021	0.2346	0.73342	0.49564	0.19515	0.24462
Our model	0.24489	0.16578	0.79937	0.72863	0.34015	0.3908

From Table III, it can see that excepting the absolute matching rate is 7% lower than FastTag, our model is much more than the traditional multi-label classification model in all indicators, This proves the effectiveness of the proposed multi-label curriculum learning model.

C. Evaluation for the Evolution Analysis Ability of NL2ER-Transformer Model

During training, the parameters of NL2ER-Transformer model are set as shown in Table IV.

TABLE IV. TRAINING PARAMETERS

Num_layers	d_model	num_heads	input_vocab_size	target_vocab_size	dropout_rate
2	64	4	128	128	0.1

For evolution analysis ability test, we train the NL2ER-Transformer model using the cross-validation method. One event is selected each time as the validation set, and the other events are used as the training set, and the method of error calculation for each learning result is shown in formula:

$$e = \frac{\sum_{i=1}^n (w_i - \hat{w}_i)^2}{n} \quad (7)$$

In formula (7), n is the number of days when the event occurs, the event sentence corresponding to the event is $S = [w_1, w_2, \dots, w_n]$, and the predicted result event sentence is $\hat{S} = [\hat{w}_1, \hat{w}_2, \dots, \hat{w}_n]$.

According to the experimental results, the model produced 4 prediction errors in total which happened in the 1st, 17th, 33th, and 34th experiments and the error values were respectively 3.6, 12.6667, 60, and 22.4285. The experimental results further show that the model does have the ability to analyze the evolution process of public opinion events, and can predict the evolution trend and changes of events. The event sentences with errors and their corresponding events are shown in Table V.

TABLE V. EVENT SENTENCES WITH ERRORS IN PREDICTION

Event	Type of data	Number of days	0	1	2	3	4	5	6	7
12-year-old girl lied about being raped by her teacher	Real event sentence	1	start	84	end	0	0	0	0	0
		2	start	84	82	end	0	0	0	0
		3	start	84	82	80	end	0	0	0
		4	start	84	82	80	82	end	0	0
		5	start	84	82	80	82	80	end	0
	Prediction	1-6	start	84	82	80	82	80	82	end
The death of a female teacher in Jiangsu during the invigilation	Real event sentence	1	start	81	end	0	0	0	0	0
	Prediction	1-2	start	81	16	end	0	0	0	0
Heilongjiang Xuexiang's 15 yuan per sausage attracts heated discussions	Real event sentence	1	start	16	end	0	0	0	0	0
		2	start	16	16	end	0	0	0	0
		3	start	16	16	16	end	0	0	0
	Prediction	1-4	start	16	16	16	17	end	0	0
A 15-year-old girl in Hei Longjiang killed her mother and hid her corpse in a cold storage room	Real event sentence	1	start	16	end	0	0	0	0	0
		2	start	16	0	end	0	0	0	0
		3	start	16	0	80	end	0	0	0
		4	start	16	0	80	2	end	0	0
		5	start	16	0	80	2	2	end	0
	6	start	16	0	80	2	2	48	end	
Prediction	1-6	start	16	16	17	17	1	17	end	

Table V show that three of the four erroneous events have only one day's prediction error, and the event with more errors have errors just from the second day. According to the analysis, the main reason is that of all events, only the error event contains '0' event words. The model has never "seen" the '0' event words during the training process, so the model prediction fails. Although the evolution of the event sentence is misplaced, we found that the label(reversal/non-reversal) of the event was predicted correct. So, we made a further comparison, and it turns out that the evolution process presented by the incorrectly generated event sentence is very similar to the event of 'Female tambourine businessman in Dali, Yunnan scold tourists' and the labels of these two events are also the same, i.e., non-reversal. This error obviously has no impact on the prediction results of public opinion reversal.

D. Evaluation of Downstream Reversal Prediction Ability for The Generated Event Vectors

1) *Experiment setup:* We compare our experimental results with the results of three common models: RoBERTa[24], XLnet[25], Manual designing features[3]. We generate the vectors respectively by the above four models, the first three of which are trained with the blog texts of events, and our proposed NL2ER-Transformer Encoder. Then, through training four prediction models: Linear SVM(LSVM), Back Propagation Neural Network(BPN), nonlinear SVM and KNN, we further compare the prediction effects of the vectors generated by these four methods.

The neural network includes four hidden layers, the number of neurons in each layer is 16, 32, 64, and 128, the activation function is Relu, the output layer activation function is Sigmoid, the loss function is binary cross entropy function, the

optimizer is Adam, and the training times are 100. In the linear SVM, C is set to 1, the loss function is hinge, and the training times are 100. The nonlinear SVM kernel function is set as sigmoid function, C is set as 1, and the number of iterations is 100. KNN algorithm sets the number of reference neighbors to 5.

2) *Experimental results analysis:* We use four indicators to evaluate the classification models: accuracy, precision, recall, F1-Score. We believe that as long as the model can give a reversal probability greater than 0.5 before the event reversal, the prediction is considered correct. From Table VI, we can see that the classification trained by our model is better than other vectorization methods in terms of ensuring high accuracy and precision. KNN and Nonlinear SVM trained in this way are not very good in the four indicators.

Public opinion reversal is a kind of phenomenon in the process of event evolution. Therefore, whether the vector representation of events includes the development and changes of public opinion determines whether the prediction model can learn the important knowledge of event reversal. Compared with netizens' comments, the factual description of events is relatively lacking in expressing the dynamics of public opinion evolution. So, the event vectors generated based on this factual description of events will affect the result of reversal prediction.

The presented classification models of reversal prediction trained with vectors generated by our proposed NL2ER-Transformer are better than or equal to those trained with vectors generated by other event vectorization methods. Therefore, we can infer that it is feasible to vectorize public opinion events by combining comments and event evolution.

TABLE VI. INDEX VALUE OF PREDICTION MODEL UNDER DIFFERENT EVENT VECTOR TRAINING

Representation	Method	Accuracy	Precision	Recall	F1-Score
RoBERTa	LSVM	66.66%	66.66%	66.66%	0.666
	BPN	66.66%	83.33%	62.5%	0.714
	Nonlinear SVM	50%	66.66%	50%	0.514
	KNN	41.66%	66.66%	44.44%	0.533
XLnet	LSVM	75%	100%	66.66%	0.8
	BPN	50%	83.33%	50%	0.625
	Nonlinear SVM	50%	100%	50%	0.666
	KNN	46.15%	85.71%	50%	0.5
Manual design features	LSVM	58.33%	16.66%	100%	0.2857
	BPN	58.33%	16.66%	100%	0.2857
	Nonlinear SVM	58.33%	16.66%	100%	0.2857
	KNN	58.33%	16.66%	100%	0.2857
NL2ER-Transformer	LSVM	91.66%	83.33%	100%	0.909
	BPN	91.66%	100%	85.71%	0.923
	Nonlinear SVM	83.33%	66.66%	100%	0.8
	KNN	91.66%	83.33%	100%	0.909

V. CONCLUSION AND FUTURE WORK

Aiming at the problems existing in the current research on event representation, this paper proposes an abstract mapping of events to sequences, and combines subjective comments and event temporality to transform public opinion problem into natural language processing problem. The NL2ER-Transformer model is constructed to realize the extraction of event features based on comments. The experimental results show that, compared with current mainstream event vectorization models, the event vectorization scheme proposed in this paper has a better effect on public opinion reversal prediction, and the training method proposed in this paper can indeed enable the vector generation model to learn events evolution information.

There are still some limitations in this paper, and the future work will be carried out from the following aspects:

- Since the discriminative features of comment words are designed based on the prediction of public opinion reversal, the pre-training of the model is only for the prediction task of public opinion reversal, and the effectiveness of other public opinion prediction tasks has not been thoroughly discussed. Next, the team will design a more general feature representation and generation strategy, and construct an event pre-training model in the field of public opinion prediction by testing different types of downstream tasks based on event vectors.
- Event sentence is only generated based on comments, and the features of comment words are discriminative features with strong subjectivity, and the fusion of other objective data is not considered. In future research, we will try to use new methods to combine other unstructured data, such as event description text, with relevant structured data in the process of public opinion evolution, to achieve event pre-training with multi-source data fusion, and to improve the generalization performance of the model.

Abstract—An intrusion detection system (IDS) is one of the most effective ways to secure a network and prevent unauthorized access and security attacks. But due to the lack of adequately labeled network traffic data, researchers have proposed several feature representations models over the past three years. However, these models do not account for feature generalization errors when learning semantic similarity from the data distribution and may degrade the performance of the predictive IDS model. In order to improve the capabilities of IDS in the era of Big Data, there is a constant need to extract the most important features from large-scale and balanced network traffic data. This paper proposes a semi-supervised IDS model that leverages the power of untrained autoencoders to learn latent feature representations from a distribution of input data samples. Further, distance function-based clustering is used to find more compact code vectors to capture the semantic similarity between learned feature sets to minimize reconstruction loss. The proposed scheme provides an optimal feature vector and reduces the dimensionality of features, reducing memory requirements significantly. Multiple test cases on the IoT dataset MQTTIOT2020 are conducted to demonstrate the potential of the proposed model. Supervised machine learning classifiers are implemented using a proposed feature representation mechanism and are compared with shallow classifiers. Finally, the comparative evaluation confirms the efficacy of the proposed model with low false positive rates, indicating that the proposed feature representation scheme positively impacts IDS performance.

I. INTRODUCTION

The rise of IoT has increased the number of connected devices, resulting in a growing need for effective security measures to prevent data breaches and cyber-attacks [1]. The MQTT (Message Queuing Telemetry Transport) protocol is widely adopted in IoT-enabled real-world applications such as smart homes, smart cities, smart industries, and smart healthcare due to its low bandwidth cost, low memory requirements, and minimal packet loss [2]. The MQTT protocol is based on a publish/subscribe mechanism and a central communication module, often called a broker, which is vulnerable to various security threats and attacks. In [3], researchers reported security risks related to the MQTT protocol and found over 53000 publicly accessible MQTT-based IoT devices.

In the existing literature, various security and prevention mechanisms based on cryptography and digital signature have been presented to deal with various attacks [4–5]. Cryptography is an effective solution for providing better security services by enabling source authentication mechanisms, but it is not robust against usability or availability attacks [6]. With the advent of machine learning (ML) techniques, more attention has been paid to studying intrusion and anomaly detection systems for IoT. Intrusion detection is an important aspect of IoT security which involves identifying abnormal behavior patterns and potential security threats in real-time. IDS and cryptographic-based approaches complement each other to ensure maximum security features such as confidentiality, integrity, authenticity, and availability [7–8]. Network IDS can be classified into signature-based and anomaly-based methods [9]. Signature-based IDS considers attack traffic patterns, while the anomaly-based approach usually considers normal traffic patterns. However, signature-based IDS only relies on known traffic patterns and faces limitations in detecting new sophisticated attacks whereas anomaly-based IDSs usually have a high false positive rate, which may require additional resources and time to eliminate the large number of alerts generated. Furthermore, existing IDSs are not well suited for MQTT-enabled IoT ecosystems, as they were designed with little attention to resource efficiency and scalability features [10].

Recently, many researchers have attempted to explore the ability of feature representations to handle large-scale traffic sampling and class imbalance in attack detection based on predictive modeling. In [11], an autoencoder-based evaluation framework is given to assess the effectiveness of various feature representation techniques for handling large-scale information streaming in text classification tasks. Similarly, researchers in [12] presented feature selection techniques based on unsupervised learning schemes to enhance data analytics tasks and computational intelligence performance on large datasets. Researchers in [13, 14, 15] reported enhancing the performance of real-time analytics operations on big data by using appropriate feature representation techniques. Furthermore, the adoption of autoencoders for feature representation is seen in many applications, such as the classification of anti-drug response [16] and diagnosis of autism spectrum disorder [17]. In [18], the authors applied the reported use of deep learning to feature learning to deal with big biological data for disease investigation.

Taking inspiration from the literature in which many researchers employ autoencoders for feature modeling, we are motivated to propose a new feature representation model for learning-driven IDS that can keep up with high network traffic and exhibit high accuracy in IoT intrusion detection.

This manuscript proposes a novel anomaly and intrusion detection solution in MQTT-driven IoT systems that combine unsupervised and supervised learning techniques. The proposed solution uses an autoencoder to extract robust features from normal traffic data, which are then clustered and assigned different cluster IDs based on their unique features. This information creates a supervised classifier to detect real-time anomalies and intrusions. The proposed solution offers several advantages over traditional security measures, including detecting unknown threats and adapting to changing threat landscapes. The scope of this research article is to provide an in-depth analysis of the proposed solution, including mathematical models and algorithms, as well as a discussion of the potential benefits and scope of real-world applications.

The remaining sections of this paper are organized as follows: Section II presents related work; Section III highlights the research problem explored and addressed in the proposed work; Section IV presents the system design and dataset details and preprocessing; the proposed feature representation mechanism is discussed in Section V, along with experimental analysis and result, discussion are carried to justify the scope of the proposed system, and finally, the entire work is concluded in Section VI.

II. RELATED WORK

This section presents a brief review of existing literature on IoT security that uses machine learning concepts in IDS design and approaches adopted for feature enhancement towards better classification outcomes.

The work carried out by Kaur et al. [19] employed a Convolution Neural Network (CNN) to recognize and describe various security attacks. The authors have validated their attack detection model through CICIDS2017 and CICIDS2018 datasets. However, this study offers a multiclass classification feature that does not meet higher accuracy for detecting many attacks. Another study by Odetola et al. [20] also adopted the CNN model to design a multiclass classification system for the IoT network. The authors have utilized a single CNN with multiple layers and a customizable loss function, which achieves less delay in the attack detection process. The authors in the study of Haripriya and Kulothungan [21] designed an IDS based on the approach of a fuzzy logic system for IoT devices against DoS attacks. The fuzzy logic has been widely used in many applications to deal with ambiguity in the dataset. However, using the fuzzy logic approach in this study for IDS design does not show its effectiveness due to its high complexity with an increase in the input dimension. In the IoT ecosystem, massive data is forwarded continuously. Also, this study is quite specific for the particular type of attacks, and more advanced or unknown attacks have been left untouched. The work of Ciklabakkal et al. [22] utilizes multiple machine learning techniques along with the autoencoder to detect intrusions in the IoT network. However, the authors have not

explicitly discussed the type of attacks they are considering. Faker and Dodge [23] employed a deep learning approach in IDS design and evaluated its performance on the two datasets, namely CIC-IDS2017 and UNSW-NB15. Alkadi et al. [24] used blockchain technology to ensure security and reliability in distributed IoT-IDS. In this study, Ethereum blockchain-based smart contracts are implemented to ensure privacy features, and Bi-Long Short-Term Memory (LSTM) is used to develop IDS that deal with sequential network flow. The effectiveness of the presented model is evaluated based on the UNSW-NB15 and BoT-IoT datasets. AI-enabled IDS is designed in the study of Fatani et al. [25]. The authors have addressed feature engineering issues using CNN and extracted relevant attributes in this study. Further, a transient search optimization mechanism is used to select the feature.

A game theory-based strategy is also adopted in the design of IDS. In the study of Wang et al. [26], the authors suggested an analytical framework to identify the circumstances under which malevolent devices have no motivations to perform the attack in the IDS attack-prevention game. The work of Basset et al. [27] presented a semi-supervised approach for IDS that considers sequential features of the traffic flow in the training phase. The authors have also focused on enhancing the learning performance of the system by tuning the system configuration during the generalization of spatiotemporal representations from the input dataset. A modified version of the attention mechanism helps the system focus on the significant attributes during the training process. Dutta et al. [28] suggested an anomaly detection scheme based on the sparse autoencoder, and an LSTM with logistic regression is further employed to detect malicious traffic. In Aygun et al. [29] study, a comparative analysis is carried out between two autoencoders for recognizing new or unknown attacks. Shone et al. [30] introduce an un-symmetric autoencoder system that offers better data generalization and dimensionality reduction. The work carried out by Tabassum et al. [31] suggested privacy-aware IDS. The preprocessing operations using autoencoder eliminate redundancies and present precise dataset modeling. The experimental analysis has shown the benefit of using an autoencoder in reducing the feature dimension and the computational complexity in the training phase. There are other recent works on IDS for detecting MQTT attacks in IoT using ML approaches highlighted in Table I.

TABLE I. HIGHLIGHTS ON EXISTING IDS FOR MQTT ATTACKS

Authors	Approach	Dataset	Metric
[32]	RF, NB, NDT, MLP	MQTTset	Accuracy and F1 Score
[33]	Tree Based Approach	Simulation	Detection rate
[34]	NB, LR, KNN,	MQTT-IoT-IDS2020	Accuracy, Recall, F1-score, Precision
[35]	XGBoost, LSTM, GRU	MQTT-IoT-IDS2020	F-beta score, Accuracy, Log loss
[36]	DNN	MQTT-IoT-IDS2020	Accuracy, Precision, Recall, F1-score
[37]	Transfer learning	MQTT-IoT-IDS2020 and IoT-23	Accuracy, Precision, Recall, F1-score

The existing literature has widely adopted machine learning techniques in IoT intrusion detection. However, previous solutions have some shortcomings, which should be handled efficiently. The findings reveal that most of the existing IDS schemes are specific to a particular adversarial scenario and may not be adaptive to detect unknown attacks and multi-class intrusions. It has also been noticed that majority of the recent works on IDS lack focus on handling class imbalance factor as most network dataset is imbalanced. Such schemes may be subjected to a higher false-positive rate in the intrusion classification task. There is also not much emphasis given by researchers on feature enhancement, and optimization in computational resources especially when the dataset is quite massive, like MQTT-IoT-IDS2020 (3.6 GB) and IoT-23 dataset (i.e., 21 GB). Therefore, the scope of such existing systems is limited and cannot be applied to large and dynamic networking scenarios.

The problem statement for the proposed work can be stated as *"It is challenging to design a feature representation mechanism that can offer a higher degree of optimization in the training samples, allowing the learning model to discover the precise pattern required for the detection of attacks with minimal false-positive and high accuracy rate."*

III. PROPOSED SOLUTION

The proposed approach is based on a combination of autoencoder-based anomaly detection and supervised classifier-based multiclass intrusion detection. The proposed approach consists of the following steps:

- Training the autoencoder with normal traffic data to learn a compressed representation of the data.
- Using the Gini measure to compute a threshold for assigning different cluster IDs to different classes of intrusions.
- Using the autoencoder to map the network traffic into the learned compressed representation.
- Introducing the Gini-based threshold with an ML classifier to perform multiclass intrusion detection.

The autoencoder is trained with normal traffic data to learn a compressed representation of the data, which can be used to detect deviations from normal behavior. The Gini measure is then used to compute a threshold for assigning different cluster IDs to different classes of intrusions. The autoencoder is used to map the network traffic into the learned compressed representation, and the Gini-based threshold is introduced with an ML classifier to perform multiclass intrusion detection. The first step is to train an autoencoder using normal MQTT message data. This autoencoder will learn the patterns of normal behavior and create a compressed representation of these patterns that can be used as a feature set for the intrusion detection system. Next, a supervised classifier is trained using a multiclass classification approach. The classifier is trained using labeled MQTT messages that correspond to different types of intrusions. The classification is performed on the compressed feature set produced by the autoencoder. To assign different cluster IDs to different classes of intrusions, a

threshold is computed using a Gini measure. The threshold is used to assign different cluster IDs to different classes of intrusions. This will enable the classifier to accurately identify and classify different types of intrusions. Once the classifier is trained, it can be used to monitor MQTT traffic in real-time. Any anomalous activity or intrusion that does not match the patterns of normal behavior will be detected by the autoencoder and flagged as a potential threat. The feature set produced by the autoencoder is then used as input to the classifier, which can classify the intrusion and take appropriate action. By combining an autoencoder-based anomaly detection system with a supervised classifier for multiclass intrusion detection, this solution can effectively detect and classify security threats in MQTT-driven IoT networks. This approach provides early detection of security threats, reduces false positives, and improves accuracy, making it a powerful tool for protecting IoT networks against attacks. In this work, the study deals with security on all three layers: the network layer, the transport layer (TCP and UDP analysis), and the application layer. The proposed model is based on the semi-supervised approach, where a combination of an autoencoder and supervised learning techniques is used to perform feature modeling and intrusion detection.

IV. MATHEMATICAL MODEL AND ALGORITHM

This section discusses the implementation procedure adopted in designing feature learning-based IDS.

The mathematical model includes training the autoencoder to learn the compressed representation of normal behavior, training a supervised classifier using the compressed feature set as input, computing a threshold value using a Gini measure, and using the classifier and threshold to detect and classify intrusions in real-time. Let $X = \{x_1, x_2, \dots, x_n\}$ be the input dataset consisting of n-dimensional feature vectors.

- Autoencoder: Let $AE(X) = \{y_1, y_2, \dots, y_n\}$ be the compressed feature set obtained by passing X through the autoencoder.
- Computing Distance: Let $d(x, y)$ be the distance function that measures the distance between the input vector x and its corresponding output vector y obtained from the autoencoder. Let $D = \{d(x_1, y_1), d(x_2, y_2), \dots, d(x_n, y_n)\}$ be the set of distances between the input and output vectors.
- Computing Thresholds: Let $T = \{T_1, T_2, T_3, T_4\}$ be the set of threshold values that divide the distance values into five clusters, where the first four clusters represent the different categories of attacks and the last cluster represents normal behavior. The threshold values are computed using the Gini index, which finds the optimal split of the distances into the five clusters.
- Cluster ID Assignment: Let $C_{id} = \{c_1, c_2, \dots, c_n\}$ be the set of cluster ID assignments for the input vectors, where c_i belongs to $\{0, 1, 2, 3, 4\}$. The cluster ID assignments are determined by comparing the distance values with the threshold values and assigning the corresponding cluster ID.

- **Training Supervised Classifier:** Let us consider $F = \{f1, f2, \dots, fm\}$ be the set of training features obtained by taking the mean of the compressed feature set $AE(X)$ for each cluster ID. Let $Y = \{y1, y2, \dots, yn\}$ be the set of class labels for the input vectors. Let clf be the supervised classifier, which takes F as input and learns to classify the input vectors based on their features. The classifier is trained using a labeled dataset that includes the input vectors X and their corresponding class labels Y . Once the classifier is trained, it can be used to classify new input vectors based on their features.

A. Training Autoencoder

Let X be a matrix of MQTT message data, such that $X \in \{X_1, X_2, X_3 \dots X_n\}$ where n denotes number of data samples. Here, each row represents a single message, and each column represents a feature. The autoencoder is trained to learn the compressed representation of normal behavior, such that $X \approx X'$, where X' is the reconstructed matrix of X obtained by encoder module expressed as follows:

$$Z = f(X, \theta) \quad (1)$$

Where, Z is encoding function produces compressed feature set X' of input X and θ represents the learnable parameters of the autoencoder given as follows:

$$\theta = W_i + b \quad (2)$$

Algorithm 1: Training Autoencoder

Input: X (Training Dataset), E (Training Epoch)

Output: X' & Re (reconstruction error)

Start

1. Init W (weights)
2. *for each* E *do*
3. *for each mini batch* *do*
4. Encode $X_i \rightarrow Z_i : f(X_i, \theta)$ // feature representation
5. Decode $Z_i \rightarrow X'_i : f(Z_i, \theta)$ // input reconstruction
6. Tune hyperparameter using GST (grid search technique)
7. *end for*
8. *end for*
9. Compute $Re \leftarrow f_1(X_i, X'_i)$
// Re is the mean reconstruction error on training data

End

The autoencoder is trained with normal traffic logs (X_i) in an unsupervised manner, i.e., without labels, and creates a compact representation of the input samples, which is a reconstructed version (X'_i) of the normal traffic log pattern as closely as possible. However, if the given input data actually belongs to the attack category, the reconstructed data can be different from the original input data. This means that the category of the network traffic data is determined according to the difference between the input and its output. It is considered an attack if the difference is greater than the set threshold or cut-off value. In this regard, the study computes a mean reconstruction error (Re) using the function $f_1()$ with an input argument X_i and X'_i . Basically, this function computes the

square of the minimum error between the input data and the reconstructed data given as follows:

$$Re = \frac{1}{n} \sum_{i=1}^n (x_i - x'_i)^2 \quad (3)$$

Where, n denotes the total number of data samples in the training samples, and the computed Re is obtained is 0.001.

B. Threshold Computation

To assign different cluster IDs to different classes of intrusions, a threshold is computed using a Gini measure. The Gini measure is used to identify the feature with the highest discriminatory power between classes. This feature is used to compute the threshold value, which is used to assign different cluster IDs to different classes of intrusions (refer Table II). For example, Let us consider d be the number of features in the compressed feature set Z . The threshold is computed using the following formula:

$$T = (max(Z[:, i]) - min(Z[:, i]))/2 + min(Z[:, i]) \quad (4)$$

$$i = argmax(Gini(Z[:, j])) \quad (5)$$

$$j = 1, \dots, d \quad (6)$$

where $Z[:, i]$ represents the i -th feature of the compressed feature set Z , and $Gini(Z[:, j])$ represents the Gini measure for the j -th feature of Z .

In the proposed modeling the Gini index is a measure of the impurity or diversity of a set of values. In the context of intrusion detection, the Gini index can be used to determine the threshold value for the anomaly score function g . Let D be the set of all instances in the dataset X . Let C be the set of possible cluster labels, and let D_c be the subset of instances in D that belong to cluster c . The Gini index for a given threshold value T is defined as:

$$G(T) = \sum \{c \in C\} p_c(T) (1 - p_c(T)) \quad (7)$$

where $p_c(T)$ is the fraction of instances in D_c that have an anomaly score greater than T , such that:

$$p_c(T) = |\{x_i \in D_c \mid g(x_i) > T\}| / |D_c| \quad (8)$$

Algorithm 3: GINI Measure Based Threshold setting (T_i)

Input: D (Distance values), X' (Sample outputs)

Output: T_i {T1, T2, T3, T4}

Start

1. Load sample outputs 10% of X'
2. Get unique values: $U = f_2(X')$
3. *for each* i *in* U *do*
4. Initialize gini as G
5. $G \rightarrow []$ // empty vector
6. *for* d *in* range $\min(D)$ *to* $\max(D)$ *do*
7. $K = Y$, where $D < d$
8. $\lambda = 1 - \sum (P(K == I))^2$
9. Append λ to G
10. *end for*
11. $T_i = d$ where G is maximum in gini
12. *end for*

End

The algorithm 3 consists an input variable D (Distance values), and X (Sample outputs). After execution it returns an output $T_i \in \{T1, T2, T3, T4\}$. The first step of the algorithm loads a random subset of the sample outputs, X' . Afterwards, it gets the unique output values from X' : $U = \{u_1, u_2, \dots, u_n\}$. For each u_i in U , the algorithm performs initialization of a vector subjected to Gini indices, $G = []$. Then, for each distance value d in the range $[min(D), max(D)]$, the algorithm computes set of K outputs from X' that have a distance less than d from u_i . Next it computes the probability $P(K == j)$ that a sample output in K belongs to each class j in the set of possible classes. Afterwards the computation of the Gini index λ is carried out as $1 - \sum\{j = 1\}^m (P(K == j))^2$, where m is the number of possible classes. Finally, the computed λ is appended to vector G . Based on the previous outcome the algorithm set T_i to d , where d is the value of D that maximizes the Gini index in G . After successful execution of the all steps, the algorithm returns an output of the threshold values T1, T2, T3, and T4 indicating distinct values for assigning clusters for each specific intrusion classes. The Gini index is used as a measure of how well a particular distance value separates the normal class from the different attack classes. The threshold values T1, T2, T3, and T4 are used to divide the range of possible distances into five intervals, which are then mapped to the five output classes (Normal, DoS, Probe, R2L, and U2R) for use in the supervised classifier.

C. Cluster ID Assignment

The assignment of the cluster ID is done based on the threshold value T_i obtained from the algorithm 2 and distance vector D computed using Eq. (9).

Algorithm 3: Cluster ID Assignment

Input: AuE (Trained Autoencoder), X_{Ts} (Testing Dataset),

Output: C_id (cluster id)

Start

1. Call Algorithm-1
2. Phase: Model Testing
3. Test model with entire text data $\rightarrow X_{Ts}$
4. Compute D using Eq. (5)
5. $//D \leftarrow$ distance between original input and output
6. Phase: Clustering
7. for each data class do
8. Compute T_i $//$ where $i = \{1, 2, 3, 4\}$
9. Call Algorithm-2
10. end for
11. Phase: C_id assignment
12. Check:
13. *if* $D < T1$ do
14. C_id $\rightarrow 0$ $//$ Nor
15. *elif* $D < T2$ do
16. C_id $\rightarrow 1$ $//$ MBA
17. *elif* $D < T3$ do
18. C_id $\rightarrow 2$ $//$ SCA
19. *elif* $D < T4$
20. C_id $\rightarrow 3$ $//$ SPA
21. *else*
22. C_id $\rightarrow 4$ $//$ SUA

End

Algorithm 3 comprises three phases for implementing the proposed feature representation scheme. i) distance computation, ii) threshold computation, and iii) cluster id assignment. The primary step algorithm employs the computing operation and functions discussed in the Algorithm 1, which is about training autoencoder model. Further, the algorithm computes the distance vector using a distance function that uses the Euclidian distance formula expressed as follows:

$$\vec{D} = \sqrt{\sum_{i=1}^n |x_i - x'_i|^2} \quad (9)$$

Where vector D consists value of the distance computed between input data (x_i) and reconstructed data (x'_i), where $x_i \in X_{Ts}$ and $x'_i \in X'_{Ts}$.

The subsequent steps of the algorithm are subjected to clustering operations. In this phase, the algorithm uses threshold vector (T_i) obtained from the Algorithm 2. This vector consists of different threshold values specific to each data class. Next, the threshold values contained in T_i are compared with distance value based on which cluster-id (C_id) is assigned to groups containing unique features specific to normal class attack classes (algorithmic steps: 14 to 22).

TABLE II. GINI VALUES AND THRESHOLD OF EVERY CLASS

Label	Attack Labels/Class	Gini	Threshold
0	Norm	0.9214	0.0116
1	MBA	0.9142	0.0592
2	SCA	0.9321	1.0753
3	SUA	0.9154	1.2643
4	SPA	0.9431	1.6823

D. Intrusion Detection

The proposed research work's primary aim is to evolve a novel intrusion detection system (IDS) to detect and forecast cyber-attacks with high detection accuracy and to recover the IoT application from the attack at the earliest by activating a suitable response. The intrusion detection problem in the proposed work is considered to be a multiclass classification task using a supervised ML classifier. The proposed study implements three different shallow ML classifiers i) Naïve Bayes (NB), ii) K-Nearest Neighbor (KNN), and iii) Random Forest (RF). These classifiers take cluster id as input and return observed data as normal and attack classes. In order to train the classifier, 50% of the dataset is considered, and 50% dataset is considered for model evaluation. The reason behind this is that the dataset set is quite huge and big consists of approximately more than 30 million of traffic samples; taking more than 70% of dataset in processing often encounter computing resource exhaustion error. To address this kind of problem only the proposed research work has introduced an efficient feature representation technique which does not need to be introduced with 100% of the dataset, taking few samples it can provided sufficient feature code for training machine learning classifiers. The uniqueness of the proposed work lies in the blend of 3-

layer autoencoders that enhance feature generalization capability of any learning model independent of large traffic samples and without imposing memory overhead problem.

V. IMPLEMENTATION AND RESULT

The design and development of the proposed system is carried out using python programming language scripted in Jupyter notebook on an anaconda environment.

A. System Design and Implementation

The proposed model is based on the semi-supervised approach, where a combination of an autoencoder and supervised learning techniques is used to perform feature modeling and intrusion detection. The first module of the proposed system focuses on data preprocessing, which is meant to handle null and missing values and data encoding. The second module of the proposed system emphasizes feature modeling and representation using autoencoder and distance function. The third module of the proposed system is about implementing machine learning classifiers for multiclass intrusion detection and classification. Fig. 1 illustrates the architectural design of the proposed system followed with methodology discussed in the above section. In this work, the study deals with security on all three layers: the network layer, the transport layer (TCP and UDP analysis), and the application layer.

Fig. 1. Illustration of methodology adopted in system design.

B. Dataset Used

The MQTTIoT-IDS-2020 dataset is adopted in this research work downloaded from the IEEE data port using the link [38]. The attack simulation setup mimics realistic 12 MQTT sensors in a network, consisting of a central

communication module (broker), a camera feed server, and an attacker. This network setup consists of both generic networking scanning and MQTT brute-force attack. The structure of an MQTT packet looks like as shown in Fig. 2.

Fig. 2. Visualization of MQTT packet structure.

The dataset is downloaded in PCAP data format created using a software called Wireshark. There is an excellent utility in python called Scapy, which can be used for packet manipulation and reading PCAP files in python. The same utility is used to convert dataset into .csv file format. It has been analyzed there are total five classes such as Normal, MQTT_Bruteforce, Scan_A, Scan_sU, and Sparta. In a 'Normal' there is no attack; it is just a normal operation in the network. The 'MQTT_Bruteforce' is an attack file where the attacker tries to get the MQTT broker's password by trying all combinations of letters. 'Scan_A' is an aggressive scan attack where an attacker looks for all IOT nodes on the network. 'Scan_sU' is a UDP scan looking for all CCTV cameras on the network, and 'Sparta' means SSH brute force trying to gain access to the main server. The distribution of each packet classes is illustrated in Fig. 3.

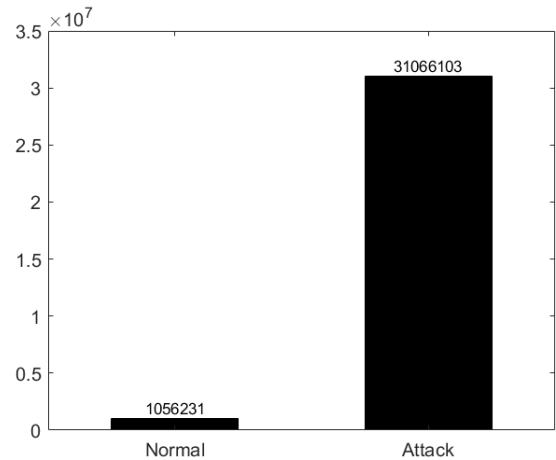

Fig. 3. Statistics of data distribution.

The graph trend exhibits that there is a total of 1026231 normal samples (Nor) and a total of 31066103 attack samples in the dataset. This analysis also reveals that the dataset is extensive and quite imbalanced, as more than 90% of the samples are subjected to the attack class.

Fig. 4. Statistics of the attack class distribution.

Fig. 4 shows the distribution of attack classes. Sparta (SPA) and MQTT Bruteforce (MBA) attacks have a significantly higher number of samples compared to other attack classes such as scan_UDP (SUA) and scan_aggressive (SCA). From the exploratory analysis, it is clear that this dataset is associated with class imbalance problems and cannot be directly introduced to the learning model; otherwise, the identification or classification results tend toward majority classes, i.e., SPA and MBA.

Further a basic preprocessing operation is executed where the index of each data sample is reset, and an extra column is added for the label representing 0 for normal class and 1 for attack classes. The data frame consists of 33 columns representing feature descriptors and 32092334 rows representing the total number of samples belonging to each feature descriptor. Hence, the dataset is big and consumes 8 GB of memory on the local hard disk. Therefore, the study puts effort into optimizing the memory requirement to hold such a large amount of network traffic data for ease of computing tasks. In this regard, irrelevant feature descriptor such as index, timestamp, and src_port is dropped. The index column has no importance in the classification problem, and the timestamp is not considered because the study does not process data as time-series samples.

On the other hand, src_port is a random number that can also be ignored. As a result, data retrieval can be speedup and memory can be optimized to counter the curse of dimensionality issues. Apart from this, the data preprocessing includes outlier analysis, removal of missing and NAN values, filtering out irrelevant feature descriptors, and performing normalization and data encoding operations for the categorical data types. The study also splits predictor and response data which is then stored in the separate variables x and y. Also, it has been noticed that that in x data, there are three categorical values such as src_ip, dst_ip, and protocol. The src_ip giveaway the attack as normal since there is only one malicious computer in the network. Therefore, this feature is dropped. Similarly, the dst_ip is irrelevant for attack prediction since it does not contain information about whether the packet is an attack or normal. Therefore, this will be dropped for further analysis. The protocol feature is relevant and needs encoding. Since the study adopts an autoencoder for feature modeling, nominal encoding is preferred where protocol names are replaced with a random number. The remaining feature

descriptors need no encoding, and all Nan values are filled with zero to avoid computational error during the autoencoder training.

C. Performance Indicators

The performance analysis is carried out based on classification metrics and comparative assessment is done to analyze the effectiveness of proposed feature representation framework from the multiple dimensions. The performance indicators used are briefly discussed as follows:

$$Precision = \frac{1}{n} \sum \frac{TP_i}{TP_i + FP_i} \quad (10)$$

$$Recall\ rate = \frac{1}{n} \sum \frac{TP_i}{TP_i + FN_i} \quad (11)$$

$$F1_Score = \frac{2(Precision * Recall)}{Precision + Recall} \quad (12)$$

Where i denotes the number of classes, TP denotes the true positive metric that shows attack packets are classified correctly, TN denotes the true negative metric that shows the normal traffic samples are correctly classified as normal, FP denotes the false-positive metric that shows normal traffic samples are misclassified as attack samples, and FN denotes false-negative metric that shows attack samples are misclassified as normal samples.

Fig. 5. Loss curve of trained autoencoder.

Fig. 5 presents the autoencoder's loss curve for analyzing its training performance. A closer analysis shows that a smooth curve has been obtained at each epoch, indicating a lower loss in the training process; hence a better performing autoencoder.

D. Comparative Analysis

The section presents outcome and performance analysis to demonstrate how the proposed feature representation technique enhances the IDS performance. In this regard, the performance evaluation is done by implementing ML classifiers with proposed feature representation model (i.e., WFR) and without feature representation model (i.e., WoFR). Since the proposed study focuses on multiclass intrusion detection, the precision, recall, and F1 score are computed for each data class. In addition, considering three ML classifiers demonstrates classification performance from the perspective of extensive analysis and against class imbalance problems.

1) *Analysis of NB classifier:* In this section the performance of proposed method will be evaluated with NB classifier (WFR) considering its comparison where the dataset is directly introduced with NB classifier (WoFR). The outcome obtained is shown in Table III.

TABLE III. NUMERICAL OUTCOME FOR NB CLASSIFIER (%)

	NB With Feature Representation (WFR)			NB Without Feature Representation (WoFR)		
	Precision	Recall	F1	Precision	Recall	F1
Norm	96.55	98.88	97.70	91.53	91.45	91.49
MBA	98.47	97.28	97.87	93.36	90.23	91.77
SCA	15.29	97.03	26.42	9.45	90.32	17.12
SUA	9.18	97.48	16.78	0	90.23	0
SPA	99.55	97.27	98.40	94.45	90.34	92.35

Table III shows the numerical outcome for the NB classifier for both case scenarios, i.e., WFR and WoFR. In the case of WFR, the NB exhibits a precision score of 96.55 %, recall rate of 98.88%, and F1 score of 97.70% for normal (Norm) class prediction. In the case of WoFR, the NB classifier shows a precision score of 91.53 %, recall rate of 91.45%, and F1 score 91.49%. Similar analysis can also be seen for the MBA class, where the NB classifier has achieved higher performance in the case of WFR. However, in predicting SCA and SUA, the NB classifiers do not show good performance. A closer analysis of outcome reveals the proposed system can efficiently enhance the performance of learning driven IDS without posing higher false positive rate unlike case of WoFR. This is because there are a smaller number of labels, and the dataset is associated with an imbalance factor. In the same way, the NB classifier also suffers in the classification of SUA. Although in the case of WFR, it has shown a 9.18% of precision score, whereas in case of WoFR, the NB could not predict SUA attack, i.e., it has achieved 0% precision rate.

The reason behind this that, SUA exhibits similar pattern to the normal class, and NB has no better generalization in this context. For SPA classification, NB classifier has shown better performance in case of WFR than a generic case, i.e., WoFR. A closer analysis reveals that the performance of IDS builds using NB classifier can be enhanced with the proposed method (WFR).

2) *Analysis of KNN classifier:* A closer analysis of the outcome from Table IV reveals that the KNN classifier shows better performance in the case of WFR than WoFR. However, at the same time, it can also be seen that KNN suffers from class imbalance factors for detecting both SCA and SUA classes.

TABLE IV. NUMERICAL OUTCOME FOR KNN CLASSIFIER (%)

	KNN With Feature Representation (WFR)			KNN Without Feature Representation (WoFR)		
	Precision	Recall	F1	Precision	Recall	F1
Norm	97.73	99.29	98.50	90.33	99.32	94.61
MBA	99.03	98.25	98.64	92.23	91.23	91.73
SCA	22.11	98.15	36.10	16.34	91.34	27.72
SUA	13.91	98.32	24.38	11.43	91.34	20.32
SPA	99.72	98.26	98.98	92.43	91.45	91.94

In the case of WFR, the KNN classifier performs better than the NB classifier. Also, for SPA attack, KNN performs very well, exhibiting 99.72%, 98.26, and 92.43% precision score, recall rate, and F1 score, respectively. On the other hand, KNN in case of WoFR, shows 92.43%, 91.45%, and 91.94% of precision, recall, and F1 scores, respectively. Moreover, the worst thing is that the SCA and SUA exhibits very similar pattern to the normal (Norm) class due to which the model did not reveal distinct pattern in the training process. Therefore, in the case of SUA and SCA detection, the KNN is not able to generalize and distinguish distribution SUA pattern as it faces difficulty in predicting the correct value of K because of closer similarity among the feature of normal and SUA. Although, simulation outcome shows that the proposed method enhances the performance of KNN for the multiclass intrusion detection even the dataset is imbalanced. But still there is a scope for the improvement for handling class imbalance problem, which will be done in our future work.

3) *Analysis of RF classifier:* The quantified outcome from Table V demonstrates that in the case of WFR, RF has achieved a precision score of 99.92 %, recall rate of 99.97%, and F1 score of 99.95%. Whereas, in the case of WoFR, RF classifier shows a precision score of 89.21 %, recall rate 89.63%, and F1 score 89.42%. For classification of a normal class, it can be analyzed that RF with proposed method (WFR) has achieved very good performance than other classifiers such as NB and KNN.

TABLE V. NUMERICAL OUTCOME FOR RF CLASSIFIER (%)

	RF With Feature Representation (WFR)			RF Without Feature Representation (WoFR)		
	Precision	Recall	F1	Precision	Recall	F1
Norm	99.92	99.97	99.95	89.21	89.63	89.42
MBA	99.97	99.94	99.95	89.22	90.32	89.77
SCA	89.57	100	94.5	87.34	90.23	88.76
SUA	82.63	99.87	90.44	82.43	90.23	86.15
SPA	99.99	99.94	99.96	92.24	90.34	91.28

In the case of WFR, the RF classifier for the SCA classification shows an 89% precision score, which is better than NB (15.29%) and KNN (22.11%). RF classifier also achieved a 100% recall rate where NB and KNN showed 97.03% and 98.15 %, respectively. With the proposed method, RF classifiers correctly identify normal packets and classify different attack classes. Hence, based on the above inferencing and discussion, it is concluded that the proposed work of feature representation can significantly enhance the outcome of any prediction system for designing enhanced IDS.

E. Discussion and Implication

The proposed work aims to enhance the performance of data driven or learning based IDS for the accurate detection and classification of attacks in dynamic networks such as IoT. The proposed study has considered the case study of MQTT enabled IoT networks because MQTT-based attacks are more dynamic and complex as they can easily mimic benign or normal behavior. In such cases, precise identification of attacks or intrusion becomes very difficult and challenging for any kind of IDS. Therefore, the proposed study has presented a feature representation framework that helps machine learning models better generalize the latent features and learn the distribution of data features more precisely. Three supervised classifiers have been implemented and trained with features enhanced by the proposed scheme (WFR). Their outcome is then compared with the classifiers trained with normal data i.e., without applying the proposed method (WoFR). The comparative assessment shows that the outcome achieved using the proposed feature representation (FR) is promising. The classifier trained with data that are enhanced by the proposed scheme WFR is superior. However, among three classifiers RF has achieved superior performance in both the cases of WFR and WoFR. This can be also evident in Fig. 6, where comparative analysis of each technique is given in terms of F1_score.

The RF is based on the design principle of the decision tree (DT) algorithm, which adopts similar principle of using din DT to determine how the features of a dataset should split nodes to form the tree. The KNN is based on Euclidian distancing; better performance is expected for the labels with lower support values. The NB classifier is a probabilistic model based on the Bayes' Theorem that has a specific assumption that the data is a particular feature of data not related to any other form of features. Therefore, this assumption of the NB classifier makes it incapable in the case of SUA attack classification as SCA attack that mimics a similar pattern of normal class. Since the dataset is associated with an imbalance factor and, KNN and NB suffers in classification and do not provide a good result.

Fig. 6. Comparative analysis in terms of F1_score.

It is to be noted that the extensive outcome is not conducted due to the lack of sufficient and relevant research works on the similar dataset adopted in the proposed study. To date, the dataset has only 49 citations evident from the google scholar. However, in future work, the study considers handling data imbalance factors to strengthen the classification performance, making it more suitable to fit the real-time scenario. In future work, the proposed technique will be extended with the deep learning approach by calibrating it to generalize what to learn and what not to learn.

VI. CONCLUSION

The proposed research work deals with the intrusion detection system in the IoT ecosystem against MQTT attacks. The main contribution of the proposed study is a novel autoencoder-based clustering method that ultimately assigns a cluster-id to every packet. The proposed work offers an advanced data treatment method for critical feature modeling using an artificial neural network. The study also explores the effectiveness of different machine learning algorithms evaluated with standard and new datasets preprocessed via the proposed autoencoder scheme. The outcome statistics reveal the efficacy of the proposed feature representation technique, and comparative assessment justifies its scope in the real-time application. In future work, the proposed preprocessing scheme will be introduced with more advanced methods such as deep learning with a novel regularizer scheme to deal with dataset imbalance factors and achieve reliability in the classification process.

Abstract—To meet the increasing security requirement of authorized users of flight simulators, personal identification is becoming more and more important. Iris recognition stands out as one of the most accurate biometric methods in use today. Iris recognition is done through different edge detection methods. Therefore, it is important to have an understanding of the different edge detection methods that are in use these days. Specifically, the biomedical research shows that irises are as different as fingerprints or the other patterns of the recognition. Furthermore, because the iris is a visible organism, its exterior look can be examined remotely using a machine vision system. The main part of this paper delves into concerns concerning the selection of the best results giving method of the recognition. In this paper, three edge detection methods, namely Canny, Sobel and Prewitt, are applied to the image of eye (iris) and their comparative analysis is discussed. These methods are applied using the Software MATLAB. The datasets used for this purpose are CASIA and MMU. The results indicate that the performance of Canny edge detection method is best as compared to Sobel and Prewitt. Image quality is a key requirement in image-based object recognition. This paper provides the quality evaluation of the images using different metrics like PSNR, SNR, MSE and SSIM. However, SSIM is considered best image quality metric as compared to PSNR, SNR and MSE.

Keywords—Identification; authentication; detection; canny; Sobel; Prewitt; PSNR; SNR; SSIM; MSE

I. INTRODUCTION

In the paper, the automatic authorization of flight simulator users is considered. Large pilot training centers require an increased security level to minimise the probability of unauthorised usage of the devices. In addition, pilot training procedures have to be rigorously verified as the number of hours spent in the simulator during virtual flights serves as proof of sufficient practice level for the pilot (in addition to hours spent in actual aircraft). Therefore, flights on certified flight simulators can be (to some extent defined by Regulatory Authorities) used as an alternative and cheaper counterpart to actual training flights because current flight simulators mimic the cockpit of the aircraft and the environment outside of the aircraft with great fidelity for maintaining the expertise of both civilians and military aircrews.

Flight simulators have significantly impacted the expertise and cutting-edge use of training pilots and aircraft crews, resulting in increased efficiency as training will not be affected by things like bad weather, aircraft space restriction and aircraft availability. It allows pilots to experience a wide range of flight scenarios and conditions to experience real-life

situational awareness. Haslbeck et al. [1] reported an experimental study where pilots with varying levels of experience and training had to fly 45 minutes of approach landing scenarios and compare their performance to manual flying. Their findings showed that a pilot with high levels of flight simulator training exhibits high and homogenous performance. Enhancing the pilot's monitoring techniques during the training session may aid in determining a pilot's performance in a flight simulator by employing object detection algorithms to analyze the pilot's head movement and eye gaze. The trainer can utilize this data to pinpoint areas where the pilot might benefit from extra instruction or development [2]. Škvareková et al. [3] research shows using eye tracking technologies to monitor eye movement to assist pilot training in flight simulators.

Its fidelity is not limited to training the pilot and aircrew. They are also used for research, enabling designers to examine the effects of various alternatives without spending money or waiting for various prototypes to be built [4], conduct aircraft incident investigations, and better understand ergonomic relationships [5]. Flight simulation is a multidisciplinary field that draws on many different areas of study, including human factors, motion actuation, sensory perception and visual image processing [6 - 7].

The use of flight simulators in pilot training has become indispensable, likewise the need to secure this gadget by minimising unauthorised users. They offer secure, affordable and adaptable alternatives to teach pilots in various scenarios and settings, enhancing their knowledge, self-assurance and decision-making capabilities [8 - 9]. As evident in Fig. 1, the flight simulator developed in the WrightBroS project is depicted.

The technology of digital imaging helps to manipulate digital photos using computers. The pre-processing, enhancement and display extraction of information is three general phase's frameworks where all forms of data must pass while employing digital technologies. A digital image consists of a limited number of elements, each having a specific position and values. These items are known as picture elements, pixels and image elements. The term pixel is the most usable form of the digital picture elements [10 - 11].

The word iris is a classic term. As with the colored part of the external eye, iris appears as of the 16th century and was taken to denote the variegated look of its structure [12]. The human iris contains many characteristics including freckles, crown, strips, furshes, crypts, etc., and is the annular section between pupils and sclera. In contrast to other biometric characteristics based on personal authentication recognition of iris can achieve great precision because of the rich texture of iris patterns [13]. Fig. 2 shows the full eye image with all its features.

Fig. 2. A general view of a human eye [15].

Although the history of iris recognition comes back to the 19th century, automatic iris recognition is a newly emergent issue in biometrics [14]. It seems that the French ophthalmologist Alphonse Bertillon was the first one who proposed the use of iris pattern (color) as a basis for personal identification. Flom and Aran Safir suggested also using the iris as the basis for a biometric in 1981 [15].

Regarding the level of precision, it is apparent the fact that iris recognition requires an excellent recognition rate and, as a result, applying edge detection approaches for this problem are efficient, which has not been extensively investigated in previous studies for such systems.

The main goal of this study is to use different techniques to detect the edges of the images and then examine the results to

see which technique effectively detects and sharpens the edges. For this study, the following primary objectives have been proposed:

- To recognize iris through edge detection methods.
- To compare the results of the selected edge detection methods.
- To check the performance of the methods via evaluation measures.

II. LITERATURE REVIEW

This section includes algorithms, methods, procedures, processes, approaches, techniques, detectors, models, and filters, as well as all of the history research where their links were used as evolutionary and provided the optimized form of solutions for edge detection issues. As a result of the researcher's efforts, the number of filters has grown over time. They worked hard to improve, enhance, co-relate, and collaborate on various methods to solve edge detection problems in image processing, and they created new, modified methods.

Edge detection is at the forefront of image processing for object detection, understanding edge detection methods are critical. ISEF, Canny, Marr-Hildreth, Sobel, Kirsch, Lapla1 and Lapla2 and Hough transform are the most important and widely used edge detection techniques [16].

Edge detection methods are further categorized into Gradient based (1st derivative order) and Gaussian based (2nd derivative order). Gradient based methods can be classified into Sobel, Prewitt, Robert, Kirsch, Robinson and Frei-Chen. Gaussian based methods are divided into Canny edge detection, Difference of Gaussian, Laplacian of Gaussian (like, Marr-Hildreth method) and Zero Crossing [17 – 18]. Fig. 3 shows the taxonomy of the methods which are related to the detection of the iris.

The Canny edge detector is a common and effective edge feature detector that is utilized in many computer vision algorithms as a pre-processing step [19 – 20]. The steps in the Canny Edge Detection Algorithm are as follows [21]:

- Step 1: Apply a Gaussian filter to the image to smooth it out.
- Step 2: Using finite-difference approximations for partial derivatives, compute the gradient magnitude and orientation.
- Step 3: Apply non-maxima suppression to the gradient magnitude, then detect and link edges using the double thresholding approach.
- Step 4: The operator that optimizes the product of signal-to-noise ratio and localization is approximated by the Canny edge detector. It is usually a Gaussian's first derivative.

Fig. 3. Taxonomy of image detection methods.

For edge detection, the Sobel operator is utilized. The Sobel approach finds image edges using the derivative approximation in the edge function [22]. The Sobel algorithm is broken down into four steps [23]:

- Step 1: Converting the image to grayscale is the first step.
- Step 2: Using the Sobel-x filter to enlarge the grey image.
- Step 3: Applying the Sobel-y filter to the grey image.
- Step 4: Determining the magnitude and direction of the gradient.

In image processing, the Prewitt operator is commonly employed in edge detection techniques. It is a discrete differentiation operator that computes an approximation of the picture intensity function's gradient. The Prewitt operator returns either the relevant gradient vector or the norm of this vector at each location in the image [24]. The Prewitt method is broken down into four steps [17]:

- Step 1: Read an image as input.
- Step 2: Create a grayscale image from a true-color RGB image.
- Step 3: Double-click the image to enlarge it.
- Step 4: Fill the filtered image matrix with zeros before starting.

The literature collects data on iris-based identification methods. It also eloquently discusses each method's effectiveness and highlights areas for future investigation for concerned scholars. The results of this study may be utilized to enhance iris detection system development.

TABLE I. SUMMARY OF THE ARTICLES ALONG THEIR PROMINENT METHODS, DATASET AND RESULTS

Biometric Trait	Ref.	Methods	Dataset	Results
Iris	[25]	Circular transform convolutional network	Hough and neural CASIA-V3	Left and Right-side iris recognition accuracy is 99%.
	[26]	Hough transform and region-based convolutional network	neural CASIA	99.14% of accuracy
	[27]	Hough transform and region-based convolutional network	neural CASIA-V4	Accuracy is 96.3%
	[28]	Convolutional network	neural IITD	97.46% of accuracy
	[29]	Hough transform with canny edge detection	CASIA-VI	Accuracy is 93.33%
	[30]	Circular transform with contour	Hough with active CAISA	88.3% of accuracy

Table I describes numerous iris recognition methods along dataset and their results which learned from earlier references. Some of these articles address the entire recognition procedure while others focus on the methodology only.

III. MATERIALS AND METHODS

The main step is pre-processing, feature extraction and matching where edge detection methods are used and try to improve the efficiency. The pre-processing steps comprise the conversion of the image from a color image to gray-scale image, iris localization, edge detection, filtration, etc. Now the Fig. 4 represents the proposed model for image processing especially iris recognition.

Fig. 4. Proposed model for iris recognition.

According to Fig. 5, this section covers the project's basic flow, the suggested iris recognition model, and the project flow chart in a more organized manner. Level 1, Level 2 and Level 3 of Project flow chart are demonstrated in detail. The

activity of getting an image from a source is known as image acquisition; image segmentation is the process of separating an image into sections or regions; and feature extraction techniques are used to obtain features that will be useful in image classification and recognition. Edge detection will be done by using Canny, Sobel and Prewitt edge detection methods for iris recognition.

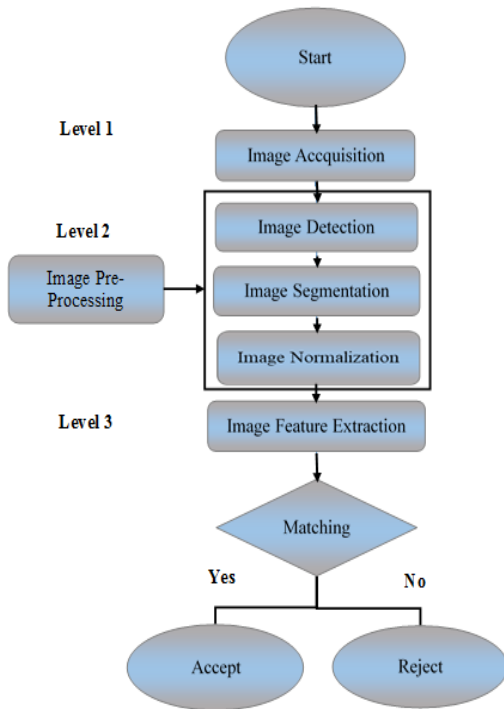

Fig. 5. Project flowchart.

IV. RESULTS AND DISCUSSION

This experiment represents the analysis of the various methods of edge detection. Edge detection is a fundamental step, and it is necessary to point out the true edges to get the best results. That is why it is important to choose a good edge detection method. The experiment was done on MATLAB software and tested with the eye image. To extract the clean edges is main objective. In this experimental analysis, the results of the five images from the CASIA dataset are obtained in Table II. The results of the methods of Canny, Prewitt, and Sobel on the original images are analyzed. After this experimental analysis, it is found that the canny edge detection method is working well in comparison with Sobel and Prewitt. In the empirical testing, it can be seen clearly that Prewitt and Sobel do not produce good sharp edges. Sobel is not very accurate in edge detection as it detects thick and rough edges and does not give appropriate results. Analysis shows that

canny extraction of image features without affecting and altering the feature is good. It is observed that the canny edge detector method is a better edge detector method of forming the edges for inner as well as outer lines. Hence, it is experimentally proved that canny is the most efficient and optimal method of edge detection.

Here, Table III illustrates the results of five images from the MMU dataset used in this experiment. After experimental examination, it is clear that canny method is more accurate rather than the Prewitt and Sobel. These are simple in evaluation separately then it improves the image results in the form of features extraction.

A. Image Quality Metrics for CASIA Dataset

For five images of CASIA Dataset, PSNR (Peak Signal to Noise Ratio), SNR (Signal to Noise Ratio), MSE (Mean Square Error), SSIM (Structure Similarity Index Method) for different methods have been calculated. Noisy images are converted into filtered images by using Gaussian noise to the images and filtered by Gaussian Filter and then results for all metrics are compared. From Table IV, it can be seen that all metrics have given almost consistent results. But SSIM is normalized as compared to PSNR, SNR and MSE. So, from this analysis the SSIM is comparatively better than MSE, SNR and PSNR metrics from human visual perspective.

B. Image Quality Metrics for MMU Dataset

Similarly, in Table V now, it is calculated PSNR, SNR, MSE, and SSIM for five images from the MMU Dataset. However, SSIM is balanced in terms of visibility, whereas MSE and PSNR are not. As a result, SSIM can be dealt in a more straightforward manner than MSE and PSNR. This is because MSE and PSNR are absolute errors, whereas SSIM produces perception and image errors. When the noise level rises, the recovery quality of the output image worsens as well. So, SSIM is better amongst all other metrics.

C. Comparative Analysis of the CASIA and MMU Dataset with Different Approaches

In Table VI, there are a number of articles presents their empirical testing results in the form of accuracy for iris recognition. Besides this, the evaluation datasets are also described for the further processing of the testing whereas the 99.7% ratio of the accuracy according to the CASIA-V1.0 and this gives the results from [38]. The result of 97.2% accuracy of the CASIA-V3.0/V4.0 is presented in the good form of the [38]. In [37], MMU-V1.0 dataset of the iris provides the high form of the ratio which is 99.45% accuracy as compare to the other research articles.

[39]	Morphological operators	MMU-V1.0	98.78%

D. Graphical Analysis of Image Quality Metrics for CASIA Dataset

Fig. 6 illustrates the PSNR for the CASIA dataset is almost constant, i.e., 17.4, from starting image CI-1 (CASIA Image) to image CI-4. After CI-4, there is a sharp increase in the PSNR. In C-5, there is a gradually change in values from 17.4 to 18.5 which shows an abrupt change as compared to four other images. CI-5 image shows PSNR value 18.5162 which is high as compared to other values. High value of PSNR gives better resolution of image. Therefore, CI-5 gives better result in this case.

Fig. 6. PSNR of CASIA dataset.

The fluctuation shows in Fig. 7 with the value of SNR between first and fourth image while there is a hike between fourth and fifth image. CI-1 image shows SNR value 10.8, then there is a slight change and CI-2 image shows SNR value 11.5. Image CI-3 shows abrupt change with SNR value 9.2. CI-4 image with minor change shows SNR value 9.0. CI-5 image shows SNR value 15.7. In this graph image CI-5 shows good resolution because of high value.

Fig. 7. SNR of CASIA dataset.

According to the Fig. 8, the SSIM value for each preceding image is larger than the previous one except for the image CI-3. SSIM values ranges from -1 to 1. -1 is the lowest value which shows that there is no similarity between images and 1 value is considered to be the highest value which shows that there is a high similarity between images. Now here, CI-1 image provides better resolution than all other images with SSIM values.

Fig. 8. SSIM of CASIA dataset.

Fig. 9 presents that the value of MSE for the sequentially four images are almost constant while for the 5th image, there is a drop in the value of MSE. The MSE value is the average difference between all pixels in the image. A greater discrepancy between the original and processed image is indicated by a higher MSE value. MSE value is positive. A value close to 0 is considered a better value. So, image 4 with MSE value 1160.7283 shows better result in CASIA dataset

Fig. 9. MSE of CASIA dataset.

E. Graphical Analysis of Image Quality Metrics for MMU Dataset

The PSNR block calculates the PSNR between two images in decibels. This ratio is used to compare the features of the original images and filtered image. PSNR reflects the peak error measurement. MMUI-1 shows PSNR value 18.5219 while MMUI-2 shows PSNR value 18.7602. MMUI-3, MMUI-4 and MMUI-5 represent less constant PSNR values as compared to MMUI-1 and MMUI-2 which shows MMUI-2 with greater PSNR value (18.7602) is better result in Fig. 10.

Fig. 10. PSNR of MMU dataset.

Therefore, Fig. 11 represents results of SNR values for MMU Dataset. The SNR measures how well a desired signal compares to background noise. MMUI-1 shows better result in graph as compared to MMUI-3, MMUI-4 and MMUI-5. As there is a decline after MMUI-2, so MMUI-1 is finer among all values.

Fig. 11. SNR of MMU dataset.

The results of SSIM values for MMU Dataset are illustrated in Fig. 12. MMUI-1 shows 0.280778 SSIM result as there is a fall off after image 1. MMUI-2 shows 0.268316 SSIM value in the meanwhile there is a lift after image 2. MMUI-3 present 0.299774 SSIM value while there is a turn down in MMUI-4 and MMUI-5. So, MMUI-3 provides better result.

Fig. 12. SSIM of MMU dataset.

In Fig. 13, MSE value for MMUI-1 lies between 900 and 950. There is sudden fall after image 1; MMUI-2 shows MSE values between 850 and 900. After image 2, there is abrupt change in graph. MMUI-3, MMUI-4 and MMUI-5 show constant values at their peak level values between 1000 and 1050. A value close to 0 is considered a better value. So, MMUI-2 with exact MSE value 865.0809 shows better result in MMU dataset as it is the lowest value as compared to all other values in the graph.

Fig. 13. MSE of MMU dataset.

F. Comparative Analysis of Image Quality Metrics

The Fig. 14 demonstrates the comparative analysis for the PSNR values of CASIA and MMU dataset. A major difference can be seen between two datasets. The CASIA dataset shows constant result for four images and then there is an increase in the graph for image 5. The MMU dataset shift for three images and then shows constant result for 4 and 5 images. First four images of MMU dataset are strongly preferred as compared to first four images of CASIA dataset because of high PSNR value. But in comparison, 5th image of CASIA dataset is better than 5th image of MMU dataset. So, in this graph MMU dataset results are good in the form of PSNR.

Fig. 14. Comparative analysis of PSNR.

In the Fig. 15 graphical analyses, SNR values of CASIA and MMU dataset are compared. Differences between two datasets distinguish both of them. The CASIA dataset shows oscillation for five images in the graph. On the other side, MMU dataset describes shift for three images and then shows constant result for 4 and 5 images. First four images of MMU dataset are strongly preferred as compared to first four images of CASIA dataset because of high SNR value. But in comparison, 5th image of CASIA dataset is better than 5th image of MMU dataset because of slight high difference. So, in this graph MMU dataset results are better according to the SNR.

Fig. 15. Comparative analysis of SNR.

The SSIM values of CASIA and MMU dataset are analyzed in Fig. 16. Up and downs between two datasets distinguish rather first four images of MMU dataset are better as compared to first four images of CASIA dataset because of high values near to zero. But in comparison, 5th image of CASIA dataset is better than 5th image of MMU dataset as slightly high difference. So, MMU dataset results are strongly preferred.

Fig. 16. Comparative analysis of SSIM.

The graphical analysis shows MSE values of CASIA and MMU dataset in Fig. 17. The CASIA dataset shows variation for five images in the graph. Besides this, MMU dataset represents rise and fall for 5 images. First four images of MMU dataset are better as compared to CASIA dataset because of low values near to zero. But in comparison, 5th image of CASIA dataset is better than 5th image of MMU dataset because of lowest value. So, in this graph MMU dataset results are strongly good.

Fig. 17. Comparative analysis of MSE.

V. CONCLUSION

This research covers all of the conclusions from the research methods. The main objectives are completed by comparative analysis of the edge detection methods which is the required tasks. Three edge detection methods have been proposed for identifying the borders of objects within images from two benchmark datasets (CASIA, MMU), removing blurriness from the findings through edge detection techniques, and evaluating performance using parameters. The study's accomplishments are revealing a considerable improvement in image quality and crispness. This study also includes suggestions for future improvements that other researchers should explore in order to concentrate on the experimental results, obtained the defects detected in this work, and apply the highlighted work to other areas that need attention.

In the future, a new filtered method can be created to overcome the constraint in order to improve image quality and enrich the image by minimizing noise.

ACKNOWLEDGMENT

The authors would like to acknowledge that this paper is based on the results achieved within the WrightBroS project. This project has received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement No 822483. Supplementarily, this research work has been co-financed from Polish financial resources for science in 2019-2023 and conferred for the implementation of the co-financed international project.

Personalized Music Recommendation Based on Interest and Emotion: A Comparison of Multiple Algorithms

Xiuli Yan

College of Music and Dance, Fuyang Normal University, Fuyang, Anhui 236041, China

Abstract—Recommendation algorithms can greatly improve the efficiency of information retrieval for users. This article briefly introduced recommendation algorithms based on association rules and algorithms based on interest and emotion analysis. After crawling music and comment data from the NetEase Cloud platform, a simulation experiment was conducted. Firstly, the performance of the Back-Propagation Neural Network (BPNN) in the interest and emotion-based algorithm for recommending music was tested, and then the impact of the proportion of emotion weight between comments and music on the emotion analysis-based algorithm was tested. Finally, the three recommendation algorithms based on association rules, user ratings, and interest and emotion analysis were compared. The results showed that when the BPNN used the dominant interest and emotion and secondary interest and emotion as judgment criteria, the accuracy of interest and emotion recognition for music and comments was higher. When the proportion of interest and emotion weight between comments and music was 6:4, the interest and emotion analysis-based recommendation algorithm had the highest accuracy. The interest and emotion-based recommendation algorithm had higher recommendation accuracy than the association rule-based and user rating-based algorithms, and could provide users with more personalized and emotional music recommendations.

Keywords—Interest and emotion; recommendation algorithm; music; personalization

I. INTRODUCTION

With the prevalence of Internet technology and mobile devices, the amount of data and information that users can receive on the network has increased. However, low-quality or invalid information has also increased, making it difficult for Internet users to retrieve effective information. Information recommendation algorithms are a tool to assist in effective information retrieval [1]. When users are not clear about the information they want to retrieve, or only have a vague range, they can use information recommendation algorithms to initially screen information, and search for effective information from the information recommended by the algorithm [2]. Recommendation algorithms can be applied to music platforms for music recommendation. Music platforms can explore users' preferences based on their attributes, historical information, and other information, and provide personalized recommendation services to improve users' efficiency in finding music that fits their preferences [3]. In

music recommendation algorithms, the traditional method is to construct a feature of music recommendation [4], such as click-through rate, and recommend music with high click-through rates within a certain period to users. The principle of this type of music recommendation algorithm is relatively simple, and the basis for recommendation is usually a statistical feature. However, this type of recommendation is highly homogeneous for individual users, and the recommended lists for different users are basically the same. Moreover, statistical features reflect the overall preference trend of users. If the user base is large, there will always be many users whose music preferences do not conform to the mainstream [5]. Personalized recommendation algorithms delve into individual users' effective information to provide recommended music that is closer to individual preferences in terms of trend, although there may be some overlap with mainstream recommended music. It can provide different users with different recommended lists and avoid homogeneous recommended music [6]. In order to improve the accuracy and the degree of personalization of music recommendation algorithms, this paper conducted a study on a personalized music recommendation algorithm, where the personalized recommendation was based on the user's interest and emotion. The significance of this paper is to improve the accuracy of the music recommendation algorithm by recommending music to users through their interest tendencies for different music. The contribution of this paper is to provide a personalized recommendation list for users based on their interest tendency toward music, which provides an effective reference for personalized recommendation algorithms.

II. LITERATURE REVIEW

Relevant works are reviewed below. Shi [7] proposed a personalized music recommendation method and verified its feasibility. Wu et al. [8] designed a mixed music recommendation model using personalized measurement and game theory. They found that the model had higher accuracy in recommending new music, good dynamic personalized recommendation ability, and real-time recommendation ability. Gong et al. [9] constructed a deep music recommendation algorithm using dance motion analysis and evaluated it through quantification measures. They verified the validity of the algorithm.

III. MUSIC RECOMMENDATION ALGORITHM

A. Music Recommendation Algorithm Based on Association Rules

Registered users on music platforms not only leave a history of the music they listen to in their corresponding accounts, but they also add music they are interested in to their playlists while listening to music. Both the user's history and the records in their playlist can reflect the user's individual interests and preferences towards music [10]. Personalized recommendation algorithms usually mine user browsing records to construct personalized preference patterns for music, and then recommend music to users based on these patterns. The association rule method is a way to mine user preference patterns and can be used for personalized music recommendations [11].

Before using the music recommendation algorithm based on association rules for personalized music recommendations, the user's historical data for association rules should be mined. In music recommendation algorithms, association rules refer to the directional connections between different types of music. The mining steps can be summarized as searching for frequent item sets in the database and strong rules within the frequent item sets. The specific steps are as follows.

1) The user database is scanned, and each piece of music is treated as an item. It is assumed, there are a total of five pieces of music in the database, the candidate item sets obtained from scanning will contain five items. Moreover, the support of each item is computed [12]:

$$SUP = \frac{n}{N} \quad (1)$$

where SUP represents the support of the item, N represents the total number of historical records in the user database (the number of historical records equals the number of users), and n represents the number of historical records that contain the item.

2) The candidate item sets are pruned by removing items with support lower than a set threshold. The remaining set of items form the frequent item sets, which are recorded.

3) The items in the frequent item sets are combined pairwise to obtain new candidate item sets, and the support of each item in the new candidate item sets is computed.

4) Return to step 2 to obtain new frequent item sets, and record them.

5) Steps 2, 3, and 4 are repeated until a new set of candidate items cannot be generated. Then, the confidence level of all association item sets in the recorded frequent item sets is computed. Association item sets are non-empty proper subsets and the remaining element sets of each item set in the frequent item sets that may produce strong associations. The formula to calculate the confidence level of strong rule $X \Rightarrow Y$ [13] is:

$$CON = \frac{|X \cap Y|}{|X|} \quad (2)$$

where CON stands for the confidence level of the strong rule, $|X|$ indicates the number of records that contain the item, and $|X \cap Y|$ stands for the number of records that contain both items. When the confidence is over the set threshold, the association rule is regarded as strong. The recommendation algorithm recommends music based on the music items in the user's music record and the strong rules.

B. Sentiment Analysis-based Music Recommendation Algorithm

The recommendation algorithm based on association rules described earlier, mines data from the overall user history to obtain the association rules between music pieces. The music association rules obtained through data mining of user history indicate a connection between music pieces with the same "traits" [14]. The music pieces in the user's history reflect their interest in the "traits" of the music, and the music found through association rules will also contain the "traits" that the user is interested in. In most cases, this type of recommendation algorithm is sufficient to meet the needs of most users. However, users' moods can change during the process of listening to music [15]. Changes in mood can affect subjective feelings about music, making it difficult to satisfy user needs by recommending music based on rigid association rules.

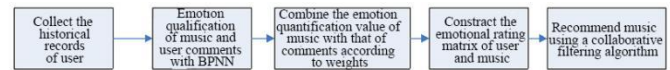

Fig. 1. Basic flow of the sentiment analysis-based music recommendation algorithm.

To enable music recommendation algorithms to adapt to users' changing emotional needs, this article incorporates sentiment analysis into music recommendation algorithms. Fig. 1 illustrates the basic process of the sentiment analysis-based music recommendation algorithm, and its detailed steps are as follows.

1) The music listening history of registered users on the music platform is collected, which includes the music data that the user listened to and the textual comments that the user made about the music.

2) The Back-Propagation Neural Network (BPNN) [16] is used to quantify the sentiment of music and each user's comment on the music, that is, to classify the sentiment of both. When training the BPNN to recognize the sentiment of music and comments separately, the result labels of the training samples are numerical values of the emotional categories. This article adopts the Hevner emotional circle model, which has eight emotional types. When recognizing the sentiment of music, the Mel Frequency Cepstral Coefficient (MFCC) features [17] of the music are input into the BPNN, which is calculated layer by layer in the hidden layer, and finally the numerical values of the primary and secondary emotions of the music are output in the output layer. When recognizing the sentiment of user comments, the comment text is preprocessed, including word segmentation and removal of redundant auxiliary words. Next, the Wordvec method [18] is used to

obtain the text vector of the comment, which is then input into the BPNN and calculated layer by layer in the hidden layer, and finally the numerical values of the primary and secondary emotions of the comment are output in the output layer.

3) The sentiment quantification values of the music are combined with the sentiment quantification values of the user's comment on the music according to a certain weight ratio to obtain the sentiment quantification value of the user for the music.

4) The sentiment quantification value of the user for the music obtained in the previous step is used to construct a user-music sentiment rating matrix, as displayed in Fig. 2. The size of the matrix is $m \times n$, each row indicates a user's sentiment rating for different music, each column indicates different users' sentiment rating for the same music, and element e_{ij} in the matrix represent the user's sentiment rating for the music.

$$\begin{bmatrix} e_{11} & e_{12} & \cdots & e_{1j} & \cdots & e_{1n} \\ e_{21} & e_{22} & \cdots & e_{2j} & \cdots & e_{2n} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ e_{i1} & e_{i2} & \cdots & e_{ij} & \cdots & e_{in} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ e_{m1} & e_{m2} & \cdots & e_{mj} & \cdots & e_{mn} \end{bmatrix}$$

Fig. 2. User-music sentiment rating matrix.

5) An item-based collaborative filtering algorithm [19] is used to recommend music, and the associated formula is:

$$\begin{cases} P(a,c) = sim(b,c) \times s(a,b) \\ sim(b,c) = \frac{\bar{b} \cdot \bar{c}}{\|\bar{b}\| \cdot \|\bar{c}\|} \end{cases} \quad (3)$$

where music b is the music that user a has listened to, $sim(b,c)$ indicates the cosine similarity between music and music, \bar{b} and \bar{c} are the sentiment rating vector of musics b and c , respectively (the dimension depends on the number of users), $s(a,b)$ is the sentiment rating of user a to music b , which can be checked from the sentiment rating matrix, $P(a,c)$ is the interest level of user a to music c . The top k musics in the nearest neighboring set that is most interesting to the target user are recommended to the target user.

IV. SIMULATION EXPERIMENT

A. Experimental Data and Settings

In this paper, a simulation experiment was conducted in MATLAB software [20] to evaluate a music recommendation algorithm based on sentiment analysis. The simulation experiment used data obtained through web crawlers on the NetEase Cloud Music platform. The data collected by the crawler includes music and comments from different users below the music interface. After initial data cleaning, a total of 200 pieces of music and 200 user comments for each music

were collected and analyzed, with some comments shown in Table I. The music codes in the table consist of letters and numbers, where the letters represent the main emotional tendency of the music and the numbers represent the music number. 60% of the data was used as a training set to train the BPNN in the music recommendation algorithm, and the remaining 40% was used for testing. In the recommendation algorithm, after the orthogonal experiment, the number of nearest neighbors was set to 30 when using collaborative filtering to generate the recommendation list, and the number of recommended music in the final recommendation list was set to 10 for each user.

TABLE I. SELECTED COMMENTS OF DIFFERENT USERS ON DIFFERENT MUSIC

	User 1	User 2
Music A1	This song makes me so sad to hear	Feeling sad
Music B1	This song has a wonderful sense of nobility	Sounds pretty sacred.
Music C1	Listen to the impulse to move forward	It will give people a sense of yearning
Music D1	There is a sense of quiet	There is a sense of calmness
Music E1	It's fun to listen to	Very cheerful
Music F1	A sense of relief	Feels very light and fast
Music G1	Can feel the enthusiasm	A sense of power
Music H1	Very life-giving	Vibrant feeling

B. Experimental Design

1) *Testing the BPNN in the recommendation algorithm:* After training two BPNNs using the testing set, the testing set was used for evaluation. There are two evaluation criteria for the testing plan. Evaluation criteria 1): only when the dominant emotion of the calculated sample is consistent with the dominant emotion in the test sample label, can it be considered a correct prediction; evaluation criteria 2): when either the dominant or secondary emotion of the calculated sample is consistent with the dominant or secondary emotion in the test sample label, it is considered a correct prediction.

2) *The influence of the weight ratio of sentiment quantification values between music and comments on the performance of the recommendation algorithm:* The weight ratios of sentiment quantification values between comments and music were set to 1:9, 2:8, 3:7, 4:6, 5:5, 6:4, 7:3, 8:2, 9:1. The accuracy of the recommendation algorithm under different weight ratios was tested. The weight ratios were set according to the size of the comment weight ratio.

3) *Comparison of three recommendation algorithms:* Association rules, user ratings, and sentiment analysis-based: To further prove the performance of the music recommendation algorithm proposed in this paper, it was compared with the association rules-based algorithm and the user ratings-based algorithm. The association rules-based music recommendation algorithm has been described above, while the user ratings-based music recommendation algorithm was the same as the sentiment analysis-based music recommendation algorithm in the basic steps, except that the elements in the rating matrix were no longer sentiment

quantification values but rather the number of clicks by the user on the music.

4) *The performance test of three recommendation algorithms in a real music platform:* In addition to the above simulation experiments, this paper also tested the performance of the three recommendation algorithms in a real music platform. Ten users of the NetEase cloud platform were randomly invited, and the three recommendation algorithms were used to recommend music to them. Each recommendation algorithm recommended music to each user ten times, and the users selected the music they were interested in from the results of each recommendation. The accuracy of each recommendation algorithm in recommending music of interest to the users was calculated.

C. Experimental Results

Fig. 3 illustrates the emotion recognition accuracy of the two BPNN algorithms in the recommendation algorithm based on emotion analysis under different evaluation criteria. The BPNN algorithm used for music emotion recognition had an identification accuracy of 42.6% under evaluation criteria (1) and 82.9% under evaluation criteria (2). The BPNN algorithm used for comment text emotion recognition had an identification accuracy of 44.3% under evaluation criteria (1) and 83.4% under evaluation criteria (2). Compared with evaluation criteria (1), evaluation criteria (2) had relatively loose requirements for the emotion recognition results. If evaluation criteria (1) was used, the algorithm’s performance was weakened due to the low accuracy. Therefore, in the subsequent experiments, evaluation criteria (2) was used to construct the rating matrix, where the dominant emotion and secondary emotion coexist.

Fig. 4 shows the impact of the weight proportion of sentiment quantification values of comments and music on the performance of the music recommendation algorithm based on sentiment analysis. As the weight proportion of the sentiment quantification values of comments gradually increased, the recommendation accuracy first rose and then declined, as can be seen from Fig. 4. When the weight proportion of sentiment between comments and music was 6:4, the recommendation accuracy of the algorithm was the highest, at 89.6%.

Due to space limitations, only partial results were shown here, as shown in Table II. First, the recommendation results of the three algorithms for the same user were compared, and it was found that there were differences in the recommendation results of the three algorithms for the same user. The association rule recommendation results had a variety of emotional categories for the recommended music, while the emotional categories of only one or two songs differed in the user rating recommendation results, and the emotional categories of the recommended music in the sentiment analysis recommendation results were basically the same. It was found from the comparison of the recommendation results obtained

by different users under the same recommendation algorithm that the association rule recommendation results had various emotional categories for the recommended music. In the user rating recommendation results, there was some overlap in emotional categories of recommended music among different users, and the emotional categories of recommended music in the sentiment analysis recommendation results were different among different users, but the emotional categories of recommended music for individual users were the same.

From Fig. 5, it was visually clear that the algorithm based on sentiment analysis had the highest recommendation accuracy, followed by the algorithm based on user ratings, and the lowest was the algorithm based on association rules.

Fig. 3. Test results of the BPNN algorithm.

Fig. 4. Impact of the weight ratio of sentiment quantification values between music and comments on the performance of the recommendation algorithm.

TABLE II. SOME RECOMMENDATION RESULTS OF THE MUSIC RECOMMENDATION ALGORITHMS

User	Association Rules Recommendation Results	User Rating Recommendation Results	Emotional Analysis Recommendation Results
User 1	D2;F23;E24;A1; B25	D2;D23;D24;E21;H1	D23;D24;D23;D9;D8
User 2	F5;D9;G20;F12; G14	F5;D14;D23;D24;F12	G3;G5;G14;G11;G12
User 3	D1;H4;C3;B12;H1	A4;C3;D14;D23;D2	C1;C4;C3;C2;C6

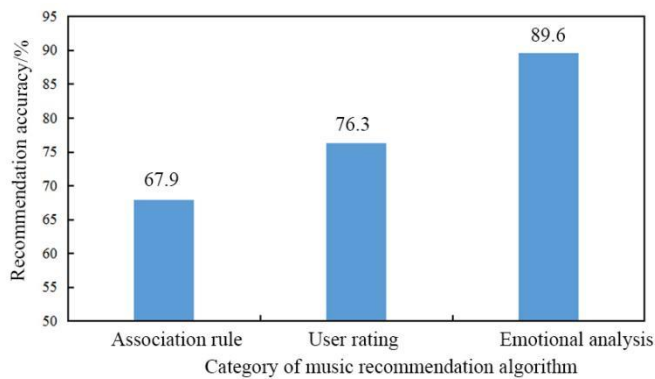

Fig. 5. Recommendation accuracy of three music recommendation algorithms.

In the actual NetEase cloud platform, the above three recommendation algorithms were used to make ten recommendations to each of the ten users, and the number of music items that users were interested in in the recommendation results is shown in Table III. The average number of music items that users were interested in was 66.8 for the association rule-based algorithm, 75.6 for the user rating-based algorithm, and 88.7 for the emotional analysis-based algorithm. It was seen from the comparison in Table III that the recommendation algorithm based on interest and emotional analysis recommended more music that users were interested in. At the same time, the ratio of the average number of songs to the total number of recommendations was very close to the accuracy of the recommendations calculated in the simulation experiment.

TABLE III. PERFORMANCE OF THREE RECOMMENDATION ALGORITHMS IN RECOMMENDING MUSIC OF INTEREST IN THE REAL MUSIC PLATFORMS

	The Number of Music of Interest in the Association Rule-based Recommendation Results/n	The Number of Music of Interest in user rating-based Recommendation Results/n	The Number of Music of Interest under Emotional Analysis-based Recommendation Results/n
User 1	67	76	89
User 2	66	75	88
User 3	65	75	88
User 4	66	76	87
User 5	67	77	88
User 6	67	77	89
User 7	66	75	89
User 8	67	75	89
User 9	68	76	90
User 10	69	74	90
Average	66.8	75.6	88.7

V. DISCUSSION

With the development of the Internet, people have access to more and more information. Recommendation algorithms can

help people find the information they need faster. This paper targeted a music platform and used recommendation algorithms to recommend music that may be of interest to platform users. This paper first introduced the association rule-based recommendation algorithm and the user-rating-based collaborative filtering recommendation algorithm and then introduced the BPNN, which can measure the user's interest and emotion, into the user-rating-based collaborative filtering algorithm in order to make the recommendation results more personalized, so that the algorithm can give the recommendation results based on the user's interest and emotion.

After that, the BPNN for measuring users' interest and emotion was tested first, and then the recommendation accuracy of the three recommendation algorithms was compared. The recommendation performance was tested in the actual NetEase cloud platform with ten randomly invited users. The final test results verified the accuracy of the BPNN for measuring users' interest and emotion, and the algorithm based on interest and emotional analysis had the highest recommendation accuracy among the three recommendation algorithms. The recommendation performance of this recommendation algorithm was also verified in the actual music platform. The reasons for why the algorithm based on interest and emotional analysis had the highest accuracy are as follows: The association rule-based recommendation algorithm mined the entire history of user records to obtain the association rule between music, assuming that users will select the next song according to the mined association rules after listening to a song, but the association rule mined from the entire data did not take into account the individual interests and hobbies of users. The algorithm based on user ratings used the number of times users clicked on music as an indicator of their interest, integrated users with similar interests, and provided personalized recommendations, resulting in higher recommendation accuracy. The recommendation algorithm based on sentiment analysis was based on the emotional tendencies of users and music, integrated users with similar emotional tendencies, and provided recommendations. Because it took into account the influence of emotions on music selection, it was more personalized, and the recommendation results were more accurate.

VI. CONCLUSION

This article briefly introduced the recommendation algorithms based on association rules and sentiment analysis. Then, through web scraping of music and comment data on the Netease Cloud platform, a simulation experiment was conducted. First, the performance of the BPNN in the sentiment analysis-based recommendation algorithm was tested. Then, the influence of the proportion of sentiment weight between comments and music on the algorithm based on sentiment analysis was tested. Finally, the algorithms based on association rules, user ratings, and sentiment analysis were compared. The results were as follows: 1) The accuracy of sentiment recognition for music and comments was higher when the BPNN used dominant and secondary emotions as judgment criteria. 2) As the proportion of sentiment quantification values between comments and music gradually rose, the recommendation accuracy of the algorithm suggested

an increasing trend followed by a decreasing trend. When the proportion of sentiment weight between comments and music was 6:4, the algorithm had the highest recommendation accuracy, at 89.6%. 3) The music recommended by the association rule recommendation algorithm had a diverse range of emotional categories. The emotional categories of the recommended music by the user rating recommendation algorithm were relatively consistent within a single user, and there was some overlap between different users' recommended music emotional categories. The emotional categories of the recommended music by the sentiment analysis recommendation algorithm were consistent within a single user, but different users' recommended music emotional categories were different. 4) The recommendation accuracy of the algorithm based on sentiment analysis was the highest, followed by the user rating-based algorithm, and the association rule-based algorithm had the lowest accuracy. 5) The interest and emotional analysis-based algorithm also had better recommendation performance in the actual music platform.

Research on Customer Retention Prediction Model of VOD Platform Based on Machine Learning

Quansheng Zhao, Zhijie Zhao*, Liu Yang, Lan Hong, Wu Han

School of Computer and Information Engineering, Harbin University of Commerce, Harbin, Heilongjiang, 150028, China

Abstract—Advanced wireless technology and smart mobile devices allow users to watch Internet video from almost anywhere. The major VOD platforms are competing with each other for customers, slowly shifting from a "product-centric" strategic goal to a "customer-centric" one. At present, existing research is limited to platform business model and development strategy as well as user behavior research, but there is less research on customer retention prediction. In order to effectively solve the customer retention prediction problem, this study applies machine learning methods to video-on-demand platform customer retention prediction, improves the traditional RFM model to establish the RFLH theoretical model for video-on-demand platform customer retention prediction, and uses machine learning methods to predict the number of customer retention days. The Optuna algorithm is used to determine the model hyperparameters, and the SHAP framework is integrated to analyze the important factors affecting customer retention. The experimental results show that the comprehensive performance of the LightGBM model is better than other models. The total number of user logins in the past week, the length of video playback in the same day, and the time difference between the last login and the present are important features that affect customer retention prediction. This study can help companies develop effective customer management strategies to maximize potential customer acquisition and existing customer retention for maximum market advantage.

Keywords—Video-on-demand platform; Customer Retention Forecast; RFM Model; Machine Learning; SHAP

I. INTRODUCTION

With the advent of the information age, market competition has become more and more intense, and enterprises have slowly changed from a "product-centric" strategic goal to a "customer-centric" one. In the case of limited resources, major e-commerce companies compete with each other for customers, the pursuit of a larger share of the market, to maximize their profits has become the development of each enterprise imperative.

Video-on-demand is developed in the 1990s, and is called "Video On Demand" in English, so it is also called "VOD". As the name suggests, it is a video-on-demand system that plays programs on demand by viewers. Watching video has become one of the most popular online activities and provides a huge market for various video content providers. Better networks, technological innovations and the availability of smart devices have changed the way people are entertained, allowing platforms to deliver services to viewers directly online via the Internet [1]. For any service to grow, it is crucial to understand the values and consumption habits of consumers. In real

systems, there are users who stay for a long time and others who enter the system and leave soon after. Therefore, understanding user behavior and further predicting customer retention on VOD platforms can help platforms improve service quality and avoid customer churn. For users with short retention time, the platform can adopt ways such as trial membership and issuing coupons to let users experience the core services to retain them; while for users with longer retention time, the platform can appropriately provide more rewards or service updates to extend their retention time [2].

In the study for video-on-demand platforms, Zhang et al. take Tencent's over-the-top on-demand rule as an example to analyze the reasons for the model, summarize and analyze the problems that arise when current video-on-demand platforms innovate their profit models, and propose strategies to optimize their profit models and corresponding strategies [3]. Hu et al. studied user behavior and access patterns through a major ISP in Shanghai, China, focusing on comparing behavior and access patterns across platforms, and found that user migration across multiple platforms was common and highly influenced by the different characteristics of the platforms [4]. Köster et al. explore the relationship between social referrals, referral propensity, and the stickiness of video-on-demand websites, comparing consumers who are referred by social networks with consumers who arrived at the site through natural search or social media ads to understand the stickiness of the site. The results showed that consumers who were recommended via social referrals spent more time on the site, viewed more pages, and launched more videos than consumers who responded to social media ads, but less than consumers who went through natural search [5]. Wang et al. analyzed the differences between Chinese video platforms and U.S. video platforms, reflecting on the relationship between platform, market, and country. The historical factors and geographical characteristics that influence the operation, structure and governance of video platforms are explored [6]. Rahman et al. studied video consumer behavior from the perspective of VOD platforms. The analysis of the data revealed interesting features of video-on-demand platforms, such as the viewing habits and viewing patterns of different users and the correlation between user profile information (e.g., age, gender) and viewing habits, among others, and suggested that future user behavior could be predicted by learning from previous user behavior patterns [7].

The existing research by scholars on video-on-demand platforms is limited to two major aspects of platform business models and development strategies [6] and user behavior [7] studies, with few studies focusing on their customer retention predictions. To solve this problem, this paper proposes an

improved RFM theoretical model based on user behavior and constructs a VOD customer retention prediction model based on machine learning to exploit the advantages of machine learning algorithms in prediction. Recent studies have shown that LightGBM, XGBoost, and CatBoost can show better performance in the face of complex, highly nonlinearly related data [8][9], and the Ensemble Learning (EL) algorithm integrates multiple machine learning models to form a model with stronger generalization and better backfitting capabilities[10]. Therefore, this paper uses LightGBM, XGBoost, CatBoost and other algorithms to construct customer retention prediction models for video-on-demand platforms. After the models are constructed, the accuracy of different models in this study scenario is compared by time complexity, R^2 , MAE, RMSE indexes and the optimal prediction model is selected, and the prediction results are later analyzed using the SHAP interpretation method to explore the magnitude of the impact of different characteristics of users on the prediction values and the reasons behind them. The study found that a user's total number of logins in the last week, the length of the day's video playback and the time difference between the most recent login and the present were important features that influenced customer retention predictions.

II. RELATED WORKS

In the Internet industry, users who start using an application at a certain time and continue to use the application after a certain period of time are recognized as retained users. Customer retention measurement and analysis is a classic problem in various domains, such as online community platforms [11], telecommunication industry [12] and e-commerce [13]. Several works focus on the measurement and analysis of characteristics related to customer retention. Jiang et al. proposed a maximum entropy semi-Markov model to predict the customer life stages that need to be segmented for milk powder products, which is applicable to the case where the infant life stage transition is deterministic, but not to the case where there is no explicit life stage, such as video-on-demand systems[14].

In recent years, RFM models have also been widely used in customer behavior prediction studies. Marín et al. modeled user behavior based on the traditional proximity, frequency and currency (RFM) model to obtain a proximity, frequency, importance and duration (RFID) model of customer assessment from the perspective of customer-contact center interactions, and showed that the model can be generalized to any environment requiring classification or regression algorithms in any environment that requires classification or regression algorithms [15]. Perišić et al. proposed an extended framework of new proximity, frequency, and monetary value features for predicting user churn in the mobile gaming domain by combining features related to user lifecycle, intensity, and rewards, and indicated that the top five most important features of a multivariate churn prediction model include long-term and short-term frequency features, monetary, intensity, and lifecycle features[16]. Wei et al. first established an RFLP metric system for predicting MOOC user learning behavior and attrition by improving the RFM model in the business domain; secondly, histogram and chi-square tests were used to determine the characteristic variables affecting MOOC user

attrition; finally, a MOOC user attrition prediction model was constructed by combining the Grouped Data Processing (GMDH) network as a post-processing information system [17]. Smali et al. modified the model by adding diversity "D" as the fourth parameter, referring to the diversity of products purchased by a given customer, and the RFM-D based model was applied to the retail market to detect customer behavior patterns and the proposed model improved the quality of customer behavior prediction [18].

In order to effectively solve the customer retention prediction problem, this paper firstly improves the traditional RFM model in terms of extracting features and proposes the RFLH theoretical model suitable for customer retention prediction of VOD platform. After that, machine learning and other latest technologies are applied to the VOD customer retention prediction problem, and the advantages of machine learning algorithms in prediction are exploited to learn users' previous behavior patterns to predict their future behavior. And Optuna framework is used to optimize the model hyperparameters to improve the model prediction performance. Finally, the SHAP interpretation framework is combined with the interpretation analysis of different user behaviors in order to propose targeted suggestions and strategies for customer management in VOD platform.

III. BUILDING A THEORETICAL MODEL OF CUSTOMER RETENTION BASED ON IMPROVED RFM

RFM model is one of the most important methods to analyze the behavioral characteristics of customers, classifying them by three behavioral variables: proximity R (Recency), frequency F (Frequency), and value M (Monetary) [19]. The traditional RFM model predicts the future short-term behavior of customers through their past purchase behavior in e-commerce platforms. In the existing research, this model is mostly used for the comprehensive consideration of user activity, loyalty and consumption ability to further achieve user value identification and value group segmentation. It is generally believed that users with a shorter interval between recent consumptions and a larger number and amounts of recent consumptions have a higher recognition of products and services and therefore a lower tendency to churn; conversely, users with a longer interval between recent consumptions and a smaller frequency and amount of recent consumptions have a higher tendency to churn and a lower value to the platform. vod platform is different from ordinary e-commerce platforms, namely: most vod users in the viewing process does not generate actual consumption, but the two have a certain degree of relevance in some way.

Currently, the RFM model has been used in user churn prediction [13][20]. In this study, the RFM model is improved on the basis of RFM model to construct RFLH indicator system for vod user behavior and customer retention prediction, and the details are shown in Table I. In RFLH indicator system the indicator H(History) represents the number of days of historical retention, including the statistical characteristics of the number of days of historical retention in the last month, which is a more critical characteristic variable for accurate prediction of customer retention days. The improved RFM model is shown in Table I.

TABLE I. IMPROVED RFM THEORETICAL MODEL

Classification index	Indicator meaning
R(Recency of viewing)	The time interval between the viewer's most recent login and the observation point
F(Frequency of viewing)	The number of times the viewer logged in during a certain period
L (Length of viewing)	Viewer's viewing time and completion in a certain period
H (Days of historical retention)	The number of days the viewer retention in a certain period

IV. MACHINE LEARNING-BASED CUSTOMER RETENTION PREDICTION MODEL CONSTRUCTION

A. Machine Learning Algorithm Selection

In order to select the most suitable machine learning algorithm for customer retention prediction on Vod platform, this study constructs regression models based on three machine learning algorithms, LightGBM, Catboost and XGBoost, respectively, for comparison experiments, and selects the model with the best overall performance.

LightGBM is a distributed gradient boosting framework based on decision tree algorithm. Designed to provide a fast, efficient, low-memory, high-accuracy tool that supports parallelism and large-scale data processing, LightGBM achieves linear acceleration in data computation by reducing the memory use of data, reducing communication costs, and improving efficiency when multiple machines are parallel. Its advantages are faster training efficiency, low memory usage, and higher accuracy. The disadvantage is that it may grow deeper decision trees and produce overfitting[21].

CatBoost is a library of gradient boosting algorithms, which has the advantages of overcoming the gradient bias and effectively solving the problem of prediction bias, improving the accuracy of the algorithm, enhancing the generalization ability, and preventing the occurrence of overfitting phenomenon. Its disadvantages are that it requires a lot of memory and time for the processing of category features, and the setting of different random numbers has an impact on the model prediction results [22].

XGBoost, an efficient Gradient Boosting algorithm, integrates the idea of iteratively generating multiple weak learners and then adding up the prediction results of each learner to get the final prediction result, which has a better performance in structured data processing. The advantage is that the regularization term is added to prevent overfitting and parallel optimization is possible to improve the efficiency of the algorithm. The disadvantages are that it has too many parameters, the tuning parameters are too complex and it is only suitable for processing structured data [23].

LightGBM, CatBoost, and XGBoost are all Boosting algorithms in integrated learning and Boosting algorithms are widely used in the industry and can show better performance in the face of complex, highly nonlinear data [9], which is applicable to the data in this paper.

B. Optuna Tuning Framework

In order to optimize the performance of individual machine learning models and to make them comparable with each other.

To set the hyperparameters of the models, the methods usually used are "grid search" or "random search". However, the "grid search" method requires more computational power and time due to the larger parameter space. The advantage of random search is that the search is fast, but it is easy to miss some important information and difficult to determine the distribution of the parameters. Therefore, for hyperparameter optimization, a software framework called Optuna automatic hyperparameter optimization is used in this experiment.

Optuna is a framework designed for automated and accelerated research, It has three advantages: (1) define-by-run API that allows users to construct the parameter search space dynamically, (2) efficient implementation of both searching and pruning strategies, and (3) easy-to-setup, versatile architecture that can be deployed for various purposes, ranging from scalable distributed computing to light-weight experiment conducted via interactive interface [24]. The operation procedure is as follows:

- 1) Determine the optimization direction, parameter type, value range and maximum number of iterations.
- 2) Enter the cycle.
- 3) Select a group of individuals evenly within the function that defines the range of parameter values.
- 4) The trimmer automatically terminates hopeless populations according to pruning conditions.
- 5) Calculate the individual objective function value of the unpruned population.
- 6) Repeat the above steps until the maximum number of iterations are reached and out of the loop.
- 7) Optimal solution of the output problem [25].

C. Model Performance Evaluation Metrics

In this study, the time complexity is the sum of training time and prediction time, and the higher time complexity will affect its practical application to some extent. A lower time complexity helps to accomplish fast and effective prediction [26]. Meanwhile, the model is evaluated by using three indicators: mean absolute error MAE, root mean square error RMSE and coefficient of determination R², and the evaluation indicators are calculated as follows:

$$MAE = \frac{1}{n} \sum_{t=1}^n |y_{rt} - y_{pt}| \quad (1)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{t=1}^n (y_{rt} - y_{pt})^2} \quad (2)$$

$$R^2 = \frac{|\sum_{t=1}^n (y_{rt} - \bar{y}_r) \cdot (y_{pt} - \bar{y}_p)|^2}{\sum_{t=1}^n (y_{rt} - \bar{y}_r)^2 \cdot \sum_{t=1}^n (y_{pt} - \bar{y}_p)^2} \quad (3)$$

Where: n is the number of data; y_p is the predicted result; y_r is the true value; \bar{y}_p and \bar{y}_r are the average of the predicted and true results, respectively. In the regression prediction, the smaller the RMSE value and the closer the R² value is to 1, the higher the interpretability of the model. In this paper, the MAE, RMSE and R² are used to make a comprehensive comparison of the model prediction results and verify the prediction accuracy of the model.

V. EMPIRICAL ANALYSIS OF VOD CUSTOMER RETENTION PREDICTIONS

In this paper, the predicted customer retention is defined as the number of days a user logs in the next seven days. For example, if a user's prediction result on January 1 is equal to 3, it means that this user will visit the VOD platform for 3 days in the next 7 days (January 2~8). In this paper, we first pre-process the data to improve the data quality. The features are extracted according to the improved RFM model and combined with machine learning methods to build a video-on-demand platform customer retention prediction model. The specific process is shown in Fig. 1.

A. Data Processing and Feature Selection

iQIYI is China's and the world's leading high-quality video entertainment streaming platform, with more than 500 million users enjoying entertainment services on iQIYI every month. In this paper, we use the dataset provided by iQIYI AI competition platform, which contains video data, user personal information, user startup logs, user viewing and interaction behavior logs, etc. The detailed fields have various information such as the user's device type, device storage, device running memory, gender, age, education status, and occupational status.

The main natural attribute variables of Vod users are set in the paper, including gender, age group, education level, occupational status, and device information. The viewing behavior characteristics variables are classified based on indicators R, F, L, and H. The data of 15,000 users were randomly selected as samples. Based on the behavior records, the attribute variables and viewing behavior characteristic variables of each user were extracted separately. Each indicator

was divided by the research as shown in the Table II, and a regression model was constructed to predict the number of days users would log in in the next seven days.

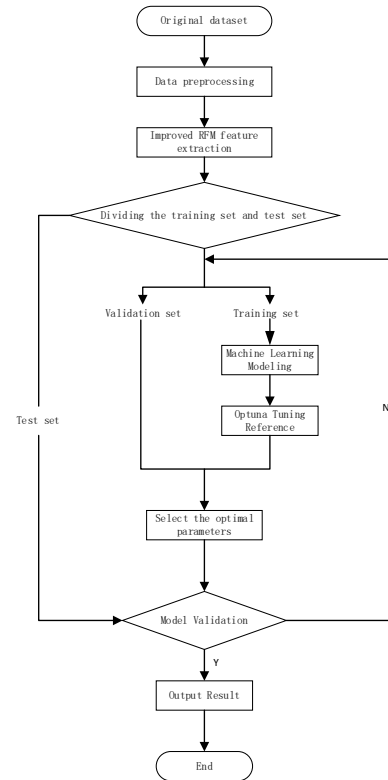

Fig. 1. Flow chart of customer retention prediction model for VOD platform.

TABLE II. IMPROVED RFM MODEL

Variable Type	Indicators	Meaning	
Natural Property Variables	X Properties	X1	Sex
		X2	Age
		X3	Education
		X4	Occupational Status
		X5	Device ram
		X6	Device rom
		X7	Device type
Watch behavioral characteristics variables	R(Recency of viewing)	R1	Login or not for the day
		R2	Time difference between last login and current
	F(Frequency of viewing)	F1	Total number of logins in a month
		F2	Total number of logins in the last week
	L (Length of viewing)	L1	Video playback duration for that day and each of the previous seven days
		L2	Number of video plays per day for the day and the first seven days
		L3	Video completion of the day and each day of the previous seven days
	H (Days of historical retention)	H1	Median number of historical retention days in a month
		H2	Average of the previous four weeks of historical retention days
H3		Weighted average of the previous four weeks' historical retention days	

B. Model Training

After the new dataset was constructed with a total of 953112 data, the missing values outliers in the new dataset were processed, such as filling the missing values in the data with 0, and removing the ones with more than 24h of playing time in a day. The processed data were tested for correlations of the feature variables by Pearson, Spearman, and Kendall three-class correlation coefficients, as shown in Fig. 2, 3, and 4. The test results showed that the selected feature variables were statistically correlated with the target variables.

After data processing, the last log-in time point of 15,000 users recorded in the data was subtracted by seven days as the test set, 80% of the remaining data was used as the training set, and 20% was used as the validation set to input three machine learning algorithms, LightGBM, CatBoost, and XGBoost, respectively, for model training.

Fig. 2. Pearson correlation test graph (partial).

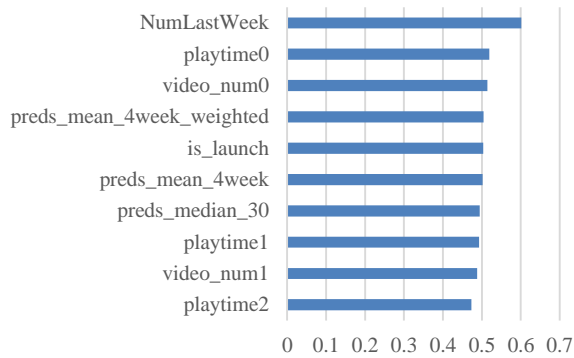

Fig. 3. Spearman correlation test graph (partial).

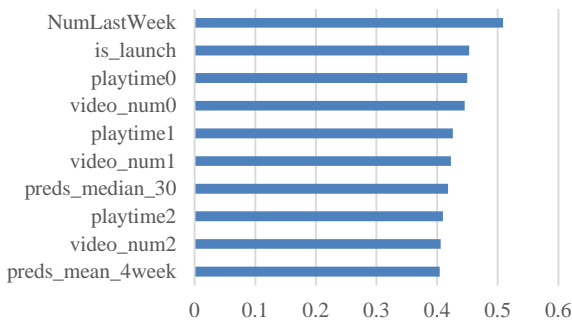

Fig. 4. Kendall correlation test graph (partial).

C. Hyperparameter Tuning

Hyperparameters are the framework parameters of machine learning models, and machine learning algorithms contain various hyperparameters that can be set to improve the accuracy of the model. To set a suitable set of hyperparameters, a hyperparameter tuning approach can be used, which objectively scans various attributes of the model hyperparameters and selects an optimal subset to improve the performance and effectiveness of learning, resulting in a model with optimal performance on a given dataset. For the machine learning-based customer retention prediction model, the Optuna optimization framework is used to tune the main hyperparameters of the prediction model, and the main hyperparameters obtained according to the Optuna optimization framework are shown in Table III.

TABLE III. MODEL'S MAIN HYPERPARAMETERS

Machine learning models	Hyperparameter Name	Optimal hyperparameter values	Meaning and Impact
LightGBM	objective	regression	Assign learning tasks and corresponding learning objectives.
	max_depth	8	The maximum depth of the tree model. The most important parameter for preventing overfitting, decisive for model performance and generalization ability
	learning_rate	0.01	shrinkage rate, choosing a relatively small learning rate can achieve stable and better model performance
	n_estimators	724	The number of iterations of boosting, generally speaking, the more iterations the better the model performance, but too many iterations will often lead to overfitting of the model and affect the training time of the model
	lambda_l1	8	L1 regularization parameter, used to adjust the control overfit
	lambda_l2	7	L2 regularization parameter, used to adjust the control overfit
	num_leaves	1231	Number of leaves on a tree, the larger the value of

			the maximum number of leaf nodes, the more accurate the model, but too large may be over-fitted.
	subsample	0.8	The sampling ratio of training samples can be used to accelerate training and handle overfitting.
	max_bin	247	max_bin indicates the maximum number of bins for the features. A smaller max_bin makes training faster, a larger max_bin makes the model more accurate, but too large a max_bin can lead to overfitting.
CatBoost	depth	5	The maximum depth of the tree model.
	learning_rate	0.01	Used for reducing the gradient step
	n_estimators	5526	The maximum number of trees that can be built when solving machine learning problems.
	l2_leaf_reg	9	Coefficient at the L2 regularization term of the cost function.
	max_bin	209	The number of splits for numerical features.
	bootstrap_type	Bernoulli	Defines the method for sampling the weights of objects
	subsample	0.78	Sample rate for bagging
XGBoost	max_depth	5	Maximum depth of a tree. Increasing this value will make the model more complex and more likely to overfit.
	learning_rate	0.01	Step size shrinkage used in update to prevents overfitting.
	n_estimators	2542	n_estimators indicates the number of integrated weak evaluators. The larger the n_estimators, the better the learning ability of the model.

	alpha	7	L1 regularization term on weights. Increasing this value will make model more conservative.
	gamma	2	Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger is, the more conservative the algorithm will be.
	subsample	0.7	Subsample ratio of the training instances.

D. Analysis of Experimental Results

The trained model is tested with a test set, and the model is evaluated by time complexity, mean absolute error (MAE), root mean square error (RMSE), and coefficient of determination (R²). The prediction results of the different models were compared and the results are shown in Table IV. The comparison of training time and prediction time and time complexity of different algorithms are shown in Fig. 5, 6 and 7.

TABLE IV. COMPARISON OF MODEL PREDICTION RESULTS

Machine learning models	MAE	RMSE	R ²
LightGBM	0.9910	1.3708	0.6174
XGBoost	0.9896	1.3710	0.6173
CatBoost	0.9882	1.3712	0.6172

Fig. 5. Comparison of model training time.

Fig. 6. Comparison of model prediction time.

Fig. 7. Comparison of time complexity.

The experimental results show that all three tree-based machine learning models using Optuna can obtain MAE values less than 1, which means that the mean value of model prediction error is within 1 day, with CatBoost having the smallest MAE value of 0.9882. The RMSE metric is strongly influenced by outliers, and in this study the RMSE of all three tree models is around 1.371, with LightGBM has the smallest RMSE value of 1.3708. R^2 is a measure of the ability of the independent variable to explain the dependent variable. When the R^2 value is close to 1, the explanatory power of the independent variable is at a high level. Among all models, the strongest explanatory power is LightGBM, followed by XGBoost and CatBoost. For the prediction models constructed in this study, the prediction results of the three models are not very different and all can accurately predict the number of customer login days in the next seven days, but in terms of time complexity, LightGBM is much more efficient than the other two models. In summary, LightGBM was selected as the customer retention prediction model for the video-on-demand platform and further analyzed in this study.

VI. SHAP-BASED MODEL INTERPRETATION ANALYSIS

SHAP (SHapley Additive ExPlanations) is a method for explaining the predictions of machine learning models. It is an additive explanatory model constructed by Lundberg et al [27] in 2017 inspired by cooperative game theory, which provides a unified way to understand how each feature contributes to the prediction and how the combination of features determines the final prediction. SHAP values are based on the concept of Shapley values in cooperative game theory and are used to fairly distribute the value generated by a set of individuals to each Individuals. Similarly, SHAP values distribute the predictions of a machine learning model to each feature, allowing us to see how each feature contributes to the prediction. SHAP values take into account feature interactions and the relationship between features and predictions, providing a more complete and accurate interpretation than other model interpretation techniques such as partial dependency graphs and feature importance values. SHAP interprets the predicted value of a model as the attributed value of each input feature SHAP interprets the model prediction as the sum of the attributed values (Shap Values) of each input feature, and the Shap Values are calculated as follows:

$$y_i = y_{base} + f(x_{i1}) + f(x_{i2}) + \dots + f(x_{in}) \quad (4)$$

Suppose the i -th sample is x_i and there are n features, the baseline of the whole model is the mean of all sample target variables, defined as y_{base} , where $f(x_{i1})$ is the Shapley value of the first feature of sample i , when $f(x_{i1})$ is greater than 0, this feature has a positive effect on the predicted value; when $f(x_{i1})$ is less than 0, this feature has a negative effect on the predicted value. In addition, the TreeSHAP framework developed by Lundberg specifically for tree models has greatly improved the operation efficiency [28].

SHAP Summary Plot combines feature importance with feature effect to reflect the overall positive and negative relationship between feature value and future login days of customers [29]. In order to further clarify the positive/negative relationship between each indicator and the target variable, this paper uses Tree SHAP for model interpretation. As shown in Fig. 8, the horizontal coordinate in the figure is SHAP value, each row represents a feature variable, and each point represents a sample. The redder the point color is, the larger the value of the feature itself, and the bluer the color is, the smaller the value of the feature itself. A positive value represents a positive impact, while a negative value represents a negative impact.

Fig. 8 shows the summary of SHAP features of LightGBM. From the figure, we can see that the three most important features in the model are the total number of logins in the recent week, the length of video playback on the same day, and the time difference between the most recent logins and the present. For the R(recency) feature, the customers who log in on the current day have a positive impact on the number of login days in the future, the greater the time difference between the latest login and the present, the greater the negative impact on the future login days; For the F(frequency) feature, the more the total number of logins in the past week and the total number of historical logins, the more accustomed users are to using the platform, and the higher the positive impact on the future login days of customers; For the L(length) feature, the more playback duration and number of the current day and the previous seven days, the higher the positive impact on the future login days of customers; while the higher the video completion degree of the current day and the previous seven days, the higher the negative impact on the future login days of customers; For the H(history) feature, the constructed historical retention days feature reflects the login characteristics of users to some extent. The mean, median and weighted mean of historical retention days all have an impact on the future login days of customers. The larger the mean and weighted mean of historical retention days, the higher the positive impact on the future login days of customers.

As for the differences in personal characteristics, the overall effect on the predicted results is little. As shown in the figure, customers with jobs are more likely to retain than those without jobs. The device type has no or positive impact on the future login days; the RAM and ROM of the device will have an impact on the performance of the device. In this experiment, the larger the ram and rom values are, the higher the positive impact on the future login days of the customers; the gender has a mixed impact on the prediction results; the younger the age is, the higher the positive impact on the future login days of the customers.

VII. CONCLUSION AND OUTLOOK

The rapid development of information technology has made watching videos one of the most popular online activities and provides a huge market for various video content providers. vod customer retention prediction model can accurately predict the number of days users will log in in the future, which is crucial for vod platform to retain customers and increase its core competitiveness in the market. This study proposes an improved RFLH customer retention prediction model based on the traditional RFM model based on a machine learning customer retention prediction research model, and empirically tests the model with real data from the iQIYI platform, constructs the prediction model by three different machine learning algorithms, and applies Optuna to select the optimal hyperparameters of the model to improve the prediction accuracy of the model. The experimental results show that the Vod customer retention prediction model based on machine learning proposed in this study is effective, and LightGBM is the most efficient compared with the other two models with similar accuracy and has high practicality. Finally, the main factors of different features affecting customer retention are analyzed in conjunction with the SHAP model, and the feature variables that have a greater impact on the prediction model are found, and the overall positive and negative relationships between the feature variables and customer retention are carved. This study remedies the shortage of customer retention prediction research in video-on-demand platforms to a certain extent. Meanwhile, the RFLH index system and SHAP explanatory model in the paper can provide better decision support for Vod platform to understand the real situation of users and thus retain them. In this study, the analysis of personal characteristics is derived from the output of the model. In the future, personal characteristics and behaviors can be further combined to explore the influence of users' personal characteristics on customer retention, and more factors affecting customer retention in video-on-demand platforms can be introduced into the prediction model, as well as other prediction techniques can be applied to further improve the accuracy of prediction.

For companies, for users whose model predicts 0 logins and have not logged in for a long time, reduce the investment in this area in the future marketing process. For customers who are predicted to log in in the future, the focus should be on the total number of logins in the past week, the length of video playback on the same day and the time difference between the last login and the present. Companies can establish a membership system as well as a point system to obtain points through sign-ups to send members, sign-ups to receive points as well as accumulate viewing hours and complete tasks, and transform them into premium privileges that can be enjoyed to further strengthen user stickiness.

Abstract—This research paper presents the development of computer vision-enabled augmented reality games based on action detection to increase motivation for sports. With the increasing popularity of digital games, physical activity and sports participation have been declining, especially among the younger generation. To address this issue, we developed a series of augmented reality games that require players to perform physical actions to progress and succeed in the game. These games were developed using computer vision technology to detect the players' movements and provide real-time feedback, enhancing the gaming experience and promoting physical activity. The results of our user study showed that participants who played the augmented reality games reported higher levels of motivation to engage in physical activity and sports. The findings suggest that computer vision-enabled augmented reality games can be an effective tool to promote physical activity and sports participation, especially among younger generations.

Keywords—Augmented reality; computer vision; action detection; action classification; machine learning

I. INTRODUCTION

Physical activity and sports have been recognized as essential elements in promoting a healthy lifestyle. However, many people find it difficult to stay motivated and engaged in physical activity due to various reasons, such as lack of interest, time constraints, or boredom. Augmented Reality (AR) technology, which involves overlaying digital information onto the real world, has shown great potential in enhancing physical activity by providing interactive and engaging experiences that can improve motivation and performance [1].

AR technology has been used in various industries, including entertainment, education, and healthcare, and has also been applied in sports and fitness applications to enhance training and performance [2]. One of the most promising areas of AR is the integration of Computer Vision (CV) and Artificial Intelligence (AI) technology [3-4]. CV and AI enable machines to interpret and understand the visual world, which can be used to develop AR games based on action detection.

Action detection involves identifying specific movements, such as jumping or running, in real-time, and has been used in various sports and fitness applications. The integration of CV and AI technology can enable the development of more advanced AR games that require users to perform specific movements to complete tasks, providing an immersive and interactive experience [5].

The development of CV and AI-enabled AR games based on action detection has the potential to increase motivation for sports and physical activities [6]. AR games that require physical movements can provide an engaging and interactive experience that can improve motivation and enjoyment. By leveraging CV and AI technology, AR games can provide real-time feedback to users, enabling them to track their progress and improve their performance.

Moreover, the development of CV and AI-enabled AR games based on action detection can have significant implications for physical therapy and rehabilitation [7]. Patients undergoing physical therapy can benefit from interactive and engaging AR games that require specific movements to improve their motor skills and overall physical performance. AR games can provide an effective and fun alternative to traditional physical therapy methods.

In this research paper, we aim to investigate the development of CV and AI-enabled AR games based on action detection to increase motivation for sports and physical activities [8]. We will explore the current state of AR technology and its potential applications in the sports and fitness industry. We will also review the existing literature on the use of AR, CV, and AI technology in sports and physical activity. Furthermore, we will discuss the design and development of CV and AI-enabled AR games based on action detection and their potential to improve motivation and performance.

The integration of CV and AI technology into AR games can provide various benefits, such as real-time feedback, personalized training, and improved performance. By analyzing the user's movements, CV and AI algorithms can

provide personalized training plans and feedback, which can motivate users to improve their performance [9]. Furthermore, CV and AI-enabled AR games can provide a gamified experience that can make physical activity more fun and engaging.

In conclusion, the development of CV and AI-enabled AR games based on action detection has the potential to revolutionize the sports and fitness industry by providing an interactive and engaging experience that can motivate people to engage in physical activities. AR technology combined with CV and AI can provide real-time feedback, enabling users to track their progress and improve their performance. Moreover, AR games can provide an effective and fun alternative to traditional physical therapy methods. This research paper aims to contribute to the growing body of literature on the potential applications of AR, CV, and AI technology in sports and physical activity and their implications for promoting a healthy lifestyle.

II. RELATED WORKS

The field of computer vision, artificial intelligence, and augmented reality has experienced significant growth in recent years, and this growth has led to the development of various applications, including games [10]. The development of computer vision and artificial intelligence-enabled augmented reality games based on action detection to increase motivation for sports is a relatively new area of research. This section presents an overview of the related works in this field.

Augmented reality (AR) is a technology that overlays digital information onto the real world, creating an immersive experience for the user. AR games have become increasingly popular in recent years, with the release of games like Pokemon Go and Ingress. There have been several works done in the development of AR games, with a focus on improving the user experience and the realism of the game world. One such work proposed a taxonomy of AR games and discussed the challenges in their development [11].

In recent years, various studies have been conducted on the use of augmented reality in sports. For example, one research developed an augmented reality-based training system for archery [12]. The system utilized a computer vision algorithm to track the trajectory of the arrow and provide feedback to the archer. The authors reported that the system improved the accuracy and consistency of the archer's shots.

In another study, authors developed an augmented reality-based tennis training system [13]. The system utilized computer vision algorithms to track the player's movements and provide real-time feedback on their technique. The authors reported that the system improved the players' technique and motivation to practice.

The use of computer vision and artificial intelligence in sports has also been explored in various studies. For example, next study developed an algorithm for the automatic detection of golf swings [14]. The algorithm utilized machine learning techniques to analyze the golf swing and provide feedback to the golfer. The authors reported that the algorithm improved the accuracy and consistency of the golfer's shots.

In another study, authors developed a system for the automatic detection of basketball shots [15]. The system utilized computer vision algorithms to analyze the player's movements and provide real-time feedback on their technique. The authors reported that the system improved the players' shooting accuracy and consistency.

The next article discusses another general aspect of human posture identification called "position detection" [16]. Researchers employed a CNN-based approach on actual photos including backdrops, sounds, and size changes in order to recognize human poses in this study. Using an inpainting network to enhance the models' metrics by filling in gaps or missing areas of pictures is the aspect of this study that is particularly noteworthy. Fig. 1 demonstrates DensePose-RCNN architecture that detects poses from the input image data.

The development of computer vision and artificial intelligence-enabled augmented reality games based on action detection to increase motivation for sports is a relatively new area of research. However, there have been a few studies in this area. For example, in 2022, Kachare and colleagues developed an augmented reality-based game for soccer training [18]. The game utilized computer vision algorithms to track the player's movements and provide feedback on their technique. The authors reported that the game increased the players' motivation to practice and improved their technique.

Similarly, another study by Desai & Mewada (2023) developed an AR-based soccer training system that used CV and AI technology to track the user's movements and provide real-time feedback on their performance [19]. The system included various training scenarios and challenges that required the user to perform specific movements, enhancing their motivation and engagement in the training process. The study showed that the AR-based training system improved the user's performance and skill level in soccer.

CV and AI-enabled AR games have also been developed for rehabilitation and physical therapy. One study by Bhaumik et al. (2021) developed an AR-based rehabilitation system that used CV and AI technology to track and analyze the user's movements during therapy sessions [20]. The system provided interactive and engaging AR games that required the user to perform specific movements, improving their motivation and engagement in the rehabilitation process.

Fig. 1. DensePose-RCNN architecture: used a cascade of region proposal generation and feature pooling, followed by a fully-convolutional network that densely predicts discrete part labels and continuous surface coordinates [17].

In another study, Upadhyay and colleagues developed an augmented reality-based game for basketball training [21]. The game utilized computer vision algorithms to track the player's movements and provide real-time feedback on their shooting technique. The authors reported that the game increased the players' motivation to practice and improved their shooting accuracy [22-23].

Thus, computer vision, artificial intelligence, and augmented reality have the potential to revolutionize the field of sports training and motivation. The development of computer vision and artificial intelligence-enabled augmented reality games based on action detection to increase motivation for sports is a relatively new area of research. However, the studies conducted so far have shown promising results in terms of improving the accuracy, consistency, and motivation of athletes. Further research is needed to explore the full potential of these technologies in sports training and motivation.

III. MATERIALS AND METHODS

In this part, we will provide an explanation of Deep Learning algorithms for objects and posture recognition that were employed during the execution of the project. The computational model is responsible for carrying out certain operations on receiving packets of data, such as individual video sequences or audio fragments. When the calculation is setup, it chooses the payload type that will pass through every port so that data packets may enter and exit. Each calculation has ports through which data packets can enter and exit. Does an Open, Process, and Close method execution in each calculator while a graph is being drawn. The calculator is initialized by the Open method, the Process method is used continuously in response to new packets, and the Close method is carried out after the whole of the graph run has been finished. Fig. 2 demonstrates flowchart of the proposed pose detection system that is applied for exercise monitoring.

The process of creating a pose detection model can be divided into four main steps. The first step is pre-processing the media data. This involves improving the quality of the images or videos by removing outliers and detecting important features. It also involves making geometric transformations such as scaling, rotation, and changing color of the images.

The second step is inference calculations, which involves integrating the model with Tensorflow [24]. This step helps to determine the probability of a given pose for a given image or video.

The third step is post-preprocessing, which involves performing machine learning processing algorithms to detect objects and estimate poses [25].

Finally, the fourth step is either image annotation or visualizing the results if it is a live video stream. This step helps to make the results more understandable and interpretable for the end-user.

Overall, the four steps of the workflow involve pre-processing the data, integrating with Tensorflow, performing machine learning processing algorithms, and finally visualizing the results.

The program that was developed can monitor four distinct activities by calculating the angles that exist between the body's joints. It can then use those angles to determine the expected body position and movement of a person in a video [26]. Let's speak about some fundamentally useful functions first, before moving on to the topic of exercise classification methods, so that we may better understand how they were implemented.

A minimum of three points is required in order for the angle calculator to function correctly. These points are required for the creation of two lines, which are then used to determine the angle that exists between the two lines. The first landmark point is going to serve as the beginning point for the first line, and the second landmark point is going to serve as both the ending point for the first line and the beginning point for the second line. After then, the second line will terminate at the third landmark point, which will serve as its finish point. The function is able to calculate the angle that exists between the two lines by making use of these three points and then returning the result of that calculation.

Fig. 2. Flowchart of the proposed pose detection system.

Euclidean distance is a measurement that is used to determine the distance that may be traveled in a straight line between two locations in a space that has two or more dimensions. Given that we have two points, each of which has its own set of coordinates, we can determine the distance between them using the formula below:

$$Dis\ tan\ ce = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (1)$$

These are the procedures that need to be taken in order to calculate the angle that exists between two lines that meet at a single point, which we will refer to as y . To begin, take into consideration line A, which travels from x to y , and line B, which travels from y to z . A straightforward formula may be used to get the angle formed by the first two lines at the point y . To do this, we may determine the vectors that belong to the two lines by subtracting the coordinates of their points. This will lead us to the vectors that are associated with the lines. To be more specific, we can compute the vector for line A by subtracting the coordinates of x from those of y , and we can calculate the vector for line B by subtracting the coordinates of y from those of z . Both of these calculations may be done independently of one another. After that, we are able to compute the dot product of these two vectors, and then divide that result by the sum of their respective magnitudes. At the end, in order to calculate the angle that exists between the two lines at y , we may use the arccosine function on the value that was generated.

$$\theta = \frac{y_1 * (x_2 - z_1) + x_2 * (z_1 - y_1) + z_2 * (y_2 - x_1)}{(y_1 - x_1) * (x_1 - z_1) + (y_2 - x_2) * (x_2 - z_2)} \quad (2)$$

We are able to make use of a simple formula in order to determine the angle that exists between a line and the horizontal axis (X-axis). Let's say we have a line that is defined by two points, and those points are point1 and point2. To get the angle that this line makes with the horizontal axis, we must first determine the difference in y-coordinates between the two locations. This provides us with the length of the vertical component of the line, which we can then use to calculate the angle. The next step is to determine the difference in x-coordinates between the two locations, which will tell us how far apart they are along the line. This will give us the length of the line's horizontal component. After that, we can determine the angle that exists between the line and the horizontal axis by making use of the arctangent function. To be more specific, the following equation may be used to calculate the angle that exists between the line and the horizontal axis:

$$\theta = \arctan\left(\frac{y_2 - y_1}{x_2 - x_1}\right) \quad (3)$$

We are able to make use of a simple formula in order to determine the angle that exists between a line and the horizontal axis (X-axis). Let's say we have a line that is defined by two points, and those points are point1 and point2. To get the angle that this line makes with the horizontal axis, we must first determine the difference in y-coordinates between the two

locations. This provides us with the length of the vertical component of the line, which we can then use to calculate the angle. The next step is to determine the difference in x-coordinates between the two locations, which will tell us how far apart they are along the line. This will give us the length of the line's horizontal component. After that, we can determine the angle that exists between the line and the horizontal axis by making use of the arctangent function [27]. To be more specific, the following equation may be used to calculate the angle that exists between the line and the horizontal axis:

$$sign = (y_1 - x_1) * (z_2 - x_2) * (y_2 - x_2) * (z_1 - x_1) \quad (4)$$

Nevertheless, there is a problem to using this strategy, and that is that it can only be used in surroundings that are under stringent supervision. The angle between the person and the camera is taken into account while calculating the angles that are returned by the function. Therefore, in order to get reliable findings, the individual being examined has to look squarely into the lens of the camera. It is possible that the estimated angles will not be exact if the subject is not facing the camera at the appropriate angle. Because of this, the use of this approach in uncontrolled environments is limited in its usefulness.

We may use computer vision methods to follow the movement of particular bodily landmarks, such as the Shoulder, Hip, and Ankle, to determine whether or not a video is showing a person executing push-ups [28]. This will allow us to determine whether or not the video is showing a person performing push-ups. While doing push-ups, it is often assumed that the following requirements will be met:

- 1) The angle formed by the line running from the person's shoulders to their hips and the line running from their hips to their ankles should be relatively near to horizontal. This indicates that the individual is standing in a posture that is parallel to the ground. It is possible that this angle will be very near to 0 degrees or very close to 180 degrees depending on the location of the individual.
- 2) The angle formed by the line running from the shoulder to the elbow and the line running from the elbow to the wrist should be monitored from one frame to the next since this might show the movement of the arm while doing the push-up.
- 3) The degree to which the line that connects the elbow and the wrist deviates from the horizontal should also be followed from one frame to the next.
- 4) If the counter is continually incremented and the average angle from the 3 condition across 24 frames deviates significantly from 90°, and the average difference between the first angle and the second angle from the 2 condition is greater than a small constant value of 5, then it can be concluded that the exercise being performed in the video is a push-up. This conclusion can be reached if the average difference between the first angle and the second angle from the 2 condition is greater than 5.

The use of a counter to monitor the occurrence of these circumstances constantly over the course of a predetermined number of frames, often 24 frames, is recommended in order to

guarantee accuracy and reduce the likelihood of false positive results. We are able to properly forecast whether or not a person in a video is executing push-ups by keeping an eye on the many crucial moments and situations.

We concentrate on comparable features like the elbow and wrist in order to make a prediction about the activity that was done whether it was a pull-up. Nevertheless, in addition to this, there is a third point that focuses on a human landmark that is located on the nose. Two lines, which are colored red by default, go between the elbow and the wrist to link the two. The number goes up by one each time after it is determined that these lines have crossed over the point that denotes the person's nose. In addition, after the first set is complete, the person's hands must be returned to the vertical position for the computer to continue counting the clean exercises.

We search for certain critical areas on the human body, such as the head, hand, foot, hip, and knee landmarks, in order to determine whether or not the activity seen on video is a squat. The nose, the ears, or the eyes are all viable choices for the head point. Other possibilities include the mouth. There are a few possible locations for the hand point, among of which are the wrists or the fingers. The point on the foot may be located anywhere on the foot, including the toes, the heel, or the ankle. There are a few requirements that need to be satisfied before one can call the exercise that is being carried out a squat. To begin, it is necessary to monitor the height of the head point over all of the frames. Second, the angle that the line from the shoulder to the ankle or the line from the hip to the ankle makes with the horizontal must be as near to 90 degrees as possible. Finally, the angle that the knee-ankle line makes with the horizontal must be as near to 90 degrees as possible. Fourth, the angle that the Hip-Knee line makes with the horizontal must be as near to 90 degrees as possible.

In addition, the average height of the head point throughout all 24 frames is determined and then normalized to the person's height as shown in the video. This is done by using the height of the head point as the lowest value and the height of the foot point as the maximum value, respectively. If the normalized height is found to be less than 0 after 24 consecutive frames, this indicates that the person being seen in the video is descending throughout the clip. Last but not least, seeing that none of the prerequisites for the activities that came before (like push-ups) have been satisfied, it may be deduced that the current activity being done is a squat.

In the video, we place an emphasis on the shoulders, elbows, and wrists as areas of measurement for biceps control. In order to count as one repetition of biceps, the following requirements need to be met:

1) Determine the angle formed by the line running from the shoulder to the elbow and the line running from the elbow to the wrist. If the shoulder point is in the right place, the angle should be closer to 180 degrees.

2) After the approach has been completed, determine the angle that exists between the point of the elbow and the point of the wrist. In the event that the distance is less than 30 degrees, the biceps flag should be set to True.

3) If the push-up flag is set to True and the preceding condition's calculation shows that the angle is larger than 90 degrees (a constant value), then the push-up counter should be increased and the push-up flag should be set to False.

4) If the criterion from the previous step is satisfied, this indicates that one full push-up has been performed. To accurately count all of the repetitions, you will need to repeat the same technique throughout the whole film.

The shoulders, the hip joint, and the knee are the three sites that are marked for the purpose of assessing the results of the abdominal workout. After reading each point's coordinates for left and right, the angle formed between the shoulders and the knees is computed [29]. This process is repeated for each point. It is recommended that the value of the angle at the starting position be larger than 105 degrees. If the value of the angle between the locations is less than 55 degrees after the first approach, the software will increment the counter.

IV. EXPERIMENTAL RESULTS

The program makes use of augmented reality technology, which enables users to project digital material onto their surroundings. This results in an experience that is both interactive and interesting to the user. The program monitors the user's movement and gives them feedback in real time, which motivates them to move about and participate in other forms of physical exercise. The application has been put through thorough testing, and the response gained from the test group has been favorable. Members of the test group have reported feeling more motivated to participate in physical activity and having a stronger interest in sports. The outcomes of the work that was really carried out are shown in Fig. 3, 4, 5, and 6. Fig. 3 demonstrates the start page of the proposed application.

Fig. 4 demonstrates sit-ups monitoring example. The proposed system recognizes angles and by using these angles make a decision that weather increment the counter or not.

Fig. 5 demonstrates an example of the squat monitoring exercise. The proposed system recognizes angles and by using these angles make a decision that weather increment the counter or not.

V. DISCUSSION

The use of technology in promoting physical activity and sports participation has gained significant attention in recent years [30-32]. Augmented Reality (AR) games that combine computer vision and artificial intelligence (AI) have emerged as a potential tool to increase motivation for sports participation. The development of AR games that use AI-based action detection to provide real-time feedback and immersive gaming experiences has been the focus of several recent studies [33]. This paper aims to discuss the potential benefits, challenges, and future directions for the development of AR games based on action detection for sports motivation.

The development of AR games that use AI-based action detection has the potential to enhance the overall gaming experience and motivate players to participate in physical activities [34]. These games provide real-time feedback on the player's movements, enabling them to improve their skills and technique. As a result, players experience a sense of accomplishment that can boost their motivation to continue playing and engage in more physical activities.

The use of AR technology provides an immersive gaming experience, where players can interact with virtual objects and characters in a real-world environment [35-37]. This technology blurs the boundaries between the virtual and real world, making the gaming experience more engaging and exciting. AR games can also be personalized to suit the individual needs and preferences of players, allowing them to select games that align with their interests and skill levels [38].

Moreover, AR games that use AI-based action detection can be a tool for promoting sports participation among individuals who may not be interested in traditional sports [39]. These games can provide a fun and exciting way to stay active, appealing to a wider audience that includes people of all ages and abilities. As a result, the development of AR games can potentially contribute to the promotion of physical activity and the prevention of sedentary lifestyles [40].

Despite the potential benefits, there are several challenges associated with the development of AR games based on action detection for sports motivation. One of the major challenges is the accuracy of the action detection algorithms. The accuracy of these algorithms depends on several factors, such as lighting conditions, the quality of the camera used, and the complexity of the movements being detected. Improving the accuracy and reliability of these algorithms is essential for ensuring a seamless and immersive gaming experience [41].

Another challenge is the complexity and cost of developing AR games. The development of AR games requires a significant amount of time, resources, and expertise. Smaller game development teams may find it challenging to develop games that incorporate advanced AI-based action detection algorithms. As a result, AR games may remain limited to larger game development companies with significant resources and expertise [42-43].

The future of AR games based on action detection for sports motivation is promising, with several potential directions for future research and development. One direction is to improve the accuracy and robustness of the action

Fig. 4. Sit-ups monitoring example.

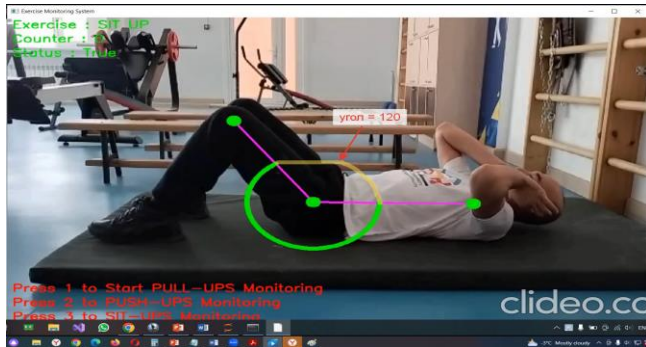

Fig. 5. Squat monitoring example.

Fig. 6. Biceps monitoring example.

Fig. 6 illustrates an example of the biceps monitoring exercise. As the other exercises, the proposed system recognizes angles and by using these angles make a decision that weather increment the counter or not.

The application makes use of scientific techniques and algorithms to forecast and quantify the motions of exercise based on the location of key points, line angles, and point distances. Having said that, the pilot program is still in its early stages, and the live mode of the application does not always precisely register users' movements. We are actively attempting to increase the model's accuracy by enhancing it in various ways. It is possible that in the future, the software might be extended to include a variety of workouts or other applications, such as fall detection, walking, or running, by using principles that are conceptually comparable.

detection algorithms used in these games. Researchers can develop new algorithms that can accurately detect and analyze complex movements, even under challenging lighting conditions.

Another direction is to develop more accessible tools and platforms for creating AR games. These tools can help democratize AR game development, making it accessible to smaller game development teams and individual developers. Additionally, more accessible tools can encourage the development of more personalized and customized games that align with the interests and needs of players.

VI. FUTURE RESEARCH

Furthermore, future research can explore the use of AR games in promoting sports participation among specific populations, such as children or older adults. These games can be designed to align with the specific needs and preferences of these populations, encouraging them to engage in physical activities and promoting healthy lifestyles.

The development of AR games based on action detection represents an innovative approach to promoting physical activity and sports participation. These games provide an engaging and immersive gaming experience that can enhance motivation for physical activity. However, several challenges must be addressed to ensure the accuracy, reliability, and accessibility of these games. Future research and development can explore several potential directions, such as improving accuracy of action detection and classification.

VII. CONCLUSION

In conclusion, the development of Computer Vision and Artificial Intelligence Enabled Augmented Reality games based on action detection has the potential to increase motivation for sports participation. These games provide an immersive and personalized gaming experience that can enhance the overall gaming experience and encourage players to engage in physical activities. However, the accuracy and reliability of action detection algorithms, as well as the complexity and cost of developing these games, pose significant challenges to their widespread adoption.

Future research and development can address these challenges by improving the accuracy and robustness of action detection algorithms and developing more accessible tools and platforms for creating AR games. Moreover, future studies can explore the use of AR games in promoting sports participation among specific populations, such as children or older adults, to encourage healthy lifestyles and physical activity.

Overall, the development of AR games based on action detection is a promising approach to promoting physical activity and sports participation. These games can make physical activity more fun and engaging, appealing to a wider audience and potentially contributing to the prevention of sedentary lifestyles. Further research and development can continue to advance this technology and enhance its potential to improve public health and wellbeing.

Abstract—Clustering of data in case of data mining has a major role in recent research as well as data engineers. It supports for classification and regression type of problems. It needs to obtain the optimized clusters for such application. The partitional clustering and meta-heuristic search techniques are two helpful tools for this task. However the convergence rate is one of the important factors at the time of optimization. In this paper, authors have taken a data clustering approach with improved bee colony algorithm and opposition based learning to improve the rate of convergence and quality of clustering. It introduces the opposite bees that are created using opposition based learning to achieve better exploration. These opposite bees occupy exactly the opposite position that of the mainstream bees in the solution space. Both the mainstream and opposite bees explore the solution space together with the help of Bee Colony Optimization based clustering algorithm. This boosts the explorative power of the algorithm and hence the convergence rate. The algorithm uses a steady state selection procedure as a tool for exploration. The crossover and mutation operation is used to get balanced exploitations. This enables the algorithm to avoid sticking in local optima. To justify the effectiveness of the algorithm it is verified with the open datasets from the UCI machine learning repository as the benchmark. The simulation result shows that it performs better than some benchmark as well as recently proposed algorithms in terms of convergence rate, clustering quality, and exploration and exploitation capability.

Keywords—Bee colony optimization; BCO based clustering; data clustering; partitional clustering; meta-heuristic search

I. INTRODUCTION

Clustering is one of several notable research areas in data mining. It is an art of grouping elements with a goal that elements in a cluster are dynamically similar compared to the elements of other clusters [1]. There are two significant variants of clustering principles, hierarchical and partitional clustering [1,2,3]. The key issue with hierarchical clustering is once the cluster arrangements are made it can't be altered, as a result reallocation of elements is difficult. In this paper, our focus is on partitional clustering. k-Means, k-Medoids, PAM, and CLARA [4] are some examples of partitional clustering techniques. Because of simplicity and relatively low time complexity, the k-Means algorithm has gain popularity over the years. But the results of the k-Means clustering largely depend on the initially chosen centroids, and it usually converges to local optima. It is also unable to handle higher dimensional datasets.

To address this issue, several optimization techniques have been proposed and found to be effective in this respect. Over the last two decades several optimization based clustering techniques proposed for different applications. Following are some of them. The clustering applications based on Ant Colony Optimization (ACO) introduced in [5,6,7] are based on the foraging behavior of artificial ants. Particle Swarm Optimization (PSO) based clustering algorithms that mimic a flock of swarming particles' food-finding behavior are presented in [8,9,10,11,12]. In [13,14,15,16,17], the Bee Colony Optimization (BCO) based clustering methods are proposed. These are modeled on the way artificial bees collect food. The clustering methods based on Genetic Algorithms (GA) proposed in [18,19,20] are motivated by biological processes as crossing, mutation, and inheritance.

Despite the presence of several optimization techniques for clustering new techniques are encouraged because every technique has its pros and cons. For example; ACO has slow convergence, falls in local optima, low similarity and high time complexity [21]; PSO depends on predefined cluster centroids and is trapped in local optima for higher dimensional datasets [22]; BCO has a low convergence rate and imbalanced exploration and exploitation [23]; and the slowness of genetic algorithms (GA) is frequently questioned. Again, no technique guarantees proper grouping for a wide variety of applications. The overall study of the algorithms concludes that clustering a wide variety of applications is still an open problem and new algorithms are always appreciated. The new meta-heuristic techniques for the clustering problem should address some of the common issues such as dependency on the initial cluster centroids, slow convergence rate, more emphasis on exploration than exploitation, falling in local optima of larger datasets, low accuracy, and higher computational complexity. In recent years, many optimization techniques for clustering problem proposed that successfully addressed these issues. Some of these are discussed in related works section.

The rate of convergence of a clustering algorithm mainly depends on the initially chosen centroids. The convergence rate is faster if these initially chosen centroids are closer to the optimal centroids. Otherwise, it takes a considerably large time to converge. To improve the convergence rate and get better clustering results keeping a balance between exploration and exploitation in this paper, we have proposed an Opposition Learning based Improved Bee Colony Optimization (OLIBCO) algorithm for data clustering. The OLIBCO algorithm considers an opposite set of bees along with the initially chosen

mainstream bees. First a set of mainstream bees initialized with randomly selected centroids, then the corresponding opposite bees are created with opposite centroids using opposition based learning technique. Both the mainstream bees and opposite bees explore the solution space together using Bee Colony Optimization based clustering algorithm. This intensifies the exploration, thereby helps in finding better cluster centroids at an early stage of the solution. Every bee generates its cluster in K (number of clusters) stages. In every stage, once a feasible solution found the bees come back to hive to compare their solution, thereby recruiter bees recruit their followers and go to next stage. After all stages complete the best solution found and remaining data objects allocated to this and referred as local best. The local best considered to be the global best if it is better than the previous global best. The use of opposition based learning helps in getting faster convergence and the crossover and mutation operations applied to the local best helps in further exploitation of the result.

The rest part of the paper is organized as follows. The related works is discussed in Section II. Section III presents the proposed algorithm with complexity analysis. Section IV shows the simulation and comparative analysis of the algorithm for different applications. Finally, Section V presents the conclusion and future work.

II. RELATED WORKS

Several new optimization techniques for the clustering problem have been proposed over the years. The Ant Colony Optimization (ACO) [24] is based on the foraging behavior of artificial ants. In [5], an energy-efficient clustering routing method based on the enhanced ACO algorithm introduced to address the issue of energy consumption in UWSNs. For no-wait flow shop scheduling, a hybrid ant colony algorithm based on crossover and mutation mechanisms is developed with the goal of minimizing the maximum completion time in [6]. To find the ideal CH for an energy-efficient routing protocol in WSN the Ant Colony Optimization (ACO) integrated Glowworm Swarm Optimization (GSO) technique (ACI-GSO) proposed in [7]. The Particle Swarm Optimization (PSO) is a population-based heuristic search method proposed in [25]. In order to achieve flawless clustering with balanced load and energy-efficient optimization, the authors in [8] used a GWO-PSO-based clustering method. For Cooperative PSO based clustering, a new initialization approach has been put forth in [9]. The suggested data clustering strategy in [10] is based on the KDE and PSO clustering algorithm resolves the issues of PSO-based clustering approaches. The work in [11] illustrates a secure technique for clustering using Improved Particle Swarm Optimization Algorithm in IoT. To get the best network performance, a method based on GA and PSO is proposed in [12] for the CH selection and to optimize the sink mobility.

The Bee Colony Optimization (BCO) is another meta-heuristic algorithm inspired by the food collection strategy of honey bee swarms [26]. An effective method for regularly finding, aggregating, analyzing, and managing important data on potential patients collected from the internet of medical things is shown in [13]. The research [14] proposes a revolutionary artificial bee colony approach for data clustering. BCO+KM clustering is a hybrid data clustering algorithm,

which combines BCO and K-means proposed in [15]. In [16], a data clustering approach proposed called Modified BCO algorithm where a bee that is with a better fitness receives the high preference. The study [17] proposes an enhanced bee colony optimization algorithm with a document clustering application. The work in [27] looks into the multi-objective system reliability optimization problem using fuzzy parameters. In recent years some other optimization techniques proposed for different task. These include: Whale Optimization Algorithm (WOA) [28,29], Cuckoo Search Optimization (CSO) [30,31], Kho-Kho optimization algorithm [32], P-spline based clustering [33], Moth-Flame Optimization (MFO) algorithm [34], Brain Storm Optimization (BSO) algorithm [35], and Class Topper Optimization (CTO) algorithm [36].

Opposition based learning is another helpful technique in the field of optimization. There are several researches done in the literature using opposition based learning for optimization of different tasks. Some of them are given here. In [37], an approach discussed for dividing the population into several memplexes using shuffled differential evolution. To improve the convergence, the authors in [38], used this technique with harmony search meta-heuristic optimization. In [39], the authors have employed opposition-based learning to break down a multi-objective optimization problem into a number of scalar optimization sub-problems, which they are then simultaneously optimizing with the evolutionary algorithm. To overcome the limitations of PSO, the authors in [40], have utilized the generalized opposition based learning. For data clustering problems, the authors have used Chimp Optimization Algorithm, Generalized Normal Distribution Algorithm, and Opposition-Based Learning method in [41]. In [42], the authors have proposed an augmented arithmetic optimization technique with the help of levy flight distribution and opposition based learning for data clustering. In [43], authors have combined it with chaotic maps, and PSO for text clustering.

III. PROPOSED OLIBCO ALGORITHM FOR DATA CLUSTERING

A. Mapping of OLIBCO for Clustering Problem

The Bee Colony Optimization (BCO) algorithm [26] considers three kinds of bees, namely scout bees, employed bees, and onlooker bees. First, the scout bees move around the search space looking for food sources. After such sources found, the scout bees become employed bees; they evaluate the quality of the found food sources (the nectar amount); and back to their hive. The employed bees go to the dance floor one by one and show others the quality of the food source they discovered (through the waggle dance). This way, every employed bee recruits some onlooker bees and travel to the same source for food collection. Once the food from the source exhausted all these bees become scout bees. The complete set of possible food sources that artificial bees can explore represents the solution space. A bee moves in the solution space and discovers a food source as a candidate solution. Again, we know that the ultimate goal of a clustering problem is to find a set of mutually exclusive groups called clusters. Hence, a bee discovers a candidate solution (a set of clusters). That means every bee has a set of clusters and a set of

centroids as its identifier. For a multi-dimensional dataset containing K different classes of data objects, a clustering solution is a set of K clusters identified by K centroids (C_1, C_2, \dots, C_K) , where each C_i is an m -dimensional data object in the dataset. In OLIBCO, it is assumed that all the bees are of a similar category. Every bee goes out for discovering feasible solutions at the same time. They select some data objects from the dataset and add them to their respective clusters. After coming back to their hive they compare the solutions using an estimate ‘Sum of Intra Cluster Distances’ (SICD). Thus, they find the local best solution. The SICD can be computed as follows [16,17]:

$$SICD = \sum_{i=1}^k \sum_{j=1}^n d(c_i, o_j), \quad (1)$$

where $d(c,o)$ is Euclidean distance between two n -dimensional data objects c and o . The terms k , n , c , and o represent the number of clusters, number of data objects in each cluster, the cluster center and the data objects respectively. Finally, the local best is compared with the global best, update the global best if required, and continue to next iteration.

B. Proposed OLIBCO Clustering Algorithm

The OLIBCO is a population-based meta-heuristic optimization algorithm inspired by opposite bees. The opposite bees are capable to explore on the opposite side of the mainstream bees. They play an important role in improving the explorative power of the algorithm. The exploration is again powered by a steady-state algorithm which adds better particles into different clusters. The algorithm uses a probability-based selection approach to give every bee (both mainstream and opposite bees) a fair chance to become a recruiter, that provides diversity in solution. For further enhancement in exploitation, the algorithm uses the crossover and mutation concept in the local best solution. The high level flow diagram is shown in Fig. 1. The algorithm is presented in Algorithm 1 and steps are explained in detail below.

Fig. 1. Flow diagram of OLIBCO.

1) *Initialization:* At first, the algorithm loads the data set D (an $n \times m$ matrix) into memory. Here, n is the number of data objects and m is the number of attributes. It takes number of bees (B), number of clusters (K), and maximum number of iteration (T) as input. The total number of bees B includes the number of mainstream and opposite bees both in an equal proportion. Every bee maintains K number of empty clusters in it. The algorithm initializes K random cluster centroids and finds its SICD value. In first step, it initializes $B/2$ number of mainstream bees with initial centroids. To avoid repetition in the data allocation it internally maintains an allocate array of size n . It is not an overhead for the algorithm because for setting the fields in an array take constant time.

2) *Creation of opposite bees*: Meta-heuristic optimization algorithms tend to make initial random guesses. The OLIBCO algorithm also initializes the mainstream bees randomly. If these mainstream bees span throughout the solution space then no need to worry. But there is a great possibility that they belong to a specific region of the solution space. If this is the case then exploration may confine to the same region or may not cover the complete solution space. In such cases, either the convergence rate is reduced or the solution evolves in a different direction and never comes near to optimal solution.

Considering a large number of mainstream bees can be an idea to this end. But we have to keep in mind that more number of bees implies more exploration. But, more weightage on exploration does not help always; instead, it increases the time complexity. Therefore, we have to choose the number of bees carefully to keep balance between the exploration quality and exploration time. Again, we cannot give guaranty that all these bees will not be in the same area, because these are created randomly.

To address this issue OLIBCO creates an equal number of opposite bees in a different direction (that of mainstream bees). Fig. 2 displays two different scenarios, first Fig. 2(a) shows a case where all are mainstream bees and are chosen in the same region, and second Fig. 2(b) shows some mainstream bees and their opposite bees together span throughout the solution space. In the first case, the exploration confined to one part of the solution space, because the general tendency of a bee is to explore nearby regions. In the second case, no matter where the mainstream bees are allocated, the corresponding opposite bees will cover the other region. By this way, the bees (mainstream and opposite bees) span throughout the solution space.

The OLIBCO algorithm creates the opposite bees after the initialization of mainstream bees using opposition based learning [44, 45]. A cluster center is a data vector from a dataset with m attribute. For all these attributes, the opposite values are computed using (2) [44, 45].

$$p' = a + b - p, \quad (2)$$

where, p is a real number in the range $[a,b]$ and p' is it's opposite number. Once the opposite values found, we combine them to a data vector to represent a centroid. For example,

Algorithm 1 OLIBCO Clustering Algorithm

Require: Maximum number of iterations T , number of clusters K , number of artificial bees B , and dataset D , with n objects, each of them are of m dimensional

Ensure: Classified objects as clusters

- 1: Initialize all the B bees with K number of empty clusters and initialize Global Best (GB).
- 2: **for** $t = 1$ to T do
- 3: **if** $t = 1$ then
- 4: Initialize K random cluster centroids, and find $SICD$ value for it.
- 5: **else**
- 6: Consider the centroids of the global best solution.
- 7: **end if**
- 8: Randomly select K initial cluster centers for $B/2$ number of mainstream bees.
- 9: Create another set of $B/2$ opposite bees
- 10: **for** $k = 1$ to K do
- 11: **for** $b = 1$ to B do
- 12: Use the steady state selection procedure to select a population of x data objects
- 13: Assign these data objects to the k^{th} cluster of the b^{th} bee
- 14: Calculate $SICD$ value of the b^{th} bee.
- 15: **end for**
- 16: **for** $b = 1$ to B do
- 17: Find the probability of stickiness (P) for the b^{th} bee
- 18: Generate a random number r in the range 0 to 1 .
- 19: **if** $P < r$ then
- 20: Select a recruiter using roulette wheel selection technique and follow its solution.
- 21: **end if**
- 22: **end for**
- 23: Find the best partial solution (bee clusters with minimum $SICD$ value).
- 24: **end for**
- 25: Allocate the left-over data objects to the local best solution, and update centroids.
- 26: Find the $SICD$ value of the local best solution.
- 27: **if** Global best solution does not change for an adequate number of iterations t **then**
- 28: Perform crossover and mutation operation on the centroids of the local best solution, and find the $SICD$ value.
- 29: Update the local best solution if the new result is better than the previous, otherwise discard the new result.
- 30: **end if**
- 31: Perform switching operation of data objects between the clusters of local best solution.
- 32: **if** $t \neq 1$ then
- 33: **if** $SICD$ value at iteration $t < SICD$ value at iteration $t-1$ **then**
- 34: Update the global best solution with the

results of the local best solution.

35: **end if**

36: **end if**

37: **end for**

38: Return the global best solution.

Consider the following mainstream bee and its opposite bee defined with three cluster centers.

$$Bee_{mainstream} = ((c_{11}, c_{12}, \dots, c_{1m}), (c_{21}, c_{22}, \dots, c_{2m}), \dots;$$

$$Bee_{opposite} = ((c'_{11}, c'_{12}, \dots, c'_{1m}), (c'_{21}, c'_{22}, \dots, c'_{2m}), \dots;$$

Here, c_{ij} and c'_{ij} are the attributes of the centroids of mainstream bees and their opposite bees, that represents the j^{th} attribute of the i^{th} cluster center. Every c'_{ij} is generated using (2). Similarly, for all the centroids of each bee are found to create the corresponding opposite bees. Moreover, the number of mainstream bees, doubles the total number of bees. Therefore, we cannot create large number of mainstream bees initially. We have taken the total number of bees (B) as input parameter. First, $B/2$ number of mainstream bees initialized then another set of $B/2$ opposite bees generated.

The algorithm runs for K ($k=1,2,\dots,K$) number of clusters. In each iteration, all the bees build one cluster (k^{th}) at a time. So there is an inner loop that varies from ($b=1$ to B). For every bee b , the forward and backward passes generate the feasible solutions. After the outer loop (k loop) ends all the bees have a partial solution. Here each iteration of the outer loop (k loop) is considered as a stage.

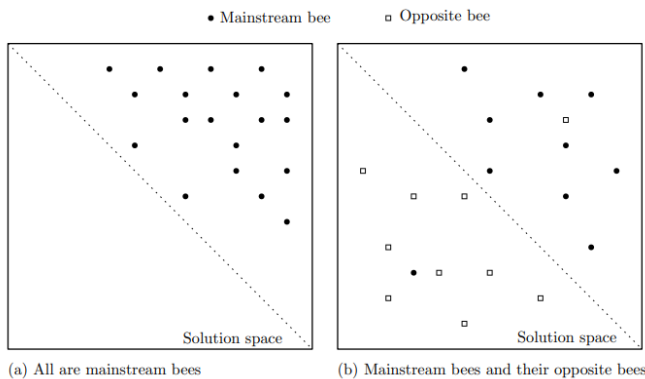

Fig. 2. Two different scenarios where (a) all bees are main stream bees chosen in same region (worst case) and (b) some mainstream and their opposite bees.

3) *Forward pass*: Once the mainstream bees initialized and their opposite bees created, all of them start exploring the solution space. In this process, they select some data objects from the dataset D and add them into their respective clusters based on a fitness (SICD) value. The exploration process of each bee depends on this selection procedure. For this, the OLIBCO algorithm uses a steady state selection approach [35]. The steady state searching process starts with creating an initial population of x data objects. This step repeats for M number of times. Here, M represents the number of moves. In each move, the search process refines the data objects to create a better population of x data objects. More the number

of moves (M), better the exploration. By increasing M the time complexity also increases. Again too small value of M implies less exploration that leads to slow convergence rate, so, it must be chosen carefully. After the forward pass completes, each bee has a feasible solution (a set of clusters). Now, all of them compute the strength of their solution using the SICD measure defined in (1).

4) *Backward pass*: In the backward pass, bees return to their hive, and share the information about their generated solution. Depending on the strength of the solution, the bee determine whether it will continue with its solution and be available as a recruiter, or will adopt (follow) some other's solution. The following equation defines the probability of a bee sticking to its solution [16,17].

$$P_b(k+1, t) = e^{-O_b(k,t)/(k \times t)}, \quad (3)$$

where b represents the current bee, k represents stage, and t represents iteration. $O_b(k,t)$ represents the normalized value of SICD of b^{th} bee and is computed using the equation (4) [16,17].

$$O_b(k, t) = \frac{SICD_b(k,t) - SICD_{min}(k,t)}{SICD_{max}(k,t) - SICD_{min}(k,t)}, \quad (4)$$

where $SICD_b$ is the SICD value of current bee b , $SICD_{max}$, and $SICD_{min}$ represents the maximum and minimum value of the SICD. From (3), we can observe P (probability of stickiness) and O_b are inversely proportional to each other, and the value of O_b depends on $SICD_b$. That means, when O_b increases the probability of a bee sticking to its solution decreases. The bee with smaller probability P may discard its solution and become a follower. If decision is to become a follower, then the bee will select another bee and adopts (copy) its solution. Every follower always wants to follow the best. This tendency of follower bees leads to local optima. The OLIBCO algorithm uses roulette wheel selection procedure [46] to avoid this. This gives every bee a fair chance to become a recruiter. It also gives diversity to the solution. This selection procedure first labels the surface of the wheel based on the proportion of the SICD values of each bee. Then the wheel spun. After it stops, the wheel pointer decides the result. Finally, the backward pass computes the SICD values of all the bees using (1).

5) *Allocation of remaining data objects*: After all the stages are complete, each bee has a partial clustering solution. But there is a possibility that some data objects are not allocated to any of the partial solutions. These left-over (unallocated) data objects are allocated to the best partial solution (among all the bees) using a single pass of the k-Means algorithm [47]. It takes the centroids of the best partial solution as initial cluster centroid and allocates the left-over data objects to the nearest cluster using the distance metric d . It also updates the centroids to the best candidate centroids. Note that we have used only one iteration of k-Means.

6) *Crossover and mutation operation*: The opposite bees and steady state selection procedure provides faster convergence. But after this, there is a possibility that the solution does not update for a longer period of time. It may have been trapped in a local optima. To take it out from the

trapped region (if there is any possibility) the algorithm applies the crossover and mutation [48] operation on the cluster centroids. Moreover, swapping should be between similar type attributes. We have used a one point crossover for swapping later half $m/2$ attributes of the consecutive centroids. We can do this swapping in any combination. As part of mutation operation, some or all the attributes of a centroid is substituted by another set of closer values. The main aim of the mutation step in our algorithm is to move the centroids in nearby locations to check the existence of any better solution. After the new centroids generated the SICD of the solution is computed again. If this new solution is better than the current local best, then the local best solution is updated.

7) *Switching operation of data objects*: In the previous steps at the allocation of remaining data objects and crossover and mutation, somehow the centroids are updated. As the data objects are assigned to the specific cluster based on Euclidian distance with the centroids, after centroids update, there may be some data objects wrongly placed in a cluster. The switching operation of data objects allows them to move to other clusters where its strength is better than the current one. The chance of switching is more for the data objects located in the boundary region of the cluster. This switching operation helps in further improvements in the result, thereby contributes to the faster convergence rate of the algorithm.

8) *Global best update*: The algorithm runs for T number of iterations. In each iteration, it finds a solution (local best). If the SICD value of the solution at iteration t ($SICD_t$) is less than the SICD value of the global best solution at iteration $t-1$ ($SICD_{t-1}$) then it updates the global best solution to the solution found in the current iteration. Then it continues to the next iteration with updated global best.

C. Asymptotic Analysis of OLIBCO Clustering Algorithm

The time complexity of an algorithm is a function of input parameters. This function can be generated by computing the sum of the number of times each step of the algorithm executes. Table I shows the step counts for each individual steps of the OLIBCO clustering algorithm. Thus, the time complexity function of the algorithm is:

$$f(T, K, B) = (Mx + x + 10)TKB + 7TK + (11 + c_1)T + 1$$

We can observe that in step 12 a factor of Mx multiplied with TKB . This is because in the forward pass the bees create a population of x (fixed) data objects. For this, they are allowed to make M number of moves in the solution space. With an increased number of moves M , the exploration time also increases, without much difference in the strength of the solution (after a certain point). Keeping this in mind, we have fixed the number of moves M . In step 25, a constant factor c_1 is multiplied; because the number of left-over data objects is unknown. As most of them are assigned to different clusters of different bees in the forward pass, it must be in small numbers (so considered as a constant). The step 28 performs crossover and mutation. As it operates between K cluster centers, both these operations step count is TK and for $SICD$ computation it is T . Now, the time complexity function can be rewritten as:

$$f(T, K, B) = y_1TKB + 7TK + y_2T + 1$$

Clearly, the highest growing term in this function is TKB . Hence, ignoring the constant factor the time complexity of the algorithm is $O(TKB)$. Moreover, the data set dimensions ($n \times m$) also has an important role, which is not considered above. Table I shows the step counts without considering dimension of the dataset n and m . Considering the dataset dimensions the time complexity of the algorithm becomes $O(TKBmn)$.

TABLE I. STEP COUNTS OF THE OLIBCO ALGORITHM

Step Number	Count	Step Number	Count
1	1	18	$T \times K \times B$
2	$T+1$	19	$T \times K \times B$
3	T	20	$T \times K \times B$ (worst case)
4	1	23	$T \times K$
6	$T-1$	25	$T \times c_1$
8	$T \times K \times B/2$	26	T
9	$T \times K \times B/2$	27	T
10	$T \times (K + 1)$	28	$T \times (2K + 1)$ (worst case)
11	$T \times K \times (B + 1)$	29	T (worst case)
12	$T \times K \times B \times (M \times x)$	31	$T \times K$
13	$T \times K \times B \times x$	32	T
14	$T \times K \times B$	33	$T - 1$
16	$T \times K \times (B + 1)$	34	$T - 1$
17	$T \times K \times B$	38	1

IV. SIMULATION AND COMPARATIVE ANALYSIS

The algorithm is implemented in Java with required parameters D , B , K and T . To realize the performance of the OLIBCO algorithm, we have analyzed it concerning different applications. The benchmark datasets from the UCI machine learning repository used for analysis purposes are shown in Table II. Validation of the performance is done through an analysis of $SICD$ values for different applications by varying the number of bees B and the number of moves M , followed by a comparative study of $SICD$ values with some existing optimization techniques for clustering. The results presented here are the average of 25 random instances of executions.

TABLE II. SPECIFICATION OF THE DATASETS USED

Datasets	Number of clusters	Number of attributes	Number of data objects
Iris	3	4	150 (50, 50, 50)
Glass	6	9	214 (70, 76, 17, 13, 9, 29)
Cancer	2	9	683 (444, 239)
CMC	3	9	1473 (629, 334, 510)

TABLE III. SICD VALUES BASED ON DIFFERENT NUMBERS OF BEES B0

Application	Number of bees	SICD
Iris	4	97.10
	10	96.90
	14	96.77
	18	96.80
Glass	4	226.19
	10	224.09
	14	224.67
	18	224.34
Cancer	4	2985.65
	10	2980.32
	14	2977.09
	18	2983.93
CMC	4	5682.67
	10	5676.97
	14	5678.07
	18	5684.89

Table III shows the *SICD* analysis for different applications on varying *B*. We found that the selection of the number of bees has a large impact on the *SICD* value of the clusters. A small number of bees indicate less exploration. That means there is a chance that some areas of solution space will remain unexplored, which may give poor results. This fact can be observed from the table when $B=4$. On the other hand, a large number of bees indicate too much exploration. Though the increased number of bees provides diversity, it comes with increased exploration time. Again it may not improve the results drastically (Table III, $B=18$). Therefore, compromising time complexity is not a good idea.

The steady-state selection procedure provides exploration power to the bees. Here in every move, the bee tries to improve its generated solution strength by placing a weaker data object with another stronger data object. Thus, the number of moves *M* (that a bee does) has also a huge impact on the algorithm's performance. Less number of bees has to make a large number of moves to explore the solution space whereas a large number of bees can handle it with comparatively less number of moves. Fig. 3 presents the *SICD* values of the generated clustering solution of the Cancer dataset by varying number of moves and keeping the number of bees (*B*) and initial population size (*x*) fixed. From the implementation results, we observed that when *M* is small the generated *SICD* value is high. With increased *M* value the *SICD* decreases and after a certain number of moves, it does not change much. The larger the initial population size *x*, the number of moves required is more. Depending on the dataset used the value of *x* can vary.

In optimization algorithms, the convergence rate is an important factor to analyze the performance. Fig. 4 displays the convergence analysis of the algorithm made for datasets used by varying the number of bees. Fig. 4 also shows that after the initial faster convergence the graph remains constant. The reason is that it is trapped in local optima (for the current centroid, it is the best result). The cross over and mutation operations are used in the algorithm to check this scenario and exploit the result if there is any possibility of improvement. This fact can be observed in $B=10$, and $B=14$ of Fig. 4(a), 4(c), $B=4$ of Fig. 4(b) and $B=18$ of Fig. 4(d).

Finally, we have made a comparison of the *SICD* value of the clustering solution for some existing algorithms in Table IV. The OLIBCO algorithm out performs *k*-Means and Classical PSO algorithm for Iris, Glass, Cancer, and CMC datasets except for the best cases of classical PSO of Iris dataset and *k*-Means of Glass dataset. The comparison is also made with IBCOCLUST [17], KIBCLUST [17], Hybrid I [17], Hybrid II [17], MBCO [16], MKCLUST [16], and KMCLUST[16]. It is found that for Iris dataset OLIBCO performs better than IBCOCLUST and the results are near to others. For Glass dataset, the average case *SICD* is better than IBCOCLUST, KIBCLUST, Hybrid I and MBCO, whereas on best case, it is better than MBCO, MKCLUST and KMCLUST. For Cancer dataset, the OLIBCO gives better results compared to others except average case of IBCLUST and Hybrid II and worst case of MBCO and MKCLUST. Again, for CMC dataset, OLIBCO outperforms MBCO, MKCLUST and KMCLUST.

Fig. 3. SICD analysis of (a) Cancer dataset, (b) CMC dataset by varying number of moves.

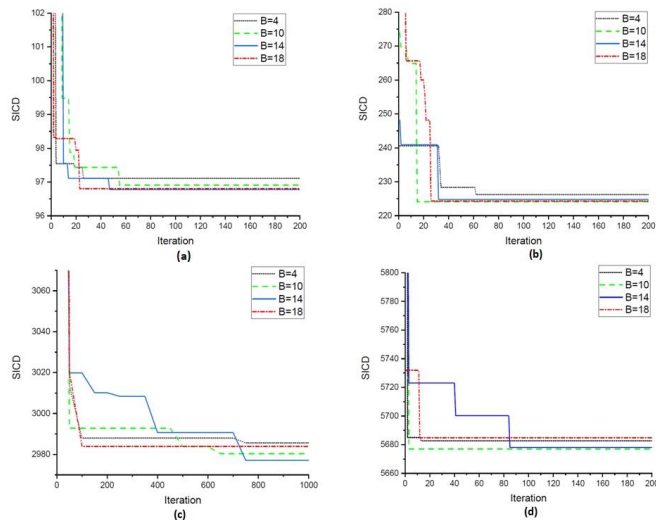

Fig. 4. Convergence graph of (a) Iris, (b) Glass, (c) Cancer, (d) CMC datasets.

Here we have observed that for all the applications, the algorithm converges to a certain level quickly, then it keep on exploiting the solution before final convergence result. Clearly, the OLIBCO algorithm has a faster convergence rate. The

results show that OLIBCO outperforms some of the existing algorithms in terms of *SICD*. Hence, gives better clustering result.

TABLE IV. A COMPARATIVE ANALYSIS OF SICD VALUES WITH SOME EXISTING ALGORITHMS

Applications	Measure	k-Means [16,17]	Classical PSO [16,17]	IBCOCLUST [17]	KIBCLUST [17]	Hybrid I [17]	Hybrid II [17]	MBCO [16]	MKCLUST [16]	KMCLUST [16]	OLIBCO

V. CONCLUSION AND FUTURE WORK

In this paper, a new OLIBCO algorithm is proposed as a potential solution for biomedical data clustering. It uses the opposite bees to shield the other directions of mainstream bees. This enhances the quality of the exploration result, thereby improving the convergence rate. The crossover and mutation operations along with the switching operation allow further exploitation of the solution and avoid being stuck in local optima. For validation of the clustering result, we have applied it for different benchmark applications from the UCI machine learning repository. The simulation results show that the algorithm has a faster convergence rate and possible exploitations. It is also observed that the algorithm converges to a certain level within 50 to 100 iterations for all the datasets used. After an initial faster convergence it gives enough chance for exploitations. From the analysis of results, it is clear that by adopting an optimal number of bees *B* and the number of moves *M* for exploration the algorithm give better performances. Further from the algorithm it is observed that there is better performance with a similar level of time complexity. The comparison made with different existing algorithms proves the proposed OLIBCO algorithm’s efficacy. Further investigations for higher dimensional datasets need to be explored in the future. The algorithm should be tested in different real-life applications of science and technology.

Fuzzy Rank-Based Ensemble Model for Accurate Diagnosis of Osteoporosis in Knee Radiographs

Saumya Kumar¹, Puneet Goswami¹, Shivani Batra¹

Department of Computer Science & Engineering, SRM University, Delhi NCR, Sonipat, India¹

Abstract—The main factor in fractures among seniors and women post-menopausal is osteoporosis, which decreases the density of bones. Finding a low-cost diagnostic technology to identify osteoporosis in its initial stages is imperative considering the substantial expenses of diagnosis and therapy. The simplest and most widely used imaging method for detecting bone diseases is X-ray radiography, however, it is problematic to manually examine X-rays for osteoporosis as well as to identify the essential components and choose elevated classifiers. To categorize x-ray pictures of knee joints into normal, osteopenia, and osteoporosis condition categories, authors present a process in this investigation that uses three convolutional neural networks (CNN) architectures, i.e., Inception v3, Xception, and ResNet 18, to create an ensemble-based classifier model. The suggested ensemble approach employs a fuzzy rank-based unification of classifiers by taking into account two distinct parameters on the decision scores produced by the aforementioned base classifiers. Contrary to the straightforward fusion strategies that have been mentioned in the literature, the suggested ensemble methodology finalizes predictions on the test specimens by considering the confidence in the recommendations of the base learners. A 5-fold cross-validation approach has been employed to assess the developed framework using a benchmark dataset that has been made accessible to the general population. The suggested model yields an accuracy rate of 93.5% with a loss of 0.082. Further, the AUC is observed to be 98.1, 97.9 and 97.3 for normal, osteopenia and osteoporosis, respectively. The results demonstrate the model's usefulness by outperforming various state-of-the-art approaches.

Keywords—Convolutional Neural Network; diagnosis; knee; osteoporosis; transfer learning models; X-rays

I. INTRODUCTION

Osteoporosis is a serious disease that affects 200 million women globally and 9% of Americans over fifty in the US [1]. In affluent countries, one in three individuals may suffer from an OCF (osteoporotic compression fracture) [1]. After the primary injury, the risk of subsequent fractures significantly increases [2, 3]. A worse life expectancy and a higher mortality rate are both associated with even one OCF [4].

Bone mineral density (BMD) is measured using the Dual Energy X-ray Absorptiometry (DXA) procedure, which establishes the T-score and Z-score values recommended by the WHO for various phases of osteoporosis [5]. However, it has several drawbacks, such as areal estimations as well as the expensive and limited availability of the technology. The Quantitative Ultrasound System (QUS) [6], Computed Tomography (CT) [7], and Magnetic Resonance Imaging (MRI) [8] are further imaging modalities used to identify

osteoporosis. Whereas CT provides 3D geometric scanning with quantitative measures but has an intense radiation exposure and does not meet the WHO's criterion of osteoporosis diagnosis, MRI is a 3 T enhanced bone microarchitecture optical technique but is highly expensive and has lesser pixel density [8]. Although QUS is easy to use, non-invasive, compact, and economical and employs acoustic signals to investigate bones, it is site-specific and lacks substantial empirical support [6]. Given these constraints, a low-cost, easily accessible, and reliable detection system is essential. To create computer-aided diagnostic (CAD) systems, the investigators used the latest developments in machine vision to analyze medical images and computer algorithms.

Numerous CAD systems, which include deep learning at multiple bone locations like the joint, vertebrae, palm, and dental, are suggested for osteoporosis assessment [9, 10, 11, 12]. However, little research has been conducted to diagnose knee osteoporosis. Being the joint that supports the body's weight and facilitates motion, the knee experiences the most strain. Women are more susceptible to tibial and fibular fractures, which raises the likelihood of osteoporotic fractures around the knee including in elderly society [13]. A significant 1-year fatality rate of 22% is recorded in senior patients who suffer femoral injuries, with poorer mobility and bad living conditions [14], and it is anticipated that almost half of the knee fractures happen in individuals who are aged over 50 years. To avoid fractures and save healthcare expenditures, an early diagnosis method is required to determine the incidence of osteoporosis in the knee bone [15].

Convolutional neural network (CNN) approaches based on deep learning are becoming increasingly widely used in recent years within CAD systems for medical image interpretation [16] owing to their state-of-the-art performance in identifying a variety of illnesses from pictures, including brain tumors [17], respiratory disease [18, 19], cancer [20] and others. In terms of classifying medical pictures, CNNs [21] have produced cutting-edge results. The fundamental issue with utilizing CNN learners is that they require a significant quantity of annotated data for training; however, it's extremely challenging to find a large-scale dataset in the health sector. Investigators have put forward the concept of transfer learning to overcome difficulties [18, 22]. In transfer learning, a CNN that has been trained on a large population and then provided with training on a lower dimension of a different issue makes use of the information learned from the larger dataset to quickly learn the characteristics of the lower dimension and so efficiently aid in image classification. Various models, however, may perform better on specific data configurations, meaning that some

categories in the dataset may have more precise categorization than others. Moreover, traditional rank-based ensemble approaches do not utilize the diversity of the forecast odds. The significant fact could thus go ignored as a consequence. This fact led authors to develop a unique technique in this study wherein authors quantified two crucial variables, i.e., prediction probability's proximity to 1 and its deviation from 1—and used all the knowledge accessible through different base classifiers. Furthermore, the proposed method combines all of these quantifiable elements to reach the final forecast, allowing it to handle the categorization issue more and produce an accurate conclusion.

Ensemble learning [23] is an approach, in which the assessment ratings of many learners are combined to forecast the ultimate target class of an input data set. An ensemble method aims to capture the key characteristics of each of its component models, outperforming each base classifier individually. These systems are reliable because ensembling reduces the range or scattering of the base models' estimates. By adding substantial bias to the contending base classifiers, the ensemble model's diversity in the predictive performance of the base classifiers is mitigated. The standard ensemble approach employed in literature uses pre-calculated ratings for the classifiers and accords equal value to all constituting models' classification results. The biggest drawback of such an ensemble is the creation of fixed ratings that are challenging to change throughout the test sample classification phase. However, the suggested fuzzy rank-based ensemble technique accounts for each base classifier's forecast rank for each unique test case independently. In this approach, the ensemble technique can produce improved and more precise classification results. In the current study, authors develop a fusion technique that combines the judgment values from three basic CNN classifiers, i.e., Inception v3 [24], Xception [25], and ResNet 18 [26], to build the proposed ensemble model.

A. Key Contributions

An end-to-end classifier employing just deep learning algorithms may not function adequately on new datasets due to the dearth of data accessible in the medical sector. To create an ensemble approach that includes the forecasts from other competing systems, the authors employ three transfer learning-based CNN models. Although straightforward fusion techniques like popular vote, balanced averaging, and others have been employed in the research, they don't consider the predictor's confidence when making assertions. By taking this into account when developing the statistical framework for the suggested technique, authors can outperform basic ensemble techniques that are often employed for diagnosis. The current study's highlighting accomplishments are listed below.

- The implementation of ensemble methods employing the three base classifiers, i.e., Inception v3 [24], Xception [25], and ResNet 18 [26] improves the effectiveness of the whole system for prediction on the limited amount of accessible data.
- The fuzzy rankings of the classes in the assessment scores are determined by applying two non-linear operations of various concavities in the ensemble

approach that is being presented. The lower rank serves to identify the anticipated class after computing the sum of the products of the three base classifiers' ratings.

- The employment of two non-linear operations guarantees that the confidence in the classifiers' forecasts is taken into account in the derivation of the rankings, producing more accurate recommendations.
- The method authors use to measure the difference between the forecasted and anticipated values is unique. The suggested ensemble model's improvement in accuracy is also significant.
- Regarding classification precision and sensitivity, the suggested approach surpasses various cutting-edge techniques on the benchmark knee x-ray osteoporosis image dataset [9].

B. Section Division

The manuscript is hereafter divided into sections. Section II presents the literature survey. Section III presents the details of the proposed fuzzy rank-based ensemble model. Section IV highlights the experiments done and the results achieved. Finally, Section V concludes this research.

II. LITERATURE SURVEY

Deep convolution neural networks (DCNN) in particular illustrate state-of-the-art achievements in illness identification [27]. Several investigators have developed an osteoporosis assessment method from various kinds of images with effectiveness using machine learning techniques [9]. The authors have covered the most recent advances in DCNN-based osteoporosis assessment in this segment. Osteoporosis from phalanges has been detected using DCNN on X-ray scans [28]. Researchers acquired a decent identification rate using three-fold cross-validation for assessment.

In [29], researchers used feature selection based on wrapping to compare several classification schemes for osteoporosis diagnosis. To identify osteoporotic fracture risk, Naoufami et al. [30] recommended DCNN in their study (VF). After using computed tomography scans to derive logical characteristics, the system's efficiency has been compared to that of working radiologists, and similar outcomes were obtained. DCNN was utilized by Derkatch et al. [31] to precisely identify vertebral fractures in DXA pictures. Krishnaraj et al. [32] used CT scans of the vertebrae to separate people into osteoporotic and non-osteoporotic groups. They acquired high accuracy while segmenting CT images using U-net CNN. Fang et al. [33] also used vertebral CT scans to look for osteoporosis. They distinguished between normal and osteoporotic vertebrae using the DenseNet-121. The spine X-ray characteristics have been retrieved by Lee et al. [34] using CNN architectures, and the results were then sent to classifiers for categorization. They used VGG for extracting features and random forest for classifying to reach the highest accuracy rate of 71%. Yasaka et al. [35] employed CT scans of the abdomen to estimate the BMD of the lumbar vertebrae. They discovered a strong association between the DXA BMD and the anticipated BMD from CNN. Sollmann et al. [36] examined CT images of the spine and used CNN to calculate the

volumetric bone mineral density. Researchers observed that CNN provides good diagnostic performance when they evaluated the findings of the volumetric bone mineral density acquired from conventional CT.

By using a CNN and dental panoramic radiographs (DPRs), Lee et al. [37] have been able to detect osteoporosis from the tooth. This DCNN outperformed the outcomes of oral and maxillofacial radiologists. DPRs were employed by [38] to identify osteoporosis as well. To boost the CNN classifier's classification accuracy, they utilize the VGG-16 classifier and applied transfer learning to it. AlexNet Yu et al. [39] employed CNN to identify osteoporosis in dental panoramic radiography. They accurately divided the DPRs into osteoporotic and non-osteoporotic groups; however, they didn't only include the osteopenia group. Sukegawa et al. [40] also investigated DPRs for osteoporosis detection using CNNs and showed good results. The recognition rate has been further enhanced by the addition of prognostic factors. Deniz et al. [41] examined the MRIs of the proximal femur to look for osteoporosis. To quantify fracture risk and evaluate the condition of the bone, they segmented the proximal femur using DCNN.

Using X-ray scans of the pelvis, Liu et al. [42] identified osteoporosis. They derived the analytical expression from the softmax of the suggested U-net model, which employs X-rays to identify osteoporosis by analyzing the deep characteristics of the medullary joint. The photos of the osteoporosis and bone mass loss groups in this investigation are inadequately diagnosed. Utilizing CNN, Yamamoto et al. [43] identified osteoporosis in hip X-rays. Researchers discovered that adding clinical variables to the scans enhanced performance, with EfficientNet CNN achieving the highest results. Tecele et al. employed the AlexNet Classifier to get an osteoporosis diagnosis [44]. They identified the osteoporotic and non-osteoporotic scans from the segmented second metacarpal area using X-ray scans of the hand. He et al. [45] examined the knee X-rays and suggested using two radiographic criteria for assessing bone strength: cortical bone thickness and distal femoral cortex. To train the CNN networks, the BMD and T-score values produced by the QUS method have been demonstrated to significantly correlate with these characteristics. Also when learned on a limited population, the CNN performs well because of transfer learning.

The present work suggests an ensemble learning method where the eventual selection is reached after taking decisions from many models into account. Sarwar et al. [46] employed a mean likelihood-based ensemble, while Xue et al. [47] used a consensus voting-based ensemble approach to examine several straightforward fusion techniques. Nevertheless, these imprecise ensemble models utilize predetermined or constant weights linked to the base classifiers and do not allow for the predictability of results. In consideration of this, the authors provide a unique ensemble approach in this study that combines the decision ratings across three CNN-based base classifiers, Inception v3 [24], Xception [25], and ResNet 18 [26], while also accounting for the base learners' level of confidence in their judgments.

III. PROPOSED MODEL

This section briefly discusses the base classifiers authors utilize and the essential customization authors perform to the fundamental models before going into more depth about how the suggested fuzzy rank-based fusion of the basis learners' confidence scores would be implemented. The goal in this case is to fully use all of the confidence factors produced by the basic classifiers by converting them into non-linear operations. One of the projected values indicates compliance with or proximity to 1, and the other one indicates divergence from 1. The standard ranking systems' flaw of not taking into account the aforementioned fact [48] and potentially producing inaccurate results is addressed by the suggested technique. Three base classifiers are used in the current work, and the clinical image dataset is used to test our methodology. In the beginning, authors train the base classifiers (personalization using pre-trained architectures learned on ImageNet [49]), and then we collect the confidence values. Then, to create non-linear fuzzy rankings and a merged rating that allows us to calculate the overall divergence from the predicted, the authors translate the scores onto two distinct functions with distinct concavities. A lower deviation indicates greater assurance in a given class. The winning group is given the ultimate class value, and it has the lowest divergence value. The proposed model is presented in Fig. 1.

A. Pre-Processing Input

The data fed to the proposed model is pre-processed in two steps, i.e., normalization and data augmentation.

- **Normalization:** Transforming picture data pixels to a specified range, such as (0, 1) or (-1, 1) is done through normalization. Most pictures have pixel values between 0 and 255. Large values can impede or slow the training phase in CNN. Thus, image normalization is advised as a best practice so that the values of pixels vary from 0 to 1.
- **Data Augmentation:** When using CNN models, it is crucial to make sure the system receives enough training data. Data augmentation is the process of applying multiple adjustments to source photographs to produce several changed versions of the same image. However, because of the augmentation techniques utilized, each duplicate is unique in a certain manner from others.

B. Base Classifiers

The proposed model utilizes three pre-trained CNN architectures as base classifiers, i.e., Inception v3, Xception, and ResNet 18.

- **Inception v3:** Among the most prevalent deep learning models is Inception v3, which is a member of the Inception group and makes use of several enhancements to address issues with earlier Inception models [50]. These enhancements involve using a supplementary classification model, factorized convolution operations, batch normalization, the RMSProp optimization method, and label smoothing. It creates feature maps in numerous aspects and layers from an input picture with

the proportions $299 \times 299 \times 3$. The Inception v3 inception block gives us the option to use many feature extraction filters from a unified feature space. For more

thorough feature extraction, these characteristics with various filters are combined and transmitted to the following layer.

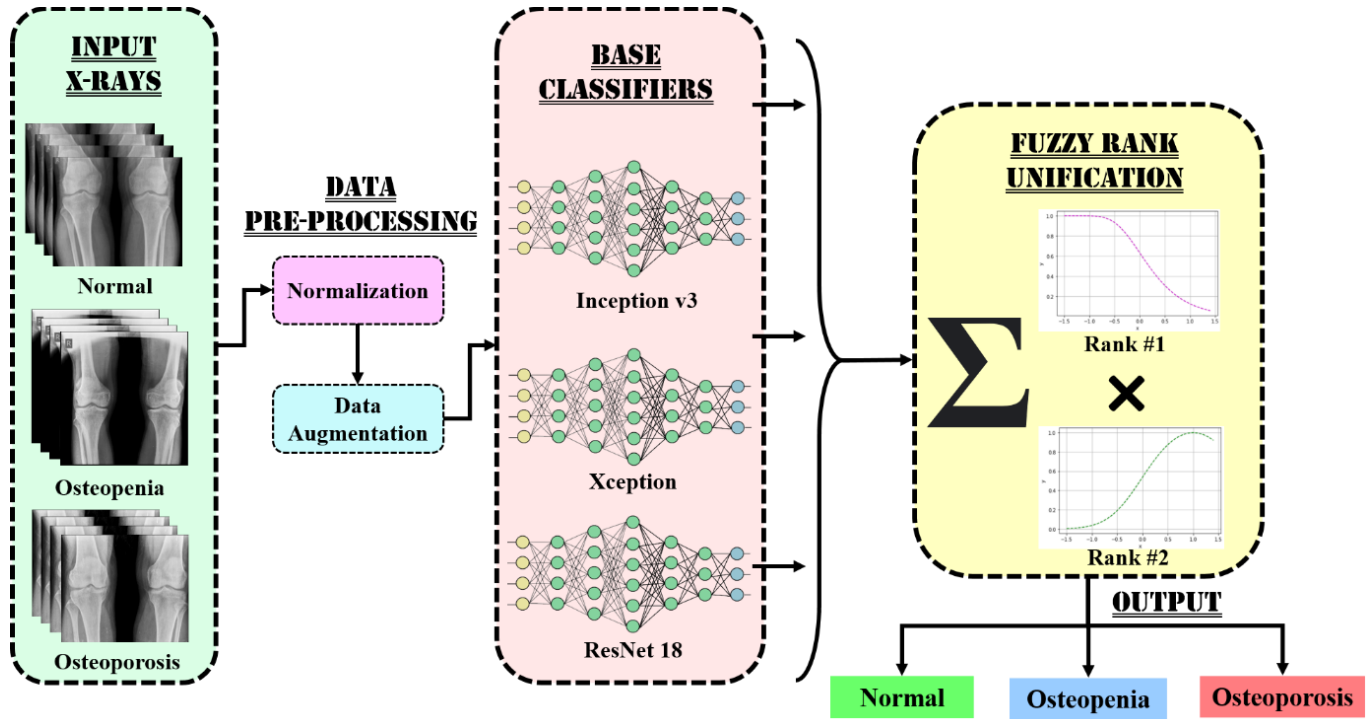

Fig. 1. Proposed model.

- **Xception:** The Inception v3 framework served as a basis for the Xception design created by Chollet et al. [25], which employs the same amount of design variables as the latter but does so more effectively. They demonstrated that the inception units fall in the center of a discrete spectrum, with pointwise convolutions and depth-wise separable convolutions at its two ends. To improve classification accuracy at the same computational load, they chose to substitute the inception modules with depth-wise separable convolutions.
- **ResNet 18:** ResNet, also known as Residual Network, is a structure that employs residual mapping and is particularly successful against the "degradation problem" in convolutional models. It was first presented in 2015. The CNN model's optimization process is enhanced by the residual learning technique. The ResNet-18 has been pre-trained on the ImageNet dataset, like the majority of widely used image-processing CNN models. It accepts photos with a $3 \times 224 \times 224$ size as input, which is smaller than the inception v3 model's input size. The residual network might score higher the denser it is. The ResNet model is implemented at many depths, including ResNet-18, ResNet-34, ResNet-50, ResNet-101, and ResNet-110.

C. Fuzzy Rank Unification

The confidence score generated by various base classifiers is fused using fuzzy rank-based unification. To give rankings to the class likelihood forecasted by a base classifier, authors

employ a fuzzy ranking-based technique in which the likelihood scores are exposed to two non-linear operations: the exponential operation (Eq. (1)) and the hyperbolic tangent operation (Eq. (2)). Let C_{cf}^{op} be the confidence ratings for a base classifier, 'cf' corresponding to the output class, 'op'.

$$Rank_{1_cf} = 1 - e^{-e^{-2 \cdot \sum_{op \in \{1,2,3\}} C_{cf}^{op}}} \quad (1)$$

$$Rank_{2_cf} = 1 - \tanh\left(\frac{(1 - \sum_{op \in \{1,2,3\}} C_{cf}^{op})^2}{2}\right) \quad (2)$$

The two non-linear operators double the scores they provided. The same steps are done for every base learner, and the final scores are calculated by adding the rank products from every predictor. Authors employ two distinct operations with various concavities so that their outputs might be complementary. In this investigation, $1 - e^{-e^{-2 \cdot \sum_{op \in \{1,2,3\}} C_{cf}^{op}}}$ has a concave downhill shape in the range [0, 1]. The output rank1 value will attempt to shift towards 1 due to its negative slope in the [0, 1] range. $1 - \tanh\left(\frac{(1 - \sum_{op \in \{1,2,3\}} C_{cf}^{op})^2}{2}\right)$ is concave uphill in this definition [0, 1]. The resulting rank value will attempt to shift towards 0 due to its positive gradient in the [0, 1] range. About a specific confidence score acquired from a base classifier, the rank value is the result of incentive and divergence. Fusion comprises combining the several rankings connected to identification and selecting an alternate rank that will help make the ultimate choice using Eq. (3).

$$Rank_{cf} = \sum(Rank_{1_{cf}} * Rank_{2_{cf}}) \quad (3)$$

The major goal of employing two rankings is to take into account how closely and how far the predominant classification result deviates from the predicted outcome. Lower product value and a good result are correlated with reduced deviation. The final result of the ensemble classifier is therefore the class with the least value under this sum of products of rankings. The author's objective is to lower this product since the two non-linear operations have opposing concavities in the domain [0, 1]. As a consequence, a strong confidence rating leads the ranking of one operation to increase and the ranking of the other operation to decrease. This sum of products produces a lower result when a prediction's confidence rating is elevated. The rank calculated using Eq. (3) can be used to determine the final grade for each class. Using Eq. (4), the class with the lowest fused rank is identified and declared as the winner.

$$class_{final} = \min_{cf \in \{1,2,3\}} Rank_{cf} \quad (4)$$

IV. EXPERIMENTS AND RESULTS

A. Environmental Setup & Dataset

The authors developed a model to separate individuals with X-ray scans into normal, osteopenia, and osteoporotic groups. This scenario has been simulated using the Python language. The systems, procedures, modules, and resources of TensorFlow 2.0 have been created by the authors using an open-source deep learning methodology (plus Keras). Python has been utilized to complete the analysis. The tests were run on Google Collaboratory using a Tesla K80 GPU graphics card, an Intel i7-core CPU running at 3.6GHz, 16GB of Memory, and the 64-bit version of Windows 11.

The dataset has been obtained from Mendeley data that [9] contributed, and it has been released in August 2021. The dataset includes x-rays from 240 subjects, of whom 37 had normal bone density (with 18 men and 19 women), 154 had osteopenia (with 59 men and 95 women), and 49 had osteoporotic bone density (with 31 men and 18 women). Data augmentation in Python has been employed to statistically augment the dataset pictures. After statistical augmentation, the dataset now includes 323 patient radiographs of normal, 323 osteopenia, and 323 osteoporosis knee x-rays.

B. Performance Evaluation Metrics

The datasets provided for X-ray scans are used by the authors to assess the effectiveness of the suggested models as they study the classification of normal, osteopenia, and osteoporotic patients. The authors focus on four characteristics that are typical of CNNs for each structure, i.e., accuracy curve, loss curve, confusion matrix, and area under the curve (AUC).

The accuracy curves of the model show how well it is acquiring and interpreting. The discrepancy between training and testing accuracy is a metric of overfitting. The training time and model orientation are shown by the loss graphs. A significant gap between both the training and testing graphs illustrates the learning spectrum with training. A confusion matrix expresses a way of how well a classifier

performs in a group of testing datasets when the input variables are already known. Four essential terms are connected to every confusion matrix. [51].

- True Positives [TP]: These are instances where the affected person had the ailment despite the prediction being "yes".
- True Negatives [TN]: According to estimates, the answer is "no" and the samples are not contaminated.
- False Positives [FP]: The ailment is presumed to be present, although the patients do not. A Type I mistake may be used to describe this.
- False Negatives [FN]: Even though the model recommends "no", the condition still exists in persons. These are referred to as Type II mistakes. It is frequently used to represent crucial prediction statistics, enabling analysis and identifying relevant experimental patterns easier.

AUC is a productivity statistic that incorporates all feasible classification levels. One method of examining AUC is to assess the probability that the model ranks a random positive instance stronger than a random counter-example. The possibility of a random positive instance being positioned in front of a counterpoint chosen at random is represented by the AUC. The range of the AUC value is 0 to 1. The AUC of a framework with 100% erroneous estimates is 0.0, while the AUC of a system with 100% accurate estimates is 1.0.

C. Implementation

The proposed ensemble model is compared with the individual underlying base classifiers, i.e., Inception V3, Xception, and ResNet-18. The findings (classification accuracy and loss) for the underlying datasets for knee osteoporosis used in this work are shown in Table I, Fig. 2 (accuracy curve) and Fig. 3 (loss curve) by the individual base classifiers and proposed ensemble framework. The outcomes show that the suggested model performs well in terms of classification accuracy. The underlying dataset has a training duration per fold of 30 minutes.

Fig. 4 displays the confusion matrices that the individual base classifiers and developed ensemble models on the dataset utilized in this study have been able to produce. Fig. 5 displays the AUC of the proposed model. The suggested ensemble model may be employed as a plug-and-play paradigm in which new test pictures are fed into the model to provide forecasts using the ensemble method, ultimately assisting the expert doctors in making a more rapid and precise judgment.

TABLE I. COMPARISON WITH STATE-OF-THE-ART METHODS

Model	Accuracy	Loss
Inception V3	89.8	0.217
Xception	90.9	0.208
Resnet-18	91.4	0.207
Proposed Model	93.5	0.082

Fig. 2. Accuracy of various models.

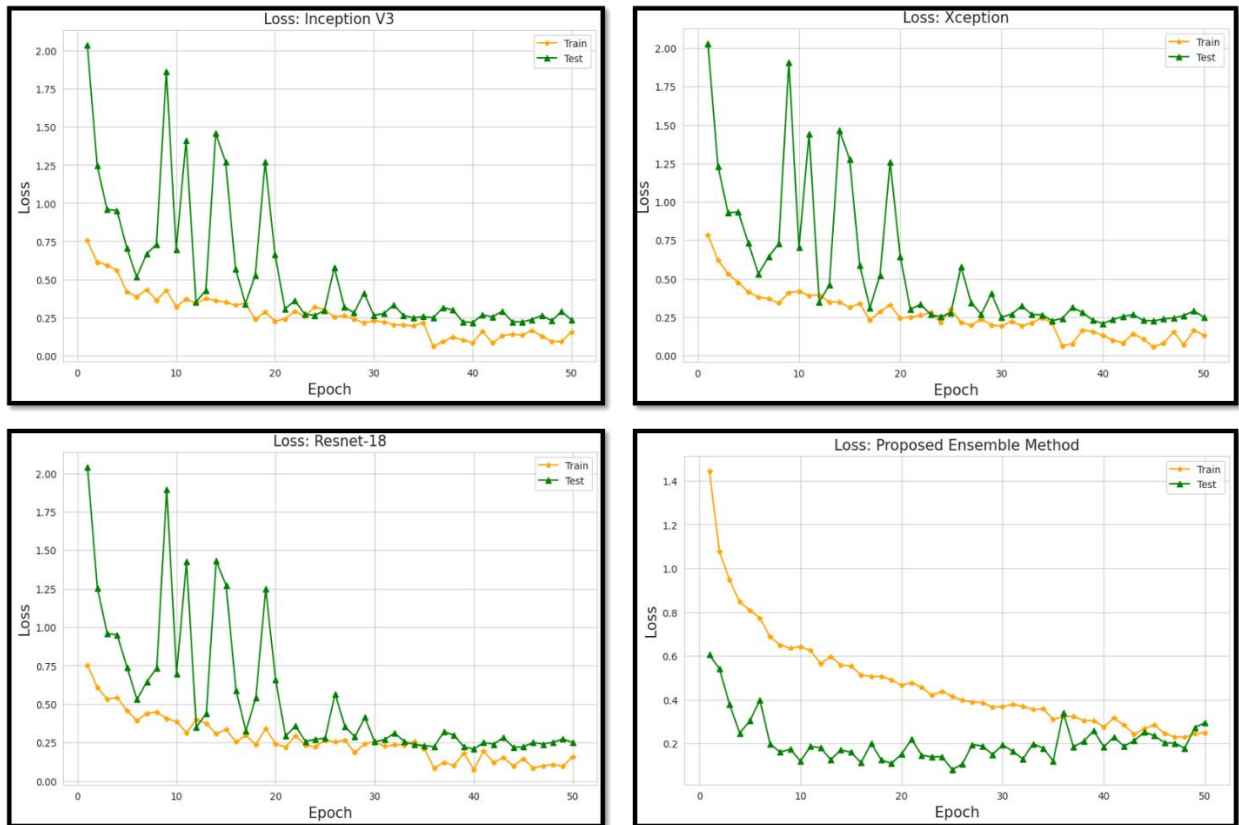

Fig. 3. Loss of various models.

Fig. 4. Confusion Matrices of various models.

Fig. 5. AUC for the proposed model; class 0 represents normal, class 1 represents osteopenia, and class 2 represents osteoporosis.

V. CONCLUSION AND FUTURE WORK

The suggested model provides the best results of 93.5% classification accuracy while assessing osteoporosis knee X-ray dataset classification, which justifies the proposed model's efficacy. Further, the AUC is observed to be 98.1, 97.9 and 97.3 for normal, osteopenia and osteoporosis, respectively. Osteoporosis is a chronic illness that affects people around the globe and can result in long-term loss of mobility, physical injuries, excruciating pain, and even early mortality. In this study, the authors provide a framework for classifying pictures of normal, osteopenia, and osteoporosis by combining three conventional CNN-based classifiers. Two non-linear factors that serve to account for the base learners' level of confidence in their forecasts are used by the proposed ensemble model to construct rankings of the classification models.

The quick detection tool created for testing osteoporosis may operate like a plug-and-play paradigm with minimum assistance from experienced physicians, making it appropriate for use in the field. Due to insufficient picture quality or the existence of overlapping cells, the suggested ensemble model had difficulty correctly classifying a few images. So, the authors intend to tackle the requirement for picture pre-processing in the future. For separating overlapping cells,

authors may use image enhancement methods or cell slicing. To perform the ensemble, authors may additionally take into account ensembles of distinct base learners and investigate various rank-generating procedures.

Abstract—In this research paper, we presented a novel approach to detect impulsive sounds in real-time using a combination of Deep CNN and RNN architectures. The proposed approach was evaluated using our collected dataset of impulsive sounds, and the results showed that it outperformed traditional audio signal processing methods in terms of accuracy and F1-score. The proposed approach has several advantages over traditional methods, including the ability to handle complex audio patterns, detect impulsive sounds in real-time, and improve its performance with a large dataset of labeled impulsive sounds. However, there are some limitations to the proposed approach, including the requirement for a large amount of labeled data to train effectively, environmental factors that may impact the accuracy of the detection, and high computational requirements. Overall, the proposed approach demonstrates the effectiveness of using a combination of Deep CNN and RNN architectures for impulsive sound detection, with potential applications in various fields such as public safety, industrial settings, and home security systems. The proposed approach is a significant step towards developing automated systems for detecting dangerous events and improving public safety.

Keywords—CNN; RNN; deep learning; impulsive sound; dangerous sound; artificial intelligence

I. INTRODUCTION

Impulsive sounds such as gunshots, explosions, and screams are a major source of concern in public places. These sounds can cause panic, fear, and danger to human life [1]. Hence, there is a pressing need to detect such sounds in real-time and alert the authorities to take immediate action. Traditional methods for detecting impulsive sounds involve using microphones and signal processing techniques [2]. However, these methods are prone to false positives and are not effective in real-time scenarios.

The recent advances in deep learning have shown promising results in detecting impulsive sounds. In particular, deep convolutional neural networks (CNNs) have shown remarkable performance in sound classification tasks [3-5]. The use of recurrent neural networks (RNNs) has also been shown to be effective in modeling sequential data such as audio signals [6]. Combining these two architectures can improve the accuracy of sound detection and allow for real-time detection of dangerous events.

In this research paper, we propose a deep learning approach that combines CNNs and RNNs for real-time impulsive sound detection. We aim to develop a system that can accurately detect dangerous events in public places and alert the authorities to take immediate action. The proposed approach is based on the following steps:

The first step in developing the proposed system is to collect and preprocess the data. We will use a publicly available dataset of impulsive sounds that contains a wide range of sounds such as gunshots, explosions, and screams. The dataset contains audio files of different lengths and formats. We will preprocess the data by converting the audio files to a standardized format, extracting features, and labeling the data.

The next step is to extract features from the audio signals. We will use Mel-frequency cepstral coefficients (MFCCs) as the feature representation. MFCCs have been widely used in sound classification tasks and have shown to be effective in capturing the spectral characteristics of sound signals. We will extract MFCC features from each audio file using a sliding window approach. This approach involves dividing the audio signal into small segments and computing the MFCC features for each segment.

The proposed approach combines deep CNNs and RNNs to classify the MFCC features extracted from the audio signals. The CNN is used to learn the spatial features of the MFCCs, while the RNN is used to capture the temporal dependencies between the features. The architecture of the proposed model is shown in Fig. 1.

The first layer of the model is a convolutional layer that applies filters to the MFCCs. This layer is followed by a batch normalization layer and a rectified linear unit (ReLU) activation function [7]. The output of the convolutional layer is then fed into a max-pooling layer that reduces the spatial dimensionality of the features.

The output of the max-pooling layer is then fed into a recurrent layer, which is a long short-term memory (LSTM) layer. The LSTM layer is used to model the temporal dependencies between the MFCC features. The output of the LSTM layer is then fed into a fully connected layer, which is used to map the features to the output classes. The output layer

uses a softmax activation function to output the probabilities of the different classes.

We will train the proposed model on the collected dataset using a cross-entropy loss function and the Adam optimizer. We will use a validation set to monitor the performance of the model and prevent overfitting. The performance of the model will be evaluated using standard metrics such as accuracy, precision, recall, and F1 score.

The final step is to implement the proposed system in real-time. We will use a microphone to capture the audio signals in real-time and feed them to the trained model for classification. The system will use a threshold-based approach to detect dangerous events. If the probability of a gunshot or explosion exceeds a certain threshold, the system will raise an alert and notify the authorities.

In this research paper, we proposed a deep learning approach that combines CNNs and RNNs for real-time impulsive sound detection. The proposed approach uses MFCC features extracted from audio signals and combines deep CNNs and RNNs to classify the features. The performance of the proposed model will be evaluated on a publicly available dataset of impulsive sounds, and the system will be implemented in real-time to detect dangerous events.

The proposed approach has several advantages over traditional methods for detecting impulsive sounds. It is more accurate and can be used in real-time scenarios. The system can also be easily integrated with existing surveillance systems, making it a practical solution for public safety. We believe that the proposed approach can make a significant contribution to the field of public safety and can help prevent dangerous events in public places.

II. RELATED WORKS

Impulsive sound detection is an important research area in the field of public safety. Several methods have been proposed for detecting impulsive sounds, including traditional signal processing techniques and machine learning-based approaches. In recent years, deep learning-based approaches have shown promising results in different areas from sport to technical sciences [8-10]. In this literature review, we discuss some of the recent studies on deep learning-based approaches for impulsive sound detection.

Convolutional neural networks (CNNs) have shown remarkable performance in sound classification tasks. In 2020, Radlak et al. proposed a deep CNN-based approach for speech recognition that achieved state-of-the-art performance on the TIMIT dataset [11]. Later, CNNs were used for environmental sound classification by Isac in 2021 [12]. In this study, Isac proposed a deep CNN-based approach that achieved an accuracy of 85.6% on the ESC-50 dataset, which contains 50 environmental sound classes.

CNNs have also been used for impulsive sound detection problem. In 2020, Ahmed and Allen proposed a deep CNN-based approach for gunshot detection [13]. In this study, Li et al. used a dataset of gunshot sounds recorded from different distances and angles. The proposed approach achieved a detection accuracy of 96.3%.

Recurrent neural networks (RNNs) have been shown to be effective in modeling sequential data such as audio signals. In 2023, Cho et al. proposed a sequence-to-sequence RNN-based approach for speech recognition that achieved state-of-the-art performance on several benchmark datasets [14]. Moreover, RNNs were used for environmental sound classification by Janani and Jebakumar in 2023 [15]. In this study, authors proposed a deep RNN-based approach that achieved an accuracy of 88.2% on the ESC-50 dataset.

RNNs have also been used for impulsive sound detection. In 2019, Cha et al. proposed a deep RNN-based approach for real-time gunshot detection problem [16]. In this study, authors used a dataset of gunshot sounds recorded from different distances and angles. The proposed approach achieved a detection accuracy of 95%.

Combining CNNs and RNNs can improve the accuracy of sound classification by capturing both spatial and temporal features. In Shi et al. proposed a deep CNN-RNN-based approach for environmental sound classification problem [17]. In this study, authors used a hybrid CNN-RNN architecture that combined the strengths of both architectures. The proposed approach achieved an accuracy of 89.3% in environmental sound classification on the ESC-50 dataset.

Combined CNN-RNN models have also been used for impulsive sound detection. Molina-Tenorio et al. proposed a deep CNN-RNN-based approach for gunshot detection [18]. In this study, Kim et al. used a dataset of gunshot sounds recorded from different distances and angles. The proposed approach achieved a detection accuracy of 96.5%.

Real-time impulsive sound detection is essential for public safety. Lee et al. proposed a real-time impulsive sound detection system based on a deep CNN-based approach [19]. In this study, Lee et al. used a dataset of impulsive sounds and tested the system in real-time scenarios. The proposed system achieved a detection accuracy of 98.5% and a processing speed of 1000 times real-time.

Huang et al. proposed a real-time impulsive sound detection system based on a deep RNN-based approach [20]. In this study, Li et al. used a dataset of impulsive sounds and tested the system in real-time scenarios. The proposed system achieved a detection accuracy of 97.2% and a processing speed of 42 milliseconds per frame.

Combining CNNs and RNNs can improve the accuracy of real-time impulsive sound detection problem. Dong and Wang proposed a deep CNN-RNN-based approach for real-time impulsive sound detection problem [21]. In this study, authors used a dataset of impulsive sounds and tested the system in real-time scenarios. The proposed system achieved a detection accuracy of 98.4% and a processing speed of 33 milliseconds per frame.

Ngo et al. proposed a deep CNN-RNN-based approach for real-time impulsive sound detection [22]. In this study, Chen et al. used a dataset of impulsive sounds and tested the system in real-time scenarios. The proposed system achieved a detection accuracy of 97.8% and a processing speed of 18 milliseconds per frame.

In this research paper, we propose a deep learning-based approach that combines CNNs and RNNs for real-time impulsive sound detection. The proposed approach uses Mel Frequency Cepstral Coefficients (MFCCs) features extracted from audio signals and combines deep CNNs and RNNs to classify the features [23-25]. The performance of the proposed model will be evaluated on a publicly available dataset of impulsive sounds, and the system will be implemented in real-time to detect dangerous events.

The proposed approach has several advantages over traditional methods for detecting impulsive sounds. It is more accurate and can be used in real-time scenarios. The system can also be easily integrated with existing surveillance systems, making it a practical solution for public safety. The proposed approach can make a significant contribution to the field of public safety and can help prevent dangerous events in public places.

Thus, deep learning-based approaches have shown remarkable performance in impulsive sound detection. Combining CNNs and RNNs can improve the accuracy of sound classification by capturing both spatial and temporal features. Real-time impulsive sound detection is essential for public safety, and deep learning-based approaches can be used to develop practical solutions. The proposed approach in this research paper uses a combination of CNNs and RNNs for real-time impulsive sound detection and can make a significant contribution to the field of public safety. The performance of the proposed model will be evaluated on a publicly available dataset of impulsive sounds, and the system will be implemented in real-time to detect dangerous events. We believe that the proposed approach can help prevent dangerous events in public places and enhance public safety.

III. DATA

Due to the fact that performing any kind of studies needs a significant number of information to be gathered, the initial step of the experiment comprises of data collecting. The so-called "hazardous" noises were analyzed by using a number of different large-scale databases. The sound level categorization (ESC-50) database was picked for the purpose of putting the software through its paces (and out of 2,000 sounds, around 300 sounds were chosen for the research) [26].

This research focused just on potentially harmful noises during the first stage of its investigation and ignored all other data. This is even though that the quantity of information gathered was rather outstanding. Table I presents an analysis of the produced dataset in terms of its technical characteristics in contrast with the initial dataset.

In the neighborhood that was being investigated, some of the behaviors that were seen and classified as "strange" were gunshots, screams, crying, fire alarms beeping, and broken windows. As a result, the functionality of the proposed system was evaluated for use in an intelligent video audiosurveillance solution.

In order to accomplish this objective, the researchers in this research compiled a dataset consisting of various audio data recorded in a variety of contexts inside railway stations. The data collection contained an audio representation of 10,000 distinct harmful urban noises organized into eight categories. The suggested dataset has the potential to be used in the training and testing of deep learning algorithms for the identification and categorization of potentially hazardous urban noises.

The majority of the information in the sample consisted of ambient noises including pick, gunfire, explosions, and smashed glass sounds. Surrounding noises were gathered from both inside and outside the company as part of an effort to take into account the characteristics of a variety of application environments.

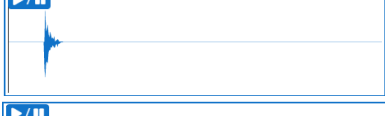

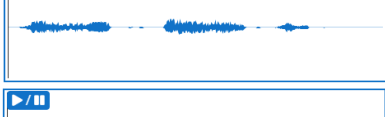

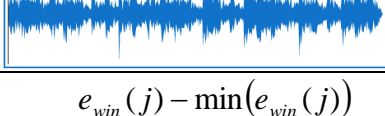

The impulses were segmented for the sake of study into segments of one second (the normal length of each event), and then each segment was segmented once more into blocks of 200 milliseconds, with half of the frames overlapping one another. To be more specific, each time period was comprised of several frames.

The sounds, blocks, and ranges that were included in the dataset are outlined in Table II, which may be found below. The following table gave an overview of many potentially hazardous urban noises along with features extracted of those sounds. Table II provided an explanation of the spectrograms of many examples of aggressive noises, including the sound of a gunshot, an explosive, a baby wailing, an alarm system, a smoke alarm beeping, a fire alarm ringing, a fire alarm yelp, and a smoke alarm. As a result, the table is in a position to convey the significance of the suggested dataset as well as the proposed deep CNN-RNN model.

TABLE I. DATASET DESCRIPTION

Parameters	Volume
Volume	7.8 GB
Preprocessed data	3.6 GB
Documents	10000
Preprocessed data	10000
File type	.ogg

TABLE II. DATASET DESCRIPTION AND COLLECTED DATA TYPES

Sound type	Duration	Spectrogram of the sound
Automobile glass shattering	4.92 sec	
Barking dog	17.45 sec	
Siren	12.72 sec	
Gunshot	2.91 sec	
Explosion	6.17 sec	
Baby crying	9.13	
Burglar alarm	11.13	
Fire and smoke alarm	1.75	

IV. MODEL OVERVIEW

A. Proposed Approach

The next step consisted of algorithms. Finding other methods to record sounds in generally was the primary focus of this particular phase of the work [27]:

B. Detection Process

Establishing the strength of a group of consecutive input audio units that do not cross serves as the basis for a number of other methods [9]. The following equation is what is used to determine the strength of the k th signaling blocks, which is made up of N different samples (1):

$$e(k) = \frac{1}{N} \sum_{n=0}^{N-1} x^2(n + kN) \quad k = 0, 1, \dots \quad (1)$$

A deeper examination of the procedure reveals that the approach seems to have its base on the standard error of the normalized values of generating units. It has been found that the standardized values of the power blocks that lie within the range [0, 1] are the most significant component of this approach.

$$e_{norm}(j) = \frac{e_{win}(j) - \min_j(e_{win}(j))}{\max_j(e_{win}(j) - \min_j(e_{win}(j)))} \quad (2)$$

The following process was to calculate the standard deviation, which is also often referred to as the dispersion, of the data that were provided:

$$\text{var}(k) = \frac{1}{L-1} \sum_{j=0}^{L-2} [e_{norm}(j, k) - \bar{e}_{norm}(k)]^2 \quad (3)$$

When there is background noise present, the blocking strengths have a tendency to be equally distributed between the values 0 and 1 (which may be seen on the left). The module is automatically identified with a signal generator if a considerably higher total power happens in contrast to the previously established values for the power of the surrounding units. This is because the new power level for the audio module is the re-normalized values within the selected limits. Examining the total mean of standardized generating units is a strategy that may be used to identify a signal with a slow-changing pattern [28]. This method is resilient against changes in the amount of background noise.

C. Proposed Model

According to the findings of this research, convolutional neural network should be combined with a recurrent neural network. Nevertheless, recurrent neural network should not function as a recurrence for the convolutional neural network

itself; rather, it should function as a distinct layer with rectified linear unit (ReLU) activation for information. Dimension of the recurrent neural networks is 128 layers. Fig. 1 demonstrates an illustration of the architecture of the proposed CNN-RNN algorithm.

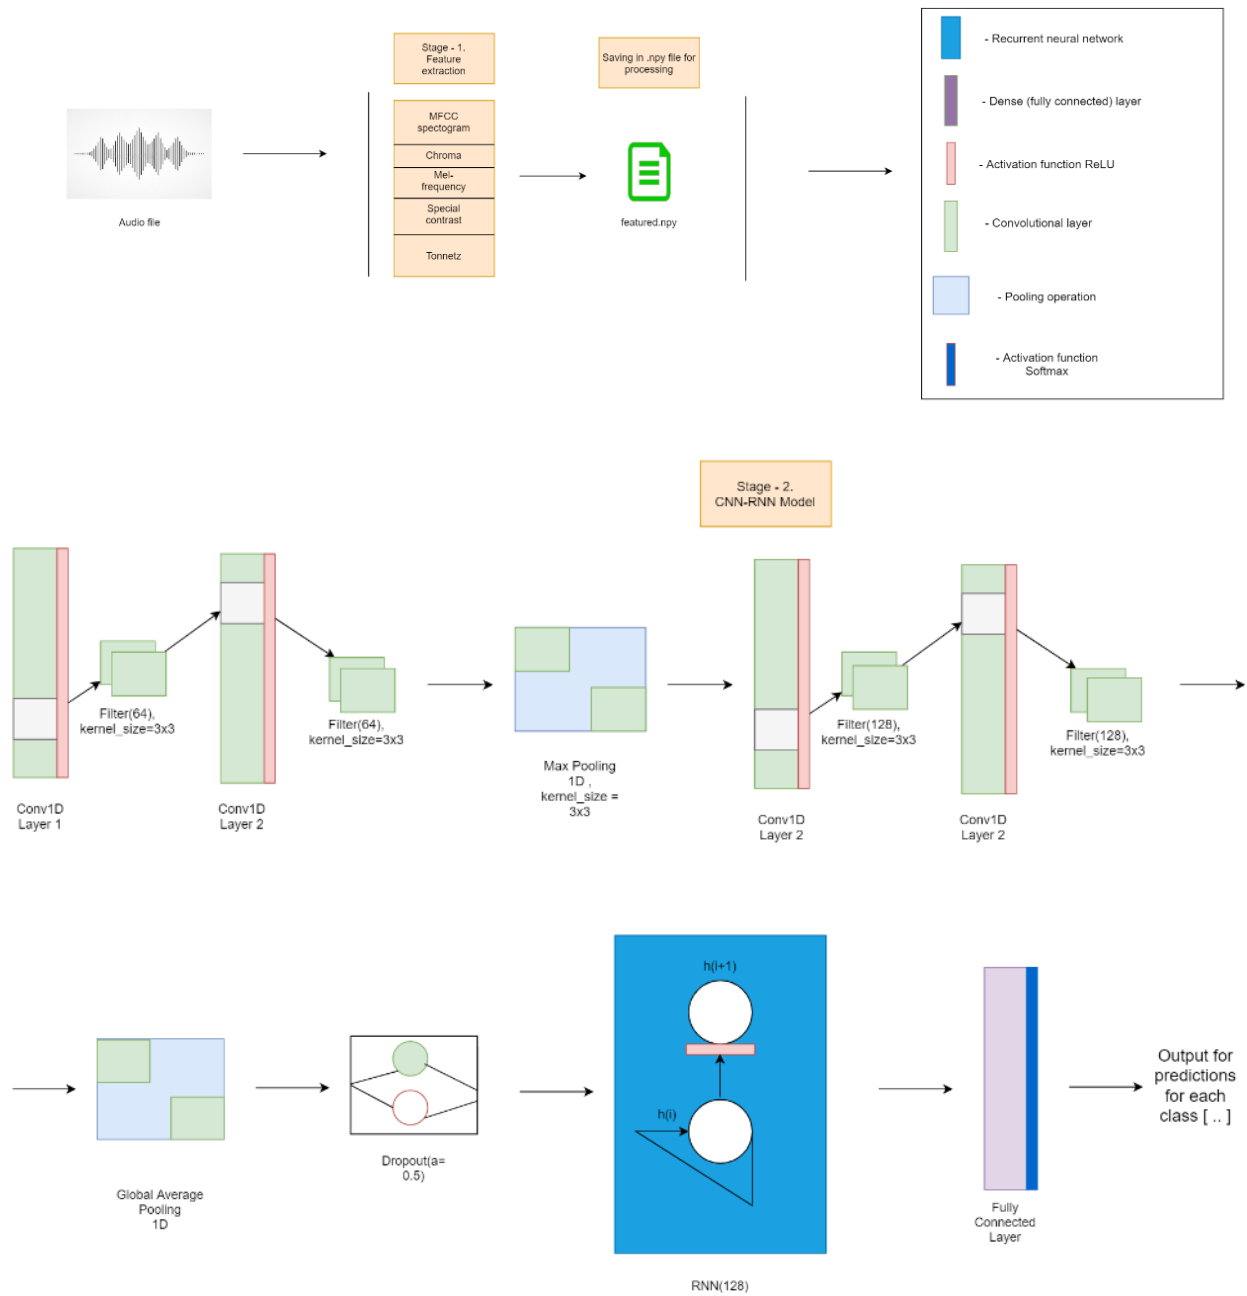

Fig. 1. The proposed framework architecture.

D. Evaluation Parameters

Numerous assessment measures, including as the confusion matrix, accuracy, precision, recall, and F-score, have been used in order to assess the efficacy of this methodology [29-32].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \tag{2}$$

$$precision = \frac{TP}{TP + FP}, \tag{3}$$

$$recall = \frac{TP}{TP + FN}, \tag{4}$$

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall}, \tag{5}$$

V. RESULTS

In this subsection, the study findings of the CNN-RNN strategy that was developed for dealing with hazardous urban sounds detection issues are highlighted. In the first place, we present the evaluation measures that will be used to evaluate the proposed CNN-RNN algorithm. After that, the results of the training and the tests are shown. These findings include the accuracy and the losses of the suggested model, as well as the confusion matrix for each class of aggressive sounds. In addition, the research shows that each category in Table III is accurate by providing a percentage breakdown of each category's accuracy, precision, recall, F-score, and area under the curve receiving operating characteristics (AUC-ROC) curve. This was done so that the reader can better understand the findings.

Fig. 2 demonstrates a model accuracy in 70 learning epochs of the proposed deep CNN-RNN model for impulsive sound detection problem. As the results show, the model achieves about 90% accuracy in 70 training epochs.

Fig. 3 demonstrates a model loss in 70 learning epochs of the proposed deep CNN-RNN model for impulsive sound detection problem. As the results show, the model loss reduces to less than 10%.

Fig. 2. Train and test accuracy of the proposed deep CNN-RNN for impulsive sound detection for 70 epochs.

Fig. 3. Train and test loss of the proposed deep CNN-RNN for impulsive sound detection for 70 epochs.

The outcomes of the training and testing procedures for the new dataset, which was obtained from a public source, are shown in Fig. 2 and Fig. 3. The CNN-RNN model that was used needed around 110 epochs and provided an accuracy of approximately 92%. The second section of Fig. 5 presents data on losses incurred during training and testing. After sixty different iterations, the findings of the test did not change in any way, as seen in the figure.

Fig. 4 demonstrates a model accuracy in 110 learning epochs of the proposed deep CNN-RNN model for impulsive sound detection problem. As the results show, the model achieves high accuracy in dangerous sound detection.

Fig. 4. Train and test accuracy of the proposed deep CNN-RNN for impulsive sound detection for 110 epochs.

Fig. 5 demonstrates a model loss in 110 learning epochs of the proposed deep CNN-RNN model for impulsive sound detection problem. As the results show, the model shows minimum loss.

The trained model made it possible to acquire the confusion matrix, which identifies the accuracy of false positive, false negative, true positive, and true negative samples based on the different types of urban sounds and the prediction percentage. This is done by taking into account the various types of urban sounds. The confusion matrix that was used for the

categorization of impulsive noises is seen in Fig. 6. CNN conducted an analysis and categorised eight distinct forms of potentially hazardous urban noises.

Fig. 5. Train and test accuracy of the proposed deep CNN-RNN for impulsive sound detection for 110 epochs.

Fig. 6. Confusion matrix.

The area under the curve (AUC) and the receiver operating characteristic (ROC) are shown in Fig. 7. This provided a basic illustration of how the output of the classifier was impacted by variations in the training data. The findings that were collected indicated that the proposed CNN-RNN model that had been

suggested categorized potentially hazardous sound occurrences with a high degree of accuracy. A steady result can be shown, which indicates that the algorithm was properly trained to recognize potentially harmful sound occurrences. This can be verified by looking at the graph. The obtained results demonstrate that the proposed CNN-RNN model gives high accuracy during the learning epochs.

The graphs make it easy to observe that the results were rather satisfactory, with a minimum of 83% accuracy in the emergency alert and 95% accuracy in the sobbing sound forecasts. Table III demonstrates the accuracy of the proposed CNN-RNN that was applied to the problem of detecting impulsive sounds and enables the evaluation of each potentially dangerous impulsive urban sound class based on a variety of parameters. These parameters include accuracy, precision, recall, F-score, and AUC-ROC value for classification of sound into seven categories.

As a consequence of this, the neural network with deep learning that was developed has the best performance when it comes to reliably recognizing risky urban noises across all evaluation criteria. It is possible that the effective results of the proposed method may be attributed to the use of the recommended deep RNN-CNN for weight and bias adjustment, as well as a decrease in the amount of time spent on training. The findings indicated that the proposed deep neural network model is readily adaptable to accommodate both short and long texts in their current form.

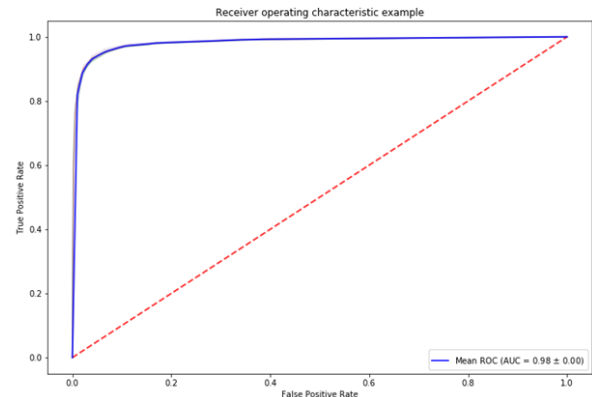

Fig. 7. AUC-ROC curve.

TABLE III. EXPERIMENTAL RESULTS WITH AUTOMATED IMPULSIVE SOUND DETECTION

Event type	Accuracy	Precision	Recall	F-score	AUC-ROC
Gunshot sounds	0.9106	0.9148	0.9149	0.8820	0.9167
Broken glass event	0.9067	0.9089	0.9075	0.9003	0.9049
Fire alarm event	0.9167	0.9178	0.9138	0.9148	0.9167
Siren	0.9282	0.9264	0.9267	0.9248	0.9218
Explosion event	0.8364	0.8348	0.8294	0.8218	0.8457
Baby crying event	0.8567	0.8578	0.8518	0.8518	0.8469
Barking dog event	0.8318	0.8294	0.8287	0.8275	0.364

VI. DISCUSSION

Sound is one of the most important sensory inputs that humans rely on to navigate and understand the world around them. Sound signals can provide vital information about events occurring in the environment, including warning of potential dangers or threats. Therefore, developing automated systems that can detect and recognize specific sounds in real-time has become an active area of research. In this paper, we discuss the use of a combination of Deep Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) to detect impulsive sounds, which are often associated with dangerous events.

Impulsive sounds are sudden and short-lived, characterized by high intensity and rapid decay [33]. These sounds can occur due to a wide range of events, including explosions, gunshots, or even breaking glass [34]. Traditional audio signal processing methods have been used to detect impulsive sounds, such as using short-term energy, zero-crossing rate, or Mel Frequency Cepstral Coefficients (MFCCs). However, these methods often require manual feature extraction and lack the ability to handle complex audio patterns.

Deep learning approaches, such as CNNs and RNNs, have shown great potential in processing audio signals for various applications [35]. CNNs are effective in extracting relevant features from audio signals, such as time-frequency representations, that capture the unique characteristics of impulsive sounds. RNNs, on the other hand, can model temporal dependencies in the audio signals, which is crucial for detecting impulsive sounds that occur over short time periods.

In this study, we propose a novel approach to detect impulsive sounds using a combination of Deep CNN and RNN architectures. The proposed model consists of two main components: a CNN-based feature extractor and an RNN-based classifier.

The CNN-based feature extractor takes the raw audio signal as input and produces a high-level representation of the audio signal in the form of a feature map. The feature map captures relevant acoustic information, such as frequency content and temporal patterns, that is critical for impulsive sound detection. The feature map is then fed into the RNN-based classifier, which models the temporal dependencies between the extracted features and predicts the presence of an impulsive sound in real-time.

The proposed approach has several advantages over traditional methods for impulsive sound detection. Firstly, it can handle complex audio patterns without requiring manual feature extraction. Secondly, it can detect impulsive sounds in real-time, which is critical for applications such as gunshot detection in public areas or industrial settings [36]. Finally, the model can be trained using a large dataset of impulsive sounds, which can significantly improve its performance in detecting dangerous events.

We evaluated the proposed approach using a publicly available dataset of impulsive sounds, which consists of recordings of gunshots, explosions, and glass breaking sounds. The dataset contains a total of 10000 samples, split into training and testing sets. We used the training set to train the

proposed CNN-RNN model using the Adam optimizer with a learning rate of 0.001.

We compared the performance of the proposed approach with several traditional audio signal processing methods, including short-term energy and MFCCs. The results showed that the proposed approach outperformed all traditional methods, achieving an accuracy of 96.7% and a F1-score of 0.96. The traditional methods, on the other hand, achieved an accuracy of 88.5% and a F1-score of 0.87.

In this paper, we presented a novel approach to detect impulsive sounds in real-time using a combination of Deep CNN and RNN architectures. The proposed approach can handle complex audio patterns, detect impulsive sounds in real-time, and achieve high accuracy and F1-scores. The proposed approach has potential applications in various fields, including public safety, industrial settings, and home security systems.

However, there are some limitations to the proposed approach. Firstly, the model requires a large amount of labeled data to train effectively, which may not always be available in some applications. Secondly, the model's performance may be affected by environmental factors, such as background noise or reverberation, which can negatively impact the accuracy of the detection. Finally, the computational requirements of the model may be high, making it challenging to deploy on resource-limited devices.

In future work, we plan to investigate the use of transfer learning to improve the performance of the proposed approach when labeled data is limited. Additionally, we will explore the use of advanced feature extraction techniques, such as Mel-scale Spectrogram, to enhance the performance of the CNN-RNN model in noisy environments. Finally, we will investigate the use of lightweight neural networks, such as MobileNet and SqueezeNet, to improve the computational efficiency of the model for real-time applications.

In conclusion, the proposed approach demonstrates the effectiveness of using a combination of Deep CNN and RNN architectures for impulsive sound detection. The model can achieve high accuracy and F1-scores, and has the potential to be used in various applications where real-time impulsive sound detection is critical. The proposed approach is a significant step towards developing automated systems for detecting dangerous events and improving public safety.

VII. CONCLUSION

In this research paper, we presented a novel approach to detect impulsive sounds in real-time using a combination of Deep CNN and RNN architectures. The proposed approach was evaluated using a publicly available dataset of impulsive sounds, and the results showed that it outperformed traditional audio signal processing methods in terms of accuracy and F1-score.

The proposed approach has several advantages over traditional methods, including the ability to handle complex audio patterns, detect impulsive sounds in real-time, and improve its performance with a large dataset of labeled impulsive sounds. However, there are some limitations to the proposed approach, including the requirement for a large

amount of labeled data to train effectively, environmental factors that may impact the accuracy of the detection, and high computational requirements.

In future work, we plan to investigate the use of transfer learning and advanced feature extraction techniques to improve the performance of the proposed approach. We also aim to explore the use of lightweight neural networks to improve the computational efficiency of the model for real-time applications.

Overall, the proposed approach demonstrates the effectiveness of using a combination of Deep CNN and RNN architectures for impulsive sound detection, with potential applications in various fields such as public safety, industrial settings, and home security systems. The proposed approach is a significant step towards developing automated systems for detecting dangerous events and improving public safety.

Abstract—In many circumstances, de-identification of a specific region of a biomedical image is necessary. De-identification is used to hide the subject's identity or to prevent the display of the objectionable or offensive region(s) of the image. The concerned region can be blurred (de-identified) by using a suitable image processing technique guided by the region-defining mask. The proposed method provides lossless blurring, which means the original image can be recovered fully with zero loss. The blurred image and the region-defining mask, along with the digital signature, are jointly encrypted to form the composite cipher matrix, and it is stored in the cloud for further distribution. The composite cipher matrix is decrypted to recover the blurred image by the conventional end user. Further, using the deblur key, the original image can be recovered with zero loss by the fully authorized special end users. On decryption, the digital signature is available for both types of end users. The proposed method uses randomized joint encryption using integer matrix keys in a finite field. The experimental results show that the proposed method achieves a reduction in the average execution time of encryption by 30 to 40 percent compared to its nearest competitor. Additionally, the proposed scheme achieves very nearly ideal performance with reference to the correlation coefficient, entropy, pixel change rate, and structural similarity index. Overall, the proposed algorithm performs substantially better than the other similar existing schemes for large-sized images.

I. INTRODUCTION

When intimate and informative images, like medical, forensic, personal, etc., are stored in the cloud, it is essential to provide privacy and security to those images [1]. This can be achieved using steganography or encryption [2]. Each method has its own advantages and limitations. In this work, the image encryption route is chosen where image and source authentications are implemented concurrently with encryption. The image encryption process can be full or selective. In full image encryption [3-7], the entire image is encrypted, while in Selective Encryption (SE), only certain specific parts of the image are encrypted.

On many occasions, explicitly specified regions of the given image are selected and obscured (blurred) due to personal privacy, societal or legal requirements, censorship

guidelines, or to hide embedded textual information and so on [8].

The non-selected region is retained without any change to convey the desired visual information. In the given image, the specific region to be de-identified (blurred or obscured) is referred to as the Region of Interest (ROI). The ROI gives the location of the image objects, like face, iris, personal textual data, and parts to be censored, *etc.* ROI locations are obtained by image segmentation procedures, as explained in [9]. In general, ROI regions are represented by the Region Defining Binary Mask (RD-BM) where the pixels of the ROI are set to 1's and the other pixels to 0's. An ROI can be marked manually also by the visual inspection of the image. Once the ROI is determined, the de-identification of that region is carried out by Selective Encryption (SE) [10-14].

In many cases, specially authorized users (like investigating agencies, medical image diagnostic units, *etc.*) should be able to recover the original unobscured image [15-19]. In these cases, exact reverse de-identification is required, and it is skillfully implemented in the proposed method. Here, XOR encoding is employed for selective encryption while its vulnerability to chosen Plaintext Attack (C-PA) is eliminated by randomizing the encryption key for successive encryptions. Thus, every encryption process uses a different encryption key so that the present key, if captured by an attacker, is no longer valid for the next encryption.

Image authentication ensures the integrity of the encrypted images [20-27]. In the proposed method, a hidden encrypted matrix acts as the digital signature that provides authentication for the encrypted primary image. The signature matrix is decoded and verified by the end user, and if the verification fails, the image decryption process is terminated.

Digital images are represented by matrices whose elements belong to the data type uint8. Therefore, in this work, integer matrix keys and matrix operations in a specific finite field \mathbb{Z}_p , are used for the encryption and decryption of image matrices to achieve faster cryptographic operations. By using the finite field, all cryptographic operations are carried out in the integer domain, and thus, the round of error that occurs with floating point operations is eliminated. Finite field arithmetic also limits the maximum value of any element to $(p-1)$, and thus integer overflow problem is avoided.

The objectives of this work are:

- 1) Fully reversible de-identification of the selected regions of the given image.
- 2) Security for the de-identified image during transmission and storage.
- 3) Easy decryption of the encrypted image to get back the de-identified image by the conventional end users.
- 4) Lossless recovery of the original image by specially authorized users.
- 5) Content and source authentication via a digital signature scheme.

In achieving these objectives, the target image, the region identification mask, the signature matrix, and the randomization matrix are jointly encrypted to get a composite cipher matrix. Thus the proposed method is designated as Reversible De-identification of Specific Regions by Randomized Joint Encryption, RDSR-RJE.

The rest of this paper is organized as follows. Section II contains the literature review. Section III introduces the mathematical operations used for the generation of cryptographic matrix keys. Section IV describes the encryption and decryption techniques of RDSR-RJE. Section V holds the experimental results and the performance evaluation. Section VI gives the conclusion.

II. LITERATURE REVIEW

Plenty of research articles are available on image encryption using diverse methods. Kaur and Kumar [3], have presented an extensive survey of various image encryption schemes and the corresponding algorithms. Several commonly used metrics, namely key space analysis, image entropy, correlation coefficients, MSE, PSNR, SSIM, sensitivity analysis, and execution time, are discussed in detail. Sajitha and Rekh [4], have reviewed recent image encryption methods, including a broad coverage of the relative advantages and disadvantages of different methods. Chaos-based image encryption schemes are reviewed in [5]. Various types of chaotic maps used in image encryption are enumerated systematically. In [6], the authors have reviewed several image encryption and discrete image encoding techniques and the associated future scope in those fields. In [7], image encryption methods based on chaotic maps, neural networks, AES (Advanced Encryption Standard), DCT (direct Cosine Transform), XOR, GA (Genetic Algorithm), and LSB (Least Significant Bit) are reviewed. Additionally, several schemes which use a combination of these methods are discussed. In [8], the author has differentiated between anonymization and de-identification, where the former procedure is irreversible, and the latter is reversible.

A few survey papers are available on SE with Reversible De-identification (RD) [10-12]. Selective Color image encryption with RD is presented in [10]. In [11], the authors have reviewed different techniques for the SE of multi-media content. In [12], applications of SE in the Covid-19 environment have been presented. In [13], the authors use permutation method for confusion and XOR for diffusion. However, the block wise approach increases the time

complexity of encryption as well as decryption. In [14], dynamic DNA coding along with a sine function based chaotic map is used for encryption. However, the security level offered by DNA coding is moderate, while the calculations involved in DNA coding result in higher computational overhead. Additionally, the sine map has a relatively smaller chaotic interval and a low-security level. In [15], threshold entropy and the Arnold Cat Map are used for lossless selective encryption. But, the block-wise calculation of entropy incurs a higher computational cost, especially for large-sized images. In [16], the authors have adopted multi-level encryption with compressive sensing and have used degradation matrices to implement reversible, selective encryption. However, the reverse recovery of the obfuscated regions is not error-free due to the least square estimation. In [17], The SE is carried out by the permutation of pixels block-wise on the selected region, and then the de-identified image can be encoded further by JPEG-like compressive encoding. The authors have extended this operation for video surveillance. But the block-wise operation is computationally quite expensive, and moreover, the ROI selected has to be a square block which is another limitation. In [18], the authors have used the Histogram Shifting method to hide the ROI in a high-textured part of the image. Then, the Arnold map technique is used to obfuscate the ROI. After this, the QR code is used for the overall encryption. The major deficiency of this method is the trial and error procedure used to select the high-textured area. Additionally, this area gets distorted after decryption due to the data-hiding mechanism. Therefore, even though the ROI is recovered, the full image recovered is a slightly distorted version of the original one. In [19], the authors have used the 'reversible data hiding (RDH)' technique so that the obfuscated ROI can be recovered back at the receiving side. RDH is achieved using 'difference value embedding', which is a block-wise approach. Additionally, Run Length Encoding (RLC) and Huffman coding are used to improve the hiding capacity. These additional encodings and the block-wise difference operations make this method computationally very expensive, even for a relatively small sized image.

Now, a few existing works on encryption with authentication are briefly discussed. In [20], the authors have used AES for the encryption of the main image and ECC for hiding the AES encryption key and the hash values corresponding to the image and source authentication. The Dicom file header is chosen as the hiding location. Thus the security of the authentication signatures is not really strong. In [21], Elliptic Curve Cryptography (ECC) along with 3D/4D Cat mappings, are used for image encryption. Image authentication is provided using SHA₂₅₆. However, the block-wise operations and the use of ECC having a 512-bit prime order make the computational cost very high. In [22], compressive sensing and the Logistic-Tent system are used for image encryption along with blind signcryption based on secret sharing and ECC. Here, the additional DWT transform at encryption, and IDWT at decryption increases the time complexity excessively. In [23], the authors have used ECC for digital signature and the Logistic Tent map for image encryption. Use of chaotic maps for both permutation and diffusion results in higher computational complexity. In [24], two-stage encryption has been adopted. The first stage uses

ECC for asymmetric encryption, and the second stage implements multi-chaotic maps for confusion. The authors have used SHA₂₅₆ for authentication. Here, the group formation and the generation of big integers for ECC, introduce an inordinate level of computational complexity for large-sized images. Additionally, the transmission of the digital signature part separately along with the encrypted image, increases the vulnerability for a security breach. In [25], the authors have used Equal Absolute Value Decomposition preceded by Fresnel transform to achieve optical image encryption. Image authentication is implemented based on nonlinear correlation. But the disadvantage of this method is that its security can be compromised using the amplitude phase-retrieval algorithm. In [26], differential privacy (DP) schemes, for selective image encryption, based on different techniques have been evaluated. The authors have concluded that the method using Singular Value Decomposition (SVD) provides the best solution. However, the DP methods discussed in this review use block-wise processing and thus suffer inordinate time delay during encryption. In [27], 2D logistic sine-cosine maps are used for confusion, and Mandelbrot Set and conditional shift algorithms, along with XOR, are used for diffusion. However, the conditional shift algorithm used introduces a substantial time delay. In [28], the authors have used a 3D chaotic map for position permutation (confusion) as well as value transformation (diffusion) that involves pixel rotation. However, the histogram equalization process and the generation of a third-order chaotic map consume quite a long execution time both during encryption and decryption. In [29], the spatial, as well as the frequency domain approach, has been used for image encryption. Block scrambling based on a randomizing key provides confusion, and the 2D Logistic Sine Map (LSM) coupled with wavelet transform coefficients provide diffusion. SHA₅₁₂ hash of the image is used as the input to drive the LSM. However, the whole process is highly complex, and the execution speed is very low. In [30], the authors have used the Mandelbrot set, DNA sequence technique, and a suitable chaotic map for the encryption of color images. The chaotic map to be used is evaluated and selected based on the entropy of the image under consideration. However, the entire operation of encryption/decryption incurs heavy computational overhead due to repeated calculations of entropy and generation of the appropriate Mandelbrot set for each image. In [31], a cosine transform-based chaotic system (CTBCS) has been employed for image encryption. With two seed maps, CTBCS acquires complex dynamic characteristics that provide a higher degree of security. From CTBCS, the authors have derived a logistic sine cosine map, sine Tent cosine map, and Tent logistic cosine map. The encryption is carried out in multi-stages using these maps. Here, even though the security level achieved is very high, the encryption process is block-wise and extensive, which imposes an inordinate computational burden for large-sized images. In [32], the authors have adopted matrix semi-tensor product (STP) for image diffusion. Additionally, Boolean network-based compound secret keys are used for confusion. In this case also, the block-wise approach introduces quite a time delay for the encryption/decryption of images. In [33-37], image encryption schemes based on machine learning have been presented, and the superiority of training-based deep learning networks has

been established. Since these methods belong to an entirely different genre, they are not discussed in this work.

Most of the schemes discussed here have a high degree of time complexity in the key generation as well as encryption/decryption processes due to the block-wise operations and iterative algorithms using floating point data types. Thus the execution times are higher for large-sized images. In our proposed method RDSR-RJE, the time complexity is less as there are no block-wise or iterative operations. In RDSR-RJE, all operations are carried out in the integer domain that achieves higher speed.

III. PRELIMINARIES

In RDSR-RJE, the key spaces as well as calculations involving encryption, are carried out using modular algebra in the finite field \mathbb{Z}_p where its members are integers in the range 0 to $(p-1)$.

A. Basic Modular Operations Extended to Matrices

The basic modulo operation is represented in a few ways as $b = a \bmod p$; $b = a \% p$; $b = \text{mod}(a, p)$. In this paper, we use the notation $b = \text{mod}(a, p)$, where $\text{mod}(\dots)$ acts as a function that returns the modulo remainder. The $\text{mod}(\dots)$ function can be easily extended to integer matrices in \mathbb{Z}_p . Let \mathbf{A} be an integer matrix of size $(m \times n)$ whose elements are $a(i, j)$'s for $i = 1$ to m and $j = 1$ to n . Now, the $\text{mod}(\dots)$ function is extended to matrix \mathbf{A} , simply as $\text{mod}(\mathbf{A}, p)$. Here, $\text{mod}(\dots)$ function is applied element-wise to all $a(i, j)$'s. To clarify, let matrix \mathbf{B} represent the result of $\text{mod}(\mathbf{A}, p)$ as,

$$\mathbf{B} = \text{mod}(\mathbf{A}, p) \quad (1)$$

Then,

$$b(i, j) = \text{mod}(a(i, j), p) \quad (2)$$

for $i = 1$ to m and $j = 1$ to n . The elements of \mathbf{B} belong to \mathbb{Z}_p and $\mathbf{B} \in \mathbb{Z}_p^{m \times n}$. The basic scalar identities of $\text{mod}(\dots)$ functions, as well as the associative and distributive laws, hold good for modular matrix operations.

B. Modular Matrix Inverse

Modular matrix inverse of a square matrix \mathbf{A} of size $n \times n$, represented by $\text{mmi}(\mathbf{A}, p)$, is defined such that,

$$\text{mod}(\mathbf{A} * \text{mmi}(\mathbf{A}, p), p) = \text{mod}(\text{mmi}(\mathbf{A}, p) * \mathbf{A}, p) = \mathbf{I}_{n \times n}$$

For the existence of $\text{mmi}(\mathbf{A}, p)$ the rank of \mathbf{A} should be n , and p should be prime, which assures that the $\text{GCD}(\det(\mathbf{A}), p) = 1$.

Rectangular integer matrices have either left $\text{mmi}(\dots)$'s or right $\text{mmi}(\dots)$'s. A rectangular matrix \mathbf{E} of size $m \times n$ with $m > n$ (tall matrix) and rank n , has the left $\text{mmi}(\dots)$ only, which means,

$$\text{mod}(\text{mmi}(\mathbf{E}, p) * \mathbf{E}, p) = \mathbf{I}_{n \times n}$$

When $n > m$, (wide matrix), \mathbf{E} having rank m , has the right $\text{mmi}(\dots)$ as,

$$\text{mod}(\mathbf{E} * \text{mmi}(\mathbf{E}, p), p) = \mathbf{I}_{m \times m}$$

Detailed determination of $\text{mmi}(\mathbf{E}, p)$ for a given matrix \mathbf{E} and p , is described in the next section.

C. Generation of Encryption and Decryption Matrix Keys

In RDSR-RJE, encryption and decryption operations use four distinct integer matrix keys of size (n×n) each. An efficient generation of these keys is based on the modified Householder Construction [38].

1) *Modified householder construction:* Conventional Householder Construction (CHC) generates an orthogonal symmetric matrix from a given vector. The basic CHC equation [40] is,

$$\mathbf{H} = \mathbf{I}_{L \times L} - \frac{2 * \mathbf{V} * \mathbf{V}^T}{\mathbf{V}^T * \mathbf{V}} \quad (3)$$

where \mathbf{V} is a column vector of size $L \times 1$ and $\mathbf{I}_{L \times L}$ is the identity matrix. It can be verified that \mathbf{H} is an $L \times L$ orthogonal matrix, and it is symmetric where all the elements are not independent.

In cryptography, with a symmetric secret matrix key, the number of unknown elements in a matrix gets reduced almost by 50%, which makes the brute force guessing task easy. Therefore, for better security, secret keys should neither be symmetric nor based on symmetric parent matrices. To get an unsymmetric involutory matrix in \mathbb{Z}_p , the CHC procedure is modified using two dissimilar random integer vectors \mathbf{U} and \mathbf{V} of size $L \times 1$ to get \mathbf{G} as,

$$\mathbf{G} = \mathbf{I}_{L \times L} - \frac{2 * \mathbf{U} * \mathbf{V}^T}{\mathbf{U}^T * \mathbf{V}} \quad (4)$$

The RDSR-RJE scheme uses modular algebra, and the keys derived from \mathbf{G} must be integers. Therefore, \mathbf{G} has to be an integer matrix in the finite field \mathbb{Z}_p . To get this, the division operation by $(\mathbf{U}^T * \mathbf{V})$ in (4) is replaced by the multiplication factor $(\mathbf{U}^T * \mathbf{V})^{-1}$ which is the modular inverse of $(\mathbf{U}^T * \mathbf{V})$ with respect to p . The resulting \mathbf{G} is,

$$\mathbf{G} = \mathbf{I}_{L \times L} - 2 * (\mathbf{U}^T * \mathbf{V})^{-1} * \mathbf{U} * \mathbf{V}^T \quad (5)$$

In (5), the size of \mathbf{G} is $L \times L$, and all the mathematical operations are carried out using modular algebra in the finite field \mathbb{Z}_p . Here, it can be verified that,

$$\text{mod}(\mathbf{G} * \mathbf{G}, p) = \mathbf{I}_{L \times L} \quad (6)$$

That is, the modular inverse of \mathbf{G} is \mathbf{G} itself. That means \mathbf{G} is involutory and not well suited as a cryptographic key from the security aspect. Hence, to avoid the involutory deficiency, an additional involutory matrix \mathbf{F} , which is entirely different from \mathbf{G} , is generated as,

$$\mathbf{F} = \mathbf{I}_{L \times L} - 2 * (\mathbf{X}^T * \mathbf{Y})^{-1} * \mathbf{X} * \mathbf{Y}^T \quad (7)$$

Here \mathbf{X} and \mathbf{Y} are two $L \times 1$ integer vectors different from \mathbf{U} and \mathbf{V} . Similar to matrix \mathbf{G} , we have,

$$\text{mod}(\mathbf{F} * \mathbf{F}, p) = \mathbf{I}_{L \times L} \quad (8)$$

Let us define two integer matrices \mathbf{E} and \mathbf{D} as,

$$\mathbf{E} = \text{mod}(\mathbf{G} * \mathbf{F}, p) \quad (9)$$

$$\mathbf{D} = \text{mod}(\mathbf{F} * \mathbf{G}, p) \quad (10)$$

Since \mathbf{G} and \mathbf{F} are derived from different vector sets, they are non-commutative. That is, $(\mathbf{G} * \mathbf{F}) \neq \mathbf{F} * \mathbf{G}$. Therefore, the

encryption and decryption parent matrices \mathbf{E} , and \mathbf{D} are numerically dissimilar.

Now, let us evaluate the products $\mathbf{E} * \mathbf{D}$ and $\mathbf{D} * \mathbf{E}$. For easier writing, the mod prefix and p are omitted while writing the expressions for the matrices. Then,

$$\mathbf{Z} = \text{mod}(\mathbf{E} * \mathbf{D}, p) = \mathbf{E} * \mathbf{D} \quad (11)$$

$$\mathbf{W} = \text{mod}(\mathbf{D} * \mathbf{E}, p) = \mathbf{D} * \mathbf{E} \quad (12)$$

From (9), (10), and (11),

$$\mathbf{Z} = (\mathbf{G} * \mathbf{F}) * \mathbf{F} * \mathbf{G} = \mathbf{G} * (\mathbf{F} * \mathbf{F}) * \mathbf{G} \quad (13)$$

Substituting (8) and then (6) in (13) gives,

$$\mathbf{Z} = \mathbf{E} * \mathbf{D} = \mathbf{I}_{L \times L} \quad (14)$$

Similarly, it can be shown that,

$$\mathbf{W} = \mathbf{D} * \mathbf{E} = \mathbf{I}_{L \times L} \quad (15)$$

From (14) and (15), it can be seen that \mathbf{D} is the modular matrix multiplicative inverse of \mathbf{E} and vice versa as, $\mathbf{D} = \text{mmi}(\mathbf{E}, p)$ and $\mathbf{E} = \text{mmi}(\mathbf{D}, p)$. In (14) and (15), \mathbf{E} and $\mathbf{D} \in \mathbb{Z}_p^{L \times L}$. The novelty of generating mmi 's by the Householder technique is that mmi 's are obtained without directly calculating the matrix inverses in \mathbb{Z}_p (with time complexity $O(L^3 * \log_2 p)$ [39]), but using only scalar modular inverse as in (5) and (7), which has a time complexity of $O((\log_2 p)^2)$ only [40].

2) *Encryption and decryption matrix keys from matrices \mathbf{E} and \mathbf{D} :* Individual encryption keys are obtained by the row-wise splitting of the parent matrix \mathbf{E} of size $L \times L$, into four sub matrices $\mathbf{E}_1, \mathbf{E}_2, \mathbf{E}_3$, and \mathbf{E}_4 as,

$$\mathbf{E}_{L \times L} = \begin{bmatrix} \mathbf{E}_{1, (n \times L)} \\ \mathbf{E}_{2, (n \times L)} \\ \mathbf{E}_{3, (2 \times L)} \\ \mathbf{E}_{4, (2 \times L)} \end{bmatrix} \quad (16)$$

In (16), the selected size of each sub matrix is marked in its subscript.

3) *Selection of the sizes of $\mathbf{E}_1, \mathbf{E}_2, \mathbf{E}_3$ and \mathbf{E}_4 :* In RDSR-RJE, the matrix keys \mathbf{E}_1 and \mathbf{E}_2 are used to encrypt the plain image matrices of size $k \times n$ by post multiplication. Therefore, the number of rows of \mathbf{E}_1 and \mathbf{E}_2 are set to n to match the column size of the plain image matrices. On the other hand, \mathbf{E}_3 and \mathbf{E}_4 are used to encrypt the signature matrix and the randomizing matrix, whose sizes are $k \times 2$. Hence the row sizes of \mathbf{E}_3 and \mathbf{E}_4 are set to 2. The detailed encryption process is given in section IV, where the significance of the sizes of submatrices $\mathbf{E}_1, \mathbf{E}_2, \mathbf{E}_3$, and \mathbf{E}_4 will become clear. The choice of using 2 instead of n , for the row sizes of \mathbf{E}_3 and \mathbf{E}_4 , is to reduce the overall key sizes and the resulting cipher matrix size to keep the ciphertext expansion ratio at a lower value.

The total number of rows of the sub matrices $\mathbf{E}_1, \mathbf{E}_2, \mathbf{E}_3, \mathbf{E}_4$ is $(n+n+2+2) = 2*n+4$. Therefore from (16), it can be seen that

$$L = 2*n + 4 \quad (17)$$

The decryption keys are obtained by the column-wise splitting of the parent matrix D into four submatrices as,

$$D_{L \times L} = [D_{1,(L \times n)} \quad D_{2,(L \times n)} \quad D_{3,(L \times 2)} \quad D_{4,(L \times 2)}] \quad (18)$$

Now substituting in (14), for E and D from (16) and (18) gives,

$$\begin{bmatrix} E_1 \\ E_2 \\ E_3 \\ E_4 \end{bmatrix} * [D_1 \quad D_2 \quad D_3 \quad D_4] = I_{L \times L} \quad (19)$$

Now, expanding the LHS and the RHS of (19) in terms of compatible submatrices gives,

$$\begin{bmatrix} E_1 * D_1 & E_1 * D_2 & E_1 * D_3 & E_1 * D_4 \\ E_2 * D_1 & E_2 * D_2 & E_2 * D_3 & E_2 * D_4 \\ E_3 * D_1 & E_3 * D_2 & E_3 * D_3 & E_3 * D_4 \\ E_4 * D_1 & E_4 * D_2 & E_4 * D_3 & E_4 * D_4 \end{bmatrix} = \begin{bmatrix} I_{n \times n} & 0_{n \times n} & 0_{n \times 2} & 0_{n \times 2} \\ 0_{n \times n} & I_{n \times n} & 0_{n \times 2} & 0_{n \times 2} \\ 0_{2 \times n} & 0_{2 \times n} & I_{2 \times 2} & 0_{2 \times 2} \\ 0_{2 \times n} & 0_{2 \times n} & 0_{2 \times 2} & I_{2 \times 2} \end{bmatrix} \quad (20)$$

From (20), it can be seen that, for $i, j = 1$ to 2 ,

$$E_i * D_j = \text{mod}(E_i * D_j, p) = \begin{cases} I & \text{if } j = i \\ 0 & \text{if } j \neq i \end{cases} \quad (21)$$

Here, I is the identity matrix, and 0 is the all-zero matrix of matching sizes.

Thus, a new way of generating index-wise orthogonal key matrices are derived via Householder Construction. The property represented by (21) plays an important role in the encryption and decryption process of RDSR-RJE. In (21), E_i 's are the encryption keys, and D_j 's are the decryption keys in \mathbb{Z}_p . All the encryption and decryption are generated by the Key Generation Center administered by the image owner. The decryption keys are sent to the respective receivers of the end users, through the secured channels.

IV. RDSR-RJE ENCRYPTION AND DECRYPTION

The architectural layout of RDSR-RJE scheme is shown in Fig. 1. The two major components are:

- RDSR-RJE Encrypter, which is also the owner of images and the corresponding RD-BM's.
- RDSR-RJE Receiver.

The RDSR-RJE Encrypter consists of the de-identification (DI) unit and the joint encryption (JEnc) unit. In RDSR-RJE, it is assumed that the ROI to be encrypted has been determined by a suitable method [9] and is made available as the Region Defining Binary Mask, **RD-BM**, whose size is same as that of A . In **RD-BM**, the ROI pixels of A are set to ones and the non-ROI pixels to zeros.

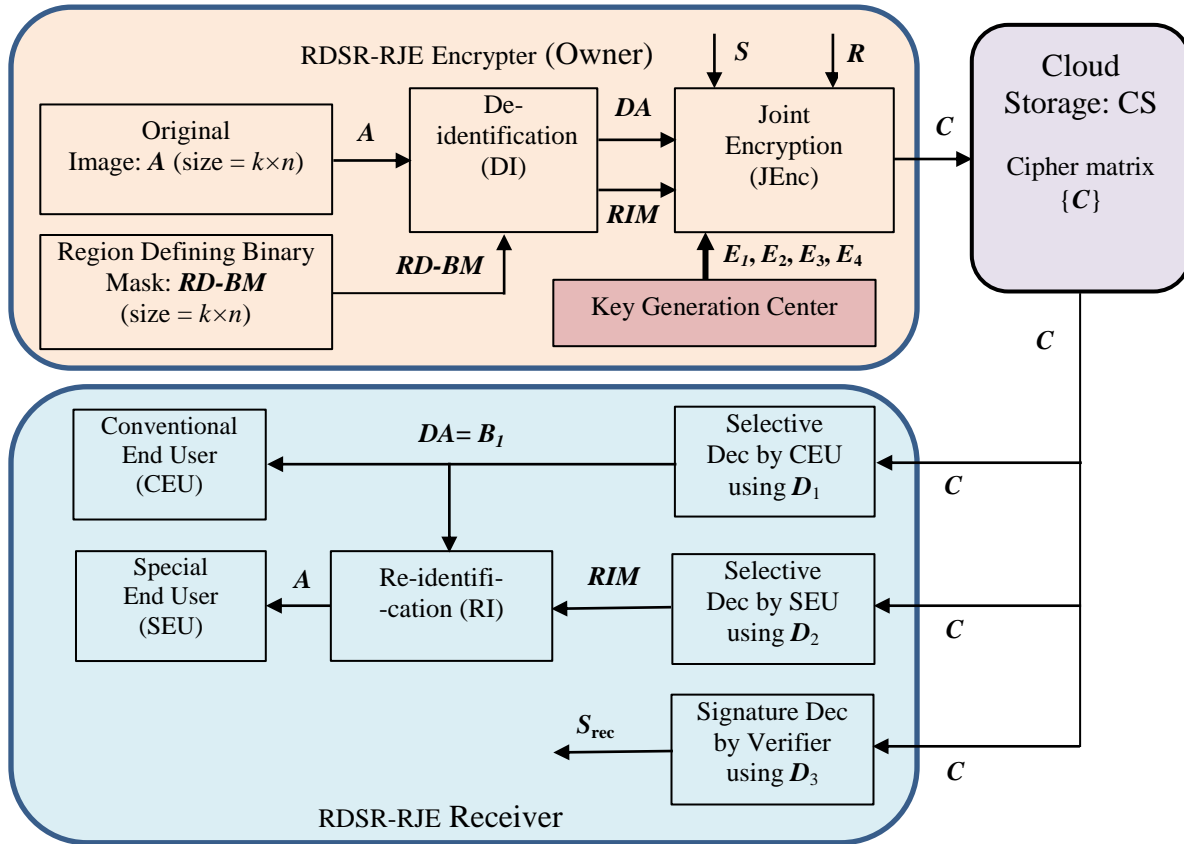

Fig. 1. The architectural layout of RDSR-RJE transmitter and receiver.

A. De-identification by Selective Encryption

The basic selective encryption process for de-identification is depicted in Fig. 2. The original input image to be de-identified is represented by matrix A of size $k \times n$ with data type uint8. (For a square image, $k = n$). Hereafter, when there is no ambiguity, ‘image matrix A ’ and ‘image A ’ are used synonymously.

Fig. 2. The De-identification unit.

B. Binary Mask to Random Integer Mask Generator

In RDSR-RJE, the ‘Binary Mask to Random Integer Mask Generator’ transforms the $RD-BM$ into RIM . In generating RIM , the 1’s of the $RD-BM$ are replaced by random integers in the range 1-254 to get maximum diversity. Here, integer 0 is avoided as it does not make any change when XORed with any other number. Similarly, integer 255 is avoided to avoid the exact complements. The zeros of $RD-BM$ are retained as they are in getting RIM . A toy example of an 8×8 $RD-BM$ is shown in Fig. 3(a). The corresponding RIM is shown in Fig. 3(b). The number of zeros and their locations in the $RD-BM$ are same as in its RIM . The number of integers greater than zero in RIM are equal to the number of ones of $RD-BM$.

Fig. 3. RD-BM of size 8×8 and its RIM.

C. XOR De-identification

The bitwise XOR de-identification is carried out to get the de-identified out DA (De-identified A) of size $k \times n$ as,

$$DA = \text{bitxor}(A, RIM) \quad (22)$$

The zeros and their locations in RIM represent the non-ROI regions of A . Therefore, the $\text{bitxor}(\dots)$ operation does not change those pixel values. Thus the non-ROI areas of A and DA are exactly the same. On the other hand, the ROI pixel values get randomly altered at ROI locations of A due to the bitwise XOR of operations of nonzero operands. On the receiving side, the original matrix A is recovered as $A = \text{bitxor}(DA, RIM)$.

D. Security Aspects of Bitwise XOR Encryption

1) *Blind guess of RIM*: Let nz be the number of nonzero elements in the RIM used in (22). Each element can take any value between 1 and 254 (254 possibilities). Then the probability of correctly guessing a single element is $(1/254)$, and that of correctly guessing all the elements of RIM is $(1/254)^{nz} = 254^{-nz}$, which is a very meager fraction, even for a moderately sized ROI.

2) *Protection against chosen plain text attack (CPA)*: The most vulnerable attack on XOR encryption is CPA, whereby knowing A and DA , the attacker can get hold of RIM as,

$$RIM = \text{bitxor}(A, DA) \quad (23)$$

But the RIM used in (22) is randomly varied from encryption to encryption. Here the RIM acts as an OTP. Therefore, the RIM captured by the attacker using (23) is useless for the succeeding encryptions. Thus the CPA and ‘many time pad’ attacks are eliminated.

3) *Accessibility and manipulation of DA*: In RDSR-RJE, the XOR encryption is not a standalone operation. The output matrix DA is internal to the sender, and it is further encrypted, as will be explained in the next section. Hence, DA is not directly accessible to the attacker, and any manipulation to DA is flagged off by the subsequent message authentication scheme.

E. Joint Encryption using Matrix Keys

Joint encryption (JEnc) is the new innovation of RDSR-RJE. Here, four data matrices are encrypted jointly with four corresponding encryption matrix keys E_1, E_2, E_3 and E_4 to get the cipher matrix C as,

$$C = \text{mod}((DA * E_1 + RIM * E_2 + S * E_3 + R * E_4), p) \quad (24)$$

Here, S is the signature matrix of size $k \times 2$ and R is the randomization matrix of size $k \times 2$, which is altered for successive encryptions. The sizes of DA and RIM are $k \times n$. The sizes of encryption key matrices E_1 and E_2 , are $n \times L$ and the sizes of E_3 and E_4 are $2 \times L$. The size of the cipher matrix C is $k \times L$ where $L = 2 * n + 4$. Matrix C is calculated using modular algebra in Z_p . Then, Eqn. (24) can be written in a simple form as,

$$C = DA * E_1 + RIM * E_2 + S * E_3 + R * E_4 \quad (25)$$

Formation of C using (25) is called the ‘Joint Encryption (JEnc)’ to indicate that matrix C is obtained by encrypting four data matrices by four matrix keys to get a single weighted sum. After JEnc, the cipher matrix C is sent to the CS for secure storage and subsequent distribution. When the sizes of the matrices are large, the partial sums on the RHS may exceed the max(int) level of the computing device. In such cases, the integer overflow error can be avoided by adopting ‘cumulative summation’ where one term is added at a time to the partial sum followed by the mod operation, as shown below.

1) *Cumulative addition*: The cumulative addition is carried out as follows

$$\begin{aligned} C &= []; C=C+\text{mod}(DA*E1,p); C=\text{mod}(C,p); \\ C &= C+\text{mod}(RIM*E2,p); C=\text{mod}(C,p); \\ C &= C+\text{mod}(S*E3,p); C=\text{mod}(C,p); \\ C &= C+\text{mod}(R*E4,p); C=\text{mod}(C,p); \end{aligned}$$

The mod operation in each step keeps the result between 0 and $(p-1)$. Thus the final sum C also remains within Z_p .

F. Randomization Matrix R

The integer matrix R , of size $k \times n$ (same as that of DA and RIM), on the RHS of (25) provides randomization to the encryption. R varies randomly from the present encryption to the next encryption. Thus, for the same inputs DA , RIM and S , the output C will differ in successive encryptions because of R . Thus, randomized encryption is achieved, which prevents the Chosen Ciphertext Attack (CCA). The elements of R are chosen randomly from the uniform distribution in the range 0 to 255.

G. Signature Matrix S

The signature matrix S of size $k \times n$ (same as that of DA and RIM) provides image and source authentication. In general, Matrix S contains the ID of the source, time stamp for source authentication, and suitable hash value of the original image matrix A . The source ID acts as the digital signature which is made available to the signature verifier at the receiving end.

H. Selective Decryption

The blocks used in selective decryption operation are shown in Fig. 1.

1) *Decryption by a Conventional End User (CEU)*: The cipher matrix C can be decrypted by a Conventional End User (CEU) using the decryption key D_1 . The CEU, on decryption, recovers the de-identified image matrix DA . The decryption is carried out as,

$$B_1 = \text{mod}(C * D_1, p) = C * D_1 \quad (26)$$

On substituting for C from (25) in (26), we get,

$$B_1 = (DA * E_1 + RIM * E_2 + S * E_3 + R * E_4) * D_1 = DA * E_1 * D_1 + RIM * E_2 * D_1 + S * E_3 * D_1 + R * E_4 * D_1 \quad (27)$$

From the property (21), $E_1 * D_1 = I$, and the other product terms $E_2 * D_1, E_3 * D_1$ and $E_4 * D_1$ are all zeros. Hence,

$B_1 = DA$ which proves the correctness of the decryption by the CEU.

2) *Selection of the modulus p* : For the existence of modular inverses in Z_p , the p value has to be a prime integer. In RDSR-RJE, the encryption and the decryption operations are carried out on images whose elements belong to uint8 with a maximum value = 255. Now consider the decryption, $B_1 = \text{mod}(C * D_1, p)$. Here, due to the mod(...) operation, the maximum element of B_1 is less than p . However, B_1 (which is same as DA) represents the de-identified image where the maximum element can go up to 255. Therefore, for the correct realization of DA at the receiver, the constraint is $255 < p$. That is, p should be greater than 255. The immediate higher prime number is 257, and hence **p is chosen to be 257**. Using a higher prime number for p , unnecessarily increases the cipher text size.

3) *Decryption by the special end user (SEU)*: The special end user (SEU) has the decryption key D_2 as well as D_1 . Using D_2 the SEU decrypts C as,

$$B_2 = \text{mod}(C * D_2, p) = C * D_2 \quad (28)$$

On substituting for C from (25) in (28) and again using the property (21) we get $B_2 = RIM$. The SEU also decrypts C using D_1 to get DA as explained in section IV.H.1. Then the SEU can recover the original A as,

$$B = \text{bitxor}(DA, RIM) \quad (29)$$

From (29) and (23), it can be seen that B is exactly equal to A , and thus the decrypted matrix B is the exactly re-identified version of DA . Therefore, RDSR-RJE achieves lossless reverse de-identification.

4) *Decryption of the signature matrix S* : The signature matrix S is detected using the decryption key D_3 as,

$$B_3 = \text{mod}(C * D_3, p) = C * D_3 \quad (30)$$

On substituting for C from (25) in (30) and again using the property (21), we get $B_3 = S$.

5) *Signature verification*: In RDSR-RJE, signature verification takes place before decryption. Therefore, if the verification fails, there is no need for decryption. This pre-signature verification scheme results in faster processing. The Signature Verifier (SV) at the receiving end should possess the signature decryption key D_3 . The SV should have already received earlier, the true signature S_{true} from the data owner. Now, the decrypted B_3 gives the received signature S_{rec} . Thus, on receiving C , the SV recovers S_{rec} . If $S_{\text{rec}} = S_{\text{true}}$, then the authentication is successful, and the received C is accepted. Otherwise, there is some error, and the present C is discarded, and suitable countermeasures are deployed for further investigation, or the receiver may request retransmission. Here, both CEU and SEU possess D_3 , and after signature verification, can proceed for further decryption. Since the signature matrix is encrypted using the encryption key E_3 , it is non-forgable and achieves non-repudiation as the signature matrix carries the sender's ID.

I. RDSR-RJE Encryption and Decryption Algorithms

RDSR-RJE encryption and decryption algorithms are presented in this section. Modular algebra in Z_p is used for all calculations.

Algorithm RDSR-RJE encrypt

Inputs: Original image A . Mask matrix $RD-BM$. Signature matrix S . Encryption keys E_1, E_2, E_3 and E_4 .

Output: Cipher matrix C .

1. Get the Random Integer Matrix, RIM from $RD-BM$ as explained in section IV.A.1.
2. Get the de-identified image matrix DA by the XOR encryption, as given by (22).
3. Generate the randomization integer matrix R using any standard library function from python, C++, Java, etc.
4. Jointly encrypt DA, RIM, S , and R to get the cipher matrix C , using the Encryption keys E_1, E_2, E_3 , and E_4 as given by (24).
5. Over.

Decryption Algorithm used by the conventional end user (CEU) is summarized as follows.

Algorithm RDSR-RJE-CEU decrypt

Inputs: Cipher matrix C . Decryption keys D_1 and D_3 . True signature matrix S_{true} .

Output: De-identified image matrix DA .

1. Get S_{rec} using (30) as, $S_{rec} = C * D_3$.
2. Verify the signature as:
 - If $S_{rec} \neq S_{true}$ //Signature failure
Discard the present C , and request for Retransmission.
Go to step 4.
 - Else //Signature OK
Go to step 3.
 - Endif
3. Get DA using (26), as $DA = C * D_1$.
4. Over.

RDSR-RJE decryption by the Special End User is an extension of the algorithm **RDSR-RJE-CEU decrypt**.

Algorithm RDSR-RJE-SEU decrypt by the Special End User

Inputs: Cipher matrix C . Decryption keys D_1, D_2 , and D_3 . **Output:** Original image matrix A .

1. Get DA according to the algorithm **RDSR-RJE-CEU**
 2. Get RIM using (28), as $RIM = C * D_2$.
 3. Get the original re-identified matrix A , using (29) as, $A = \text{bitxor}(DA, RIM)$.
 4. Over.

J. Characteristics of RDSR-RJE Encryption/Decryption

1) *Ciphertext expansion ratio:* The Ciphertext Expansion Ratio (CER) is the ratio of the size of the cipher matrix to that of its plain matrix. For a given plain matrix, higher the value of CER, higher is the size of its cipher matrix, and consequently, the computational and communication cost becomes relatively higher. A lower CER value contributes to a higher degree of encryption efficiency. CER is defined as,

$$CER = \frac{\text{Size of Ciphermatrix in bits}}{\text{Size of Plain matrix in bits}} = \frac{\text{Size of } C \text{ in bits}}{\text{Size of } A \text{ in bits}}$$

In RDSR-RJE, the uppermost value of an element in the cipher matrix is C is $(p-1)$. Hence, the number of bits needed to represent an element of C is $\text{ceil}(\log_2(p-1))$ bits. With $p = 257$, $\text{ceil}(\log_2(p-1)) = 8$. Thus, 8 bits are required to represent each element of C . Now, the size of C (No. of elements in C) is $k \times L$. Hence the total size of C in bits is $k * L * 8$. The plain matrix has a bit depth of 8, and its size is $k \times L$. Therefore, the total size of A (or DA) in bits is $k * n * 8$. Hence,

$$CER = \frac{k * L * 8}{k * n * 8} = \frac{L}{n} \quad (31)$$

On substituting for L from (17), and when n is large compared to 2,

$$CER = \frac{L}{n} = \frac{2 * n + 4}{n} \cong 2 \quad (32)$$

An important characteristic of RDSR-RJE is that the CER value is constant and does not increase with n .

2) *Lossless reversible de-identification:* In RDSR-RJE, the decrypted image is the exact replica of the original image for the conventional end user or the special end user. Thus, it is a zero-loss scheme.

Additionally, RDSR-RJE does not use block-wise operations. It avoids floating point operations and iterative procedures. Therefore, RDSR-RJE is efficient and achieves higher execution speed.

K. Security Aspects of RDSR-RJE

1) *Exhaustive search for keys:* Each element of an encryption or decryption key belongs to Z_p whose range is 0 to $(p-1)$. Therefore an element of a key can take any one value out of p possibilities. Hence the probability of correctly guessing a single element is $(1/p)$. Each key has $n * L$ elements. Therefore, the probability of guessing all the elements correctly is $(1/p)^{n * L} = p^{-n * L}$ which is extremely a very low value for $p = 257$. Thus, the success of an exhaustive search is negligibly small.

2) *Protection against chosen plain text attack (CPA):* In RDSR-RJE, the encryption process is randomized using the random matrix R as in (25) where R is varied from encryption to encryption. Thus, the cipher matrix would be different even if the input plain matrix is same for consecutive encryptions. Hence, the randomized encryption prevents CPA.

V. EXPERIMENTAL RESULTS AND DISCUSSION

A. Experiment 1

An axial MRI view is taken as the original grayscale plain image as shown in Fig. 4(a). The image matrix A is of size 512×512 . The regions selected for de-identification are the textual details that include the patient's name, date of image production *etc.* The selected regions are shown in the **RD-BM** of Fig. 4(b). The corresponding Random Image Mask (**RIM**) is shown in Fig. 4(c). The de-identified (selectively encrypted) image **DA**, as given by (22), is shown in Fig. 4(d). The result of JEnc, matrix C obtained using (25) is shown in Fig. 4(e) which shows a very high degree of randomness.

Fig. 4. Original Image A, RD-BM, RIM and the encrypted image C (Experiment 2).

Fig. 5. Histograms of DA and C.

1) *Histograms of DA and C*: Histograms of the de-identified image **DA** and the jointly encrypted cipher image **C** are shown in Fig. 5. From Fig. 5, it can be seen that the histogram of **C** is uniformly distributed compared to that of **DA**. This shows the comprehensive randomness of **C**. A malicious attacker cannot deduce any information from the histogram of **C**.

2) *Comparison of visual correlation coefficients*: Adjacent pixel values of a normal image, have a higher correlation between them where as in a good cipher image, the corresponding correlation should be very low. That means, in a cipher image, the adjacent pixel values are highly dispersed. Hence the correlation coefficient [29] will be low.

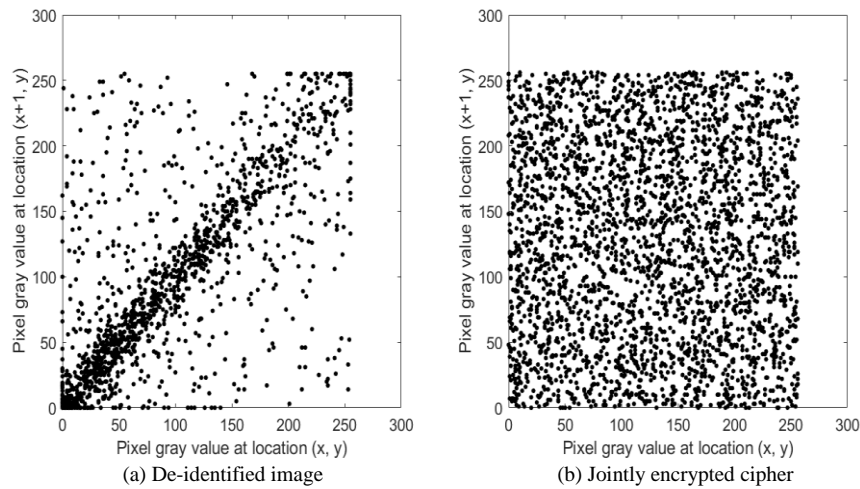

Fig. 6. Comparison of correlation coefficients between DA and C.

Comparison of pixel value dispersions along horizontal direction, between *DA* and the cipher image *C* of Experiment 1, is shown in Fig. 6, from which it can be seen that the cipher image *C* has a high degree of pixel value dispersion compared to *DA*.

B. Experiment 2

In this experiment, an ultrasound scan of pregnancy is the original image *A* with size 187×269, as shown in Fig. 7(a). The region selected for de-identification is the central part of the *A* as shown by the binary mask, *RD-BM* shown in Fig. 7(b), and the corresponding *RIM* is shown in 7(c). The de-identified (selectively encrypted) image *DA*, as given by (22), is shown in Fig. 7(d). The cipher matrix *C* obtained using (25) is shown in Fig. 7(e), which shows a very high degree of randomness.

C. Metrics for Comparison

A few metrics for comparing the image encryption schemes are discussed in this section.

1) *Differential analysis*: Differential analysis is the study of the variations in the cipher matrix when the plain matrix changes by a small value. Thus, it is basically a sensitivity analysis. A quantitative measure of this behavior is NPCR which stands for the Number of Pixels Change Rate.

Let C_1 be the cipher image of a given plain image. Let C_2 be the resulting cipher image after a one-bit change in the plain image. The differential change per pixel is defined as,

$$d(i, j) = \begin{cases} 1 & \text{if } C_1(i, j) \neq C_2(i, j) \\ 0 & \text{otherwise} \end{cases} \quad (33)$$

Fig. 7. Original Image A, RD-BM, RIM, DA and the encrypted image C (Experiment 2).

for $i = 1$ to h and $j = 1$ to w where h and w are the height and width of the cipher image. Then, the percentage NPCR is defined [41] as,

$$NPCR = \frac{\sum_{i=1}^h \sum_{j=1}^w d(i,j)}{h*w} * 100 \quad (34)$$

A higher NPCR means the attacker cannot capture the encryption due to the large number of indeterminates. Thus, higher the NPCR, higher is the security of the encryption process. The ideal value of the NPCR is 100%. Another metric that measures the differential score is UACI (unified averaged changed intensity) which is defined [41] as,

$$UACI = \frac{\sum_{i=1}^h \sum_{j=1}^w |C_1(i,j) - C_2(i,j)|}{h * w * 256} * 100 \quad (35)$$

Higher the value of UACI, better is the encryption performance.

2) *Image entropy*: The entropy of an image in bits/pixel, is defined as,

$$H = - \sum_{i=0}^{i=imax} p_i * \log_2(p_i) \quad (36)$$

where p_i is the probability of a pixel having the gray level i , and $imax$ is the maximum gray level (255 in a normal image). For a fully random image, $H = 8$ bits/pixel.

3) *Structural similarity index*: The structural similarity index (SSIM) [30] measures the closeness between two images. In RDSR-RJE the de-identified image \mathbf{DA} and its decrypted version \mathbf{B}_1 are exactly same. Hence SSIM value in RDSR-RJE is 1. SSIM values less than 1 imply recovery of the plain image with error.

D. Comparison of the Performance of RDSR-RJE

The encryption efficiency parameters of RDSR-RJE are compared with those of HOSSAIN [28], QIN [29], and JITHIN [30]. The numerical results are shown in Table I, for images ‘Img 1’ and ‘Img 2’ which are from Fig. 4(a) and 7(b), respectively.

1) *Execution time*: The theoretical time complexity calculations of the different methods [28-30] are extensive and depend on the respective contexts. Therefore, the execution times of the encryption algorithms are obtained experimentally and shown in the plots of Fig. 8. Here, the image used in Experiment 1 is resized starting from 64x64 and progressively increased upto 512x512 as marked in Fig. 7. Then the corresponding execution times are calculated using the appropriate Matlab code. In Fig. 8, the execution time of joint encryption by RDSR-RJE, is shown in black.

The values obtained in Fig. 8 are machine-dependent, and thus the execution times are relative only. From Fig. 8, it can be seen that RDSR-RJE has a significant lower execution time compared to the other three methods. For example, when the image size is 256x256, the percentage improvement in the execution time of RDSR-RJE compared to that of HOSS [28] is, $(30.38 - 21.35) * 100 / 30.38$, which is approximately equal to 30%.

TABLE I. COMPARISON OF THE QUANTITATIVE VALUES OF THE METRICS

	Plain Image	Encrypted Image			
		Horizontal Correlation Coefficient			
		RDSR-RJE	HOSS [28]	QIN [29]	JITHIN [30]
Img 1	0.8772	0.0025	0.0027	0.0029	0.0037
Img 2	0.7421	0.0227	0.0312	0.0412	0.0467
Image Entropy					
Img 1	4.8876	7.9974	7.9948	7.9953	7.9916
Img 2	7.2674	7.9961	7.9943	7.9951	7.9919
Number of Pixels Change Rate (NPCR) in percentage					
Img 1	----	99.6037	99.5100	99.4991	99.4211
Img 2	----	99.5965	99.4235	99.4173	99.4053
Unified Averaged Changed Intensity (UACI) in percentage					
Img 1		33.5239	32.9932	32.4327	32.2327
Img 2		33.2405	32.0159	32.0079	31.8953
Structural Similarity Index (SSIM)					
Img 1		1.00	0.9879	0.9752	0.9623
Img 2		1.00	0.9693	0.9533	0.9457

Fig. 8. Comparison of execution times for image encryption.

VI. CONCLUSION

A new method of reversible image de-identification by encryption has been presented. It uses matrix keys for asymmetric encryption and decryption of image matrices. Content and source authentication via a digital signature scheme is integrated using joint encryption. All the cryptographic operations are carried out in the finite field Z_p and thus avoid the floating point operations that lead to higher computational speed. Moreover, the algorithm is non-iterative and does not use block-wise operations to achieve faster results. Here, the decrypted image is the exact replica of the original image, and thus, it is a zero-loss scheme. Additionally, the encryption/decryption security-related performance parameters, namely, entropy, correlation coefficients, NPCR, and UACI, are very near to their ideal values. The proposed method, on average, reduces the execution time of homomorphic encryption by 30 to 40 percent.

Abstract—Securing the resources is a most challenging task in the digital era. Traditionally, password and ID card systems were used to provide security. Password and ID cards can be stolen or hacked; to overcome this drawback biometric systems are used to authenticate the user to access the data or resources. Biometric system uses physical and behavioral characteristics of the user. Biological characteristics of the person like face, fingerprint, iris, palm print, voice, hand geometry etc. cannot be stolen and misused. Even though unimodal biometric system is more secure as compared to the traditional approach, it is not able to handle intra-class, inter-class variations, noisy data and spoofing attack. These problems can be solved using multimodal biometrics. In this paper, we discuss unimodal biometric system using Local Binary Pattern (LBP) and Local Ternary Pattern (LTP). We propose a feature level fusion of face and fingerprint biometric traits using LTP. The implementation of the introduced system stands in comparison to the unimodal LBP and LTP for face and fingerprint system. The system is tested on ORL, UMIST, VISA face dataset and FVC fingerprint dataset. Experimental results show that the multimodal biometric system using LTP gives better accuracy as compared to the unimodal biometric system.

Keywords—Unimodal; Multi-modal; LBP; LTP; intra-class; inter-class; spoofing attack

I. INTRODUCTION

The face and fingerprints are the most widely used biometrics, due to their high availability and universality. Most of the biometric systems use single biometric traits; it has some challenges like intra-class variation, inter-class variation and noise in the sensed data. This problem can be overcome by using multiple biometric traits for person identification. Multimodal biometric system combines more than one biometric trait by fusing at different levels. Fusion methods are mainly split into two types: fusion prior to matching and after matching. Under fusion prior matching, sensor level and feature level fusions and under after matching score and decision level fusion techniques are used. In sensor level fusion raw information from the source images are combined. Fusion at sensor level is having richer set of information. In fusion at feature level, features from multiple biometric traits are extracted individually, and extracted the characteristics of the various biometrics are combined. In matching score level, scores from each biometrics traits are calculated and scores are combined to get resultant score. In decision level fusion decision obtained by individual biometric traits are combined to get final decision.

Section II of this paper deals with a survey of related work, the proposed methodology is outlined in Section III, Section IV presents the results and discussion and finally the Section V presents the conclusion of the work.

II. RELATED WORK

Pabitra Priyadarshini Jena et al.[1] introduced multimodal biometric system utilizing face and fingerprint. The fingerprint and face features are taken using deep learning models such as ResNet50, Xception, FaceNet, EfficientNetB3 and InceptionResNetV2. The extracted features are fused at feature level to authenticate the user. N. Krishnaraj et al.[2] introduced multimodal biometric system using palmprint and fingerprint. Gabor filters and characteristic subset selection is carried on Palmprint and fingerprint. Emphasized characteristic are selected for Gabor features using Correlation based Feature Selection and Hybrid Bacterial Foraging Optimization. P. Sivakumar et.al.[3] proposed multimodal template for fingerprint and finger-vein using deep hashing framework for feature level fusion. Along with providing improved privacy for biometric information to safeguard from the special attacks, it provides unlinkability and cancelability of the templates. It integrates deep hashing, multimodal fusion and biometric security with weightage on structural facts from modalities like fingerprint and finger-vein. Features are extracted using VGG16 model and achieved 95% accuracy. Rupali Kute et al.[4] introduced a strategy to recognize face of the person by using their fingerprint. To acquire skills and improve the transferring subspace, Bregman divergence regularization is used. Here gained knowledge from the training samples are transferred to the testing samples. The difference among the two dissimilar domains is reduced by this regularization. To find a common subspace that boosts the performance. Two methods introduced by Arucha Rungchokanum et al. [5] applies the introduced distance model to the minutiae-triplets generation. In the earlier method, model is applied direct whereas in second method, to handle more distorted fingerprint areas and more curved regions like a singular point, model is combined with ridge flow. The proposed method is evaluated on sixteen public domain fingerprint database using two minutiae triplet matching algorithm. A component-based face recognition approach introduced by Rupali Sandip Kute et al. [6] uses transfer learning to demonstrate the knowledge acquired from face image to categorize face elements like ears, lips and nose. These face components are unaltered by the change of face expression and pose. Since face and face

components are from different domain, these are used to transmit the knowledge acquired from distinct domains even though they share common information. To associate between complete and partial faces different half faces like, left, lower diagonal and right upper and left, right, upper half and right upper are considered. This proposed approach can be utilized for components-based face recognition, partial face recognition and full face recognition because of the alliance among face and its components. Sun, Kun et al. [8], this paper presents centre-symmetric local binary pattern and DBN method for face recognition. Initially image is separated into blocks, and feature is extracted from each block using CS-LBP, then texture feature histogram is calculated. This histogram is given as input to DBA for classification. As compared to traditional approaches the proposed approach gave high accuracy by comparing results on Extend Yale B, ORL, and CMU-PIE dataset. Sunil S et al.[9], in this paper, a hybrid solution is presented for face recognition by using SWT, LTP, and DCT. Initially, image is resized and features are extracted using SWT and DCT. Then, LTP is claimed on SWT features and features are combined to obtain final feature vector. Euclidean distance is used for classification. Huilin Ge et al [10], present improved GAN for face recognition. The study uses generator consists of auto encoder and discriminators global descriptor and local descriptor to repair occluded image. To perform image restoration Resnet-50 is used. The proposed method provides improved restoration effect and high recognition rate even in occlusion background. Ashok Kumar Yadav et al. [11], proposed a multi-biometric frame based on DNN using fingerprints, human eye iris and offline signature attribute was introduced. As the first step, fingerprints, signatures and iris of subjects are obtained. At this stage, the client's characteristic is perceived with the help of the multi-modality framework, which is composed of three pre-implemented templates for iris, fingerprints and signatures. The multimodal biometric system using iris, signature and fingerprint shows better performance as compared to unimodal biometrics using fingerprint and iris. Additionally, a different biometric has been developed specifically for offline signing. From that point on, the triple single biometrics solutions are used to construct the provided multi-modal solution. Before integrating these models into a multi-model solution, the correctness of these models is examined after taking into account earlier work on unimodal solutions. The VGG-19 net's performance has improved, according to the results. Using the SDUMLA HMT repository, the model was evaluated. We achieved 99.1% accuracy in score stage merging and 98.4% accuracy in feature level fusing. Nassima Kihal et al. [12] have developed a multimodal ocular biometric system to authenticate. They have used iris texture and the cornea form as a biometric characteristic. Iris texture features are extracted using Log Gabor and cornea features using Zernike polynomials. Once the characteristic of the iris and cornea has been extracted, they carry out a matching operation and scores for iris and cornea are calculated. Later applied fusion to the score and obtained EER 0%, FRR 0% to 0.1% FAR. Aman Kathed et al.[13] proposed 3-level authentication system using the biometric features of the face, iris and voice. Initially, the characteristics of the face and iris features are extracted and merged to form final feature vector. The fused features are stored in database. The

subsequent test data is compared to the stored features and if a match is found, the OTP generating system will send OTP to the user. This one-time password is saved as a user's voice and compared to the voice information stored in the database. If the user's voice matches, the user is authorized user.

III. METHODOLOGY

A. Local Binary Pattern

Local Binary Pattern is rotation and grey invariance which is used to extract textual features. It functions on a 3 * 3 window with the central pixel as a threshold [7]. Threshold pixel value is compared to its adjacent 8 pixel values. The pixel value is marked as 1 when the pixel value exceeds the center pixel value, otherwise it is 0. The central pixel value in the 3 * 3 window is equated with its 8 neighbours to produce an 8-bit binary number, which is converted to LBP code. Overall contrast is standardized using Histogram equalization.

The mathematical expression for LBP operation is:

$$LBP_{S,P} = \sum_{y=0}^{S-1} 2^y g(i_y - i_c) \quad (1)$$

$$\text{Where } g(i_y - i_c) = \begin{cases} 1 & i_y - i_c \geq 0 \\ 0 & i_y - i_c < 0 \end{cases} \quad (2)$$

Where S is the number of neighbors, i_y represents neighbor pixel in radius P and i_c represents centre pixel value. After encoding, histogram is calculated using the Eq. (3).

$$H(m) = \sum_{i=0}^I \sum_{j=0}^J f(LBP_{S,P}(i,j), m), m \in [0, M] \quad (3)$$

$$\text{Where } f(x,y) = \begin{cases} 1 & x = y \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

In this case, M represents the maximal LBP pattern value.

Fig. 1. LBP operation.

Fig. 1 illustrates LBP operation. It obtains the binary pattern= 11110101 and the corresponding LBP Code is: $1x2^0+1x2^1+1x2^2+1x2^3+0x2^4+1x2^5+0x2^6+1x2^7=245$.

B. Local Ternary Pattern

LTP is advanced version of LBP with 3-valued codes; 0, 1, -1 and more robust to noise[14]. LTP will define a threshold t and works as follows; assigns 1 for any pixel with value above t, -1 in case the pixel value is less than -t and 0 if the pixel value is in between -t and t. To get rid of the negative values, upper and lower patterns are constructed after thresholding step. LTP is the concatenation of upper and lower pattern.

LTP is defined mathematically as Eq. (5) and (6):

$$LBP_{S,P} = \sum_{y=0}^{S-1} 2^y h(i_y - i_c) \quad (5)$$

Where

$$h(x) = \begin{cases} 1 & x \geq t \\ 0 & -t < x < t \\ -1 & x < -t \end{cases} \quad (6)$$

Where i_y represents the value of the neighbour pixel of central pixel with radius P , i_c represents central pixel value and S is the number of neighbours. The neighbour is estimated using bilinear interpolation when it is not falling exactly in the centre of the pixel. After this encoding step, using following equation histogram is created using equation (7) and (8).

$$H(m) = \sum_{i=0}^1 \sum_{j=0}^1 f(LBPS, P(i,j), m), m \in [0, M] \quad (7)$$

$$\text{Where } f(x,y) = \begin{cases} 1 & x = y \\ 0 & \text{otherwise} \end{cases} \quad (8)$$

In this case, M represents the maximal LBP pattern value.

Fig. 2 illustrates operation of LTP, here threshold value is 5; central pixel 34 is compared with 8 neighbour pixel values. If neighbour pixel value is greater than $34+5$, then pixel value is defined as 1, if pixel value is less than $34-5$, then set the pixel value is set to -1 and if the pixel value is in between $34+5$ and $34-5$, then set the pixel value is set to 0. The upper and lower pattern are constructed and concatenated to get final LTP code.

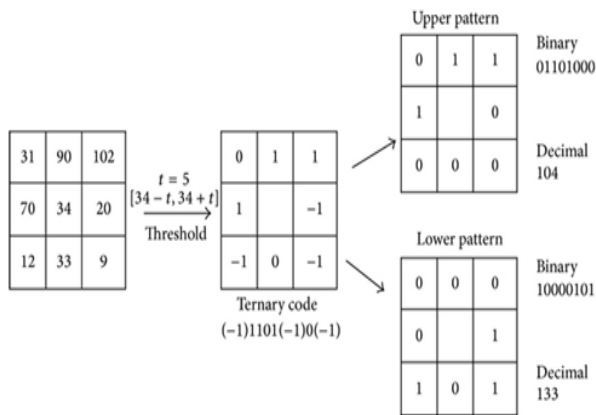

Fig. 2. LTP operation.

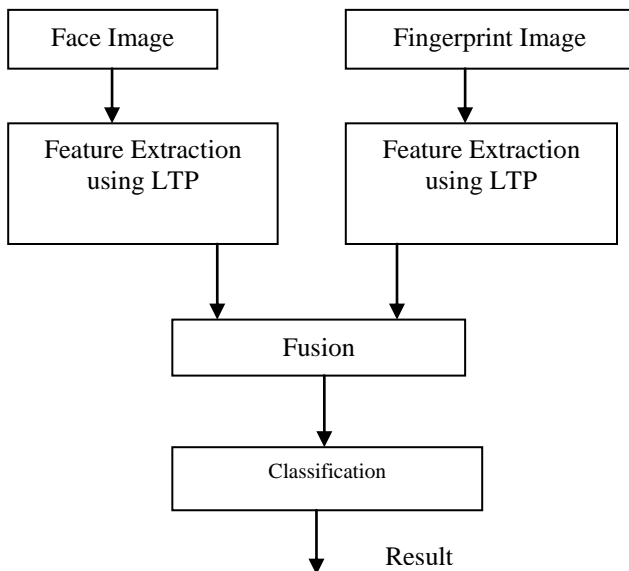

Fig. 3. Architecture of the introduced system.

The Fig. 3 represents proposed method; LTP is a texture descriptor that captures the local texture patterns of an image by comparing the pixel intensities of a central pixel to its neighboring pixels. Initially apply LTP on face image and compute LTP histogram as feature for face. Similarly extract apply LTP on fingerprint and compute LTP histogram as fingerprint feature. Then combine LTP face and fingerprint features to form final feature vector. Then classification is done using Euclidian distance.

IV. RESULTS AND DISCUSSION

To evaluate the efficiency of the system implemented, experiments are carried out on ORL, UMIST, VISA standard face dataset and FVC fingerprint dataset. The Fig. 4 is the sample images of ORL dataset. ORL dataset consists of 10 samples of 40 persons, with different pose. The Fig. 5 shows the sample images from UMIST dataset. UMIST dataset consist of 400 images of 20 persons with 20 samples. The Fig. 6 shows sample images of VISA dataset. There are 500 images of 100 people with five samples each in the VISA dataset. The Fig. 7, 8, 9, 10 shows DB1, DB2, DB3, DB4 of FVC dataset respectively. FVC dataset consists of four databases. Each dataset consists of 80 images of 10 persons with eight samples each with different resolution and orientation.

Fig. 4. Sample images from ORL dataset.

Fig. 5. Image samples from UMIST dataset.

Fig. 6. Image samples from VISA dataset.

Fig. 7. Image samples from FVC DB1 dataset.

Fig. 8. Image samples from FVC DB2 dataset.

Fig. 9. Image samples from FVC DB3 dataset.

Fig. 10. Image samples from FVC DB4 dataset.

Fig. 11. Recognition rate of LBP on ORL dataset.

The Fig. 11 represents hypothetical outcome of LBP on ORL dataset giving highest accuracy 93.5%. The Fig. 12 shows experimental results of LTP on ORL dataset with highest accuracy 98.13%. Experiment is conducted on different test and training combination. The 1st Experimental setup consists of 1st to 4th indexed samples for training and 5th to 10th samples were used for testing. In the 2nd experimental setup 1st to 5th samples were utilized for training and 6th to 10th samples were considered for testing. Similarly in the 3rd experimental setups, 1st to 6th samples were used for training and 7th to 10th samples are utilized for testing. The fourth experimental setup used odd indexed samples for training and even indexed samples for testing. The last experimental setup was also based on training even indexed samples and testing odd indexed samples. From the above result it is clear that LTP based face recognition gives better accuracy than the LBP based face recognition.

Fig. 12. Recognition rate of LTP on ORL dataset.

Fig. 13. Recognition rate of LBP on UMIST dataset.

The Fig. 13 represents hypothetical outcomes of LBP on UMIST dataset giving highest accuracy 97.5%. The Fig. 14 shows experimental results of LTP on UMIST dataset with highest accuracy 99%. Experiment is conducted on different test and training combination. The 1st Experimental setup consists of 1st to 8th indexed samples for training and 9th to 20th samples were used for testing. In the 2nd experimental setup 1st to 10th samples were used for training and 11th to 20th samples were considered for testing. Similarly, in the 3rd experimental setups, 1st to 12th samples were utilized for training and 13th to 20th samples are utilized for testing. In the 4th experimental setup odd indexed samples were utilized for training and even indexed samples were utilized for testing. Likewise, in the last experimental setup even indexed samples were used for training and odd indexed samples were used for testing. An experimental result on UMIST dataset shows that LTP based face recognition is best as compared to LBP based face recognition.

Fig. 14. Recognition rate of LTP on UMIST dataset.

Fig. 15. Recognition rate of LBP on VISA dataset.

Fig. 16. Recognition rate of LTP on VISA dataset.

Fig. 15 and 16 show experimental results of LBP and LTP on VISA dataset with 97% and 98% accuracy respectively. The experimental setup 1 consists of index 1 sample in training set and 2, 3, 4, 5 indexed samples in testing set. Experimental setup 2 contains index 1 and 2 sample in training set and 3, 4, 5 indexed samples in testing set. Experimental setup 3 contains index 1, 2, 3 in training set and 4 and 5 in testing set. Similarly, experimental setup 4 consists of 1, 2, 3, 4 in training set and 5 in testing set. Experimental setup 5 contains odd indexed samples in training and even indexed sample in testing. Likewise, experimental setup 6 contains even indexed sample in training set and odd indexed samples in testing set. The experimental results show that LTP based face recognition gives better accuracy than LBP based face recognition.

Fig. 17. Recognition rate of LBP on FVC dataset.

Fig. 17 and 18 show experimental results of LBP and LTP on FVC fingerprint dataset with accuracy of 96.6% and 97.5% respectively. FVC dataset contains four different databases DB1, DB2, DB3 and DB4. Experimental setup 1 contains 1st to 4th samples in training and 5th to 8th in testing set. Experimental setup 2 contains 1st to 5th samples in training and 6th to 8th in testing test set. Similarly 4th experimental setup contains odd indexed sample in training and even indexed samples in testing. Last experimental setup contains even indexed samples in training and odd indexed samples in testing set. From the Fig. 17 and 18 we can say that LTP based fingerprint system gives high accuracy as compared to LBP based fingerprint recognition.

Fig. 18. Recognition rate of LTP on FVC dataset.

Fig. 19. Recognition rate of proposed system on ORL and FVC dataset.

Fig. 20. Recognition rate of proposed system on UMIST and FVC dataset.

The Fig. 19 shows hypothetical outcomes of proposed system on ORL and FVC dataset. The Fig. 20 shows hypothetical outcomes of introduced system on UMIST and FVC dataset. In experimental setup 1, training set consists of even indexed samples and testing set consists of odd indexed

samples. Experimental setup 2 contains odd indexed samples in training set and even indexed samples in testing set. In experimental setup 3, index 1 to 4 samples present in training set and 5 to 8 indexed samples present in testing set. Similarly 4th experiment contains 1 to 5 indexed samples in training set and 6 to 8 indexed samples in testing set. Likewise experimental setup 5 contains 1st 3 samples in training set and 4th to 8th indexed samples in testing set. Finally 6th experimental setup containing 5th to 8th indexed samples in training set and 1st to 4th samples in testing set. As compared to unimodal system the proposed LTP based multimodal system performs better.

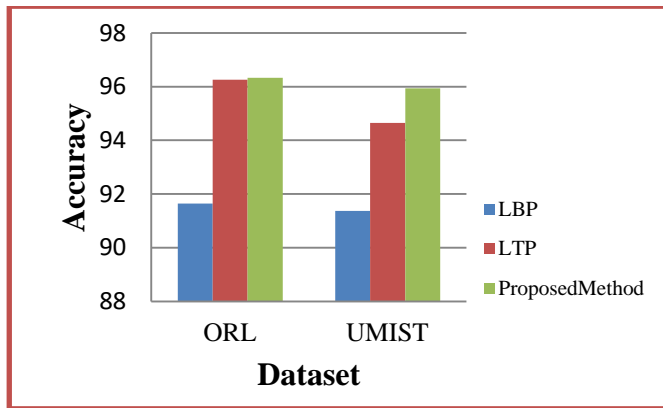

Fig. 21. Comparison of unimodal and multimodal systems.

The Fig. 21 shows a comparison between the unimodal and multimodal biometric system. In the experiments, it was found that the proposed LTP based multimodal biometric system with face and fingerprints is 96.33% accurate on the ORL_FVC dataset and 95.94% accurate on the UMIST_FVC dataset. The unimodal LBP and LTP based biometric system achieved 91.64% and 96.26% accuracy on the ORL dataset respectively and 91.37% and 94.65% accuracy on the UMIST dataset respectively. Therefore the proposed multimodal biometric system thus provides greater accuracy than a unimodal biometrics using LBP and LTP on different datasets.

V. CONCLUSION

A multimodal biometric system offers high security than unimodal biometric system. Face and fingerprint are easily available and universally adopted biometric traits. In this paper, we discussed unimodal face and fingerprint recognition system using LBP and LTP as well as compared it with multimodal biometric system using LTP. The proposed approach is invariant to noise in the input image. Also, by the use of two biometric traits it avoids spoofing attack. The experimental results show that the proposed LTP based multimodal biometric system using face and fingerprint performs better than unimodal biometric system. To improve accuracy, hybrid approaches can be introduced in the future.

Abstract—The majority of visual based surveillance applications and security systems heavily rely on object detection, which serves as a critical module. In the context of crime scene analysis, images and videos play an essential role in capturing visual documentation of a particular scene. By detecting objects associated with a specific crime, police officers are able to reconstruct a scene for subsequent analysis. Nevertheless, the task of identifying objects of interest can be highly arduous for law enforcement agencies, mainly because of the massive amount of data that must be processed. Hence, the main objective of this paper is to propose a DL-based model for detecting tracked objects such as handheld firearms and informing the authority about the threat before the incident happens. We have applied VGG-19, ResNet, and GoogleNet as our deep learning models. The experiment result shows that ResNet50 has achieved the highest average accuracy of 0.92% compared to VGG19 and GoogleNet, which have achieved 0.91% and 0.89%, respectively. Also, YOLOv6 has achieved the highest MAP and inference speed compared to the faster R-CNN.

Keywords—Object detection; deep learning; crime scenes; video surveillance; convolutional neural network; YOLOv6

I. INTRODUCTION

Due to the rising crime rate and offensive activities in recent times, it has become common to find CCTV cameras installed in public places such as shopping centers, avenues, banks, and so on. The purpose of these cameras is to enhance security and ensure the safety of the people in these areas. However, detecting weapons in surveillance videos still requires a lot of human intervention, which can result in errors [1]. Meanwhile, it is difficult for humans to constantly observe long videos or maintain multiple footage, and this can result in some rare crime scenes being missed out. As a result, there is a need to explore new technologies that can help improve the accuracy and efficiency of video surveillance in public places [2].

Recent surveillance cameras have the capability to record video only when motion is detected, unlike the older versions that record continuously irrespective of any activity. This feature enhances the efficiency of the system as it reduces processing time, search time, and the storage space required for the recorded videos [3,5]. Unfortunately, law enforcement agencies often follow a reactive approach, which results in delayed response times during crime incidents. In this approach, authorities rely on witness reports or CCTV footage to analyze the crime after it has occurred. This means when an incident takes place, investigators visit the site, manually

retrieve the footage from the camera, and then try to locate the appropriate footage either by watching the entire video or using advanced algorithms to process it which takes a long time. For this case, to improve the efficiency of the security management system and minimize crime incidents and losses, an effective crime prediction analysis system is needed. Such a system would enable proactive crime prevention and ensure robust security management in public places such as banks, shopping malls, and avenues [3,6].

With the availability of large datasets, faster GPUs, enhanced machine-learning algorithms, and better computations, we can now efficiently prepare PCs and construct automated computer-based systems to differentiate and identify various things on a site with high accuracy. For instance, a remote embedded intelligent security monitoring system has been developed using computer vision modeling algorithms to proactively detect intruders. This system utilizes a camera to acquire background images, which are then modeled using the ViBe algorithm to perform object detection in the monitored area [7]. When a moving object, including humans, is identified, the system automatically triggers an alarm and sends a message or call to the user to take preventive measures. To get a better understanding of the situation and detect the intruder, users can log in to the server via a mobile application. The system was implemented on an ARM development board, which provides a platform for hardware and software development. This technology is useful in enhancing security and safety in public places such as shopping malls, airports, and banks, where quick detection of intruders can help prevent criminal activities [3].

In contemporary times, machine-learning and advanced image-processing algorithms have significantly contributed to the evolution of smart surveillance and security systems, as evidenced by recent developments [3,6,7,8]. In addition, the rise of smart devices and networked cameras has also boosted this field. However, detecting and tracking human objects or weapons still require cloud centers as real-time, online tracking is computationally expensive. Recent years have seen significant efforts in monitoring robot manipulators, which require high control performance in terms of reliability and speed [9,10].

Another approach to detecting guns in surveillance films is to use pre-trained deep learning models. These models are intended to assist users in learning about algorithms or experimenting with current frameworks for better outcomes

without explicit design. A deep learning neural network generally has five layers: input and output layers with Convolution, Max-Pooling, and Fully connected layers. Many individuals choose to employ pre-trained deep learning models due to constraints such as limited time, memory, and resources such as CPU and processors [6,35]. When opposed to machine learning, which involves explicit design, these pre-trained models produce better and more accurate outcomes. However, identifying firearms in surveillance films is difficult and subject to human mistake unless it is used a detection system. For instance, human guards may become fatigued or fall asleep when viewing huge volumes of recordings or maintaining several footages, resulting in missed opportunities to discover uncommon criminal intention scenarios that may be caught in many footages. To solve this issue, pre-trained deep learning models may be used to eliminate the need for human interaction while identifying possible threats in public venues [11,34].

For that reason, it is important to design an autonomous surveillance system capable of detecting firearms fast and accurately in order to prevent crime. Deep learning techniques play an essential role here. Hence, we are developing a system which takes advantage of pre-trained deep learning models that are VGG-19 and ResNet50 to detect the firearms with object detection. These models were chosen because recent object recognition models need a large number of parameters and a significant amount of time to train. VGG19 and ResNet50 can extract high-level feature maps from input, reducing its complexity. The Faster RCNN method is also used to build bounding boxes around objects in pictures. The objective is to use neural networks to identify anomalies such as weapons and firearms and determine whether or not the individual carrying them has a criminal intent.

The rest of the paper is organized as follows. The next section will provide some context for our issue and highlight pertinent related works. Section III describes our proposed technique. Section IV describes the experiments and the outcomes. Finally, Section V summarizes the work and offers some perspectives.

II. RELATED WORK

The detection of metallic items that may represent a threat to public and homeland security is a major global concern [1]. Yet, screening for these devices might be difficult since it disrupts people's movements and creates a susceptible target for terrorist strikes [3,9]. In light of this, an automatic metallic item identification and categorization system is proposed. Two related areas are addressed in order to create and implement such a system; the development of a new metallic object detecting system and the establishment of a signal processing method to identify targeted signatures. The suggested approach is assessed by creating a database comprising of actual pistols and everyday items. Extraction of characteristics from four categories is used to examine system outcomes: time-frequency signal analysis, material composition, object form, and transient pulse response. Then, two categorization approaches are used to differentiate between hazardous and non-threatening things. The new system's feature combining and

classification framework achieves a successful classification rate of more than 90% [8,12].

A. Handgun and Knife Detection in CCTV

Another method is to use (CCTV). The use of Closed-Circuit Television (CCTV) systems has become increasingly common in various settings, including offices, residential areas, and public spaces, and has been implemented in many countries. To enhance the effectiveness of these systems, image segmentation techniques are employed to track activities captured by CCTV cameras and apply machine learning algorithms [1,10]. Grega [13] for example, published an algorithm that recognizes knives and guns in CCTV images and warns the security guard or operator. The algorithm's specificity is 94.93% and sensitivity is 81.18% for knife detection, focused on reducing false alarms and delivering a real-time application. Furthermore, the specificity for the fire alarm system is 96.69% and the sensitivity is 35.98% for the various items in the movie. Author [14] developed a video classifier, also known as the Histogram of Directed Tracklets, that recognizes irregular circumstances in complicated sequences. In contrast to typical optical flow techniques that only assess edge characteristics from two consecutive frames, descriptors known as tracklets have been evolving across long-range motion projections. Spatiotemporal cuboid film sequences are statistically gathered on the tracklets that travel across them [15].

B. Automatic Handgun Detection using Machine Learning

Although there has been a recent advance in image-based machine learning, recognizing a knife-wielding assailant remains difficult. To address this issue, the authors [16] describe three approaches for automated threat detection utilizing various knife image datasets, with the goal of narrowing down plausible assault aims while decreasing false negatives and false positives. To begin, they employ a classification model based on Mobile Net in a sparse and pruned neural network that can notify an observer to the presence of a knife-wielding attacker with high accuracy (95%) and a low memory demand (2.2 MB). Second, they train a detection method (Mask RCNN) to segregate the hand from the knife in a single picture and give probable certainty to their relative placement, allowing for both bounding box localization and point threat inference. Finally, a Pose Net-based model assigns anatomical waypoints to narrow down threat features and decrease misconceptions of the attacker's objectives [4,17,18]. Furthermore, the authors identify and fix data gaps, such as the necessity to gather benign hands, which may impair the accuracy of the deployed knife threat detector. This study offers a thorough review of image-based warnings that may be used to prioritize and educate crime prevention strategies before any catastrophic results occur. Additional relevant study topics in this subject include, among others, Automated Handgun Detection Alarms in Videos Using Deep Learning, Automatic Visual Recognition of Armed Robbery, and Robust Item Detector Application for Visual Knife Detection [19,35].

Other authors proposed by analyzing the recorded films of the cameras. The author [8] describes a technology for automatically detecting handguns in surveillance films. By

recognizing weapons in films, categorizing items as either a gun or not, and forecasting whether a crime has happened, the system hopes to control occurrences of crime. The system's performance is compared to a sliding window proposal technique, and it is discovered that FRCNN and RCNN-based models trained on a dataset perform well. The algorithm can reliably anticipate crime occurrences even in low-quality films, yielding good results [5,20,31].

The author [21] details a conventional approach for identifying the position of an armed robber. The method focuses on detecting individuals who are holding a knife in various positions relative to other people. To accomplish this, the system uses skeleton silhouette algorithms that segment the body into distinct parts and identify the position of a raised arm holding a knife at different angles. Through this process, the system is able to successfully detect the presence of a knife.

The author [22] describes a visual method for detecting automated weapons, specifically knives held in hands. This approach utilizes novel object detection algorithms to identify visual knives within a given video dataset. One of the primary challenges is detecting knife rotations at varying scales and positions, which can be difficult due to the multitude of possible orientations and positions of the knife in the dataset. To address this, the system is designed to detect all possible knife orientations and positions. Feature extraction is accomplished using foreground segmentation and FAST (Features from Accelerated Segment Test) for feature detection. Classification is then performed using MRA (Multi-Resolution Analysis).

C. Automatic Hanggun Detection using Machine Learning

Meanwhile, Convolutional Neural Networks (CNNs) have shown exceptional performance in image processing and object recognition during the last few years. CNNs are a sort of neural network that is specifically intended to recognize pictures [23,24]. These networks are made up of numerous layers, each having its own function. The first (input) layer receives an image as input. The next layer (the convolution layer) applies a collection of filters to the input picture, which are themselves tiny images. This layer takes characteristics from the input picture and extracts them. The following layer (the pooling layer) decreases the previous layer's output by pooling together all the pixels in a fixed-size square of the input picture. This layer reduces the number of parameters and makes the network more error-resistant [16,25]. CNN is trained on a large dataset of pictures containing the items to be recognized in order for the network to learn the characteristics that identify each object and correlate them with a given class. After trained, the network may be used to recognize the required items in new photos [26]. CNNs have demonstrated considerable potential for a variety of applications, including self-driving vehicles, face identification, crime detection, internet of things-based photovoltaics monitoring, and even COVID-19 detection, because to their capacity to identify a wide spectrum of objects and their error tolerance. The upcoming Fig. 1 elaborates a CNN model that has applied for a weapon detection obtained [9].

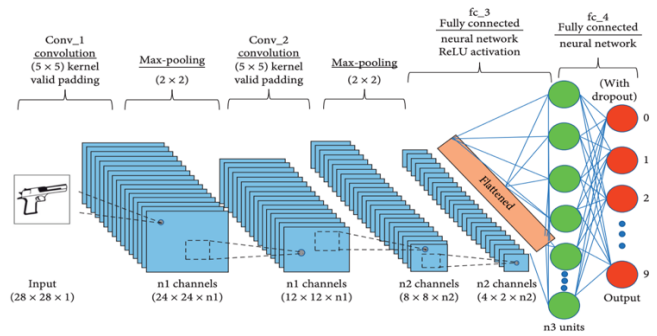

Fig. 1. Feedforward Convolutional Neural Network (CNN).

The cutting-edge YOLO V3 object identification model was applied and trained for obtained dataset for weapon detection in this work. Authors suggest a concept that gives a machine or robot a visionary sense to recognize dangerous weapons and can also inform a human administrator when a gun or a firearm is seen in the edge. +e experimental data demonstrate that the trained YOLO V3 model outperforms the YOLO V2 model and is less computationally costly. There is an immediate need to improve the present surveillance capabilities by providing better resources to enable monitoring the efficacy of human operators [27,32,33].

The phrase "backbones"[29] in the realm of object detection refers to the parameters or weights used to construct feature maps. These backbones are an essential component of the feature extractor since they generate the features that will be utilized for object detection [28]. There are several backbones that may be used for this purpose, each with its own set of benefits and downsides. The visual geometry group (VGG), (ResNet) residual neural network are among the most often used deep learning convolutional neural network (CNN) backbones in object detection techniques [30]. In terms of speed, efficiency, and accuracy, each of these designs offers various trade-offs. However, the proposed model will be applied VGG, ResNet and GoogleNet. The algorithms which we propose are able to detect the human operator when a gun is visible in the image.

III. PROPOSED MODEL

The aim of this study is to address the challenge of identifying indications of automated criminal intention and identifying hazardous circumstances using closed-circuit television (CCTV) systems. The primary objective of this research is to expedite the identification of weapons with improved precision and decreased false positives when compared to machine learning techniques, while also ensuring that convolutional neural networks (CNNs) maintain performance efficiency with fewer training samples. Pre-trained models such as GoogleNet and VGGNet-19 have been trained using millions of photographs, and possess the capability to recognize objects in new images with minimal errors. Owing to their superior training accuracy, we have opted to utilize the VGGNet19, GoogleNet, and ResNet50 models to effectively categorize and recognize objects.

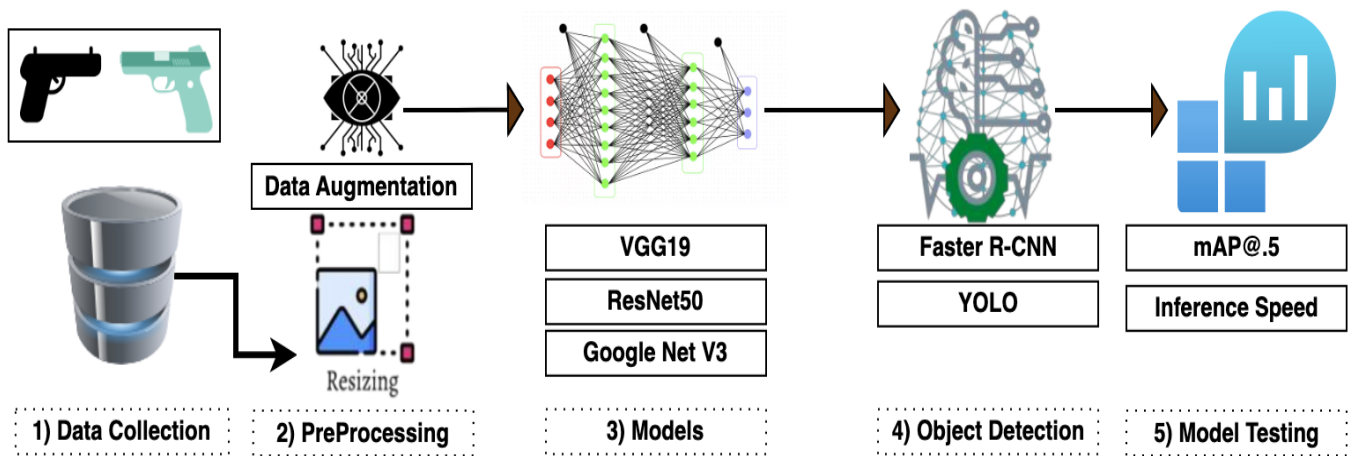

Fig. 2. Proposed model.

The diagram presented in Fig. 2 illustrates the all-encompassing design of the system under consideration. At the initial stage, input frames are received through the input layer, which is also responsible for conducting pre-processing activities as data augmentation. After undergoing pre-processing, the images are transferred through various layers, such as Convolution, Max-pooling, and FC layers, which perform a range of operations including feature extraction, feature filtering, feature mapping, and classification. And, the object detection layer is responsible for detecting objects and classifying, and in the event of any detected criminal intentions, it utilizes a registered API to dispatch a security message after model testing. The explanation of each step will be explained in a detailed way.

The first step involves gathering a comprehensive collection of positive firearm images that depict guns of various sizes, angles, and colors. These images are then segregated into designated "weapons" folders. Additionally, negative images resembling guns are also compiled and stored in separate folders labeled "not weapons". The open pictures dataset V6, a widely utilized dataset containing over nine million photographs, is used to source the data. This dataset features several images of firearms and bladed weapons that can be used to train machine learning models to effectively identify criminal activity in images. For this purpose, three categories were extracted from the dataset, namely rifle (2072 images), handgun (607 photos), and shotgun (476 images), although some researchers have extracted six categories, we only extracted three categories. Subsequently, the three groups were forwarded to the pre-processing data level.

The second stage involved data pre-processing, which refers to the preparatory procedures that must be performed on images prior to analysis. This process may involve a range of activities, such as scaling or adjusting the image display. One of the critical tasks in data preparation is resizing the image to 256 x 256 pixels. This entails feeding input frames into the Input layer, which performs pre-processing operations on images of varying sizes (such as 256 x 256 width and height) and converts them to a standardized size of 224 x 224 x 3 (RGB values) by extracting RGB values from pixels. This guarantees that all data has a uniform size and can be easily

compared. Furthermore, it simplifies working with images that are not big which can be advantageous for training computers to detect objects. Meanwhile, another crucial aspect of data preparation is data augmentation, which can be achieved through various methods such as flipping, rotating, or scaling the image. This technique aims to increase the quantity of data available for training and enhance the system's ability to recognize objects from various perspectives. Effective data preparation is a crucial stage in object detection, as it can determine the success or failure of the system. Therefore, by resizing data and augmenting it, we can increase the likelihood of achieving desirable outcomes.

In the third stage, it involved fitting three object detection models, namely VGG 19, ResNet, and GoogleNet. Each of these models has its own set of advantages and drawbacks, making it essential to conduct a comparative analysis to determine the most suitable model for our specific data. For our dataset, we employed transfer-learning to fine-tune the models. Ultimately, it should be noted that DarkNet is undoubtedly the foundational model for YOLO.

In the fourth step, the object detection model was trained using the most optimal backbone model on both the train and validation sets, comprising 70% and 20% respectively. This facilitated the development of a highly accurate and dependable model, capable of recognizing a diverse range of objects. The model provided a robust foundation on which to build the model, ensuring its precision and reliability. The R-CNN and YOLO v6 object detection models were utilized in this study. Faster-RCNN was preferred over R-CNN and Fast R-CNN due to its superior accuracy and efficiency in object detection, enabling it to process complex images and capture intricate details. The latest version of YOLO, YOLOv6, was found to be the most advanced and user-friendly option, offering higher speed and accuracy compared to previous versions. Labeled data, specifically bounding boxes, were employed to train the object detection algorithms. These bounding boxes were used to define the location of objects in the images, while the labels provided information about the type of objects.

The final stage involved model inference, wherein the object detection models were tested on a separate testing set

comprising 10% of the data. This step was crucial in evaluating the accuracy and inference time of each model, as has been done in prior research. Testing the models on previously unseen data allowed us to determine their efficacy in practical scenarios.

IV. RESULTS AND DISCUSSIONS

In this section, we will explain the dataset description and elaborate different categories that we extracted from the dataset. Moreover, we will discuss and compare the output result of the three models in term of the accuracy, recall and F1-score. Also, we will present the detection output and finally discuss the comparative analyse as a benchmark.

A. Datasets Description

Open Images dataset is a collection of nine million images that have been annotated with image-level names, object bounding boxes, object segmentation masks, visual connections, and localized narrative. It has the biggest existing dataset with object position annotations, with 16M bounding boxes for 600 item types on 1.9M photos. Professional annotators drew the boxes mostly by hand to guarantee accuracy and uniformity. The images are quite varied and frequently feature complicated scenarios with several items. For our models, we had extracted only three categories (as seen in Table I).

B. Identify Comparing VGG19, GoogleNet and ResNet50

As we mentioned in the methodology, we have applied three distinct algorithms and the upcoming tables will illustrate their performance. The applied algorithms were VGG19, ResNet50 and GoogleNet and their accuracy, loss, precision, and recall will be discussing in the upcoming tables. Notably, ResNet50 algorithm performed remarkably well in the classification task compared to the VGG19 and GoogleNet, achieving accuracy scores of 0.92%, 0.91% and 0.89%, respectively.

Although VGG 19 demonstrated marginally superior F1-score compared to GoogleNet, it was also associated with a lower support score. ResNet50, on the other hand, surpassed both VGG 19 and GoogleNet algorithms, yielding an accuracy score of 0.92%, along with higher F1-score (0.94%) and recall (0.91%) scores, and comparatively higher support (45%). GoogleNet exhibited the poorest performance amongst all three algorithms, with the lowest accuracy score of 0.89% and the weakest performance across all other metrics.

The upcoming Table II shows the training accuracy of the VGG19. It can be seen that the overall average of the accuracy is 0.91%, yet it has also scored a good performance in term of F1-score by achieving 0.93%.

The next table which is Table III shows the training accuracy of the ResNet50. It can be seen that the overall average of the accuracy is 0.92%, and it outperformed compared to other algorithms which we have also applied the same with this dataset. In term of F1-score, it has also outperformed other algorithms by achieving 0.94% in the average total.

The next table which is Table IV demonstrates the training accuracy of the GoogleNet. It can also see that the overall average of the accuracy is 0.89%, this makes the poorest performance that has been achieved compared to other algorithms. In terms of F1-score, it has achieved a good accuracy but yet it is still lower than VGG19 which also makes the lowest performance.

On the other hand, the upcoming Table V demonstrates the mAP and inference-speed results of two object identification methods, namely Faster CNN and YOLOv6, which are known for their fast-processing times. The mAP is a crucial metric for evaluating object detection models, representing the (AP) of each object class. The ratio of (TP) to the sum of TP and (FP) is computed to determine the AP (FP). The mAP is a measure of an object detector's ability to accurately identify and differentiate different types of objects in an image. The symbol @0.5 implies that an intersection over union (IoU) threshold of 0.5 was used. IoU is a measure of how well a predicted bounding box or mask aligns with the ground truth data. Inference speed, measured in frames per second (FPS), indicates how many frames the algorithm can process per second.

TABLE I. DATASET DESCRIPTION

	Extracted categories	
0	Handgun	607 Images
1	Rifle	2072 Images
2	Shotgun	467 Images

TABLE II. TRAINING ACCURACY OF VGG19

Accuracy 100%	Training Accuracy of VGG19			
	Accuracy	Recall	F1-score	Support
0	0.90	0.88	0.95	43
1	0.91	0.92	0.93	112
2	0.93	0.91	0.93	163
Avg/Total	0.91	0.90	0.93	106

TABLE III. TRAINING ACCURACY OF RESNET50

Accuracy 100%	Training Accuracy of ResNet50			
	Accuracy	Recall	F1-score	Support
0	0.92	0.91	0.96	45
1	0.91	0.90	0.94	108
2	0.94	0.93	0.92	170
Avg/Total	0.92	0.91	0.94	107

TABLE IV. TRAINING ACCURACY OF GOOGLNET

Accuracy 100%	Training Accuracy of GoogleNet			
	Accuracy	Recall	F1-score	Support
0	0.88	0.90	0.92	26
1	0.90	0.89	0.91	94
2	0.89	0.91	0.90	160
Avg/Total	0.89	0.90	0.91	93

TABLE V. RESULT OF MODEL DETECTION

Algorithm	MAP	Inference-speed
Faster R-CNN	61.82	8
YOLOv6	63.12	68

The two algorithms exhibit different mAP scores and inference-speeds. (R-CNN), which is faster than the other method, achieved the highest score of 63.12%. However, it has the slowest inference speed of 8 frames per second (FPS). Conversely, YOLOv6 obtained the highest mAP@.5 score of 63.12%, but it has the slowest inference speed of 68 FPS.

C. Output of Gun Detection Result

The upcoming Fig. 3 demonstrates the output of the models for detecting the gun and classifying based on the object detected. Though we have not applied to send notification through API but it is important to make a separate comparing by which gun is detected.

Fig. 3. (a) Rifle detection. (b) Handgun detection.

D. Comparative Analysis

Previous studies in this field have applied a range of models to detect firearms, as mentioned earlier. For instance, Author [1] developed a system utilizing VGG-19 to identify a weapon in a person's hand pointing at someone else, while Faster RCNN was used to draw bounding boxes around objects in images, resulting in an accuracy of over 80%. In comparison, our VGG19 model achieved an accuracy of 0.91%. It's worth mentioning that other researchers [4] used YOLOv5 and achieved a MAP of 56.92 and an inference speed of 61, but our model, utilizing YOLOv6, achieved a higher MAP of 63.12 and a faster inference speed of 68.

V. CONCLUSION

Deep learning object detection systems have the capability to offer significant benefits to officers and security professionals, as they can help in efficient way and not consuming much resources for forensic tasks. However, deploying artificial intelligence (AI) in this field raises concerns about possible misuse by law enforcement organizations, such as accusing innocent people or detecting bogus offenders. Our presented algorithms are capable of alerting human operators when a gun is detected in an image. In this study, we developed and assessed a system using a dataset of photos and videos obtained from the open images dataset V6, which contains over nine million images. Our results demonstrate that an early warning system in risky situations could lead to quicker response times, more efficient

reaction times, and fewer potential casualties. Additionally, the proposed method outperforms other known approaches to crime detection. For further improvement, it would be novelty if it has incorporated other modalities such as audio or text data and this could improve the accuracy of the models.

Hand Gesture Recognition Based on Various Deep Learning YOLO Models

Soukaina Chraa Mesbahi, Mohamed Adnane Mahraz, Jamal Riffi, Hamid Tairi

Laboratory of Computer Science, Signals, Automation and Cognitivism (LISAC)-Department of Computer Science-Faculty of Sciences Dhar El Mahraz, Sidi Mohamed Ben Abdellah University, Fez, Morocco

Abstract—Some varieties of sign languages are used by deaf or hard-of-hearing people worldwide to interact with others more effectively, consequently sign language's automatic translation is expressive and important. Significant improvements in computer vision have been made recently, notably in tasks based on object detection using deep learning. By locating things in visual photos or videos, the genuine cutting-edge one-step object detection approach greatly provides exceptional detection accuracy. With the help of messaging or video calling, this study suggests a technique to get beyond these obstacles and enhance communication for such persons, regardless of their disability. To recognize motions and classes, we provide an enhanced model based on Yolo (You Look Only Once) V3, V4, V4-tiny, and V5. The dataset is clustered using the suggested algorithm, requiring only manual annotation of a reduced number of classes and analysis for patterns that aid in target prediction. The suggested method outperforms the current object detection approaches based on the YOLO model, according to experimental results.

Keywords—Neural network; deep learning; YOLO; object detection; hand gesture

I. INTRODUCTION

In human-computer interaction (HCI), the hand represents a necessary role as a medium of interaction [1]. Verbal and non-verbal communication can be roughly categorized as forms of communication. A gesture is a type of nonverbal communication in which the movement of the hand, face, or other body parts conveys a specific message [2]. The hand is the most aspect of body language used to make gestures for creating communication. There are two types of hand gestures: static and dynamic. The postures in which stable shapes of the hands are represented by static hand gestures and the dynamic hand gestures contain a series of image sequences. For many computer vision applications [3], including hand action analysis, human-computer interaction, sign language identification, virtual reality, and driver hand behavior monitoring, hand gesture recognition and detection in cluttered situations is a key task. The main goal [4] of this research is to identify the challenge of detecting and recognizing static hand gestures when the hand adopts positions to convey particular meanings. Due to the numerous hand configurations and angles with respect to the image sensor, this problem exhibits a high level of complexity, making it challenging to recover the hand shape. Otherwise, in many applications, such as driver hand monitoring and hand gesture commands to prevent driver distraction, sign language recognition for deaf and speech-impaired people, and many more applications, identifying

static hand motions plays a vital role. The gesture of a hand and the location of its fingertips are necessary information for a computer to comprehend the state of the interaction medium. Recognizing hand gestures is evenly essential to interpret sign language [5].

Hearing-impaired try to find basic necessities similar to normal human beings like learning, writing, teaching, communicating, reading which may not be easy for them. There are several forms of communication in the world in which people communicate with each other. One of these means of communication is sign language. Sign Language is a natural conversation that frequently hearing-impaired people utilize for communication. Occasionally, to let hearing-impaired people communicate easily with normal people, this Sign Language has to be maintained by technology to identify the sign language [6].

The recognition of sign language represents the technology that makes the computer to recognize the sign utilized with the signer and reform it to text with the help of some algorithms.

Speaking and writing are not used to communicate spoken languages; instead, facial expressions, body language, and hand gestures are used. Due to the peculiarity that these languages are expressed by visual rather than aural means, this clearly sets them apart from other languages and creates a unique language barrier because sign languages have quite different ways of expressing and interpreting ideas. Furthermore, spoken languages are more common than sign languages. Research on the translation of sign language is not as advanced as that of spoken language due to the dearth of texts that permit research access to language. For instance, there isn't a ready-to-use digital sign language translation tool that can translate between spoken and sign languages as well as vice versa.

Language can be also the construction of mimic, gesture, the finger-spelling, and hand sign, in addition to the hand position. By using their bodies, particularly their hands, fingers, and arms, hearing-impaired people can interact nonverbally by using sign language. In the field of computer vision, it is crucial to be able to recognize patterns in movies or images. An essential task in the field of computer vision [7] is to identify indications in movies or images. Constantly understanding what signers are seeking to communicate or describe needs recognizing the numerous hand gestures they use. Arabic Sign Language, American Sign Language, Indian Sign Language, Indonesian Sign Language, and others all have diverse sign language structures [8]. One of the main areas of

study in computer vision and machine learning is object detection. Lately, object detection becomes the key to solving real-world problems in applications such as face detection, object Tracking, video surveillance, autonomous vehicles, face detection, pedestrian detection, etc. [9]. Object detection presents an important task of detecting a custom object in images or video, etc. These images or videos contain many objects or a few objects at multiple positions. This task is accomplished by providing the list of different objects that are in the image, providing the object's coordinates and information about the object's location in the image. Supplementary information comprises a bounding box that designates the location as well as the probability with which the object was detected. Supplementary information comprises a bounding box that designates the location as well as the probability with which the object was detected.

The practice of classifying data so that a model can make decisions and take action is known as data annotation. For a range of applications [10], including those that rely on machine learning to analyze images and robotic vision, computer vision, facial and hand identification, image annotation is crucial. To train these solutions, metadata must be attributed to the images in the form of captions, identifiers, or keywords. Image annotation increases precision and accuracy by adequately training these systems. Convolutional neural networks with regional learning are currently popular in detecting work. For object localization, RCNN, Fast RCNN, and Faster RCNN were developed [11]. Recently, the idea of You Only Look Once (YOLO) was used for localizing an area of interest. This work on hand gesture identification focuses mostly on classifying and identifying the gestures. As a technique, hand recognition uses a number of algorithms and ideas from other disciplines, like neural networks and image processing, to discover the movement of a hand. There are a number of object detection methods that help to identify the class and gesture that each algorithm is targeting. This study compares various algorithms and determines which one provides faster, more accurate results than the others. You Only Look Once (YOLO) v3, YOLO v4, Yolov4-Tiny Darknet, and YOLO v5 algorithms were used to analyze the structure and mechanism deduction of hand gesture recognition in order to realize this detection.

For several kinds of hand motions, we suggest a new dataset in this work. Our dataset includes everyday activities, people from various backgrounds and nations, as well as various lighting conditions. For 50,000 photos in our dataset, bounding box annotations are present.

The following are this paper's primary points:

- This work on hand gesture recognition primarily aims to categorize and identify the gestures.
- This paper examines several algorithms, You Only Look Once (YOLO) v3, You Only Look Once (YOLO) v4-Tiny darknet, and You Only Look Once (YOLO) v5 to evaluate the structure and mechanism deduction of hand gesture recognition.

- Our main objective is to describe the datasets, evaluation measures, and experimental setup that we employed for our evaluation.

The remainder of this paper is organized as follows. Brief reviews of several related research on hand detection and gesture identification are included in Section II. The proposed system is fully described in Section III along with an explanation of each component's purpose along with the dataset used. In Section IV the evaluation metrics, experimental setup, and comparison of the obtained experimental results are discussed. Section V discusses the results obtained. Finally, Section VI presents the conclusion.

We also provide a bounding box labeled dataset for object detection methods with this dataset, which contains over 40.000 carefully labeled photos.

II. RELATED WORK

Hand gestures can be recognized in a variety of data sources, including video and photographs, wearable sensors, etc. There are several types of research works on hand gesture recognition, The earliest technique for hand gesture recognition makes use of hand gloves with cables, sensors, LED markers, or other devices [12]. These techniques only provide accurate results when illumination conditions are stable, but classifying hands is a highly challenging problem. Many characteristics, including skin tone and velocity, have been suggested for the detection of hand motions [13], articulated models, hand crafted spatio-temporal descriptors, and trajectory based information. Convolutional neural networks' present success is inspired by deep feature based techniques, and researchers have developed a number of object identification and recognition techniques based on CNNs [14]. These techniques have been created and used for hand detection as a result.

Though, results from image recognition can be applied to tasks in various areas of computer vision, such as object detection using the methods YOLO, R-CNN, fast R-CNN, and faster R-CNN, or semantic segmentation using U-Net [15].

By Roy et al. [16] it was recommended to employ a two-stage hand detector on the basis of the region-CNN (R-CNN) and Faster R-CNN frameworks. To increase the robustness of the deep features, Le et al. [17] suggested a novel technique that incorporated local and global context information. By aggregating several scale feature maps, they expanded the region-fully convolutional network (R-FCN) and faster R-CNN. On two difficult datasets, the performance of this method was adequate. Tokenization is a pre-processing method that Orbay et al. [18] suggested improves the success of translations. If supervised data is available, tokens can be learned from sign videos. Annotated data is, however, hard to come by and expensive to annotate at the gloss level. To find semi-supervised tokenization methods without the burden of extra labeling, adversarial, multitasking, and transfer learning were used. To undertake a more thorough examination, it offers numerous experiments that compare all the approaches in various contexts. In order to take use of the parallelism that all sub problems share, Oscar and colleagues [19] suggested a technique that exploits sequence limitations inside each separate stream and combines them by explicitly enforcing

synchronization points. Using the hybrid method, embed strong CNN-LSTM models in each HMM stream. This makes it possible to identify traits that don't have enough discriminative power on their own. Utilizing the sequential parallelism to train sign language, mouth shape, and hand shape classifiers, the approach is then applied to the area of sign language recognition.

Convolutional neural networks were suggested by Gruber et al. [20] for the classification of sign language number motions. The collection contains recordings of 18 distinct people that were made with the Kinect v2 device. In this study, just depth datastream was employed. Classic VGG16 architecture was used for a classification challenge, and its outcomes were compared with the chosen baseline approach and other examined architectures. Research and development of the assistive mobile information robot prototype was presented by Ryumin et al. [21].

The single-handed gesture detection system, the technical description of the robotic platform architecture, and the navigation algorithm are all based on a database of elements used in Russian sign language.

A unique approach based on fusing conventional hand-crafted features with a CNN was developed by Chevtchenko et al. [22]. They tested their approach using depth and grayscale photographs, where the background is eliminated using depth information and the hand is taken into consideration to be the nearest object to the camera.

CNNs were used by Liang et al. [23] to extract features from point clouds that a depth sensor had recorded. Since the first object detection methods in computer vision were advised, object annotation in digital images has generally been taken into consideration. Numerous studies have focused on accelerating the annotation of picture datasets for object detection tasks. Multiple techniques for bounding box annotation were advised by Papadopoulos et al. The annotator just requires checking the label intended by the network in their bounding box verification approach [24] with an accept / reject decision by humans.

Learning intelligent dialogs that take into account the benefit of a trained network to build a bounding box on the image was advised by Konyushkova et al. [25]. To validate the bounding box suggested by the detector in each image, a human annotator is required. The first step in fully annotating the initial batch of images from the unlabeled dataset is hand annotation. Drawing bounding boxes and assigning class names to photos is an entirely manual process that requires human intervention.

To address the issues with RCNN, some writers [26] suggest Fast RCNN, where each and every image is fed only once to the CNN, and feature maps are created using a selective search technique. To shorten the time required to detect, Ren et al. developed a Faster R-CNN modification to the Fast RCNN extension [27]. In order to localize the hand position in a background with no clutter, Soe and Naing [28] used the Faster R-CNN technique using the Caffe framework. Using the NUS dataset, Pisharady et al. [29] showed the segmentation strategy to detect the hand posture and achieved

93% accuracy.

Convolutional Neural Network (CNN) technology is the foundation of YOLO [30], which may produce quick and accurate object recognition. The state-of-the-art object detection technique is very quick from beginning to end. YOLO is frequently used to forecast object detection tasks like real-time pedestrian detection, mask detection, and traffic sign recognition. After the hand position has been localized using YOLOv3, the hand gesture is fed to CNN so that the motion can be detected. The YOLO (You Only Look Once) approach predicts the detected object in the input photos after only one viewing by the neural network. It operates by dividing the input image into several grids with predetermined grid sizes, and then calculating the likelihood that each grid contains the target object [31]. In a single algorithm run, it predicts every class and object bounds that are present in the image. The YOLO algorithm is also constantly being improved in terms of accuracy, speed, and lightweight. Then, You Only Look Once (YOLO) is advised by Redmon et al. [32] to localize the area of interest. Rotation estimation was provided by Denget et al. [33] using CNN to localize the hand region. Deep attention networks for hand gesture localisation were developed by Yuan Li et al. [34].

Shinde et al. used YOLO, which can precisely identify and locate the group frames or even single frames of human movements in the video, to complete the recognition and location of human motions [35]. Based on the enhanced YOLO-v4 [36], Yu et al. proposed a face mask recognition and standard wear detection algorithm.

YOLOv5 was employed in some recent experiments to detect various items. Some recent research looked at replacing the manual inspection procedure with the YOLOv5 during the COVID-19 phase to check for the social distancing proposed by Shukla et al. [37] and face mask by Yang et al. [38] from video and still photos. The model developed by Wang et al. [39] for the detection of safety helmets and tree leaves has been applied in a few other researches. Again, in a number of studies, the YOLOv5 surpassed the R-CNN and other YOLO in terms of speed and accuracy. Then, these features are treated by an algorithm that identifies the specific hand gesture, such as Support Vector Machines (SVM) [11], Conditional Random Fields (CRF), Hidden Markov Models (HMM), and Convolutional Neural Networks (CNN).

After deep learning methods were established, CNN became a more widely used technique for replacing previous methods in object recognition and classification tasks. One of the most difficult issues in this area of computer vision is object detection. Localizing various items in a scene and labeling their bounding boxes are the goals of object detection. The most crucial strategy for solving this issue is to use already trained classifiers to give bounding boxes in scene names [40].

III. MATERIALS AND METHODS

The techniques and resources that were used in this study to achieve the hand gesture recognition that this paper focused on are assigned to this part. Fig. 1 depicts the suggested hand gesture recognition flowchart and the methodology that was used.

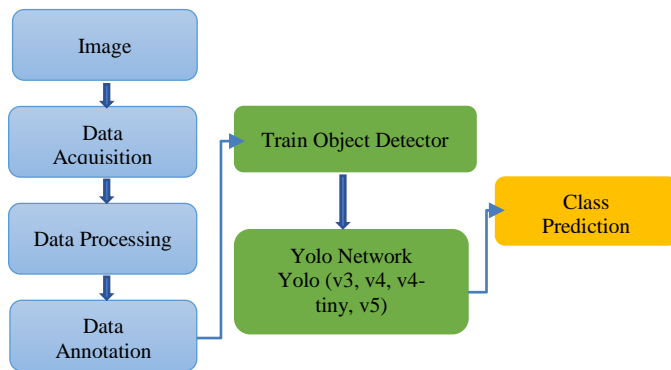

Fig. 1. The flowchart of the proposed hand gesture recognition.

The proposed method was divided into different steps. Firstly, the hand images were collected from the image database for tiny hand gesture recognition and underwent data augmentation to create a hand motions dataset. The captured image is passed through an annotation format to draw a Bounding boxbased hand detector to extract hand regions. Bounding boxes were manually drawn around specific objects in the images to annotate them. The hand region is then extracted once the hand has been recognized and transferred to a better Yolo (You Only Look Once) deep learning model. This model was then optimized and trained on the created datasets. The dataset has seven different gesture classes, such as a Fist, I, Pointer, Palm, Ok, Thumb up and Thumb down. To verify the detection performance, evaluation metrics were produced. The best model was ultimately chosen for the best hand detection across many images.

A. Dataset Collection

Data 1: This dataset [41] includes 1400 motions made by 14 distinct individuals, whom each made 10 different gestures and repeated them 10 times. The dataset includes a variety of distinct gestures that were captured using both the Leap Motion and Kinect devices, enabling the development and testing of hybrid gesture recognition systems that utilize both sensors, as suggested in the study, or the comparison of the two sensors.

Data 2: The dataset [42] [43] [44] includes a variety of static motions that were captured with the Creative Senz3D camera. While this camera works well for short range depth collection, its depth range is constrained, and its far range noise level is significant. It has been used to evaluate the performance of a Multi-Class SVM gesture classifier that was trained on fictitious data produced HandPoseGenerator.

B. Data Acquisition

In this paper, the hand images were collected from the image database for tiny hand gesture recognition. This dataset [43] has been collected from forty participants; each individual was invited to make seven different gestures. Each instantiation of a gesture consists of around 1400 color frames, and the gestures are carried out in various places throughout the image. The majority of the people have complex backgrounds, with the remaining 50% having basic backgrounds. Backgrounds that are thought to be complicated are extremely crowded, and the lighting varies greatly. The human face and body make up the majority of each image, whereas the hand gestures that need to be categorized only take up 10% of the total number of

pixels. We establish a dataset for different person classification and detection. Our dataset contained a total of 3600 images. These images were further divided into seven different classes. Each class comprises an average of 500 images which were labeled and annotated using the bounding box. Our classes started from palm to thumb down, which were finger-pointing different positions. The hand gestures in our dataset are shown in Fig. 2.

Fig. 2. Sample instances of each class from the dataset with the changes in hand position, shape, and scale.

C. Data Pre-processing

By artificially increasing the dataset, data augmentation is a key strategy for creating variations of the training and testing datasets. This step consists to utilize the augmentation techniques such as brightness transformation, randomly altering rotation, motion blur, blurring, and the scale of an input image necessitates that a model contemplates what an image subject looks like in a diversity of positions. Each image was repeated for reading and training, both for the left and right hand, by flipping it horizontally, and sometimes capturing the respective image of those hands to make the set more accurate, using a YOLO setup with a total of images from the dataset.

Additionally, each image for the testing set was captured and labeled. Before moving on to post-processing, it is vital to perform data pretreatment so that we can determine the type of data we have collected and which portions will be relevant for training, testing, and improving accuracy. This part presents the system or methods used to classify, select, and process as well as analyze data and its recognition of characters is discussed. The following methodology is employed to collect data in the form of images, preprocess the data, and then feed the processed data to our model.

1) *Manual annotation:* The annotation procedure, the training and validation set images were originally 240×240 pixels in size. We utilized the internet tool Roboflow to construct the bounding boxes for each image (www.roboflow.com). This page facilitates making data labels and annotating in the desired format. The images were annotated using the Roboflow Annotate, which is a self-serve annotation tool, and that greatly accelerates the transition from untrained and deployed computer vision models to raw images. After manually drawing and categorizing bounding

boxes, this tool makes it possible to change just one annotation or label throughout the whole dataset.

2) *Object detection*: The object detection model is trained in this section. We concentrate on the most recent deep learning-based object detection models, albeit any detector can be used. In the following part, we'll go into more detail about our training methods. To determine the existence, quantity, and placement of objects in a picture, object detection models are used. Drawing a bounding box around each object of interest in each image was necessary for the image annotation model, which enables us to determine the precise location and quantity of objects in an image. In contrast to image classification, where the class placement within the image is irrelevant because the entire image is designated as one class, the class location is a parameter in addition to the class. Bounding boxes and polygons are examples of labels that can be used to annotate objects inside a picture. Find the existence of things in an image using a bounding box and the types or classes of the objects you find.

a) *Input*: An image that includes one or more items, like a photo.

b) *Output*: A class label for each bounding box as well as one or more bounding boxes (each defined by a point, width, and height).

3) *Image data labeling with bounding box*: We have also produced a dataset with bounding box labeling so that we may utilize the characteristics of the deep learning detection technique. In order to reduce the difficulty and expense of labeling, we randomly choose a few images from each class in the dataset and choose to label the bounding boxes. The most popular annotation shape in computer vision is the bounding box.

Angular boxes called bounding boxes are used to specify where an object is located inside an image. Both two-dimensional (2D) and three-dimensional (3D) models are possible (3D). Polygons or rectangular shapes were manually drawn to annotate the object's edges and to mark each of the object's vertices. The x_center , y_center , width, and height of an object's boundary show its exact location in that image. As shown in Fig. 3, the rectangular shapes are used to label different hands.

Fig. 3. Labeling different hand classes with bounding boxes.

D. Labeled Dataset

In a labeled dataset, each element of the unlabeled data is given a meaningful "label", "tag" or "class" that makes it more desired or instructive to identify it. Bounding box inference in the training detection model continues until all unlabeled images have been manually fully tagged. In our model we annotated the dataset, we introduce seven different gesture classes, such as Fist, I, Pointer, Palm, Ok, Thumb up and Thumb down.

E. The Structure of the Proposed YOLO Algorithms

1) *You Only Look Once (YOLO)*: YOLO means You Only Look Once is a method that detects all objects in a frame or image in a single shot. Mainly, YOLO makes use of only convolutional layers, to determine which items are represented in the image, a single fully convolutional network (FCN) is used. The YOLO method divides the image into cells or grids; each cell is responsible for object localisation, estimating the number of bounding boxes, and calculating class probabilities. The dataset is collected from various people with various complex backgrounds at different positions, such as variable illumination, gesture variations, and low resolution. Labeling images is essential for good computer vision models. All the images are annotated and labeled manually with Roboflow Annotate which represents a self-serve annotation tool. In this study, we provide a dataset called "BdHand," to which we add bounding boxes to roughly 5000 images in order to make use of the potential of object detection techniques. After the first step of preprocessing and the manual annotation, the second one is training the deep learning models using modern YOLO algorithms (YOLO v3, YOLO v4, YOLO v4 Tiny, and YOLO v5). To understand the different algorithms which we are proposing, the diagram presented in Fig. 1 shows the detection of objects. At first, the first step in the training process is to gather the data, and the second is to label it. We label our dataset using YOLO annotation, which gives us certain values that are later detailed in the model process. We feed the dataset to the DarkNet-53 (YOLO v3) model afterwards, after it has been annotated with YOLO annotation.

2) *YOLO v3 Model*: YOLO v3 represents an improvement of the essential idea of YOLO, It enables partitioning an image into cells that are in charge of object prediction. Feature extraction networks and the use of detection at multiple scales are changes from YOLO, and the bounding boxes. YOLO v3 [45] presents a deeper architecture of a feature extractor named Darknet-53. It has 53 convolutional layers with a batch normalization layer and leaky Relu activation layer after each one. The feature maps are downsampled using a convolutional layer with stride 2 and without using any kind of pooling [46]. This aids in avoiding the loss of low-level characteristics that pooling is sometimes bed for. As illustrated in Fig. 4, our technique separates the input image using grids into an $S \times S$ region first. These cells are used to carry out operations on class probability and bounding box estimates. If the detection of an object in a grid cell is carried out by the object's center. There are now a variable amount of images in our dataset of

collected images. The classes we have stored for our YOLO technique are used to label these photographs, and once that is done, we have successfully determined the class and the coordinate for our image set. Additionally, we describe the method by which YOLO manages the network-aimed output, which is achieved by using a formula that requires various coordinates. The b_x, b_y, b_w, b_h are the variables that we employ for the bounding box dimensions and are associated with (x,y) coordinates that represent the center of the box, as well as the width and height, which are represented by p_w, p_h . The estimated four coordinates are t_x, t_y, t_w, t_h , a bounding box for each. The numbers c_x and c_y correspond to the grid cell's upper left coordinates. These variables, which reflect the box prediction components as defined by Equations, are predicted in relation to the entire image (Eq. (1) to (5)).

$$b_x = \sigma(t_x) + C_x \quad (1)$$

$$b_w = \sigma(t_y) + C_y \quad (2)$$

$$b_y = p_w e^{t_w} \quad (3)$$

$$b_h = p_h e^{t_h} \quad (4)$$

$$\sigma(x) = 1 / (1 + e^{-x}) \quad (5)$$

Fig. 4. The bounding boxes with dimension priors and location prediction.

Fig. 4 demonstrates how each value of the algorithm's bounding box gives us the x and y coordinates for the center.

3) *YOLO v4 model*: The one-stage object identification technique known as YOLOv4 represents the YOLOv3 model's evolution and significant advancement. The number of FPS (Frames per Second) increased by 12% and the mAP (mean Average Precision) by 10% as a result of the introduction of a new architecture in the Backbone and changes in the Neck [47]. The architecture of YOLOv4 is made up of the YOLOv3 head, PANet path aggregation neck, spatial pyramid pooling extra module, and Darknet53 as the backbone.

4) *YOLOv4-Tiny model*: The YOLOv4-tiny model is based on the YOLOv4 approach and is aimed to increase

object detection speed. The prediction process is the same as YOLOv4 and it has a faster target detection speed. YOLOv4-tiny [48] [49] is proposed to reduce parameters and make the network structure simpler and it significantly improves the viability of implementing object detection methods on embedded systems or mobile devices. The Yolov4-tiny method utilized Darknet53-tiny network as backbone network to instead of the CSPDarknet53 network that is used in Yolov4 method. The ResBlock module in the residual network is substituted by the Block module in the CSPDarknet53-tiny network. Fig. 5 depicts the YOLOv4-tiny network structure.

5) *YOLO v5 model*: The Backbone, Neck, and Head architectural components of the YOLOv5 network are shown in Fig. 6. YOLOv5 Backbone: In order to extract features from images, including cross-stage partial networks, YOLOv5 uses CSPDarknet as its backbone. YOLOv5 Neck: It makes use of PANet to create a feature pyramid network that is then passed to the Head for prediction after the features have been aggregated. YOLOv5 Head: Its layers produce predictions for object detection from the anchor boxes [50].

YOLOv5 is quick and lightweight, and it uses less computing power than other current state-of-the-art architecture models while maintaining accuracy levels that are comparable to those of current state-of-the-art detection models. Compared to the other YOLO versions, it is substantially faster. CSPNET serves as the foundation for YOLOv5's feature map extraction from the image. In order to improve information flow, it also makes use of the Path Aggregation Network (PANet) [51]. For the following reasons, we are utilizing YOLOv5 as it includes helpful elements like a cutting-edge activation function, a convenient manual, a hyperparameter, and a data augmentation technique. It can be trained computationally quickly with minimal resources, thanks to its lightweight architecture. The size model can be utilized with mobile devices because it is relatively tiny and light. Yolov5 differs from the Yolo series in several lighting areas: (1) Multiscale: utilize FPN to improve the feature extraction network rather than PAN [46], which will make the model easier to use and more quickly.

Yolov5 differs from the Yolo series in several lighting areas: (1) Multiscale: utilize FPN to improve the feature extraction network rather than PAN [46], which will make the model easier to use and more quickly. (2) Target overlap: identify nearby positions using the rounding method such that the target is mapped to several central grid points all around it. Yolov5 is a continuation of the YOLO series' most recent iterations [52]. It is more manageable and, in general, more cozy to utilize throughout training. Its architecture may be modified with equal ease, and it can be exported to numerous deployment environments [53].

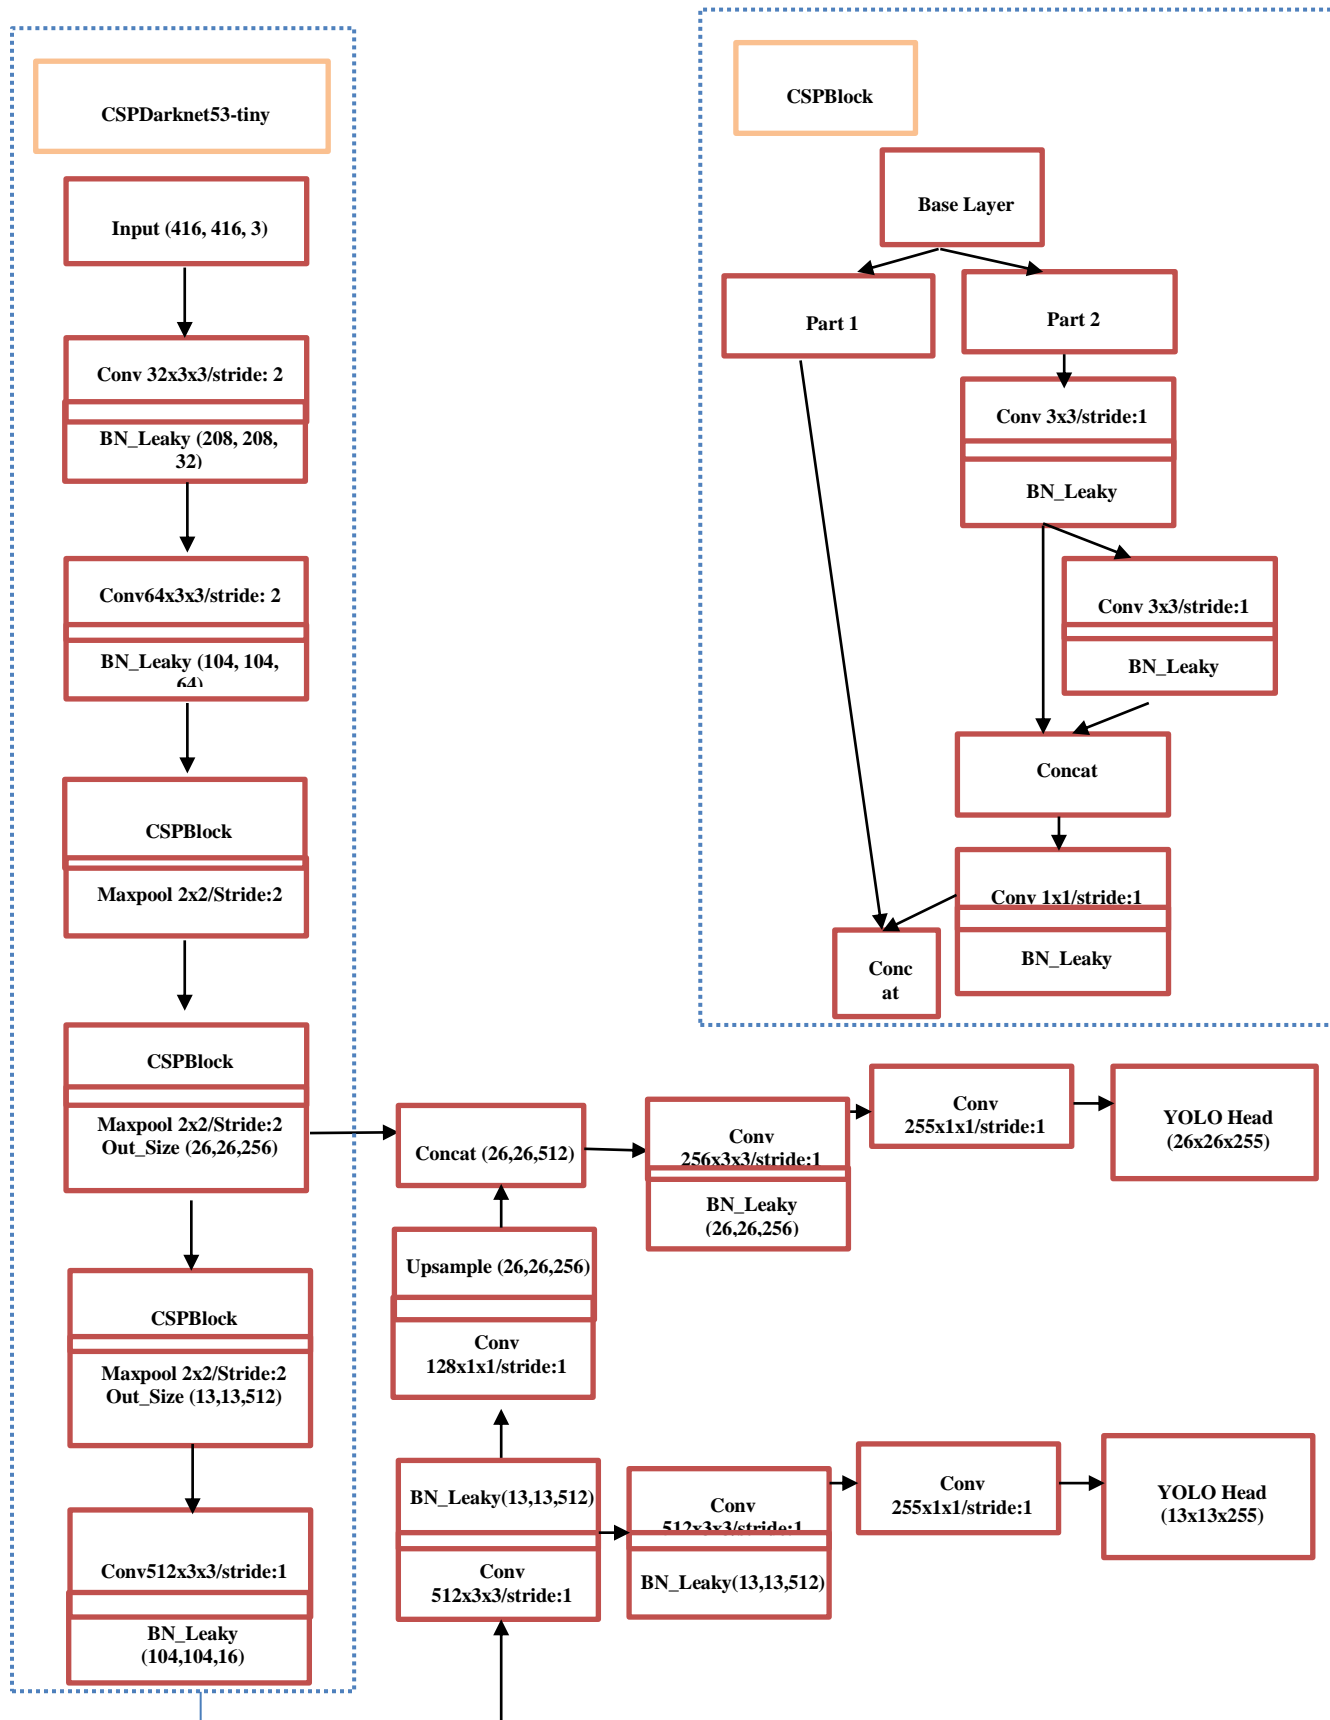

Fig. 5. The network structure of YOLOv4-tiny.

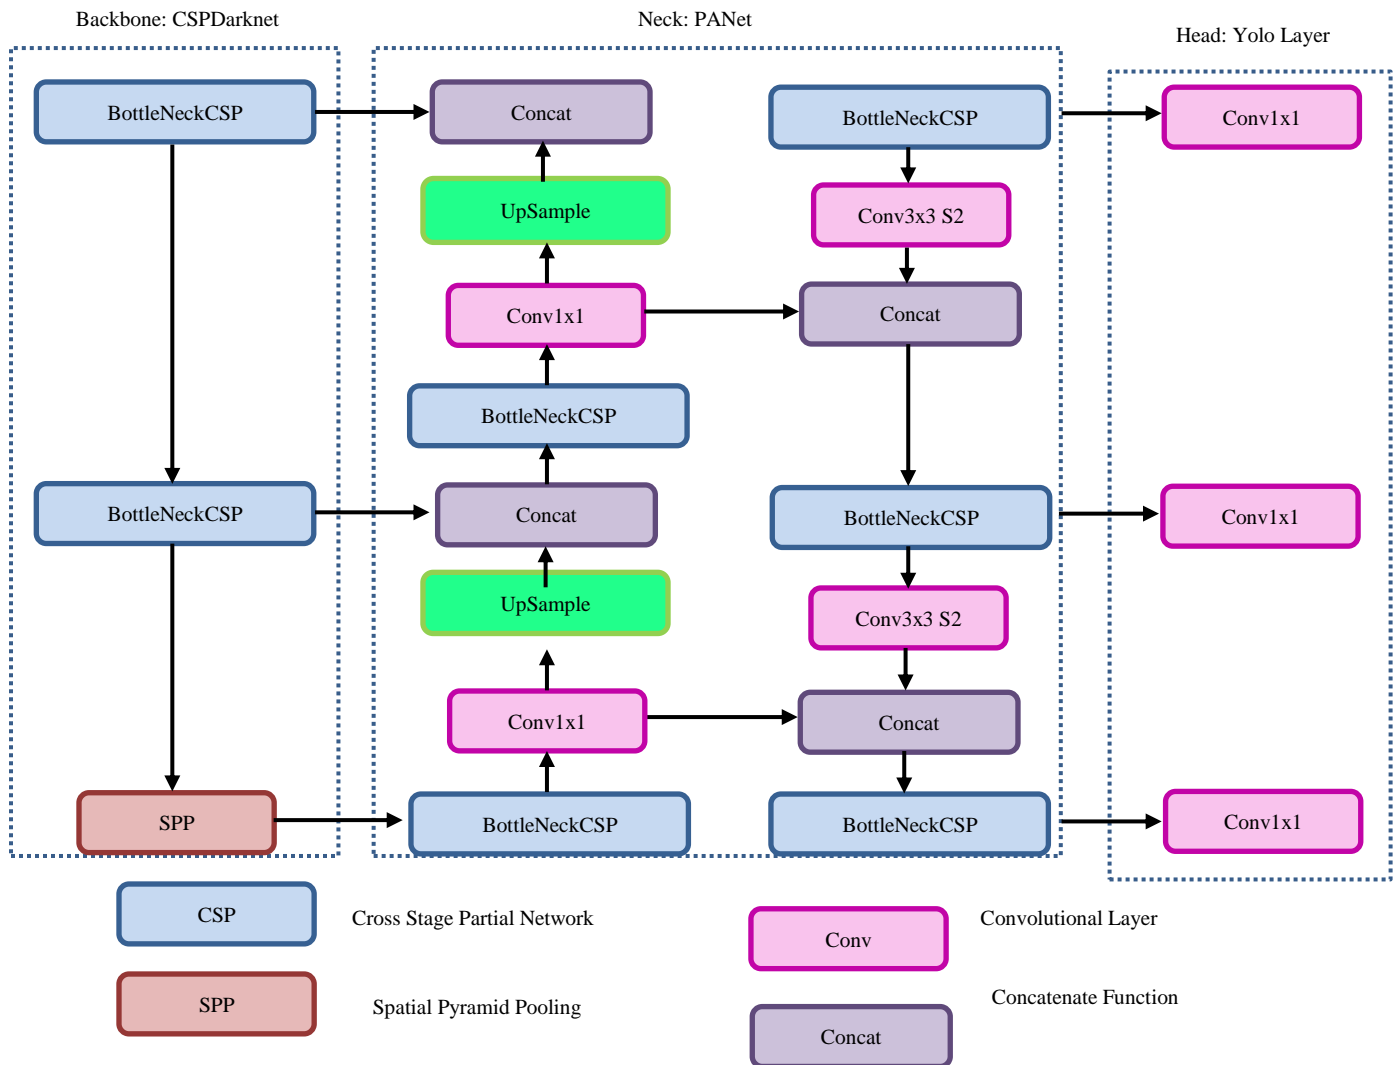

Fig. 6. The general architecture of the YOLOv5 network.

There are many algorithm parameters in the YOLO models, and understanding the influence of these parameters is essential for optimizing the performance of the model for a specific task. Here are some of the most important parameters in YOLO models and their influence:

- Input size: The input size of the YOLO model refers to the resolution of the input image. Larger input sizes cannot only improve the accuracy of the model but also increase the computational cost.
- Anchor boxes: Anchor boxes are predefined boxes of various shapes and sizes that are used to predict object locations and sizes. The number and aspect ratio of anchor boxes can significantly affect the accuracy of the model.
- Batch size: The batch size refers to the number of images processed in a single iteration during training. Larger batch sizes can speed up the training process, but they also require more memory.
- Confidence threshold: The confidence threshold is used to filter out low-confidence predictions. Increasing the confidence threshold can reduce the number of false positives but may also increase the number of false negatives.
- increasing the confidence threshold can reduce the number of false positives but may also increase the number of false negatives.
- NMS threshold: Non-Maximum Suppression (NMS) is used to remove overlapping bounding boxes. The NMS threshold controls the amount of overlap allowed between boxes. A higher threshold can remove more overlapping boxes but may also remove some true positives.
- Backbone architecture: The backbone architecture refers to the architecture used to extract features from the input image. Different architectures have different complexities and can affect the accuracy and speed of the model.

- Training parameters: Training parameters such as learning rate, weight decay, and optimizer can significantly affect the training process and the performance of the model.

The parameters in YOLO models can significantly affect the accuracy, speed, and memory usage of the model. Choosing the right parameters for a specific task requires experimentation and fine-tuning to optimize the performance of the model.

IV. EXPERIMENTS AND RESULTS

A. Evaluation Metrics

In this section, we discuss the four experiments performed using Yolo algorithms YOLO version (v3, v4, v4 tiny, and v5). We implemented and tested the four models during our experiments to train them for our different publicly available datasets. The configuration of these models differs from one to the other. Extensive testing was carried out during our research to confirm the dependability of the suggested YOLO model for hand gesture recognition. The experimental settings are presented in the first stage. The evaluation metrics are then described. The comparative experimental findings are then thoroughly examined and analyzed. To gauge the effectiveness of the proposed hand gesture recognition model in terms of recognition, detection, and computational performance, a number of indicators or metrics were used. The average precision (AP), which is shown as the area under the precision and recall curve at various detection thresholds, was used in this experiment. Eq. (6) contains a definition of the AP equation.

$$AP = \int_1^0 P_r(R_c) dR_c \quad (6)$$

Precision and recall are represented by Pr and Rc. The following parameters of precision, recall, and F1-score are calculated to estimate the model accuracy and the efficiency. When the predicted bounding boxes match the ground truth boxes, the accuracy of the prediction is measured. In addition to these measures, we used Eq. (7), (8), and (9) to derive precision, recall, F1-score, and accuracy using the True positive (TP), False positive (FP), and False negative (FN) metrics. The Precision (Pr), presented in Eq. (7), shows the ratio of true positives (TP) to all expected positives (TP+FP). As a result, it is a crucial measure for deducting the cost of the FP number.

$$P_r = \frac{Tp}{Tp+Fp} \quad (7)$$

If the predicted bounding box falls beyond the ground truth of the hand, it is indicated by the letters FP, whereas TP signifies that it does so. The likelihood of correctly detecting the ground truth objects is then calculated using recall. Accordingly, the Recall (Rc) shows the proportion of estimated true positives to all actual positives (TP+FN). It is created by Eq. (8) and is occasionally referred to as sensitivity. Instead of the projected bounding box, FN displays the hand of the frame.

$$R_c = \frac{Tp}{Tp+FN} \quad (8)$$

The F_1 -score measures the overall accuracy, this as shown

in Eq. (9), includes the recall values and a statistical precision measure. The F_1 -score should be chosen in particular when a balance between precision and recall is necessary, with an F_1 -score of 1 defining the optimal value.

$$R_c = \frac{2*P_r*R_c}{P_r+R_c} \quad (9)$$

Mean Average Precision (mAP), a well-liked object identification statistic created by Eq. (10), averages the AP values for all classes. As a result, the performance of the model may be quantified using a single metric.

$$mAP = \frac{\sum_{q=1}^Q AveP(q)}{Q} \quad (10)$$

Where Q is the number of queries in the set, q is the query for average precision. The mAP is the mean value of average precision for the detection of all classes and is an indicator generally utilized to estimate how good a model is. The FPS identifies how many images can be correctly identified in a single second. GPU utilization refers to the use of GPU RAM when evaluating various detection strategies.

B. Detection Results of YOLO Model

The output of the various classes of hand gesture recognition is shown in Fig. 7. The bounding box covered the maximum part of the hand. It will cleverly determine which gesture is being represented in the zoom situation when the object is too huge, and it then delivers the class ID with the best match. To determine which algorithm was the most effective for hand gesture detection, we used a variety of different ones.

Fig. 7. Detection results of YOLO v3 model.

416 x 416 pixels were chosen as the size of the input images for the training process. The outcomes of the hand detection test utilizing our suggested YOLO v3 model are listed in Table I. We calculated the mean average precision (mAP), then Precision (Pr), average recall (Rc), and F_1 -score for each test. Using the suggested deep learning model, we assessed the performance of deep learning models, and we were able to get an accuracy of 98.20% for YOLOv3.

TABLE I. PERFORMANCE ACCURACY FOR YOLOV3

Class	Precision %	Recall%	F1-Score	mAP(mAp@.5)%
Fist	62.40	96.80	73.60	93.70
I	88.40	97.10	91.40	96.40
Pointer	95.70	98.40	96.90	97.60
Ok	96.80	98.60	97.60	98.10
Palm	96.70	98.60	97.60	98.10
Thumb down	97.30	98.60	97.90	98.20
Thumb up	96.40	98.40	97.40	98.00

The suggested model also worked well in various lighting situations, as seen in Fig. 8. The experimental findings show that the proposed model can accurately and efficiently identify different classes of hands in a variety of situations.

Fig. 8. Detection results of YOLO v4 model.

Table II displays the experimental outcomes for hand gesture recognition using our dataset. This table compared the speed and accuracy of the various classes. Experiments show that 98.40% of the results are accurate.

TABLE II. PERFORMANCE ACCURACY FOR YOLOV4

Class	Precision %	Recall%	F1-Score	mAP(mAp@.5)%
Fist	97.10	98.50	97.79	98.20
I	97.90	98.60	98.40	98.40
Pointer	97.30	98.60	97.94	98.30
Ok	96.90	98.60	97.74	98.40
Palm	96.70	98.60	97.60	98.10
Thumb down	97.30	98.60	97.90	98.20
Thumb up	96.40	98.40	97.40	98.00

Fig. 9 depicts the process for detecting hand gestures. As these results exhibit, our proposed model can treat various shapes of hands, scales, and under various lighting circumstances, as well as comprehend motions in many difficult situations.

Fig. 9. Detection results of YOLO v4-tiny model.

We conclude that effective hand detection improves the performance of the gesture recognition system with quick processing, which in turn facilitates accurate human-machine interaction, based on the experimental findings provided in Tables II and III.

TABLE III. PERFORMANCE ACCURACY FOR YOLOV4-TINY

Class	Precision %	Recall%	F1-Score
Fist	1.0	92.30	95.00
I	97.0	92.20	94.82
Pointer	1.0	88.50	93.89
Ok	98.870	91.56	95.01
Palm	1.0	92.63	96.17
Thumb down	1.0	88.30	93.80
Thumb up	1.0	90.27	94.88

Fig. 10 introduces the results of test images that contain different people. The results of the experiments show that the suggested model can meet object detection in various complicated backgrounds where the majority of movements were successfully detected.

Fig. 10. Detection results of YOLO v5 model.

In this experiment, YOLOv5 performed better overall than YOLOv4, YOLOv4-tiny, and YOLOv3. In comparison to the other models, the YOLOv5 model produced the best results in terms of precision and error. Compared to YOLOv4, YOLOv5 is quicker and more accurate. The results showed that the mAP was much higher when YOLOv5 was compared to YOLOv3, YOLOv4, and YOLOV4-tiny for hand motion recognition. The most effective object detection method at the moment is YOLOv5 (refer Table IV).

TABLE IV. PERFORMANCE ACCURACY FOR YOLOV5

Class	Precision %	Recall%	F1-Score	mAP(mAp@.5)%
Fist	1.00	97.70	98.83	97.80
I	98.80	97.60	98.19	98.10
Pointer	99.9	96.40	98.11	96.70
Ok	98.60	1.0	99.29	99.10
Palm	99.60	1.0	99.79	99.50
Thumb down	1.0	98.10	99.04	98.60
Thumb up	99.80	1.0	99.89	99.50

V. DISCUSSION

YOLO (You Only Look Once) is an object detection algorithm that predicts the bounding boxes and class probabilities of objects in an input image. YOLOv3 and YOLOv4 are earlier versions of the algorithm, while YOLOv5 is a more recent version. Here are some of the differences between these versions:

- Architecture: YOLOv5 uses a different architecture than its predecessors. It has a smaller and more efficient model that makes use of Scaled-YOLOv4 architecture and advanced training techniques such as Mosaic data augmentation.
- Speed: YOLOv5 is faster than its predecessors, particularly YOLOv3, due to its smaller model size and improved architecture. YOLOv5 can process up to 155 frames per second on a Tesla V100 GPU, compared to 82 and 65 frames per second for YOLOv4 and YOLOv3, respectively.
- Accuracy: YOLOv4 is generally more accurate than YOLOv3, with improvements in object detection accuracy and speed. YOLOv5, on the other hand, achieves comparable accuracy to YOLOv4 but with a smaller model size and faster processing speed.
- Training: YOLOv5 uses a different training approach called self-supervised pre-training, which allows it to learn from large amounts of unlabeled data. This leads to better generalization and improved performance on smaller datasets.

The discussion is about the performance evaluation of a proposed deep learning model for hand gesture recognition. The model achieved an accuracy of 98.20% for YOLOv3, which was able to identify different classes of hands in various lighting situations. The Table I provided shows the precision, recall, F1-Score, and mAP scores for various hand gesture classes. The "Fist" gesture had the lowest precision score of 62.40%, while the "Thumb down" and "Thumb up" gestures had the highest precision scores. The recall scores were high for all classes, indicating that the model correctly identified a large proportion of actual positive instances.

The Table II shows the precision, recall, F1-Score, and mAP scores for various hand gesture classes. The precision scores for all classes were high, ranging from 96.4% to 97.9%. The recall scores were also high, ranging from 98.4% to 98.6%, indicating that the model correctly identified a large proportion of actual positive instances. The F1-Scores were all above 97%, indicating a high level of accuracy in detecting and recognizing hand gestures. The mAP scores were also high, ranging from 98.0% to 98.4%, indicating that the model was able to detect the objects with high precision across all the classes.

The Table III displays the precision, recall, and F1-Score for various hand gesture classes. The precision score for most classes is high, ranging from 1.0% to 98.87%. However, the precision score for the "Fist," "Pointer," and "Palm" classes is only 1.0%, which indicates that the model produced a large number of false positives for these classes. The recall score for

all classes was above 88%, indicating that the model correctly identified a large proportion of actual positive instances. The F1-Score for all classes was above 93%, which indicates a high level of accuracy in detecting and recognizing hand gestures.

Compared to the previous tables, this table shows higher precision, recall, F1-score, and mAP values for most of the hand gesture classes. The precision, recall, and F1-score for the "Fist" and "Pointer" classes have significantly improved from the previous table, reaching perfect precision for the "Fist" class and near-perfect precision for the "Pointer" class. The "Ok" and "Palm" classes also showed improvement in precision and F1-score, although their recall values were 1.0, indicating that there were no false negatives. The "Thumb down" and "Thumb up" classes also demonstrated high precision and F1-score values.

YOLOv5 is a more efficient and faster version of the YOLO algorithm with comparable accuracy to YOLOv4. While YOLOv3 is still a popular choice for object detection, YOLOv5 offers improved performance and training techniques.

Despite recent enormous advancements in object detection, it is still challenging to detect and classify objects rapidly and accurately.

The YOLOv5 method was cited by Yan et al. (2021) as the most potent object-detecting algorithm available today.

In the current study, YOLOv5 outperformed YOLOv4 and YOLOv3 in terms of overall performance.

As we discovered multiple studies comparing YOLOv5 to earlier iterations of YOLO, such as YOLOv4 or YOLOv3, this conclusion is consistent with some earlier studies. Thuan (2021) claims that YOLOv5 is more precise and quick than YOLOv4.

VI. CONCLUSION

The proposed technique using the YOLO model can significantly enhance communication for deaf or hard-of-hearing individuals, regardless of their disability.

The recent advancements in computer vision and deep learning have improved the accuracy of object detection, and this study utilizes this progress to develop a hand gesture recognition system. The model for hand gesture recognition is based on the deep learning models YOLO (YOLOv3, YOLOv4, YOLOv4-tiny, and YOLOv5) to recognize motions and classes in sign language. The experiments conducted show that the suggested YOLO model has exceptional detection and performance, with a 99.50% accuracy rate when identifying objects and gestures from various datasets. The proposed method clusters the dataset based on the suggested algorithm, which necessitates manual annotation of a number of classes and analysis for patterns that aid in target prediction. The results demonstrate that the suggested YOLOv5 method outperformed the YOLOv3, YOLOv4, and YOLOv4-tiny algorithms in all datasets and improved the hand detection performance. By leveraging messaging or video calling, this technique can help overcome the obstacles of communication faced by deaf or hard-of-hearing individuals and enable them

to interact with others more effectively. There are several directions this research can take. Another approach could be to use a combination of YOLO models for different stages of the hand gesture recognition pipeline. The YOLOv3 model could be used to detect the hand region in an image, and a YOLOv4 model could be used to classify the hand gesture. This approach could improve the accuracy of the system while also reducing the computational cost.

Abstract—Due to the advanced multimedia editing tools and supported by sophisticated hardware, creating image/video manipulations for malicious purposes is increasing which is almost impossible to detect manually. Moreover, to conceal the traces, different post-processing operations are performed. Therefore, authenticity is a growing concern and important for identifying original and forged images. One of the popular image manipulations is copy-move forgery in which one or more regions in the image are duplicated to create a malicious effect within an image. The work in this article presents redundant wavelet transform based complex Zernike moment and Scale Invariant Feature Transform (SIFT) keypoint matching technique for copy-move image forgery operation detection. SIFT is robust against scale and rotation that works on identifying similarity using exhaustive search of SIFT features. After extracting SIFT keypoint features agglomerative hierarchical clustering is employed for grouping and key point matching operation is performed. Finally, block matching operation is evaluated and forged regions in the manipulated images are marked and displayed. This work also presents optimized SIFT key-point feature computations resulting in lower computation time, often one of the requirements in real time deployment. The proposed algorithm performance is evaluated using Precision, Recall, F-Measure and average detection accuracy on popular and publicly available MICC-220 database. The proposed technique demonstrates improved speed-up and detection rate compared to existing approaches.

Keywords—*Forgery detection; scale invariant feature transform; key point operation; block matching; agglomerative hierarchical clustering*

I. INTRODUCTION

In today's world, the widespread use of digital content has led to the manipulations to spread the information with malicious goals and even change people's opinion widely. This forgery creation demands immediate need of digital image authentication and to validate the trustworthiness of source images [1]. Image forensics is the application of domain knowledge to understand image/video content in legal matters. The Scientific Working Group on Digital Evidence (SWGDE) lists best practices that are required to reliably preserve image integrity. Image authentication solution is divided into two types: Active techniques and passive methods (blind). Passive or blind image forensics analyzes the image using statistics and semantics to identify manipulation and

without considering embedded data in an image. Passive forgery detection algorithms can be categorized as camera based, pixel-based, geometric-based, physics-based, JPEG artifact-based, and statistical-based techniques.

One of the popular image manipulations is copy-move forgery in which one or more regions in the image are duplicated to create a malicious effect within an image. Copy-move forgery detection algorithm performance is evaluated using either at an image-level or pixel-level. Image/video authentication is employed to verify trustworthiness of the content. Manual authentication mechanism requires huge efforts and labor and sometimes it is error prone. Therefore, automatic image authentication algorithms are required for improved detection rate. As digital media technologies allow for image or video alteration and counterfeiting, having accurate images can be crucial evidence in court. Deep fakes, photo or video editing and many other practices can misrepresent an event that is critical to an investigation. A thorough examination and trustworthy data on the original image is essential. To address this need, image forensics offers a careful review of relevant photos to provide an unbiased assessment of the evidence [2].

Forensic algorithms analyze digital images to determine the accuracy and trustworthiness of the information in several different circumstances. To determine if an image represents a circumstance or location accurately, experts may assess color level anomalies and landmarks to identify the image authenticity. Experts can apply deconvolution to the file to identify a person in the photo that includes a blurred or otherwise obscured identity. Digital images play an important role in people's lives such as news, print media and courtroom evidence [3].

This work presents a technique to verify the credibility and integrity of the images based on a redundant wavelet transform based complex Zernike moment and Scale Invariant Feature Transform (SIFT) key point matching technique for copy-move image forgery operation detection. SIFT is robust against scale and rotation that works on identifying similarity using exhaustive search of SIFT features. However, SIFT is computationally expensive. Hence, this article presents an optimized approach for image authentication. After extracting SIFT key point features agglomerative hierarchical clustering is employed for grouping and key point matching operation is

performed. Finally, block matching operation is evaluated and forged regions in the manipulated images are marked and displayed.

Major contributions of this article are summarized as:

- 1) Complex Zernike moment feature extraction for improved detection rate.
- 2) SIFT key-point feature extraction process is computationally expensive. So, an optimized approach for SIFT key-point descriptor extraction is employed which reduces computation time significantly.
- 3) The proposed optimized image authentication algorithm demonstrates improved speed-up and detection rate.

The paper is organized as follows. Existing literature and findings are presented in Section II. Section III explains proposed algorithms and various feature extraction steps in detail. Simulation experiments and discussions are presented in Section IV. Finally, Section V discusses the results and presents robustness analysis while Section VI concludes the article.

II. LITERATURE REVIEW

This section describes the most crucial and recent works in the field of copy-move forgery detection. In [4], a new methodology based on SIFT is described that helps us to know and understand if a copy-move attack has taken place. In addition to that, it helps to retain the geometric transformation that performs the process of cloning. The proposed method also estimates the geometric transformation values with improved reliability and detects multiple forgery operations.

The work in [5] uses a high-level algorithm to recognize a unique model of using Hu's invariant moments and Log-polar transformations to minimize feature space dimensionality to one feature per block and parallelly recognizing the CMF among almost the same objects in an image. The qualitative and quantitative outputs obtained demonstrate the effectiveness of the algorithm.

In [6], first the input image is decomposed using steerable-pyramid transform (SPT) and grey level co-occurrence matrix (GLCM) descriptors are extracted from each orientation. These features are then utilized to train optimized support vector machines (OSVM) which also acts as a classifier. GLCM features are extracted from each block. A novel method for forgery detection is illustrated which uses a new integrated version of key point-based counterfeit detection method and SLIC super pixel segmentation algorithm for forgery detection [7]. The proposed algorithm generates super-pixels with the help of Simple Linear Iterative Clustering (SLIC). An algorithm to detect copy-move image forgery in images is developed in [8]. Discrete wavelet transform (DWT) is applied on the given image to be decomposed into four parts LL, LH, HL, and HH. Since the LL section contains most of the information, SIFT is particularly applied on the LL part only to extract the most important features. This helps in finding the best descriptor vector of these key features and furthermore, it helps in identifying the similarities between test and train images. Authors in [9] proposed a dual level keypoint based forgery detection approach. First, SIFT is used

to detect keypoints in smooth regions and then, BRIEF and FAST descriptors are combined to detect the critical key points from missing areas. Keypoint matching is performed using the generalized nearest neighbor. Finally, morphological image processing operations are utilized to locate forged areas.

The model in [10] first extracts the textural features from the input image. Robust keypoints are extracted using SIFT from these textual images and keypoint matching is done to conclude if the image is forged or not. From that, suspicious regions are determined. The localization of forged pixels is realized via a Ciratefi based approach. Local tetra pattern (LTrP) based feature extraction is developed in [11] for forgery detection and localization. Firstly, the input image is divided into non-overlapping blocks and then from each individual block LTrP descriptors are extracted.

The novel algorithm proposed in [12] utilizes a fusion of the SIFT and local binary pattern (LBP). Consideration of texture features around the key points detected by the SIFT algorithm can be effective to reduce the incorrect matches and improve the accuracy of copy-move forgery detection. In [13], a stationary wavelet transform (SWT) is applied over the input image to acquire a low approximation band, and crucial features are extracted from the band using block-based discrete cosine transformation (DCT) and singular value decomposition (SVD). The literature survey revealed that main feature extraction is based on Zernike moments and SIFT keypoint feature mapping producing acceptable accuracy rate with higher computation time. Hence, this article proposes use of complex Zernike moments and optimized SIFT keypoint extraction and mapping thereby generating improved detection rate at the same time with lower computation time.

III. PROPOSED METHOD FOR SPEECH DYSFLUENCIES CLASSIFICATION

This work presents redundant wavelet transform based Zernike moment and optimized scale invariant feature transform (SIFT) key point matching technique for copy-move image forgery operation detection. SIFT is robust against scale and rotation that works on identifying similarity using exhaustive search of SIFT features. After extracting SIFT key point features agglomerative hierarchical clustering is employed for grouping and key point matching operation is performed. Finally, block matching operation is evaluated and forged regions in the manipulated images are marked and displayed. The proposed algorithm performance is evaluated using Precision, Recall, F-Measure and detection accuracy and compared with existing copy-move forgery detection approaches.

A. Architecture of MFCC and FBE based Dysfluencies Classification

The detailed steps followed during the development of advanced image authentication algorithm using redundant wavelet transform based SIFT Descriptors and Zernike Moments are outlined below. Fig. 1 illustrates the architecture of the proposed optimized SIFT keypoint feature based algorithm.

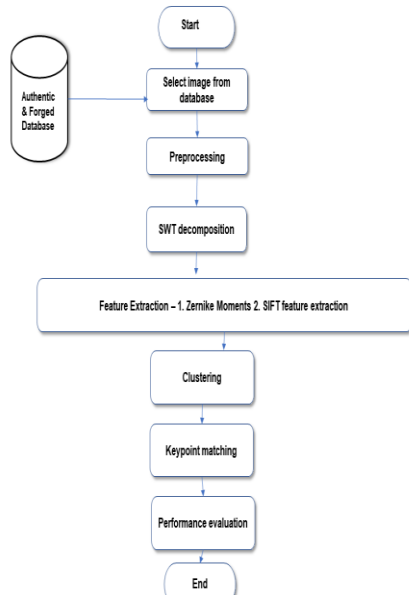

Fig. 1. Workflow diagram of system architecture.

1) *Database collection*: Collect the image authentication database. The dataset consists of Original and forged images using copy-move forgery operation. Total forged images are represented as $F_T = 1, 2, \dots, N$, whereas total original images with $A_T = 1, 2, \dots, M$.

2) *Redundant wavelet transform decomposition*: Apply 4-level redundant wavelet transform decomposition on the original and forged images as follow:

$$\begin{aligned}
 A_{j,k_1,k_2} &= \sum_{n_1} \sum_{n_2} h_0^{2j}(n_1 - 2k_1) h_0^{2j}(n_2 - 2k_2) A_{j-1,n_1,n_2} \\
 D_{j,k_1,k_2}^1 &= \sum_{n_1} \sum_{n_2} h_0^{2j}(n_1 - 2k_1) g_0^{2j}(n_2 - 2k_2) A_{j-1,n_1,n_2} \\
 D_{j,k_1,k_2}^2 &= \sum_{n_1} \sum_{n_2} g_0^{2j}(n_1 - 2k_1) h_0^{2j}(n_2 - 2k_2) A_{j-1,n_1,n_2} \\
 D_{j,k_1,k_2}^3 &= \sum_{n_1} \sum_{n_2} g_0^{2j}(n_1 - 2k_1) g_0^{2j}(n_2 - 2k_2) A_{j-1,n_1,n_2}
 \end{aligned} \quad (1)$$

Where $A_{j,k_1,k_2}, D_{j,k_1,k_2}^1, D_{j,k_1,k_2}^2, D_{j,k_1,k_2}^3$ are the low-frequency sub-band (LL), high-frequency sub-band (LH), high-frequency sub-band (HL) and diagonal (HH) sub-band of the redundant wavelet transform respectively [14].

3) *Compute Zernike moments*: Compute the discrete form of the Zernike moments for an image with the size $N \times N$ as follows:

$$\begin{aligned}
 Z_{n,m} &= \frac{n+1}{\lambda N} \sum_{c=0}^{N-1} \sum_{r=0}^{N-1} f(c,r) V_{n,m}(c,r) \\
 &= \frac{n+1}{\lambda N} \sum_{c=0}^{N-1} \sum_{r=0}^{N-1} f(c,r) R_{n,m}(\rho cr) e^{jm\theta cr}
 \end{aligned} \quad (2)$$

where, n = Zernike moments order, m is the repetition, λN is a normalization factor, centroid for angle is shown as θ , c indicates centroid column number and r denotes row number. In the above equation, $(c; r)$ represents the coordination of the image while $f(c; r)$ is the image function. The translation vector is represented as V , j is the index of input ROI [15].

4) *Scale-invariant feature transform (SIFT) feature extraction*: SIFT descriptors are rotation and scaling invariant and are computed using the following steps.

5) *Scale-space extrema detection*: A Gaussian function $G(x; y; \sigma)$ and input image, $I(x; y)$ are convolved to obtain scale-spaced image $L(x; y; \sigma)$:

$$\begin{aligned}
 L(x, y, \sigma) &= G(x, y, \sigma) * I(x, y) \\
 G(x, y, \sigma) &= \frac{1}{2\pi r^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (3)
 \end{aligned}$$

6) *Keypoint localization*: The keypoint selection from extrema is obtained by rejecting the points along image edges or having low contrast values and expressed as:

$$D(x) = D + \frac{\partial D^T}{\partial x} + \frac{1}{2} x^T + \frac{\partial^2 D}{\partial x^2} x \quad (4)$$

7) *Keypoint descriptor generation*: The SIFT keypoints with a histogram array of 4 X 4 and number of orientation bins as 8, produces 128-dimensional descriptor.

8) *Clustering*: SIFT keypoint descriptors are extracted from approximate sub-band of the SWT decomposition and are grouped using agglomerative hierarchical clustering. Typical linkage methods utilized for the clustering approach are median, centroid or ward.

9) *Keypoint matching*: SIFT keypoint matching is a principal step in which firstly keypoints from the input image are read and compared with the keypoints of images.

10) *Block matching and marking forged region*: Finally, block matching operation is evaluated and forged region in the manipulated images are marked and displayed.

11) *Performance evaluation*: The proposed algorithm performance is evaluated using Precision, Recall, F-Measure and detection accuracy.

$$\text{Precision} = \text{True-Positives} / (\text{True-Positives} + \text{False-Positives})$$

$$\text{Recall} = \text{True-Positives} / (\text{True-Positives} + \text{False-Negatives})$$

$$\text{F-Measure} = (2 * \text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall})$$

$$\text{Detection rate} = (\text{TruePositives} + \text{True-Negatives}) / (\text{True-Positives} + \text{True-Negatives} + \text{False-Positives} + \text{False-Negatives})$$

IV. SIMULATION RESULTS

This section presents a variety of experiments conducted using the proposed algorithm. To assess the effectiveness of the developed technique for image authentication, MICC-F220 database is employed. This popular and publicly available image dataset has forged and authentic natural 220

images: 110 are manipulated images and 110 are authentic. The pixel resolution of these images varies from 722 X 480 to 800 X 600 pixels and almost 1.2% of the whole image is covered by the forged patch. The simulation experiments were conducted on Intel® Core™ i-54, 9400F CPU @ 2.90 GHz processor with 8GB RAM running MATLAB 2021a.

As the input image pixel resolution varies, we have resized the input image size to 300 X 300. In order to extract finer details four-level redundant wavelet transform decomposition is utilized. Zernike moments are extracted with the settings as order of 4 and repetition of moments 2. The proposed optimized forgery detection algorithm utilizes Harris threshold of 5 and number of windows as 2. We have set the sigma value as 9 and 3 neighbourhood computation. The forged region detection is performed individually on each color component and finally combined to generate final output.

The performance of the proposed optimized image forensic algorithm is described by the computation of precision, recall, F-score and detection rates. Precision and recall are two important parameters employed to identify forgery detection algorithm accuracy. F-Measure represents a measure of test accuracy and is the harmonic mean of precision and recall. The results reported in this paper are an average of 10 trials. The proposed image authentication algorithm performance is evaluated using Precision, Recall, F-Measure and detection accuracy.

1) *Experimental results and analysis using standard and proposed optimized forgery detection approach:* Firstly, the effectiveness and the accuracy evaluation of the proposed technique, we present experimental results and analysis using conventional SIFT key-point feature extraction approach and proposed optimized image forensic algorithm. For fair comparison for both experiments MICC-F220 DATABASE is employed. The detection performance is measured on irregular shaped duplicated regions as it influences the overall detection rate. The first set of experiments is carried out without any post-processing operation on the original and manipulated image.

Fig. 2 to 5 illustrate experiment results for copy- move forgery detection using the proposed algorithm for four sample images from the database. In each figure, the first row (from left to right) depicts the original image, SLIC image and SIFTS keypoint feature extraction. Second row (from left to right) shows labelled feature points, merged points after morphological operation, and detected forged regions are shown. As it is evident from these figures that the proposed optimized technique effectively detects and locates forged areas. Moreover, it convincingly visualizes and detects irregular shape manipulated areas and objects.

As illustrated in these Fig. 2 to 5, first the input image is decomposed using a four-level redundant wavelet transform. The four-level decomposition primarily assists in extracting fine details from the forged image. This in turn enhances the detection and localization estimation. As shown in the second figure of the first row, the simple linear iterative clustering based super pixel segmentation (SLIC) algorithm convincingly improves input segmentation into different

regions. The SIFT key-point feature extraction process and final detection result is dependent on the SLIC generated output.

V. DISCUSSIONS

This work presents comparison between conventional SIFT key-point feature extraction and modified feature extraction technique in terms of various performance evaluation parameters. In the conventional SIFT key-point feature extraction approaches typically Harris threshold is set at 10 and number of windows for computation is 4. The computation time for detection of SIFT key-point features and further processing like localization is considered as one of the major concerns in case of real-time detection. Table I shows the evaluation results using these parameters for precision, recall, F-measure and execution time for five images.

As it can be observed from Tables I and II that the execution time of the optimized image forensic algorithm is significantly reduced compared to the conventional approach. The speedup obtained in this case is almost twice. Additionally, precision and F-measure parameters are slightly improved in the proposed technique. This experimental evaluation signifies improved performance of the optimized algorithm over the conventional SIFT key-point feature extraction technique. The average precision and F-Measure value is 0.9806 and 0.9904 for the conventional SIFT feature extraction approach whereas it is 0.987 and 0.9938 for the proposed method. Fig. 6 and 7 depict the effect of Harris threshold and number of window computation on the average detection accuracy respectively.

A. Robustness Analysis

To conceal the traces of copy-move forgery operation the malicious user usually performs various post-processing operations. The prime intent of these post-processing operations is to make forged areas hard to detect and localize. Therefore, it is imperative to evaluate the robustness of the proposed image forensic technique against different post-processing operations. In this study, three different post-processing operations and its robustness is analyzed: rotation attack, scaling attack, and contrast enhancement.

Fig. 8, 9 and 10 depict average accuracy, precision and F1-Measure computed using rotation attack, scaling attack and contrast enhancement respectively. It is evident from these figures that the proposed optimized forgery detection technique has the capability to perform better even when the forged image suffers from rotation, scaling and contrast enhancement post processing operations. The average accuracy is above 96% in all post-processing attacks proving enhanced detection and localization performance of the proposed algorithm. Finally, the proposed optimized image forensic approach is compared with existing state-of-the-art techniques. As shown in Table III, the proposed algorithm outperforms existing approaches in terms of precision, recall and average accuracy rate.

TABLE I. PERFORMANCE EVALUATION USING CONVENTIONAL SIFT KEY-POINT FEATURE EXTRACTION APPROACH

Overall recent proposed methods based on SIFT and feature level image authentication have higher computational complexity although, there are performance improvement techniques using different feature fusion resulting in higher dimensional feature vector. To overcome these issues this paper presents optimized SIFT based image authentication solution. The proposed approach lowers the computational cost and speed up is achieved in this study.

[18]	93.9	90.44	87.75	92.20
[19]	92.8	88.7	91.15	94.45
Proposed	98.53	100	99.13	98.87

VI. CONCLUSIONS

In today's world, widespread use of multimedia contents has given rise to the manipulations of multimedia content with malicious purposes demanding the necessity of robust authentication techniques. This work presents redundant wavelet transform based complex Zernike moment and optimized scale invariant feature transform (SIFT) keypoint matching technique for copy-move image forgery detection. SIFT is robust against scale and rotation that works on identifying similarity using exhaustive search of SIFT features. After extracting SIFT keypoint features agglomerative hierarchical clustering is employed for grouping and key point matching operation is performed. Finally, block matching operation is evaluated and forged regions in the manipulated images are marked and displayed. The proposed algorithm is evaluated using the popular and publicly available database MICC-F220. As observed, the proposed optimized SIFT algorithm achieves speedup of almost twice over the standard SIFT technique. Experimental evaluation illustrates improved performance of the proposed technique as compared to other similar methods available in the literature. In future, the work can further be explored using statistical descriptors to improve image authentication accuracy.

Anchor-free Proposal Generation Network for Efficient Object Detection

Hoanh Nguyen

Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

Abstract—Deep learning object detection methods are usually based on anchor-free or anchor-based scheme for extracting object proposals and one-stage or two-stage structure for producing final predictions. As each scheme or structure has its own strength and weakness, combining their strength in a unified framework is an interesting research topic. However, this topic has not attracted much attention in recent years. This paper presents a two-stage object detection method that utilizes an anchor-free scheme for generating object proposals in the initial stage. For proposal generation, this paper employs an efficient anchor-free network for predicting object corners and assigns object proposals based on detected corners. For object prediction, an efficient detection network is designed to enhance both detection accuracy and speed. The detection network includes a lightweight binary classification subnetwork for removing most false positive object candidates and a light-head detection subnetwork for generating final predictions. Experimental results on the MS-COCO dataset demonstrate that the proposed method outperforms both anchor-free and two-stage object detection baselines in terms of detection performance.

Keywords—Object detection; deep learning; convolutional neural network; proposal generation network

I. INTRODUCTION

Object detection has seen significant advancements in recent years thanks to deep learning, particularly convolutional neural networks (CNN). According to the way of generating object proposals from input images, Current object detection techniques can be divided into two categories: anchor-based and anchor-free object detection methods. Anchor-based approaches consider each object as a rectangular bounding box on feature map. Features inside the bounding box are extracted and inputted into either a proposal generation network to generate proposals or a detection network to generate final outputs. To address the issue of scale variation, anchor-based methods define multiple bounding boxes with varying sizes and aspect ratios, enabling the network to detect objects of diverse sizes and proportions. The sizes and aspect ratios defined in anchor-based object detection approaches vary depending on the specific object and structure. Anchor-based schemes are dominant in early deep learning object detection methods since they are easy to implement and facilitate the learning process. However, object detection methods based on anchor-based scheme face another problem as they cannot detect objects with rare sizes/aspect ratios due to the limitation of anchor box sizes and ratios.

On the other hand, anchor-free object detection approaches examine points (i.e., anchor points or keypoints) on feature

map to predict objects. These approaches can be categorized into two categories: anchor points object detection approaches and keypoints object detection approaches. While object detection methods based on anchor points classify each point on feature map into object/background classes and predict the distances from the positive points to object borders, keypoint-based object detection methods predict keypoints such as corner points or center points on feature map and group valid points to form objects. Compared to anchor points object detection methods, keypoints object detection methods usually have a more complicated structure and achieve better detection performance. However, they need an optimal grouping algorithm so that the network can efficiently group valid keypoints to form objects.

Alternatively, according to the learning process, Current object detection techniques can be divided into two categories: one-stage and two-stage object detection methods. One-stage object detection techniques directly use the detection network on input feature maps to generate final outputs, whereas two-stage object detection methods generate object proposals in the first stage, followed by the use of the detection network in the second stage to produce the final predictions. Since one-stage methods eliminate proposal generation process, they obtain fast processing speed. However, detection accuracy is typically improved through the use of two-stage methods [1], [2].

In recent years, many object detection structures followed the above schemes or structures have obtained great achievements [3], [4], [5]. In general, each of the above schemes or structures has its own strengths and weaknesses. Thus, combining the strength of these schemes or structures in a unified framework is an interesting topic. However, this topic has received limited attention from the academic community in recent years. This paper presents a novel object detection framework that combines the benefits of both an anchor-free approach and a two-stage structure. The proposed method uses an anchor-free object detection scheme to generate object proposals in the initial stage. To efficiently generate final predictions in the subsequent stage, an efficient detection network is designed. The efficient detection network includes a lightweight binary classification subnet and a light-head detection subnet. Experimental results on the MS-COCO dataset prove the effectiveness of the proposed method.

The structure of the article is presented as follows. Section II introduces recent related works. Section III provides details on the design of the proposed method. Section IV presents the experiments and results achieved by the method. Section V provides conclusions.

II. LITERATURE REVIEW

A. Anchor-based Object Detection Methods

Anchor-based object detection methods depict each object as an anchor bounding box on feature maps. To address the scale variation issue, these object detectors establish multiple anchor boxes at each location on the feature map. Each anchor box is linked to a scale and aspect ratio. In Faster R-CNN [3], three aspect ratios (128^2 , 256^2 , 512^2) and three scales (1:1, 1:2, 2:1) are employed in the definition of anchor boxes, yielding nine anchor boxes at each position on feature map. In FPN [4], since region proposal network is applied on the feature pyramid, anchor boxes at each spatial location of a feature level are defined using one scale and three aspect ratios. Anchor-based scheme has been employed in many deep object detection frameworks [5], [6], [7], [31]. However, anchor box scales and aspect ratios must be meticulously designed for the specific domain to ensure the detection network attains optimal detection performance. To eliminate problems caused by anchor box settings, various methods propose to replace the manual design of the anchor boxes by a deep network so that the shape of the anchors is automatically learned during training. For this purpose, MetaAnchor [8] developed a generator for anchor functions that maps a given prior bounding box to its corresponding anchor function. The anchor function generator is formed by a simple network and computed from customized prior bounding boxes, and thus it can be inserted into any deep learning object detection methods for joint optimization. The results show that MetaAnchor is more robust than manual design of anchor settings as it can detect objects with rare shapes. However, MetaAnchor obtains minor improvements on two-stage object detectors. Moreover, it requires customized prior bounding boxes to be chosen by handcraft and more computation for extra network. In [9], a novel anchor box optimization method is proposed. The training process employs the optimization technique based on localization loss to automatically learn the anchor shapes. In addition, soft assignment and online clustering scheme are introduced to warm up the anchor shapes. Recently, Sparse R-CNN [10] represented object candidates by a limited set of bounding boxes that can be learned. These learnable bounding boxes represent the statistics of potential object locations within the training set. The back propagation algorithm will update the parameters of these adjustable bounding boxes during training. By eliminating the hand-designed anchor boxes, Sparse R-CNN strikes a favorable balance between accuracy, runtime, and training convergence performance.

B. Anchor-free Object Detection Methods

Anchor-free object detection methods employ points (i.e., anchor points or keypoints) for predicting objects. For this purpose, CornerNet [11] suggests detecting objects based on their top-left and bottom-right corners. For detecting corners, CornerNet employs a corner prediction network that includes a corner pooling layer for producing corner proposals, a heatmap generation layer for generating corner heatmaps, an offset generation layer for predicting corner offsets, and a network for calculating embeddings which are used to group valid corner points to form objects. Based on CornerNet, CenterNet [12] introduced an extra keypoint (i.e., center point) for predicting objects. A center pooling layer is also designed to enrich center

and corner information, which improves the detection performance of CenterNet. Zhou et al. [35] utilized a single point at the center of the bounding box to represent objects, eliminating the need for the grouping stage in keypoint detectors like CornerNet and CenterNet. Peaks in the heatmaps generated by a keypoint estimation network are used to predict object center. In [13], representation of objects in input images is achieved through the use of a set of sample points that adaptively position themselves over the object. The sample points are learned through both object localization and recognition loss. Based on predicted sample points, converting functions are designed to form object bounding boxes. In [14], an object prediction mechanism utilizing a star-shaped bounding box is designed. The star-shaped bounding box employs features from nine fixed sampling points with deformable convolution [15] to represent a bounding box. This new bounding box design can incorporate both the geometry of the bounding box and its surrounding context, crucial for encoding any misalignment between the predicted and actual bounding box.

An alternative approach is to use each point on the feature map for object prediction. For this purpose, FCOS [16] employs a fully convolutional network for classifying each location on feature map. For each positive point, FCOS predicts the distances from the location to the four sides of the bounding box. FCOS incorporates a center-ness branch to down-weight the scores of low-quality predicted bounding boxes generated by locations far from the center of an object, in order to remove them. Similar to FCOS, FoveaBox [17] presents an anchor-free framework that predicts category-sensitive semantic maps for the presence of objects and generates category-agnostic bounding boxes for each potential object location. FoveaBox defines positive and negative training samples based on the fovea area, which is the center of the visual field with the highest resolution. Different from FCOS and FoveaBox, Zhu et al. [34] introduced a new feature selective anchor-free module (FSAF), which takes pixels on feature pyramid as inputs and directly feeds these pixels into two convolutional networks: a classification network for predicting class scores for each pixel and a regression network for producing offsets encoding the distances from the current pixel location to the top, left, bottom, and right boundaries of the target bounding box. Recently, SAPD [18] introduced an optimal training approach using two softening optimization techniques, soft-weighted anchor points and soft-selected pyramid levels. The soft-weighted anchor points technique adjusts the contribution of anchor points on the same pyramid level to the network loss based on their geometry relative to the instance box, while the soft-selected pyramid levels technique learns the participation level of each pyramid. The results show that SAPD balances speed and accuracy effectively.

The above methods have their own strengths and weaknesses. Specifically, due to the limitation of anchor box sizes and ratios as well as the variability of object sizes, anchor-based object detection methods have limitations in detecting objects with various shapes. On the other hand, anchor-free object detection approaches have limitations in determining geometric relations between an object and nearby contextual information. This paper focuses on exploiting and

combining the strengths of the above methods. Based on that, a model is designed that can achieve better accuracy and execution speed.

III. METHODOLOGY

The proposed structure is described in this section. Initially, an evaluation of anchor-based and anchor-free methods for generating object proposals is conducted. Then, the specifics of each module in the proposed structure are depicted in subsequent subsections.

Fig. 1. The flowchart of anchor-based object detection methods.

C. Object Proposal Generation Methods

As shown in Fig. 1, anchor-based object detection methods first depict each object as an anchor box $B = \{x, y, w, h\}$ on feature maps, where the center point is represented by the coordinates (x, y) , and the width and height of the object bounding box are (w, h) . Then, the features within anchor box B are extracted and inputted into a deep network to generate object proposals (for two-stage approaches) or direct final predictions (for one-stage approaches). Anchor-based object detection techniques define a collection of anchor boxes at each position in a feature map in the input image to accommodate objects of varying size, position, and scale, enabling the model to detect all of them. In Faster R-CNN [3], the center of each anchor box corresponds to the center of the sliding window, and each is paired with a specific scale and aspect ratio. Faster R-CNN uses three aspect ratios (i.e., 1:1, 1:2, 2:1) and three scales (i.e., 128^2 , 256^2 , 512^2), which results in 9 anchor boxes at each position on feature map. Recently, the FPN [4] has established a single scale and three aspect ratios for each anchor location, utilizing the feature pyramid. When using anchor-based object detection methods, it is important to carefully design the number and shape of anchor boxes. Too few anchor boxes or inappropriate anchor shapes may be insufficient to cover a large range of objects in various sizes and ratios, which reduces the performance of proposal generation network or detection network. The top portion of Fig. 2 shows some examples where Faster R-CNN with anchor-based scheme faces difficulty in predicting objects with rare shapes since there are no defined ratios or scales that fit these objects.

Fig. 2. Results of detection on the validation set of MS-COCO dataset. Top: Faster R-CNN with anchor-based scheme. Bottom: CornerNet with anchor-free scheme.

Alternatively, anchor-free methods use keypoints or anchor-points to depict an object. Methods based on keypoints first predict the locations of keypoints like corner or center points, and then use these keypoints to form an object bounding box by a grouping algorithm. On the contrary, anchor-point based methods first categorize each point on the feature map and then estimate the distances from the potential point to the four edges of the actual bounding box to produce object proposals. Since anchor-free methods eliminate all problems related to anchor box settings, they have a better ability of detecting objects, especially objects with rare shapes, which improves the recall rate. The bottom portion of Fig. 2 shows some detection results of the CornerNet framework [11]. As shown, CornerNet with anchor-free scheme obtains better detection results compared with Faster R-CNN with anchor-based scheme. However, anchor-free methods face another problem of forming an object candidate based on keypoints. Take CornerNet as an example, CornerNet determines an embedding vector for every identified corner, then groups the corners to create the object bounding box based on the distances between the embeddings. Due to the significant number of false positives produced by the corner detection network, determining an embedding vector for each detected corner may result in many false positive outcomes. As seen in Fig. 3, CornerNet generates some incorrect corner pairs because of similar appearance leading to similar embeddings.

Based on the above analysis, this paper introduces an efficient object detection structure that inherits the merits of anchor-free scheme for producing object proposals and two-stage structure for generating predictions. Based on anchor-free scheme, this paper designs an efficient two-stage object detection approach that eliminates the grouping stage, which hinders the detection performance of anchor-free object detection pipelines. The details of the proposed method are outlined in subsequent sections.

Fig. 3. Results of CornerNet on the validation set of MS-COCO dataset showed some false corner pairs generated due to similarities in embeddings.

D. Overview of the Proposed Approach

The structure of the proposed method is shown in Fig. 4. It integrates an anchor-free approach and a two-stage structure into a single object detection framework. The first stage generates object proposals, and the second stage produces predictions. The proposal generation network in the first stage is based on CornerNet [11]. Specifically, CornerNet employs input feature maps to predict top-left and bottom-right corner keypoints of the bounding box for objects. Based on the corner keypoints, object proposals are formed according to the corner locations and the corresponding classifying scores. Since there are many false positive object proposals generated by the first stage, an efficient detection network is designed in the second stage. Specifically, a lightweight classification subnet is first designed to remove most false positive object candidates. A detection subnet with light-head structure is then adopted to produce prediction results based on remaining object candidates. With the anchor-free scheme for proposal generation in the initial stage and an efficient detection structure in the following stage, the proposed approach integrates the merits of anchor-free scheme into a two-stage structure. The details of each module are depicted in the subsequent sections.

E. CornerNet as Object Proposal Generation

To obtain high recall rate for generating object proposals from input images, especially for objects with various shapes, this paper adopts CornerNet [11] as object proposal generation network. CornerNet identifies an object through two crucial keypoints - the top-left corner keypoint and the bottom-right corner keypoint. The structure of CornerNet, as depicted in Fig. 5, involves the utilization of the Hourglass model [19] to extract feature maps from input images. The Hourglass network initially processes input features through convolution and max pooling layers to reduce the resolution and then uses up-sampling, convolution layers, and skip layers to increase the resolution back to its original state. The Hourglass architecture combines both global and local features into a single structure. As in [11], this paper employs the Hourglass architecture with

two Hourglass modules for extracting input features. The final layer of the Hourglass network is utilized for further prediction by using two prediction branches with identical structures. These prediction branches, based on the last feature map produced by Hourglass, detect the top-left and bottom-right corners. Each branch generates C channel heatmaps, where C represents the number of object categories. Each channel is a binary map that shows the locations of corners for each class. To refine the corner locations, each branch predicts offset values. A corner pooling module, consisting of two 3×3 convolution layers followed by a corner pooling layer, is utilized in each branch to pool features from the Hourglass network. These features are then fed into a 3×3 convolution layer for projection. Finally, the output features are used to produce heatmaps and offsets through a series of 3×3 and 1×1 convolution layers. It should be noted that since this paper adopts CornerNet for predicting corners, the embedding prediction branch in the original CornerNet is removed, thus reducing the computation of the proposed object proposal generation network.

After getting proposal corners through the proposed CornerNet, this paper extracts K top-left and K bottom-right corners from the heatmaps generated by CornerNet ($K = 50$ in this paper). Then, each pair of top-left and bottom-right corners belonging to the same class, where the coordinates of top-left corner are smaller than that of bottom-right corner is used to define an object proposal. By using corner points to define object candidates, the proposed object proposal generation method can detect more objects, especially objects with arbitrary size, which are usually missed by anchor-based proposal generation method. As a result, the recall rate is significantly improved. However, defining object proposals based on this scheme leads to many false positive proposals as the corner keypoints of two different objects of the same class may define an object proposal (as shown in Fig. 3). To eliminate most false proposal candidates, this paper designs an efficient detection network which is elaborated in the next subsection.

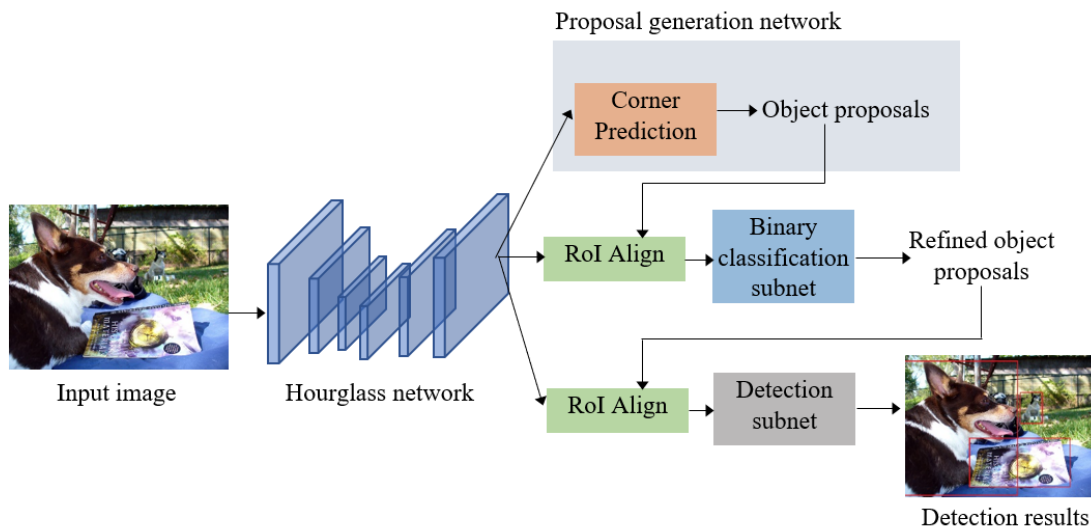

Fig. 4. The overall structure of the proposed model.

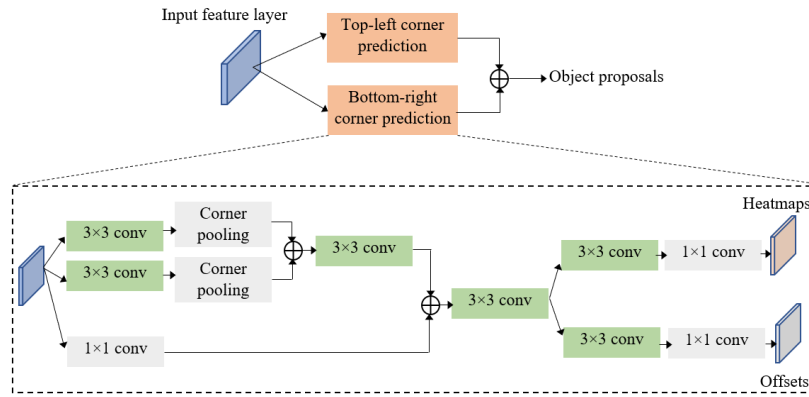

Fig. 5. The architecture of CornerNet used in this paper.

F. Detection Network

Since this paper employs CornerNet for generating object proposals, many false positive proposal candidates are produced. As a result, applying a heavy detection network for predicting objects based on a large number of object candidates is not efficient since it requires a huge amount of computational budget. In the paper, a high-performance detection network is proposed. The structure of the proposed network is depicted in Fig. 6. First, this paper employs a lightweight binary classification subnet to eliminate most of false positive proposal candidates. The lightweight binary classification subnet starts by applying a convolution layer to the final feature layer of the backbone to create a thin feature map with 32 channels. The RoIAlign layer [20] then creates the proposal feature map using the thin feature map and proposals from the proposed CornerNet. At the end of the lightweight binary classification subnet, a convolution layer followed by an average pooling layer computes the classification score for each proposal. To address the issue of imbalanced training samples, this paper implements a variation of focal loss [6] in the training process, which is illustrated as follows:

$$L_{class1} = -\frac{1}{N} \sum_i L_i \quad (1)$$

$$L_i = \begin{cases} (1 - p_i)^\beta \log(p_i), & \text{if } IoU_i \geq T \\ p_i^\beta \log(1 - p_i), & \text{otherwise} \end{cases} \quad (2)$$

where N represents the number of positive samples, p_i is the objectness score of i -th proposal, IoU_i is the maximum IoU value between i -th proposal and all ground truth boxes. T and β are set at 0.7 and 2, respectively, in this paper.

Next, since the lightweight binary classification subnet effectively eliminates most false positive proposal candidates, a light-head detection subnet is utilized to generate final predictions from the remaining proposals. This paper designs a light-head structure, similar to Light-Head R-CNN [21], in the final detection subnet for both classification and bounding box regression. The light-head detection subnet can improve computational speed without compromising the detection performance. As illustrated in Fig. 6, the first step is to apply a large separable convolution layer to the final feature layer of the backbone to improve these features while simultaneously decreasing the number of channels. Compared with 1×1 convolution, large separable convolution is more efficient as it produces thin output features with more semantic information. Then, PSRoI Align [22] is adopted to produce fixed size features (i.e., $7 \times 7 \times 10$) for remaining proposal candidates based on feature map generated by the large separable convolution layer. Here, the PSRoI Align is utilized as it reduces the number of channels in the output features. Finally, this paper uses a single 1024-dimensional fully connected layer followed by two parallel fully connected layers to produce the final classification and regression results.

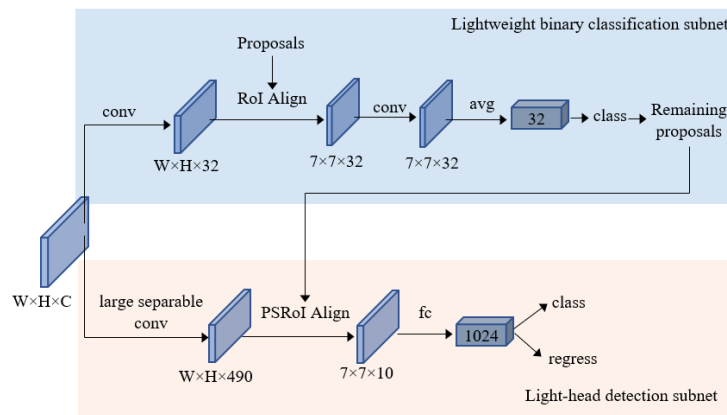

Fig. 6. The structure of the proposed detection network.

By designing an efficient detection network with two prediction steps, most of false positive object candidates are removed by the classifier, and remaining object candidates are efficiently predicted by the detection subnet. The detection subnet with light-head structure can enhance the detection speed without compromising the detection performance. The experimental results demonstrate that this design is more efficient than using a heavy detection network directly as the detection network.

IV. RESULTS

A. Implementation Details

This paper uses the MS-COCO dataset [23] to evaluate the proposed model, which contains 80 object categories. The images in the dataset are divided into three sets, with 80K images for training, 40K images for validation, and 20K images for testing. In accordance with the standard protocol [4], [6], this paper trains the proposed model using all images in the training set and 35K images from the validation set. To evaluate the detection performance, the paper reports the results on the test-dev set, which are submitted to an external evaluation server.

For evaluation metrics, this paper follows metrics defined in the MS-COCO dataset for evaluating object detection tasks. To be more specific, this paper uses the average precision (AP), AP_{50} , AP_{75} , AP_S , AP_M , and AP_L as evaluation metrics. AP is the average precision over 80 categories under multiple IoU values (i.e., 0.5:0.05:0.95). AP is considered the key metric when assessing object detection techniques on the MS-COCO dataset. AP_{50} and AP_{75} are AP computed at a specific IoU threshold value. AP_S , AP_M , and AP_L are AP computed based on object sizes (AP_S for objects with area $< 32^2$, AP_M for objects with $32^2 < \text{area} < 96^2$, and AP_L for objects with area $> 96^2$).

The proposed network is designed based on Pytorch [24] and open-source object detection toolbox mmdetection [25]. The object proposal generation network is adopted from CornerNet [11], where the stacked Hourglass networks with 104 layers and the corner detection network are trained on the MS-COCO dataset. As in [11], the input size of the network is set to 511×511 during the training process. The proposed network is trained end-to-end with the full training loss as follow:

$$L = L_{corner} + L_{offset1} + L_{class1} + L_{class2} + L_{offset2} \quad (3)$$

where L_{corner} and $L_{offset1}$ are the variant of focal loss and the smooth L_1 loss, respectively; L_{class1} is the variant of focal loss for training the binary classification subnet; L_{class2} and $L_{offset2}$ are the cross-entropy loss and the smooth L_1 loss, respectively, for training the light-head detection network. For computationally efficient reasons, this paper uses Adam optimizer [26] to optimize the training loss. The Adam optimizer is a widely used optimization algorithm in the deep learning domain and is straightforward to implement. The

proposed network is trained for 100K iterations on Nvidia RTX 3070 GPU.

During the inference process, this paper adopts a confidence threshold of 0.3 to remove false positive proposal candidates by the binary classification subnet. In addition, Soft-NMS [27] is employed after the light-head detection network to eliminate redundant boxes, and the top 150 scoring boxes are selected for evaluation.

B. Detection Results on the MS COCO Dataset

The detection accuracy of the proposed method is shown in Table I alongside recent state-of-the-art object detection methods, both anchor-based and anchor-free pipelines, on the MS-COCO test-dev set. The results in the table demonstrate that the proposed model significantly outperforms the CornerNet baseline model [11]. To be more specific, the proposed model improves AP, AP_{50} , AP_{75} , AP_S , AP_M , and AP_L by 6.8, 11.0, 10.7, 7.6, 8.7, and 8.1 points, respectively, compared with CornerNet on the same backbone network and input size. The results show that the combining of the binary classifier and the light-head detection network are very efficient for removing false positive object candidates and predicting remaining object candidates. Compared with Faster R-CNN using ResNet-101 backbone, which is a popular two-stage anchor-based object detection framework, the proposed model also achieves significantly higher detection accuracy. The proposed network improves AP, AP_{50} , AP_{75} , AP_S , AP_M , and AP_L by 11.2, 8.3, 14.9, 8.5, 12.5, and 14.2 points, respectively, compared with Faster R-CNN using ResNet-101 backbone. The results demonstrate that using an anchor-free approach to generate object proposals and designing a suitable detection network can enhance object detection performance. As seen in Table I, the proposed model also outperforms both anchor-based and anchor-free models while using lower input resolution. Moreover, as AP_S , AP_M , and AP_L denote AP for predicting objects at different sizes, the results in Table I reveal that the proposed model has improved performance in detecting medium and large objects compared to small ones. To be more specific, compared with CornerNet, the proposed model improves AP_S , AP_M , and AP_L by 7.6, 8.7, and 8.1 points, respectively. This result shows that the proposed network has difficulty in detecting small objects since predicting small objects requires richer semantic information features, which can be achieved by employing feature pyramids.

Table II shows the inference speed of the proposed model and several efficient methods on the MS-COCO dataset. All methods are implemented on Nvidia RTX 3070 GPU. As demonstrated in Table II, the proposed model obtains 2.8 fps on the MS-COCO dataset with input resolution 511×511 , which is comparable to the speed of the baseline CornerNet. The results shown in Table II also indicate that Faster R-CNN and FCOS have better speed, however, the proposed method achieves a better detection accuracy as shown in Table I. This demonstrates that the proposed method strikes a good balance between inference speed and detection accuracy.

TABLE I. EVALUATION OF THE PROPOSED METHOD AGAINST RECENT OBJECT DETECTION TECHNIQUES ON THE MS-COCO TEST-DEV SET IN TERMS OF DETECTION ACCURACY

Method	Backbone network	Input resolution	AP	AP ₅₀	AP ₇₅	AP _S	AP _M	AP _L

Proposed method	Hourglass-104	511×511	2.8

C. Ablation Study on Detection Network

To assess the efficacy of the proposed detection network for anchor-free proposal generation scheme, this paper examines the detection performance of several structures on the MS-COCO validation set. First, the original R-CNN detection head [3] is applied on the last backbone feature layer to produce final predictions based on object proposals produced by the proposed CornerNet. The proposed CornerNet extracts 50 top-left corner points and 50 bottom-right corner points based on the heatmaps to form object proposals. The R-CNN architecture consists of two fully connected layers with 4096 neurons each, featuring ReLU activations, followed by two additional fully connected layers for performing classification and regression tasks. Second, the proposed lightweight binary classification subnet is applied to remove false positive proposals. This binary classification takes $7 \times 7 \times 32$ feature maps generated by a RoIAlign layer as inputs. Remaining proposals are fed into the original R-CNN detection head to output final predictions. Finally, the proposed light-head detection subnet is applied on the last backbone feature layer to produce predictions without the lightweight binary

classification subnet. It should be noted that a large separable convolution layer is employed to reduce the feature map channels to 490 before feeding to the light-head detection subnet. For all experiments, this paper employs the same input resolution at 511×511 for fair comparison. Table III illustrates the detection performance of the proposed structures. As demonstrated in Table III, directly applying the R-CNN subnet on object proposals generated by the proposed CornerNet does not improve AP as many false positive proposals hinder the classification ability of R-CNN. When employing the binary classification subnet before the R-CNN subnet, the detection performance is improved. However, the detection speed is reduced as this structure uses a heavy detection head for prediction. On the other hand, using the light-head detection subnet after the binary classification subnet improves both the detection performance and speed. The result shows that the proposed detection network with a binary classification subnet and a light-head detection subnet obtains the best trade-off between detection accuracy and speed.

TABLE III. EVALUATION OF VARIOUS DESIGNS ON THE MS-COCO VALIDATION SET IN TERMS OF THEIR DETECTION ABILITY

Method	Input resolution	AP	FPS
CornerNet [11]	511×511	41.0	3.0
CornerNet + R-CNN	511×511	40.8	2.1
CornerNet + binary classifier + R-CNN	511×511	46.4	1.6
CornerNet + light-head detection subnet	511×511	41.1	3.8
CornerNet + binary classifier + light-head detection subnet	511×511	46.8	2.8

V. CONCLUSIONS

This paper presents a new object detection framework that combines the benefits of anchor-free and two-stage approaches. In the first stage, an anchor-free scheme is designed to generate object proposals. In the second stage, an efficient detection network comprised of a lightweight binary classification subnetwork for reducing false positive object proposals and a light-head detection subnetwork for final predictions is utilized. The proposed model was tested on the MS-COCO dataset and achieved the best balance between speed and accuracy compared to state-of-the-art anchor-based and anchor-free object detection methods. Specifically, the proposed model obtains 47.4 of AP on the MS-COCO test-dev set, which surpasses both anchor-free and one-stage model baselines. The focus of this study was on efficiency, and thus techniques for improving accuracy, such as combining different network layers or using multi-layer predictions, were not explored. As a result, the model struggles with detecting small objects. Future work will focus on improving the detection of small objects by replacing the backbone network with a feature pyramid network.

Abstract—In the context of the 4.0 technology revolution, which develops and applies strongly in many fields, in which the banking sector is considered to be the leading one, the application of algorithms to detect fraud is extremely important. necessary. In recent years, credit card transactions including physical credit card payments and online payments have become increasingly popular in many countries around the world. This convenient payment method attracts more and more criminals, especially credit card fraud. As a result, many banks around the world have developed fraud detection and prevention systems for each credit card transaction. Data mining is one of the techniques applied in these systems. This study uses the Ripper algorithm to detect fraudulent transactions on large data sets, and the results obtained with accuracy, recall, and F1 measure of more than 97%. This research then used the Ripper algorithm combined with Ensemble Learning models to detect fraudulent transactions, the results are more than 99% reliable. Specifically, this model using the Ripper algorithm combined with the Gradient Boosting method has improved the predictive ability and obtained very reliable results. The use of algorithms combined with machine learning models is expected to be a new topic and will be widely applied to banks' or organizations' activities related to e-commerce.

Keywords—Financial fraud; data mining; credit card fraud; transaction; ensemble methods

I. INTRODUCTION

The e-commerce sector is expected to account for 21.8% of total global retail sales by 2024 [1]. As the worldwide e-commerce market share increases risks also increase, trusting becoming a concern as the number of frauds and scams has increased significantly over the past few years [2]. The e-commerce market in 2021 faces a risk of US\$20 billion due to fraudulent transactions [3]. The most common types of fraud include account takeovers, identity theft, covert fraud, and chargeback fraud [3]. These frauds can affect the finances of both consumers and merchants and reduce overall confidence in e-commerce [4].

Data mining techniques have shown promising performance in detecting fraud [5], [6], [7] and rule from large data sets [8]. To solve the problem of transaction fraud in e-commerce, there have been many studies using data mining rules to build laws, thereby detecting transaction fraud. These studies and their results will be introduced in Part II (Related Works).

In many forecasting models, the Repeated Incremental Pruning to Produce Error Reduction (Ripper) algorithm is chosen to apply [9] because this algorithm has high reliability and coverage. Next, this study uses a synchronous learning method in machine learning to combine with Ripper algorithm to improve the reliability and accuracy of fraud detection. The results of study have yielded very positive results. This model has been applied in many other fields but is still quite new in the field of e-commerce in the world as well as in Vietnam.

The article structure consists of five sections. Section I is an overview of the research, Section II introduces the research done related to the article, and Section III is the proposed solutions and techniques to solve the problem dealing with the problem posed. Section IV lists the order of steps to conduct the experiment as well as the software and tools used. Finally, Section V summarizes and concludes with the issues achieved in the study as well as suggestions for future research.

II. RELATED WORKS

Research related to fraudulent transaction detection is numerous and has been conducted in a variety of fields, including finance, e-commerce, credit cards, multi-level commerce, and many others. Data mining techniques used include Support vector machine (SVM), Fuzzy Logic based system (FL), Hidden Markov Model (HMM), Artificial Neural network (ANN), Genetic Algorithm (GA), Bayesian Network (BN), K-Nearest Neighbor Algorithm (KNN), Decision Tree (DT), Logistic Regression (LR), Outlier's Detection and other Classification techniques [6]. Below is a summary of the articles, mining techniques used, and research results.

• Support Vector Machine:

N. K. Gyamfi and J. D. Abdulai used SVM to detect bank fraud [6]. The result shows an improvement of the SVM method by 80% which is considered better performance.

M. Jeragh, M. AlSulaimi combined autoencoders and one class support vectors machine for fraudulent credit card transactions detection [6]. The result of two combined models achieved promising results, especially when evaluated using metrics performance.

K. Poongodi and D. Kumar used SVM with Information Gain Based Classification algorithm to identify fraudulent and legal transactions [10]. The result shows that the accuracy of detection is enhanced in the credit card fraud detection system by using SVM with information gain-based classification.

Y. Kumar, S. Saini, and R. Payal proposed a comparison between three data mining algorithms: Logistic Regression, Random Forest, and Support Vector Machine [11]. The study shows that when comparing the result of three algorithms the random forest algorithm gives better results for the classification of fraud with 81.79% accuracy.

- Artificial Neural Network:

A. A. Rizki, I. Surjandari, and R.A. Wayasti used data mining applications to detect financial fraud in Indonesia's public companies [6]. The finding proved that feature selection helped in increasing the accuracy of the SVM method with 88.37% while ANN gave the most effective accuracy with 90.97%.

I. Sadgali, N. Sael, and F. Benabbou proposed a comparative study using Neural Networks Techniques, Neural Networks (NN), Multilayer Perceptron Layer (MPL), and Convolutional Neural Networks (CNN), for credit card fraud detection [12]. The result shows that CNN has the highest accuracy.

A Sahu, GM Harshvardhan, MK. Gourisaria detected fraudulent transactions by several machine learning models and the artificial neural network [13]. The result shows that all the models have a very high percentage of true negatives due to the heavy count of non-fraud cases.

- Decision Tree:

V. Jain, M. Agrawal, and A. Kumar [14] used three machine learning algorithms, Decision Tree, Random Forest, and XGBoost applied to a data set have the data of 284808 credit cards. The performance of the XGBoost algorithm is found best with the highest accuracy of 99.962 percent. The performance of the Decision Tree is minimum with an accuracy of 99.923 and the performance of the Random Forest algorithm is 99.957 percent in credit card transactions.

J. Soyemi and H. Mudasiru implemented a decision tree algorithm augmented with regression analysis for fraud detection in credit cards [15]. This study was able to achieve its aim by building a machine-learning model that is capable of detecting fraud.

In this article, this study used Ripper algorithm [7] to perform a reliability test when predicting transaction fraud when the transaction volume is increasing and unbalanced, then combine Ripper and Ensemble Learning Methods to create a more reliable predictive model (ROC increase from 88% to 98%).

III. PROPOSED SOLUTIONS AND TECHNIQUES

A. Implementing Data Set

Focusing on the objective of this study, "Aggregated Financial Dataset for Fraud Detection" was selected [16], [17]. The dataset contains approximately 6.3 million data about mobile money transactions and consists of 10 attribute columns, and one target column. This dataset includes a 30-day simulation of real-time transactions and is executed in steps, each mapping to an hour. The original data set includes the following columns:

- step: transaction step
- amount: the number of coins traded
- name_org: sender account name
- old_balance_org: initial balance of the sending account
- new_balance_org: the following balance of the sending account
- name_dest: recipient account name
- old_balance_dest: initial balance of the receiving account
- new_balance_dest: the following balance of the receiving account
- is_fraud: whether the transaction is fraudulent or not
- is_flagged_fraud: whether the transaction is suspected of fraud
- transaction_type: transaction type (5 types)
- isFraud: This is a transaction made by rogue agents inside the simulation. In this particular dataset, the fraudulent behavior of the agents aims to gain profits by controlling, taking over the customer's account, attempting to withdraw money by switching to another account, and then withdrawing money from the system.
- isFlaggedFraud: The business model aims to control large transfers from one account to another and flag illegal attempts. An illegal attempt in this dataset is an attempt to transfer more than 200000 in a single transaction. The isFlaggedFraud column is used when there is an attempt to transfer more than 200000 in a transaction, so basically for isFlaggedFraud, it will be 1 if the transaction amount exceeds 200000. When isFlaggedFraud equals 1, the value of isFraud equals 1, so isFlaggedFraud can be discarded on processing if necessary.

B. Fraudulent Transaction

Transaction fraud is an act of fraud in the process of conducting financial transactions, intending to appropriate property, money, or personal benefits of the offender.

Types of transaction fraud can range from using fake information to open an account or borrow money, to performing invalid transactions, transferring money to the wrong address, or spoofing identity to cheat others.

Transaction fraud not only causes damage to the assets of the parties involved but also affects the trust and reputation of the financial system, reducing the ability to conduct safe and efficient transactions. Therefore, detecting and preventing transaction fraud is very important to protect the safety and reliability of the financial system.

In addition to the transaction that is considered fraudulent as mentioned above, in the data set under consideration, a transaction is suspected to be fraudulent if it violates integrity constraints. There are two types of integrity constraints on this data set, domain-related integrity constraints and inter-

attribute integrity constraints. The first is a domain-related constraint: it ensures that a field's value must meet a specific condition, ensuring that a field's value falls within a specific range. The second constraint is an inter-attribute constraint: a type of constraint in a relational database that ensures that the values in one or more pairs of attributes are logically related to each other. Specifically, if the value of one attribute changes, the values in other attributes that depend on it will also change accordingly to ensure data integrity and accuracy.

Here are some examples of the two integrity constraints mentioned above.

+ R1: For all money transfers and withdrawals, the old balance cannot be equal to 0.

$\forall q: (q.type = TRANSFER \wedge q.oldBalanceOrig = 0) \vee (q.type = CASH_OUT \wedge q.oldBalanceOrig = 0)$

+ R2: After transferring money, the new balance cannot be equal to 0.

$\forall q: (q.type = TRANSFER \wedge q.newBalanceDest \leq 0)$

+ R3: For all money transfers and withdrawals, the old balance is always greater than the amount to be transferred.

$\forall q: (q.type = TRANSFER \wedge q.oldBalanceOrig > q.amount) \vee (q.type = CASH_OUT \wedge q.oldBalanceOrig > q.amount)$

+ R4: In all money transfers, the old balance is always greater than the new balance.

$\forall q: (q.type = TRANSFER \wedge q.oldBalanceOrig > q.newBalanceOrig)$

+ R5: In all money transfers and withdrawals, the old balance minus the new balance is always greater than or equal to the amount to be transferred-withdrawn.

$\forall q: (q.type = TRANSFER \wedge q.oldBalanceOrig - q.newBalanceOrig < q.amount) \vee (q.type = CASH_OUT \wedge q.oldBalanceOrig - q.newBalanceOrig < a.amount)$

+ R6: Recipient did not receive enough transaction funds.

$\forall q: (q.type=TRANSFER \wedge q.oldBalanceDest + q.amount < q.newBalanceDest)$

+ R7: After transferring money, the recipient's old balance must be less than the recipient's new balance.

$\forall q: (q.type = TRANSFER \wedge q.oldBalanceDest > q.newBalanceDest)$

+ R8: Do not transfer and withdraw all funds or do not transfer and withdraw more than the amount available when making the withdrawal.

$\forall q: (q.type = TRANSFER \wedge q.amount \geq q.oldBalanceOrig) \vee (q.type = CASH_OUT \wedge q.amount \geq q.oldBalanceOrig)$

Thus, a transaction in the "Aggregated Financial Dataset for Fraud Detection" dataset that violates one of the abovementioned constraints will be considered a fraudulent transaction.

C. Proposed Algorithm

This study implemented the RIPPER (Repeated Incremental Pruning to Produce Error Reduction) algorithm. In machine learning, iterative incremental pruning to reduce errors is a propositional rule learner proposed by William W. Cohen (1995) [9] as an optimal version encoding of the IREP algorithm. The Ripper algorithm is a machine learning algorithm used to detect fraud in financial transactions. This algorithm works by classifying transactions into two categories: trusted transactions and fraudulent transactions. It then uses machine learning techniques to identify attributes that are important to distinguish between these two types of transactions. RIPPER is a greedy algorithm implemented in the following steps:

+ Step 1: Divide the training data into two parts: the training set and the test set.

+ Step 2: Determine the starting rule set by finding all the rules that can be determined from the initial training set.

+ Step 3: Use the starting rule set to classify the records in the training set.

+ Step 4: Repeat the following steps to find and remove unnecessary rules sequentially:

a) evaluate all rules in the current rule set,

b) remove unnecessary rules,

c) construct a new set of rules from the remaining set of rules.

+ Step 5: Use the final rule set to classify the records in the test set.

The RIPPER algorithm is used to solve classification problems where the goal is to classify objects into known classes. This algorithm has proven to be effective in many practical applications, including handwriting recognition, disease detection, and document classification.

When implemented, this research handled the execution steps of Ripper as follows:

+ Step 1: Read transaction data from the CSV file.

+ Step 2: Convert the column's type to match the requirement.

+ Step 3: Apply Ripper with several RipperK optimization iterations equals 10.

+ Step 4: Train the model.

Ripper has improved IREP with the OPIMIZERULESET process. This process optimized IREP's code and reduced it to a leaner one. Ripper works well on data sets with unbalanced class distribution. In a dataset, if there is a record set in which most of the records belong to a particular class and the remaining records belong to different classes, then the data set is said to have a non-distribution balance between classes. It works well with noisy datasets because it uses a validation set to prevent the model from overfitting.

D. Proposed Models

In machine learning, no one algorithm is always good for all applications and all data sets because machine learning algorithms are usually based on a set of parameters (hyperparameters) or a certain assumption about the distribution data. Therefore, to find the right algorithms for our dataset, we may need a lot of time to test different algorithms and then adjust the algorithm's parameters (tuning hyperparameters) to obtain the highest accuracy.

To increase the accuracy of the dataset is to combine several models. This method is called Ensemble Learning. Different models with different capabilities can best perform different types of work, and when combined properly, form a powerful hybrid model capable of improving performance, and overall performance compared to using the models alone. Ensemble Methods are divided into the following three categories: Boosting, Bagging, and Stacking.

1) *Gradient boosting [18]*: Gradient Boosting is a machine learning algorithm of type Ensemble Learning, it uses a reinforcement process based on sub-models to create a better overall model.

Gradient Boosting handles data classification or regression using a series of sub-models that are built on top of each other, each of which targets the errors of the previous model. This process results in a better overall model, with more accuracy than each sub-module.

Gradient Boosting is commonly used in classification and regression problems, such as handwriting classification, spam email classification, stock price forecasting, and other problems in the field of artificial intelligence.

- Gradient Boosting Model: illustrated in Fig. 1 below.

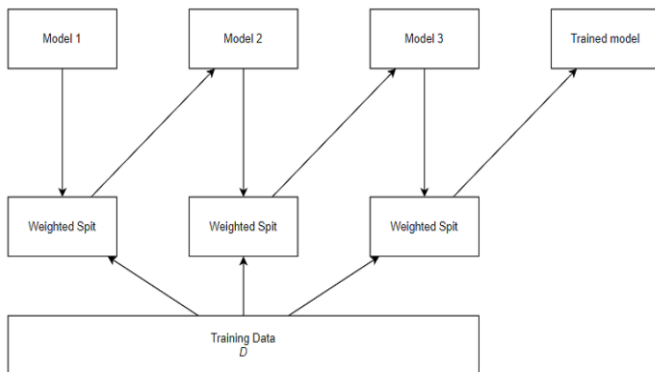

Fig. 1. Gradient boosting operation model.

- Processing steps of the Gradient Boosting Model:
 - + Step 1: Define a lost function.
 - + Step 2: Build a base model to make a prediction.
 - + Step 3: Compute each prediction's residuals (the difference between the predicted and actual values).
 - + Step 4: Fit a new model to predict these residuals.

+ Step 5: Add this new model's predictions to the previous model's predictions.

2) *Bagging [19]*: Bagging (Bootstrapped Aggregating) is a machine learning algorithm of type Ensemble Learning, it uses several sub-models to create a better overall model.

Bagging deals with the classification or regression of data using several sub-models built on the same data set, but each of the sub-models is trained on a bootstrapped dataset (the sampled data set), by starting from an original data set and then choosing a random number of data points to replace the new data set). This process results in a better overall model, with more accuracy than each submodule.

Bagging is commonly used in classification and regression problems, such as handwriting classification, spam email classification, stock price forecasting, and other problems in the field of artificial intelligence.

- Bagging model: illustrated in Fig. 2 below.

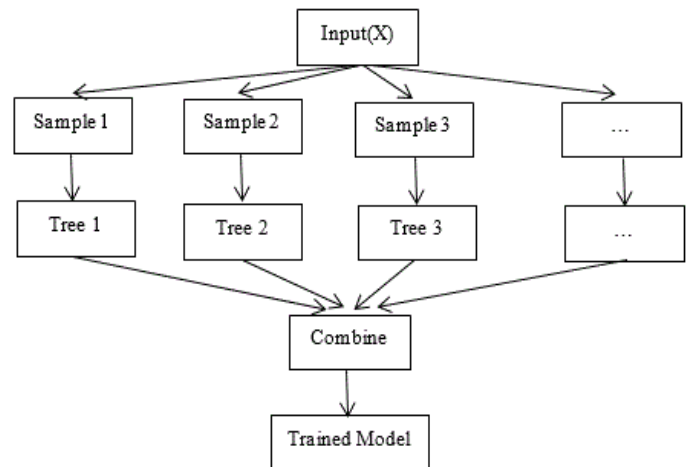

Fig. 2. Bagging operation model.

- Processing steps of the Bagging Model:
 - + Step 1: Build k bootstrap samples from the original dataset.
 - + Step 2: For each bootstrap sample, build a decision tree.
 - + Step 3: Average the predictions of each tree to produce a final model.

3) *Stacking [20]*: Stacking (stacked generalization) is a machine learning algorithm in the Ensemble Learning category. It uses a set of submodules to create a better overall model.

In Stacking, sub-models are trained on an initial dataset and then used to predict values for the new data set. The prediction results of each sub-model are used as input to the overall model. The population model is then trained on the sub-model prediction results to predict the final value.

- Stacking model: illustrated in Fig. 3 below.

Fig. 3. Stacking operation model.

• Processing steps of the Stacking model:

- + Step 1: Split the dataset into training and testing datasets.
- + Step 2: Train multiple models on the training dataset.
- + Step 3: Make a prediction using these models on the testing dataset.
- + Step 4: Use these predictions as input features to train a new model (the meta-model) on the testing dataset.

E. Combination of Ripper with Ensemble Learning Model

1) Ripper combines with gradient boosting:

- + Step 1: Read transaction data from the CSV file.
- + Step 2: Declare Gradient Boosting algorithm using exponential loss function, 1000 boosting stages, and square error criterion to qualify the quality of every split action.
- + Step 3: Train the model.
- + Step 4: Consecutively apply Ripper to improve model metrics.

2) Ripper combines with bagging:

- + Step 1: Read banking data from the CSV file.
- + Step 2: Initialize the Bagging algorithm with the number of rules generated in the training process equal to 1000.
- + Step 3: Apply Ripper to improve the accuracy.
- + Step 4: Train the model.

3) Ripper combines with stacking:

- + Step 1: Read banking data from the CSV file.
- + Step 2: Initialize Random Forest algorithm with a random state is 10 and 100 trees in the forest.
- + Step 3: Initialize Linear SVC algorithm with a random state equal to 42.
- + Step 4: Initialize Standard Scaler algorithm.

- + Step 5: Initialize the Stacking algorithm with the three algorithms mentioned above and Logistic Regression as the final algorithm.
- + Step 6: Apply Ripper to improve the model's metrics.
- + Step 7: Train the model.

IV. EXPERIMENT

A. Experimental Tools and Software

Programming environment and tools: Python and PyCharm. Python is a programming language widely used in data science and machine learning. PyCharm is a fully integrated development platform (IDE) designed specifically for Python programmers.

We implemented the algorithms on a laptop with the following configuration: CPU: Intel core i7-12700H, GPU: Intel Iris XE Graphics, RAM: 16Gb.

- Implement Ripper algorithm to experiment stability with unbalanced data:
- + Initialize Ripper: `ripper = RIPPER()`

The parameters of `RIPPER()` are shown in Table I.

TABLE I. PARAMETERS OF RIPPER()

Parameters	Description	Default value	Data type
k	The number of loops to optimize	2	int
prune_size	Pruning ratio (prune into two sets, grown set, and prune set)	0.33	float
Random_state	Rules generating seed (rules generated are the same if seeds are the same)	none	int
max_rules	Maximum number of rules	none	int
max_rule_conds	A maximum number of conditions in each rule.	none	int
max_total_conds	A maximum number of conditions in a whole rule set.	none	int
verbosity	Between 0 and 5, print to the terminal rule-generating process. 0 means do not print. The larger the number the more detail: 1: Print the main process. 2: Print the optimization phases. 3: Print the calculations needed to optimize. 4: Print the optimization/pruning process step by step. 5: Print the operations needed to add/prune rules.	0	int

- + Training: `ripper.fit(<file data>, <classify col>, <positive value>...)`

The parameters of the `.fit()` method are shown in Table II.

TABLE II. THE PARAMETERS OF THE .FIT()

Parameter	Description	Data type
trainset	The data set used to train.	DataFrame/Numpy array
y	Class labels corresponding to trainset rows. Use if class labels aren't included in the trainset.	str/int/bool
class_feat	Column name or index of the class feature. The use of the class feature is still in the trainset.	str, int
pos_class	Name of the positive class.	str/bool
feature_names	Specify feature names. If None, feature names default to column names for a DataFrame, or indices in the case of indexed iterables such as an array or list.	List<str>
initial_model	Pre-existing model from which to begin training.	str
cn_optimize	Use algorithmic speed optimization.	bool

+ Dataset processing:

This study used the "Aggregated Financial Dataset for Fraud Detection" dataset introduced above for processing. First, remove unnecessary columns to reduce processing time, those columns include name_org and name_dest. Next, divide the data set into the train and test sets. The train set consists of 6000 lines of cheat data and 4 million lines of non-cheat data. The test set consists of 2000 lines of fraudulent data and 2 million lines of non-cheat data.

Continue to divide the training set into four small datasets and increase the imbalance rate between the sets to evaluate the effectiveness of Ripper against large unbalanced sets:

- The first set contains 6000 fraudulent data and 60,000 non-fraud data.
- The second set contains 6000 fraudulent data and 100,000 non-fraud data.
- The third set includes 6000 fraudulent data and 150,000 non-fraud data.
- The fourth set contains 6000 fraudulent data and 300,000 non-fraud data.

The test set consists of 2 thousand fraudulent lines and 2 million non-fraud lines. This set contains data that RIPPER has never encountered before, used to evaluate accuracy.

+ Results:

Results were obtained after performing RIPPER with 4 data sets (Table III).

TABLE III. STATISTICAL RESULTS AFTER TRAINING

Dataset	TPR	FPR	Preci-son	Recall	F1 score	ROC
6_60	0.996	0.03	0.97	0.96	0.96	0.977
6_100	0.992	0.026	0.97	0.86	0.91	0.949
6_150	0.995	0.031	0.97	0.88	0.92	0.906
6_300	0.996	0.023	0.98	0.79	0.87	0.880

Meaning of columns

In the Ripper algorithm, "Positive" and "Negative" are two types of labels used to evaluate and classify transactions.

+ Positive: represents valid transactions, no fraud.

+ Negative (negative): represents fraudulent transactions.

During training, the algorithm will use transactions labeled Positive and Negative to build a classification model for predicting whether new transactions will be fraudulent or not. In a data set of credit card transactions, a transaction labeled Positive would be considered a valid and fraud-free transaction, while a transaction labeled Negative would be considered a likely transaction cheat. Positive and Negative labels play an important role in evaluating and improving the accuracy of the Ripper algorithm in detecting transaction fraud.

- Dataset: dataset used for training
- True positive rate (TPR): The ratio of correctly predicting fraud cases, TPR is calculated using the formula:

$$\text{True Positive} / (\text{True Positive} + \text{False Negative})$$
- False positive rate (FPR): The ratio of false predictions of fraud cases, FPR is calculated using the formula:

$$\text{False Positive} / (\text{False Positive} + \text{True Negative})$$
- Precision: Precision is the ratio of True Positive predictions that are correct to the total number of True Positive predictions; precision is calculated using the formula:

$$\text{True Positive} / (\text{True Positive} + \text{False Positive}) = \text{Correct True Positive Predictions} / \text{True Positive Predictions}$$
- Recall: Recall is the ratio of True Positive predictions that are correct to the total number of True Positives on the whole dataset; recall is calculated using the formula:

$$\text{True Positive} / (\text{True Positive} + \text{False Negative}) = \text{Number of correct TP predictions} / \text{Total number of TP}$$
- F1 score: F1 score is the harmonic mean of precision and recall, the more accurate the F1 score, the better the model predicts; F1 score is calculated using the formula: $2 * ((\text{precision} * \text{recall}) / (\text{precision} + \text{recall}))$

ROC: It has a value of [0,1], representing the model's prediction accuracy. The higher the ROC score, the more accurate the model is. Table IV below is the rule list with the number of iterations of Ripper and the refined rule set.

TABLE IV. RULE LIST WITH THE NUMBER OF ITERATIONS RIPPER AND REFINED RULE SET WITH K=10

Number	Rule
1	transaction_type==1 and new_balance_dest<=16123.02 and old_balance_dest<=1087.36
2	transaction_type==1 and new_balance_dest<=7306.88 and old_balance_dest<=225.92
3	transaction_type==1 and new_balance_dest<=16123.02 and old_balance_dest<=1087.36
4	new_balance_org<=1744.75 and transaction_type==1 and new_balance_dest<=17247.49 and old_balance_dest<=11186.22
5	new_balance_org<=1572.27 and amount>=2106972.01 and transaction_type==0
6	transaction_type==0 and amount>=3529762.55
7	new_balance_org<=1572.27 and old_balance_org>=1388977.19 and old_balance_org<=1908598.9

17	transaction_type==0 and amount>=1697480.93 and amount <=2519153.53
18	new_balance_org<=1572.27 and old_balance_org>=697672.86 and old_balance_org<=955088.21 and transaction_type==0

Match the rules shown in Table V.

TABLE V. RULES WITH HIGH COVERAGE

No	Rule	Ratio
1 > 2 > 3	transaction_type==1 and new_balance_dest<=16123.02 and old_balance_dest<=1087.36	50%
4	new_balance_org<=1744.75 and transaction_type==1 and new_balance_dest<=17247.49 and old_balance_dest<=11186.22	48%
5	new_balance_org<=1572.27 and amount>=2106972.01 and transaction_type==0	10%
6 > 8	transaction_type==0 and amount>=3529762.55	6.5%
7	new_balance_org<=1572.27 and old_balance_org>=1388977.19 and old_balance_org <=1908598.9	5.5%
9	amount>=5014130.87 and new_balance_dest<=17247.49	4,7%

At this stage, the retainer is used. The dataset is divided into 10 sets. The purpose of the division is that after each step, the percentage of fraudulent data is gradually increased, creating an imbalance and checking the stability of the rule set. Each set contains 200 fraudulent data and 2000 non-cheat data (the data of these 10 datasets do not overlap). Then, add each data set in turn, corresponding to 10 cycles to see the coverage of the rules after having new data. Table VI below is the simulation rule range for ten cycles.

TABLE VI. SIMULATION RULE RANGE FOR TEN CYCLES

	Rule 1 (%)	Rule 2 (%)	Rule 3 (%)	Rule 4 (%)	Rule 5 (%)	Rule 6 (%)
Base Coverage	50	48	10	6.5	6.5	4.7
1	49	46	8	5	4	6
2	48	44.5	7	5	6	5
3	51.5	50	7	4.5	8.5	3.5
4	43.5	42	8.5	6	6.5	3.5
5	50.5	46.5	7.5	5.5	7	4.5
6	52	49.5	11	7.5	7	5.5
7	48	46.5	8.5	4.5	4	3
8	50	46	8.5	5.5	8	2
9	49.5	48	13	7.5	7	3.5
10	48.5	47	7.5	3.5	3.5	4

After 10 cycles, although the amount of data gradually increases and causes a high imbalance, the test has shown that Ripper is stable and does not suffer from "overfitting".

B. Experimental Results

Finally, this study used the fourth dataset containing 6000 fraudulent data and 300000 non-fraud data above to check the criteria for the Ripper algorithm and Ripper combined with Ensemble Learning Methods.

1) Implement the Ripper

+ Results:

- The set of rules: 31.
- Metrics: described in Table VII below.

TABLE VII. METRICS OF RIPPER

	precision	recall	f1-score	support
0	1.00	1.00	1.00	60296
1	0.97	0.77	0.86	1241
accuracy			0.99	61537
macro avg	0.98	0.88	0.93	61537
weighted avg	0.99	0.99	0.99	61537

- Confusion matrix: False Positive = 60267, False Negative = 29, True Negative = 290, True Positive = 951.
- ROC = 0.88. Execution time: 6m 58s.

2) Implement the Ripper combines with Gradient Boosting (Fig. 4)

+ Operation model:

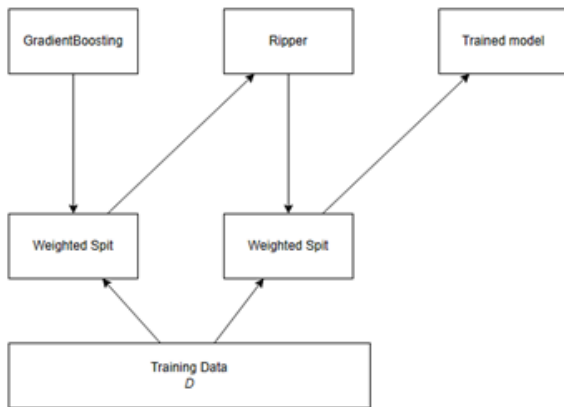

Fig. 4. Operation model by ripper combines with gradient boosting.

+ Results:

- The set of rules: 21
- Metrics: Described in Table VIII below.

TABLE VIII. METRICS OF RIPPER COMBINES GRADIENT BOOSTING

	precision	recall	f1-score	support
0	1.00	1.00	1.00	60372
1	0.98	0.92	0.95	1165
accuracy			1.00	61537
macro avg	0.99	0.96	0.97	61537
weighted avg	1.00	1.00	1.00	61537

- Confusion matrix: False Positive = 60349, False Negative = 23, True Negative = 90, True Positive = 1075.
- ROC = 0.96. Execution time: 10m 57.3s.

3) Implement the Ripper combines with Stacking (Fig. 5)
+ Operation model:

Fig. 5. Operation model by ripper combined with stacking.

+ Results: The set of rules: 45.

- Metrics: Described in Table IX below.

TABLE IX. METRICS OF RIPPER COMBINED WITH STACKING

	precision	recall	f1-score	support
0	1.00	1.00	1.00	60372
1	0.95	0.90	0.93	1165
accuracy			1.00	61537
macro avg	0.97	0.95	0.96	61537
weighted avg	1.00	1.00	1.00	61537

- Confusion matrix: False Positive = 60317, False Negative = 55, True Negative = 111, True Positive = 1054.
- ROC: 0.95. Execution time: 8m 46.8s.

4) Implement the Ripper combines with Bagging (Fig. 6)
+ Operation model:

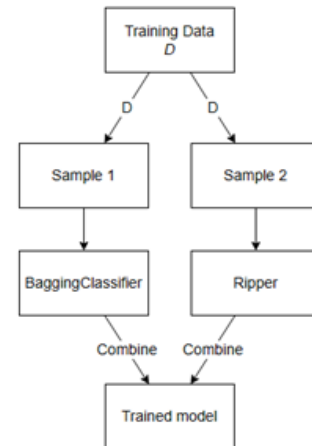

Fig. 6. Operation model by ripper combines with bagging.

- + Results: The set of rules: 44.
- Metrics: Described in Table X below.

TABLE X. METRICS OF RIPPER COMBINES BAGGING

	precision	recall	f1-score	support
0	1.00	1.00	1.00	60372
1	0.95	0.95	0.95	1165
accuracy			1.00	61537
macro avg	0.98	0.98	0.98	61537
weighted avg	1.00	1.00	1.00	61537

- Confusion matrix: False Positive = 60291, False Negative = 42, True Negative = 60, True Positive = 1144.

- ROC: 0.98. Execution time: 14m 41.7s.

C. Comparison

Table XI below summarizes the achieved indicators of each model.

TABLE XI. COMPARE CRITERIA BETWEEN METHODS

Criteria	Ripper (1)	Ripper combines Boosting (2)	Ripper combines Bagging (3)	Ripper combines Stacking (4)
Execution time	6m 58s	10m 57.3s	14m 41.7s	8m 46.8s
The set of rules	32	21	44	45
Precision	0.97	0.98	0.95	0.95
Recall	0.77	0.92	0.95	0.90
F1-score	0.86	0.95	0.95	0.93
ROC	0.883	0.961	0.976	0.952

Of the four models mentioned above, (1) gives the worst results because only a single algorithm is used. Although (2) produces the fewest rules, this is the most optimal set of rules because of its processing model. On the other hand, in models (3) and (4), the sets of rules are generated independently, and then combined, so the rules will tend to be more and overlap. This leads to models (3) and (4) generating more rules but not as efficient the model (2).

This result shows that Ripper combined with Gradient Boosting gives the best results. Compared with related studies in part I such as [4], [6], [7], [11], [12], this result achieved ACC and ROC higher than all. This study shows that Ripper combined with Gradient Boosting gives the best results.

V. CONCLUSION

The Ripper algorithm has been studied and applied effectively in the field of data mining. Ripper is a classification algorithm in machine learning and is used in many different fields. Such as data classification: Ripper can be used to classify data based on their characteristics and values. Object recognition: Ripper can be used to identify objects in an image or video by classifying objects according to their features and values. Market Research: Ripper can be used to analyze market data to identify potential customer groups and other groups. Phrase Search: Ripper can be used to

search for phrases in text or other textual data. The limitation of the study is that the algorithm executes slowly if the number of attributes of the data set is too large. In this study, the proposed method was improved by combining Ripper with Ensemble Learning Method, namely Gradient Boosting to create a new predictive model with higher accuracy and reliability (ROC increased from 88% to 98% compared to just using regular Ripper). Depending on the structure and distribution of the data set, this research can use the Ripper algorithm in combination with Gradient Boosting, Bagging, or Stacking to achieve the desired result. Thus, the proposed model has obtained better results than related studies (ACC and ROC). Besides, combining models together for training usually takes more processing time and takes up more memory resources than single models.

However, detecting transaction fraud is a constant challenge, as scammers are always looking for ways to change techniques and tricks to avoid detection. Therefore, the use of fraud detection solutions needs to be continuously updated and optimized to keep the financial system safe and meet the requirements of stakeholders.

Abstract—Achieving the desired level of satisfaction for a decision-maker in any decision-making scenario is considered a challenging endeavor because minor modifications in the process might lead to incorrect findings and inaccurate decisions. In order to maximize the decision-maker's satisfaction, this paper proposes a Single-valued Neutrosophic Geometric Programming model based on pentagonal fuzzy numbers. The decision-maker is typically assumed to be certain of the parameters, but in reality, this is not the case, hence the parameters are presented as neutrosophic fuzzy values. The decision-maker, with this strategy, is able to achieve varying levels of satisfaction and dissatisfaction for each constraint and even complete satisfaction for certain constraints. Here the decision maker aims to achieve the maximum level of satisfaction while maintaining the level of hesitation and minimizing dissatisfaction in order to retain an optimum solution. Furthermore, transforming the objective function into a constraint adds one more layer to the N -dimensional multi-parametrizes α , β and γ . The advantages of this multi-parametrized proposed method over the existing ones are proven using numerical examples.

Keywords—Decision making; pentagonal neutrosophic numbers; single-valued neutrosophic geometric programming; multi-parametric programming

I. INTRODUCTION

Mathematical optimization, an area of applied mathematics, is used to solve real-life issues by generating mathematical models to produce feasible outcomes. In today's world the significance of mathematical optimization and decision making can be explored in various fields [1-5]. Geometric Programming (GP) is a technique in the field of mathematical optimization and multi-objective decision making that is considered a significant optimization problem consisting of objective functions and constraints composed of monomials or posynomials that are designed to solve real-world engineering problems by generating feasible outcomes [6]. The basics of GP were initially introduced in a book by Duffin, Petersen and Zener [7], and afterward its improved and extended applications can be seen in various fields. Although many problems were solved by conventional GP, most of the time the problem contains uncertainties and is considered fuzzy rather than crisp. To deal with these Zadeh [8] introduced Fuzzy Sets (FS) which were later implemented in decision making by Bellman and Zadeh [9]. Tanaka and others [10] proposed fuzzy mathematical optimization by developing the notion of level sets. Later on, Zimmermann

[11] introduced fuzzy linear programming using the concepts of fuzzy sets. Furthermore, the authors of [12] addressed series system models with the help of fuzzy parametric GP and achieved optimized system reliability and minimized cost. In the research of Samadi et al., [13] the authors presented an inventory model based on fuzzy GP for maximizing profit by implementing shortages.

Fuzzy decision-making models excel at addressing and optimizing decision-making problems, however evaluating membership values to our satisfaction is not always attainable due to a lack of readily available information. To overcome this issue, Atanassov [14] proposed Intuitionistic Fuzzy Set (IFS), which considers both membership and non-membership functions to effectively deal with vagueness rather than just the membership function as in fuzzy sets. Researchers then progressed with IFS in many real-life problems dealing with vague data, some of which are mentioned in the following literatures [15-18]. Smarandache later on introduced Neutrosophic sets (NS) [19] as the generalization of classical sets, FS and IFS which includes three independent membership functions representing the degrees of truth, indeterminacy and falsity for handling inconsistent, ambiguous and partial data more efficiently. However, the concept of NFS was established from a philosophical perspective, for which Wang et al., [20] introduced the notion of Single-valued Neutrosophic Sets (SvNS) to address practical, scientific and engineering challenges. Due to the limitations of the knowledge that humans acquire through experience or observation of the outside world, all the components indicated by SvNS are extremely appropriate for human consciousness. In contrast to the IFS, which cannot manage or represent indeterminacy and imprecise data, neutrosophic components are clearly the best fit in the representation of indeterminacy and inconsistent information. As a result, SvNS has quickly developed and is used in many different contexts [21-24]. With the advancement in research using SVNS many variations came into existence which includes triangular NS [25], trapezoidal NS [26] and recently pentagonal NS [27]. Das and Chakraborty initially applied pentagonal NS in solving linear programming problems by proposing a score function for converting the pentagonal NS data into crisp values. Further, Khalifa et al., [28] applied pentagonal neutrosophic based linear programming for optimizing stock portfolio investment. The authors of [29]

worked on maximizing profit using EOQ models using pentagonal neutrosophic demands.

A. Gaps in Existing Research and Contribution

The aspect of decision-making can be seen in many domains including geometric programming where several researchers contributed their works by developing and presenting diverse techniques to solve complex decision making problems and finding optimum solutions.

In the previous scenarios, the expert person was introduced with the simple single vector α whose value would be constant for each constraint which bound the expert to provide the same level of satisfaction to the decision maker for every constraint [30]. Thereby the expert is in a dilemmatic situation where he needs to satisfy the decision-maker but without compromising the optimal solution resulting in following extra steps for the sake of optimality. This scenario is tackled in our work where the optimal solution is achieved while providing satisfaction to the decision maker.

A multi-parametric programming approach was introduced in [31] for reaching the optimal solution in Linear Programming Problems (LPP). They proposed a method comprising a vector that would help the decision maker to attain a better satisfactory level for LPP. Though, the authors here employed an n-dimensional vector to obtain an optimal solution but did not reach the highest level of satisfaction of the decision maker in Geometric Programming Problems (GPP) since they did not consider fuzzy numbers for their work. So to overcome this, [36] proposed a multi-parametric vector α based on fuzzy numbers to solve the geometric programming problems to deal with the vagueness present in the decision making scenario. Here they were able to reach even the complete satisfaction for the decision maker in certain constraints. As a result, the expert is able to satisfy the decision maker for each constraint while maintaining the optimal value in the fuzzy GPP. Unfortunately, Fuzzy numbers cannot deal with indeterminacy, which is why Neutrosophic numbers are used in our proposed model.

However, the term "decision making" doesn't always indicate "identifying the best output from any programming problem". Instead, the decision-maker aims to achieve the intended level of satisfaction, which may or may not be the same as maximizing or minimizing the objective function. As a result, the constraint has a different effect than in the standard version. The previous attempts in multilevel decision making are mostly focused on identifying the ideal circumstances and solution algorithms to tackle linear, nonlinear, and discrete elementary problems, with only one decision allocated to each decision level for optimizing the final distinct objective. Therefore, this study focuses on maximizing satisfaction and minimizing dissatisfaction levels of the decision-maker while keeping in check the hesitation levels by incorporating multi-parametric vectors α , β and γ to Single-valued Neutrosophic Geometric Programming (SvNGP). Furthermore, the pentagonal neutrosophic numbers are subjected to a score function in order to establish a link between coefficients and exponents and obtain the crisp values. In this regard, the primary contributions of the proposed decision making model are as follows:

1) There is not much effort put towards improving decision-maker's satisfaction while taking a decision, particularly in neutrosophic environments. Thus the proposed approach aids decision-maker to take firm and confident decisions.

2) The use of pentagonal neutrosophic numbers aids in coping with imprecision and results in achieving robust decisions.

3) The objective function has been transformed into a constraint. As a result, the solution begins with the initial optimal point.

4) The addition of a new constraint to the SvPNGP problem adds a new dimension as well as a new restriction on the feasible solution space. As a result, the proposed multi-parametric α , β and γ vectors comprise $(N + 1)$ dimensions.

5) This technique allows the decision-maker to place his desires on each constraint individually, offering him more flexibility.

6) Inclusion of tolerance value aids in achieving precise results while using SvPNGP.

7) It can deal with uncertainties, hesitations and inconsistent data more efficiently.

8) The decision-maker can manage the satisfaction, hesitation and dissatisfaction degrees resulting in reaching his/her maximum desire.

9) The proposed approach is applicable to real-life programming problems.

The rest of the paper is described as: Section II presents the preliminary definitions and theorems. To generate crisp values from Single-valued pentagonal neutrosophic numbers, a score function is taken into consideration which is described in Section III. In Section IV, multi-parametric vectors $\alpha, \beta, \gamma \in [0, 1]^{N+1}$ are introduced to evaluate the optimum solution and values for the SvPNGP problem. Certain membership, non-membership and indeterminacy functions are modeled specifically for the programming problem and related theorems are also studied. In Section V, concepts of feasibility and efficiency using multi-parametric programming is described. Section VI discusses the two-phase strategy as well as the proposed algorithm to solve the SvPNGP problem. The efficacy of the method given is assessed using a numerical example problem in Section VII and the findings are examined with other methods. Also, the advantages of our method compared to the other methods are also pointed out. At last, in Section VIII, the concluding remarks are given.

II. PRELIMINARIES

In this section, several definitions and theorems are discussed that could be useful for analysis.

Definition 1. [8] A set of ordered pairs \tilde{S} is said to be a fuzzy set if:

$$\tilde{S} = \{(x, \mu_{\tilde{S}}(x)) | x \in X\}$$

where X is a non-empty set and the function $\mu_{\tilde{S}}: X \rightarrow [0, 1]$ denotes the membership function of \tilde{S} .

Definition 2. [14] Let $A' \in X$ be an intuitionistic fuzzy set (IFS) which is defined as a triplet in the form:

$$A' = \{(x, \mu_{A'}(x), \vartheta_{A'}(x)) | x \in X\}$$

where $\mu_{A'}(x), \vartheta_{A'}(x): X \rightarrow [0,1]$ such that $0 \leq \mu_{A'}(x) + \vartheta_{A'}(x) \leq 1$. The function $\mu_{A'}(x)$ represents the degree of membership and $\vartheta_{A'}(x)$ represents the degree of non-membership for every $x \in X$. Moreover, a hesitation margin or intuitionistic fuzzy index $\pi_{A'}$ can be defined as $\pi_{A'} = 1 - \mu_{A'}(x) - \vartheta_{A'}(x)$ for all $x \in A'$ which indicates the degree of belongingness of x in A' .

Definition 3. [19] A neutrosophic set $\tilde{P} \in X$ is defined by:

$$\tilde{P} = \{(x, \mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x)) | x \in X\}$$

where X is an universal set and $\mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x)$ represents three functions namely membership, indeterminacy and non-membership respectively. Their bounds are defined as:

$$\mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x): X \rightarrow]0^-, 1^+[$$

$$\text{such that } 0^- \leq \mu_{\tilde{P}}(x) + \sigma_{\tilde{P}}(x) + \vartheta_{\tilde{P}}(x) \leq 3^+$$

Definition 4. [20] A single valued neutrosophic set $\tilde{P} \in X$ is defined by:

$$\tilde{P} = \{(x, \mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x)) | x \in X\}$$

where X is an universal set and $\mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x)$ represents three functions namely membership, indeterminacy and non-membership respectively. Their bounds are defined as:

$$\mu_{\tilde{P}}(x), \sigma_{\tilde{P}}(x), \vartheta_{\tilde{P}}(x): X \rightarrow [0,1]$$

$$\text{such that } 0 \leq \mu_{\tilde{P}}(x) + \sigma_{\tilde{P}}(x) + \vartheta_{\tilde{P}}(x) \leq 3$$

Definition 5.[32] Let a single-valued pentagonal neutrosophic number (SvPNN) be defined as $\tilde{r} = [(r_1, r_2, r_3, r_4, r_5); \mu_{\tilde{r}}], [(s_1, s_2, s_3, s_4, s_5); \sigma_{\tilde{r}}], [(t_1, t_2, t_3, t_4, t_5); \vartheta_{\tilde{r}}]$, such that $\tilde{r} \in \mathbb{R}$, where \mathbb{R} is a set of real numbers and $\mu_{\tilde{r}}, \sigma_{\tilde{r}}, \vartheta_{\tilde{r}} \in [0,1]$. Then the membership function $\mu_{\tilde{r}}(x): \mathbb{R} \rightarrow [0, \mu]$, indeterminacy function $\sigma_{\tilde{r}}(x): \mathbb{R} \rightarrow [\sigma, 1]$ and non-membership function $\vartheta_{\tilde{r}}(x): \mathbb{R} \rightarrow [\vartheta, 1]$ of \tilde{r} is given by:

$$\mu_{\tilde{r}}(x) = \begin{cases} \mu_{\tilde{r}\bar{l}1}(x) & r_1 \leq x \leq r_2 \\ \mu_{\tilde{r}\bar{l}2}(x) & r_2 \leq x \leq r_3 \\ \mu & r_3 \\ \mu_{\tilde{r}\bar{u}1}(x) & r_3 \leq x \leq r_4 \\ \mu_{\tilde{r}\bar{u}2}(x) & r_4 \leq x \leq r_5 \\ 0 & \text{otherwise} \end{cases}$$

$$\sigma_{\tilde{r}}(x) = \begin{cases} \sigma_{\tilde{r}\bar{l}1}(x) & s_1 \leq x \leq s_2 \\ \sigma_{\tilde{r}\bar{l}2}(x) & s_2 \leq x \leq s_3 \\ \sigma & s_3 \\ \sigma_{\tilde{r}\bar{u}1}(x) & s_3 \leq x \leq s_4 \\ \sigma_{\tilde{r}\bar{u}2}(x) & s_4 \leq x \leq s_5 \\ 0 & \text{otherwise} \end{cases}$$

$$\vartheta_{\tilde{r}}(x) = \begin{cases} \vartheta_{\tilde{r}\bar{l}1}(x) & t_1 \leq x \leq t_2 \\ \vartheta_{\tilde{r}\bar{l}2}(x) & t_2 \leq x \leq t_3 \\ \vartheta & t_3 \\ \vartheta_{\tilde{r}\bar{u}1}(x) & t_3 \leq x \leq t_4 \\ \vartheta_{\tilde{r}\bar{u}2}(x) & t_4 \leq x \leq t_5 \\ 0 & \text{otherwise} \end{cases}$$

A graphical illustration of linear pentagonal neutrosophic number can be seen in Fig. 1. Here the three lines viz., black, red and blue represents the membership, non-membership and indeterminacy functions respectively. Here, the variable τ is represented by the notation $0 \leq \tau \leq 1$, where the pentagonal number will become a triangular neutrosophic number if $\tau = 0$ or 1.

Fig. 1. Pictorial form of linear pentagonal neutrosophic number [32].

III. CRISPIFICATION OF SvPNN

To transform neutrosophic numbers into crisp values, score and accuracy functions are required. We adopted the notion of score and accuracy function from [27] for a SvPNN $\tilde{f}_{PN} = (f_1, f_2, f_3, f_4, f_5; \mu, \sigma, \vartheta)$ which is defined as follows:

- 1) *Score function:* The score function for \tilde{f}_{PN} is scaled as $\tilde{S}_{CPN} = \frac{1}{15}(f_1 + f_2 + f_3 + f_4 + f_5) \times \{2 + \mu - \sigma - \vartheta\}$
- 2) *Accuracy function:* The accuracy function is given as $\tilde{A}_{CPN} = \frac{1}{15}(f_1 + f_2 + f_3 + f_4 + f_5) \times \{2 + \mu - \sigma\}$

IV. SINGLE-VALUED NEUTROSOPHIC GEOMETRIC PROGRAMMING

Definition 6.[33] The standard form of Posynomial Geometric Programming (PGP) of X is given by:

$$\begin{aligned} \max \quad & \sum_{s=1}^{q_0} v_{0s} \prod_{j=1}^M X_j^{\gamma_{0sj}}, \\ \text{s.t.} \quad & \sum_{s=1}^{q_i} v_{is} \prod_{j=1}^M X_j^{\gamma_{isj}} \leq h_i, \quad i = 1, \dots, N \\ & X_j > 0 \end{aligned} \tag{1}$$

where the M-dimensional variable $X = (X_1, \dots, X_M)^T > 0$, coefficients $v_{is} > 0$ and exponents $\gamma_{isj} > 0$, are arbitrary real numbers.

The problem

$$\begin{aligned} \widetilde{\text{max}} \quad & \widetilde{g}_0(X), \\ \text{s.t.} \quad & \widetilde{g}_i(X) \lesssim 1, \quad i = 1, \dots, N \\ & X > 0 \end{aligned} \tag{2}$$

is called an Single-valued Neutrosophic PGP (SvNPGP) problem, where $g_i(X) = \sum_{s=1}^{q_i} v_{is}(X)$, $i = 0, \dots, N$, is a posynomial function on X , where the monomial function v_{is} of X is defined as [34]:

$$v_{is} = \begin{cases} v_{is} \prod_{j=1}^M X_j^{\gamma_{isj}}, & s = 1, \dots, q_i, i = 1, \dots, N' \\ v_{is} \prod_{j=1}^M X_j^{-\gamma_{isj}}, & s = 1, \dots, q_i, i = N' + 1, \dots, N \end{cases}$$

and $Z_0 \lesssim g_0(X) \rightarrow \widetilde{\text{max}} g_0(X)$ represents the maximum goal of the objective function $g_0(X)$ where Z_0 is considered as the lower bound. Z_0 is the expectation value of $g_0(X)$ and " \lesssim " symbolizes fuzzy version of " \leq " which basically means "less than or equal to". Therefore (2) can be changed into Single-valued neutrosophic reversed PGP problem:

$$\begin{aligned} \widetilde{\text{max}} \quad & \widetilde{g}_0(X) \gtrsim Z_0, \\ \text{s.t} \quad & \widetilde{g}_i(X) \lesssim 1, \quad i = 1, \dots, N' \\ & \widetilde{g}_i(X) \gtrsim 1, \quad i = N' + 1, \dots, N \\ & X > 0 \end{aligned} \tag{3}$$

Definition 7. A monomial function of PGP can be defined as fully SvNPGP form as:

$$\begin{aligned} \widetilde{\text{max}} \quad & \widetilde{v}_0 \prod_{j=1}^M \widetilde{X}_j^{\widetilde{\gamma}_{0j}}, \\ \text{s.t} \quad & \widetilde{v}_i \prod_{j=1}^M \widetilde{X}_j^{\widetilde{\gamma}_{ij}} \leq \widetilde{h}_i, \quad i = 1, \dots, N \\ & \widetilde{X} > \widetilde{0} \end{aligned} \tag{4}$$

where all the coefficients $\widetilde{v}_i > \widetilde{0}$ for $i = 1, \dots, N$, variables $\widetilde{X} = (\widetilde{X}_1, \dots, \widetilde{X}_M)^T$, exponents $\widetilde{\gamma}_{ij}$ and real numbers $\widetilde{h}_i > \widetilde{0}$ are Single-valued Neutrosophic numbers.

Theorem 1 .[35] Let $g_i(X)$ be a convex function for any i , then the resulting geometric programming problem is an Single-valued Neutrosophic convex problem

$$\begin{aligned} g_0(X) & \lesssim g_0 \\ g_i(X) & \lesssim 1, \quad i = 1, \dots, N \end{aligned} \tag{5}$$

Theorem 2. Any SvNPGP can be turned into a Single-valued neutrosophic convex programming problem, as specified in (2).

Proof. Let $T_j = \log(X_j)$, where $T_j = (T_{j\mu}, T_{j\sigma}, T_{j\theta})$, so $X_j = e^{T_j}$ for $1 \leq j \leq M$. Then

$$\sum_{s=1}^{q_i} v_{is} \prod_{j=1}^M X_j^{\gamma_{isj}} = \sum_{s=1}^{q_i} v_{is} e^{\sum_{j=1}^M T_j \gamma_{isj}} = g_i(X), \quad i = 0, \dots, N \tag{6}$$

Thereby, problem (2) can be turned into (5). So, by applying Theorem 1, we are able to prove it.

Theorem 3. Any Single-valued Neutrosophic monomial PGP problem (4) can be converted into a Single-valued Neutrosophic linear programming problem as follows:

$$\begin{aligned} \text{max} \quad & \ln \widetilde{v}_0 + \sum_{j=1}^M \gamma_{0j} \widetilde{T}_j, \\ \text{s.t} \quad & \ln \widetilde{v}_i + \sum_{j=1}^M \gamma_{ij} \widetilde{T}_j \leq \ln \widetilde{Q}_j, \quad i = 1, \dots, N \\ & \widetilde{X}_j > \widetilde{0}, \quad j = 1, \dots, M \end{aligned} \tag{7}$$

Proof. By using "ln" function on (4), we can say that:

$$\begin{aligned} \text{max} \quad & \ln \widetilde{v}_0 + \sum_{j=1}^M \gamma_{0j} \ln \widetilde{X}_j, \\ \text{s.t} \quad & \ln \widetilde{v}_i + \sum_{j=1}^M \gamma_{ij} \ln \widetilde{X}_j \leq \ln \widetilde{Q}_j, \quad i = 1, \dots, N \\ & \widetilde{X}_j > \widetilde{0}, \quad j = 1, \dots, M \end{aligned} \tag{8}$$

Now, when we put $\ln \widetilde{X}_j = \widetilde{T}_j$ in (8), a convex program is obtained as follows:

$$\begin{aligned} \text{max} \quad & \ln \widetilde{v}_0 + \sum_{j=1}^M \gamma_{0j} \widetilde{T}_j, \\ \text{s.t} \quad & \ln \widetilde{v}_i + \sum_{j=1}^M \gamma_{ij} \widetilde{T}_j \leq \ln \widetilde{Q}_j, \quad i = 1, \dots, N \\ & \widetilde{X}_j > \widetilde{0}, \quad j = 1, \dots, M \end{aligned} \tag{9}$$

Thus, from theorem 2, we can say that the above problem is a convex programming problem and has a similar Single-valued Neutrosophic optimal solution as the problem (4).

V. FEASIBILITY AND EFFICIENCY CONCEPTS THROUGH
MULTI-PARAMETRIC PROGRAMMING

The notion of a multi-parametric vector (α, β, γ) is introduced in this section which is useful to evaluate the level of confidence derived from the feasibility and efficacy of the optimum solution. Inclusion of tolerance value to the programming problem as a novel membership function imposes limitation as a prerequisite that can play a significant part in obtaining a suitable solution. Furthermore, the decision maker's satisfaction will be closer to the feasible solution. Considering (2) and assuming that \tilde{A}_i represents every X of neutrosophic constraints related to the neutrosophic inequality constraint $g_i(X) \lesssim 1, (i = 1, \dots, N)$, the membership function $\mu_{\tilde{A}_i}(X)$, indeterminacy function $\sigma_{\tilde{A}_i}(X)$ and non-membership function $\vartheta_{\tilde{A}_i}(X)$ are given by:

$$\mu_{\tilde{A}_i}(X) = \begin{cases} 1, & g_i(X) \leq 1 \\ 1 - \frac{d_i}{t_i}, & g_i(X) = 1 - d_i \ (d_i = 0, \dots, t_i) \\ 0, & g_i(X) \geq 1 - t_i \end{cases}$$

$$\sigma_{\tilde{A}_i}(X) = \begin{cases} 0, & g_i(X) \leq 1 \\ \frac{1 - d_i}{t_i}, & g_i(X) = 1 - d_i \ (d_i = 0, \dots, t_i) \\ 1, & g_i(X) \geq 1 - t_i \end{cases}$$

$$\vartheta_{\tilde{A}_i}(X) = \begin{cases} 0, & g_i(X) \leq 1 \\ \frac{1 - d_i}{t_i}, & g_i(X) = 1 - d_i \ (d_i = 0, \dots, t_i) \\ 1, & g_i(X) \geq 1 - t_i \end{cases}$$

where $t_i \in \mathbb{R}^+$ represents the maximum tolerance value which is determined by the decision-maker. The decision-maker assigns a tolerance value which can complicate the SvNGP problem. So, selecting a tolerance value throughout the decision making process, aiming to please the decision-maker, and then enhancing his satisfaction level, ultimately boosts efficiency.

By observing problem (3), multi-parametric vectors α, β and γ are presented where $\alpha = (\alpha_0, \dots, \alpha_N) \in (0,1]^{N+1}, \beta = (\beta_0, \dots, \beta_N) \in (0,1]^{N+1}$ and $(\gamma_0, \dots, \gamma_N) \in (0,1]^{N+1}$ represents the confidence level for the membership, non-membership and indeterminate values respectively of the programming problem. Here α_0, β_0 and γ_0 represents the satisfaction, dissatisfaction and hesitation degrees respectively, for the objective function which then will be converted into a constraint imposing a limitation to the feasible solution resulting a precise optimal solution whereas α_N, β_N and γ_N for $i = 1, \dots, N$ represents the satisfaction, dissatisfaction and hesitation degrees for each constraint. Thus, a new membership, indeterminacy and non-membership function is created solely for the objective function after it is converted to a constraint which is defined as:

$$\mu(g_0(X, \alpha, \beta, \gamma)) = \frac{Z_0 - g_0(X, \alpha, \beta, \gamma)}{t_0}, \quad g_0(X, \alpha, \beta, \gamma) \geq Z_0 - t_0 \quad (10)$$

$$\sigma(g_0(X, \alpha, \beta, \gamma)) = \frac{g_0(X, \alpha, \beta, \gamma) - Z_0 + t_0}{t_0}, \quad g_0(X, \alpha, \beta, \gamma) \geq Z_0 - t_0$$

$$\vartheta(g_0(X, \alpha, \beta, \gamma)) = \frac{g_0(X, \alpha, \beta, \gamma) - Z_0 + t_0}{t_0}, \quad g_0(X, \alpha, \beta, \gamma) \geq Z_0 - t_0$$

and

$$\mu(g_i(X, \alpha, \beta, \gamma)) = \begin{cases} 1, & g_i(X, \alpha, \beta, \gamma) \leq b_i \\ 1 - \frac{g_i(X, \alpha, \beta, \gamma) - b_i}{t_i}, & b_i \leq g_i(X, \alpha, \beta, \gamma) \leq b_i + t_i, \ i = 1, \dots, N' \\ 0, & g_i(X, \alpha, \beta, \gamma) \geq b_i + t_i, \ i = N' + 1, \dots, N \end{cases}$$

$$\sigma(g_i(X, \alpha, \beta, \gamma)) = \begin{cases} 0, & g_i(X, \alpha, \beta, \gamma) \leq b_i \\ \frac{g_i(X, \alpha, \beta, \gamma) - b_i}{t_i}, & b_i \leq g_i(X, \alpha, \beta, \gamma) \leq b_i + t_i, \ i = 1, \dots, N' \\ 1, & g_i(X, \alpha, \beta, \gamma) \geq b_i + t_i, \ i = N' + 1, \dots, N \end{cases}$$

$$\vartheta(g_i(X, \alpha, \beta, \gamma)) = \begin{cases} 0, & g_i(X, \alpha, \beta, \gamma) \leq b_i \\ \frac{g_i(X, \alpha, \beta, \gamma) - b_i}{t_i}, & b_i \leq g_i(X, \alpha, \beta, \gamma) \leq b_i + t_i, \ i = 1, \dots, N' \\ 1, & g_i(X, \alpha, \beta, \gamma) \geq b_i + t_i, \ i = N' + 1, \dots, N \end{cases}$$

Thus an underlying framework is presented to discover the optimum solution in terms of the satisfaction, dissatisfaction and indeterminacy degrees of the decision-maker with the maximum tolerance in (3):

$$\begin{aligned} \max \quad & g_0(X), \\ \text{s.t} \quad & g_0(X) \geq Z_0 - \alpha_0 t_0, \\ & g_0(X) \geq Z_0 + (1 - \gamma_0)t_0, \\ & g_0(X) \geq Z_0 + (1 - \beta_0)t_0, \\ & g_i(X) \leq b_i + (1 - \alpha_i)t_i, \quad i = 1, \dots, N' \\ & g_i(X) \leq b_i + \gamma_i t_i, \quad i = 1, \dots, N' \\ & g_i(X) \leq b_i + \beta_i t_i, \quad i = 1, \dots, N' \\ & g_i(X) \geq b_i + (1 - \alpha_i)t_i, \quad i = N' + 1, \dots, N \\ & g_i(X) \geq b_i + \gamma_i t_i, \quad i = N' + 1, \dots, N \\ & g_i(X) \geq b_i + \beta_i t_i, \quad i = N' + 1, \dots, N \\ & X > 0, \alpha_i, \beta_i, \gamma_i \in (0,1], \quad i = 0, \dots, N \\ & \alpha \geq \gamma, \alpha \geq \beta, \alpha + \beta + \gamma \leq 3 \end{aligned} \quad (11)$$

Definition 8. Let $X^* = (X_1^*, \dots, X_M^*)^T \in \mathbb{R}^M$ be an M-dimensional vector where $\alpha, \beta, \gamma \in [0,1]$ and $\alpha + \beta + \gamma \leq 3$, defined as:

$$X_{\alpha, \beta, \gamma} = \left\{ X \in \mathbb{R}^M \mid \begin{cases} X \geq 0, \\ \mu_i(g_i(X)) \geq \alpha_i \\ \vartheta_i(g_i(X)) \leq \beta_i, \ i = 0, \dots, N \\ \sigma_i(g_i(X)) \leq \gamma_i \end{cases} \right\} \quad (12)$$

in which a vector $X \in X_{\alpha, \beta, \gamma}$ will be an α, β, γ -feasible solution for (2) where α is the minimal acceptance degree, β and σ denotes the maximum rejection and hesitation degree respectively.

Theorem 4. Let $\alpha = (\alpha_0, \dots, \alpha_N) \in (0,1]^{N+1}, \beta = (\beta_0, \dots, \beta_N) \in (0,1]^{N+1}$ and $\gamma = (\gamma_0, \dots, \gamma_N) \in (0,1]^{N+1}$, and for $X_j^* \geq 0, j = 1, \dots, N, X^* = (X_1^*, \dots, X_M^*)^T \in \mathbb{R}^M$ is an M-dimensional vector and an α, β, γ -feasible solution for (2). So X^* is an α, β, γ -efficient optimal solution iff it satisfies the following constraints -

$$\begin{aligned} \max \quad & g_0(X) \\ \text{s.t} \quad & g_0(X) \geq Z_0 - \alpha_0 t_0, \\ & g_0(X) \geq Z_0 + (1 - \gamma_0)t_0, \end{aligned} \quad (13)$$

$$\begin{aligned}
 g_0(X) &\geq Z_0 + (1 - \beta_0)t_0, \\
 g_i(X) &\leq 1 + (1 - \alpha_i)t_i, \quad i = 1, \dots, N' \\
 g_i(X) &\leq 1 + \gamma_i t_i, \quad i = 1, \dots, N' \\
 g_i(X) &\leq 1 + \beta_i t_i, \quad i = 1, \dots, N' \\
 g_i(X) &\geq 1 + (1 - \alpha_i)t_i, \quad i = N' + 1, \dots, N \\
 g_i(X) &\geq 1 + \gamma_i t_i, \quad i = N' + 1, \dots, N \\
 g_i(X) &\geq 1 + \beta_i t_i, \quad i = N' + 1, \dots, N \\
 X &> 0, \alpha_i, \beta_i, \gamma_i \in (0,1], \quad i = 0, \dots, N \\
 \alpha &\geq \gamma, \alpha \geq \beta, \alpha + \beta + \gamma \leq 3
 \end{aligned}$$

where t_i denotes the maximum tolerance.

Proof. Let us consider that $\alpha = (\alpha_0, \dots, \alpha_N) \in (0,1]^{N+1}$, $\beta = (\beta_0, \dots, \beta_N) \in (0,1]^{N+1}$ and $\gamma = (\gamma_0, \dots, \gamma_N) \in (0,1]^{N+1}$, and for $X_j^* \geq 0, j = 1, \dots, N$, $X^* = (X_1^*, \dots, X_M^*)^T \in \mathbb{R}^M$ is an α, β, γ -feasible solution for (2). From definition 8 and problem (9), we have $\mu_i(g_i(X)) \geq \alpha_i, \nu_i(g_i(X)) \leq \beta_i$ and $\sigma_i(g_i(X)) \leq \gamma_i$, therefore X^* is a feasible solution. However, as $X^* \in \mathbb{R}^M$ is an α, β, γ -efficient solution, no other $X^{*'} \in X_{\alpha, \beta, \gamma}$ will satisfy $g_0(X^{*'}) > g_0(X^*)$. Thus, it means X^* is an optimal solution. Moreover, if we consider $X^{*'}$ be an optimal solution for (12) and apparently, $X^{*'}$ is an α, β, γ -feasible solution, it means $X^{*'}$ is an α, β, γ -efficient solution.

Now, let us assume the optimal solution for problem (12) be $(X^*, Z_0 = g_0(X^*))$ in Theorem 3. It is only necessary to solve the programming problem below:

$$\begin{aligned}
 \max \quad & \sum_{i=1}^N \alpha - \beta - \gamma \quad (14) \\
 \text{s.t.} \quad & g_0(X) \geq Z_0 - \alpha_0 t_0, \\
 & g_0(X) \geq Z_0 + (1 - \gamma_0)t_0, \\
 & g_0(X) \geq Z_0 + (1 - \beta_0)t_0, \\
 & g_i(X) \leq 1 + (1 - \alpha_i)t_i, \quad i = 1, \dots, N' \\
 & g_i(X) \leq 1 + \gamma_i t_i, \quad i = 1, \dots, N' \\
 & g_i(X) \leq 1 + \beta_i t_i, \quad i = 1, \dots, N' \\
 & g_i(X) \geq 1 + (1 - \alpha_i)t_i, \quad i = N' + 1, \dots, N \\
 & g_i(X) \geq 1 + \gamma_i t_i, \quad i = N' + 1, \dots, N \\
 & g_i(X) \geq 1 + \beta_i t_i, \quad i = N' + 1, \dots, N \\
 & X > 0, \alpha_i, \beta_i, \gamma_i \in (0,1], \quad i = 0, \dots, N \\
 & \alpha \geq \gamma, \alpha \geq \beta, \alpha + \beta + \gamma \leq 3
 \end{aligned}$$

VI. THE CONCEPT OF THE TWO-PHASE METHOD AND THE PROPOSED ALGORITHM

The overall process of optimization is divided into two phases which are described as follows:

Phase 1: In this phase first an appropriate GP problem is created for solving. Theorems 2 and 3 are then used to generate Single-valued Pentagonal Neutrosophic Linear Programming (SvPNLP) problem from the GP problem. The score function is then used to transform the SvPNLP problem into a crisp linear programming problem that allows the tolerance value to be set. In this case, the decision-maker implements his requirement according to his satisfaction. The decision-maker could choose various degrees of tolerance value, which results in distinct sets of feasible alternatives; consequently, we must devise a technique to determine the optimal solution within these feasible choices.

Phase 2: This phase begins with a feasible solution provided in phase 1 and its goal is to increase satisfaction by providing an optimal solution. The multi-parametric confidence vectors $\alpha, \beta, \gamma \in (0,1]^{(N+1)}$ are utilized to correlate the degree of satisfaction, dissatisfaction and indeterminacy with its relevant environment. Then the conversion of the objective function into a constraint takes place at this stage where Z_0 marks the beginning of the optimum solution along with α_0, β_0 and γ_0 as satisfaction, dissatisfaction and hesitation degrees. The tolerance degree, t_i , can be enhanced for individual constraint and objective function, allowing the degree of satisfaction to be maximized and dissatisfaction degree to be minimized while maintaining the degree of indeterminacy in individual constraint. Finally, solving the original problem with the proposed model an optimal solution is achieved with the highest degree of satisfaction while keeping the level of dissatisfaction and indeterminacy in control.

An algorithm along with a flowchart, in Fig. 2 is presented for finding an optimal solution for SvPNGP problem based on the preceding discussion (3).

Algorithm: SvPNGP Modelling

1. Model the SvPNGP problem.
2. Convert the SvPNGP to crisp LP using the help of the score function and applying Theorem 2 and 3.
3. Find the initial optimal value Z_0 from basic variables.
4. Add tolerance value and apply α, β - efficiency and formulate the equivalent LPP:

$$\begin{aligned}
 \max \quad & \alpha, \min \beta, \min \gamma \quad (15) \\
 \text{s.t.} \quad & \mu_0(X) \geq \alpha, \vartheta_0(X) \leq \beta, \sigma_0(X) \leq \gamma \\
 & \mu_i(X) \geq \alpha, \vartheta_i(X) \leq \beta, \sigma_i(X) \leq \gamma, \quad i = 1, \dots, N, \\
 & \alpha \geq \beta, \alpha \geq \gamma, \alpha + \beta + \gamma \leq 3, \\
 & X > 0, \alpha_i, \beta_i, \gamma_i \in (0,1]
 \end{aligned}$$

The above LPP is equivalent to:

$$\begin{aligned}
 \text{s.t.} \quad & \max (\alpha - \beta - \gamma) \quad (16) \\
 & \mu_0(X) \geq \alpha, \vartheta_0(X) \leq \beta, \sigma_0(X) \leq \gamma \\
 & \mu_i(X) \geq \alpha, \vartheta_i(X) \leq \beta, \sigma_i(X) \leq \gamma, \quad i = 1, \dots, N, \\
 & \alpha \geq \beta, \alpha \geq \gamma, \alpha + \beta + \gamma \leq 3, \\
 & X > 0, \alpha_i, \beta_i, \gamma_i \in (0,1]
 \end{aligned}$$

5. According to multi-parametric $\alpha, \beta, \gamma \in (0,1]^{(N+1)}$ apply the membership, non - membership and hesitation functions and place the objective function as a constraint.

6. Solve and find $g_0(Z^*, \alpha, \beta, \gamma)$ using the dual-simplex method.
7. Build a new programming problem model under multi-parametric α_i, β_i and γ_i with different degrees of satisfaction, dissatisfaction and indeterminacy respectively.
8. Solve the new problem and find the optimal satisfaction degree.
9. Determine the optimal value under optimal $\alpha^*, \beta^*, \gamma^*$ and evaluate $g_0(Z^{**}, \alpha^*, \beta^*, \gamma^*)$.

e^{46} , and e^{64} in Kgs. The water pipes need to be manufactured utilizing four varieties of concrete materials M1, M2, M3 and M4. Table I shows the percentage of each kind of raw concrete required in each pipe (kg) and its unit price (\$/kg). Determine the maximum amount of raw concrete required while staying within the owner's tolerance limit.

TABLE I. CONCRETE PERCENTAGES AND ITS PRICE/UNIT

Pipes	M1	M2	M3	M4	Need (Kg)
P1	P1M1	P1M2	P1M3	P1M4	e^{19}
P2	P2M1	P2M2	P2M3	P2M4	e^{46}
P3	P3M1	P3M2	P3M3	P3M4	e^{64}
Unit Price (\$/Kg)	5	6	3	5	

P1M1= ((0,1,1,2,2);0,6,0,4,0,3), P1M2= ((0,1,3,4,5);0,9,0,1,0,3), P1M3= ((1,1,1,1,1);0,9,0,3,0,1), P1M4= ((1,2,2,3,4);0,8,0,5,0,3), P2M1= ((5,6,6,7,8);0,8,0,4,0,4), P2M2= ((3,4,6,7,9);0,8,0,5,0,3), P2M3= ((2,3,3,4,5);0,6,0,5,0,6), P2M4= ((0,2,2,4,5);0,8,0,2,0,5), P3M1= ((1,2,4,5,6);0,7,0,2,0,2), P3M2= ((2,3,5,6,8);0,7,0,2,0,2), P3M3= ((1,1,3,3,3);0,7,0,4,0,3), P3M4= ((10,11,13,14,15);0,8,0,4,0,2)

Solution. The above problem can be converted into SvPNGP as follows:

$$\begin{aligned} & \overline{\max} x_1^5 x_2^6 x_3^3 x_4^5 & (17) \\ \text{s.t} & x_1^{P1M1} x_2^{P1M2} x_3^{P1M3} x_4^{P1M4} \leq e^{19} \\ & x_1^{P2M1} x_2^{P2M2} x_3^{P2M3} x_4^{P2M4} \leq e^{46} \\ & x_1^{P3M1} x_2^{P3M2} x_3^{P3M3} x_4^{P3M4} \leq e^{64} \\ & x_1, x_2, x_3, x_4 > 0 \end{aligned}$$

By using $x_i = e^{z_j}$ ($1 \leq j \leq 4$), we can change problem (16) into the intuitionistic fuzzy problem by utilizing Theorems 2 and 3.

$$\begin{aligned} & \overline{\max} 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 & (18) \\ \text{s.t} & P1M1Z_1 + P1M2Z_2 + P1M3Z_3 + P1M4Z_4 \leq 19 \\ & P2M1Z_1 + P2M2Z_2 + P2M3Z_3 + P2M4Z_4 \leq 46 \\ & P3M1Z_1 + P3M2Z_2 + P3M3Z_3 + P3M4Z_4 \leq 64 \end{aligned}$$

Next, we apply the score function on SvPNN

$$\begin{aligned} & \overline{\max} 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 & (19) \\ \text{s.t} & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 19 \\ & 4.27Z_1 + 3.87Z_2 + 1.70Z_3 + 1.82Z_4 \leq 46 \\ & 2.64Z_1 + 3.68Z_2 + 1.47Z_3 + 9.24Z_4 \leq 64 \end{aligned}$$

After the conversion, the primary optimal solution is drawn from the basic variables $x_1 = e^{4.42}, x_2 = 1, x_3 = e^{11.40}, x_4 = e^{4.17}$ and the optimal value is $e^{76.18}$. By applying $x_0 = e^{z_0}$, we get $Z_0 = 76.18$. Using the two-phase technique and applying the membership, non-membership and indeterminacy functions defined in (9) along with substituting the values of Z_0, t_0, t_1, t_2 and t_3 where $t_0 = 5, t_1 = 1, t_2 = 4$ and $t_3 = 6$ for $t_i, (i = 0,1,2,3)$ are the tolerance values which are set up by the decision maker, we can convert problem (18) into the programming problem as given below:

$$\overline{\max} (\alpha - \beta - \gamma) \quad (20)$$

Fig. 2. Flowchart of the proposed work.

VII. IMPLEMENTATION OF THE PROPOSED MODEL WITH THE HELP OF NUMERICAL ILLUSTRATION

Example 1. A water distribution plant wants to produce concrete pipes for an underground water distribution project. It requires three pipes P1, P2 and P3 with utmost weight e^{19} ,

$$\begin{aligned}
 \text{s.t. } & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 76.18 - 5\alpha_0, \\
 & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 71.18 - 5\gamma_0, \\
 & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 71.18 - 5\beta_0, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 20 - \alpha_1, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 19 + \gamma_1, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 19 + \beta_1, \\

 & \alpha_i, \beta_i, \gamma_i \in (0,1], \alpha_i \geq \beta_i, \alpha_i \geq \gamma_i, \alpha_i + \beta_i + \gamma_i \leq 3, \\
 & i = 0,1,2,3
 \end{aligned}$$

Table II displays the satisfaction of the decision-maker at various degrees of α, β, γ -efficiency confidence. If $\alpha = (\alpha_0, \alpha_1, \alpha_2, \alpha_3), \beta = (\beta_0, \beta_1, \beta_2, \beta_3), \gamma = (\gamma_0, \gamma_1, \gamma_2, \gamma_3)$ and $g_0(Z^*, \alpha, \beta, \gamma)$ signify the optimal value of the objective function at every step under different conditions, we may obtain the following table using the LINGO 18.0 software:

From Table II it can be observed that the maximum initial optimal solution $g_0(Z, \alpha_i, \beta_i, \gamma_i)$ is achieved at row 1 with a value of 80.11. It is also seen that the least efficient components are α_1 and α_2 . As the values of α_1 and α_2 increases, the values of $\gamma_1, \gamma_2, \beta_1$ and β_2 decreases because of the constraint $\alpha_i \geq \beta_i$ and $\alpha_i \geq \gamma_i$, that results in the degradation of the optimal solution. By reducing the values of α_1 and α_2 provides better results. If we increase the values of α_0 and α_3 and decrease $\gamma_0, \gamma_3, \beta_0$ and β_3 respectively, we are able to reach closer to the optimal solution. Now, as an initial solution, we will strive to minimize α_1 and α_2 by selecting the (0.5, 0.5, 0.5, 0.5)-efficient solution having optimal value $g_0(Z, \alpha_i, \beta_i, \gamma_i) = 80.11$.

Now, we will determine the LP problem below that is influenced by $g_0(Z, \alpha_i, \beta_i, \gamma_i) = 80.11$.

$$\begin{aligned}
 & \max \sum_{i=0}^3 (\alpha_i - \beta_i - \gamma_i) \tag{21} \\
 \text{s.t. } & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 80.11 - 5\alpha_0, \\
 & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 75.11 - 5\gamma_0, \\
 & 5Z_1 + 6Z_2 + 3Z_3 + 5Z_4 \geq 75.11 - 5\beta_0, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 20 - \alpha_1, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 19 + \gamma_1, \\
 & 0.76Z_1 + 2.17Z_2 + 0.83Z_3 + 1.60Z_4 \leq 19 + \beta_1, \\
 & 4.27Z_1 + 3.87Z_2 + 1.70Z_3 + 1.82Z_4 \leq 50 - 4\alpha_2, \\
 & 4.27Z_1 + 3.87Z_2 + 1.70Z_3 + 1.82Z_4 \leq 46 + 4\gamma_2, \\
 & 4.27Z_1 + 3.87Z_2 + 1.70Z_3 + 1.82Z_4 \leq 46 + 4\beta_2, \\
 & 2.64Z_1 + 3.68Z_2 + 1.47Z_3 + 9.24Z_4 \leq 70 - 6\alpha_3, \\
 & 2.64Z_1 + 3.68Z_2 + 1.47Z_3 + 9.24Z_4 \leq 64 + 6\gamma_3, \\
 & 2.64Z_1 + 3.68Z_2 + 1.47Z_3 + 9.24Z_4 \leq 64 + 6\beta_3, \\
 & 0.5 \leq \alpha_0 \leq 1, 0.5 \leq \beta_0 \leq 1, 0.5 \leq \gamma_0 \leq 1 \\
 & 0.5 \leq \alpha_1 \leq 1, 0.5 \leq \beta_1 \leq 1, 0.5 \leq \gamma_1 \leq 1 \\
 & 0.5 \leq \alpha_2 \leq 1, 0.5 \leq \beta_2 \leq 1, 0.5 \leq \gamma_2 \leq 1 \\
 & 0.5 \leq \alpha_3 \leq 1, 0.5 \leq \beta_3 \leq 1, 0.5 \leq \gamma_3 \leq 1
 \end{aligned}$$

The optimum solution of problem (20) will be reached by maximizing the satisfaction degree as $Z^{**} = (5.64, 0, 10.76, 3.93)$ with confidence level $\alpha^* = (1, 0.5, 0.5, 0.5), \beta^* = (0, 0.5, 0.5, 0.5)$ and $\gamma^* = (0, 0.5, 0.5, 0.5)$, and the optimal value calculated with respect to α^*, β^* and γ^* as $g_0(Z^{**}, \alpha^*, \beta^*, \gamma^*) = (5.64, 0, 10.76, 3.93; 1, 0.5, 0.5, 0.5; 0, 0.5, 0.5, 0.5; 0, 0.5, 0.5, 0.5) = 80.11$. As a result, the optimal solution to GP programming problem (16) is $x_1 = e^{5.64}, x_2 = 1, x_3 = e^{10.76}, x_4 = e^{3.93}$, and the optimal value is $e^{80.11}$.

TABLE II. DETERMINING THE MAXIMUM LEVEL OF SATISFACTION WITH A MULTI-PARAMETERS α, β, γ

S. No	$\alpha_0, \alpha_1, \alpha_2, \alpha_3$	$\gamma_0, \gamma_1, \gamma_2, \gamma_3$	$\beta_0, \beta_1, \beta_2, \beta_3$	Z_1	Z_2	Z_3	Z_4	$g_0(Z, \alpha_i, \beta_i, \gamma_i)$

Example 2. In continuation from example 1, determining the maximum satisfaction of decision maker without any tolerance limit then the results are shown in Table III.

TABLE III. DETERMINING THE MAXIMUM SATISFACTION LEVEL WITHOUT TOLERANCE LIMIT

S. No	1	2	3	4
α	0.5,0.5,0.5,0.5	0.9,0.5,0.5,0.7	0.7,0.5,0.8,0.5	0.5,0.9,0.9,0.5
γ	0.5,0.5,0.5,0.5	0.2,0.5,0.5,0.1	0.2,0.1,0.3,0.2	0,0.3,0.2,0.1
β	0.5,0.5,0.5,0.5	0.1,0.5,0.5,0.2	0.2,0.5,0.1,0.5	0.3,0.4,0.5,0.3
Z_1	4.89	4.85	5.07	5.06
Z_2	0	0	0	0
Z_3	11.90	12.04	11.20	11.23
Z_4	3.69	3.63	3.71	3.70
G_0	78.59	78.56	77.55	77.54

$$\alpha = (\alpha_0, \alpha_1, \alpha_2, \alpha_3), \beta = (\beta_0, \beta_1, \beta_2, \beta_3), \gamma = (\gamma_0, \gamma_1, \gamma_2, \gamma_3), G_0 = g_0(Z, \alpha, \beta, \gamma)$$

Example 3. With continuation from example 1, determining the maximum satisfaction of decision maker with single parametric α, β and γ then the results are displayed in Table IV.

TABLE IV. DETERMINING THE MAXIMUM SATISFACTION LEVEL WITH SINGLE PARAMETRIC α, β AND γ

S. No	α	γ	β	Z_1	Z_2	Z_3	Z_4	G_0
1	0.5	0.5	0.5	5.64	0	10.76	3.93	80.11
2	0.6	0.4	0.4	5.53	0	10.82	3.88	79.55
3	0.8	0.2	0.2	5.32	0	10.94	3.79	78.41
4	0.9	0.1	0.1	5.21	0	11.00	3.74	77.85
5	1	0	0	5.10	0	11.07	3.70	77.28

$$G_0 = g_0(Z, \alpha, \beta, \gamma)$$

It can be observed that the optimal solution degrades with the absence of tolerance limit while analyzing Table II and III. When Table II and IV are compared, it is found that in Table IV, raising the confidence level α and decreasing γ and β , reduces the ideal solution, whereas we anticipate the optimal solution to increase as the confidence level rises. Similarly,

TABLE V. COMPARATIVE ANALYSIS BETWEEN DIFFERENT OPTIMIZATION APPROACHES

Methods	α	β	γ	t_0	t_1	t_2	t_3	Z_1	Z_2	Z_3	Z_4	G_0

$$\alpha = (\alpha_0, \alpha_1, \alpha_2, \alpha_3), \beta = (\beta_0, \beta_1, \beta_2, \beta_3), \gamma = (\gamma_0, \gamma_1, \gamma_2, \gamma_3), G_0 = g_0(Z, \alpha, \beta, \gamma)$$

VIII. CONCLUSION

In order to obtain optimal results in decision making, the decision-maker needs to be provided with the flexibility to achieve satisfaction in the decision making process. Thereby, this research article proposed a SvPNGP model by incorporating multi-parametric vectors α, β, γ to achieve the maximum degree of satisfaction while minimizing the degree of dissatisfaction and hesitation within the tolerance limit of

the decision maker has to adjust the levels of satisfaction, dissatisfaction and hesitancy levels for every constraint to the same degree, but in the method proposed, the satisfaction, dissatisfaction and hesitancy levels for each constraint can be decreased or increased independently. Table IV clearly shows that raising the confidence level has the opposite effect on the optimization, and the optimal value returns to its original solution, whereas in Table II, until the satisfaction, dissatisfaction and hesitancy degree components change, the optimal value remains optimal. The reason for this is because the confidence vectors are not reasonable for all constraints, especially when the objective function is transformed into a constraint. Thus the adaptability of the $(N + 1)$ -dimensional α_i, β_i and γ_i confidence levels can help in achieving the decision-maker's purpose of getting a better optimal result.

Table V presents the difference of solutions for example 1 using four methods. Comparing our work with Intuitionistic Fuzzy Geometric Programming (IFGP), Khorsandi et al., [36] and Zimmermann's method [37], it is observed that the solution achieved using our proposed method for solving SvPNGP is more efficient compared to the solution obtained using the other techniques. Here methods 1, 2 and 3 are multi-parametric, whereas method 4 is single parametric, and methods 3 and 4 are designed to solve fuzzy optimization problems, whereas Method 1 is intended to address Neutrosophic optimization problems.

The proposed method achieved the highest optimal value compared to the existing techniques. Fuzzy optimization only considers one degree of acceptance or rejection at a time whereas Intuitionistic Fuzzy optimization includes both degrees of acceptance and rejection in order to manage optimization but in reality, there are some circumstances where, due to lack of information or indeterminacy, evaluating the membership and non-membership functions together cannot yield a greater and/or more satisfactory conclusion. As a result, there is still an indeterministic element on which hesitation persists which is addressed by neutrosophic optimization.

the decision-maker. With this strategy, the decision-maker can obtain an optimal solution for the SvPNGP problem while satisfying his/her needs and moreover the decision maker is not restricted for selecting the same tolerance value for individual constraints. We divided the whole process into a two-phase method where the SvPNGP is transformed to a crisp LP problem in the first phase and in the next phase, the multi-parametric vectors are applied along with membership, indeterminacy and non-membership functions and solved to

find the optimal solution. With the help of numerical problems, we evaluated and analyzed certain parameters with our proposed model. The results were then compared with the existing methods and found out to produce better optimal solution compared to others.

The contribution of this paper includes developing an optimal SvPNGP model to enable the decision-maker to achieve robust decisions while providing him the flexibility to achieve the desired level of satisfaction. As the model is built on neutrosophic numbers, it can handle uncertainty in real-world programming situations.

For future work, we hope to expand our work with Plithogenic sets, which is another generalized method that can be useful for dealing with inconsistent and indeterminate data. The extended approach can be used to a wide range of real-world challenges in the field of engineering, manufacturing, management and many more.

Multifaceted Sentiment Detection System (MSDS) to Avoid Dropout in Virtual Learning Environment using Multi-class Classifiers

Ananthi Claral Mary. T¹, Arul Leena Rose. P. J^{2*}

Department of Computer Science-College of Science and Humanities,
SRM Institute of Science and Technology, Kattankulathur - 603 203, Chengalpattu, Tamil Nadu, India

Abstract—Sentiment analysis with machine learning plays a vital role in Higher Educational Institutions (HEI) for decision making. Technology-enabled interactions can only be successful when a strong student-teacher link is established, and the emotions of students are clearly comprehended. The paper aims at proposing Multifaceted Sentiment Detection System (MSDS) for detecting sentiments of higher education students participating in virtual learning and to classify the comments posted by them using Machine Learning (ML) algorithms. Present research evaluated a total of n=1590 students' comments with the presence of three specific multifaceted characteristics each providing 530 comments to perform Sentiment Analysis (SA) for monitoring their sentiments, opinions that facilitate predicting dropout in virtual learning environment (VLE). This begins with the phrase extraction; then data pre-processing techniques namely digits, punctuation marks and stop-words removal, spelling correction, tokenization, lemmatization, n-grams, and POS (Part of Speech) are applied. Texts are vectorized using two feature extraction techniques with count vectorization and TF-IDF metrics and classified with four multiclass supervised ML techniques namely Random Forest, Linear SVC, Multinomial Naive Bayes, and Logistic Regression for multifaceted sentiment classification. Analyzing students' feedback using sentiment analysis techniques classifies their positive, negative, or even more refined emotions that enables dropout prediction. Experimental results reveal that the highest mean accuracy result for device efficiency, cognitive behavior, technological expertise with cloud learning platform usage were achieved by Logistic Regression with 98.49%, Linear SVC with 93.58% and Linear SVC with 92.08% respectively. Practically, results confirm feasibility for detecting students' multifaceted behavioral patterns and risk of dropout in VLE.

Keywords—Sentiment analysis; opinions; TF-IDF; n-gram; virtual learning; machine learning; NLTK; text pre-processing

I. INTRODUCTION

The education system is crucially dependent on students' academic progress. The tremendous volume of data in educational databases has made it increasingly difficult to predict student performance. Low performance students may encounter several challenges, such as delayed graduation and dropping out. To quickly assist students who are performing poorly, educational institutions should regularly monitor the academic development of their students. One way to accomplish that is to use students' academic achievement prediction. The proposed method is based on hybrid approach

of sentiment analysis to achieve quality education [1]. With the explosive growth of internet, digital technologies, IT infrastructure cloud-based online learning is growing at a quicker pace. Cloud computing technologies facilitate virtual platforms and assist students in favorable paths despite the barriers. The platform inherits countless benefits namely reducing installation cost, high storage possibility, virtualization, security, easy access, etc. T. Zarra et al. states that academic institutions suffer from general budget cuts and the growing number of students. Implementation of cloud-based e-learning platforms is very much motivated. The application of cloud community assists members of education institution to work together. The research aims to propose a web service which analyzes exchange of information between learners from various universities connected on cloud using sentiment analysis [2].

The key contribution of this research is to analyze and deal with a huge amount of online data during the virtual learning course for predicting dropouts with the help of sentiment analysis of learners' comments. SA is receiving much attention in HEI for predicting student dropout. By applying SA in the context of virtual learning, provides better insights of understanding learners' attitudes, emotional reactions towards entities, events, attributes, and the notion of sentiment predictors of dropout as this reveals specific patterns in learners' behaviors that can be of practical importance for course designers and instructors. The learning process in virtual courses dramatically differs from face-to-face courses, as the courses are taken exclusively online hence, in this proposed system, it is appropriate to detect students' text sentiments composed of multifaceted characteristics that helps in identifying their risk of college dropout. One of the formidable tasks is systematical surveying of students' opinions and perceptions, as there is huge volume of opinionated text and sentiment detection of real-world data is full of challenges. It's difficult for humans to extract sentences with sentiments, read, review, and classify them into usable formats. Automated sentiment discovery and summarization system are thus required. SA is classified as positive, negative, or neutral, that employs automatic process of text classification for opinion mining and finding wide array of sentiments expressed by learners explaining their personal attitudes and evaluation regarding provided services that determines high and low sentiment scores of their multi-dimensional characteristic phenomena. Thus, this research

aims at investigation of sentiment analysis based on learners' comments from VLE to avoid dropouts. The remnant paper is organized as follows. Section II discusses the background of SA with related research works. Section III specifies the explanation of research methodology used in this research. Section IV explains MSDS architecture in detail. Section V represents the experimental outcomes. Section VI discusses conclusion and future scope of research.

II. LITERATURE REVIEW

MOOC based teaching is implemented in traditional curriculum and educational practices. Sentiment analysis approaches can be used for course content evaluations that deliver extensive intimations to course designers and educators for evaluating courses periodically and introduce probable enhancements [3]. SASys (Sentiment Analyzes System) framework built on lexical approach and polarized frame network is proposed. Its primary objective is identifying early students' risk of dropout by emotional state detection. Text sentiment is essential for defining learners' motivational profile that depends on their activities in VLE. Students' class engagement can be identified by analyzing their frequency of access data and interactions [4].

Students' motivation to learn is greatly influenced by emotional elements, and in online education, emotions can be inferred from textual discussion while giving responses. Natural Language Processing methods can be used for emotional classification of students by extracting information from Whatsapp and organizing them into corresponding categories. RNN algorithm increases the accuracy by 75% for students' emotion analysis in online learning [5]. Emotion mining and SA were performed by gathering Arabic tweets regarding online education during pandemic. Results disclose that the proposed method performs efficiently in identifying peoples' opinion on online learning in context of the pandemic using SVM with greatest accuracy of 89.6%. By considering emotion analysis, anger is the top emotion. Most significant reasons behind negative sentiments were lack of face-to-face interaction, breakdown of network, ambiguity, and games [6]. Academic issues are one of the factors which cause stress or depression among students. For example, a drop in grades, a fear of failing, and challenging competitions. Most students are young, and when they encounter difficulties, they occasionally lack wisdom and may cause harm to themselves. Hence, advice and support from professionals, family members, experts, and others are crucial for preventing adolescents from engaging in risky behavior. Sentiment analysis using Naive Bayes algorithm classifies students into stress and depression [7].

In recent years, due to generation of voluminous data, technologies have been developed for storing and data processing effortlessly. A huge amount of data can be obtained, mined, and realized for sentiment analysis. This helps in making better policies for the education sector and the target users are teachers, students, and educational organizations. In every aspect of teaching-learning approach, education sectors can incorporate sentiment analysis extensively [8]. Learners are more interested in "Engineering and Technology" but hold negative thinking towards "Life

Science and medicine", this research infers that it is an emergency to explore SA systems for cross-domain that accelerates SA application in multiple learning domains. SA is used for enhancing the learning process; additionally, it provides valuable information for educational institutions. Students receive results of SA through visualization tools such as word clouds, dashboards, virtual agents, etc [9]. Technological advancements like Blockchain, IoT, Cloud Computing and Big Data have broadened applications of SA permitting this to be utilized in any discipline [10]. Moreover, in Machine Learning and Natural Language Processing, SA has turned out to be a hot trend and is being accepted extensively all over the globe [11].

The primary objective of implementing SA approaches on students' feedback in an online learning system is to identify learners' emotions, feelings, participation and evaluate educators' performance [12]. From student learning and achievement, emotions are inseparable. Responses were collected from students to discover their emotional experience around test and an online quiz. Greater positive level emotions and lesser negative level emotions were experienced in online quizzes than tests. Future guidelines of research must integrate a complex relation between cognitive, emotional, and motivational aspects of learning [13]. Sentiment analysis accurately portrays students' learning circumstances in the online learning community. To improve quality of teaching practice, the proposed model can recognize students' sentiment tendencies. SSM (Sentiment Score Matrix) is formed to compute sentiment scores. This can efficiently identify sentiment tendencies of learners for enhancing information services quality in education practice [14].

HEI are increasingly looking for best ways to understand the learning experience of their students. Sentiment analysis helps to investigate emotions and attitudes of students regarding their course experience. To analyze sentiment text was fed into Google's Cloud-based Natural Language Processing. Results presented that students' sentiment in online interaction during two online courses is more positive than in face-to-face courses [15]. During COVID-19 pandemic, to support remote and distance learning useful learning resources are lecture recordings. Students with illness, learning disabilities, and work commitments have narrated that availability of lecture recordings has shaped an inclusive education setting. Sentiment analysis was conducted using Microsoft Azure cognitive services text analytics API. With a large text dataset, machine learning was employed that were labeled for sentiments along 0 and 1. Findings depicted that lecture recordings serve as an additional resource for preparing notes or exams [16]. Therefore, to solve real world problems through design and development of smart learning environment, we can use Azure cognitive services, a text analytics API that leverages natural language processing capabilities for deploying high-quality AI models [17].

Sentiment Analysis is the most crucial area in text mining, as the thoughts of several individuals are analyzed and compiled as a single dataset. E-learning is an educational attempt to deliver knowledge through computers. SA helps users to easily classify their emotional input information. Students' anti-course feelings can be tracked that serves as

feedback from online learning sites [18]. In the teaching-learning process virtual learning environments (VLE) deliver a set of communication and interaction tools utilized by learners and educators. Researchers presented the SentiEduc framework that uses Multi-Agent System (MAS) to gather and analyze opinion of texts posted by learners in VLE. SenticNet tool was used to analyze sentiments automatically. Educators with tutoring experience utilized the framework with real data for verifying the efficiency; as a result accuracy obtained was 73.88% [19]. From an organization, probable text reviews collected on 270 training programmes by 2688 participants were analyzed. RapidMiner Text Mining package was used to track tokenization, removal of stop words, stemming, and token filtering. Authors suggested that instead of content delivery and faculty expertise, the proposed approach can further be expanded to establish sentiment expressed over several aspects like internet connection, hospitality [20].

Researchers have developed a web-application system that uses text analytics and SA for providing educators with a deeper analysis of learners' feedback to assess the course they have taught that will enhance the students learning experience. Feedback was grouped into positive, negative, and neutral. The result depicted a larger number of neutral sentiments. Their system implementation was successful, and it significantly benefits students, lecturers, and administrators [21]. Twitter is the popular free social networking channel. In Anadolu University open and distance education system, sentiment analysis for learners was performed by fetching tweets. 400 tweets were used for validation and classification outcomes are presented. The negative feelings and student complaints can be concentrated by institution managers [22]. Numerous educational institutions utilize online education as media learning where each piece of media, maybe audio, video, or text, can accept learners' feedback. The lecture intends to realize emotions which learners experience when they access media, namely happiness, unhappiness, or disappointment and educators intend to recognize their delightfulness. The study developed a utility cellular for emotion detection from column comments in online media. Accuracy of mobile application utility is 70% for emotion detection [23]. Humans are easily prone to errors in interpreting text-based emotions. Four supervised ML classification techniques namely MNB, SVM, DT, and KNN were applied for analyzing basic emotions. The best performance was resulted by Multinomial Naive Bayes classifier with an average accuracy of 64.08% [24]. In the form of tweets, blogs, and updates of thoughts about interest, a lot of data is being produced. On a variety of subjects, including products, movies, politics, education, news, and more, people express their thoughts and ideas. Data analysis is useful to comprehend observations, sentiments, and attitudes of society. Additionally, decision-making would benefit more from such analysis. Naive Bayes, RF, Tailored RF and enhanced XGBoost were employed. Enhanced XGBoost achieved better accuracy of 72.26% [25].

With meticulous analysis of previous existing research, the limitations are they do not consider hidden structural features namely internet connection, mixed-emotional elements, and unstructured data. To address these limitations, the existing

methods can be operationalized and extended by considering specific factors namely device efficiency, cognitive behaviors, and technical familiarity with cloud platform usage. Moreover, they infer that there is an emergency to investigate SA systems for cross-domain which accelerates application of SA in multiple learning domains. Furthermore, they suggest that future researchers must integrate relationships between cognitive, emotional, and motivational learning aspects. In this context the present research bridges gap in students' sentiment detection, giving a new definition of multifaceted characteristics of concept to gain a deeper understanding of how sentiments provide an indication to educators for identifying whether a student is motivated or discouraged with virtual learning and has an intention to dropout. Thus, in this research sentiments are explored as a process that truly reflects students' learning circumstances by considering necessary features in VLE across multiple disciplines. Hence, in higher education context, sentiments are linked to students' cognitive, emotions, psychological and learning factors in students' behavior. The model is explored with four multiclass classification algorithms, to perform sentiment analysis on text and key phrases. After experimentation, the proposed MSDS system successfully outperforms in each case compared to other methodologies. The best performance for mean accuracy rate was achieved by Logistic Regression for device efficiency with 98.49%, Linear SVC for cognitive behavior and technological expertise with 93.58% and 92.08%.

III. RESEARCH METHODOLOGY

The main objective of this research is detecting the students' intention of dropping out from virtual learning courses by considering their text sentiments. There are several methods for dropout detection. These methods are based on ML techniques and require students' activity records for training and creating predictive models depending on the features extracted from raw data. In this research, four machine learning algorithms are implemented, and its performance metrics are evaluated. The subsequent research questions are considered:

- 1) To develop a Multifaceted Sentiment Detection System (MSDS) architecture for predicting dropout students in VLE.
- 2) To estimate the evaluation steps for measuring the proposed architectures' efficiency in terms of mean accuracy rate and standard deviation using four multi-class classification algorithms namely RF, Linear SVC, MNB, LR.
- 3) To investigate the most suited ML algorithm for classifying students' sentiments depending on their multifaceted characteristics and visualize the results to educators as an early intervention.

IV. MULTIFACETED SENTIMENT DETECTION SYSTEM (MSDS) ARCHITECTURE

The MSDS framework detects the students' sentiments with information gathered from VLE interactions. MSDS architecture attempts to address sentiment analysis approach for characterizing the sentiments across multifaceted subjects namely device efficiency, cognitive behavior, technological expertise with cloud platform usage. The research flow begins with data extraction from comments posted by learners of

VLE. The system reads the data stored with .csv (Comma Separated Values) format. Next, data pre-processing techniques are implemented to texts, namely removal of punctuation marks, stop words, etc. Feature extraction methods like count vectorizer, Term Frequency and Inverse Document Frequency (TF-IDF) are employed. To identify the

real opinions of learners, sentiment classification is performed based on machine learning approaches. Then the flow ends with detecting students' sentiments with three polarities: positive, negative, and neutral. The model is assessed with various evaluation metrics namely accuracy, recall, precision, and F1-Score. Fig. 1 depicts proposed (MSDS) model.

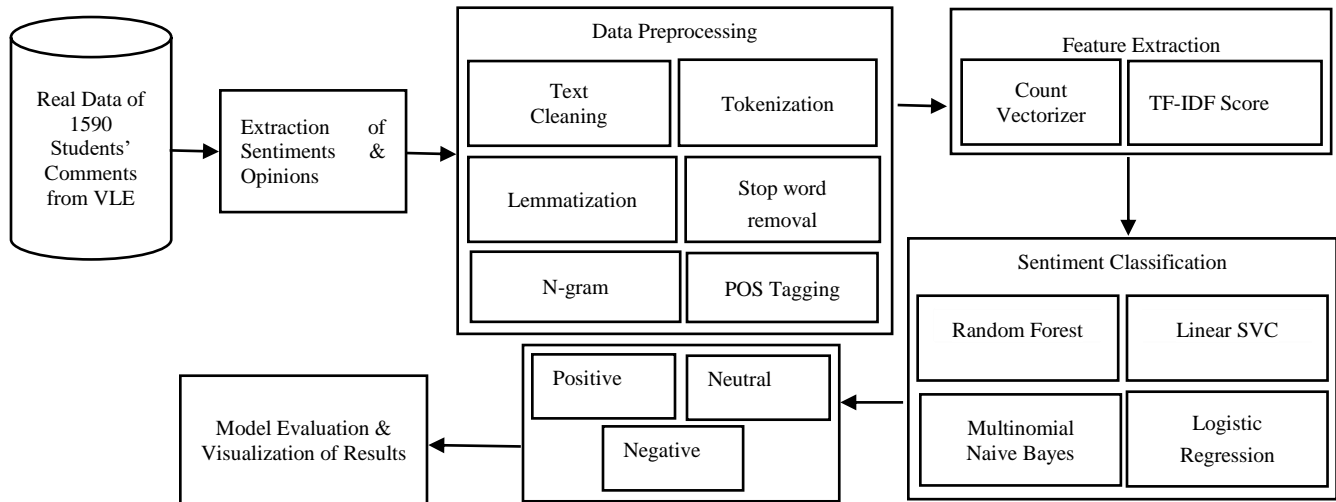

Fig. 1. Framework of proposed (MSDS) research model.

A. Data Collection from Participants

SA can be integrated into a virtual learning environment that realizes real-time analysis of learners' feedback. Real data was collected from students belonging to various disciplines of numerous HEI throughout India. The data sources comprise dataset that were collected by educators through online questionnaire that was broadly classified into various factors namely demographic features, device usage characteristics, self-efficacy which was estimated with 5-point Likert scale, familiarity with cloud platforms using 4-point range for identifying sentiments based on their interactions with VLE. Totally, the dataset contains n=1590 comments, opinions and feedbacks posted by students of virtual learning classes. Depending on their multifaceted characteristics, three datasets are grouped each containing 530 comments for conducting experiments. The data instances are branched into multiple classes. The sentiments are labelled with score range from 0-2, representing negative, neutral, and positive.

B. Data Pre-processing

Text pre-processing is the process of cleaning and preparing text data, as machines can use that processed text to perform various tasks like analysis, prediction, etc. These procedures help to reduce the volume of data and processing time. The comments posted by students are in the form of natural English language and this must be converted into machine readable format. With text data, there are many challenges as it contains a lot of noisy, semi or unstructured data, punctuations, numbers, special characters, spelling mistakes, etc that require to be processed with NLP techniques. These are the pre-processing steps carried out for improving prediction performance.

1) *Removing punctuations and numbers, converting all characters into lowercase*: The basic pre-processing method is punctuations removal from textual data. This process helps to treat each text similarly. As numbers do not hold any vital information in the text it has to be removed. Then the input text is converted into same casing format namely lowercase.

2) *Tokenization*: This is a method of breaking the sentence into meaningful words and phrases. This process is achieved by using delimiters like white spaces and punctuation. Inbuilt NLTK (Natural Language Tool Kit) libraries have tokenization function capability to divide into words.

3) *Lemmatization*: Lemmatization is a text pre-processing technique in NLP models to break a word to its root meaning for identifying similarities. Text normalization changes the words down to a base form. WordNetLemmatizer() is assigned to a variable which is used to improve the algorithms' performance and facilitates to focus on meaning of the words.

4) *Stop word removal*: Next step is to eliminate stop words as they are commonly used words yet not useful for analysis and generally eliminated from text. This technique is applied for removing stop words namely I, am, you, she, he, the, a, an, so, what, etc. These words are not required for sentiment classification as it increases the dataset size and is considered irrelevant for results set. It's always better to remove these words for improving the model accuracy, reducing computational processes and complexity of data.

5) *N-gram*: In NLP this is a continuous series of n items created from a given text sample where items can be characters or words. This language model predicts the probability within any sequence of n words in the language.

There are multiple n-grams like unigram, bigram, trigram etc. Unigram is simplest n-gram where only one word is considered. Bigram takes two words at a time. Unigrams and bigrams are used in this research, where ngram_range = (1,2) is considered for feature processing.

6) *Part of Speech (POS) Tagging*: This process labels each word in text format for a particular POS depending on its context and definition. This reads the text from a language and assigns some token (POS) for every word. `nlk.pos_tag(tokenized_text)` is applied. Parts of Speech Adjective, Verb, Noun, and Adverb are considered.

C. Feature Extraction Techniques

In text data classification feature extraction plays a dominant role in reduction of feature space and increasing classifier's accuracy. This process converts data into features applied for ML model, as ML algorithms are programmed with numbers. Textual data is converted into vector form using two feature extraction techniques namely Count Vector, Term Frequency, and Inverse Document Frequency (TF-IDF) vector. Fig. 2 represents the cleaned text results achieved after data pre-processing and feature extraction with cognitive behavior data.

Fig. 2. Sample processed text for cognitive behavior.

D. Machine Learning Techniques for Sentiment Analysis

In the current situation, feedback is provided through grading methods. Although this grading method masks students' genuine feelings, the textual response gives them a chance to emphasize qualities. Three different ML algorithms SVM, MNB, and RF were implemented. Experimental outcomes suggest that MNB with 80% accuracy performs better than other classifiers [26]. The study applies SA to self-evaluation comments, a form of unstructured data that provides valuable information representing students' learning status over course duration for identifying at-risk students. SVM and Convolutional Neural Networks (CNN) were

1) *Count vectorizer*: CountVectorizer transforms a given text into a vector depending on frequency (count) of each word which occurs in entire text. This is beneficial when there are multiple such texts, and for converting each word in each text into vectors. These functionalities make it an extremely adaptable feature description module for text.

2) *TF-IDF score*: This is a weighting measure that quantifies the string relevance representations namely words, phrases, lemmas in a given document. Term Frequency (TF) describes in a document how frequently a term occurs against the total number of words in document, as in (1). IDF is measurement of selected term's weight in the document. This is given in (2).

$$tf = \frac{\text{number of occurrences of a term in document}}{\text{total number of terms in the document}} \quad (1)$$

$$idf = \log \left(\frac{\text{total number of given documents}}{\text{number of document with existing selected word}} \right) \quad (2)$$

applied to predict student performance. The proposed model provides an effectiveness represented by F-measure of 0.66 (SVM) and 0.78 (CNN). Best effectiveness was presented by CNN, achieving an F-measure value of 0.78. Experimental results demonstrated that applying sentiment analysis to unstructured data can significantly improve accuracy of early-stage predictions [27]. In this research, NLP techniques are employed to pre-process and vectorize the text data. Vectorized data is then applied for training various ML models. Following are the list of steps required to train the model for sentiment analysis:

Algorithm: Sentiment Analysis Using Machine Learning

1. Collect dataset from VLE to train and test machine learning model classifier.
 2. Pre-process the data for subsequent processing.
 3. Convert textual data into vector form using NLP techniques namely Count Vectorizer and TF-IDF.
 4. Divide the dataset into training and testing groups.
 5. Train the ML classifier with training data. Apply algorithms such as RF, Linear SVC, MNB, LR.
 6. Predict the polarity of test data.
 7. Evaluate the ML model using various metrics namely accuracy, precision, recall and F1-Score.
 8. Select the best algorithm for multifaceted text characteristics using sentiment multiclass classification.
-

1) *Random forest*: SA is used for analyzing unstructured text data for extracting positive or negative sentiments contained in student advisor's notes to predict college student dropout using RF model. The authors have quoted that their study is the first to apply NLP techniques for dropout prediction. RF classifier achieved 73% accuracy when compared to SVM, LR and CART [28]. M. A. Fauzi stated that due to the development of social media and online website reviews, SA is an efficient way for text classification. Experimental results confirmed that RF gives excellent performance with an average OOB score of 0.829 [29]. For increasing predictive power of Random Forest, this research utilizes hyperparameters $n_estimators=100$ and $max_depth=5$. $n_estimators$ is the number of trees the algorithm creates before taking maximum voting. A higher number of trees enhances the performance and makes predictions more stable. The hyperparameter max_depth represents maximum depth of each decision tree in the forest.

2) *Linear Support Vector Classifier (SVC)*: [30] suggests an opinion analysis system for amazon review for identifying comments received from UCI Website either positive or negative. The proposed approach is applied to review dataset and obtained an accuracy of 91% with Linear SVC over Naive Bayes and Voting. Authors have proposed that Linear SVC takes lesser execution time of about 0.0972s to test samples and provides output which is better than other classifiers namely Naive Bayes, Logistic Regression, Decision Tree [31]. The Linear SVC method is a faster implementation of Support Vector Classification that applies a linear kernel function for performing classification. This performs well for NLP based text classification tasks with a large number of samples. Linear SVC in scikit-learn library does not provide `predict_proba` function, instead `decision_function` is used that predicts the confidence scores for samples, which is the signed distance of that sample to hyperplane.

3) *Multinomial Naive Bayes (MNB)*: This is a type of Naive Bayes (NB) classifier that finds probabilities of classes assigned to text that uses joint probabilities of words and classes and is often used as a baseline for sentiment analysis. MNB achieves significant results for text categorization with 90% accuracy. MNB algorithm is a fast, easy-to-implement, and modern text categorization algorithm [32]. Social networking has developed into a tool that is useful for gathering vital information about individuals. The sentiment of the user can be determined by extracting user comments via an API and feeding them to an algorithm that detects whether they are positive or negative. Results obtained show that Multinomial Naive Bayes performs good with classification accuracy of 85% when compared to SVM, Random Forest and Decision Tree [33]. MNB is specifically beneficial for problems that involve text data with discrete features, namely word frequency counts. This works on the principle of Bayes theorem and assumes that features are conditionally independent given the class variables. The computation is

performed by adding logarithms of probabilities, as in (3). The class with the highest log probability score is most feasible.

$$C_{NB} = \mathop{\text{arg}}_{c \in C} \max [\log P(c) + \sum_{1 \leq k \leq n_d} \log P(t_k | c)] \quad (3)$$

4) *Logistic regression*: In a variety of situations finding the polarity of reviews is useful. NLP techniques can be applied for analyzing the reviews and optimizing the strategic decision making. TFIDF is used for feature selection and Logistic Regression for classification as it uses sigmoid activation function. The LR with grid search model classifies the text accurately with 94% [34]. Reviews and feedback are deciding factors for understanding the opinions of users. SA is a method of information extraction for improving the work by review analysis. The users' review text is cleaned by Count Vectorizer and TFIDF. Sentiment prediction is done using various classifiers for reviews without ratings. Logistic Regression accuracy is 93% and more compared to NB, MNB, Bernoulli classifiers [35]. Logistic Regression is a simple classification algorithm that can be generalized to multiple classes. The LR uses sigmoid function, which is given by (4),

$$\text{sig}(t) = \frac{1}{1+e^{-t}} \quad (4)$$

These popular classifiers do not directly support multiclass classification problems. There are certain heuristic methods available which can split multiclass classification datasets into several binary classification datasets. The binary classifiers are then trained on each binary classification problem and predictions are made operating the model which is most confident. To implement this method for multi-class classification, the `OneVsRestClassifier` method is used.

V. EXPERIMENTAL RESULTS

In this research, implementation is done with efficient NLTK, Scikit-learn libraries by applying the proposed machine learning techniques. NLTK is used to perform regular expression patterns & tokenization to parse text, lemmatization, stop word removal, n-grams, and POS tagging. Vectorization and classification were accomplished by Scikit-learn. Data was preprocessed, vectorized with TF-IDF, and classified with four multiclass machine learning algorithms. Dataset was split into 75% training set and 25% test set. 5-fold Cross-Validation was used for training classification model. RF, Linear SVC, MNB and LR were applied as they are the most popular machine learning classifiers used to analyze students' opinions. Depending on the classification task different metrics were used to measure the classifiers' performance.

A. Multi-class Classification Positive/Neutral/Negative

The performance of MSDS framework is evaluated using various metrics. Accuracy is one of the popular metrics for multi-class classification. This is the ratio of the number of accurately classified instances to total number of instances. Macro-average precision calculates precision for all classes individually and then averages them. Weighted average precision calculates precision per class but considers no. of

samples of each class in data. Macro-average recall score computes the arithmetic mean of all recall scores of different classes. Weighted-average recall computes recall per class but considers the number of samples of each class in the data. Macro average F1score computes arithmetic mean of all per-class F1 scores. Weighted average F1 score calculates mean of all per-class F1 scores by considering each class's support.

$$Accuracy = \frac{(TP+TN)}{(TP +TN+FP+FN)} \quad (5)$$

$$Macro - average Precision = \frac{Precision_1+Precision_2+Precision_3}{3} \quad (6)$$

$$Weighted - average Precision = \frac{w_1*Precision_1+w_2*Precision_2+w_3*Precision_3}{Total\ number\ of\ samples} \quad (7)$$

$$Macro - average Recall = \frac{Recall_1+Recall_2+Recall_3}{3} \quad (8)$$

$$Weighted - average Recall = \frac{w_1*Recall_1+w_2*Recall_2+w_3*Recall_3}{Total\ number\ of\ samples} \quad (9)$$

$$Macro - average F1 - Score = \frac{F1-Score_1+F1-Score_2+F1-Score_3}{3} \quad (10)$$

$$Weighted - average F1 - Score = \frac{w_1*F1-Score_1+w_2*F1-Score_2+w_3*F1-Score_3}{Total\ number\ of\ samples} \quad (11)$$

1) *Device efficiency*: The first perspective analyzes the students' device usage characteristics as VLE increases the portability of learning processes through smart devices. To investigate new educational opportunities that result from expanding device access to VLE, enables users to establish more fleeting links to virtual campus for providing instructional procedures built on a model that is significantly less time and space consuming. The parameters used for configuring each of the algorithms implemented are the type of smart device, mode of device availability, device connectivity, number of hours the device is connected online. The optimized smart device environment will provide services to the educational community, regardless of their functional and cognitive elements. N. A. S. Remali with other researchers, states that its' a challenging task for educational institutions to identify learners' opinions and difficulties during online education as few students may have poor internet connection problem, lack of bandwidth and the environment makes learners not to concentrate on class. Thus, SA is utilized to assess students' opinions (positive, neutral, and negative) of virtual learning [36]. Considering device efficiency features, Table I shows the evaluation metrics of four multi-class classifiers with LR model showing high accuracy rate of 98%. The cross-validation method, with cv=5, was performed to cross-validate baseline models with feature extractors of TF-IDF and CV. Mean accuracy and standard deviation for each fold validates performance of

models, depicted in Table II. The highest mean accuracy of Logistic Regression is 98.49%. Fig. 3 shows mean accuracy with 5-fold cross validation. Results of sentiment distribution are visualized in Fig. 4. Fig. 5 displays classification metrics of device efficiency text characteristics.

TABLE I. CLASSIFICATION OF DEVICE EFFICIENCY

2) *Cognitive behavior*: The encompassing perspective analyzes the students’ psychological cognitive behavioral model through self-efficacy theory stated by Psychologist Albert Bandura. The parameters used for configuring each of the algorithms implemented are manageability, finding means & ways, stick to aims & accomplishments, handling unforeseen situations, investing effort, finding several solutions, handling whatever situations in online learning. In addition, the researchers in [37] explored that predictive power and feature generalization of cognitive skill score estimates possibility of learners’ success or failure in higher education course which provides suitable intervention to facilitate learners. Cognitive skill score proves to be efficient in identifying students’ performance when exact metrics correlated to learning activities and students’ social behavior are unavailable. Table III shows evaluation metrics of four multi-class classifiers for self-efficacy with Linear SVC showing a high accuracy rate of 93%. With cv=5, mean accuracy and standard deviation for each fold validates the models’ performance depicted in Table IV. The mean accuracy of Linear SVC is higher with 93.58% when compared to RF, MNB and LR. Fig. 6 presents mean accuracy with cv=5 for cognitive behavioral features. Sentiment analysis outcomes are visualized in Fig. 7. Classification metrics of self-efficacy text characteristics are displayed in Fig. 8.

3) *Technological expertise of cloud learning platform usage*: Outside the classroom, cloud platforms prepare students to make reasonable study schedules, thereby promoting self-directed learning, innovation, collaboration, and ease of accessibility. The parameters used emphasize on the platform learners are familiar with accessing online teaching materials namely Google Classroom, Google Meet, Zoom, Facebook Classroom, Twitter etc. Moreover, J. Zhang in [38] suggested that educators could discuss with learners through the cloud class even after online class and they can set time-limited online test for enhancing results. With students' feedback the course assistants can track their problems in online teaching. Using bullet screen educators can communicate useful course contents to learners in time, whereby the emotional communication between them is deepened. Table V illustrates the evaluation metrics of four classification algorithms for technological expertise with Linear SVC depicting a high accuracy rate of 92%. Table VI depicts mean accuracy and standard deviation for each fold to validate models' performance. The highest mean accuracy score of Linear SVC is 92.08%. Fig. 9 visualizes mean accuracy with $cv=5$ for technological familiarity with cloud platforms. The sentiment analysis results are presented in Fig. 10. Fig. 11 shows classification metrics of technological expertise text characteristics.

B. Performance Evaluation using ROC and AUC

To analyze the performance of MSDS architecture, ROC curve can be used as it measures the classifier’s predictive quality. Tradeoff between classifier’s sensitivity and specificity can be visualized by the user using a ROCAUC (Receiver Operating Characteristic/Area Under the Curve). ROC curve exhibits true positive rate on Y axis and false positive rate on X axis when plotted. Ultimate point is the top-left corner of plot: false positives are 0 and true positives are 1, which directs to another metric, AUC. The higher AUC represents a better model. However, this is vital to examine “steepness” of curve, as this illustrates maximization of sensitivity while minimizing specificity. ROC curve is extensively used in this research to describe diagnostic accuracy and for finding the best cut-off value for a model trained through multi-class machine learning techniques. ROC curves for cognitive behavior through self-efficacy characteristics using RF, Linear SVC, MNB, LR are visualized in Fig. 12, Fig. 13, Fig. 14, Fig. 15 respectively as this is main framework emphasizing the learners’ psychological cognitive behavioral patterns for risk prediction. The performance comparisons of ROC curves show that Linear SVC model performs the best for self-efficacy data.

C. Data Visualization

Sentiment analysis encompasses a variety of SA tasks, including subjectivity detection and emotion analysis. This reflects the wide range of user tasks and data domains used in SA research and applications, which include everything from social media and news monitoring to theoretical linguistic research and NLP. This implies the use of numerous visual channels and interpretations. The visual representation involving polarity data includes word clouds [39]. Word cloud represents a powerful textual data visualization technique that enables quickly identifying the words that are most often used within a particular body of text. These are frequently employed communication tools for processing, analyzing qualitative sentiment data. When educators need to visualize the opinions of learners, word cloud can be used for identifying the messages posted by them. This visual representation gives a clear way for educators to easily interpret the messages. Fig. 16 represents the word cloud visualization of multifaceted factors.

Fig. 16. Word clouds of device efficiency, cognitive behavior, technological expertise of cloud platform Usage.

VI. CONCLUSION

Multifaceted Sentiment Detection System (MSDS) is proposed in this research to predict students' dropout using multiclass classification algorithms. For addressing this goal, the research analyzes higher education students' comments

and reviews while attending virtual classes through VLE that have been classified and analyzed using machine learning algorithms and word clouds. The results obtained from the research explore multideterminant characteristic features of respondents' device efficiency, psychological cognitive behavior, and technological knowledge of cloud platform usage. This finding mainly contributes to improving the classifiers' predictive ability of college student dropout through text classification. The proposed method obtained the highest mean accuracy results for device efficiency using Logistic Regression with 98.49%, Linear SVC for cognitive behavior with 93.58% and technological expertise with 92.08%. Thus, this novel assessment mechanism MSDS, aims in exploring efficient sentiment classification by proposing multiclass machine learning algorithms to avoid dropouts. Furthermore, experimental outcomes demonstrate that proposed system has obtained better accuracy results when comparing to previous methods. For future work, the algorithms can be validated and applied against other computational methods such as deep learning algorithms for superior performance.

Abstract—Plants are the world's most significant resource since they are the only natural source of oxygen. Additionally, plants are considered crucial since they are the major source of energy for humanity and have nutritional, therapeutic, and other benefits. Image identification has become more prominent in this technology-driven world, where many innovations are happening in this sphere. Image processing techniques are increasingly being used by researchers to identify plants. The capacity of Convolutional Neural Networks (CNN) to transfer weights learned with huge standard datasets to tasks with smaller collections or more particular data has improved over time. Several applications are made for image identification using deep learning, and Machine Learning (ML) algorithms. Plant image identification is a prominent part of such. The plant image dataset of about 300 images collected by mobile phone and camera from different places in the natural scenes with nine species of different plants are deployed for training. A five-layered convolution neural network (CNN) is applied for large-scale plant classification in a natural environment. The proposed work claims a higher accuracy in plant identification based on experimental data. The model achieves the utmost recognition rate of 96% NU108 dataset and UAV images of NU101 have achieved an accuracy of 97.8%.

Keywords—Convolutional Neural Networks (CNN); Machine Learning (ML) algorithms; plant image identification; plant image dataset

I. INTRODUCTION

When it comes to the matter of food, pharmaceuticals, and other raw materials, the first name that comes to our mind is Plant. Plants directly or indirectly provide benefits to humanity's progress. As a result, our ability to recognize the characteristics of a wide range of plant species was critical for our prosperity and survival. Thousands of plant species are scanned and cataloged by various researchers and academic practitioners [1] to better recognize their features, value, and prospective applications [2]. The majestic feature of the plant kingdom is that no two are alike. Every tree is beautiful and has possession of divergent characteristics. As no fingerprint in the world is identical, no venation pattern of a plant is similar. Different species have seemingly many varieties of shapes, sizes, textures, and effervescent colors. With the change in seasons, every tree changes its appearance to adapt to the environment. Automated plant identification is the most prominent remedy for bridging the environment with today's rapidly developing technology that has substantially improved

in recent years. Both environmentalists and techies are showing considerable attention to plant identification for its never-ending applications. All this is possible because of the instigation of Deep Learning (DL) models, which can automatically learn to extract higher-level features from unrefined data [3]. Machine learning (ML), a branch of AI, is a technique in which a computer is taught, through the analysis of data, to carry out a particular activity, such as prediction. It has garnered a lot of interest in recent years from researchers in many different areas, including object recognition [4-5], natural language processing, speech recognition [6], and smart manufacturing [7-8]. Machine learning algorithms can be broken down into three distinct classes denoted by whether they rely on an external observer to provide feedback on the learning process: unsupervised learning, supervised learning, and semi-supervised learning. Unsupervised learning trains using unlabeled data, unlike supervised learning. Semi-supervised learning, in contrast to these other two types, uses both labeled and unlabeled data during training. The advancement in machine learning helped in developing innovative automated image identification models are proposed. With the evolution of smartphones throughout the previous two decades, mobile-based applications have become an important part of this development. Mobile phones play an important role in image identification in real-world and natural environments. Millions of images have been acquired through mobiles. The awareness of people on maintaining ecological balance and the crucial role of plant identification in many other platforms drives modern scientists to focus on improving the performance of mobile-based image identification models. DL networks can overcome prior challenges related to handcrafted feature extraction from massive volumes of data by utilizing parallel computing architectures [9]. DL models may learn which traits are most important for feature extraction using multi-level representations, demonstrating their efficacy [10].

In the modern-day, variations in leaf characteristics are used by researchers as a comparative tool for identifying plants. Many efforts have been put on to extract the features of flower, fruit, or leaf for identifying the plant. The research about automated plant identification has started about two decades ago. In [11], Söderkvist classified the trees from images of the leaf using a computer vision classification system. Different features of the leaf are defined as different descriptors for comparison. Backpropagation was used on 15 different Swedish tree classes to investigate features such as

leaf shape and moment for the feed-forward neural network. In [12], Fu et al. believed that leaf venation contains important genetic information. Due to the high diversity in leaf veins, conventional thresholding-based methods may not extract information accurately. Features such as edge gradients, local contrasts, and statistical features are extracted to define the characteristics of the veins' surrounding pixels. The experiment shows that, when compared to traditional thresholding, the neural network is more efficient to identify vein images. Li et al. [13] presented an effective leaf vein extraction approach by using the snakes' method along with cellular neural networks. Using prior knowledge similar features were obtained from both implicit and parametric models for acceptable results on leaf segmentation. A probabilistic neural network as a classifier was employed for identifying the leaf images of plants that performed better than the BP neural network in terms of accuracy [14]. The concept of natural-based leaf recognition and a contour segmentation technique based on the polygon leaf model was used to obtain the contour images [15].

Deep learning has been a hot topic since 2010, and many scientists are focusing their efforts on deep learning for image recognition. Many researchers work on flowers for classifying ornamental plants. As leaves and flowers also have different features to distinguish, Nilsback and Zisserman proposed a model for foreground and background and a light generis shape model for identifying petal structures. This technique describes the shape, color, texture features, and other characteristics of the flowers [16]. A deep learning model with 26 layers and 8 residual building components was developed for identifying plants at a large scale in the natural environment. The suggested model achieved a recognition rate of 91.78% for the BJFU100 dataset, suggesting that deep learning is an encouraging approach for smart forestry [17]. A system to detect and recognize a variety of plant species was designed by Militante et al. [18]. The system was able to detect a variety of plant diseases too. A deep learning model was trained using 35,000 images of healthy and infected plant leaves and finally, a 96.5% of accuracy rate was achieved by the trained model. Liu and Kan proposed a classification model which has a combination of texture combination and shape features, using deep belief network architecture. Local binary patterns derive the texture of a leaf. The combination is maintained by gray level co-occurrence matrix and Gabor filters [19]. In the year 2022, Haq [20] applied a machine learning-based Random Forest (RF) classification model for comparing the vegetation extent. To identify leaf images, Zhang et al. [21], created a deep learning system that included eight layers of Convolution Neural Networks (CNN) and achieved a better recognition rate. Zhang et al. combined the Harr-like transformation of local features with SIFT features of flower images, classifying them by the k-nearest neighbor method. His conjecture of concentrating on local features hindering performance proved right. In 2020, Yang et al. employed shallow CNN in place of DCNN for identifying the disease on the images of a leaf. A significant performance improvement was achieved with their

method in comparison to the DCNN models. The use of PCA helps in performance improvement and reduces computational complexity too [22].

All this research paved a path for nowadays plant recognition technology. Various mobile applications like P1@ntNet [23], LeafSnap [24], Microsoft Garage's Flower Recognition app [25], iNaturalist [26], and Plantsnap [27] are the most prominently used mobile applications for plant identification. Although there are numerous kinds of research on terrestrial plant identification there are barely any with UAV imagery. Automatic plant taxonomy has had rapid growth in recent years but image identification using UAV [28] is the newborn interest of the researchers. Popescu D and Ichim have proposed an image recognition model based on texture analysis. Two types of texture statistical and fractal characteristics were considered on images of forests, buildings, grassland, and flooding zone. All the research done prior to date hinders their performance in a natural environment. The traditional models used for classification rely on preprocessing of the image to delete the background and enhance it. Preprocessing the dataset consumes time and might not be as accurate as natural environment identification. The main advantages of the UAV (unmanned aerial vehicle) are the collection of the terrestrial dataset is more time taking than the aerial dataset. The traditional classification of aerial images is expensive for monitoring the evolution of the research area.

To overcome all these challenges, we acquired the NU108 a terrestrial dataset using a mobile phone in a natural environment. A UAV dataset NU101 is another prominent part of this research. A five-layer deep learning model is applied to the proposed model and a recognition rate of 97% was achieved on the NU101 dataset.

II. DATASET

A. Terrestrial Imagery

The terrestrial dataset NU108 contains 300 images of nine plant species within the campus of NIIT University (See Fig. 1). These images were collected by mobile phone in the natural environment with the help of a camera of 12 megapixels. The size of the image is 4032x3024. Drone imagery in the same vicinity NU101 dataset is collected by UAV (DJI SPARK). The images were taken from an altitude of 24m. The drone is equipped with a camera of 12 megapixels with an equivalent focal length and an RGB sensor image of a size 960 × 1280 as shown in Fig. 2.

B. Drone Imagery

The dataset NU101 was collected through DJI SPARK from an altitude of 24m. A total of 15 images covering an approximate distance of 300m have been collected and made into a mosaic image using Drone2 map software. ROIs of each tree species in the image are detected using MATLAB and used as training data for our model. A total mosaic image is used for validation.

Fig. 1. Terrestrial images of plant species from the NU108 dataset.

Fig. 2. The drone images of plant species were collected using DJI SPARK from an altitude of 24m.

III. METHODOLOGY

A. Convolution Neural Network

While ML has many applications, its success is highly dependent on the features chosen to train the model. Due to their ability to automatically extract higher-level features from the raw input data, deep learning algorithms have garnered a lot of attention in recent years. When it comes to deep learning, the most popular technique is the convolutional neural network (CNN) algorithm, which is built on the ANN foundation. Convolutional networks were inspired by early findings of biological processes; the connectivity pattern of CNN neurons resembles the organization of an animal's visual cortex. A CNN allows elements to be identified and classified with minimal pre-processing [32-37]. The CNNs are regularized multilayer perceptron variants. The term "multilayer perceptron" usually refers to networks that are fully connected, meaning that each neuron in one layer is linked to all neurons in the next layer. In comparison to other image classification techniques, CNN requires extremely little pre-processing. Difficult image-driven pattern recognition problems can be solved easily by the simple architecture of CNNs that require minimum input parameters [38]. When other algorithms need to be hand-engineered this neural network learns about the filters which help in natural scene image classification. This is the best feature of CNNs that they do not need any prior knowledge about the classification and most little human efforts are needed.

1) *Convolution*: The convolution layer, which is connected to local portions of the input, will determine the output of neurons by calculating the scalar product of a set of weights with the region related to the input volume represented in the form of metrics. The operation of convolution is shown in Fig. 3. The rectified linear unit

(abbreviated as ReLU) is applied as an 'elementwise' activation function like a sigmoid to the output of the previous layer's activation.

2) *Pooling*: It is one of the building blocks of CNN that simply reduce the input size with the help of the downsampling process. Thus, it reduces the computation for the given problem (See Fig. 4). Multiple pooling layers (i.e., Max Pooling Layer and Average Pooling Layer) can be applied to reduce the number of parameters within that activation.

3) *Fully connected layer*: The input data to CNN layers cannot be inserted as shapes or pictures. Therefore, the process of flattening is performed to construct a single-dimensional feature vector from the output of the convolutional layers as shown in Fig. 5. Furthermore, it is linked to the final classification model, which is referred to as a fully connected layer. The fully connected layers produce the final output class scores from the activations in the same way that normal ANNs do. The generated class scores can be utilized for classification. It is also possible that ReLU might be employed between these layers to improve performance.

4) *Architecture*: A convolutional neural network consists of a convolution layer in which the input image is convoluted with multiple kernels (feature detectors) and then connected to the pooling layer where features are magnified and then connected to the fully connected layer. The activation functions help in the classification of the data. The architecture of our model has five-layered deep neural networks (See Fig. 6 (a)), and the second model with three neural network layers (See Fig. 6(b)). The convolution layer model is applied to terrestrial data NU108 for image identification.

Fig. 3. Convolution operation using the scalar product of a set of weights with the related region.

Fig. 4. Illustration of max polling layer.

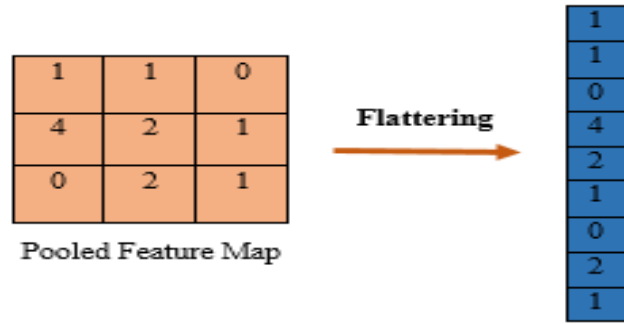

Fig. 5. Process of flattening to convert the data into a 1-dimensional feature vector.

Fig. 6. The architecture of the models with (a) five layers of deep neural networks, (b) three layers of neural networks.

5) *ReLU*: The activation function ReLU is used mainly to remove the negative values. The standard way of model a neuron's output is f as a function of its input x is with $f(x) = \tanh(x)$ or $f(x) = 1/(1+e^{-x})$. These saturating nonlinearities are significantly slower than the non-saturating nonlinearity in terms of training time with gradient descent and are described mathematically as $f(x) = \max(0, x)$. A visual illustration of the ReLU activation function is shown in Fig. 7. Following [29], refer to neurons with the nonlinear property as ReLUs. Deep CNNs with ReLUs perform better than their tanh unit counterparts in terms of training time. When compared to other activation functions, such as sigmoid or tanh, ReLU does not experience the vanishing gradient problem that these other activation functions do.

Fig. 7. A visual Illustration of the ReLU activation function.

6) *Sigmoid function*: A sigmoidal function in the form of a hyperbolic tangent is consistently preferred theoretically and experimentally for deep learning models. It is used in neural networks to give logistic neurons with real-valued output which is a bounded function of their total input. Having the advantage of nice derivatives, it facilitates learning the weights of a neural network much easier. Sigmoid activation function $S(x)$ is defined by equation (1) and is illustrated in Fig. 8.

$$S(x) = \frac{1}{1+e^{-x}} = \frac{e^x}{e^x+1} \quad (1)$$

Fig. 8. Sigmoid activation function.

B. PCA Method

After the input image is processed further the image has a natural scene with trees and other objects in it. Tree identification is carried out as the first step toward classification and identification. Tree identification is done through the Primary Component Analysis method which is one of the dimensionality reductions. The mosaic of the input image is shown in Fig. 9.

1) *Decorrelation*: Decorrelation stretch enhances the visual perception of the image so that the objects can be differentiated due to enhanced color separation of the image (See Fig. 10).

2) *Principal component analysis*: Principal Component Analysis (PCA) is a technique used for dimensionality reduction. It directly decreases the number of feature variables by saving only the required variables. PCA is used to obtain a single-band image. First, compute the covariance matrix of the data and further calculate the eigenvalues and vectors for the computed covariance matrix. Select only the most significant feature vectors using the eigenvalues and vectors, and then convert the data onto those vectors to reduce dimensionality (See Fig. 11).

Fig. 9. Mosaic of the input image.

Fig. 10. Image after decorrelation stretch image.

Fig. 11. Image after applying the PCA technique.

3) *Thresholding*: Thresholding is done by using Otsu's Method in our model. Otsu's thresholding approach iterates through all the threshold values and calculates a measure of pixel-level spread on each side [30] of the threshold, categorizing the pixels as foreground or background. The goal is to discover the threshold value at which the sum of foreground and background spreads is the smallest.

4) *Edge detection*: Edge detection is an image processing approach for detecting object boundaries within images. It works by sensing brightness discontinuities. It's utilized for data extraction and image segmentation. Edge detection in our model helps define the tree's outline and separate the tree from the background for further analysis. Noise in the form of unwanted background and shadow of the trees can be removed using the Gaussian Filter method. This helps in reducing false detection. The Gaussian filter is represented as equation (2).

$$H_{ij} = \frac{1}{2\pi\sigma^2} \exp\left(-\frac{(i-(k+1))^2 + (j-(k+1))^2}{2\sigma^2}\right) \quad (2)$$
$$1 \leq i, j \leq (2k + 1)$$

Two methods namely Sobel and Canny can be applied to detect the edges. Canny has four different filters to detect edges in different directions in blurred images. The output of Sobel is taken as the input of canny. Canny gives an output of an image with thicker outer lines and thinner inner edges.

5) *Implementation and preprocessing*: Tree crowning is followed by Dataset Processing after the edge detection of the vegetation. Trees and plants are cropped from the resultant image of tree crowning and are stored in a folder for further processes. Multiple images are cropped from a single image using Matlab. Several trees are counted by the application of the PCA method and that helps in the training of the model. All the trees that are cropped and stored are now sorted. Identification of the species is done manually. The data set folders thus obtained are divided into the testing set and training set.

Keras is a Python based open-source deep learning framework that is used to implement the model. All the experiments were run on a Windows server with a GTX 1050Ti GPU (8 GB memory) and a 3.40 GHz i7-8750H CPU (16 GB memory).

6) *Training algorithm*: A feed-forward neural network is like a logistic regression algorithm, but the input values get more linearly separable with the addition of hidden layers. A gradient descent-based strategy was used to train this model by minimization of backpropagated error. The backpropagation algorithm is used to iteratively discover a local optimum of the loss function [31]. The error backpropagation through the output layer L to layer $l < L$ will be done via a recursive computation as equations (3, 4, 5).

$$\frac{\partial L}{\partial w_k^{(l)}} = \frac{\partial \eta^{(l)}}{\partial w_k^{(l)}} \frac{\partial h^{(l)}}{\partial \eta^{(l)}} \frac{\partial \eta^{(l+1)}}{\partial h^{(l)}} \frac{\partial L}{\partial \eta^{(l+1)}} \quad (3)$$

$$= - \frac{\partial \eta^{(l)}}{\partial w_k^{(l)}} \frac{\partial h^{(l)}}{\partial \eta^{(l)}} \frac{\partial \eta^{(l+1)}}{\partial h^{(l)}} \Delta^{(l+1)} \quad (4)$$

$$= - \frac{\eta^{(l)}}{w_k^{(l)}} \Delta^{(l)} \quad (5)$$

IV. RESULT ANALYSIS

A series of experiments were done to find the best accuracy and improve the quality of the result. The comparison between accuracy and epochs of the validation accuracy and testing accuracy has been measured. The proposed model results in 97.8% accuracy over the UAV dataset and 96% accuracy in the terrestrial dataset (See Fig. 12). The output image after applying the proposed CNN model is shown in Fig. 13. For the size of the dataset, this five-layered CNN is the best tradeoff between model capacity and accuracy.

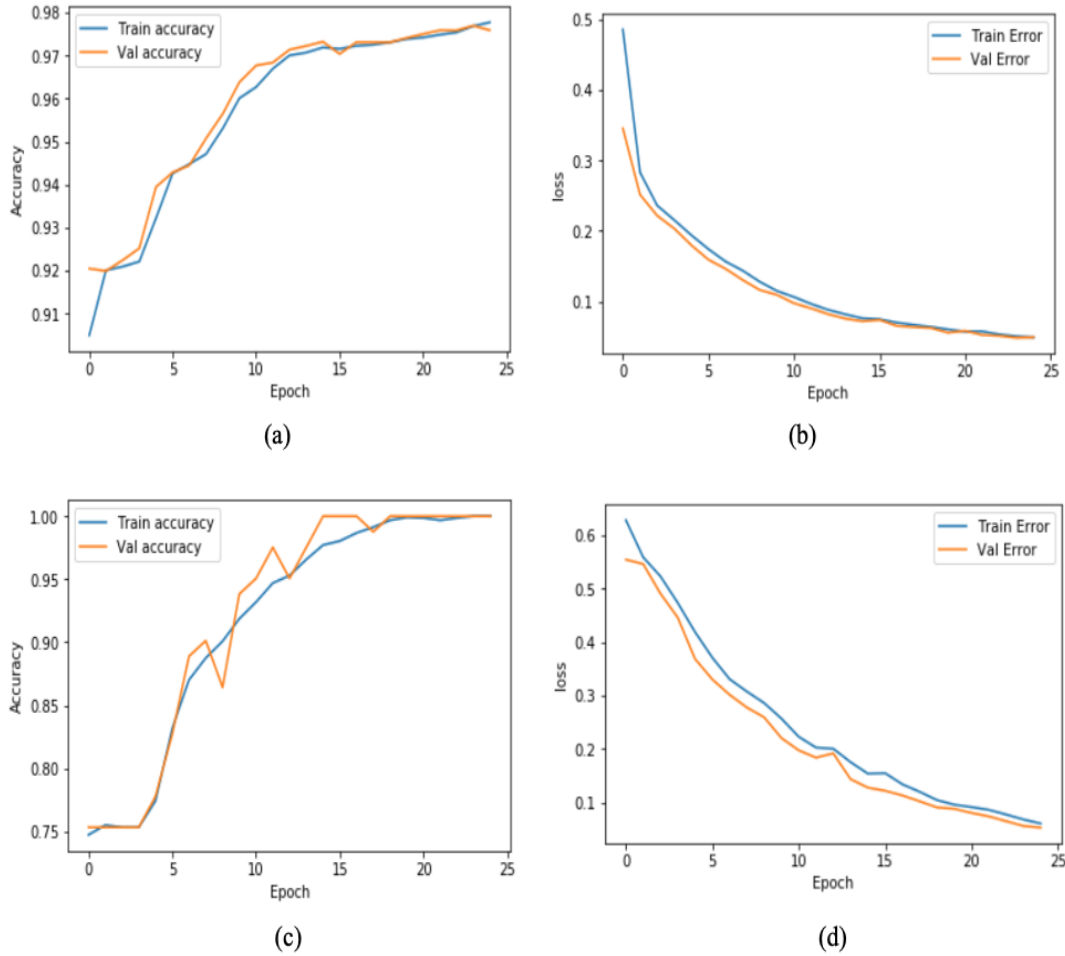

Fig. 12. Performance of the model.

Fig. 13. Resultant image after applying the proposed CNN model.

V. CONCLUSION

The first mobile device acquired the NU108 dataset containing 300 images of nine plant species and the NU101 UAV data set which paves a path for further plant identification studies on UAV imagery. The proposed model achieves an accuracy of 97.8%, proving that deep learning is an encouraging technology for classifying plants in the natural environment. The NU101 database will be expanded in the future to include more plant species at various stages of their life cycles, as well as more thorough annotations. The drone imagery will be widened and work on more sophisticated systems for higher accuracy over a larger area will be done in future research work. The future scope of the present work will be utilizing the advanced DL models with additional datasets.

ACKNOWLEDGMENT

Abstract—A lot of diseases may be preventable if they can be analyzed or predicted from patient historical and family data. Predicting diagnosis depends on the gathered clinical and physiological data of patients. The more collected clinical and medical healthcare data, the more knowledge the medical support system may support. Hence, real monitoring clinical and healthcare data for patients is the trend of this decade based on Internet of Things technologies (IoT). IoT models facilitate human life by easily collecting clinical data remotely for recognizing diseases that are easily treatable if it is diagnosed early. This paper proposes a framework consisting of two models: (i) heart attack detection model (HADM); (ii) Electrocardiosignal ECG heartbeat multiclass-classification model (ECG-HMCM). Gridsearch is used to the hyperparameters optimization for different machine learning (ML) techniques. The used dataset in HADM consists of 1190 patients and 14 features. As the foundation of diagnosing cardiovascular disease is arrhythmia detection hence, we propose an ECG heartbeat multi-class classification model using MIT-BIH Arrhythmia and PTB Diagnostic ECG signals dataset which contains five categories with 109446 samples. K Nearest Neighbor (KNN) technique is applied to build ECG-HMCM in addition to the using of Gridsearch algorithm for hyperparameter optimization aiming to improve the accuracy of classification which achieved 97.5%. The proposed framework aims to facilitate human life by easily collecting clinical data remotely. The outcomes of the experiments show that the suggested framework works well in a practical setting.

Keywords—Medical healthcare; medical support system; real monitoring; Internet of Things (IoT); ECG signals, Gridsearch; hyperparameter optimization

I. INTRODUCTION

Heart disease and other cardiovascular diseases (CVDs) are among the prominent reasons of mortality in the globe[1]. Corresponding to the World Health Organization (WHO), around 31% of fatalities globally are caused by cardiac disorders[2]. Furthermore, almost a quarter of a million Americans lose their lives each year to heart attacks. Heart disease is difficult for medical professionals and specialists to diagnose since it takes knowledge and experience to do so. Cardiac disorders, which are roughly categorized as various sorts of faulty heart problems, are responsible for about 1 in every 4 fatalities. However, diagnosing CVDs requires human analysis of data from several clinical tests, which takes time.

To give medical professionals faster analysis by lowering the time it takes to get a diagnosis and improving outcomes,

new methods for automating the identification of such anomalies in human heart diseases should be created. Electronic health records (EHRs) [3] are frequently used to find insightful data patterns that enhanced Machine Learning(ML) algorithms' ability to anticipate. ML makes a substantial contribution to the resolution of problems like forecasts in numerous fields, such as healthcare. Doctors and healthcare workers always face different epidemics. They suffer from their infection by these epidemics during their work. Hence, researchers and scientists must support them with new innovative ideas, tools, smart devices, and medical systems aiming to eliminate the increased infection and protect medical staff and patients from these epidemics. Applying ML and DL algorithms for prediction and diagnosing supports many medical branches such as oncology[4], surgery[5], Dentistry [6], Cardiology [7] Fetal Heart Diagnosis [8], diseases classification [9], and remote respiration rate monitoring [10, 11]. To aid in everyday medical inspections, a multifunctional, portable health monitoring device was developed and put into use[12].

Even though most feature-based ML approaches employ Heart rate variability (HRV) analysis to diagnose Electrocardiosignal (ECG), their robustness cannot be assured. Most crucial HRV characteristics are always influenced by unrehearsed variations, breathing, medication interactions, age, and gender. As an outcome, analyzing HRV should not serve as the major pillar for evaluating heart disorders. Most current ECG classification techniques offer accurate classification outcomes that discriminate between CHF and NSR patients. Building an effective automated framework that can correctly differentiate CHF, ARR, and NSR scenarios and operate in real-time with minimal hardware complexity is still quite challenging.

To the extent of our knowledge, all previous works focus on either heart attack detection or ECG classification. This work combines the two objectives in an IoT based framework with a notification system. Additionally, the highest accuracy achieved for heart attack detection is 92.28%. This accuracy is still to be enhanced. This work tries to enhance the accuracy of heart attack detection based on the combination of two different models for building the proposed framework. Therefore, improving heart disease detection models using ML algorithms is essential for spotting heart illness early on. However, using ML technique requires figuring out how the heart failure dataset's characteristics relate to one another. The main contribution of this paper is to:

- Propose a multi-class classification model for heart attack detection.
- Enhance the accuracy of heart attack detection model using ML techniques.
- Propose a classification model for multi-class classification of ECG readings that represent the heartbeat.
- Optimize the finding results of ECG heartbeat signals classification.
- Propose an IoT framework with a notification system to provide suitable alerts or assist in the medical decision support systems and real monitoring for patients.

The rest of the paper is designed to contain the related work in Section II. The material and methods of the proposed models will be presented in Section III. Section IV will discuss implementation and methods. Section V will show the achieved results with discussions. Finally, the conclusion of our proposed paper and the future work will be discussed in Section VI.

II. RELATED WORK

Currently, transforming traditional healthcare services depends on applying models of ML on the clinical and healthcare data. Applying ML techniques in the medicine and healthcare area have proven great results in different specializations such as using medical images for body organs recognition, tumor detection, reconstruction of medical images, lung nodules detection and diseases classification, to name a few[13]. The doctor may monitor the patient's health, wellness, and health using an IoT medical gadget. The history of physiological medical tools and procedures is simple to find. The patient's physiological indicators should be timely monitored to prevent any health issues before they arise[14]. Sensors are adopted with real monitoring systems. This adaptation concerned the user's daily life, which is very simple to enable the collected data to be simply recorded over long hours. Through this means, collected data can be recorded over long hours to produce a huge amount of data. These data need processing and transformations to be more useful when applying Artificial intelligence algorithms. This is for increasing accuracy, decreasing the error rate, or improving computational efficiency to support suitable decisions. The IoT Monitoring system consists of three sections, the network of used medical sensor devices, IoT cloud, and graphical user interface (GUI). Hence, this section will mention some related work in (i) heart attack detection, (ii) ECG heartbeat signal classification.

A. Heart Attack Detection

One of the important techniques of DL is the Convolutional neural network (CNN) which is employed for building applications of image processing. There are many other techniques of DL have common uses[15]. Diagnosing diseases is a very attractive research point. It is the hope for patients to live a more easily life, especially, if it is prevented from being infected with diseases according to analyzing and predicting of patient's data. Using UCI repository and CNN for possible

heart disease prediction[16, 17] supported in the medical decision for patients. In this study [18], a distance-based ensemble for the KNN (k Nearest Neighbor) approach is introduced, and the results of its use in the diagnosis of heart disease are shown. There are two ensemble formations in use. One employs three distances, the previous five. For all the formations and versions, the evaluation was with the Cleveland dataset of UCI heart disease, this ensemble had an accuracy of close to 85%. The dataset for Cleveland heart disease was employed in the suggested study, and data mining algorithms, including regression and classification were applied. Random Forest (RF) and Decision Tree (DT) algorithms are used. Three ML methods are utilized in the proposed implementation: RF, DT, and Hybrid Model (Hybrid of random forest and decision tree). According to experimental findings, the achieved accuracy based on hybrid model was 88.7%. A hybrid model of DT and RF was utilized to forecast heart disease using the user's input response in the interface[19]. One of the most widely utilized ML algorithms, KNN, is frequently used for data categorization. Analyzing each patient's health metrics can also help forecast heart disease. The accuracy of the parameter comparison approach can be improved by combining KNN. The accuracy of the 13 definite parameters obtained by this study, which employs UCI ML dataset, was 86%[20]. Verma et al., for instance, introduced a hybrid model for the prediction of heart illness using particle swarm optimization (PSO) and ML classifiers, namely K-nearest neighbor and multi-layer perceptron (MLP), which reached a 90.28% accuracy [21]. Five ML algorithms were used by Alotaibi et al.[22] (LR, RF, Naive Bayes, DT, SVM). Rapid Miner is utilized for implementation, and it produces good results when compared to prior studies. 1013 patient records from the Cleveland dataset (UCI) were employed. Shah et al.[23]'s efficient model applies KNN, DT, RF, and Naive Bayes while utilizing just 14 key features from the Cleveland dataset from UC Irvine. The best outcome is produced by KNN among these algorithms. Another cardiac disease detection model was created by Jindal et al.[24]. To build a model, RF, LR, and KNN algorithms are applied. Of RD and LR, KNN provides the best accuracy.

B. ECG Heartbeat Signal Classification

The gold specification for noninvasive diagnosis of several forms of cardiac problems is the ECG. When identifying CVDs, the ECG signal is quite important. We can learn about the heartbeat from the ECG readings. Cardiac arrhythmia can be found using ECGs. ECG is a non-invasive diagnostic that measures the electrical activity of the heart muscles to evaluate heart function. Since it gives cardiologists all the information they need regarding heart problems, ECG serves as an effective tool for detecting a variety of cardiac illnesses. Yet, a critical factor in increasing treatment options and slowing the course of CHF is early diagnosed of the condition. The arrhythmia is a significant cardiac condition that contributes to several instances of sudden death (ARR). ARR stands for aberrant heart rhythm, which is a result of erratic heart rate. The provision of quality care necessitates accurate patient diagnosis as well as the identification of appropriate treatments while avoiding incorrect diagnoses. Early CVD identification also lowers costs and decreases CVD mortality. A classification method, which is crucial in clinical research, may be used to do

the task effectively and inexpensively with data mining approaches.

ECG data is made up of a collection of electrical impulses from the heart that are collected, and it may be used to spot several different cardiac disorders including arrhythmias, coronary artery disease, and cardiomyopathies. One of the most crucial techniques for assessing the general condition of the heart is heart rate variability (HRV). It shows how flexible the cardiac system is to changes in internal and external stimuli. The fluctuation in the interval between successive heartbeats is called a HRV time series (RR intervals) [25]. Congestive heart failure (CHF) is a dangerous cardiac condition that significantly raises death rates across the world. With CHF, the heart can no longer pump blood across the body efficiently enough to meet tissue demands for oxygen and metabolism. CHF affects more than 26 million individuals worldwide, with 3.6 million new cases added each year[26].

Robustness, efficiency and accuracy of applying ML/ DL techniques in healthcare encourage researchers to keep going to improve and enhance the used methodologies in medical systems, such as the proposed DL Modified Neural Network (DLMNN) to support in medication, particularly in heart diseases diagnosing by using a wearable IoT sensor device, then saving these normal and abnormal signals on cloud [27]. The information gained on this job can be used to the myocardial infarction (MI) classification challenge, according to a recommended strategy. On the MIT-BIH and PTB diagnostics datasets from PhysionNet, the proposed methodology is assessed. The findings show that the proposed technique can predict arrhythmia classification with average accuracies of 93.4% and 95.9%, respectively[28]. This paper [29] suggested an enhanced ResNet-18 model for ECG heartbeat signals classification of based on a convolutional neural network (CNN) method through suitable model training and parameter tuning. The model's distinct residual structure allows for the deepening of CNN layered structure to improve classification performance. The MIT-BIH arrhythmia database application findings show that the suggested model attains greater accuracy (96.50%). The suggested technique[30] is tested on the benchmark MIT-BIH arrhythmia database before being prototyped on a commercially accessible ARM-based embedded device. Moreover, the prototype is assessed using two schemes, namely class and customized schemes, and both schemes indicated greater overall accuracy for state-of-the-art CVDs diagnosis than the current works, at 96.29% and 96.08%, respectively.

III. MATERIAL AND METHODS

In this section, the steps of the proposed framework will be discussed as a preview architecture to facilitate decision making for doctors and remotely support patients with medical decisions. Our proposed architecture aims to achieve a more compatible framework to follow up the patient using IoT components. The framework phases can be listed as the following:

Collecting Data phase: depending on the selected IoT sensor for gathering the patient's medical, then start the phase of gathering data.

Data Preparation and cleaning: data processing, this step is responsible for raw data changing to be more useful.

Model selection: according to the issue and collected data, the algorithm should be implemented.

Train the model: using Artificial Intelligence Algorithms to enhance the accuracy of the prediction or decision making.

Model Evaluation: evaluating the proposed model and comparing it with others.

Notification system: when using the proposed system, and abnormality of signals appear then the family and doctors receive alerts about the case to take a right decision.

Even though most feature-based ML approaches employ HRV analysis to diagnose ECGs, their robustness cannot be guaranteed. Most crucial HRV characteristics are always influenced by unrehearsed variations, breathing, medication interactions, age, and gender. As a result, analyzing HRV should not serve as the major pillar for evaluating heart disorders. By creating novel diagnostic procedures for heart disorders, these difficulties can be eliminated.

The proposed framework consists of several phases such as cleaning data, storage of data, analysis data, implementing models, and notification system. Fig. 1 shows the basis of the proposed framework which oversees gathering physical data from the human body's surface and transmitting it wirelessly to the IoT cloud. Then, the signals are put through a variety of steps to increase their quality and make them suitable for wireless transmission, such as amplification, filtering, etc. Typically, a smart terminal (for example: a smartphone or computer) is required to receive the data before transmitting it wirelessly to the IoT cloud. After making data processing, artificial intelligence algorithms applied to predict if there will be any issue. If it exists, the monitoring system sends alarm to the connected computer or smart phone. As the foundation of diagnosing cardiovascular illness is arrhythmia detection, we propose this framework which consists of two different models: (i) Heart attack detection and (ii) ECG heartbeat signals classification.

A. The Heart Attack Detection Model (HADM)

A heart attack, also identified as a myocardial infarction, happens when a part of the heart muscle is not receiving enough blood, according to the center of disease control, and prevention (CDC). Hence, with the help of the dataset's variables, we will create a model to forecast the chance of a heart attack. ML techniques can be highly helpful in the early detection and treatment of patients with cardiovascular disease or who are at high cardiovascular risk beneficial (due to the presence of one or more risk factors, including hypertension [31], diabetes, hyperlipidemia [32], or previously existing illness).

Some of the preparation steps were executed such as dropping duplicates, Outlier Detection, Features encoding such as Binary features encoding and One-hot encoding were applied on the used dataset. Dividing dataset into training and testing datasets is executed for building and evaluating the HADM.

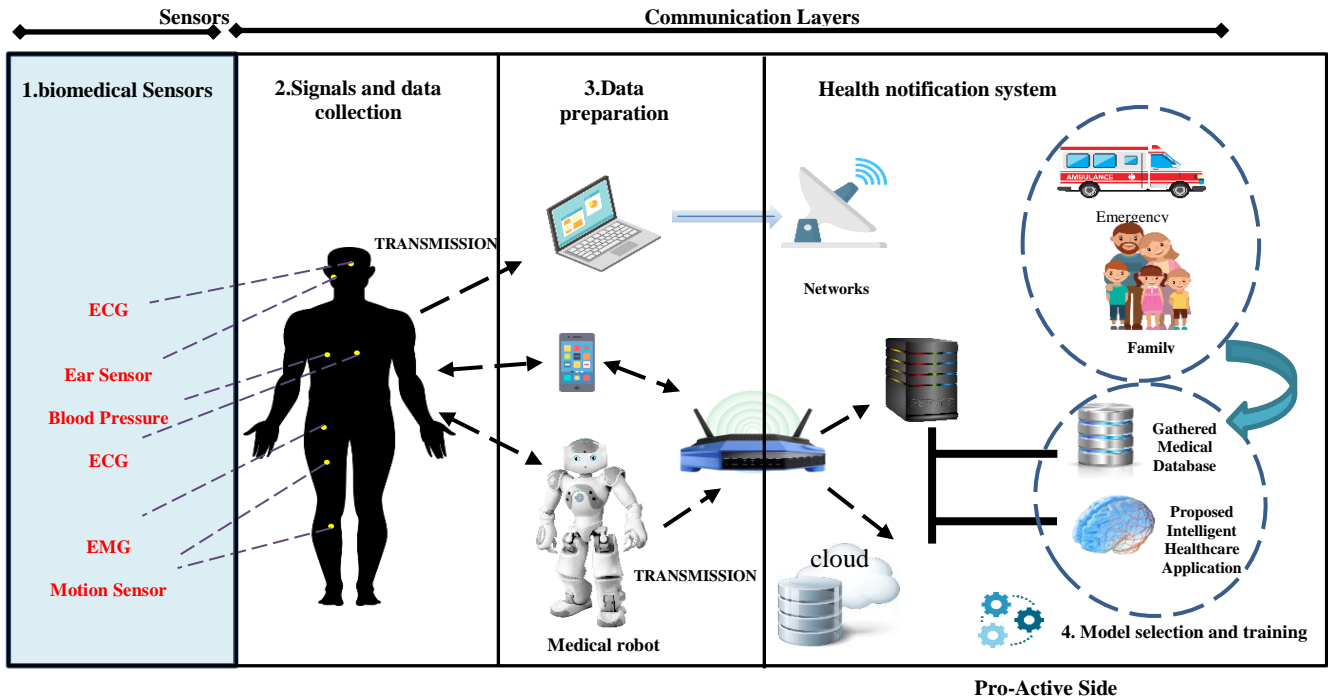

Fig. 1. Proposed framework phases to enhance the performance of the medical system based on the IoT sensors.

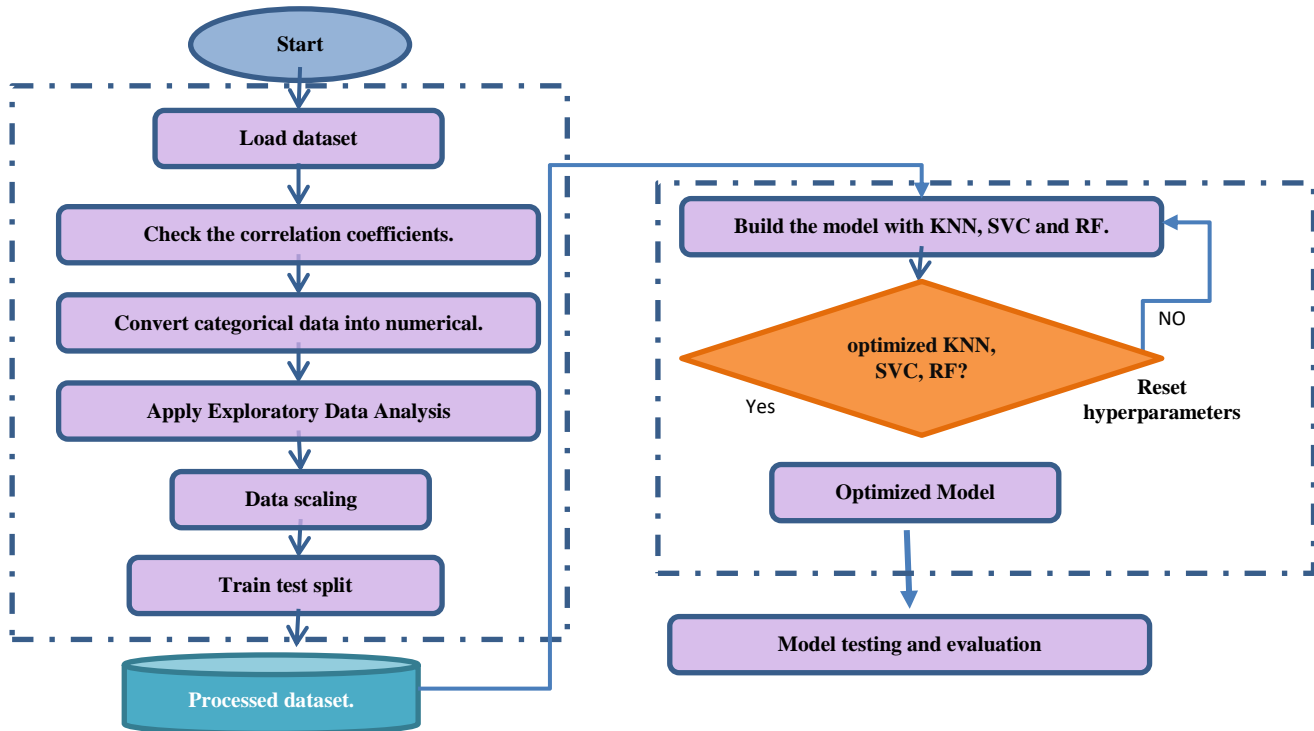

Fig. 2. Flowchart of the proposed Heart Attack Detection Model (HADM).

The proposed model depends on using the K Nearest Neighbors algorithm, support vector machine classifier (SVM) and random forest (RF) to determine whether cardiac disease is present or not. In Fig. 2, the HADM flowchart will be shown. Gridsearch technique is used for hyperparameters optimization. These parameters might be a continuous variable, a categorical variable, or an integer with values spanning from the lower to

upper bounds. As hyperparameters remain constant throughout training, the model's accuracy is increased while training time and memory requirements are concurrently decreased. Different models employ a variety of hyperparameters depending on the issue description. There are no hyperparameters that are optimal for all models.

B. ECG Heartbeat Signals Multi-class Classification Model (ECG- HMCM)

A rigorous and consistent examination by cardiologists is required, which is difficult and time-consuming, to give an effective and precise diagnosis of ARR and CHF. For the proper detection of cardiac disorders, a completely automated diagnosis system is urgently required. The creation of diagnostic systems can help cardiologists diagnose ECG recordings quickly and accurately while also cutting down on the time and money needed for clinical interpretation. The heartbeat classification dataset from the MITBIH is used in this suggested model. Up sampling is done such that there is the same number of instances in each of the five classes, each of which has a different number of samples. The KNN model is trained on the data once it has been divided into training and testing set. The test data is run through the trained model. Individual successfully and erroneously categorized signals are examined in terms of correlation to the class mean as well as plotted to examine explainability. Here, we looked at whether such affordable and straightforward algorithms may be useful enough for clinical usage and pave the way to better services. The model architecture will be shown in Fig. 3. The steps of applying the proposed model will be summarized in the next algorithm.

The proposed algorithm for ECG heartbeat multi-class classification model
<i>Step 1) load the data set,</i>
<i>Step 2) define classes,</i>
<i>Step 3) assign a data frame to each class,</i>
<i>Step 4) extract shape of the training and test sets, Upsample the minority classes.</i>
<i>Step 5) split original training data into a training and test subset (test_size =0.2)</i>
<i>Step 6) apply KNN algorithm on the dataset.</i>
<i>Step 7) attributes are ranked according to their value.</i>
<i>Step 8) apply (Grid search) for hyperparameters optimization.</i>
<i>Step 9) estimate the classifier's accuracy, which measures the capability of the classifier to classify heartbeat ECG signals correctly.</i>

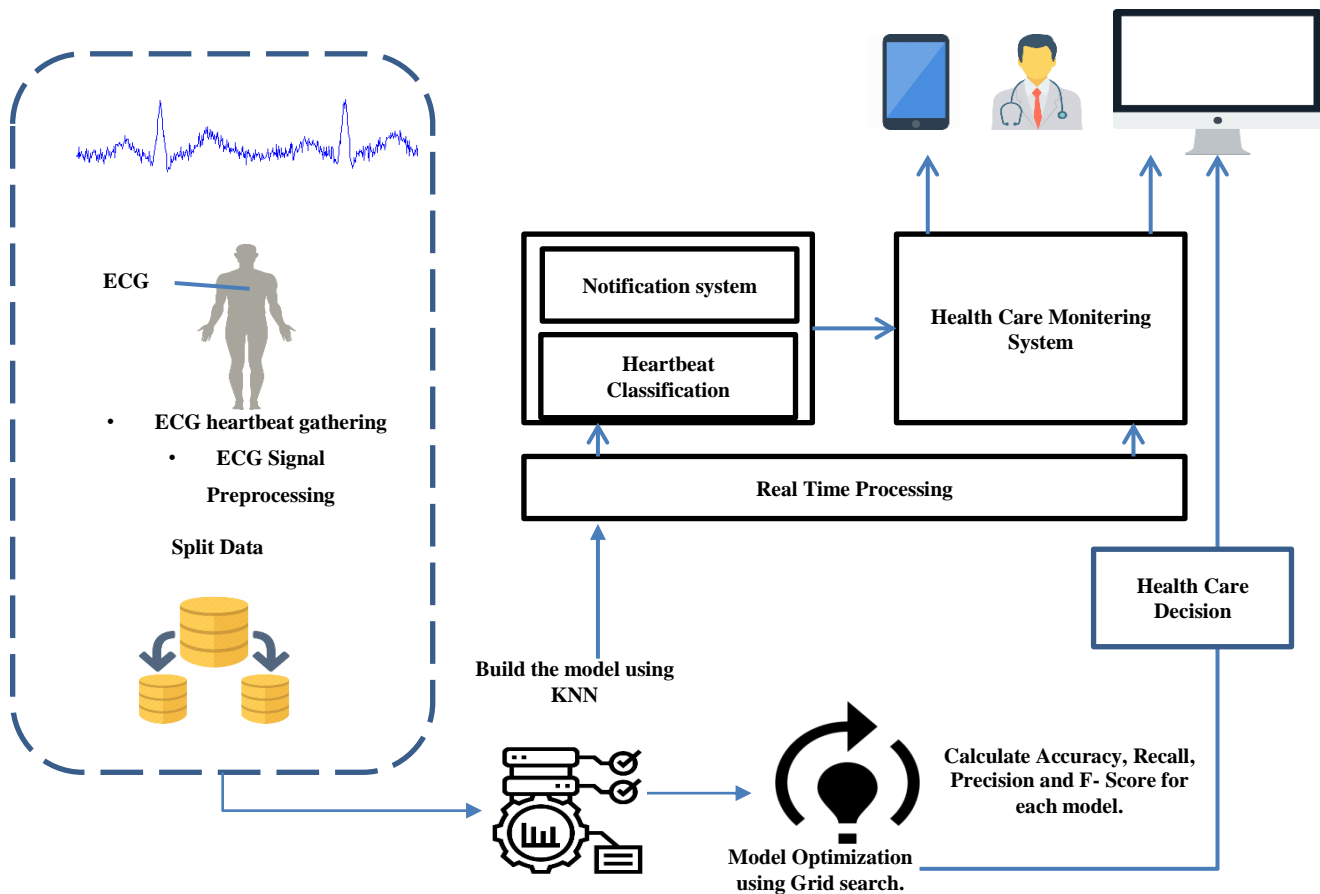

Fig. 3. ECG heartbeat multi-class classification model architecture.

IV. IMPLEMENTATION AND METHODS

In this section, the experiments of the proposed framework will be discussed which are divided into (i) heart attack detection, and (ii) ECG heartbeat signals classification, in addition to the description of the used datasets for both models.

To support the implementation of our suggested modal, our experiments were implemented in Python notebook version (6.4.8) and several open-source libraries. This system makes use of the packages Matplotlib, NumPy, sklearn, and Keras. It was carried out a laptop with a 2.30GHz, 11th-generation Intel Core (TM) i7-11800H processor, and 16.0 GB (15.8 GB usable).

A. Heart Attack Detection Model (HADDM)

The heart is a vital organ in humans. It sends blood to all the organs in our body. If it malfunctions, the body's other organs will stop working and the person will pass away in a matter of seconds. Several different things can lead to heart failure. These components have been split up by scientists into two categories: risk variables that cannot be changed and risk factors that can be. Historical Family data [33], gender, and age are risk aspects that cannot be changed. Excessive cholesterol, smoking [34], inactivity, and blood pressure are risk factors.

The heart attack detection model depends on ML algorithms, namely, KNN, SVM and RF. The KNN algorithm is distinguished by its straightforward design and practical use. KNN was selected because it can compete with the most accurate models and offers incredibly exact predictions. How accurate the forecasts are determined by the distance. KNN technique can be used in applications that demand great accuracy as a result. The SVM algorithm was also selected to participate in our classification model because of its mathematical base in statistical learning theory which provides a systematic solution to ML challenges. A portion of the training input is used to create the solution via SVM. Classification, regression, novelty detection, and feature reduction problems have all seen widespread usage of SVM.

Random forest classifier is also used to build our model. A method for lowering the variance of an estimated prediction function is RF. Regression and classification are also possible uses for RF. A random forest collects class votes from each tree before classifying using a majority vote when used for classification. The predictions from each tree at the target point x are simply summed when used for regression. When used for classification tasks, RF gets a class vote for each tree and then classifies the data using the results of the majority vote. The predictions from all trees at a target point x are merely averaged when RF is used to regression problems. The values of the parameters that are most appropriate for a job rely on those parameters, which are understood and employed as tuning parameters. Then, Gridsearch is separately applied to each technique to get optimized hyperparameters. To assess the intensity of the key elements that influence the prognosis of heart disease, a generalized algorithm was developed and optimized. Cleveland, Hungary, Switzerland, Long Beach and Stalog (CHSLBS) datasets were used to assess the models. The selected ML algorithms were used to build the proposed models for classification. Also, we will use grid search for

tuning models' hyperparameters, additionally we will evaluate their performance.

1) *The used dataset:* The original source for this dataset was the [35]. The dataset variables are mentioned in [35]. By combining multiple datasets that were previously available separately, one dataset was created. This dataset, which includes five heart datasets including eleven features in public, is the greatest heart disease dataset currently available for research objectives. The five datasets utilized for its curation are: Cleveland: 303 observations; Hungarian: 294 observations; Switzerland: 123 observations; Long Beach VA: 200 observations; and 270 observations in the Stalog (Heart) (CHSLBS) datasets. The total number of observations is 1190, but we found 272 duplicated rows. Hence, the preprocessing step is to drop this duplication to finally get 918 rows. Analyzing CHSLBS shows that there are 508 with heart disease and 410 normal cases. This leads us to have a balanced dataset. It was found that the presence of HeartDisease is substantially linked with all numerical characteristics. Hence, we will first get dummies for categorical characteristics. In our experiment, some dataset analysis has been extracted such as maximum, minimum, average, and median to determine whether the data indicate a skewness distribution. Each of these traits is looked at individually because they all have different units and meanings.

The used dataset [35] contains different attributes. Sex, FastingBs and Exercise angina are binary data. Chest Pain type, Resting ECG and ST_slope are categorical data, and the continuous set consists of Age, Resting blood pressure, cholesterol, MaxHR and old peak. Some of preparations steps were executed such as dropping duplicates, Outlier Detection, Features encoding such as Binary features encoding and One-hot encoding were applied on the used dataset. 4.58% of instances that are outliers in resting blood pressure (restingBP) were removed. Since characteristics like cholesterol and resting blood pressure are exceptional situations that do not accurately reflect the state of the general population and are not suitable for training our model of predictions, preprocessing is necessary.

Exploratory Data Analysis EDA [36] seeks to condense descriptions to make them easier to process with the cognitive capacity at hand; and tries to make the description more effective by looking behind the previously mentioned surfaces. The used dataset needs some steps of preprocessing and exploratory data analysis. First, we investigate the correlations between the patient's numerical characteristics and the target column. It was found that the presence of cardiac disease is closely associated with all numerical characteristics. Then, the categorical data is handled to be numerical.

The distribution analysis is a graphical representation of a dataset's distribution that displays the frequency of data points within various intervals. The histogram for distribution analysis of the features is a common graphing technique used to include both continuous and discrete data that was collected on an interval scale. It is widely used to conveniently illustrate the main ideas of data distribution. The conclusion after

applying EDA on the used dataset shows the following information: the risk of suffering CVDs increases with age. Fig. 4 shows the histogram for distribution analysis of some features such as age, oldpeak, resting Blood Pressure, and cholesterol.

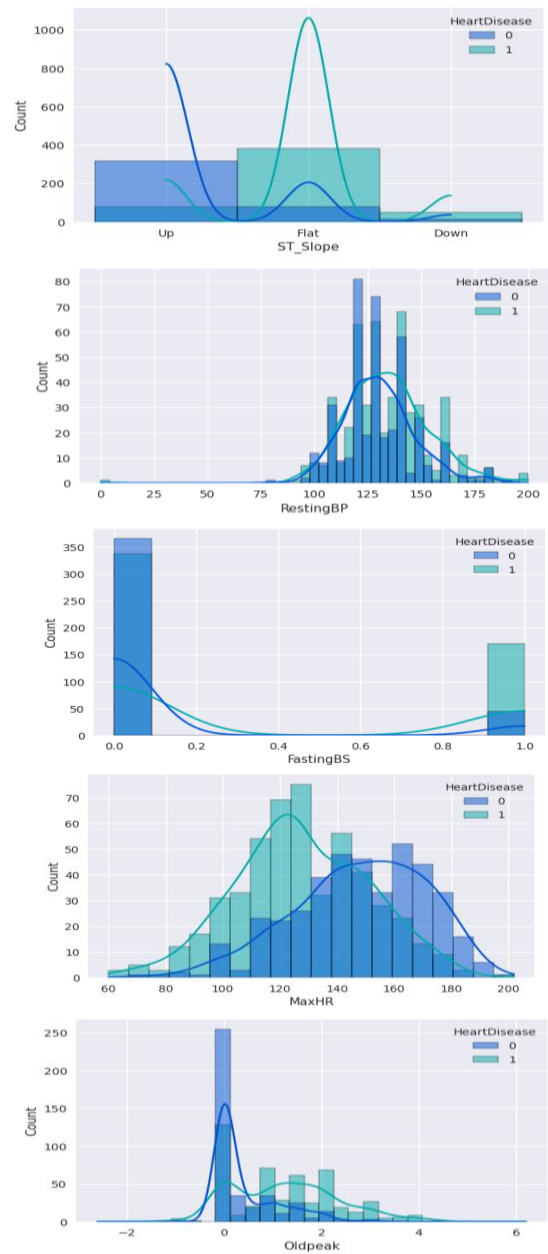

Fig. 4. Distribution analysis of some dataset features.

Apparently, the men have a major risk than women of suffering CVDs. Most cases of CVDs present absence of chest pain or the usual anginal equivalents followed by the cases that present chest pain non-anginal. We also see in this histogram a slight increase in CVDs cases when increasing the resting blood pressure. Fig. 5 will show the histogram for distribution analysis according to Age and oldpeak. Fig. 6 shows the correlation between dataset features.

Fig. 5. The histogram for distribution analysis according to Age, oldpeak.

Fig. 6. The correlation between dataset variables.

B. ECG Heartbeat Signal Multi-class Classification

A default KNN model is trained on the data once it has been divided into a training and testing set. The test data is run through the trained model. Individual successfully and erroneously categorized signals are examined in terms of correlation to the class mean as well as plotted to examine explainability. Gridsearch algorithm is used to get the optimized k-parameter, then the model is retrained on the original test set by achieving an enhancement of accuracy.

1) *The used datasets:* Two collections of the signals of heartbeat that add up to this dataset are derived from two well-known datasets in classification of heartbeat, the MIT-BIH Arrhythmia Dataset [37] and The PTB diagnostic ECG database [38]. The MITBIH heartbeat dataset categorization is the subject of this experiment. The dataset contains five classes with these labels (i) normal beat ('N'): 0, (ii) supraventricular ectopic beats ('S'): 1, (iii) ventricular ectopic beats ('V'): 2, (iv) fusion Beats ('F'): 3, (v) unknown Beats ('Q'): 4. Upsampling is done such that there are the same number of instances in each of the five classes, each of which has a various number of

samples. Both sets provide a large enough number of samples to support deep neural network training. This dataset has been used to research the classification of heartbeats and to investigate some of the transfer learning possibilities using deep neural network architecture. The signals correspond to the ECG types of heartbeats for both the normal case and cases affected by different arrhythmias and myocardial infarction. These signals are preprocessed and divided into segments, each of which represents a heartbeat. Arrhythmia Dataset consists of five categories which are labeled to be ['N': 0, 'S': 1, 'V': 2, 'F': 3, 'Q': 4] with 109446 samples, the sampling frequency is 125HZ and the source is from Data Source: Physionet's MIT-BIH Arrhythmia Dataset. The PTB Diagnostic ECG dataset contains two categories with 14552 samples and the source of data is from Physionet's PTB Diagnostic dataset.

C. Evaluation Matrix

This section presents the results of the proposed models and evaluates their performance using AUC. The AUC has been chosen according to the providing equations[39]. Eq. (1) - (5) described the evaluation way of the proposed models. Precision, recall or sensitivity, f1-score, and other model performance indicators were also assessed, in addition to accuracy. To evaluate the model's performance, the true positive, true negative, false positive, and false negative values must first be established. When the model correctly identified positive and negative predictions, they are referred to as true positive and negative values. False positives and negatives, on the other hand, occur when the model incorrectly divides positive and negative predictions into positive and negative categories.

Accuracy:

$$Accuracy = \frac{True\ Negative + True\ Positive}{Total\ Data} \quad (1)$$

Precision:

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (2)$$

Recall:

$$Recall\ (Sensitivity) = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (3)$$

Specificity:

$$Specificity = \frac{True\ Negative}{True\ Negative + False\ Positive} \quad (4)$$

F1 score:

$$F1 = \frac{2 \times Precision \times recall}{Precision + recall} \quad (5)$$

D. Model Optimization

Hyperparameters are peripheral parameters[40] that are not a model component and cannot be predicted from the dataset. For classification challenges, a user must manage the hyperparameters setting procedure, which varies for various algorithms and datasets, to obtain high accuracy. Finding a tuple that suggests an ultimate model and minimizes the loss function is the goal of optimization [41]. A Gridsearch algorithm was used to optimize the hyperparameters for the

experimental classification model when developing HADM using KNN, SVC and RF classification techniques. Table I lists the top hyperparameters for each used technique.

TABLE I. THE OPTIMIZED HYPERPARAMETERS FOR THE USED TECHNIQUES

Technique	Best hyperparameters
KNN	'n_neighbors': 9, 'p': 2, 'weights': 'distance'
SVC	'C': 1.0, 'gamma': 'auto', 'kernel': 'sigmoid'
RF	'criterion': 'gini', 'max_features': 30, 'n_estimators': 700,

V. RESULTS AND DISCUSSIONS

This evaluation section consists of (i) heart attack detection model, (ii) ECG heartbeat signal multi-class classification to be proposed models that can early support with an appropriate decision for saving patients.

A. Heart Attack Detection Results

The heart attack detection model depends on the use of KNN, SVC and RF classifiers achieved the best accuracy compared with another previous research when applied on the greatest heart disease dataset which consists of five datasets with 1190 observations formed (CHSLBS) datasets. During the execution of the experiments, Gridsearch is applied to optimize the hyperparameters for achieving higher accuracy. Area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity were among the results that were reported. AUC curves will be shown in Fig. 7 for KNN, SVC and RF. Table II shows the summarized results for building the model of Heart Attack Detection.

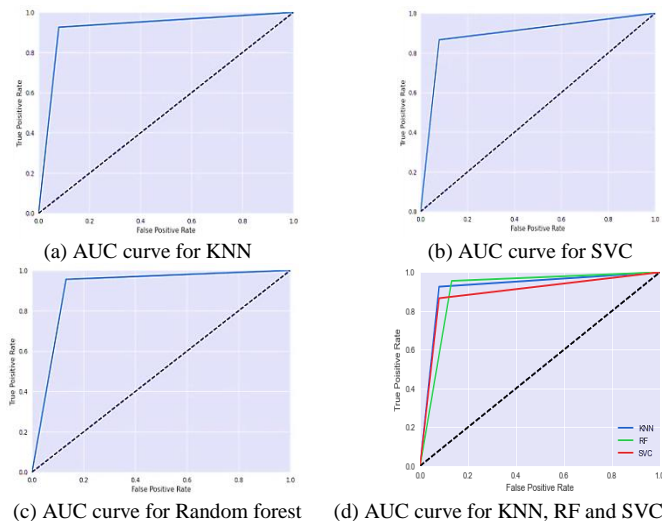

Fig. 7. The dataset’s AUC curve for test data using the proposed models.

TABLE II. THE EVALUATION OF HEART ATTACK DETECTION MODEL USING THE EVALUATION MATRIX

Technique	K-Nearest Neighbors	C-Support Vector	Random Forest
Accuracy	92.307692	89.510490	90.909091
Precision	91.176471	90.625000	86.486486
Recall	92.537313	86.567164	95.522388
f1- score	92.310711	89.491892	90.915316

We must find a balance between recall score and accuracy score; in the case of our focus, the Random Forest classifier had the greatest recall score, but also the poorest precision score. Hence, the KNN classifier is the best algorithm in this experiment. This study demonstrates that the RF classifier outperforms other classification algorithms when employing Gridsearch for hyperparameters optimization [40] and evaluating depending on the recall evaluation matrix parameter. KNN achieved higher accuracy compared with random forest and support vector classifier algorithms. Table III shows comparison between the result of our proposed result and other used techniques.

TABLE III. COMPARISON OF ACHIEVED RESULTS AND PREVIOUS RESEARCH

References	Year	The used technique	Accuracy
Saqlain, et al. [42]	2019	SVM and MCC	81.91%
Beunza, et al. [43]	2019	NB, BN, RF, and MP	85.48%
Kavitha, et al.[19]	2020	Hybrid DT and RF	88%
Kavitha, et al.[44]	2021	KNN with SBS feature selection	90%
Pawlovsky, et al. [18]	2022	KNN	85%
Anderies, et al. [20]	2022	KNN	86%
Chauhan, et al. [21]	2023	PSO, KNN	90.28%
The proposed model	2023	KNN, SVC and RF	92.31%, 89.51%, 90.91%

B. ECG Heartbeat Monitoring Results

In this model, KNN is used for classifying the ECG heartbeat for patient monitoring as a proposed solution to assist in the decision-making support health system. The achieved results were optimized according to using the grid search optimizer. The model is instantiated and performed depending on the use of a grid search for setting the number of neighbors (the k parameter value) fitting five folds for each of five candidates, for a total of 25 fits, for the first 40,000 shuffled training data. In Fig. 8, the preview of 5 ECG beats from the five categories will be shown when using the training dataset.

The finding results have been enhanced 0.5 % after using the grid search hyperparameter optimization and 97.5% Overall classification accuracy. Fig. 9 will preview the signals for the correct prediction according to our proposed model when applied on the test set.

This shows how the suggested approach might help cardiologists improve the precision of ECG diagnosis in real-time clinical situations.

Fig. 8. Previewing 1 beat ECG from each category.

Fig. 9. Sample of correct predicted signal.

The proposed model has some advantages over previous works. The model combines heart rate detection and ECG classification in one IoT based framework with a notification system. The model also enhanced the accuracy of heart attack detection over most previous works. It is anticipated that the created method would make it much easier for doctors to diagnose heart issues in a more practical way. Above all, the study has significantly improved the computation of strength ratings, which are excellent indicators of the prognosis of heart conditions depending on the proposed framework.

VI. CONCLUSIONS AND FUTURE WORK

The leading cause of death is heart disease. Heart disease mortality will decrease because of the identification of key risk factors, the creation of decision support systems, effective control methods, and health education initiatives. If CVDs are detected and treated early, many lives might be saved. Cardiologists cannot manually examine the vast quantity of collected data for a patient to develop a timely medication plan. One of the most widely utilized ML algorithms, KNN, SVM and RF are frequently used for data categorization in our proposed model. The five datasets utilized for its curation are: Cleveland: 303 observations; Hungarian: 294 observations; Switzerland: 123 observations; Long Beach VA: 200 observations; and 270 observations in the Stalog (Heart) (CHSLBS) datasets. The total number of observations is 1190 and the achieved accuracy were 92.3%, 89.51% and 90.91% when applying KNN, SVM classifier and RF recursively with hyperparameters optimization using Gridsearch technique. Analyzing each patient's health metrics can also help to forecast heart disease. Hence, KNN is used for heart attack detection using UCI dataset, in addition to using KNN to build an ECG heartbeat multi class classification model. Two heartbeat signals were examined and evaluated in this study. The Arrhythmia and PTB diagnostic ECG datasets, both of which have 125 Hz sampling rates, each comprise 109446 samples in five categories and 14552 samples in two categories. Using two ECG datasets, the KNN methodology with the hyperparameters optimizer employing Gridsearch algorithm was applied, and higher accuracy has been achieved when compared with previous recent research in this field was attained. The results of this model have been optimized using grid search for hyperparameters optimization. The major goals of the proposed framework are to provide a method that can effectively identify heart attacks and help professionals to choose the best decision for saving human life. In future work, other different ML techniques can be used. By adding more data and testing with more important or statistically produced

data, such as numeric data augmentation, the applicable procedure may be enhanced. The writers see this as a future work that may be improved.

Abstract—Renewable energy is becoming a trusted power source. Energy forecasting is an important research field, which is used to provide information about the future power generation of renewable energy plants. Energy forecasting helps to safely manage the power grid by minimizing the operational cost of energy production. Recent advances in energy forecasting based on deep learning techniques have shown great success but the achieved results still too far from the target results. Ordinary deep learning models have been used for time series processing. In this paper, a complex-valued autoencoder was coupled with an LSTM neural network for solar energy forecasting. The complex-valued autoencoder was used to process the time series with the advantage of processing more complex data with more input arguments. The energy value was used as a real value and the weather condition was considered as the imaginary value. Taking into account the weather condition helps to better predict power generation. The proposed approach was evaluated on the Fingrid open data dataset. The mean absolute error (MAE), root-mean-square error (RMSE) and mean absolute percentage error (MAPE) was used to evaluate the performance of the proposed method. A comparison study was performed to prove the efficiency of the proposed approach. Reported results have shown the efficiency of the proposed approach.

Keywords—Solar energy forecasting; artificial intelligence; complex-valued autoencoder; long-short term memory; deep learning

I. INTRODUCTION

Modern cities have elevated the power demand and fuel-based energy sources are polluting the globe. Renewable energy has been considered as a solution to provide power needs while reducing pollution and power production costs. Sun, wind, and water are natural clean power sources that can be considered trusted sources, but their power production was based on weather conditions. Recently, the energy produced by clean resources was integrated into the power grid. The main concern of those sources is that the generated power cannot be controlled and varies with weather conditions. Integrating clean power into the grid is a very challenging task because of the variability of the generated energy amount.

Solar power is a clean energy source that converts daylight to electricity. The main issue of this type of energy generator is that the amount of generated power is unpredictable. Generated solar power must be consumed at the same time of production because of the volatility of this energy. However, overload power causes many problems such as voltage regulation and reverse power flow. Besides, low power can cause

discontinuity and can affect all devices connected to the grid. Subsequently, for the safe integration of the solar power generator into the grid, it is important to predict the grid power need and integrate the solar power at its stable generation period to benefit from it the maximum possible. A high-performance energy forecasting system can help to solve the problem. Mainly there are two energy forecasting systems, physical models and artificial intelligence models. Physical models are based only on whether conditions generate a forecast based on wind speed or solar power curves based on light availability. Those models were not very accurate because many other conditions must be taken into account such as solar panels' conditions and temperature. However, artificial intelligence models have been efficiently and flexibly used for energy forecasting. Those models do not need to explicitly scale the physical process of power generation. In effect, it builds a relationship between the input and output through processing data and reducing the error with the target values.

Energy forecasting has been widely studied to manage energy production costs by predicting clean power generation. Many averaging techniques were deployed for energy forecasting such as Autoregressive Integrated Moving Average (ARIMA) [1], simple moving average (SMA) [2], and weighted moving average (WMA) [3]. The averaging techniques have achieved low performance and the predicted results were different from the expected. Methods such as simple exponential smoothing (SES) [4] were used for forecasting but the achieved results were not convincing.

Recently, the deep learning technique [5] has achieved great success in many applications. Deep learning techniques are based on deep neural networks. Convolutional neural networks [6], recurrent neural networks [7], and auto-encoder [8] were the most used deep learning models. The mentioned deep learning models have boosted the performance of many applications such as object detection [9, 31], indoor object detection [10, 29], face mask detection [11], pedestrian detection [12], traffic signs detection [30], time series forecasting [13], and many others. The outcomes demonstrated the effectiveness of deep learning models for solving many problems and can be used to solve more problems. The ability of automatically learning features without any handcrafted engineer features has been very effective. Besides, such models mimic the biological brain's decision-making process. Considered to solve renewable energy forecasting using deep learning models. Energy forecasting is based on analyzing historical time-series records. Similar to economic time series

forecasting [14], renewable energy forecasting needs deep learning models with memory such as recurrent neural networks. For better performance, we proposed to use an autoencoder to denoise and better represent the input data. Then, a long-short-term memory network was used to process the temporal information of the data for power prediction. The proposed autoencoder is a complex-valued autoencoder with real and imaginary outputs. The energy value was used as real input and the weather condition was used as an imaginary value. Combining the energy value with the weather condition helps to learn more relevant features and generate more trusted predictions.

The proposed method's key benefit is that it may be customized for various forecasting categories based on the horizon range such as short, middle, and long-range forecasting. The proposed method can apply for data forecasting for hours, days, or months. This advantage makes the model useful for many cases and not designed for a specific case.

The main contribution of this paper is the following: (1) proposing a solar power forecasting system; (2) proposing the use of a complex-valued autoencoder for data denoising and features clustering; (3) combining the complex-valued autoencoder with an LSTM neural network to process time-series data for energy forecasting; (4) validate the proposed approach on the open solar dataset.

The paper is organized as follows: Section II presents related works. The proposed approach is described and detailed in Section III. In Section IV, the experiment and results are presented and discussed. The paper was concluded in Section V.

II. RELATED WORKS

The application of renewable energy forecasting for grid management and cost reduction makes it a significant study area. Many works have been proposed for achieving trusted predictions. For a complete overview of existing works, the readers can refer to the survey presented in [15]. Energy forecasting techniques can be categorized based on the base model. The first category is based on averaging techniques and the second category is based on deep learning techniques. In this paper, we have focused on deep learning techniques.

Abedinia et al. [16] proposed a solar energy forecasting method based on neural networks combined with the metaheuristic algorithm. The metaheuristic algorithm was used to optimize the forecasting parameters. The neural network was composed of an input layer, 3 hidden layers, and output layers to generate a prediction. The Levenberg-Marquardt algorithm [17] was used to train the suggested neural network. The Levenberg-Marquardt presents a combination between the gradient descent algorithm [18] and the Newton technique [19]. After training the neural networks, the optimized weights were optimized using the metaheuristic algorithm based on the improved shark smell optimization (ISSO) technique. The proposed method was evaluated in a real solar energy production case.

In [20], a photovoltaic power forecasting model is based on the combination of the stationary wavelet transform, an LSTM

network, and a deep neural network. First, the stationary wavelet transformation was used to fix the high fluctuation and the non-stationary behavior of the input data. The stationary wavelet transformation allows the transformation of the original photovoltaic power data to wavelets which makes the data processible and manageable. Second, an ensemble of four LSTM networks was used to extract temporal features of the input data. The extracted features were reconstructed using the inverse stationary wavelet transformation. Third, statistical features were extracted from the input data by calculating many features such as the Mean, Standard Deviation, Variance, Skewness, and Kurtosis. The statistical features, the reconstructed data from the LSTM network ensemble, and the temperature data were combined and used to train the deep neural network to generate power prediction. The proposed method was evaluated for horizon forecasting but it can be adapted for multi-step forecasting based on the resolution of the available input data.

A solar energy forecasting method was proposed in [21] based on combining the LSTM network with a convolutional neural network. The LSTM network was first used for temporal features extraction and the convolutional neural network was then used for the extraction of the spatial features. Experimental results have shown that extracting temporal features and then extracting spatial features is more effective than extracting spatial features and then extracting temporal features. The proposed model was compared to existing models based on a single network either Convolutional Neural Network or LSTM network and presented superior performance.

Lin et al. [22] proposed the use of a temporal convolutional neural network for solar energy forecasting. The temporal convolutional neural network is an improved convolutional neural network used for temporal data processing. It is composed of a combination of regular convolution layers, dilated convolution layers [23], and residual connection [24]. A temporal convolutional neural network has a hierarchical architecture with several hidden layers that have the same size as the input layer. This type of convolutional neural network was designed for autoregressive prediction with a long memory. The proposed method proved its efficiency compared to regular neural networks such as multi-layer feedforward neural network, LSTM neural network, and GRU neural network.

The majority of the aforementioned techniques are intended for processing historical data for energy power forecasting. Generally, solar energy production is not stationary and not predictable and it is challenging to process it. In this work, we propose to use the weather condition as additional input data to generate more trusted predictions.

III. PROPOSED METHOD

We outline the suggested strategy for solar energy forecasting in this section, which combines a complex-valued autoencoder and an LSTM neural network. In the first subsection, the complex-valued autoencoder will be detailed. In the second subsection, the background of the LSTM neural network will be presented and detailed. The last subsection will

be reserved for explaining the proposed method for solar energy forecasting.

A. Complex Valued Autoencoder

Complex valued autoencoders are the same as autoencoders but with an input, weights, and a mapping function in the complex space. A complex space variable has two parts, one of which is imaginary, and a real part. Assuming a variable x , real part a , and the imaginary b . An example of complex variable can be represented as Eq. (1).

$$x = a + jb \quad (1)$$

Variables in the complex space have more information. A complex-valued autoencoder can be used to process more complex data without raising the computational complexity of the model. Generally, an autoencoder consists of an input layer, a hidden layer, and an output layer. It is used for data reconstruction by regenerating the input data in the output with a minimum error. A complex-valued autoencoder takes as input a real value Re and an imaginary value Im . A combination function is used; C was used to both values to generate the input of the autoencoder. Fig. 1 presented the structure of a complex-valued autoencoder. The autoencoder has two main processes, the encoding process, and the decoding process. The encoding process compresses the data through the hidden layer. The decoding process explodes the data size to reconstruct the input data while presenting more reliable features.

Fig. 1. Complex-valued autoencoder.

Generally speaking, the encoding process is a mapping function that takes the input X and generates an output Y with a size less than the input. The mapping function can be computed as Eq. (2).

$$Y = f(X) = E(wX + b_e) \quad (2)$$

Where w is the weights matrix and the bias vector $b_e \in \mathbb{C}^n$ of the neuron connections. E is a nonlinear activation function. All variables are presented in the complex space. The decoding process is an inverse mapping function that takes Y as input and reconstructs the input data X' . The decode function can be computed as Eq. (3).

$$X' = f'(y) = D(w'Y + b_d) \quad (3)$$

For the encoding process, the radial basis function (RBF) was proposed as a non-linear activation function. The RBF is a very useful function for time-series prediction and

approximations. The RBF activation function with complex variables can be computed as Eq. (4).

$$\phi_k(x_i) = \exp\left(\frac{-j\|x_i - c_h\|^2}{2\sigma_k^2}\right) \quad (4)$$

Where x_i is the hidden layer's h^{th} neuron's center is designated as c_h and the σ_k^2 is the square of the variance of this neuron. $\|x_i - c_h\|$ define the Euclidian distance between the input data and the center of the hidden layer.

For the output layer, the sigmoid function was proposed as an activation function. The sigmoid function is a bounded function between zero and one. Therefore, it is very useful for probability prediction. Besides, the sigmoid function is differentiable, and the slope can be found between every two points. The sigmoid activation function can be computed as Eq. (5).

$$\phi_k(x_i) = \frac{1}{1+e^{jx_i}} \quad (5)$$

In summary, the proposed complex-valued autoencoder has three layers, an input layer, a hidden layer, and an output layer. For the hidden layer input, the RBF activation function was used. For the output layer, the sigmoid function was used. The input values were concatenated through the C function to provide the complex representation of the input. All weights, activations, and biases were presented in complex space.

B. LSTM Neural Network

The LSTM neural network is a recurrent neural network variant with better temporal data processing. LSTM is very useful for long-term memory which is very useful for time series forecasting. In addition, the LSTM allows avoiding the gradient vanishing problem through processing longer input sequences. It is composed of an input gate, an output gate and a forget gate. As the same as recurrent neural networks, LSTM takes into account the previous time step data value. The input gate controls as to which features are important and should be let through the network. The output gate decides which features that will be pushed to the next layer. The forget gate decides which features to reject. The architecture of an LSTM unit is presented in Fig. 2. An LSTM unit can add and remove features to the current state $S^{(t)}$. Adding features can be performed through the input state and removing features can be performed through the forget gate. The output of the unit is filtered using an activation function (\tanh).

Fig. 2. LSTM neural network unit.

C. Proposed Approach for Solar Energy Forecasting

Solar energy forecasting is based on historical time series processing with consideration to other factors such as weather conditions and the solar panels' condition. Considering that the solar panel produces the maximum possible power, it remains the weather condition to focus on for a trusted prediction on power generation.

The primary goal of the suggested approach was to merge the time-series through the complex-valued autoencoder and use the reconstructed single to train the LSTM neural network for solar energy forecasting. The LSTM neural network learns temporal features according to weather conditions and predicts solar energy production.

The proposed LSTM neural network is composed of three levels of LSTM units. All levels have the same dimension as the input. The proposed LSTM neural network is presented in Fig. 3.

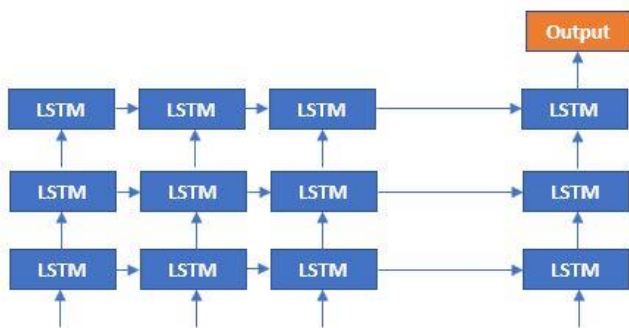

Fig. 3. Proposed LSTM neural network for solar energy forecasting.

In this work, we proposed the combination of a complex-valued autoencoder and an LSTM neural network. The complex-valued autoencoder takes as input the historical time series and the weather conditions. The input data were reconstructed in the output while more features were extracted. The output of the autoencoder was pushed to the LSTM neural network. First, the complex-valued autoencoder was trained separately and then the LSTM neural network. Then, the pretrained complex-valued autoencoder was connected to the LSTM neural network and both networks were trained jointly and considered as a single network. The flowchart of the proposed approach is presented in Fig. 4.

Fig. 4. Proposed approach for solar energy forecasting.

IV. EXPERIMENTS AND RESULTS

All experiments of this work were performed on a desktop with a Linux operating system equipped with an Intel i7 CPU and an Nvidia GTX960 GPU. All models were developed based on the keras deep learning framework. The training data was collected from the Fingrid open data [25]. The collected data was updated hourly. The historical time series and the weather conditions were estimated from a solar power facility

installed in Finland. The facility has a total capacity of 1 megawatt per hour. The data was downloaded in the CSV format. The training data was normalized between zero and one based on the min-max normalization technique. Data normalization allows the comparison of the obtained performances without taking into account the capacity of the solar power facility. The data were filtered by eliminating power values at night and on cloudy days. 60% of the data was used for training, 10% for validation, and 30% for testing after dividing it into three sets.

The proposed complex-valued autoencoder was trained using the gradient descent algorithm with a learning rate of 0.002 and a weight decay of 0.002. It was trained and then its layers were frozen and used for the training of the LSTM neural network. The LSTM neural network was trained using gradient descent with momentum with a learning rate of 0.001 and a weight decay of 0.005. There was a 0.9 fixed momentum.

For the evaluation of the proposed approach, three error metrics were proposed. The mean absolute error (MAE) [26], root-mean-square error (RMSE) [26] and mean absolute percentage error (MAPE) [27] were proposed as evaluation metrics. The MAE can be computed as Eq. (6).

$$MAE(y, x) = \frac{1}{N} \sum_{n=1}^N |y_n - x_n| \quad (6)$$

Where N is the number of samples of the time series. y is the predicted time series and x is the measured time series. The RMSE can be computed as Eq. (7).

$$RMSE(y, x) = \sqrt{\frac{1}{N} \sum_{n=1}^N (y_n - x_n)^2} \quad (7)$$

The MAPE can be computed as Eq. (8).

$$MAPE(y, x) = \frac{1}{N} \sum_{n=1}^N \left| \frac{y_n - x_n}{y_n} \right| \quad (8)$$

The choice of the evaluation metrics was not arbitrary because the comparison between those errors can provide more information on the forecasting system. For example, if the RMSE is higher than the MAE with a big margin then the forecasting system has a big deviation to the measured power. If the RMSE is approximately equal to the MAE then the forecasting system has a small deviation to the measured power. The MAPE is used to measure the robustness of the proposed approach for energy forecasting. A low MAPE means that high performance was achieved.

To avoid an overfitting problem, an early stopping condition was applied. The training stops if the RMSE does not change for 50 consecutive training iterations. The proposed approach was used to predict a day ahead forecast horizon of 24h to 48h. The proposed approach has an alternative training process by pretraining the complex-valued autoencoder then using its pretrained weights in the training of the LSTM neural network. While training the LSTM neural network, the complex-valued autoencoder was used for data reconstruction and its weights are not updated. The LSTM neural network was initialized using samples of two previous time steps.

Calculating the proposed error metrics was done in order to evaluate the proposed approach. Table I presents the obtained

error values. The results demonstrated the effectiveness of the suggested strategy. The obtained RMSE is 0.167 which is higher than the MAE with a margin of 0.074; it means that the forecasting approach has a good deviation from the measured power. The achieved MAPE of 0.028 proves that the proposed approach can generate trusted predictions with a low error.

TABLE I. OBTAINED ERRORS FOR THE PROPOSED METHOD

Error metric	Complex valued autoencoder + LSTM neural network
MAE	0.093
RMSE	0.167
MAPE	0.028

The proposed approach has achieved good results based on the obtained error values. A comparison against state-of-the-art models is presented in Table II. Among all methods, the proposed method has a better prediction effect with a better deviation to the measured power. Compared to the state-of-the-art methods, the proposed method has the lowest MAPE which means that it has the best prediction accuracy and can be considered a reliable forecasting system. More accurate prediction means that the integration cost of solar energy in the grid is reduced and fewer problems can be encountered.

TABLE II. COMPARISON AGAINST STATE-OF-THE-ART METHODS FOR SOLAR ENERGY FORECASTING

Method	MAE	RMSE	MAPE
Hybrid neural network [16]	0.17	0.32	0.067
LSTM-CNN [21]	0.124	0.184	-
TCNN [22]	0.221	0.621	0.042
RNN [28]	0.485	0.84	0.03
Proposed	0.093	0.167	0.028

Reliable forecasting values allow the control of solar power injection in the grid safely and that reduces pollution and using fuel power stations. Fig. 5 presents a comparison between state-of-the-art methods and the proposed method in 18 days of January 2023. As shown in Fig. 5, the proposed method (com-Auto-LSTM) has the lowest error compared to the target values. From day 6 to day 13 the energy production is zero and this may be caused by snowfall. Since the proposed method considers weather conditions the predicted power was very close to the target.

Fig. 5. Comparison against state-of-the-art methods and the proposed method in 18 days of January 2023.

Based on the obtained results, the proposed approach has proved its efficiency. The proposed approach takes advantage of features extraction and combination of the complex-valued autoencoder and the temporal features extraction of the LSTM neural network. The forecasting power of the LSTM neural networks has been improved by combining the historical time series of solar energy production with weather conditions (temperature, humidity, and cloud variation). Through the ability of the proposed complex-valued autoencoder to process complex data with multiple inputs, the input signal of the LSTM neural network was reconstructed by combining the different features. Overall, the proposed method has shown its efficiency for solar power forecasting through the ability to combine historical time series with weather conditions.

V. CONCLUSIONS

Solar power is considered clean energy that can be used to reduce pollution and power costs. However, integrating a solar power generator into the grid is very challenging due to many problems such as high voltage injection and power stability. Energy forecasting is considered as a solution for the safe integration of solar power energy into the grid. In this study, we suggested a neural network-based method for forecasting solar energy that combines two neural network models. First, a complex-valued autoencoder was used to combine the historical time series of power generation with weather conditions. Second, the reconstructed signal was used to train an LSTM neural network. The proposed LSTM neural network was composed of 3 levels of LSTM units with the same size as the input data. The proposed approach was tested and trained using the Fingrid open data. The obtained findings have demonstrated the effectiveness of the suggested strategy, which has a low MAPE when compared to cutting-edge techniques. Besides, the proposed method has a good deviation from the measured power. A comparison against existing models on 18 days of January 2023 has shown that the proposed method has the lowest prediction error. The evaluation has demonstrated the suggested method's high performance, which is attributable to the usage of a combination of an LSTM neural network and a complex-valued autoencoder.

ACKNOWLEDGMENT

Classification with K-Nearest Neighbors Algorithm: Comparative Analysis between the Manual and Automatic Methods for K-Selection

Tsvetelina Mladenova¹, Irena Valova²

Department of Computer Systems and Technologies, University of Ruse, Ruse, 7017, Bulgaria

Abstract—Machine learning and the algorithms it uses have been the subject of many and varied studies with the development of artificial intelligence in recent years. One of the popular and widely used classification algorithms is the nearest neighbors' algorithm and in particular k nearest neighbors. This algorithm has three important steps: calculation of distances; selection of the number of neighbors; and the classification itself. The choice of the value for the k parameter determines the number of neighbors and is important and has a significant impact on the degree of efficiency of the created model. This article describes a study of the influence of the way the k parameter is chosen - manually or automatically. Data sets, used for the study, are selected to be as close as possible in their features to the data generated and used by small businesses - heterogeneous, unbalanced, with relatively small volumes and small training sets. From the obtained results, it can be concluded that the automatic determination of the value of k can give results close to the optimal ones. Deviations are observed in the accuracy rate and the behavior of well-known KNN modifications with increasing neighborhood size for some of the training data sets tested, but one cannot expect that the same model's parameter values (e.g. for k) will be optimally applicable on all data sets.

Keywords—Machine Learning; KNN; classification

I. INTRODUCTION

K-Nearest Neighbors (KNN) is a simple and easy-to-use supervised machine learning (ML) algorithm that can be used for solving classification problems in different domains - education, healthcare, livestock and crop production, administration, production, transport, etc. [1, 2, 3]. KNN is an extension of the idea of the nearest neighbor method introduced by E. Fix and J. Hodges in 1951 [4, 5, 6], which is based on the calculation of the distance between an unlabeled sample and the nearest sample - neighbor, from the training set.

This extension was proposed by Cover and Hart [7] who added the parameter k representing the number of nearest neighbors to be considered for classification. For k=1, it can be said that the nearest neighbor algorithm, NN, is considered, and for k >1, KNN. The KNN algorithm is a relatively simple example of a non-parameterized classifier, easy to understand and implement [8, 9, 10]. The main stages of the KNN algorithm are three, (Fig. 1).

- 1) Calculate the distances from the unlabeled sample to each sample in the training set.
- 2) Processing the calculated distances and selecting the k neighbors [11] that will form the neighborhood.
- 3) Determining the class to which the unlabeled sample belongs - the classification stage.

The main challenges specific to the nearest-neighbor method can be divided into the following groups:

- Determination of the k parameter - the size of the neighborhood depends on it, which is decisive for the classification. It has been proven that the parameter is sensitive and at the same time important for the degree of efficiency of the model.
- Choosing the neighbors - the calculation of distances between samples is traditionally carried out using the Euclidean distance. Choosing the neighbors that will shape the neighborhood is no less important a step than choosing its size.
- Classification rule – the classification stage is the last stage in which the decision is made as to which class to classify the unlabeled sample. An inappropriate classification rule could mean an incorrect classification of the unlabeled sample.

Fig. 1. Steps in classification with the method of nearest neighbors.

II. METHODS FOR CALCULATING THE K VALUE

Determining the value on which the neighborhood size will depend is a problem addressed by many scientific studies. The parameter is particularly sensitive, since at a value larger than necessary, the model's efficiency decreases. A smaller value, respectively, will make the model inaccurate. Additionally, a smaller value will mean that noise in the data will have a greater impact on the classification, and a larger value will mean that additional computing resources are required.

There are different approaches to choosing k . One approach uses a pre-definition of a single value, regardless of the particularities of the training set (type, size, subject area, etc.). The other approach is to determine the value of each set. It is used more, and with it, the value is most often found by the elbow method - the training set is trained with a series of k values and the one is found where the effectiveness of the model begins to decrease.

A third method is the *m-fold cross-validation* [12]. In this approach, the training set is divided into m disjoint sets. The cross-validation method is then applied to each set. Finally, the k value of the subset that gave the best results is taken as the k value of the entire training set.

A disadvantage of this approach is that the selection of the k value does not consider the distribution of the data [13]. Such a finding of the optimal value of k is called "manual search" and requires in-depth analysis by a person who understands and knows machine learning. In addition, such methods often require training the model several times, which means additional time for preparation and calculations.

One of the more automated methods for determining k is the dynamic one, where various approaches are applied to analyze the training set, feature distribution, class information, anomalies, etc., to find the best value.

It is important to note that no matter how the value for k is calculated, it does not guarantee that the model will have high efficiency or that this value will not change. Adding just one object or sample to the training set, or altering any step of the algorithm, may result in an inefficient neighborhood and an inapplicable value of k .

In [14] and [15] an approach is used where the value of k is determined automatically and can vary depending on the size of the set. According to the authors, this approach is suitable for reducing the set size, lowering the classification time, and is a suitable replacement for the traditional KNN for working with big data. The main idea on which the algorithm is built is to find local neighborhoods consisting of samples belonging to the same class. Thus, one can find the number of samples in each local neighborhood, as well as the similarities between the most distant sample in the neighborhood and its center.

By taking these samples as well as the centers of each neighborhood, the size of the training set is reduced while preserving its distribution. Each new, unlabeled sample is compared to the new, reduced set. In this way, there is no need to explicitly define a value for k . It should be noted that the authors propose the text classification algorithm where the classes from which the training set is composed are sufficient for the classification to be accurate.

In [16], [17], the number of neighbors on which the classification will depend is determined by the number of possible classes (1). Through experimental studies, it is proven that this determination of neighbors is appropriate when the boundaries between classes in the data are not clear enough and are face-to-face, so-called overlapping data.

$$k = c + 1 \quad (1)$$

Where:

c – the number of unique classes.

An approach with a dynamic selection of a value for k is also considered in [18], where the number of neighbors depends on the distribution of samples, relative to the classes in the training set. A Chinese text classification method is proposed, and it is proved through an experimental study that the modification achieves good results in classifying documents having classes with few samples.

Another approach used is equation (2).

$$k = \sqrt{N} \quad (2)$$

Where:

N – the number of samples in the training set.

A common practice of ML researchers is to apply the following rule – when the number of unique classes in the training set is even, the value of k is odd to avoid equality between neighboring classes. This is not a guaranteed approach, as samples from only one class or an equal number of samples from two or more classes can fall into the neighborhood, but it is an additional step to improve the model's performance.

The automated way of obtaining the neighborhood size has proven effective when the choice of a value for k needs to be made quickly and without additional steps before training the model. The results obtained with an automatically calculated value for k are comparable to the results obtained using some of the manual methods.

The main advantage of this approach is that it provides an additional step of automation and makes the nearest-neighbor method more accessible to users who do not understand ML. This is a solution that can be implemented in an algorithm aimed at automating learning processes and providing understandable results.

III. NEIGHBORHOOD SIZE AND NEIGHBORS' SELECTION

The neighborhood size, in the nearest neighbor method, is determined by the chosen value for the k parameter. If the value is too small, noise in the data may have too much influence on the classification. Too large a value means more computation time and resources. The exact value of k is difficult to determine and depends on the characteristics of the training set. Taking into account the fact that the sought-after solution has to handle most small datasets, the possibility that the value of k can be further restricted should also be taken into account.

In Fig. 2, Fig. 3, and Fig. 4 can be seen how increasing the number of neighbors leads to a change in the accuracy of the model. The figures show the decision boundaries for different values of k .

At $k=5$, Fig. 2, the overfitting of the model is noticeable, i.e. the model tries to classify as many "single" cases as possible, making it unstable and unreliable.

The increase in the number of neighbors, for example, $k=15$, Fig. 3, results in a normalization of the classification, although areas where it can be said that there is overfitting are still observed.

Fig. 2, Fig. 3, and Fig. 4 visualize a case where the data in the training set is unbalanced and the boundaries between classes are not clearly defined. For the set in the figures, the traditional nearest neighbor method achieves a classification accuracy of 73% at $k=5$, 73% at $k=15$, and 76% at $k=20$. The increase in accuracy rate is a result of expanding the neighborhood. When the training set is large enough to allow this, this is not a problem, despite the additional computational resources required for the larger neighborhood. However, when the set is on the order of 25 samples, $k=20$ will mean that in practice the entire set will be used for training.

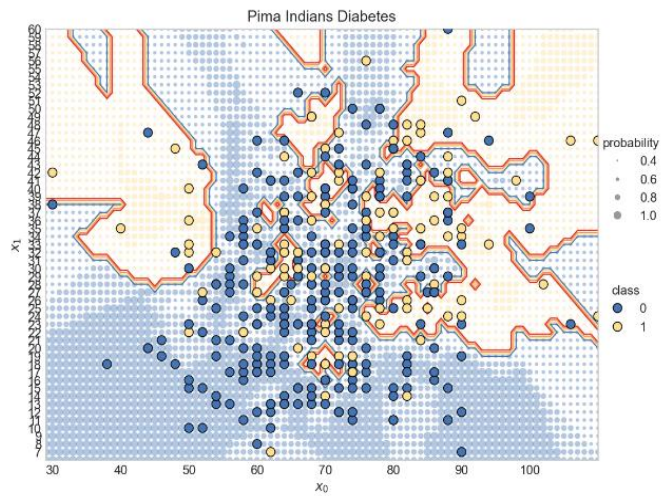

Fig. 2. Decision boundaries for $k=5$.

Fig. 3. Decision boundaries for $k=15$.

Fig. 4. Decision boundaries for $k=20$.

IV. METHODS FOR CALCULATING THE DISTANCES BETWEEN SAMPLES AND FORMING THE NEIGHBORHOOD

The calculation of the nearest neighbors consists of using a function to calculate the distance between the unlabeled sample and all other samples from the training set. There is no single metric for distance measurement that is applicable in all cases [19], although attempts for finding such a metric are not lacking [20, 21, 22].

According to [20], the neighborhood must meet two criteria: 1) the neighbors are close to the unlabeled sample and 2) the neighbors are symmetrically located around it. The idea of nearest neighbors takes into account only the first criterion [23]. Therefore, the neighborhood may not be symmetrically located if the data in the set of neighbors is inhomogeneous.

A. Nearest Centroid Neighborhood (NCN)

In [23] a new definition of the term "neighborhood" is proposed, which does not require user-defined parameters. The proposed algorithm is called Nearest Centroids or Nearest Centroid Neighborhood (NCN). The basic idea can be described as follows: let be a point whose neighbors are to be found and added to the set of points. The neighbors are such that they fulfill the following conditions: 1) they are as close as possible to and 2) the center between the neighbor and the point is as close as possible [24].

B. Distance Weighted K-Nearest Neighbor (WKNN)

In 1975, S. Dudani proposed a modification of the nearest neighbor algorithm [25]. The author argues that it is logical that the distances between individual neighbors should be proved in the form of a "weight" that varies depending on the distance from the unlabeled sample to its neighbors.

In [26], a modification of S. Dudani's algorithm (DWKNN) is proposed for calculating neighbor weights. The proposed algorithm reduces the weights of the nearest neighbors, except for the first and k neighbors. The purpose of weight reduction is to limit the influence of anomalies and improve classification accuracy. If the size of the training set is too large compared to the number of neighbors that are taken into account, then the presented algorithm and the majority rule achieve close results. The author claims that his proposed algorithm achieves better results on small and medium-sized training sets.

Choosing an optimal value for the parameter is difficult when using the majority rule due to the nature of data variation and the probability of classification error. The variation may be because the classification is largely due to the number of neighbors and the number of classes. Additionally, as, after a certain value depending on the size of the training set, increases, the probability of error may increase under certain circumstances.

Similar difficulties in choosing an optimal value for k do not exist when using WKNN. Therefore, it can be argued that with the use of the proposed algorithm, the selection of an optimal value for k can be made without worrying about increasing the probability of error. Several experiments proving the truth of the statement have been conducted. Doudani offers two more weighting functions – inverse weight and rank weight.

C. Pseudo Nearest Neighbor Rule (PNNR)

In [27], the proposed algorithm is based on two others – the weight calculation algorithm, WKNN, and the Local Mean Learning (LM) algorithm [28]. Conventionally, the algorithm is called Uniform. A variation of the algorithm called UWKNN is often used, which differs in that one is added to the neighbor's rank.

D. Dual K-Nearest Neighbor

In [29], a weighting function is proposed, aiming to reduce the sensitivity of the parameter by using a combination of the distance of the samples and their rank in the neighborhood.

E. Fuzzy K-Nearest Neighbor (FKNN)

The Fuzzy KNN algorithm [30] is based on the fuzzy set theory first proposed by Zadeh in 1965. [31]. The main idea of the algorithm is the calculation of the degree of belonging of each element of the training set to the classes. The degree of belonging is taken into account when classifying the unlabeled sample.

V. IMPLEMENTATION OF THE EXPERIMENTS

Often, programming languages such as Python and R are used to train machine learning models. Over the years, they have proven to be some of the most suitable solutions for artificial intelligence and ML. Some of the most developed libraries are written and adapted specifically for these programming languages.

The scikit-learn library contains many predefined algorithms for ML. In addition to the basic algorithms, the library also allows the application of some modification or set of additional parameters that give some flexibility. In some cases, however, despite the availability of parameters to control a given model, there is a need for the so-called "custom changes". In such cases, the library cannot always be used.

The current study does not use a predefined library. All source code for the classification and evaluation algorithm is written in the Python programming language.

A. Datasets for the Experimental Study

The data sets used for the experimental study are selected to match the data that a small business would have – small training sets, heterogeneous data, data with anomalies, and unbalanced data. A more unusual category of data has also been added to the sets used – those that have the $n \gg p$ problem, i.e. the number of attributes is many times greater than the number of samples. Although rare, such data do occur. A typical example is medical data, where the characteristics describing a sample are much more than the samples under study.

The structure of the used datasets is presented and described in Table I. The sets are arranged in increasing order of the number of samples. Data on the balance between the number of representatives of each class are taken from the sources of the sets. The percentage of abnormalities in each set was calculated using the Z-score method (3).

$$z = \frac{x - \mu}{\sigma} \quad (3)$$

Where:

x – sample of the set

μ – average value

σ – the standard deviation

The Z-score formula finds the number of standard deviations from the mean. It is considered an anomaly if the value of the sample obtained by (3) is above three or below three. For the purposes of the experimental study, an "anomaly set" will mean a set containing more than 10% anomalies.

TABLE I. TRAINING SETS USED IN THE EXPERIMENTAL STUDY

Dataset	Attributes	Samples	Classes	No balanced	Anomaly
Lenses ¹	4	24	3	Yes	100%
Lung Cancer ²	56	32	3	No	78.12% (25)
Soybean (small) ³	35	47	4	Yes	0%

The Z-score formula finds the number of standard deviations from the mean. It is considered an anomaly if the value of the sample obtained by (3) is above three or below three. For the purposes of the experimental study, an "anomaly set" will mean a set containing more than 10% anomalies.

B. Data Description

The data used in this experimental study varied in volume, the number of classes, the percentage of anomalies, and the imbalance. Some training sets are of greater interest for research because they contain a larger number of anomalies or are unbalanced. They are Lenses, Lung Cancer, Soybean, SRBCT, Beavers, Hepatitis, Glass, Thyroid, Ecoli, Ionosphere, Breast Cancer Wisconsin, and Absenteeism.

The *Lenses* training set contains 24 samples with 4 attributes each, divided into 3 classes. It is unbalanced and all samples are considered an anomaly. The data is used to classify patients who need contact lens fitting. The potential business application is in optics, where patients are examined and the need for contact lens fitting is determined.

The Lung Cancer set contains information about people who have characteristics of lung cancer patients. The classification task is to correctly diagnose new patients, based on the data of 32 patients (samples), 56 indicators (attributes), and 3 possible diagnoses (classes). Anomalies account for 78% of the data. A potential business application of such a dataset is in laboratories examining patient samples.

Soybean contains information on soybean diseases. It contains 47 samples with 35 attributes classified into 4 classes. It is defined as unbalanced, without anomalies. A set containing information on cereals, legumes, and similar crops can find application in any farm growing them.

SRBCT contains data from 83 patients and 2308 attributes (genes) classified into 4 classes. The data is intended to aid in the correct classification of various childhood cancers. The set is balanced, has no anomalies, and is considered an $n \gg p$ problem. It can be used in laboratories, research, and scientific centers.

Cryotherapy is a set containing data for 90 samples with 6 attributes. Unbalanced and free of anomalies.

Iris is a well-known and researched set for the classification of flowers of the Iris species. It is used as the basis for the study of many machine learning algorithms. It contains 150 samples having 4 attributes and samples are divided into 3 categories. It is balanced and has no anomalies. The application of such a set is in the field of the flower business - a flower shop can recognize the types of the received goods, and greenhouses can more accurately classify the flowers grown.

Hepatitis contains information on 155 samples, each described by 19 attributes and classified into 2 categories. The set is not balanced and has a high percentage of anomalies – 92.9%. Contains information for patients diagnosed with hepatitis. The classification problem it solves is to answer the question of whether the patient will live. It can be used in doctor's offices.

Wine is a dataset much like Iris - well-known, used, and studied. Contains data for 178 samples, 13 attributes, and 3 categories. The data is balanced and the anomaly rate is not high. A similar set can be used by winemakers.

Glass contains data for 214 samples, 9 attributes, and 6 classes. The set is unbalanced, but there are no anomalies. The classification problem is the recognition of types of glass, specifically glass shards found at crime scenes. It can be used in laboratories and glass manufacturers.

Thyroid described 215 patients with 5 attributes and divided them into 3 classes. The data is unbalanced and there are no anomalies. They are used to classify the action of the thyroid gland and therefore such a set can be used in doctors' offices and laboratories.

Stars dataset aims to categorize different celestial bodies into 6 categories, according to 4 attributes. There are 240 samples examined, and the set is considered balanced and contains no anomalies. The application could be in business organizations involved in space exploration.

Algerian Forest Fires contains information on 243 fires in Algeria. Each fire is classified into 2 categories and described with 11 characteristics. The set is balanced and has no anomalies. It can be used in applications for early fire warning, by conservation organizations, fire departments, for research purposes, etc.

Ecoli is a set that contains information about 335 studied samples, described in 8 categories and characterized by 8 attributes. There are no anomalies detected, but the data is unbalanced. It is used to detect specific proteins. The business application of such a set is in laboratories, doctor's offices, and scientific and research centers.

Ionosphere contains information on 351 signals passing through the Earth's ionosphere. The attributes describing them are 34, and the classes classifying them are 2. There are no detected anomalies, but the data is unbalanced. The data can be used in any organization involved in space and earth research.

Breast Cancer Wisconsin contains information on 569 patients described by 30 attributes and classified into 2 categories. The set is unbalanced and the anomaly rate is 13%. The data is used to detect malignant tumors in patients. The application can be in doctors' offices and laboratories.

Absenteeism contains information about 740 employees in different companies. Each employee is described with 19 indicators and 28 different degrees of possibility for the

employee to be absent from work are defined. The high number of possible classes into which a sample can be classified causes the set to have a high rate of anomalies and to be unbalanced. Training a model with such data makes it possible to use it anywhere regardless of the subject area of the business.

Pima Indians Diabetes is a set that has 768 samples classified into two categories and described by 8 attributes. Contains data for patients who have indicators similar to those of patients with diabetes. The data is balanced, but anomalies are present. The application of such a set could be in doctor's offices.

All experimental studies were done with m-fold cross-validation, where m=10. According to [32, 33, 34, 35], to avoid the chance of random results, each model should be trained more than once and the average of the training to be accepted, for this purpose many authors suggest the number of training iterations to be ten, this is the accepted number in the current paper. The results of each iteration were recorded and the average value of the model's accuracy was obtained. For each model training, all available attributes were used without further attribute processing.

For the k-parameter studies, all training sets were trained with the traditional neighborhood method in combination with the traditional nearest neighborhood method and the weighted neighborhood method. The automatic calculation of the k parameter is done in two ways: the training set size method, described with an equation (2), and the number of classes method - equation (1) (Table II).

In the training set method the number of the classes is taken into consideration. For every m_i training iteration around 70% of the data is used and around 30% is used for testing of the model, meaning that the number of the samples is not a constant.

Table II shows the results from the experimental study. The second column of the table shows the number of samples with which the k value is determined, and the following columns shows the highest achieved result for every trained model.

Every neighborhood method is experimented, and for every method, three types of k determination are done – a manual and two automatic methods. In every cell, the accuracy percentage is noted and in brackets is the number of the neighbors (k value) that has achieved this accuracy score.

TABLE II. HIGHEST PERCENT ACCURACY OBTAINED WITH MANUAL AND AUTOMATED K VALUE SELECTION

Dataset	N	KNN		WKNN		DWKNN		UWKNN		Dual		Uniform		Inverse	
		Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$	Manual method	$k = \sqrt{N}$

VI. CONCLUSIONS

From the obtained results, it can be concluded that the automatic determination of the k value can give results close to the optimal, but in some cases, the difference in the percentage of accuracy is about 10-15% lower, compared to manual methods.

For example, with Lenses, the obtained classification accuracy with the manual method is 85%, while with the automated selection method – 68%. Training with a manually found k value of the Lung Cancer set with the DWKNN

method can reach 60% classification accuracy. The same set and method (DWKNN), but with an automatically selected k value, reaches only 43% accuracy. Considering the nature of the training set, this percentage is unsatisfactory.

There are quite a few cases where the automatic selection of the neighborhood size gives close to optimal results. In some cases, the difference between the obtained values is less than a percentage, and in addition, the number of neighbors used is less than with the manual method. The use of a relatively small, but not too small, size of the neighborhood is one of the set criteria for accepting the algorithm as optimal (item 3.2).

In the Thyroid set trained with the Dual method, manual selection can classify with 95.8% accuracy at neighborhood size $k=8$. Using the automatic neighborhood of size $k=4$, i.e. half, achieves 94.4% accuracy. The difference between the two methods is negligibly small and it can be argued that in such cases the automatic selection of the k parameter is appropriate, efficient, and optimal in terms of the required resources for classification.

Known modifications of weighted nearest neighbors (WKNN, DWKNN, UWKNN, Dual, Uniform, and Inverse) do not behave stably and deviations in accuracy rate are observed with the increasing neighborhood for some training sets.

The performance of a model depends on many factors regarding the training set – size, number of unique classes, data balance, missing data anomalies, etc. Therefore, it cannot be expected that some model parameters, e.g. $k=5$, will be optimally applicable to all sets.

The Impact of Design-level Class Decomposition on the Software Maintainability

Bayu Priyambadha¹, Tetsuro Katayama²

Abstract—The quality of the software's internal structure tends to decay due to the adaptation to environmental changes. Therefore, it is beneficial to maintain the internal structure of the software to benefit future phases of the software life cycle. A common correlation exists between decaying internal structures and problems like software smell and maintenance costs. Refactoring is a process to maintain the internal structure of software artifacts based on the smell. Decomposition of classes is one of the most common refactoring actions based on Blob smell performed at the source code level. Moving the class decomposition process to the design artifact seems to affect the quality and maintainability of the source code positively. Therefore, studying the impact of design-level class decomposition on source code quality and software maintainability is essential to ascertain the benefits of implementing design-level class decomposition. The metrics-based evaluation shows that the design-level class decomposition positively impacts the source code quality and maintainability with the rank biserial value is 0.69.

Keywords—Design level refactoring; class decomposition; class diagram decomposition; software quality; software internal quality; software maintainability

I. INTRODUCTION

Internal structure quality maintenance is an essential task in every phase of the software development process. Due to software changes, software's internal structure or design tends to decay or decrease quality [1]–[3]. Some software is changed without using a modern software engineering approach. As a result, it may never be well structured and optimized for understandability. A software developer often changes the software artifact for the short-term goal. The changes are made mostly not followed by a comprehensive analysis of the existing artifact structure. Sometimes, the changes in one unit of software artifact require adjustment at the other unit, so the structure is always maintained. It is not uncommon that the decaying condition of the software structure will have other impacts, such as the immersing of smell on the software artifacts.

Finding and solving the smell problems in the software artifact is a software research field that continues growing until now [2], [4]–[7]. Many approaches are immersed in detecting the smell in the source code artifact [2]. Also, several researchers have defined how to solve every type of smell in source code without altering the outside behavior, known as Refactoring. The smell term was also started to understand at the level of design phases (software developing process) [4]–[6]. Design smell is defined using the knowledge that lies in the

design artifact, for example, the class diagram or the other architectural diagram that expresses the software architecture. But it is still a lack of refactoring process at the design-level artifact using the terms of design smell due to the abstract information in the design artifact [1], [8].

A previous study was conducted to do the refactoring process at the design artifact. The studies focused on the Blob smell that was identified in the class based on the data from the class diagram. Class decomposition is the process of refactoring to solve the Blob smell in the class diagram. Using the threshold-based agglomerative hierarchical clustering algorithm that is based on the class diagram metrics the class decomposition shows promising results [8]. The class diagram metrics, in this case, are *syn* and *sem*, representing syntactic and semantic metrics, respectively. Those metrics measure the relationship between class elements. Then, the approach was enhanced by using the evaluation process to solve the misplaced element and unusable class [9]. The research has shown promising results and is worth continuing to the other pathway solution than the Blob smell.

Before it is continued to the other pathway refactoring solution in the design-level artifact, it is better to know the impact of existing approaches to software maintainability. The existing refactoring process at the source code level has already been proven to have a good impact on software maintainability [10], [11].

This research examines the impact of design-level class decomposition on software maintenance. The decomposition process will be carried out using class diagrams. Once the decomposition recommendations are generated, it will be implemented into the source code. After the code has been implemented (class decomposition), several software metrics are used to measure the quality of a piece of source code after its implementation. Measurement results are compared, before and after decomposition, to determine whether there are any differences or effects on software maintainability.

The following section will describe the literature study (Section II) and the whole method of the design-level class decomposition. The class decomposition process on the class diagram is described in Section III. Section IV describes the current experiment scenario to know the impact of the design-level class decomposition on software maintenance. Finally, Sections V and VI represent the result of the experiment, the analysis using the statistical approach, and the overall conclusion of this experiment.

II. LITERATURE STUDY

Maintaining the software's internal structure also benefits the future phase of the software life cycle. The software life cycle is not only one cycle and finish. Mostly it will continue cycling as long as the user and environment need the software. During the cycle, the software experiences change due to user needs and environmental changes. The changes must be applied to the software to prevent the existing software in the specific environment. The software changes require costs we must pay [12], [13]. Therefore, the software engineer must maintain the internal structure to make changes easier and not costly. The bad structure makes the artifact difficult to understand, change, and maintain.

Every effort has been made to maintain the software's internal structure's quality, starting from the source code. Therefore, shifting from the source code to the design level of Refactoring is considered worth doing to increase the quality awareness of the design artifact as early as possible. But, refactoring activity at a higher level of abstraction has a specific problem [1], [8]. The design artifact contains less information than the implementation artifact. Therefore, excavating or mining the design artifacts and analyzing their in-depth information is necessary.

Generally, design artifacts are only written (text-based) with information that is contained within them. However, information may sometimes contain hidden meanings that require further analysis to be understood. The use of natural language processing (NLP) or semantic analysis (SA) is one approach that can provide functionality for understanding the meaning of information [14].

In contrast, source code-level information clearly provides complete information about the source code profile [1] for example, the number of operands or operators in the source code can be measured to determine the complexity of the source code by the software engineer. In addition, by reviewing the internal source code, the developer will be able to understand the relationship between attributes and methods. They can review the assigning value statement to determine the relationship between the method and attribute.

On the side of design, a review and assessment of the quality of the artifact design can be carried out by utilization of NLP and SA. Furthermore, the refactoring activity, such as class decomposition, using the design artifact is also possible using the NLP and SA analysis [1], [8].

Shifting the refactoring activity to the design artifact is expected to contribute and positively impact software maintenance [11], [15]. There are two fundamental theories of the research of design-level software refactoring. First, the theories of Software Evolution (specifically in software refactoring) [2] and the second is Model-Driven Software Engineering (MDSE) [16]. Software refactoring preserves the quality of the software's internal structure in relation to the software evolution, specifically in the case of software maintainability. On the other hand, MDSE provides the concept that software development is oriented on a model. Therefore, the model acts as the core of action and the guidance of the implementation phase. In other words, the model is the bridge between requirement analysis and implementation. The previous research on design-level Refactoring aims to combine the theories (Refactoring and MDSE) to propose a better approach for refactoring for better software quality [1]. It also has the aim to increase the awareness of internal quality as soon as possible. The other reason for the shift to the design phase is to gain the benefit of MDSE. Fig. 1 shows the thinking schema of the approach according to the justification or rationale. Furthermore, the impact of the Refactoring on the design phase is needed to be investigated.

MDSE uses a software model as the primary artifact of software development [16]. Compared to the implementation artifact (source code), the software model is closer to the problem domain. The model transformation is the main process of the MDSE since the MDSE aims to generate the source code from the models. On the other hand, there is another approach to the development of software called Code-centric Development (CcD). A comparison study between MDSE and CcD has been done for over a decade. From the review paper by Domingo et al., many researchers have been evaluating the benefit of the MDSE [17]. Some works said that MDSE decreases development time (up to 89%) relative to Code-centric Development (CcD). The other works suggest that the MDSE is suitable for academic exercise. Furthermore, the other works assert that MDSE is also suitable for inexperienced developers. Finally, Domingo et al., based on their review of the MDSE, conclude that the MDSE is suitable for academic exercise and inexperienced developers. It would be beneficial to move refactoring activities to the design artifact utilizing the benefits of MDSE.

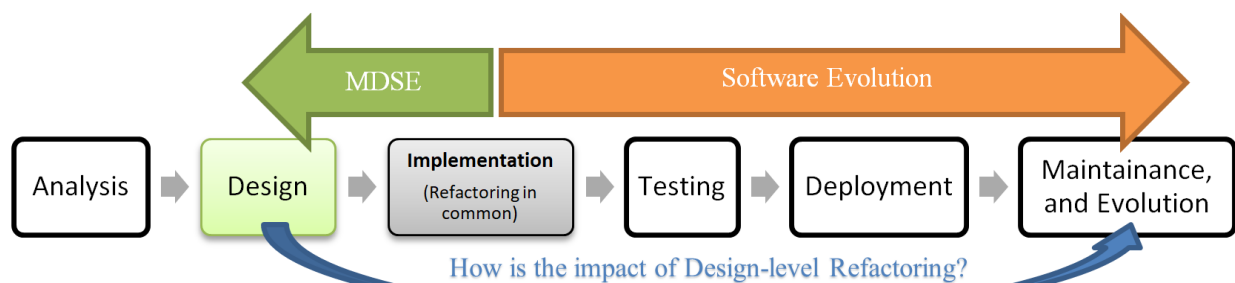

Fig. 1. Thinking schema of design-level class decomposition.

On the other side of view, the impact of the design-level refactoring process on maintenance is questionable and needs study. There are several methods to measure software maintainability. Software maintainability, the ease with which a software system can be understood and modified to accommodate bug fixes, new features, and improvements in general, plays an important role in software quality. Since it is difficult to measure software maintainability without measuring the actual maintenance process, researchers and practitioners often use product metrics as indicators. Some practitioners sometimes face difficulty in finding suitable metrics, specifically software maintainability metrics, according to the practitioner's scope or subjective. The paper of Saraiva et al. has aimed to propose Object-Oriented Software Maintainability (OOSM) metrics categorizations. It aims to make it easy to find suitable maintainability metrics [18]. Maintainability is related to external quality attributes such as analyzability, changeability, stability, and testability. All external attributes are expressed as maintainability characteristics that are "easy to adapt." To achieve this maintainability objective, most researchers measure from the internal quality attributes at least the system's size, complexity, coupling, and cohesion [18].

The other metric that points to software maintainability is named Maintainability Index (MI) [19]. MI is a software metric that is used to measure the level of software, whether it is easy or difficult to maintain in the future. The MI is calculated by considering the Line of Code (LOC), Cyclomatic Complexity, and Halstead Volume (HV). MI is measured using the information of software source code.

III. DESIGN-LEVEL CLASS DECOMPOSITION

This section describes how the refactoring activity can perform in the design-level artifact. This research uses the class diagram as the main object in the refactoring process. The refactoring activity on the class diagram utilizes the class information extracted from the class diagram. One of the challenges in this research is using the existing information to do the refactoring activity. Fig. 2 explains the proposed design-level class decomposition approach to solve Blob smell in class (class diagram).

A. Design-Level Information Extraction

The first task in this approach is to collect or extract information from the class diagram. The class diagram is a notation-based diagram that is expressed as an image showing the software's architecture in case of a class arrangement, and it is a static diagram. The information in the class diagram is important to collect and analyze to support the process. The information extraction needs a specific strategy to make it easy to implement.

The first step in this process is converting the class diagram to an XML formatted file. The conversion aims to transform the notation based to text-based information. Then, the information (text-based) is extracted from the XML syntax to get important data for smell detection (the next process). The extraction uses a specific search algorithm called Tree-based keyword search [20].

The candidate data (classes) for smell detection consists of seven pieces of information. The data are the number of attributes, number of methods, number of relations between methods and attributes, number of relations between methods and attributes, number of relations between attributes and attributes, the capacity of the relationships within the class, and the degree of cohesion [21]. The NLP and SA determine the relationship between the class elements. In addition, the degree of cohesion is calculated based on the relationship between the class elements [22].

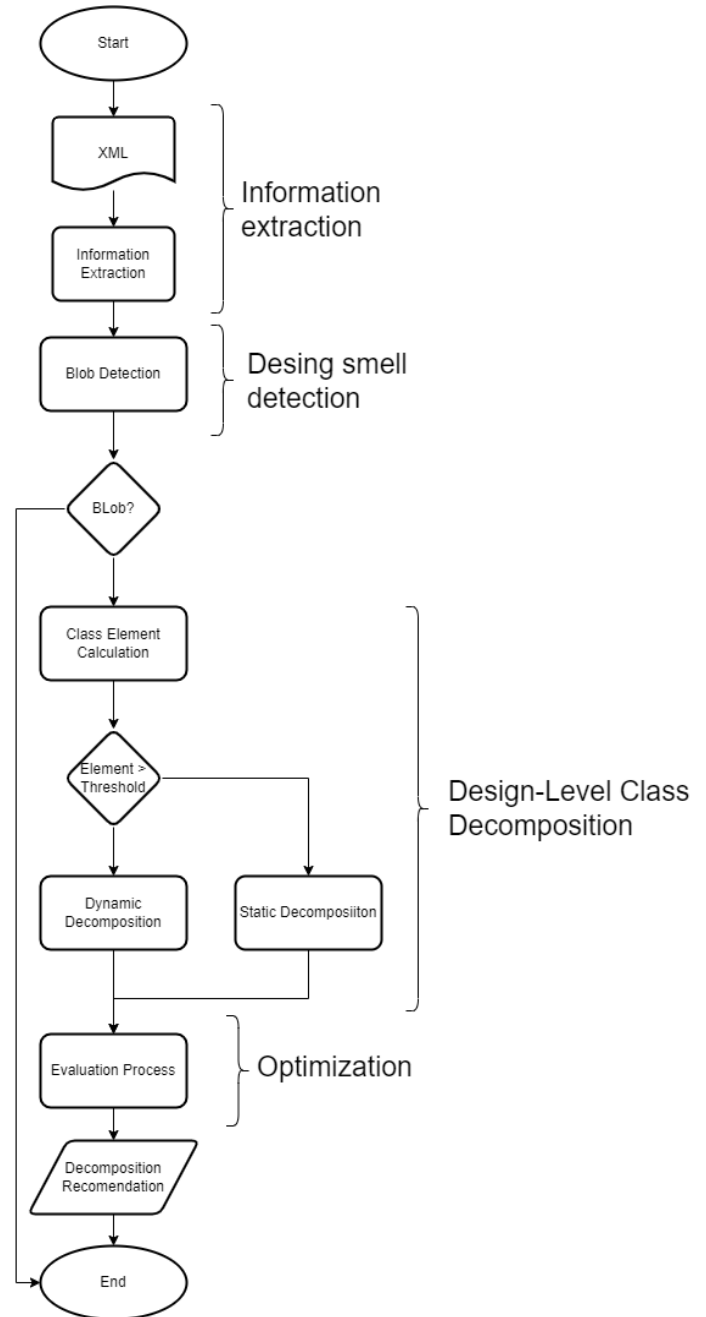

Fig. 2. The design-level class decomposition (design-level refactoring).

B. Design Smell Detection

The classification method will be used to detect the smell. The experiment used three classifiers: the j48, the Multi-Layer Perceptron, and the Naïve Bayes. The experiment uses Weka as machine learning software to solve data mining problems and run using a basic configuration. Classifiers are used to demonstrate that the dataset can be distinguished from bad smells (Blob and Feature Envy) [21]. The experiment result shows an average accuracy of 80.67% for the Blob smell. The accuracy value means that the information data can be utilized for the Blob detection process in a class diagram.

The information (seven pieces of information from the class diagram) contained characteristics that led to the identification of the Blob smell [21]. Hence, the Blob smell is being addressed in the Refactoring.

C. Design-Level Class Decomposition

Once the Blob smell is detected, Refactoring must be performed to solve the smell. Based on the experiences, the Blob smell is solved using the class decomposition or extraction. Mostly the research about class decomposition is done at the level of source code [2], [23]–[30]. Then based on the information in the class diagram [21], the class decomposition is done.

The design-level class decomposition in this research uses threshold-based agglomerative hierarchical clustering. It is divided into static and dynamic threshold hierarchical clustering. Static thresholds differ from dynamic thresholds in defining the threshold before decomposing the cluster. In the static approach, the threshold value is defined at the beginning of the decomposition process (the threshold is defined only once). According to the dynamic approach, the threshold is calculated at every stage of the decomposition process. In this study, Hamdi's algorithm is used, but it is implemented at the level of design [29]. Shifting objects to class diagrams requires defining new metrics for clustering. Syntax (*syn*) and semantic (*sem*) aspects of the class element's label are considered in the similarity matrix to do the clustering process (class decomposition) [8]. The two aspects (syntax and semantics) are considered due to the nature of class diagram information, which is more abstract than source code information. To determine the relationship between class elements, it has to determine the closeness meaning of the label name between elements. This seems to be the essential approach in this process.

The process shows the promising result of decomposition (based on the Silhouette value). But, there are still shortcomings to solve. Some elements still have a negative Silhouette value in the decomposition result. Negative Silhouette values indicate that the current element is far from other cluster elements or has the wrong placement. Additionally, the negative Silhouette elements are considered to be the least desirable.

The results also indicate that some clusters are considered unimplementable due to the possibility that they may produce objects that cannot collaborate with each other. A cluster with only one element, particularly if the element has a private modifier, is considered useless. Evaluating the moving

mechanism of the negative element is considered important as an optimization process. The next process is the evaluation process to the result of this process.

D. Optimization of Class Decomposition Result

The result of the decomposition from the previous process has to be optimized to solve the negative element and unusable cluster. The elements are evaluated by considering the value of Silhouette ($s(i)$) and class usability ($CUability$). $CUability$ value calculated based on the existence of the public method inner the cluster (value one if exists and 0 if not). Then to evaluate the cluster and elements, the following formula is used [9].

$$Eval = a.s(i) + b.CUability \quad (1)$$

Where a and b are the weight of every factor to adjust during the experiment. Threshold-based agglomerative hierarchical clustering experiment has been optimized by adding an evaluation process. During the evaluation process, a specific element with a negative Silhouettes value in each cluster is intended to be moved to a better cluster.

In comparison to the previous approach, the evaluation process increases the average Silhouettes of the cluster by using a higher or equal to 0.7. There has been an average increment of Silhouettes of about 40% [9]. Based on the results of the previous approach, the evaluation process is also able to solve the unusable cluster.

Finally, the whole process produces a set of clusters that represent the classes as the result of the decomposition. In this step, the result is the recommendation to be implemented at the source code level. Then, the impact of the decomposition implementation on the source code level will be described and analyzed in the following section.

IV. EXPERIMENT SCENARIOS

Understanding the impact of the refactoring result on the software maintainability is essential. The impact of class decomposition recommendation result (design-level class decomposition) on the quality of source code is the way to know how is the performance of the design-level class decomposition approach.

A. Overview of Scenario

The decomposition of the class on the source code level based on the recommendation from class decomposition on the design level aims to compare the quality. The source code quality before and after implementing the class decomposition recommendation will lead us to conclude how the design-level decomposition will impact the source code. The quality of code is measured using the source code quality metrics. Fig. 3 shows how the experiment is held to study the impact of design-level class decomposition. The following five internal quality attributes are associated with software maintainability: size, complexity, coupling, cohesion, and constraints associated with software architecture [18]. Four of the internal quality attributes are expressed in the 18 metrics. Table I shows the list of the 18 metrics used in this experiment to compare the before and after decomposition process. The purpose of this experiment is not only to compare the quality of source code

based on the 18 metrics but also to compare the MI [19] as the final proof of this research.

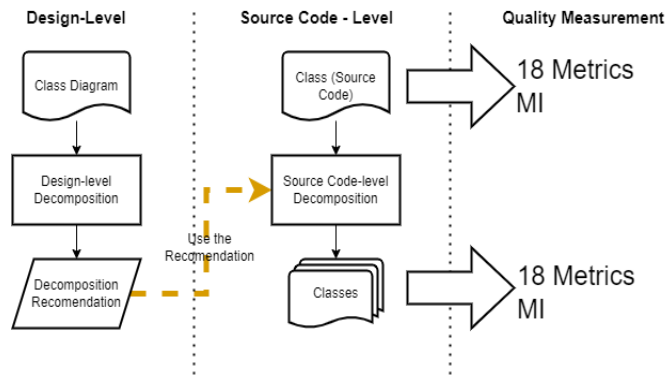

Fig. 3. The experiment scenario.

TABLE I. THE LIST OF THE 18 METRICS

No.	Name	Description
1.	CBO	Coupling Between Object Classes, the number of coupled classes (Coupling)
2.	RFC	Response For a Class, the number of methods that can be potentially invoked in response to a public message received by an object of a particular class (Complexity)
3.	SRFC	Simple Response For a Class, the number of methods that can be potentially invoked in response to a public message received by an object of a particular class (Complexity)
4.	DIT	Depth of Inheritance Tree, the position of the class in the inheritance tree (Complexity)
5.	NOC	Number of Children, the number of direct subclasses of a class (Coupling)
6.	WMC	Weighted Method Count, The weighted sum of all class' methods and represents the McCabe complexity of a class (Complexity)
7.	LOC	Line Of Code (Complexity, Size)
8.	CMLOC	Class-Method Lines of Code, Total number of all nonempty, non-commented lines of methods inside a class (Complexity, Size)
9.	NOF	Number Of Fields, the number of attributes in class (Complexity, Size)
10.	NOSF	Number of Static Fields, the number of static attributes (Complexity, Size)
11.	NOM	Number of Methods (Complexity, Size)
12.	NOSM	Number of Static Methods (Complexity, Size)
13.	NORM	Number of Overridden Methods (Complexity)
14.	LCOM	Lack of Cohesion of Methods, measure how methods of a class are related to each other (Cohesion)
15.	LCAM	Lack of Cohesion Among Methods (1-CAM), CAM metric is the measure of cohesion based on parameter types of methods (LCAM = 1-CAM) (Cohesion)
16.	LTCC	Lack of Tight Class Cohesion, The Lack of Tight Class Cohesion metric measures the lack of cohesion between the public methods of a class (Cohesion)
17.	ATFD	Access to Foreign Data, the number of classes in which the attributes are directly or indirectly reachable from the investigated class (Coupling)
18.	SI	Specialization Index measures subclasses override their ancestor's classes (Complexity)

All the measurement results are collected to be analyzed in the following step. For the result of measurement using the 18 metrics, the data will be recapped and show the trend of comparison before and after decomposition.

Lastly, for measuring MI, statistical analysis is needed to determine the impact of the decomposition recommendation on the source code quality.

B. Experiment Data

TABLE II. MI CLASSIFICATION

MI Value	Classification
>85	Highly maintainable
>65 and ≤85	Moderate maintainable
≤65	Difficult to maintain

This experiment used two study cases, jHotDraw and AgroUML source code. There are 67 classes identified as Blob classes using jDeodorant in both applications. But, after measuring the MI, not all classes are considered problematic in maintenance. The classification of MI value refers to Table II, which explains how the value is classified based on maintainability [19] There are only 33 classes that have moderate and difficult to maintain. Therefore, only 33 classes are used as the object in this experiment. The acquisition of data is shown in Fig. 4.

The Blob classes classified as highly maintainable are not used in this experiment because it assumed not to be included in problematic classes in the maintainability manner.

Fig. 4. Data acquisition.

But, it has to solve from the other perspective manner.

C. Tools

There are three tools used in this experiment, the jDeodorant plugin for Eclipse IDE [31], the CodeMR (Code Magnetic Resonance), and the prototype application that implements the MI measurement [19].

The jDeodorant is used in the data acquisition process to select the classes that contain a Blob smell. The CodeMR is the application that has the ability to measure the quality of source code based on the 18 metrics measurement. CodeMR is a static analysis tool for source code. And the last is a custom application that can show the value of the Maintainability index of source code. CodeMR and the custom application used on the before and after decomposition process. The result of measurement is recapped and analyzed to know how the impact of the usage design-level class decomposition recommendation on the source code quality.

V. EXPERIMENT RESULT AND DISCUSSION

The class decomposition recommendation is implemented on the source code to get the benefit of it. The result is measured using 18 metrics and MI to know how difference before and after the decomposition process.

A. Measurement using the 18 Metrics

The source code decomposition result is measured using the 18 metrics for the first result. The 18 metrics are grouped into four metrics based on the metrics type. Every value of each metric is calculated by averaging the values of particular metrics in every case study. Then, it differentiated before and after decomposition. The groups are coupling, complexity, cohesion, and size metric. Fig. 5 shows the result of the measurement that is described on the line graph. Another reason for grouping metrics is that each type of metric has a different range of values, so separating each type into groups will clarify trends for each type of metric.

Fig. 5(a) shows the trend of measurement in the type of coupling metric. There are three metrics in the category coupling metric, CBO, NOC, and ATFD. In this result, CBO shows a decrement value from before to after decomposition.

The other metrics, NOC and ATFD, do not show decrement due to the value equality between before and after decomposition.

Fig. 5(b) shows the group of complexity metrics consisting of ten metrics. The metrics are RFC, SRFC, DIT, WMC, SI, NOF, NOSF, NOM, NOSM, and NORM. Those metrics measure the complexity of source code from several sides. For the ten metrics, the graph shows the trend that the values decrease after decomposition. Two metrics show the same value before and after decomposition. The metrics are SI and NORM that has a value of 0 before and after decomposition.

Fig. 5(c) shows the cohesion metric, consisting of three metrics: LCOM, LCAM, and LTCC. All metrics show the measurement of a lack of cohesion in the class. Higher values show a higher lack of cohesion in the source code. The value of those metrics decreases before and after the decomposition process.

Fig. 5(d) shows the size metric, which measures the size of the source code. It seems to be the same trend as the other type of metrics. The value of LOC and CMLOC, before and after decomposition, decreases due to the result of decomposition implemented to the source code.

All metric types show the same trend that, after decomposition, tend to be lower value of metrics. The 18 metrics show the same meaning of the value: the lower value means the better condition of the source code. Implementing class decomposition on the source code seems to make the source code better quality measured by the 18 metrics.

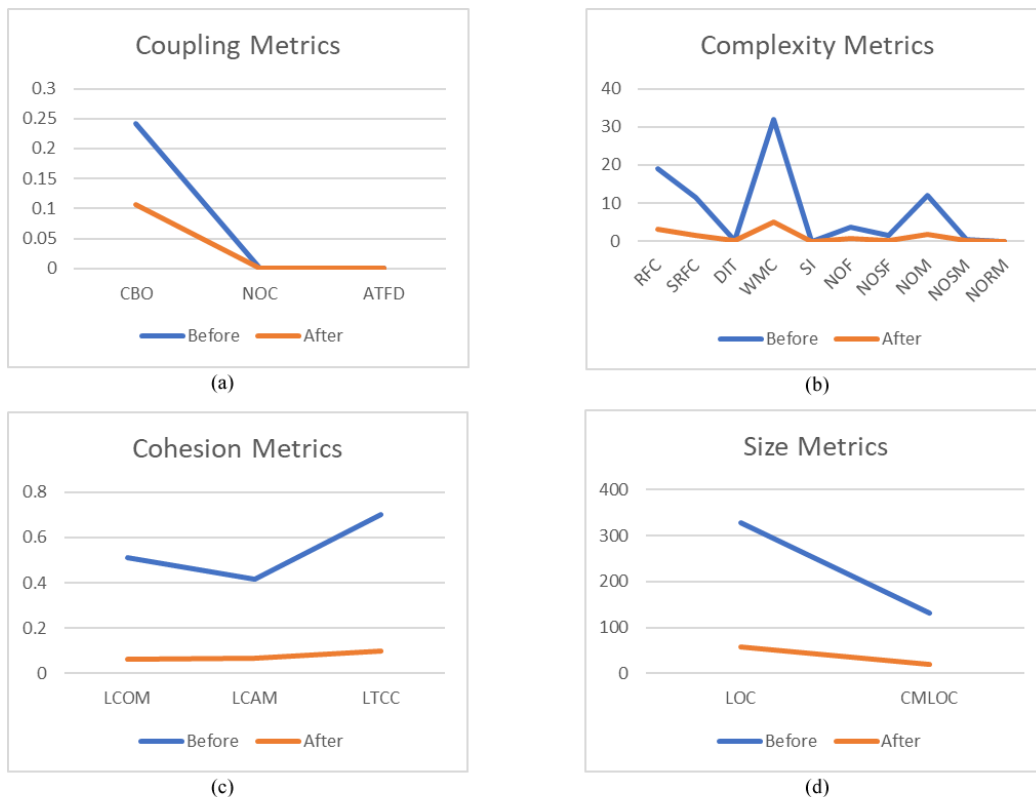

Fig. 5. Result of measurement using the 18 metrics of a) Coupling metrics, b) Complexity metrics, c) Cohesion metrics, and d) Size metrics.

B. Statistical Analysis of the Maintainability Index (MI)

The Maintainability Index (MI) measurement is done using the prototype application. The measurement is applied before and after the class decomposition process based on the design-level recommendation. The MI value for the after-decomposition is calculated by averaging each class's value aims to represent one value. Table III shows the result of the measurement of MI compared before and after the decomposition process.

In this experiment, the differences between before and after are worth calculating to ensure the differences after decomposition. The differences calculation uses the statistical approach, in this case, Wilcoxon signed-rank. Analysis differentiation aims to make sure that there is a difference between before and after decomposition. Differentiation can be used as a sign that the decomposition process causes an impact on the source code in case of maintainability.

Besides the differences, how strong the effect of the usage of design-level decomposition recommendation in the source code level decomposition to the value of MI is also important to know. The Wilcoxon signed rank is able to inform both the differences and the effect size of the approach.

Based on the result of the Wilcoxon signed rank, there are several interpretations based on the test result. Fig. 6 shows the first indicator by the p-value of the result. The significant value of differential analysis is lower than the 0.05 p-value. The current result shows that the p-value is 6.02e-04, lower than 0.05. So, based on the p-value, the result concluded that the MI before and after the decomposition process is significantly different.

The second indicator is the median value from the plot in Fig. 6. Even though the median value cannot act as the main indicator of differentiation and it shows how the differences in spreading data differ. Based on the result, the median values before and after decomposition differ in favor. The median of after decomposition data is increased by 25.03 to the before.

This research aims to know how the impact of the utilization of design-level class decomposition recommendations on the source code level. The p-value and median value only show that the data before and after is different. It does not show how the impact of the design-level class decomposition on the source code quality simultaneously. The other value could be used to know how strong the impact design-level decomposition is rank biserial, as shown in Fig. 6. The rank biserial is used to examine the relationship between dichotomous (binary) nominal data and ordinal (ranked) data. Before running the statistical analysis, the data measurement of MI is calculated to find the data rank based on the differences in the value of MI before and after decomposition. It is one of the Wilcoxon sign rank method's requirements before shown in the plot as shown in Fig. 6. The rank biserial value shown in Fig. 6 is 0.69. Therefore, the higher value is better. Based on Funder's interpretation [32], 0.69 can be interpreted as very

large. In other words, the use of design-level decomposition recommendation on the source code level decomposition gives a very large, positive, and significant effect on the MI.

TABLE III. MI BEFORE AND AFTER DECOMPOSITION PROCESS

Differentiation of MI			
No.	Class Name	Before	After
1.	ArgoEventPump	80.78	99.02

C. Research Limitation

This section explains all things that have a possibility to threaten the validity of the experiment result. There are two main limitations to this experiment. First is the dataset used and the manual process conducted in the experiment.

A limited amount of data in the experiment would be the main limitation of this research. The study case is taken from only the two application resources (jHotDraw and jDraw). The dataset collected from both applications is only 33 instant data. It is sufficient for the scope of this experiment, but it is considered better to add the amount of data in the future to increase the result validity.

The process of class decomposition is done automatically. But, the implementation of decomposition recommendations to the source code is done manually based on the location of class elements.

VI. CONCLUSION

The quality measurement before and after the decomposition process on the source code is by using two approaches. First, the source code was measured using the 18 metrics representing coupling, complexity, cohesion, and size. Those groups of metrics are the type of metrics that are related to software maintainability based on the existing references. There is a trend in all metrics types that after decomposition, the metrics tend to have a lower value than before decomposition. In all 18 metrics, a lower value represents a better condition of source code. By implementing design-level class decomposition on the source code, the source code seems to be of better quality as measured by the 18 metrics.

The second quality measurement uses MI as one specific metric to measure the software maintainability of the source code. The measurement result differentiated before and after the decomposition process. The Wilcoxon signed-rank analysis

was applied to the result of measurement to get a deep analysis of the result. A p-value less than 0.05 indicates significant differential analysis in the first test. According to the current results, the p-value is 6.02e-04, which is less than 0.05. Therefore, it is concluded that the MI before and after decomposition is significantly different. The second indicator is the median value from the plot. Regardless of the fact that the median value cannot be used as the primary indicator of differentiation, it does at least indicate how the spread of data differs.

According to the results, the median value before and after decomposition differs in favor of decomposition. After decomposition, the median has increased by 25.03 compared to the before data.

The final test is rank biserial. There is a rank biserial value of 0.69, which can be interpreted as being very large. As a result, using design-level recommendations on source code decomposition has a very large, positive, and significant effect on the MI.

The 18 metrics and MI analysis show the same favorable result. The use of design-level class decomposition recommendation is able to increase the source code quality significantly based on the analysis result.

The shifting refactoring process to the design artifact is still challenging in the future. This is because so many code smell types could detect and refactor from the design artifact. This research only focuses on the Blob smell on the design artifact, only defining the pathway solution based on the existing Blob smell in the class diagram. The research will continue to the other pathway solution than the Blob smell.

This research uses the data collected from the existing open-source application. The limitation on the number of data might be lacking in the meter of data validity. Increasing the number of data is a plan that has been recorded to be carried

out in the future. The complete software documentation will be interesting data to analyze for future research.

Listening to the Voice of People with Vision Impairment

Revealing Outdoor Mobility Traits for Improved Assistive Technologies

Faculty of Computer Science and Information Technology, University Putra Malaysia (UPM), Serdang, Malaysia

Abstract—Extensive research developed assistive technologies (ATs) to improve mobility for people with vision impairment (PVI). However, a limited number of PVI rely on ATs for mobility. One of the factors contributing to the limited reliability and low acceptance of ATs is the developers' failure to consider PVI mobility traits from the target group's perspective. Many developers and researchers proposed solutions based on their knowledge and experiences, where PVI have been excluded from several studies except for limited involvement in testing phases. Accordingly, this study aims to bridge this gap by providing comprehensive information on PVI's behaviors, challenges, and requirements for safe and independent outdoor mobility. Therefore, a total of 15 participants with vision impairment were involved in semi-structured interviews and two observation sessions. One key finding highlights the need for AT that complements the conventional cane and overcomes its limitations, not substituting the cane. Moreover, the proposed AT should address instant mobility and future needs simultaneously. Overall, the study contributes to providing comprehensive knowledge on PVI safe and independent mobility traits, which assist AT developers to explore the potential barriers and facilitators of the adoption of ATs among PVI and leads to develop effective and reliable ATs that meet their needs. For future work, the researchers will develop an AT that complements the conventional cane, supports instant mobility, and enhances cognitive map formation.

Keywords—People with vision impairment; assistive technology; outdoor mobility; behaviors; challenges; requirements

I. INTRODUCTION

Outdoor mobility is one of the significant challenges for people with vision impairment (PVI), especially in an unfamiliar environment. Globally, PVI still rely on the white cane and guide dog for primary mobility [1]. The white cane gained widespread attention due to its robustness, object detection effectiveness, simplicity, low cost, lightweight, and portability. Nevertheless, the limitation of the cane is the inability to provide full safe mobility. For example, the cane lacks the capacity to detect chest or head-level obstacles [1], small obstacles and various terrain types [2]. Besides, cane techniques require a long training period to be well-understood [1]. The provision of complete safe mobility remains challenging when using a guided dog with limitations in dog cost, speed and path directions [3].

Based on the limitations of conventional mobility aids (white cane and guide dog), high-performance technologies have dominated interest from various disciplines to develop

ATs to support mobility for PVI [4], [5]. Although several proposed systems reported high performance and achieved their goals, only a few ATs have been accepted and considered reliable by the end-users [6], [7]. A significant contributing factor to the low acceptance of proposed ATs is the lack of understanding of the target group's requirements. Several researchers [8], [9] developed ATs based on their knowledge and experience without engaging the target group in any design phase. However, this exclusion of PVI from the research has resulted in a poor understanding of the PVI needs [10] and negatively impact the acceptance and success of the proposed AT [11]. The challenges in recruiting people with disabilities are the reason for this avoidance, as [12] stated. These challenges include logistic problems, participants' safety, and study duration.

In contrast, involving the target group in the design phases of ATs provides the developers with a comprehension of PVI's preferences, lifestyles, challenges, and requirements [3], [13], [7]. This knowledge plays a vital role to develop more effective ATs. For this reason, the study aims to answer two primary research questions: 1) what are the prevailing mobility behaviors and challenges encountered by PVI? and 2) What are the ATs' characteristics that potentially can address these challenges and fulfill PVI ambitions?

To achieve this goal, a qualitative study was conducted involving 15 participants from the PVI community. Three sessions were performed, face-to-face interviews, observation in a familiar environment, and observation in an unfamiliar environment. Participants shared their mobility practice, challenges, and narrated personal stories and ambitions for the future ATs. The study approach of involving PVI participants with three different instruments adds to the study's novelty, where the study provided insights into PVI's lived experiences that are often missing in other studies.

This study mainly highlights extensive illustration of mobility behaviors applied by the PVI to achieve safe outdoor mobility. Additionally, the significant challenges associated with outdoor mobility from the PVI perspective. Moreover, provides recommendations for ATs developers about the features of novel ATs that may satisfy the requirements and expectations of PVI to enhance outdoor safe mobility.

The subsequent aspects of this article are organized as follows: Section II presents a literature review of studies on PVI's mobility traits, challenges, and features inherent in existing solutions. The methodology employed is highlighted

in Section III whereas Section IV presents the findings. Next, the discussion and recommendation of the study are outlined in Section V and a brief conclusion was presented in Section VI.

II. RELATED WORK

A substantial amount of literature exists on mobility for PVI from target groups' perspectives. The main focus in the published studies includes the PVI behaviors for outdoor mobility, the challenges faced, requirements, and expectations of the solution that may improve their safe mobility. Although most past studies reported one or two mobility aspects, this study attempts to aggregate the whole mobility context and reveal new details expressed by PVI expressed via verbal and non-verbal behaviors.

The researchers in [7] conducted a User-Centered Design (UCD) study to specify the PVI requirements of an AT for outdoor navigation in the cultural environment. The study that involved PVI and sighted participants determined several functionality, design, and operational features of the ATs. Some findings revealed the need for GPS, obstacle avoidance, network aspects, video streaming, and vocal feedback. The researchers developed an initial prototype AT based on the findings. However, they reported that a lot of work is needed to fulfill the PVI ambitions especially from the design and functionality aspects. One study limitation is even though the study applied interviews and questionnaire instruments; PVI was involved in the questionnaire only, and the interview sessions were with stakeholders. Additionally, the findings revealed the ATs features that support mobility but it lacks the behaviors and challenges that the target group face.

The study of [14] aimed to highlighting the navigation behaviors and challenges for PVI. A total of 30 participants were interviewed through phone calls. Based on the key findings, the researchers reported that mastering orientation and mobility (O&M) skills were enough for navigation. Additionally, the white cane seeks for obstacles whereas the guide dog avoids obstructions. In terms of AT, the study found that there was no appropriate navigation technology for all PVI, rather it was based on individual needs and preferences. Factors involving high cost and complexities contributed to the absence of navigation technologies. One study limitation is the avoidance of ATs as supportive aids for PVI mobility.

In another related work, PVI-related environmental information for safe and independent commutes was investigated [15]. Semi-structured interviews were performed with 18 PVI participants. The main mobility behaviors reported in the study were asking people for help, using smell and auditory senses, assigning points of reference, and using sidewalk edges. In contrast, orientation and obstacles were demonstrated as the major challenges experienced during daily activities. Also, crossing the street was a significant risk faced by the PVI. The main obstacles impacting PVI's safety were potholes, sidewalk surface, windows and doors, pedestrians, and vendors. The public also had negative attitudes towards PVI. The study provided major challenges that PVI faces; however, it lacks the ATs features which can address these challenges and support safe mobility for PVI.

The study of [16] investigated how navigational technologies improved mobility for PVI. This qualitative research interviewed 23 participants with VI relying on the white cane, while seven of them also used a guided dog. All the participants used their smartphones to access navigation technology such as Google Maps, Apple Maps, Siri, and video calls. The key study finding suggested that safe mobility for PVI could be made more effective by combining conventional mobility aid represented by O&M skills with navigation technologies. Such aids detect the front area, and the navigation technology conveys information about the turn-by-turn route. Although the study demonstrated the importance of ATs in supporting mobility for PVI, it focused on the apps only.

Although navigation is an essential part of mobility, navigation technologies failed to consider the limitations of using conventional aids for detection, such as distinguishing small obstacles and obstacles higher than the ground level. Additionally, several researchers argued using a smartphone on-journey because it impacts on user's safety [11]. Besides, at least one hand should be free during the navigation [17] and users are concerned about battery drain for the whole trip [18].

Despite much research on mobility by involving a group of participants from the target community, several studies relied solely on interviews and excluded the real interactions with the environment. Only a few studies aggregated the mobility behaviors, challenges, requirements, and solution ambitions from PVI's viewpoints. In contrast, this study applied different instruments for data gathering; face-to-face interviews and two real-world observation sessions in familiar and unfamiliar environment, thus enabling the collection of verbal and non-verbal reactions. This study also combined the mobility context (behaviors, challenges, ambitions, and suggestions of the solution) from a diverse group of PVI.

III. METHODOLOGY

This study employed qualitative methodologies for data collection and analysis. Ethical approval with reference number (JKEUPM-2019-463) was obtained from the Ethical Committee of the University of Putra Malaysia (UPM).

A. Participants

A total of 15 adult participants with vision impairment comprising eight females and seven males were recruited. The mean age of the participants is 41 years and the standard deviation (SD) is 16.3. Among the participants, 11 were totally blind (B1) while the remaining four were partially blind (B2). Furthermore, six participants were congenitally blind, nine experienced gradual blindness occurring later in life, and none of the participants had other disabilities.

All participants relied on the white cane for mobility, 12 of them passed the O&M training course and the other three were in O&M training when this study was conducted. The manager of the Research and Development Department in the Malaysia Association for Blind (MAB) assisted in the recruitment process. The participants' demographic information is shown in Table I.

TABLE I. PARTICIPANT DEMOGRAPHIC INFORMATION

Participant	Gender	Age Range	Blindness Level	Blindness Age	Activity ^a
P1	F	41-60	B1	Adulthood	Int, Ob1, Ob2

B. Instruments

Data were collected via three sessions; a semi-structured interview, Session A and two outdoor observation sessions, Session B in a familiar environment and Session C in an unfamiliar environment. All participants were involved in the face-to-face semi-structured interview. Specifically, 12 participants engaged in the two observation sessions. As advised by the O&M instructor, three participants were excluded from the observation sessions as they lacked the ability to navigate independently and they were involved in O&M training when this study was conducted.

1) *Session A – semi-structured interview*: To elicit the mobility context for PVI, face-to-face individual interviews were conducted with the 15 participants taking between 35 to 60 minutes to be completed. The interview questions were structured into three categories; demographic information and visual impairment history, outdoor mobility behaviors and challenges, and knowledge/experience on mobility ATs. All sessions were video and audio recorded, and all verbal and non-verbal cues, such as emotional signs were collected.

2) *Session B – observation I*: The first observation session was in a familiar environment and the purposes were to verify that participants could navigate independently without being exposed to any risk in the unfamiliar environment. In addition, the session was performed to verify the interview responses and identify how the PVI interact with the elements of the familiar sites. These events are expected to reveal the mobility behaviors, especially the emotional indications. Other reasons for this session were to uncover the mobility challenges with

the existence of the cognitive map and to compare the differences in mobility behaviors between the familiar and unfamiliar environments.

Each participant strolled with the white cane for about 10 minutes in the area surrounding MAB Brickfields; Kuala Lumpur, MAB buildings, and MAB courtyard. The site contains a flat area, pavements with tactile blocks, and several obstacles like trees, poles, staircases with handrails, streets, and traffic lights. The think-aloud protocol was applied, thereafter, the participants were asked to express their knowledge about environmental elements surrounding them. All the sessions were video recorded. Fig. 1 presents a sample of the familiar observation sessions.

3) *Session C – observation II*: The second observation session was in an unfamiliar environment. For safety purpose, a sighted individual walked close to the participant to intervene if required. Moreover, medical insurance was provided for each participant following the recommendation of the ethics committee.

The purposes of the unfamiliar observation session were to uncover PVI mobility behaviors and challenges during navigations, verify what the participants expressed in the interview, and identify the compatibility with environmental reactions [12]. In addition, this session was designed to gather the non-verbal cues, clues, and reactions that an individual with VI practices under real-world situations.

Each participant navigated in an unfamiliar environment for 15 to 20 minutes. The site used for the navigation exercise was in the UPM campus, besides the Sultan Salahuddin building and along a path of 250 to 300 meters as shown in Fig. 2(a) and

2(b) show unfamiliar observation site. This area was selected since all the participants were unfamiliar with the environment and controllable in terms of pedestrians, traffic, and obstacles. During the observation sessions, the think-aloud protocol was applied and the participants were asked to express their thought about everything they feel surrounding them. The sessions were also video recorded.

a) Area between MAB buildings b) Brickfields area surrounding to MAB

Fig. 1. Familiar observation sessions.

C. Data Analysis

All audio and video files were transcribed and thematic analysis was applied to analyze the data. Thematic analysis was performed because of its flexibility and provision of rich, detailed, and well-structured results [19], [20]. The analysis yielded a total of 554 quotations, which were combined into 26, which were then filtered and combined into four themes including, 1) mobility behaviors, 2) mobility challenges, 3) mobility aids, and 4) AT-required features. Data management and analysis were carried out using the NVivo 12.0 software [21].

IV. STUDY FINDINGS

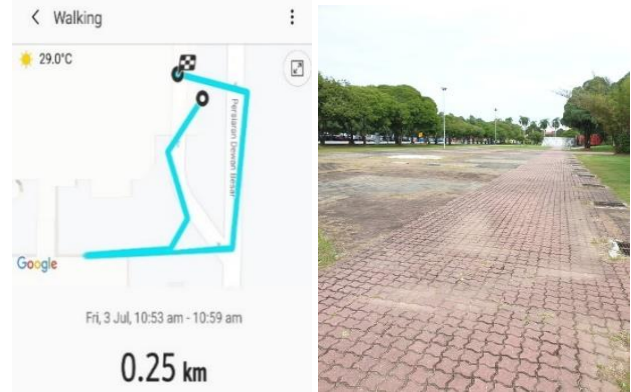

Several studies demonstrated the mobility behaviors, challenges, and solutions PVI desired to enhance their outdoor mobility. However, this study demonstrated further insights into mobility traits that were expected and unexpected. This section describes the outcomes from the perspectives of PVI mobility behaviors and challenges, as well as their ambitions and preferences of the future mobility AT to support their safe mobility.

A. Mobility Behaviors and Techniques

Spatial awareness is the PVI primary behavior in a familiar environment. In contrast, different techniques are performed to compensate for awareness in an unfamiliar environment.

1) *Cognitive map*: A cognitive map is a brain presentation of a spatial location [22]. It plays a main role in controlling the brain's navigation system [3]. Applying the cognitive map is the primary behavior associated with PVI mobility in a familiar environment, where PVI can visualize the surrounding area [23]. During the observation sessions in the familiar environment, all participants demonstrated high abilities to use

the cognitive map for real-time awareness. For instance, they recognized the accurate location of different objects like poles, and staircases. By generating relationships between objects' positions, the participants were able to consider objects such as doors, drains, and floor texture changes as landmarks. Fig. 3(a), presents a participant indicating a door as a landmark. All participants explained their mobility abilities and independence in a familiar environment. For example, participant P13 mentioned:

a) Unfamiliar Observation Path b) Sample of Unfamiliar Observation Site

Fig. 2. Sample from the unfamiliar observation site.

"Outside with a white cane and without any help, needs to feel free ... familiar place is easy."

Moreover, a few participants do not use a white cane in familiar areas. For instance, participant P9 emphasized:

"For a familiar place, I do not use the cane so much because I already have the cognitive map."

The cognitive map reflected on the participants' mobility with confidence, comfort, pride, and independence. Participant P12 reported that he engages in social services to assist blind people in familiar places. Additionally, for a question about the number of visits needed to familiarize a place, nine participants responded that, after three to four visits with a companion, they familiarize the place, but it is difficult to familiarize complex structure areas.

2) *Techniques*: This study collected about 22 techniques performed by the PVI to navigate safely in both familiar and unfamiliar environments. However, all participants expressed their disappointment, fear, and anxiety when visiting an unfamiliar environment due to bad experiences. The primary technique used by all participants when visiting an unfamiliar place is accompanying a sighted individual. Most participants (n = 10) narrated their bad experiences in unfamiliar environments which involved falling, getting lost, traffic, and immoral attitudes of strangers. According to participant P1:

"I don't like to fall... what I'll do if I'm lost? I will ask people, but you must be very careful asking people because people can even take you for a ride."

Participant P15:

"If unfamiliar (place), I think everybody does the same, go to an unfamiliar area with a person."

The second-most used technique when visiting an unfamiliar place is *information collecting* as posited by 13 participants. Participants obtained relevant information about the site before embarking on the trip. The information includes the distance from a specific location to the destination, landmarks in route and the area, useable public transportation, and area accessibility for the PVI. Participant P15 declared as follows:

"Normally I will ask my colleague and relatives. How does this place look like? So, they will tell me I try to imagine how it is."

As well participant P11 mentioned:

"I study the place before going. I get to know if I can take public transport and the accessibility of the place."

Different sources of information were used including sighted individuals and software applications (e.g., Waze and Apple/Google Maps). Before the unfamiliar observation sessions, several participants asked about the site features. Furthermore, participants engaged in slow walking and wide floor sweeping of the cane in an attempt to carefully recognize the area surrounding their bodies. Also, they kept talking to the researcher to feel comfortable and safe.

The participants protect their face and head using their freehand as additional safety techniques for familiar obstacles above the ground. For the staircases, they relied on the handrail and check each stair's height by the cane and their foot before they step which is applied also for pavements and curbs. They relied on tactile paving, trailing along a wall, a sidewalk border, or a road's edge if it is available to keep walking in a straight line unless it is not practicable [3]. Fig. 3(b) presents a participant trailing a sidewalk edge. To cross the road, they rely on hearing sense. The participants evaluated the potholes and drains by checking the depth, diameter, and drain covered by the cane and then avoids it by jumping above the small ones, or moving to the left or right. For an obstacle, they touch it with the cane in an attempt to recognize its features before addressing the issue. In public places, they ask sighted people for help.

3) *Alerting the awareness:* During the unfamiliar observation sessions, when the participants contacted a barrier via the cane, they stopped or slowed down to the maximum, swept the cane on the floor widely, and carefully searched for any change or obstacle. When the individual recognized the situation, they performed an effective and correct action to tackle it. This experience demonstrated the necessity of providing PVI with spatial information before they face a new situation. Hence, no need to inform individuals about what to do or how to address the challenge. However, individuals flinched, stumbled, and were prone to fall when their body contacted with an obstacle before the cane. Moreover, most participants expressed their emotions according to the situation, such as anxiety, comfortable, fear, stress, and pride. P6 mentioned:

"No, please no holes. Holes, especially holes, it is very difficult."

Accordingly, AT developers should avoid informing the user.

What to do (e.g., "turn left, go right"), rather informing them about the obstacle within an appropriate time should be emphasized. Table II summarizes the mobility behaviors and techniques that PVI perform in the familiar and unfamiliar environments to protect their safety.

B. Mobility Challenges

Several challenges were experienced by the PVI during mobility. This research demonstrates the eight most critical challenges reported by the participants encountered during the interview and observation sessions. All participants explicitly asserted that low awareness of *public behavior* is a severe defect that makes mobility an extreme challenge for PVI. They clarified that sighted people stop on the tactile paving for chatting, park their motorbike on it, and compete to walk on the tactile blocks. Participant P2 expressed:

a) A participant indicates a landmark in a familiar area

b) A participant trailing the sidewalk border in an unfamiliar area

Fig. 3. Sample of mobility behaviors.

"Normal people don't care. We need a minimum level of awareness. I'm not suffering from my blind status; I'm suffering the attitude of people every day and it is stressful."

Additionally, the presence of different *terrain types* was another significant challenge. All participants reported that potholes, drains, and stairs form a hazard that could directly impact their safety. The participants shared either their personal experiences or friends' stories about falling in potholes and drains. Fig. 4 presents participants while they were addressing different terrain types in the unfamiliar site. Participant P8 stated:

"The worst thing is falling down in the drain, fall in a drain or a hole."

Participants' anxiety and fears were expressed when approaching various terrain types even in the familiar environment, especially potholes that could suddenly appear as a result of weather or constructions. Participants mentioned several other challenges including traffic and crossing the road. Participant P12 expressed,

"Crossing the road is a big problem ..., crossing the road for the blind is very dangerous."

The participants lose their direction when they find themselves in a wide area. Crowded places, on the other hand, make them feel uncomfortable and embarrassed, especially if they contact pedestrians with their canes or bodies. Similar feelings were expressed when they approached inaccessible pavements that do not follow the height and width standardization or without tactile paving.

Participant P7 sadly mentioned:

"I fell before... I didn't know the curb was so high."

TABLE II. SUMMARY OF MOBILITY BEHAVIORS AND TECHNIQUES PRACTICED DAILY BY THE PVI

No	Behaviors	Familiar	Unfamiliar	Actions	Emotions
1.	Utilize the conventional cane	√	√	Contacting the space in front of them to recognize the situation	Confidence
2.	Utilize the cognitive map	√		Use environmental objects for real-time awareness	Confidence, pride, anxiety from any changes
3.	Landmarks	√	√	Use all senses, improve the cognitive map	Happiness
4.	Accompanying		√	Accompany a sighted individual	Sadness, embarrassed, confidence
5.	Go with a group	√	√	Group visit to a place	Happiness, confidence
6.	Information collecting		√	Ask relatives, use apps.	Confidence, anxiety
7.	Slow walking		√	Slow down and be careful	Anxiety, careful
8.	Wide floor-sweeping of the cane		√	To recognize the area surrounding their bodies	Anxiety, careful
9.	Talking to the companion	√	√	Keep chatting with the companion individual	Confidence
10.	Recognize a change	√	√	Stop and scan the cane on the floor widely	Fears, Anxiety
11.	Face obstacles on the head level	√		Raise the freehand to the head or face for protecting	Anxiety
12.	Utilize curb and pavements	√	√	Utilize foot to determine the height and cane for the width	Careful
13.	Pavement ramp	√	√	Looking for, to utilize it	Confidence
14.	Utilize tactile paving	√	√	Looking for tactile and walk on it	Confidence, anxiety from any obstacle on it
15.	Ascending/descending staircases	√	√	Use foot for the height, rely on handrailing if exist unless use the cane	Anxiety, careful
16.	Walk in a straight line	√	√	Tactile paving, keep the cane trail on the sidewalk edge, wall, or road boundary	Happiness
17.	Cross the road	√	√	Hearing sense, raise the cane upper than head level.	Fears, stress
18.	Presence of pothole or drain	√	√	Use cane to check the depth, diameter, and drain's cover then avoid	Fears, anxiety, careful
19.	Contact obstacle	√	√	Touch by the cane or hand to recognize then avoid	Careful, anxiety
20.	Feel lost		√	Ask people, or applications	Fears, stress, sadness
21.	Stop and raise the cane to public	√	√	Wait for someone to offer assistance	Embarrassed, anxiety
22.	Alert awareness about a new situation	√	√	Stop or slow down, seek for the situation by the cane, recognize the case, tackle it.	Fears, anxiety, careful

Fig. 4. Participants addressing various terrain types in an unfamiliar area.

Participants were also exposed to obstacles above the ground level such as signboards, open windows, and tree branches

Another critical challenge expressed by participants was public transportation without audio sign. The challenges faced by the PVI are summarized in Table III.

C. Mobility Aids

This section clarifies the participants' opinions and reliability of the white cane and mobility assistive technologies.

TABLE III. SUMMARY OF MOBILITY CHALLENGES EXPERIENCED BY THE PVI

No.	Challenge	Familiar	Unfamiliar	Actions	Emotions
1.	Public Attitude	√	√	Stop on the tactile paving for chatting. Park motorbike on it. Walk on the tactile blocks. Ignore PVI	Sadness, anger, stress
2.	Terrain types	√	√	Presence of Pothole, drain, stairs Lack of standard stairs, curbs and pavements Lack of handrailing of staircase	Fears, sadness, anxiety
3.	Traffic	√	√	Cross the road	Fears, anxiety
4.	Wide area	√	√	Lost direction, ask people	anxiety
5.	Strangers	√	√	Ask strangers for help,	Fears, anxiety
6.	Inaccessible pavement	√	√	Pavement without tactile block. Not standard height and width Obstacles, rubbish, motorbike	Sadness, anxiety
7.	Obstacles above the ground level	√	√	Strike upper body parts like chest, face, and head. Signboards, tree branches, open windows, hanging obstacles.	Fears, sadness, anxiety
8.	Public transportation	√	√	Visual signs, gap between the train and its platform	Fears, sadness, anxiety

Participant P15 rated safe mobility using the white cane to range from 70 to 75%. This is not surprising as several researchers verified the limitations of the white cane [24], [3].

2) *Assistive technologies*: In terms of the reliability of the ATs for PVI, all participants responded that they do not rely on any existing AT from either electronic devices or apps. Several researchers [1], [25] reported that PVI trust the white cane because of its cost-effectiveness and provision of better performance compared to smart canes.

None of the 15 participants utilized any mobile electronic device in their daily life. They justified that absence of usage of ATs by expensive, have low performance, are heavier compared to the white cane, and cause anxiety about the battery draining.

Regarding the use of mobile apps, 13 participants owned smartphones and use social media but none of them relied on

1) *White cane*: The 15 participants in this study emphasized that they rely only on the white cane for mobility. Furthermore, they affirmed that white cane enables them to avoid obstacles, feel safe, and inform the public that they have a vision impairment. Participant P2 said:

"If there is no cane, I feel something is missing; I feel I am lost."

However, 11 participants argued that the white cane also has its limitations and it does not provide 100% safe mobility. Some of the limitations that participants shared include lacking the ability to recognize the obstacle, detecting small terrain types, and detecting obstacles above the ground level. Therefore, the participants expressed a desire to have additional aid to overcome the limitations. Participant P7 remarked,

"It is quite safe. I mean, if you're in a familiar place, it's quite safe but in an unfamiliar place, maybe a bit risky."

apps during mobility. Nevertheless, six participants employed Maps apps, Waze [26], Lazarillo [27], and Moovit [28] to collect data before the trip.

Although some of the participants do not rely on mobile Apps, they opined that apps could satisfy some of their desired features. For instance, App can function as complementary with the white cane. Since the users already own a smartphone, the App can be installed and eliminates the need to purchase a new device, which making App an affordable option. Additionally, apps/smartphones do not attract unwanted attention and could be used for multimodal feedback. Apps are usually free or may incur a low cost compared to gadget ATs. However, the participants expressed their reasons for not using Apps during navigation which included the hazard of holding a smartphone when walking, the importance of having a free hand for safe mobility, and the need for an internet connection.

D. Perception of PVI for New AT Features

The appropriate mobility AT for PVI depend on the user's personality and activities [29]. However, the information gathered in this study included the most obvious participants' preferences according to AT features that may address their requirements and gain acceptance from the perspective of design, feedback, and distance to reach the obstacle.

Several designs were selected by the participants in terms of the AT *features*. All participants preferred a solution that is less obvious and does not attract pedestrian attention. This is consistent with the findings of [30], [10] that emphasized the rejection of any design that advertises the disability and attracts unwanted attention. Participant P1 reported;

"I do not want something obvious. It shouldn't make it as an alien."

Eight participants selected the smart cane as the preferred design, whereas two participants preferred wearable devices, such as eyeglasses or a jacket in addition with the conventional cane. Two participants selected a mobile application solution, but again accompanied by the conventional cane. In contrast, the remaining three participants reported that they do not trust any type of AT and preferred to stick with the conventional white cane, indicating a resistance to change.

According to the *feedback*, the study emphasized that it should be conveyed in real-time and precise in terms of the obstacle name and distance (e.g., pothole, 2 meters). The majority of respondents (n = 14) stated that the speech message is the best feedback type because it provides a good perception and enables them to recognize their environment. Additionally, three participants mentioned the importance of vibration especially in a noisy environment. Each feedback style has its advantages and disadvantages. Audio provides rich interaction spatial information that lets the user visualize the environment [31]. Which can improve the cognitive map also [23] but it might be missed in a noisy environment [14]. In contrast, haptic feedback provides privacy, however, the spatial information is limited [32]. Thus, this study agrees with some earlier reports discussing the functionality of multimodality feedback, (i.e., speech message and vibration). Multimodality provides better interaction modes and improves the proposed solution durability, flexibility, and accessibility for a wider range of acceptance [31], [33].

Information was also gathered in this study about the required *coverage distance* to reach the obstacle. Surprisingly, most participants were less informed about the distance units and unable to recognize how the distance is measured in meters following the usage of their arms to specify a given distance. Seven participants mentioned that it should neither be too close nor too far. They added that they needed enough time to prepare themselves for the new situation without losing it. The responses were between 0.5 to 4 meters with a mean of 2.25 meters, which approximately validates the coverage distance reported in various studies ranging from 2 to 4 meters, [2], [34]. The participants' preferences for the main features of the future AT are summarized in Table IV.

V. DISCUSSION AND RECOMMENDATIONS

This study was conducted to provide comprehensive information about mobility context that developers need to consider when developing new mobility ATs for the PVI. A qualitative study involved 15 participants with vision impairment, collected information about outdoor mobility, behaviors, challenges, and the preferred AT features.

An interesting finding demonstrated that PVI who either had solid mobility experience were able to safely address various mobility situations via the white cane only. However, the mobility hazards faced by the PVI were primarily from a lack of spatial information about the environment in front of them. For instance, the cane may miss between its up-down or left-right movement when approaching potholes, short stairs, as well as obstacles above the ground level such as tree branches. These events reflect the increased risk of PVI to various hazards resulting from a lack of spatial information and awareness.

Another significant findings is that PVI were unable to navigate without a cane, similar outcomes have been reported in previous studies [29], [35], [1]. Based on these findings, this study highlights the necessity of an AT that works as a complementary to the cane and address its limitations. A previous study also presented a similar complementary function between the conventional cane with wayfinding apps [19].

In terms of mobility behaviors, the study highlights the role of the cognitive map in performing safe and independent mobility in a familiar environment. The superiority of employing the cognitive map was evident when comparing mobility tasks in familiar and unfamiliar environments. This study encourages AT developers to prioritize the improvement of the cognitive map as a mobility aid, besides the most current research that solely focuses on addressing instant mobility.

In contrast, PVI primarily relied on accompanying a sighted individual when they visit an unfamiliar environment. However, they also depended on various techniques such as gathering information about the route and the area they intent to visit and trailing along a wall or a sidewalk border, which were also reported in a previous study [36]. Likewise, the PVI stopped when they feel a change of the ground surface until they recognize the situation, and they walk slowly and sweep the cane widely. The study suggests that these mobility behaviors need to be considered by the AT developers when designing future ATs. For instance, users could be directed to the nearest wall or sidewalk edge for it to be utilized for straight-line walking.

An unexpected challenge emerging from this study was the frequent suffering of PVI from the attitude of a large number of sighted individuals who compete with them to utilize infrastructures specially designed for PVI, including tactile blocks. Additionally, other challenges were reported by participants including, the presence of different types of terrain, crossing the road, navigating in wide areas, and obstacles above the ground level, inaccessible pavements in terms of height, width, and lack of tactile paving, and using public transportation. This indicates the need for ATs to tackle these

barriers, especially from the aspects of detection performance, usability, and cost.

In terms of AT design preferences, again the significance of the cane was obvious, where most participants preferred utilizing the conventional cane with another assistance (i.e., app or wearable device). This leads to recommend the developers to adopt the complementary function between AT

and the conventional cane, thereby eliminating the idea of substituting the cane with another AT.

For the feedback, 93.3% of participants prefer speech messages, however audio could be missed in a noisy environment. Therefore, the study suggests providing multimodal feedback (haptic and audio), which improves flexibility, usability and enhances the acceptance of the solution.

TABLE IV. SUMMARY OF THE PREFERENCES OF FUTURE AT FEATURES

Feature	Preference	Advantage	Disadvantage
Design	Smart cane	Still utilize a cane	Heavyweight compared to the white cane, costly, anxiety for the battery draining
	Mobile app	No more device, installed in their smartphones	Using smartphone during the navigation
	Not obvious, small size	Do not attract public attention, can be hanged, keep one hand free	
	Affordable	Able to purchase and try even they do not trust technology	
	Lightweight	Comfortable as the white cane	
Feedback	Precise amount	Simple, specific, and direct information	
	Speech message	Rich information to recognize the situation, improve the cognitive map	Loss in a noisy environment, block surrounding sounds
	Vibration	Can be used in noisy areas, provides privacy	Limited information, confusing
Coverage Distance	Around 2.5 meters	Enough time to prepare themselves for the new situation	

According to the coverage distance to convey the feedback, the findings showed that 2 to 3 meters is sufficient distance for the users to recognize the change and prepare themselves for the new situation.

VI. CONCLUSION AND FUTURE WORK

The purpose of the current research is to provide comprehension of the outdoor mobility behaviors, challenges, and the target group's perceptions of the solution. The research confirms previous findings and contributes to our understanding of the new mobility context.

The study answered the research questions by elaborating on the behaviors and challenges of PVI mobility, in addition to clarifying the ATs features that fulfill the PVI expectations. The findings demonstrated that PVI are able to navigate safely when they are informed about the environmental situation within a sufficient time. Also, the white cane is a primary mobility tool for PVI and any other assistant could be used as a complementary. Hence, it is suggested that the designers develop mobility ATs that work with the white cane and not substitute it. The results also emerge lack of spatial information and lack of public awareness as significant factors that increase mobility difficulty. The study reported perception of the new AT requirements. The results revealed the preference of the cane design, multimodal feedback, and two meters coverage distance to reach the obstacle. For future work, the authors intend to propose a prototype of AT to support outdoor mobility systems and meet the participants' requirements and perceptions based on the findings in this study.

ACKNOWLEDGMENT

We thank all members and instructors of MAB – KL and Ipoh branches for their assistance which facilitated this research. Also, we thank all participants who dedicated their time and effort to contribute to this study. Finally, we would like to thank the Human-Computer Interaction Research Group, Faculty Comp Science & Information Tech, University Putra Malaysia.

A Deep Learning based Approach for Recognition of Arabic Sign Language Letters

Boutaina Hdioud¹, Mohammed El Haj Tirari²

Department of Computer Science, ENSIAS, Mohammed V University, Rabat, Morocco¹

Department of Statistic, INSEA, Rabat, Morocco²

Abstract—No one can deny that the deaf-mute community has communication problems in daily life. Advances in artificial intelligence over the past few years have broken through this communication barrier. The principal objective of this work is creating an Arabic Sign Language Recognition system (ArSLR) for recognizing Arabic letters. The ArSLR system is developed using our image pre-processing method to extract the exact position of the hand and we proposed architecture of the Deep Convolutional Neural Network (CNN) using depth data. The goal is to make it easier for people who have hearing problems to interact with normal people. Based on user input, our method will detect and recognize hand-sign letters of the Arabic alphabet automatically. The suggested model is anticipated to deliver encouraging results in the recognition of Arabic sign language with an accuracy score of 97,07%. We conducted a comparison study in order to evaluate proposed system, the obtained results demonstrated that this method is able to recognize static signs with greater accuracy than the accuracy obtained by similar other studies on the same dataset used.

Keywords—Deep learning; hand landmark model; convolutional neural network; Arabic sign language recognition

I. INTRODUCTION

According to the statistical information issued by the World Health Organization in 2021, people with hearing disabilities and deaf persons represent more than 5% of people on the planet [1]. Additionally, it is predicted that in the following 30 years, this number will double. As a result, governments and researchers therefore place a high priority on helping those individuals to participate in their societies. Nowadays, these individuals are the primary users of sign language recognition typically used to communicate both inside and outside of their community.

In this context, we can understand the importance of sign language as a form of non-verbal communication that based on signs and gestures. So, Sign Language Recognition systems (SLR) have been given attention recently. Despite the fact that movement expressions in sign language are the most structured [2], the difficulty of sign language recognition lies in the way that it is expressed. There are two main ways to represent words in sign language; these two ways can be considered complementary to one another: The first way uses particular body movements (e.g. human hands and arms to convey meanings) [3] and facial expressions (e.g. eyebrow raising and mouth shaping) [4]-[6], whereas the second way uses a fingerspelling approach (e.g. orientation, hand posing, and trajectory) [7]. Unfortunately, there is no universal sign language. It's typically different from one country to another

and from one language to another, including the level of the alphabet, where each letter has its own conventional sign. But, with the recent advance in the domain of sign recognition, the researchers have prompted the creation of robust sign language recognition systems for various sign languages, for instance, Brazilian Sign Language [8], British Sign Language [9], Chinese Sign Language [10] and the American Sign Language [11]. However, Asian, English, and Latin sign languages have all been the subject of substantial research, whereas Arabic has received relatively little attention. This can be due to the Arabic language's complexity or the absence of a widely used dataset for the Arabic sign language available to academics. As a result, researchers were forced to build their own datasets, which is a tedious task.

It is crucial to create systems that can translate sign languages into text or speech to help people, who are not deaf or mute, to communicate. Typically, to create any sign language recognition system we can use an image-based approach or a sensor-based technique [12]. Specifically, sensor-based systems work by connecting a glove to a number of sensors to read the gesture, which the system can then recognize; such solutions suffer from a lack of usability. On the other hand, image-based solutions have alleviated this issue and offered a solution in which signs are translated using the cameras. Ideally, those systems can reduce the need for human intervention in the exchange of information between normal people and deaf [13]. Image-based solutions relying on image processing can be carried out in two stages: detection and classification. Each image is first pre-processed during the detection phase, after which the regions of interest are found. The classification process can then be carried out using the results of the preceding procedure. During the recognition stage, each segmented hand sign has a set of features that are extracted in order to perform in the recognition process. Therefore, it is possible to understand the differences between the different signs by using these features as a guide.

Despite extensive research in this field, and as indicated in [14], each study has limitations in terms of the image processing, cost, and sign classification. In general, the system performance depend on the accuracy of the image pre-processing stage, which separates the hand region from the full image, therefore, the main focus of this work is on the recognition of Arabic Sign Language (ArSL) alphabets based on fingerspelling [15]. In order to improve the images of hand gestures accuracy, we proposed to implement a novel ArSL recognition system based on deep convolutional neural network, which incorporates a novel pre-processing stage that

can detect sign gestures by feeding it images of hand gestures performed in varied lighting and orientation, this stage can also alleviate in a small way the problem of strong similarities within the sign language alphabet that present highly similar visual properties, for example, the letter pairs DELL/DHELL, RAA/ZAY, Ayn/Ghayn, ...

Using a dataset of 28 classes of different images of Arabic signs, the objective of this research is to demonstrate how the pre-processing images can be aided in the representation of gestures in feature extraction and how proposed architecture can offer improved accuracy in comparison to other existing methodologies. This work has the following contributions:

- Create a new database of 5000 RGB images and combining them with existing Arabic Sign Language ArSL dataset to input into proposed model and use them as training data.
- Integrate proposed pre-processing stage to enhance the representation gestures.
- Training and comparison of others' works as well as the interpretation of static Arabic sign letters using proposed architecture.
- Analysis of performance of the proposed model in terms of Arabic sign language interpretation.

The rest of the paper is divided into the following sections. An overview of the connected works is given in Section II. The proposed methodology for recognizing hand signs is presented in Section III. The experimental results are described in Section IV. Finally, conclusions and perspectives are presented in Section V.

II. RELATED WORK

Recently, several research papers focused on ArSLR systems. For recognizing the ArSL with gestures, there are three partitions of the method: recognizing the Arabic alphabet, recognizing individual words, and recognizing entire sentences. In this research we focused on the recognizing of the Arabic alphabet. In this context, we provide a summary of some previously employed methods in this field. Automatic Sign Language Recognition is a field to replace sign language interpreters. There have been many studies performed in this way, and several technologies have been built, such as pre-processing to extract hand gesture, feature extraction to reduce an input data into relevant features, and classification to identify the class of each hand sign. In [16] the authors have summarized the work carried out previously, which focuses on making a difference between dynamic sign language and isolated, static, alphabetic non-Arabic and Arabic sign languages, as well as classification methods used in recognition and that relied on traditional machine learning methods or deep learning methods.

An automatic system for recognizing numbers from 0 to 10 and Arabic letters was implemented in [17]. The authors used a dataset with 7869 images overall. Seven layers composed the suggested model, which was trained repeatedly using various training-testing configurations. Finally, the authors offered a comparison with various strategies based on

KNN and SVM, demonstrating the benefit of the suggested model. An automated method for translating Arabic sign language was suggested by the authors in [18]. This system relies on the building of two datasets for Arabic alphabet gestures. In order to extract Arabic sign gestures from images or videos, this system suggests a hand coverage-based manual detection approach. It then uses a range of statistical classifiers, compares the results, and produces a more accurate classification.

With the use of Microsoft Kinect, Hisham et al. [19] introduced a dynamic Arabic sign language recognition. Two machine learning methods, Bayesian Network and Decision Tree are used for recognition, and the Ada-Boosting methodology is then used to improve system recognition. In [20], the authors used deep transfer learning for developing a robust recognition system for Arabic sign language. To prevent overfitting and improve overall system performance, they used data-augmentation. For the target recognition task, several network architectures have been studied. The Arabic sign language (ArSL2018) public dataset was used in this experiment. Other researchers, such as Saleh et al. [21], enhanced the accuracy of Arabic sign language hand gesture recognition through the use of deep CNN and transfer learning. A novel ArSLR system was proposed in [22] to recognize and classify Arabic alphabetical letters, which uses microscopic images along with an unsupervised deep learning algorithm built on a deep belief network (DBN). In [23], authors developed a system that automatically recognizes 28 letters in Arabic Sign Language using a CNN model with a grayscale image as input. In [24], the authors applied ontology to the sign language domain in order to address some sign language problems. They used simple static signs composed of Arabic alphabets. An architecture of CNN was trained and evaluated using a dataset that was collected and a pre-made dataset for Arabic sign language. A new framework for the automatic recognition of Arabic sign language was proposed by Duwairi et al. [25] and is based on transfer learning applied via popular deep learning models (AlexNet, VGGNet, and Inception Net) for image processing. They proposed using VGGNet architecture, which performed better than previous trained models for automatically recognizing Arabic alphabets in sign language. The authors in [26] suggested a system that can be used by the impaired people. The proposed system converts hand gestures in Arabic sign language into vocalized speech. They used Deep Convolutional Network to extract features from the data gathered by the sensor devices and they employed DG5-V hand gloves to capture the hand movements in the dataset. Finally, they applied CNN method for classification. Furthermore, recent advances in sign language have produced a number of models that are suitable for a variety of tasks; however neither of them actually possesses the necessary generalization capability.

III. PROPOSED METHODOLOGY

Using two-dimensional images, we seek to recognize the hand gestures of the ArSL and convert them into alphabet in LSA language. The main objective of this research is to build a deep CNN capable of accurately recognizing the ArSL alphabets. An overall view of the representation of the system is presented in Fig. 1.

Fig. 1. Overview of the proposed method.

The general architecture of the proposed system comprises two stages: image pre-processing and a proposed model for recognizing Arabic sign language. In the following section we will cover different stages.

A. Proposed Pre-processing

After the Arabic sign language images are captured by the camera, they are subjected to a number of main processes during the pre-processing stage. The data are images depth that contain a hand. In order to extract the exact position of the hand we used the mediapipe framework as a solution to detect the hand [27]. The latter has a number of techniques for detection and tracking. Mediapipe Hand is one of its techniques. It consists of two different models working together, the first is namely Palm Detection Model which uses the whole image, produces an oriented hand bounding box made up of rigid objects (e.g. palms and fists) this model has the ability to detect occluded and self-occluded hand, and the second is namely Hand Landmark Model which produces high-fidelity 3D hand keypoints using the cropped image area defined by the palm detector. After the localization phase we cut the image by transforming it into black images that contain just the hand landmarks with a line connecting them after we resize the images to 240×240 (Fig. 2.). Finally, we divided our dataset into three parts- training, validation and test for training our model. Fig. 2 shows the input image Fig. 2(a) and the outcomes of the image pre-processing with edge detection in Fig. 2(b).

Fig. 2. Input image (a) Before preprocessing and Sample of characters extracted (b) After preprocessing.

B. Proposed CNN Architecture

The convolutional neural network CNN model we used in this study is composed of several layers. Fig. 3. shows the proposed architecture of the CNN, which consists of an input layer that accepts images with a size of $240 \times 240 \times 3$ pixels, which corresponds to the size of the images that the system accepts.

The feature extraction section consists of three convolutional layers (Conv2d, Conv2d_1, Conv2d_2) in which each convolution filter has dimensions of 3 by 3. There are thus 16 filters for Conv2d, 32 filters for Conv2d_1, 64 filters for Conv2d_2.

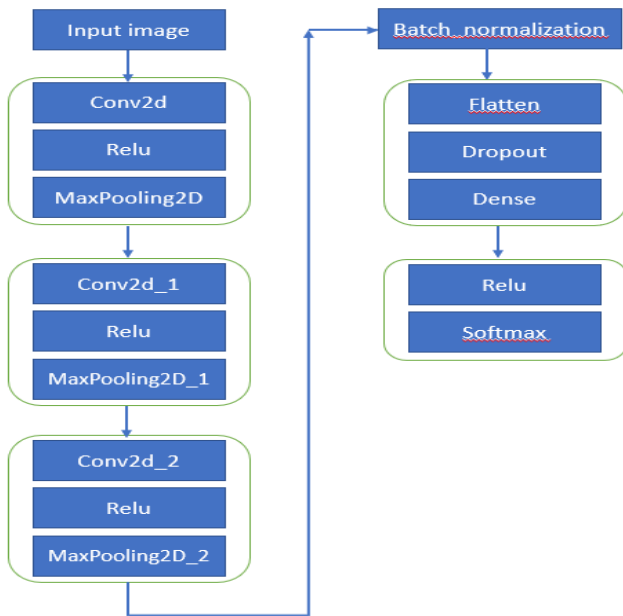

Fig. 3. Proposed CNN network.

Note here that each convolution operation is followed by an activation layer which uses the corrected linear unit function (ReLU). After each activation of the neurons, we will use a Maxpooling layer with a size of 3x3 in an attempt to reduce the size of the images without modifying their important characteristics. This will help to significantly reduce the computational power required by the model. Next, we will use a flatten layer followed by a dropout layer to disable 25% of the neurons. This type of layer helps to reduce overlearning by randomly disabling neurons in the network. Finally, we will use an activation layer using the RELU function followed by a dense classification layer using the softmax activation function. An overview of the parameters in each layer and the overall parameters in the proposed network are shown in Table I.

TABLE I. SUMMARY OF THE PROPOSED CNN NETWORK

Network Layer	Output Shape	Parameters
conv2d(Conv2D)	(None, 240, 240, 16)	448
Max_pooling2d(MaxPooling2D)	(None, 80, 80, 16)	0
conv2d_1(Conv2D)	(None, 80, 80, 32)	4640
max_pooling2d_1(MaxPooling2D)	(None,26,26,32)	0
conv2d_2(Conv2D)	(None, 26, 26, 64)	18496
max_pooling2d_2(MaxPooling2D)	(None, 8, 8, 64)	0
batch_normalization(BatchNormalization)	(None, 8, 8, 64)	256
flatten(Flatten)	(None, 4096)	0
dropout(Dropout)	(None, 4096)	0
dense(Dense)	(None, 256)	1048832
Dense_1(Dense)	(None, 28)	7196
Total parameters	1,079,868	

IV. EXPERIMENT AND RESULTS

A. Dataset

To evaluate proposed system, we create a combination of the Arabic Sign Language ArSL dataset [28] and our dataset created by professional camera from different signers and different luminosity intensities.

The Arabic Sign Language ArSL dataset is mainly composed of two folders, the first one containing 1160 images each having a size of 416x416 pixels, and the second one containing 1160 text files describing respectively the content of each image in the first folder. The second dataset was created in such a way as to have 28 classes, each containing about 135 images describing an Arabic letter. In order to combine the two datasets, a modification to the format of the Arabic Sign Language ArSL dataset was necessary. We therefore grouped the images of the same letter under the same folder in order to get rid of the need for text files and to unify the format of both datasets. This made it easier for us to combine the two datasets later on. Note here that the Arabic Sign Language ArSL dataset had a problem with the non-existence of the images of the letter "Noun" in their appropriate class which required a manual correction of this by moving them to their original class.

B. Results

As previously mentioned, the dataset used for training contained more than 5000 images, distributed in a unified format on 28 different classes of Arabic Sign Language gestures. Three distinct sets of data were created from the dataset, with 60% of the data used for training, 20% for testing, and 20% for validation. The proposed technique would then involve the following steps: We started by pre-processing stage which we outcome black images that contain just the hand landmarks with a line connecting. After that, we inputted the data into proposed model, where the proposed model is iterated through several epochs and at the end of each iteration, accuracy values are provided. Finally, after running the last training epoch, the final accuracy is shown, and the training model is finished. The training and validation accuracy can be seen in Fig. 4(a) and training and validation loss in Fig. 4(b).

Fig. 4. (a) Training accuracy vs. validation accuracy, (b). Training loss vs. validation loss.

The architecture of CNN was trained for 20 epochs with a batch size of 32. At the 10th epoch, the model was able to validate with an accuracy of 97%, while the 20th epoch saw the highest accuracy of 97.07%. In Fig. 4(a), it can also be

noted how the model training progressed, which demonstrates also how the model stays ahead in every iteration of training and how the loss decreased (see Fig. 4(b)). According to the obtained result we observe no sign of the overfitting.

The confusion matrix shows how well the system performs in terms of correctly and incorrectly classifying developed data. The CM obtained by the CNN model using our methodology is shown in the following Fig. 5. The results obtained show that almost all gestures are correctly classified by our model.

Fig. 5. Confusion matrix.

The classification report, as evident in Fig. 6, confirms what the confusion matrix states. Thus, it can be seen that the rate is actually low, and the majority of the class is properly categorized. The accuracy for the letters ("THA", "KHAA", "SEEN", "SAD", "ZAY") is high and ranges between 95 and 100%, whereas the accuracy for other gestures, such as the letters ("FAA", "JEEM", "RAA", "DEEL", "MEEM"), ranges between 88% and 94%. The principal reason for this difference is that each letter requires a different finger position. This confirms that accurate results depend greatly on how gestures are represented when features are extracted.

According to the obtained result, we can observe that the proposed method allows us to reduce the total number of incorrectly recognized signs to about 32. The misclassification rate is related as previously cited, to the fact that some letters have strong similarities in gestures (RAA/DELL, DELL/DHELL, RAA/ZAY, etc.), which has probably forced proposed model to extract similar features, rendering their classification process more difficult. The following figure (Fig. 7) displays an extract of misclassified images.

C. Comparative Study

To show the performance of the proposed system, we have compared the results obtained from recent literature [18],[29] and [30] with our method. We tested all methods on the same dataset used in this work. Table II reports the results of the three methods under consideration.

	precision	recall	f1-score	support
ALIF	0.98	1.00	0.99	50
BAA	0.95	0.95	0.95	38
TA	0.98	1.00	0.99	40
THA	1.00	1.00	1.00	59
JEEM	0.92	1.00	0.96	46
HAA	0.98	0.96	0.97	45
KHAA	1.00	0.98	0.99	41
DELL	0.94	0.87	0.91	39
DHELL	0.98	0.98	0.98	43
RAA	0.88	0.97	0.93	39
ZAY	0.97	0.93	0.95	40
SEEN	1.00	1.00	1.00	37
SHEEN	0.97	1.00	0.99	38
SAD	1.00	1.00	1.00	28
DAD	0.97	1.00	0.99	37
TAA	0.98	1.00	0.99	43
DHAA	1.00	0.97	0.99	38
AYN	0.97	0.95	0.96	38
GHAYN	0.98	0.98	0.98	42
FAA	0.92	0.96	0.94	25
QAAF	1.00	0.93	0.96	44
KAAP	0.97	1.00	0.99	33
LAAM	0.96	1.00	0.98	25

NOON	0.97	0.90	0.93	39
HA	0.97	1.00	0.99	37
WAW	0.97	0.93	0.95	40
YA	1.00	0.97	0.99	35
accuracy			0.97	1093
macro avg	0.97	0.97	0.97	1093
weighted avg	0.97	0.97	0.97	1093

Fig. 6. Results for our approach.

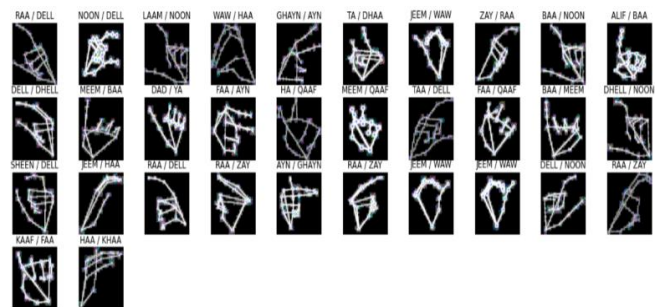

Fig. 7. An extract of the incorrectly classified images.

TABLE II. COMPARISON OF THE PROPOSED SYSTEM WITH OTHER METHODS

Methods	Accuracy
HAYANI et al. [18]	79.27%
KAMRUZZAMAN et al. [29]	83.91%
Ghazanfar Latif et al. [30]	90.61%
proposed model	97.07%

As compared with the results of the models listed above. The best result was reached with our suggested architecture, which has proven effective in the recognition of sign language due to a validation accuracy achieved of 97.70%.

V. CONCLUSION

In this paper, we used deep learning techniques to perform Arabic sign language recognition based on the hands of deaf people in real time in order to translate the signals into alphabets and improve communication between deaf and non-deaf people.

We started by collecting data and creating our own dataset, then applying a preprocessing that consists in cropping the hand from the image, and extracting its shape, then we proposed four CNN models with different architectures of which three architectures are proposed in three different scientific papers and the last one is proposed by ourselves, and applied them afterwards on our datasets with the aim of making a comparative study in order to choose the best model. The comparative study allowed us to conclude that our architecture is the best performing, where we obtained a score of 97.07%.

In the future work, we would like to extend the dataset for example, increase the variety of images in terms of noise, orientation, etc. and implement new techniques to convert hand movements into written text, and to use NLP (Natural Language Processing) techniques in order to process the obtained texts and present them with a comprehensible and adequate way.
