Because of the hollow region in the middle of the metering compartment where the electricity meter is located, there is a significant depth difference inside and outside the edge of the metering compartment. As shown in Fig. 5, an outer template  $mask_{out}$  and an inner template  $mask_{in}$  are introduced to determine whether the current contour is the edge of the measuring box. The size and the shape of  $mask_{out}$  and  $mask_{in}$  are consistent with the current contour. As shown in Fig. 5, in the  $mask_{out}$ , the outermost two layers of the outer template are all assigned the value of 1, and the values of the remaining layers are all set to 0. In the  $mask_{in}$ , the outermost two layers of the outer template are all assigned values of 0, and the values of the remaining layers are all set to 1. The two structure templates with the metering compartments in depth image  $R_{DP}$  are combined, and the distance difference between the edge and the interior of the bounding box in the depth camera can be calculated. The distance difference can be expressed as follows:

$$diff = \left| I \cdot \frac{mask_{out}}{num_{out}} - I \cdot \frac{mask_{in}}{num_{in}} \right| \quad (12)$$

where  $num_{out}$  and  $num_{in}$  represent the number of elements with values of 1 in the  $mask_{out}$  and  $mask_{in}$ , respectively.

When the contour moves to the true edge, due to the difference in the depth values between the inner and outer edges, the  $diff$  value will reach its maximum value (the red point in Fig. 6). In this work, when the  $diff$  starts to decrease, it is considered to meet the constraint condition and the iterations stop. The contour obtained in this iteration is the corrected edge.

Fig. 5. The proposed structure templates: (a) outer template and (b) inner template

#### D. Automated Size Measurement based on the Proposed Equal-Region Averaging Algorithm

Due to the errors caused by the infrared pattern projected by the depth camera during the imaging process, as well as the

errors caused by the stereo matching algorithm, some pixels' depth information is missing or deviating in the depth image [29]. To obtain more accurate depth-channel information and realize automated size measurement, the Equal-Region Averaging algorithm is proposed in this work. The steps are as follows:

Step 1: Calculate the bounding box of the segmented region. The segmented components are the door shell, window and metering compartment.

Step 2: Obtain the four corners of the bounding box. Set  $a_i$  ( $i=1,2,3,4$ ) as the distance parameters between each corner and all the points on the segmented region.

Step 3: Define four pseudo-corners as the points on the segmented contour, which have the minimal distances to their corresponding corners. The pseudo-corners cut the contour into four segments.

Step 4: For each segment, find the midpoint of each segment, and take the midpoint as the center to obtain a detection area with a length of one-quarter of the side length. In Fig. 7, the red box line represents the length detection range of the door shell, window or metering compartment. And the green box line represents the width detection range of the component.

In the defined detection region, the corresponding pixel points on the opposite sides are connected. The length of each line can be calculated as:

$$h_i = \sqrt{(x_i - x'_i)^2 + (y_i - y'_i)^2 + (z_i - z'_i)^2} \quad (13)$$

where the 3D coordinate values of the corresponding pixel pair are  $F_i(x_i, y_i, z_i)$  and  $F'_i(x'_i, y'_i, z'_i)$ .

The vector of the heights is:

$$height = [h_1, h_2, h_3, \dots, h_i] \quad (14)$$

and the vector of widths is:

$$width = [w_1, w_2, w_3, \dots, w_i] \quad (15)$$

The mode of these two vectors is calculated, and the values  $h_m$  and  $w_m$  are the height and weight of the component.

$$h_m = mode(height), w_m = mode(width) \quad (16)$$

Fig. 6. The proposed edge correction algorithm based on the Depth Difference (Dep-D) Constraint

Fig. 7. Schematic diagram of size measurement region of door shell, window and metering compartment.

### III. EXPERIMENTAL RESULTS AND ANALYSIS

In this work, an automated type identification and size measurement method is proposed for the low-voltage metering boxes, which are among the most critical pieces of equipment in a power system.

#### A. RGB-D Image Data of Low-voltage Metering Boxes

Six types of low-voltage metering boxes are collected in this work, namely single-phase single-meter, single-phase four-meter, single-phase six-meter, single-phase nine-meter, three-phase single-meter, and three-phase two-meter low-voltage metering boxes. Table I shows the diagrams of the outer shell and the inner surfaces of these six types of low-voltage metering boxes.

The RGB-D images are captured using the Intel RealSense D415 depth cameras developed by Intel Corporation. The image resolution is 1280\*720. A total of 732 images are collected as experimental data.

#### B. Experimental Results of Type Identification for Low-voltage Metering Box

In the RGB channel, the metering compartment and connection terminal block are segmented by using the Mask-RCNN network first. Then, the number of connection terminal blocks is estimated by using the proposed Sub-Region Closer-Neighbor algorithm. Combined with the depth information, the contours of the metering compartments are re-fined. The number of metering compartments is estimated, by counting the connected do-main of metering compartment regions. Finally, the type of low-voltage metering box is identified by using the number of metering compartments and connection terminal blocks.

1) *Experimental results of type identification for low-voltage metering box:* In this work, six types of low-voltage metering boxes are classified. Table II shows the detection accuracies for these six types of low-voltage metering boxes.

From Table II, it can be seen that average detection accuracies of the proposed type identification method for the low-voltage metering boxes reach up to 94.8%. The detection accuracies for six types of low-voltage metering box range from 92.3% to 96.8%.

TABLE I. SIX TYPES OF LOW-VOLTAGE METERING BOXES

Single-phase single-meter		Single-phase four-meter	
Outer shell	Cabinet	Outer shell	Cabinet
Single-phase six-meter		Single-phase nine-meter	
Outer shell	Cabinet	Outer shell	Cabinet
Three-phase single-meter		Three-phase two-meter	
Outer shell	Cabinet	Outer shell	Cabinet

TABLE II. DETECTION ACCURACIES OF DIFFERENT TYPES OF LOW-VOLTAGE METERING BOXES

Type	Detection accuracy	Average accuracy
Single-phase single-meter	92.3%	94.8%
Single-phase four-meter	96.8%	
Single-phase six-meter	93.6%	
Single-phase nine-meter	95.7%	
Three-phase single-meter	92.5%	
Three-phase two-meter	93.1%	

The recognition accuracies of single-phase single-meter and single-phase nine-meter metering boxes are lower than those of the other types, mainly due to the misdetection of the number of connection terminal blocks. The counting accuracy of the connection terminal blocks is reduced due to illumination, occlusion, and other problems. In particular, the baffle plate in front of the connection terminal blocks significantly affects the segmentation accuracy. In this work, the Sub-Region Closer-Neighbor algorithm is proposed to reduce the influence of occlusion. The proposed method could increase the recognition accuracy even if the connection terminal blocks are incompletely segmented. Moreover, even if part of the connection terminal block is misdetected, the proposed method could still reduce the detection error, by inducing the (8). The distance between the detected number and the standard number (4 or 8) is calculated. The final number of connection terminal blocks is the number with the smallest distance from the standard number. If the connection terminal blocks are fully occluded, misjudgment of the phase could occur.

2) *Experimental results of critical components segmentation and number detection method:* To identify the types of low-voltage metering boxes, the critical components in the metering box are segmented first. Then, the Sub-Region Closer-Neighbor algorithm is proposed to estimate the number of terminal blocks. The defined Depth Difference (Dep-D) Constraint is used in the edge correction algorithm, to refine the contour of the metering compartments. The number of metering compartments is estimated based on the segmentation results. Table III lists the results of the automated segmentation and counting methods for metering compartments and connection terminal blocks.

As shown in Table III, the Intersection over Union (IoU) values for the segmentation of the connection terminal block, rang from 75.5% to 89.6%.

The precision of segmentation for the connection terminal blocks is affected by many factors. The color of the connection terminal block is gray, which is close to color of the metering cabinet panel. The location of connection terminal block is below the metering compartment. Most of the time, there is a baffle plate set in front of the connection terminal block, in order to protect the wires. The connection terminal block could only be seen in the gap of plate stripes. Sometimes, the wires can occlude the connection terminal block as well. Fig. 8 illustrates the situations which affect the detection accuracy of connection terminal blocks.

TABLE III. RESULTS OF AUTOMATED SEGMENTATION AND COUNTING METHODS FOR CONNECTION TERMINAL BLOCK AND METERING COMPARTMENT

Type of metering box	Component	IoU	Number counting	Type identification
Single-phase single-meter	CTB	78.6%	94.7%	92.3%
	MC	93.3%	100%	
Single-phase four-meter	CTB	75.5%	88.9%	96.8%
	MC	90.2%	99.5%	
Single-phase six-meter	CTB	80.5%	90.5%	93.6%
	MC	94.5%	99.7%	
Single-phase nine-meter	CTB	83.6%	90.0%	95.7%
	MC	90.6%	98.7%	
Three-phase single-meter	CTB	86.4%	93.8%	92.5%
	MC	90.6%	98.6%	
Three-phase two-meter	CTB	89.6%	90.6%	93.1%
	MC	94.9%	97.5%	

Component CTB: Connection Terminal Block, Component MC: Metering Compartment

Due to the occlusion, illumination, and shooting angle, the connection terminal blocks could be mis-segmented, or incompletely segmented. Although the IoU of the segmentation of the connection terminal block is lower than 89.6%, the accuracy of the number counting ranges from 88.9% to 94.7%, for the proposed Sub-Region Closer-Neighbor algorithm.

The segmentation of the metering compartments is implemented by Mask-RCNN network in the RGB images. The shape and structure features of the metering compartment are identical in the metering cabinet. Sometimes, occlusion or incomplete image acquisition occur due to the different shooting angles. These will influence the segmentation accuracy. In spite of these influences, the number counting accuracy of the metering compartment is still above 97.5%. In the number counting algorithm, as long as the object is classified as the metering compartment, the number of metering compartments is counted. This will reduce the influence of occlusion. Based on the critical component segmentation and number counting, the type of metering box is identified. The detection accuracy is above 92.3%.

### C. Experimental Results of Automated Size Measurement for Low-voltage Metering Box

The size and structural design of the low-voltage metering boxes should fully consider the layout of the components and the functional requirements of the appearance.

According to Enterprise Standard Q/GDW 11008-2013 "Technical Specification for Low-Voltage Metering Box" [23], released by the State Grid Electric Power Co., Ltd., the component sizes of the low-voltage metering boxes should meet the enterprise standard, and the size errors should be within a certain range. Size inspection is required over the whole life of the metering box, including the manufacture, transportation, on-site installation, and daily usage.

1) *Quantitative metrics for size measurement:* In this work, an automated size measurement method is presented, to automatically detect the size of the door shell, door window, and metering compartment in the cabinet.

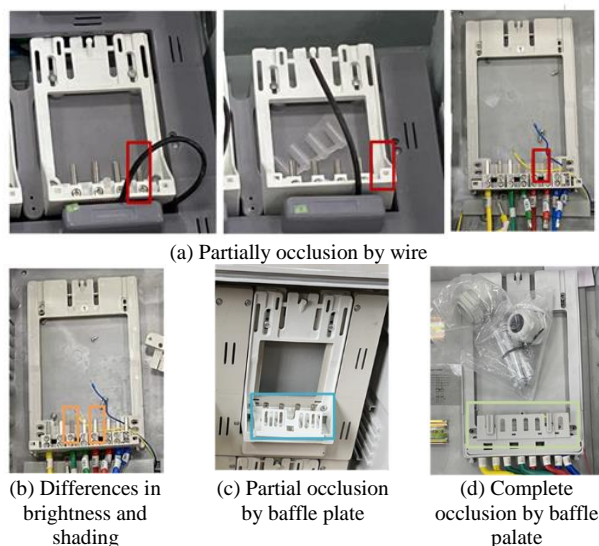

Fig. 8. The situations which affect the detection accuracy of connection terminal blocks.

The critical components are segmented by using the Mask-RCNN network in the RGB images. The edge correction algorithm based on the Depth Difference (Dep-D) Constraint is proposed in this work. The refinement algorithm uses the information in the depth-channel. Based on the refined contours of the components, the size is measured based on the proposed Equal-Region Averaging algorithm.

The precision of the proposed size measurement algorithm is indicated by the following metric:

$$p = \begin{cases} \text{ture}, & \text{error} < \alpha \\ \text{false}, & \text{error} \geq \alpha \end{cases} \quad (17)$$

If the average calculation error is within  $\alpha$ , then this measurement result is correct.

2) *Experimental results for size measurement:* In the Enterprise Standard Q/GDW 11008-2013 "Technical Specification for Low-Voltage Metering Box", it is stipulated that the size error of the metering box shell should not exceed 5mm. This work set the  $\alpha$  as 5mm, 4mm, 3mm, and 2mm. The experimental results are shown in Table IV.

As shown in Table IV, the accuracy of the size measurement is 92.6%, when  $\alpha$  is set to 5mm. When the  $\alpha$  is set to 2mm, the detection accuracy is still above 85%.

In this work, three critical components need to be measured, which are the door shell, door window, and the metering compartment in the cabinet. The regions of these components are segmented in the RGB images using the Mask-RCNN network.

For the Intel Real Sense depth camera, the RGB image is aligned with that in the depth image. The spatial location information of the object is acquired in the depth channel. The Intel RealSense D415 camera is used to capture depth data by projecting an infrared laser pattern onto the scene, and measuring how it is reflected back to the camera's sensors.

TABLE IV. RESULTS OF AUTOMATED SIZE MEASUREMENT FOR THE CRITICAL COMPONENTS OF LOW-VOLTAGE METERING BOX (%)

Type of metering box	Component	Measuring Accuracy			
		$\alpha_1$	$\alpha_2$	$\alpha_3$	$\alpha_4$
Single-phase single-meter	DS	94.3	93.5	90.6	90.3
	DW	90.1	88.4	86.4	85.1
	MC	94.3	91.5	89.6	87.3
Single-phase four-meter	DS	93.2	92.7	91.2	90.9
	DW	93.7	92.3	91.9	91.2
	MC	91.4	91.5	90.3	89.4
Single-phase six-meter	DS	95.2	92.5	90.6	89.5
	DW	94.2	92.7	91.3	89.4
	MC	90.5	89.3	88.5	87.5
Single-phase nine-meter	DS	94.3	92.5	91.6	90.1
	DW	92.2	91.8	89.3	87.6
	MC	95.3	92.3	90.5	88.1
Three-phase single-meter	DS	93.3	91.5	89.6	88.3
	DW	93.4	91.5	89.3	85.6
	MC	94.8	92.5	92.5	86.7
Three-phase two-meter	DS	93.6	92.5	91.8	89.9
	DW	91.5	90.3	89.1	88.3
	MC	93.1	92.5	90.2	89.5
Average measuring accuracy:		92.6% ( $\alpha_1=5\text{mm}$ )	91.8% ( $\alpha_1=4\text{mm}$ )	90.4% ( $\alpha_1=3\text{mm}$ )	87.5% ( $\alpha_1=2\text{mm}$ )

Component DS: Door Shell, Component DW: Door Window, Component MC: Metering Compartment

The segmented contours in the RGB images are used as the initial borders in the depth images. Then, the proposed edge correction algorithm based on the Depth Difference (Dep-D) Constraint is applied. This border refinement algorithm considers the depth difference between the outside and inside of the border. The actual contour is estimated after iteration, by balancing the gradient on the border.

#### D. Comparison with State-of-the-art Methods

In this work, a method is proposed to classify six types of low-voltage metering boxes. In this section, the proposed method is compared with state-of-the-art methods: the VGG [30], YOLO [31-32], EfficientDet [33], and ResNet [34-35] networks.

The VGG network comprises of different variants of convolutional neural networks, stacking multiple convolutional layers with small-sized convolution filters along with max-pooling layers [30]. The YOLO network uses a single convolutional neural network to predict both object class probabilities and bounding boxes directly from full images in one go [32]. The EfficientDet network applies a compound scaling approach to optimize both model architecture and input resolution [33]. The ResNet network solves the problem of vanishing gradients in the deep neural networks by using residual connections that allow the network to pass information directly from the input to the output [34]. All of these above networks have been widely used on various image classification tasks. Table V shows the comparison results.

TABLE V. RESULTS OF AUTOMATED IDENTIFICATION OF SIX TYPES OF LOW-VOLTAGE METERING BOXES (%)

Type of metering box	VGG [30]	YOLO [31-32]	EfficientDet [33]	ResNet [34-35]	Ours
Single-phase single-meter	73.4	69.3	75.2	80.4%	<b>92.3</b>
Single-phase four-meter	81.4	89.2	83.2	90.2%	<b>96.8</b>
Single-phase six-meter	80.5	85.2	79.3	82.9%	<b>93.6</b>
Single-phase nine-meter	85.7	90.1	89.2	91.4%	<b>95.7</b>
Three-phase single-meter	71.5	73.5	78.9	75.2%	<b>92.5</b>
Three-phase two-meter	87.4	86.4	92.5	84.5	<b>93.1</b>

As shown in Table V, our proposed type identification method achieves the highest classification accuracy. The classification accuracies for six types of low-voltage metering box are above 92.3%.

The state-of-the-art networks achieve the classification accuracies ranging from 69.3% to 92.5%. For these networks, the metering box images with labels are input to the networks, to implement a six-type multi-class classification task. The dataset tested in this work includes a total of 732 images, which could lead to overfitting, where the model becomes too specialized to the training data.

Although the metering compartments are notable features in the images, the type of the metering boxes need to be decided by the number of metering compartments and connection terminal blocks at the same time. The detection of connection terminal blocks is more difficult, due to their shapes, sizes, colors and locations. The misdetection of connection terminal blocks could lead to the wrong classification of metering box types.

Our proposed method considers many factors in the type identification task. The proposed Sub-Region Closer-Neighbor algorithm could count the number of connection terminal blocks in scenarios with complex illumination and occlusion.

#### IV. CONCLUSIONS

The low-voltage metering box is one of the most crucial pieces of equipment in a power system network. In this work, a metering box identification system based on the computer vision techniques is studied to realize automated detection of the appearances and structures of metering boxes. An automated type identification and size measurement method for the low-voltage metering box is proposed.

The following are the main steps of this proposed method. The critical components, including the door shell and window, connection terminal block, and metering compartment in the cabinet, are segmented first using the Mask-RCNN network. Then the proposed Sub-Region Closer-Neighbor algorithm is used to estimate the number of connection terminal blocks. Combined with the number of metering compartments, the type of metering box is classified. To refine the borders of the metering box components, an edge correction algorithm based on the Depth Difference (Dep-D) Constraint is presented.

Finally, the automated size measurement is implemented based on the proposed Equal-Region Averaging algorithm.

The primary contributions of this study are as follows. Firstly, the proposed Sub-Region Closer-Neighbor algorithm enables a more precise estimation of the number of connection terminal blocks, which is an essential parameter for the type identification of a metering box. This results in higher classification accuracies when compared to existing deep learning methods [30-35]. Secondly, to obtain more accurate size measurements, an edge correction algorithm is proposed. Then the automated size measurement is implemented based on the proposed Equal-Region Averaging algorithm.

There are two primary challenges in this study. The first is the occlusion of the connection terminal block, which leads to incorrect classification of the metering box type. The second challenge is the limitations of the depth camera, which introduces errors in size measurement. While this study proposes solutions to overcome these challenges, there is a need for further work to enhance detection and measurement accuracy.

One drawback of this article is that it involves numerous calculation steps, making the calculations complicated. Furthermore, in order to capture both segmentation and depth information, the system requires the processing of both RGB and depth images. In future research, it may be worthwhile to explore algorithms that can accomplish automated inspection using depth-images exclusively.

In the future, the improvement of automation level is a development trend in the power system industry. Compared with manual inspection, which can be time-consuming and labor-intensive, the integration of artificial intelligence technology in this field can significantly reduce costs, enhance overall efficiency and optimize resource utilization.

**Abstract**—The paper highlights the importance of using data-driven decision-making tools in Higher Education Institutions (HEIs) to improve academic performance and support sustainable development. HEIs must utilize data analytics tools, including educational data mining, learning analytics, and business intelligence, to extract insights and knowledge from educational data. These tools can help HEIs' leadership monitor and improve student enrolment campaigns, track student performance, evaluate academic staff, and make data-driven decisions. Although decision support systems have many advantages, they are still underutilized in HEIs, leaving field for further research and implementation. To address this, the authors summarize the benefits of applying data-driven decision approaches in HEIs and review various frameworks and methodologies, such as a course recommendation system and an academic prediction model, to aid educational decision-making. These tools articulate pedagogical theories, frameworks, and educational phenomena to establish mainstay significant components of learning to enable the scheming of superior learning systems. The tools can be utilized by the placement agencies or companies to find out their probable trainees/recruitees. They can help students in course selection, and educational management in being more efficient and effective.

**Keywords**—Business intelligence; data analytics tools; decision-making framework; decision-making support systems

## I. INTRODUCTION

Assuring the high quality of the offered educational services is among the main goals of all higher education institutions (HEIs). Nowadays, many HEIs receive funding according to the number of students and the research activity. This necessitates continuous monitoring of the activities and management decisions that guarantee quality education of the educational services provided in HEIs [1-2]. HEIs' management bodies must make daily decisions to follow the institutions' strategies and achieve the set goals. This management context in higher education requires adequate and reliable support for making management decisions [1]. Higher education management is progressively realizing the priority of accurate and available information that endorses both basic operations and long-term strategic planning [3]. For this reason, many modern universities are searching for ways to improve their traditional management processes and solve the challenges linked to them.

Recently, HEIs have become increasingly dependent on data collection, storage, and processing [4]. Contemporary HEIs use software systems to automate their activities, e.g.

student information systems, learning management systems, human resource systems, scientific activity reporting systems, and have rich data sets from external systems (registers, databases with scientific information, etc.) that can support management decisions to improve ongoing processes. The collected data has no real value if HEIs' leadership does not realize the strategic significance of the data and does not extract information from the data to make data-driven decisions.

It is very difficult for HEIs' leaderships to find the accordant information required for the decision-making when there is a plethora of systems [3]. Data collection and analysis require human resources involvement and manual perusing of ceaseless data streams. In addition, the presented data does not provide information about the HEI's current state of play and should be analysed again any time when HEI's manager needs up-to-date data. This leads to the increasing interest of HEIs' leadership in using collected and analyzed data to support decision-making [5-6]. They are trying to apply new strategies and solutions for extracting data from software systems and turning it into knowledge that supports ongoing processes' optimization, management and improvement in all major areas [2, 7-9] and can be used to inform strategic decisions at all organizational levels.

The last requires investments in appropriate technologies which support all management processes [10], e.g. incl. semantic and linked-data technologies, Educational data mining, Learning analytics and Academic analytics, Business intelligence [11]. Data analysis tools allow automatic data extraction, analysis and classification from different systems [12]. They allow HEIs' leadership to track and analyse trends and KPI performance through intuitive dashboards [13-14] presenting summarized information in graphical form (charts, tables and measurement graphs [15]) and find hidden patterns in the data, trends or anomalies [16]. The resulting information helps HEIs' leadership manage the institution more effectively, measure the impact of their initiatives, make strategic decisions for improving the ongoing processes [17-18], and collect evidence for informed decision-making. By leveraging such tools, HEIs stakeholders can gain insight and monitor progress over time on almost all aspects of HEIs activities, such as student performance, enrollment trends, academic productivity, career development, cost management, regulatory compliance, research activity, collect data on ongoing educational and research processes and take measures for improvement. By using software solutions to support the decision-making

process HEIs managers can offer alternative solutions [19], minimize the risk and negative impact of errors [2, 4, 20-21], increase the validity of the management decisions taken [22] and contribute to achieving sustainable development of HEIs, save time in discovering relevant information for decision-making and funds to pay experts to extract relevant information and give better insight and control over operations. Implementing and using decision-making systems in higher education reduce the cost and time needed to outline problems, complications or obstacles in higher education systems and make the best decisions [23-25]. Implementing and using decision-making systems in higher education reduce the cost and time required to outline problems and find the most appropriate solutions to distinguish complications or impediments of higher educational systems.

The integrated software system that will support academic decision-makers to make timely and right solutions is a significant step in implementing new educational policies. Implementing analytical tools to support management decision-making is a long process that often does not run smoothly. In implementing such tools, HEIs face several technological challenges and challenges related to privacy and ethical and responsible use of data [26]. Furthermore, large datasets do not necessarily guarantee better decisions [26]. The implementation process usually goes through six steps (justification, planning, business analysis, design, construction, and deployment [27]). During this process, a thorough study of the ongoing processes has to be done [11, 28], incl. the selection of appropriate data for processing, selection of solutions for data extraction and visualization, implementation of data warehouses, integration of relevant data sources, etc. In addition, HEIs leaders should consider how they can use data analytics most effectively, address privacy and security issues, how data strategies can aid informed decision-making. At the end of this process, they have to integrate analytic tools as part of the HEI decision-making structure, which demands institutional strategic planning and resource allocation to reflect its rising relevance in supporting the institution's mission. The successful admission of a data-based decision-making culture in HEI requires trained staff, technologies for data integration, data management systems, and tools for reporting, analysis, and data visualization [26].

The paper highlights the importance of using data-driven decision-making tools in HEIs to improve academic performance and support sustainable development. It also focuses on how these educational data mining tools play a major role in the holistic improvement of learners and thus aids a paradigm shift from traditional to data-driven decision making by the HEIs. Section II summarizes the benefits of applying data-driven decision approaches in HEIs. Section III reviews developed tools that support HEIs leadership in decision-making. The Section IV summarizes the approaches used. Section V outlines the limitations of the paper and opportunities for future research in the field.

## II. APPLICATION AREAS AND BENEFITS

Many studies have been conducted globally on the benefits of applying data analysis and management decision-making tools to improve processes for organizing and conducting

student candidate campaigns, student training, academic staff development, effective resource allocation, etc.

HEIs' leadership can apply data analytics tools to optimize the student enrollment process. Data analytics tools allow them to monitor and evaluate current campaign performance versus previous periods, detect enrollment trends [29], identify actions related to student attraction and recruitment [30] and allocate resources for marketing campaigns. Modern analytical tools help the HEIs' managers to monitor the current candidate enrolment campaign and make informed decisions to optimize and improve the process of recruiting students, conduct a targeted marketing campaign based on data on the interest of prospective students in previous years and improving strategies for attracting suitable students and managing the enrollment process for future campaigns. Detailed analysis shows how well the institution is performing, and HEIs' leadership can use the results to identify key trends that could affect the overall success of HEIs' admissions.

Data analytic tools deepen the awareness of HEIs' managers of students' success rates and allow them to track trends over time [31]. The governing bodies have access to aggregate data for students' achievements, which allows them to monitor students' progress [24], identify at-risk students [24, 32] and predict graduation rate [33-34]. They can use this summarized information to identify the reasons for low graduation rates, develop intervention plans [32, 35-37], and improve students' completion rate [38-40]. Tools allow managers to identify the most effective and desired programs [33], to take measures to increase the quality of learning resources and training [41-43].

Data analytic tools can support HEIs' leadership in monitoring research activity and making informed decisions to stimulate it based on the summarized data from university systems, online libraries and databases. HEIs' leadership and people who are responsible for monitoring research activity can make comparisons between the achievements of teachers (e.g. published books and articles, citations, research grants and awards) at different levels (university, faculty, department) over different periods and based on the results to give recommendations to scientists to improve their research activities.

Data analysis and decision support tools make it easier for universities to deal with one of the most frequent obstacles continuously faced in the decision-making process – the selection of human resources. This process is significant for any HEI and determines its future stability and development. HEIs' managers can apply the tools to identify and differentiate candidates' personal and professional qualities [10] and to predict their advancement and performance determined for different occupations and hierarchy levels [10]. Based on generated reports on the structure of the academic staff and the free hours in separate units, the governing bodies can make informed decisions about announcing competitions for the development of the academic staff. Such tools help managers to improve the selection process [40, 45] and evaluate teachers' work, to select the most appropriate teacher for a new course based on course content and academic staff qualifications [10]. In addition, HEIs' leadership can make decisions to stimulate

teachers to update curricula, learning resource and change teaching methods [46-48] and thus, to provide students with a better learning environment and enhance the quality of training [34].

Data analytics tools enable HEIs' managers to create and distribute various reports, incl. HEIs' annual performance reports with meaningful summarized historical data. Such annual reports assist managers to answer tactical questions for making data-driven decisions across all departments and divisions [31, 49-50] and determine whether measures are effective and sustainable.

HEIs' leadership can analyze and manage big data to provide transparency in management, predict future outcomes and identify potential problems [31]. In addition, HEIs' leadership can use data analytics tools to make the data-driven decision for cost reduction [40] and allocate resources more efficiently [43, 46-47, 50], meet the desire for accountability for internal and external stakeholders [51] and policymaking [52].

Data analytics tools allow stakeholders to conduct extensive education analysis and share findings across HEIs. From this point of view, HEIs' managers can use data analysis tools to monitor and improve the performance indicators and create a competitive strategy to increase the HEI rank among competing institutions [53].

HEIs' leaders understand that implementation of data-driven decision support tools can significantly transform how they work, enabling new ways to increase student enrolment, improve the quality of educational services, and increase the productivity of teachers and researchers. The proof of this is the large number of successful examples of implementing data-based decision-making solutions in various aspects of HEIs' activities. HEIs' leadership is applying data analytics tools to identify at-risk students and reduce drop-out rate [3, 54-59], provide better feedback [60], identify effective teaching strategies [32], track student engagement and predict student success [32, 56, 61-63], improve student success and graduation rate [61, 64-68], improve HEI evaluation results [61], outline realistic targets to strategically tackle inefficiencies and solve declining student enrolment problems [56]. There are also examples of successful experiments for using data analysis tools to help HEIs' leadership make data-driven decisions on quality assurance, improving institutional processes and student achievement, and reducing drop-outs [69-72].

### III. APPROACHES AND TOOLS

Today, HEIs use decision-making support systems to deal with various challenges, but their use is still partially implemented. According to Mora [1] there is still potential to utilize them at HEIs and corresponding knowledge gaps need to be studied further. The results of a study conducted [84] show that HEIs in developed countries are ready to deal with globalization and take steps towards implementing digital solutions to improve university processes.

Mansmann and Scholl [73] have presented a methodological approach that enables the assessment of educational capacity and the planning of its distribution and

usage. They have also developed a decision support system that allows simulation and evaluation of different proposals and scenarios based on this approach. The system is designed to integrate input data from various sources into an autonomous data warehouse, extract meaningful details and dependencies from the data, and present them to decision-makers in an appropriate format. By utilizing this system, policymakers can expedite planning procedures, gain deeper insights into the data and the methodology, and ultimately improve academic administration efficiency.

Bresfelean and Ghisoiu [7] propose a system supporting decision-making about teaching, research, curricula, examination materials and procedures. The system has three main modules – Students, Teaching and Research. The modules extract and process data from university systems and databases, including a research activity management system, a library system, administrative systems (financial, accounting, etc.), management of school records application, web-based grade book, fee management application, distance education portal, e-mail, research management application, periodic academic quality assessments, research and teaching staff evaluations, surveys of PhD students and graduates, etc. The results from the data processing can be used for quality assessment, analysing the organization's practices, and making decisions on management issues.

According to Olsson [74], business intelligence tools are of great use for managing a HEI. The GLIS tool informs top-level governing bodies about the annual planning and reporting process. It also can be used by governing bodies at different levels for handling the admissions process, planning student intake, subsequent analysis of educational programs and bibliometric analysis of publications data.

Şuşnea [4] develops an intelligent support system for decision-making which increases the efficiency of academic processes. The system includes three integrated sub-systems: a sub-system for data management necessary for training the models (data on graduates, students, academic and non-academic staff, faculties, financial resources, educational resources, and e-learning), a sub-system for generating and managing models based on data from the data management sub-system and data extraction through data mining techniques and analytical tools, and user interface. The system provides users with access to data from many sources and the ability to choose a data aggregation level. In addition, it assists the decision-makers in monitoring, modelling and predicting the quality of higher education and contributes to knowledge transfers and collaboration between institutions interested in quality assurance.

Denley [75-77] created a system which suggests what sequence of courses a student should take to enhance his/her success. The Degree Compass system is based on an algorithm which instead of taking the student's choices and preferences, relies on grade and enrollment data. After retrieving all records of student attributes, enrollment choices and grades received, the system ranks the courses based on the chance of successful completion. Furthermore, the algorithm uses the same approach to design a pattern (i.e. the sequence of courses) and predict student's assessment in each course. A straightforward

web-based interface, that gives students access to the ranking results, indicates the intensity of recommendation for different course combinations by designating stars (1 to 5). The algorithm that evaluates the courses also reflects on the decisions that students have already made, particularly about their major and prior exams. By analyzing huge datasets to produce predictions about the courses that are most likely to promote student success, the MyFuture add-on module offers details on degree paths and the transition between the HEI and the workforce.

Sarker [78] explored the applicability of the Linked Data technique to promote student retention, progress, and graduation. Two experiments were conducted with the developed academic prediction model – to predict the probability of students being at risk of dropping out and to predict students' academic performance/grades by using readily available data from internal institutional sources/data repositories and external open data sources.

In their work, Fulantelli [79] introduces a framework for mobile learning that facilitates educational decision-making by considering the connections between different types of interactions that occur during mobile learning activities and the relevant pedagogical tasks for each activity. To demonstrate how the framework may be used in mobile learning contexts, they produced a case study.

Lei et al. [80] propose a decision-making framework for educational institutions that aims to improve educational decisions and quality through following student development. The framework contains a student development system, educational data mining, and a decision process. Based on extracted data on student development, the framework supports decision-making to promote it.

Karlstad University invests in business intelligence solutions to help governing bodies find concerning financial, human resource and educational matters. The KULI tool [81] has sections for presenting pre-made and customized information presentations. The pre-made presentation allows monitoring of the budget based on historical economic data, planning of the recruitment process based on the age distribution among the staff data, and supporting the capacity planning process (number of classrooms, number of teachers) based on the data for study programmes and courses. The Custom Information Presentation module allows users to process and adapt data to extract the personalized information they seek.

Cadme and Piedra [82] use a Linked Data technique to explore scientific activity and help universities incorporate scattered teacher-researcher production into the network, form scientific networks, discover potential priority areas where legislators can help formulate science and technology policies.

Indrayani and Pardiyono [83] developed a system that helps future students to choose a HEI based on criteria from a service quality model. The system generates an ultimate decision according to a number of criteria (reliability, responsiveness, assurance, empathy, and tangibles) by using an analytical hierarchy process. Such a process has been used in developing

other decision-support systems for educational environments [84].

Komleva et al. [85] developed a decision support system that automates the data collection process from conducted surveys. The system architecture allows working with different fine-grained data sets, which is a prerequisite for the constant development of the system.

Piri et al. [86] use visual information to support the decision-making process. They form the KPIs through structured interviews with 30 people in management positions in the HEI. After analyzing the results, they organized 85 KPIs in the digital dashboard. The developed system has a three-layer architecture – user interface, business layer and database layer. The dashboard utilizes a combined dataset from the learning management, e-learning, accounting and research information systems. The dashboard allows executives to apply filters to view different results and charts. Visualized information helps academic managers identify trends, strengths and weaknesses and make decisions as quickly as possible. In this way, they can improve the quality of all university services, track the university's performance in national and international rankings and conduct advertising campaigns to attract students and PhD students.

Chitpin [87] proposes an Objective Knowledge Growth Framework (OKGF) that helps managers make more effective decisions in solving practice problems. The OKGF framework can improve institutional performance and increase student achievement.

Alisan and Serin [88] propose a decision support system that maintains the quality and positioning of departments and courses offered. This system works in three steps – collecting Internet data by using web scraping methods, converting it into meaningful and processable information using natural language processing methods, and ranking the alternatives using multi-criteria decision-making methods. The suggested system provides useful information to various stakeholders – universities, teachers and students. The qualities of the proposed decision support system in terms of application and reliability are demonstrated by conducting information extraction experiments on computer engineering job postings and university course content in Turkey.

Ashour [44] offers an educational ontology that governing bodies can follow when selecting the most appropriate and qualified teacher for a new course. The ontology summarizes the long steps of mapping course content and faculty member profiles. In a subsequent study, Ashour [10] proposed a solution to support the selection process through the Linked data. They apply the technique to generate a link between university semantic data and research data from online libraries. The Linked Data generation methodology has three steps – initialization (selection of local data source and university ontology, selection of external data source, specification of the linked data set), innovation (identification of restrictions and writing of linkage rules), validation (publication and evaluation). The proposed solution is tested at King Abdulaziz University.

Tadić, Marasović, and Jerković [87] have created a fuzzy multi-criteria decision support model for appointing research and teaching staff in HEIs, which is based on the technique for order preference by similarity to ideal solution (TOPSIS). The model uses both quantitative and qualitative selection criteria, as well as the competencies of experts, in a hierarchically structured manner. The authors have successfully applied this model to the selection of teaching and research staff in higher education institutions in Croatia.

Prasetyo [2] designed a decision support system for determining the HEI's resource need. The system comprises three sub-systems for managing model, data and user interface. The system manages the model base that stores the mathematical model (sessions, estimates of the number of new students, financial income, financial expenses, educational and student operational costs) and result values. By altering the data for the number of lecturers, classrooms, students and guest lecturers, the simulation's outcome value may be determined. Simulation models help management identify problems and use the results to support decision-making.

Makki et al. [90] proposed an admission/decision support system for capacity planning based on a framework for student enrollment and HEI admission.

Du [91] used a decision support system to improve the curriculum. The system uses mobile learning technologies to analyze students' feedback at the end of training. The resulting dataset is used as input to the fuzzy logic system for analysis. The experimental results indicate that the mobile learning technology combined with the fuzzy logic system offers a more effective approach for decision-making analysis related to curriculum optimization for both students and teachers.

To address the challenges of European mobility programs that seek to involve students with multidisciplinary competencies, Teixeira, Alves, Mariz & Almeida [92] have developed a decision support system for selecting students for short-term Erasmus+ mobility. The researchers utilized an analytic hierarchy process based on a four-layer model that collects information about the specifics of each project and student profile and promotes greater inclusion and homogenization of project teams. They tested the proposed system with 6 test scenarios, and the results demonstrate that the proposed model can be applied with various selection criteria among students and consider their hard and soft skills. The system can support decision-making to build project teams where students' knowledge is aligned with the technical skills required to complete the projects.

Gaftandzhieva, Doneva and Bliznakov [93] propose software tool for monitoring the career designed for different stakeholder groups (faculty staff, members of quality committees, head of departments, top and middle management) having a role in stimulating career paths in academy. The AcadStaffAnalyst tool allows them to monitor the career development of the faculty staff based on the 68 quantitative indicators divided into 7 groups (Acquisition of scientific degrees, Occupying scientific positions, Occupying management positions, Publishing activity, Projects activity, Activity in scientific events, Gender gap) and make data-informed decisions to stimulate career paths, ensure equal

access to options for career growth, set priorities and adjust them when the situation allows it. The tool can generate self-assessment reports with data for the faculty staff for the need of accreditation procedures. Indicator values are obtained by extracting and processing data from human resource systems, academic staff development systems, and research reporting system.

To help university decision-makers make decisions to increase retention rate and improve student success rate Gaftandzhieva, Doneva and Bliznakov [94] offer a tool for monitoring student success from. The StudAnalyst tool allows programme managers, deans and rector to monitor 42 quantitative indicators divided into 3 groups (Student success during the training, Student success in graduation, Gender gap) and generate reports for each indicator with retrieved values when s/he wants to see the current situation in the faculty/university depending on its user role. The tool can also generate such reports automatically following the predetermined schedule and store them in its repository. Reports contain summarized data visualized in tables and diagrams and help users to perform various analyses and make data-informed decisions.

#### IV. DISCUSSION

Studies cited in this paper show that data-driven decision-making tools can improve decision-making in HEIs. HEIs are complex organizations with multiple stakeholders, making decision-making a challenging task. By using data-driven decision-making tools, HEIs can make more informed decisions leading to better performance, higher student achievement, and increased competitiveness of departments and courses offered.

One of the approaches proposed to support decision-making is using decision-support systems. Such systems can collect data from various sources, analyse the data, and present the results in a meaningful format to different stakeholders. The studies by Alisan and Serin [88] and Prasetyo [2] proposed decision support systems for capacity planning and determining the need for higher education resources, respectively. These systems can help management identify problems in operating systems and use the results to support decision-making.

Another approach proposed is the use of fuzzy multi-criteria decision support models. The study by Tadić et al. [89] developed a fuzzy multi-criteria decision support model for research and faculty staff in HEIs' appointments based on the technique for order preference by similarity to the ideal solution (TOPSIS). The model uses hierarchically structured quantitative and qualitative selection criteria and the competencies of the experts. The proposed model, which refers to a specific set of rules and procedures, has been implemented for the purpose of choosing faculty members who will be involved in both teaching and research activities in Croatia. This process likely involved analysing various factors such as educational qualifications, research experience, and other relevant criteria in order to make informed decisions about the candidates most suitable for the job.

The studies by Ashour et al. [10, 44] proposed educational ontology and linked data techniques to support the process for selecting the most appropriate and qualified teacher for a new course. The ontology summarizes the long steps of mapping course content and faculty member profiles, while the linked data technique generates a link between university semantic data and research data from online libraries.

Finally, the study by Du [91] used a data-driven decision support system to improve the course curriculum. The system uses mobile learning technologies to analyze students' feedback at the end of training. The dataset of student responses is set as input to the fuzzy logic system to perform the analysis. The results of experiments showed that mobile learning technology with the fuzzy logic system offers improved decision-making analysis for curriculum optimization for the student and teachers.

In conclusion, the studies reviewed in this article demonstrate the potential of data-driven tools to support decision-making in HEIs. By using these tools, HEIs can make more informed decisions leading to better performance, higher student achievement, and increased competitiveness of departments and courses offered. Further research is needed to determine the most effective tools and approaches for supporting decision-making in HEIs.

Table I presents a summary of the reviewed tools. The "Data Sources" column contains a brief description of the source types, as mentioned in the references. The "Users" column refers to the intended audience for each tool. The "Purpose" column provides a concise statement of what problem the tool is designed to solve.

TABLE I. SUMMARY OF THE RELEVANT TOOLS

Authors & References	Data Sources	Users	Purpose
Mora et al. (2017) [1]	Various data sources	Higher education institutions' (HEIs) managers and decision-makers	Provide open opportunities to apply decision-making support systems in HEIs

## V. CONCLUSIONS

HEIs are complex organizations that require effective decision-making to improve performance and increase competitiveness. This article reviewed several studies that proposed data-driven tools for supporting decision-making in HEIs. The studies proposed decision-support systems, fuzzy multi-criteria decision-support models, educational ontology, linked data techniques, and mobile learning technologies to analyse student feedback.

The studies showed that data-driven decision-making tools are able to support decision-making in HEIs. These tools can help management identify problems in operating systems and use the results to support decision-making. The studies also demonstrated that HEIs' leaders could use different approaches to support decision-making, incl. decision support systems, fuzzy multi-criteria decision support models, educational ontology, linked data techniques, and mobile learning technologies.

Overall, the studies reviewed in this article highlight the importance of data-driven decision-making in HEIs. By using these tools, HEIs can make more informed decisions leading to better performance, higher student achievements, and increased competitiveness of departments and courses offered.

The cited works highlight that data-driven decision-making methods can support decision-making in HEIs. However, HEIs need to consider certain limitations when applying these methods. One limitation is the lack of quality data. Much data collected in HEIs can be inconsistent, incomplete, or unavailable. Therefore, it is significant to ensure HEIs collect relevant and reliable data. Another limitation is the difficulty in identifying the right questions to research. To successfully apply data-driven decision-making methods, it is significant to identify the right questions for research. This requires knowledge of the decision-making process and specific challenges that HEIs face.

Data-driven decision-making methods have many areas of application, including analysis of student feedback, monitoring of student success, identification of trends in course selection, and optimization of resource management. They also help the companies in the campus placement and help all the stakeholders of the education system at one go. Despite their wide application in various fields, these methods should be adapted to the specific HEI's needs.

Given the limitations and application areas, further research is needed to determine which tools and approaches are most effective in supporting decision-making in HEIs.

**Abstract**—Face detection and localization has been a major field of study in facial analysis and computer vision. Several convolutional neural network-based architectures have been proposed in the literature such as cascaded approach, single-stage and two-stage architectures. Using image segmentation based technique for object/face detection and recognition have been an alternative approach recently being employed. In this paper, we propose detection of faces by using U-net segmentation architectures. Motivated from DenseNet, a variant of U-net, called Semi-Dense U-Net, is designed in order to improve the binary masks generated by the segmentation model and further post-processed to detect faces. The proposed U-Net model have been trained and tested on FDDB, Wider face and Open Image dataset and compared with state-of-the-art algorithms. We could successfully achieve dice coefficient of 95.68% and average precision of 91.60% on a set of test data from OpenImage dataset.

**Keywords**—Semi-Dense U-Net; face detection; segmentation; U-Net

## I. INTRODUCTION

Face detection deals with the localization of face in a given image. At the outset, detection process takes an input image containing one or more faces, applies a detection and localization model and produces a confidence score and a set of bounding-box parameters containing the coordinates of the face and its dimension. Face detection being the first phase in face analysis, the detected face is subjected to facial analysis process for machine learning and computer vision applications. Over decades, several algorithms have been proposed using a variety of approaches to detect faces in the image for diverse applications addressing uncontrolled illumination, scale variance, rotation in plane, occlusion, low quality image, large and tiny faces, masked faces, faces with makeup etc. These algorithms are designed to address a subset of these issues but no algorithm can address all the issues.

A variety of face detection techniques for computer vision applications can be found in the literature. Several new techniques and approaches have been explored at a great extent in the literature, each approach trying at its maximum

to address a selected subset of the issues in face detection using the available dataset. Over time, the complexity of the face dataset has widened considerably covering very high- and low-resolution images and with facial features that has laid challenges in achieving good detection rate and further promoting development of new algorithms to address the issues. Early work on face detection dates back to 1992 in [1], that used artificial neural networks. However due to the limited computational and storage resources, it did not gain considerable attention. In contrast to traditional algorithms, capability of convolutional neural networks (CNN) to learn features from its input has led to a number of recent advancements in the field of face detection using CNN. With improved computing power through GPU and now TPU's, there is more scope for research promoting construction of complex models for AI based applications. CNN architectures have made it possible today to learn complex features from large and complex datasets. Several novel architectures such as AlexNet [2], VGGNet [3], GoogLeNet [4], ResNet [5], DenseNet [6], DarkNet [7] and its variants have been used as backbone network for feature extraction. This has improved the performance of face detection frameworks over time.

Figure 1 shows a face detection process used in our work. The input color image of any scale is subjected to preprocessing, that scales down the input image to a standard size of 256×256 or 512×512. In our work, three U-Net architecture variants are used, each trained with three standard datasets. The outcome of feature extraction is a binary feature map/mask representing the segmented image, as shown in the figure. As the network output does not always produce a very fine and sharp segments, it is further refined to generate sharp rectangular regions suitable for detection of bounding box in the final step.

The remainder of the paper is organized in the following manner. Section II presents some of the prominent face detection architectures, U-net segmentation architectures and its variants used for various applications, Section III presents the proposed architectures, Section IV highlights on implementation details with the experimental results and Section V summarizes with conclusion.

Fig. 1. General model of proposed face detection architecture. The first binary image (at bottom) is the model output and second is output of post-processing module.

## II. RELATED WORK

CNN segmentation architectures are being used for several applications, such as, for medical images [8][9], object and instance segmentation such as Mask-RCNN [10], video object segmentation [11] to name a few. It however has been used to segment the entire region of the object and can be extended to recognition applications. U-Net [8] is one such neural network architecture designed for biomedical image segmentation. Its U-shaped network consists of an encoder CNN that gradually reduces the spatial size of the input image while increasing the number of feature maps to retains high-level contextual information and a decoder section that reconstruct the segmentation map by gradually increasing the spatial size of the features and concatenating them with the corresponding features from the encoder part using skip connections for precise localization information. The study [12] proposed a simplified UNet architecture for medical image segmentation. UNet++ [9] is a U-Net based architecture using nested and dense skip connections designed to improve the accuracy of medical image segmentation. It improved U-Net by adding skip pathways that connect the two sub-networks and uses deep supervision. The deep supervision module enables the model to operate in an accurate mode, where the outputs from all segmentation branches are averaged; and fast mode that selects the final segmentation map from the segmentation branches. This choice determines the extent of model pruning and speed gain. Motivated by DenseNet architecture [6], Li et al. [13] proposed H-denseunet segmentation architecture for liver and liver tumor segmentation. The study [10] is another such approach to detect faces using a segmentation architecture. Using improved Mask R-CNN, Lin et al. proposed G-Mask [14] for detection and segmentation of face that incorporates both into one framework. It used ResNet-101 for feature extraction, RPN to generate RoIs, and fully convolutional network to generate binary mask. A most recent work on U-Net can be found in [15] that segments lungs in the chest radiography images. With several recent segmentation architectures and its improvements thereof, we find them being applied in a diverse domain meaningfully able to elaborate on the semantic aspects of the problem domain to the solution space. Each architecture has tried to extract and extend the prominent features of the base architecture and inherit prominent features of other architectures to address the drawbacks in the base architectures. In this paper, our proposed architecture inherits the features of U-Net, DenseNet and ResNet to build an improved segmentation architecture that produces more accurate segmentation output and successfully applied it on a face detection problem. The

outputs observed are on par with some of the standard convolutional face detection architectures.

## III. PROPOSED ARCHITECTURES

U-Net based segmentation architectures have been widely used on medical images for disease detection and localization. In this paper, U-Net architecture is used as a base to develop an improved U-Net architecture to improve the accuracy of the binary mask generated that will be postprocessed to detect faces. Here, we use three U-Net based architectures for face detection application. The details of the architectures used are as follows:

### A. Using U-net

Our experiment uses U-Net architecture comprising of six blocks at encoder with two convolutional layers in each with the kernel size of 3, same padding, he\_normal kernel initializer, relu activation, max pooling of size 2 and a dropout of 0.2. Input to the architecture is a single channel image of dimension 512, with the corresponding training output being its binary image with masks at the face regions. Size of the feature map converges at the encoder generating 512 feature maps of size 16 and decoder upsamples it to a single binary feature map image of size 512 generating a segmented binary image for the given input. The segmented regions represent the faces predicted. The prediction may not have always a clear and sharp edge. These variations are addressed by a post-processing module that refines the prediction of segmented regions. Bounding box is then computed over the refined image.

### B. Using VGG16-Unet

Transfer learning today speeds up the training time by using pre-trained weights of a backbone network. This is experimented by using a pre-trained VGG-16 backbone network at the encoder side of U-net, configured with ImageNet dataset weights. The weights at the encoder side were configured to be non-trainable and the decoder part to be trained with the input dataset. The network is expected to learn faster as the encoder is already in possession of valuable weights. The model takes a colored image of size 512 and produces a binary segmented image of same size. As mentioned in the above model, the output is further refining using a post-processing module to improve the segmented regions. Bounding box is then computed over the refined image.

### C. Using Semi-Dense U-Net

In a general CNN, each layer produces a set of features and is forwarded to the next layer for deep feature extraction. ResNets [5] introduced a concept of skip-connections where an output can bypass the normal flow of non-linear transformations with an identity function and get combined with a layer down the network. With transition function  $H_l$  for the  $l^{th}$  layer, we can represent the result of skipped layer as:

$$x_l = H_l(x_{l-1}) + x_{l-1} \quad (1)$$

U-Net uses this skip-connection to connect between encoder and decoder. The research [6] further improved it by adding a dense connectivity between layers where each layer will be learning features from its all-previous layers. Hence the transition function will have feature maps  $x_0, \dots, x_{l-1}$ , as input. This can be formulated as

$$x_l = H_l([x_0, x_1, \dots, x_{l-1}]) \quad (2)$$

This generates a strong feature map through which each layer will be encapsulating low- to high-level feature. This architecture is referred as DenseNets. Motivated from ResNets and DenseNets, a modified U-net architecture is proposed by adding skip-connections at the encoder side that connect to layers within the encoder and dense connections at the decoder side with links from various layers at the encoder side scaled down at respective levels at the decoder side, and we name it *Semi-Dense U-Net*. Our proposed architecture uses seven blocks at the encoder side and six blocks at the decoder,

as shown in Fig. 2. Feature maps are increased progressively from 16 at the first block, B1, to 512 at the seventh block, B7.

1) *Layer structure*: Each layer is built using two convolution layers with kernel size of three, same padding, he\_normal kernel initializer with relu activation, batch normalization, max pooling of size two and a dropout of 0.2. At the encoder side, the normalized output at layer  $l$  is concatenated with feature map from layer  $l - 1$  followed by max pooling. At the decoder side, output of the dense feature scale module is a  $512 \times 512$  color image scaled down to  $8 \times 8$  with 256 channels followed by decoder network up-sampling the features back to single channel of size  $512 \times 512$ . In U-Net and VGG16-Unet model, dropout of layers B1, B2, B10, B11 is 0.1, B3, B4, B8, B9 is 0.2 and B5, B6, B7 is 0.3. Semi-Dense U-Net uses dropout of 0.1 at layers B1, B2, B12, B13 and 0.2 at all others.

2) *Dense feature scaling module*: Dense feature scaling module scales down feature maps of each upper layer to 16 feature maps using max pooling. Hence, at layer  $l$ , we get  $(l - 1) \times 16$  feature vectors. This will be later concatenated with the feature maps generated at level  $l$  along with the up-sampled feature map from level  $l + 1$  at the decoder side. More semantic information are obtained from the feature maps at deeper layers [16]. Our feature map progressively encapsulates high to low range features as we go deeper. Hence, semantic information from the dense features is extracted by using a  $1 \times 1$  convolution layer and is normalized.

Fig. 2. Semi-Dense U-Net architecture. Each pink block represents multi-channel feature map and colored blocks at the decoder, the feature maps scaled down from upper layers using BXMY module.

3) *Growth rate*: At the encoder, if the function  $H_l$  at layer  $l$  produces  $k$  feature maps, it follows that layer  $l$  has input feature-maps from layer  $(l - 1)$  and  $(l - 2)$ , where  $l \geq 0$  and  $l = -1$  representing channels from the input vector. This can be visualized in Fig. 3. It can also be observed from the Fig. 2 that block 4 and 5 carries forward a constant number of 128 feature vectors. This effectively controls the expanding parameters of the network. At the decoder side, feature maps of encoder are scaled and squeezed to a fixed number of 16 feature maps at each level, as discussed above. By limiting it to a constant value, the number of parameters of the network can be kept small. Hence, if a layer  $l$  generates  $k$  feature maps, the decoder concatenates  $2k + 16(l - 1)$  feature maps at each layer.

Fig. 3. Growth rate at the encoder side of the network.

#### D. Post-processing Module

Output of the network is an image that may contain traces of black within white predicted regions (Fig. 4 (a)). The network does not always generate a clear rectangular region. Further, there can be certain regions in the output with light traces of white pixels that are in fact false predictions. Hence the output image certainly should be subjected to post-processing to refine the predictions and eliminate false predictions. This module uses image enhancement techniques to produce a clear and sharp image, as shown in Fig. 4 (b), suitable for computing the bounding box of the predicted regions.

Fig. 4. Post-processing result. a) Model output b) Post-processing output c) Haar-like edge features.

Refinement has been experimented using two approaches: thresholding and grid-based region growing approach. With thresholding, image is first enhanced using Otsu threshold and further refined using opening morphological operation with kernel of  $3 \times 2$ px. Image is further contoured to extract boundaries of the segments. Overlapped segments are further processed to extract distinct rectangular regions out of the segmented regions and their bounding boxes. The post-processed result is shown in Fig. 4(b).

In the grid-based region growing approach, the image of  $512 \times 512$  is divided into grid of size  $4 \times 4$ . Intensity of the grid

is evaluated using  $G_{i,j} = \frac{1}{16 I_{max}} \sum I_{p,q}$ , where  $I_{max}$  is the maximum intensity of the image,  $I_{p,q}$  is the  $p, q^{th}$  pixel intensity of grid cell  $G_{i,j}$ . Based on the value of  $G_{i,j}$ , the cell is initially classified as, full-white (FW), full-black (FB) or fuzzy (FZ). Cells with  $G_{i,j} \geq 70$  are labeled as FW and  $G_{i,j} \leq 30$  are labelled as FB. Remaining are considered as fuzzy cells. FZ are further processed base on adjacency positions and haar-like features [17]–[19] to relabel them as FB/FW. Haar-like edge features (Fig. 4 (c)) are analyzed in each cell. Based on the pixel intensity proportion in the adjacent bands and its adjacency to the FW/FB, cells are labelled as FW or FB. This is then followed by contouring, extraction of boundaries and bounding box, as discussed for thresholding approach.

#### IV. EXPERIMENTS

The model is trained using TensorFlow deep learning API's on a Nvidia Tesla P100-PCIE (12 GB) GPU. For the U-net architecture, the image is initially converted to grayscale before feeding into the network. Inputs to the other two networks are color images. Feature refinement module partially uses OpenCV library for image enhancement and morphological operations. Image is preprocessed by scaling down to  $512 \times 512$ .

##### A. Training Datasets

Each model is trained and tested on Fddb, Wider face and OpenImage dataset. Fddb dataset contains 5,171 faces in 2,845 images. As Fddb dataset represents faces using ellipses, our models are trained to generate elliptical segments, as shown in Fig. 5. The post processing module extracts the elliptical regions coordinates, angle, major and minor axis. Model is tested using 10-fold cross validation and accuracies averaged. Wider face dataset contains faces with a high degree of variability in scale, pose and occlusion with images organized based on 61 event classes. Dataset randomly select 40%/10%/50% data as training, validation and testing. It contains 3,93,703 annotated faces in 32,203 images. We have used 12,880 training images to train our model and 3,226 validation images to test our model. Faces are classified as easy, medium and hard based on the face size of less than 50px, 50px to 300px and above 300px respectively. OpenImage-v6 face dataset contains 3,44,043 annotated images with 10,60,312 faces. It is classified into 3,31,627 training images (1,037,710 faces), 3,124 validation images (5,594 faces) and 9,292 test images (17,008 faces). Due to hardware resource limitations, we use 10,000 annotated training images as our dataset with 80%:20% for training and validation/testing. Model is trained to produce rectangular segments for the detected faces in OpenImage and Wider face datasets as provided in the dataset.

All models have been trained for 150 epochs with early stopping where validation loss is monitored with the patience of 10.

Fig. 5. Predicted binary mask image by the model and its corresponding image with face ellipses. Green ellipse represents ground truth and red represents prediction by the model for samples from Fddb dataset.

**B. Model Hyperparameters**

Model has been trained with adam optimizer with a constant learning rate of 0.001. Each layer is appended with batch normalization (BN) to optimize the segmentation accuracy. All the convolutional layers have been configured with relu activation function, he\_normal kernel initializer and sigmoid function at the last layer. Models have been trained with binary cross-entropy loss function for 150 epochs and batch size of 16 for U-Net and 8 for VGG16-UNet and Semi-Dense U-Net architectures. U-Net model used contains 7.7M parameters and VGG16-unet contains a total of 25.8M parameters with 11.3M trainable parameters. The proposed Semi-Dense U-Net, is optimized with only 5.8M parameters.

**C. Effect of Batch Normalization**

Models have been experimented with and without BN. Fig. 6 shows the results on two sample images drawn from wider face dataset. Fig. 6 (a) and 6(d) are the model output without BN whereas 6(b) and 6(e) are with BN. With BN, we can observe a comparatively better and sharper approximation than without BN. Further we can observe certain cloudy region at the rightmost side of the image in 6(a) leading to false positives. With BN, such regions have been eliminated in 6(b). In 6(d), it can be observed that leftmost two segments are not sufficiently predicted as a facial region, leading to false

negative. With BN, we get a better approximation of the region that is suitable to come under true positive even with an iou of 80%. Hence, BN has normalized the covariate values of the dataset and has given a better prediction accuracy. Fig. 6(c) and 6(f) show the original image with face bounding boxes obtained with BN.

**D. Evaluation on Datasets**

Table I tabulates the training and validation accuracy of the three models on Fddb, Wider face and OpenImage datasets. The accuracies observed are on par with the standard datasets. We can observe that Semi-Dense U-Net comparatively gives better accuracy than the other two. The accuracies mentioned in the table for Fddb dataset are the average accuracy over 10-fold cross validation. Fig. 7 to Fig. 9 show training and validation accuracy curves of U-Net, VGG16-UNet and Semi-Dense U-Net model on all three datasets. Training accuracy curves on Wider face dataset are projected for easy, medium and hard samples. In wider face dataset, the performance is found to fluctuate frequently for hard faces. This can be possibly due to the tiny faces in the samples. Most of the time, tiny faces are part of crowd images. Wider face dataset contains several classes of images that has crowded people. Often such faces are blur in nature, making it hard to extract detailed features.

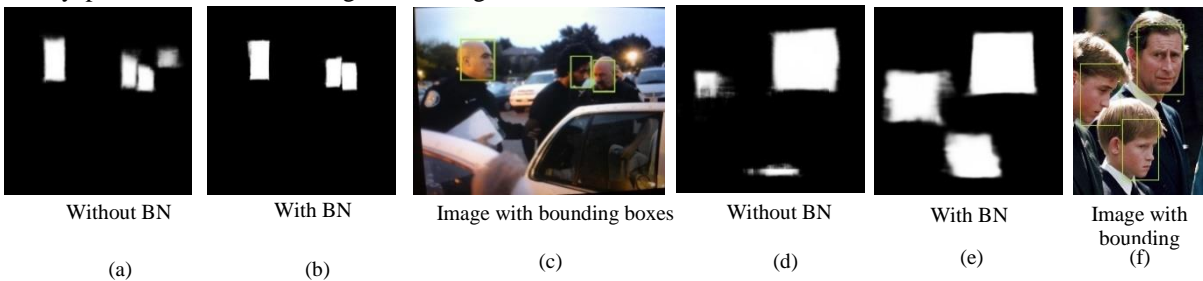

Fig. 6. Sample images projecting effect of introducing batch normalization at the end of each layer. (a), (c) without BN; (b), (e) with BN; (c), (f) Original image with face bounding box using outcome with BN.

TABLE I. TRAINING AND VALIDATION ACCURACIES OF Fddb, WIDER FACE AND OPENIMAGE DATASET

	Fddb Dataset (Accuracy in %)		Wider Face Dataset (Accuracy in %)						Open Image dataset (Accuracy in %)	
			Easy		Medium		Hard

### E. Results and Discussion

The core architecture used in this paper is based on U-Net and as discussed earlier, it is a segmentation architecture that produces image segments for regions of interest with matched features. The image segments are first extracted in post-processing module and then bounding boxes or elliptical parameters are formulated. Commonly used metrics for evaluating the performance of the segmented images are Jaccard coefficient to measures similarity between finite sample sets and is represented as  $J(A, B) = \frac{|A \cap B|}{|A \cup B|}$  indicating the ratio of intersection over union, and dice coefficient  $DC = \frac{2TP}{2TP+FP+FN}$ , a parameter to measure the test accuracy, were

TP, FP and FN represents true positive, false positive and false negative respectively and is commonly called as  $F_1$  score. Metrics precision, recall and  $F_1$  scores are computed at IoU of 0.4. Further we compare our performance with state-of-the-art face detection algorithms. Table II shows precision, recall and  $F_1$  score of the various models on the three standard datasets.

Table III tabulates the average precision of the models on FDDB and OpenImage dataset at iou's 0.4, 0.6 and 0.8. The results tabulated for FDDB are average of 10-fold cross validation. It can be observed that, at AP@40 U-Net achieves 86.5%, vgg16-unet achieves 52.8% and Semi-Dense U-Net achieves 98.97%. In contrast to the standard MTCNN that produced AP of 98.8%, Semi-Dense U-Net performed better

than MTCNN for AP@40. At higher iou, the performance of Semi-Dense U-Net is comparatively less than MTCNN but is observed to be on par with MTCNN. Comparing the performance of Semi-Dense U-Net with U-Net and vgg16-unet, U-Net and Semi-Dense U-Net performs much better than vgg16-unet. On the contrary, Semi-Dense U-Net performs much better due to better feature learning from skip and dense connections. A similar instance can be observed with OpenImage dataset where performance of Semi-Dense U-Net is on par with MTCNN and better than U-Net and VGG16-Unet. Table IV shows the average precision of the models on Wider face dataset. Comparing the results of easy, medium and hard, the proposed model performs well for easy and medium datasets but observed to perform very poorly on hard dataset. It was observed from the predictions that the model under performs for accurate prediction of tiny faces but manages to predict faces greater than 50px. A similar result can be seen in U-Net and vgg16-unet. A deeper analysis of the prediction reveals that the output of the Semi-Dense U-Net model is able to accurately predict frontal face of medium and large size and lightly blur faces but accuracy of predicting

heavily blur and occluded faces are not as expected. This has led to the degradation of the performance at various stages. Comparing the results of easy and medium, we observe model to perform better on medium than easy. The reason is due to the limited number of large faces (>300px) in the dataset compared to the medium size face samples. Hence, the model possibly had far a smaller number of images to extract diverse large size features to accurately tune the model parameters. The performance is expected to improve by training the model with a greater number of large sized face samples. Table V projects performance of state-of-the-art CNN algorithms for face detections on wider face dataset. Comparing the results of U-Net and Semi-Dense, we can infer from the results that the performance is close to each other but Semi-Dense U-Net performs better than U-Net. This is due to the better feature learning from the previous layers and better representation of the binary mask features at the model output. This enabled accurate detection of facial regions and its corresponding bounding box during post-processing at various scales making it an improvement of standard U-Net architecture.

TABLE II. PRECISION, RECALL AND F1 SCORE OF THE THREE MODELS

	FDDB dataset			OpenImage dataset			Wider face (Easy)			Wider face (Medium)			Wider face (Hard)

TABLE V. PERFORMANCE OF STATE-OF-THE-ART FACE DETECTION METHODS ON WIDER FACE DATASET

Method	Easy	Medium	Hard
Faceness [20]	0.713	0.664	0.424
ScaleFace [21]	0.821	0.818	0.701
MTCNN [22]	0.851	0.820	0.607
G-Mask [14]	0.902	0.854	0.662

Table VI (a) and (b) shows the model output for all three models and (c), (d), its corresponding detected faces for two samples drawn from Fddb dataset. We use elliptical annotations as used by the dataset. It can be inferred from the “Predictor Output” column that segments generated by U-Net are blur in nature and fails to detect some faces accurately leading to false negatives. On the other hand, VGG16-unet generates a sharper representation but fails to predict a face in (b) of the predictor output. Further, the rightmost segment of (b) has incomplete face regions. In the “Detection Results” column, face circled green are ground truth annotations and the one in red are detection by the model for the respective images in Predictor Output column. Comparatively, Semi-Dense U-Net is observed to have better accuracy in terms of prediction of face regions as well as sharpness of the segments. Several samples are observed to possess cloudy regions in the predicted image at several places in the U-Net and VGG16-Unet but are eliminated in the Semi-Dense U-net architecture.

In Table VI (e) to (h) and Table VII we observe similar outcomes for samples from OpenImage and Wider face dataset respectively. Semi-Dense U-net produces better segmentation results compared to the other two. By producing better and sharper segmented results, we can reduce the time of post-processing as it will eliminate the need for image enhancement to predict the bounding boxes. It can easily be computed over the predicted image. This proportionately will increase the overall detection speed. The average prediction time is observed to be approximately 30ms per image and post processing time is approximately 15ms. At this performance, we will be able to process around 22.22 images per second. By improving the prediction accuracy, the need for complex post-processing can be eliminated, thereby improving the computation time per image. While the prediction time is independent of the number of faces, postprocessing time varies based on the number of faces detected in the binary mask image.

## V. CONCLUSION

Segmentation architectures are gradually increasing in numbers as does its applications. Performance of the architecture is still of concern even today. In this paper, we proposed to improve standard U-Net segmentation architecture commonly used in medical image segmentation and applied it to face segmentation and human faces detection. Our proposed architecture, Semi-Dense U-Net, produces improved results compared to standard U-Net architecture. Here, feature learning is improved by introducing skip connections and dense connections at various levels. While it produced considerably good prediction results for medium and large face, the model may not be suitable for application with tiny face detection requirements. In the future work, the architecture will be further improved to detect tiny faces and will be fine-tuned to predict occluded and heavily blur faces.

# End to End Text to Speech Synthesis for Malay Language using Tacotron and Tacotron 2

Azrul Fahmi Abdul Aziz<sup>1</sup>, Sabrina Tiun<sup>2</sup>, Noraini Ruslan<sup>3</sup>

Center for Artificial Intelligence Technology, National University of Malaysia, Bangi, Malaysia<sup>1,2</sup>  
Environmental Management & Conservation Research Unit, Universiti Tun Hussein Onn Malaysia, Pagoh, Malaysia<sup>3</sup>

**Abstract**—Text-to-speech (TTS) technology is becoming increasingly popular in various fields such as education and business. However, the advancement of TTS technology for Malay language is slower compared to other language especially English language. The rise of artificial intelligence (AI) technology has sparked TTS technology into a new dimension. An end-to-end (E2E) TTS system that generates speech directly from text input is one of the latest AI technologies for TTS and implementing this E2E method into Malay language will help to expand the TTS technology for Malay language. This study involves the development and comparison of two end-to-end TTS models for the Malay language, namely Tacotron and Tacotron 2. Both models were trained using a Malay corpus consisting of text and speech and evaluated the synthesized speech using Mean Opinion Scores (MOS) for naturalness and intelligibility. The results show that Tacotron outperformed Tacotron 2 in terms of naturalness and intelligibility, with both models falling short of human speech quality. Improving TTS technology for Malay can encourage its use in a wider range of contexts.

**Keywords**—Text to speech; end-to-end TTS; Tacotron; Tacotron 2; Malay language; artificial intelligence; mean opinion score (MOS); naturalness; intelligibility

## I. INTRODUCTION

Text-to-speech (TTS) or speech synthesis technology has been under development for decades, with the goal of making a system that can turn text input into natural, expressive, and understandable human speech. Early TTS systems were built using rule-based methods, where the algorithms responsible for transforming text into speech were based on a set of linguistic rules and heuristics. As TTS research moved forward, concatenative synthesis [1][2][3] became a popular method. In this method, small pieces of speech segments were put together to make a complete sequence of speeches. Even concatenative synthesis methods worked better but requires a complex pipeline and requiring significant resources and manpower. Additionally, the synthesized audios often suffer from glitches or instability in prosody and pronunciation, leading to an unnatural sound compared to human speech. [4].

Study by [3] stated that, another traditional and yet proven way to use TTS technology is to use the Statistical Parametric Synthesis (SPSS) model to generate speech. SPSS uses less data than the concatenative model, but the sound is not natural. An example of a SPSS model is the Hidden Markov Model (HMM). With huge developments in artificial intelligence, the Deep Neural Network (DNN) method has been introduced in TTS. DNN is an improved method compared to SPSS but requires huge datasets [5]. DNN is a neural network with

multiple hidden layers; learns by mapping text and speech and then predicting the spectral parameters that define the speech signal, such as frequency and spectrum, and then generating speech from the text input.

The end-to-end TTS systems were eventually developed as researchers started to use artificial neural networks to model the complexities of human speech. By learning to generate speech directly from text inputs, these systems did away with the need for explicit rule-based systems and separate processing stages. A groundbreaking advancement in the field of end-to-end TTS came with the introduction of the Tacotron model, which was introduced in 2017 by [6].

Tacotron [6] and Tacotron 2 [7] are two Deep Neural Networks that use an end-to-end pipeline. Both use a sequence-to-sequence model, which eliminates the need for a complex feature extraction or alignment process in TTS compared with traditional TTS. Generally, both models employ an encoder-decoder architecture in which the encoder network processes the text input and generates a compact representation, while the decoder network generates the speech signal from the encoded representation. Both models can generate high-quality speech with natural prosody and intonation with a simple signal processing.

This paper focuses on implementation of end-to-end TTS for Malay language. The Malay language, a member of the Austronesian family, is one of the many languages spoken globally. [8]. The Malay language is widely use in Southeast Asia, particularly in Malaysia, Indonesia, Singapore, Brunei, and some other countries in the region. Approximately, 250 million individuals are estimated to be speakers of this language [9]. The basic writing system in Malay is based on the Rumi script and uses the Latin alphabet. Malay language consists of 26 Latin letters [5] and 25 phonemes [9]. The Malay language has a long history and has evolved over time because of its exposure to various languages and cultures. Today, Malay language plays an important role, especially in Malaysia, and it is used in a variety of contexts, such as education, government, media, and everyday communication. As a result, progress in TTS research using Malay language plays an important role in preserving Malay as a lingua franca language in Southeast Asia.

Numerous studies focusing on Tacotron and Tacotron 2 models for TTS applications have been carried out, predominantly targeting languages like English [6][7], Chinese [10], Spanish, Korean, Japanese, Mongolian [11], and Myanmar [12][13]. Yet, the exploration of these two models

for Malay language TTS applications remains relatively limited. Previous TTS research for the Malay language has not employed an end-to-end methodology.

This study pioneers the implementation of Tacotron and Tacotron 2 in an end-to-end TTS model for the Malay language, aiming to compare their performance in naturalness and intelligibility, extending beyond traditional confines to harness their potent capabilities for the unique linguistic intricacies of Malay.

This paper consists of six Sections where Section I is the introduction of this paper, Section II will discuss the background of studies, Section III will venture any related works done before, Section IV explained the proposed methodology. Evaluation and discussion is presented in Section V. In Section VI

fig , it was concluded that the Tacotron model surpassed the Tacotron 2 model in performance, though both models were still unable to match the quality of human voice.

## II. BACKGROUND

End-to-end TTS models have taken the place of outdated statistical parametric speech synthesis (SPSS) systems based on hidden Markov models (HMMs) and deep neural networks (DNN) because of advancements in deep learning techniques [14]. Previous TTS techniques involved complex pipelines and language specific linguistic features, which were resource-intensive and often resulted in unnatural sounding audio. However, the end-to-end generative TTS models like Tacotron and Tacotron 2, simplified the speech synthesis process by utilizing a single neural network for future generation [4]. This section explains how Tacotron and Tacotron 2 were built.

Both Tacotron and Tacotron 2 models start with text processing, which involves text normalization, tokenization, and character embedding. These processes prepare the input text for speech synthesis by standardizing its format, breaking it down into smaller units, and transforming it into vector representations that capture semantic and syntactic data that helps both models generate more accurate and natural-sounding speech.

### A. Tacotron

Tacotron is a text-to-speech (TTS) model that generates speech in an end-to-end manner using a sequence-to-sequence (seq2seq) framework with attention [6] which includes an encoder-decoder that uses a convolutional neural network (CNN) and a recurrent neural network (RNN) to produce linear spectrograms [11]. To convert the linear spectrograms into speech waveforms, Tacotron adopts the Griffin-Lim algorithm [15] for phase estimation, followed by an inverse short-time Fourier transform. This end-to-end TTS model is designed to generate high-quality speech directly from text. Tacotron eliminates the need for phoneme-level alignment, enabling it to efficiently scale with large volumes of acoustic data and accompanying transcripts. With the capacity to be trained entirely from scratch using random initialization, Tacotron represents a significant advancement in the TTS domain. Tacotron has the capability to be trained entirely from scratch, given a set of paired text and audio. The Tacotron's block

diagram, shown in Fig. 1, consists of a pre-processing unit, encoder, decoder, and vocoder.

The text is first processed and embedded, and then transformed using a pre-net to reduce overfitting and improve training stability. The encoded characters are then fed into a series of encoder blocks, where a CBHG (Convolutional Banks, Highway Networks, and Gated Recurrent Units) module which contains 1-D convolutional banks, max pooling, a 4-layer highway and a bidirectional GRU is used to convert the pre-net outputs into the final encoder representation. Meanwhile, the attention mechanism computes the context vector using the outputs of the text encoder and the previous decoder state, enabling the model to focus on different parts of the input sequence at each decoding step. In the decoder block, a pre-net, attention RNN, decoder RNN, and CBHG module are used to focus on relevant parts of the input text and align speech signal frames.

Finally, the generated Mel-scale spectrograms from the RNN decoder's previous outputs are input into a CBHG module to correct prediction errors for each frame. From here, linear spectrograms can be predicted. The vocoder block uses Griffin Lim to convert the linear spectrograms into speech waveforms as the output.

Fig. 1. Tacotron block diagram.

### B. Tacotron 2

Tacotron 2 is a deep neural network that generates speech directly from text, similar to its predecessor Tacotron. Fig. 2 summarizes the Tacotron 2 block diagram. The network utilizes a recurrent sequence-to-sequence model that maps character embeddings to mel-scale spectrograms, which represent the frequency content of audio signals. The encoder processes the character embeddings using convolutional layers to generate encoded features, followed by a bidirectional LSTM. The decoder, which is an autoregressive recurrent neural network, uses a location-sensitive attention network to predict a Mel spectrogram from the encoded input sequence. The decoder also includes pre-net and attention context vectors, which are passed through a stack of unidirectional LSTM layers to predict the target spectrogram frame. The predicted Mel spectrograms are then passed through a post-processing network consisting of CNN layers and a linear projection layer to generate the final Mel spectrograms. Finally, the Mel spectrograms are converted into sound waveforms using either Griffin Lim [13] or Wavenet [7]. Other than Griffin Lim, wavenet is also one of the vocoders that are used to convert mel-spectrograms to speech sounds [16]. Wavenet can learn how to match acoustic properties to speech waveforms on a sample-by-sample basis. In conclusion, the Tacotron 2 model is capable of generating speech with high

naturalness and intelligibility and has the potential to be used in various speech synthesis applications [7][13].

Fig. 2. Tacotron 2 block diagram.

### III. RELATED WORK

This section will discuss the development of TTS for the Malay language and previous work done on other languages using Tacotron and Tacotron 2.

#### A. Development of TTS for Malay Language

Even though TTS technology is rapidly evolving, especially in the English language, Malay language TTS technology however still has untapped potential. Several studies have been done on TTS for the Malay language, including studies that suggest a text to speech system based on Hidden Markov Models (HMM) and context-dependent labels to produce high-quality synthetic speech in Malay language [17]. The use of context-dependent labels is a common technique in TTS that allows for more natural-sounding speech by taking the surrounding linguistic context into account. This study developed a grapheme-to-phoneme database and identified the contextual factors of Malay language to generate the labels. This sequence of labels is then fed into the HMM-based acoustic model, which generates the corresponding speech waveform. The score of intelligibility and naturalness of the synthetic utterances were evaluated to gauge the module's effectiveness.

Another research for Malay language TTS involves using a bilingual voice synthesis system for Standard Malay and Indonesian using a hybrid method of Hidden Markov Model and Deep Neural Network (HMM-DNN) [5]. This study combines the corpus of these two similar languages Malay and Indonesian and introduces speaker codes to examine the bilingual speech synthesis system, comparing it with the monolingual speech synthesis system. The method involves training a hybrid system on a large corpus of speech data using HMMs to model the spectral and duration information, and DNNs to model the acoustic mapping function. The effectiveness of the TTS synthesis was assessed using the MOS score for naturalness of synthesis sound.

Both studies demonstrate that improvements are being made to the TTS system for the Malay language. However, utilizing the most recent TTS technology will help to advance TTS generally in the Malay language. Thus, the introduction of an end-to-end TTS method for the Malay language will enable the development of Malay TTS technology more quickly.

#### B. Tacotron

One of the famous studies for Tacotron is from [6]. This research focuses on the English language as the input data. The

model started with the data collection. The researcher collects a dataset of speech and text pairs using an internal North American English dataset that contains 24.6 hours of speech data. The text data is then processed by normalizing each character. The normalized text and speech data will go to a Tacotron model that contains an encoder and decoder, and the output will be a linear spectrogram. Finally, the linear spectrogram will be synthesized using the Griffin Lim synthesizer to create a speech sound from the designated input text. The quality of the outcome is evaluated based on a MOS score test, in which eight raters evaluate approximately 100 unseen phrases. This study compared the Tacotron MOS to the concatenative and parametric approaches and discovered that the Tacotron method is superior to the parametric method.

Research on Tacotron models is also available in Myanmar. The official language of Myanmar is Burmese, a Sino-Tibetan language that is written and spoken in Myanmar [12]. Like the research from [6], it starts with data collection. For this project, nearly 5000 pairs of text and audio from male speakers and 3000 pairs from female speakers were used. After that, the text is normalized. The Tacotron model will then be used with both normalized text and sound. The linear spectrogram created from the Tacotron model will then be synthesized using the Griffin Lim synthesizer to create an audio sound in Myanmar. The results are compared using the MOS method by comparing the MOS on naturalness and intelligibility of the Tacotron model with the original audio from the recorded speech. Around 20 speech outputs were used for this evaluation, with 5 people as evaluators.

#### C. Tacotron 2

One of the studies on Tacotron 2 done by [7] focuses on the English language. Data from a single female speaker's 24.6 hours of speech were used to begin this study's data gathering. The text will then be processed by normalizing each text and going for character embedding. The pair of processed text and sound is then inserted into the Tacotron 2 model, which consists of an encoder and decoder to create a Mel spectrogram. The Mel spectrogram is then synthesized using a wavenet synthesizer to create an audio sound from the input text. Similar to Tacotron [6] the subjective evaluation is based on the MOS score from eight raters with 100 unseen phrases. By contrasting the MOS with several TTS techniques, including parametric, Tacotron with Griffin Lim, concatenative, Wavenet, and ground truth audio, which is an authentic human voice, the synthesis audio from the naturalness of the Tacotron 2 model was evaluated. For intelligibility evaluation, this paper runs a MOS evaluation by generating 37 news headlines and comparing the MOS score on the Tacotron 2 model with the Wavenet model. In addition to the subjective assessment, the authors also conducted an ablation investigation to examine the effects of various model components on the performance of the entire system. These investigations aid in their comprehension of the significance of various model components, such as the attention process and WaveNet's conditioning on Mel spectrogram predictions.

The research report by [13] also addresses Tacotron 2. The paper focuses on the Myanmar language as a test subject. From a variety of sources, the researchers created a corpus of Myanmar speech which contains over 5000 pairings of

Myanmar's text and speech, with each audio pair's length ranging from 2 to 12 seconds. They then used a syllable segmenter and text normalizer to separate the Myanmar text into characters. Next, the researcher used a recurrent seq2seq network to map character embeddings to Mel-scale spectrograms. Finally, they used the Griffin-Lim algorithm to produce Myanmar speech output from the input text. The MOS score was used to assess the synthesis's quality. This study examined Tacotron and Tacotron 2 MOS scores for naturalness and intelligibility in the Myanmar language.

#### IV. PROPOSED METHOD

The journey of end-to-end TTS started with the speech corpus creation. For both models, audio and text from a single Malay speaking male speaker are paired together to make a dataset. The dataset was downloaded through the Speech Malaya website [18]. The datasets consist of text corpus files and wav files for audio. Both text and audio files are paired and numbered accordingly. The text corpus contains over 6445 lines of Malay sentences that were taken from the audio context, and the text corpus was saved in CSV format. The text corpus is a complete sentence ending with a full stop. For the audio file, it was a wav file recorded at a sampling rate of 24 kHz with a total duration of 14.29 hours. The audio data were cut into small sizes with minimum and maximum durations of 1.752 seconds and 21.24 seconds respectively, to make a total of 6445 pairs of text and audio datasets in Malay language.

The text will be fed into the pre-processing channel for text normalization, tokenization, and character embedding. In this paper, the setting for text normalization for Malay words is under the "malay\_cleaners" configuration inside the hyperparameter. Table I is an example of text normalization in which an input text is normalized by converting numbers to text, lowercasing the input text, and removing any punctuation marks.

TABLE I. EXAMPLE OF MALAY TEXT NORMALIZATION

No	INPUT TEXT	NORMALIZED TEXT
1	Daripada jumlah tersebut seramai 2,359 iaitu 44.6 % orang ibu tunggal	daripada jumlah tersebut seramai dua ribu tiga ratus lima puluh sembilan iaitu empat puluh empat persepuluh enam peratus orang ibu tunggal
2	Pada tahun 2010 jumlah pinjaman perumahan yang diluluskan oleh sistem perbankan adalah sebanyak	pada tahun dua ribu satu puluh jumlah pinjaman perumahan yang diluluskan oleh sistem perbankan adalah sebanyak
3	SOALAN 33 Dr Mansor Bin Abd Rahman minta MENTERI PERDAGANGAN ANTARABANGSA DAN INDUSTRI	soalan tiga puluh tiga doktor mansor bin abd rahman minta menteri perdagangan antarabangsa dan industri

From Table I, in the input text number 1 in Malay, "Daripada jumlah tersebut seramai 2,359 iaitu 44.6 % orang ibu tunggal" which means "Out of that number 2,359 44.6% are single mothers" in English, is being normalized into "daripada jumlah tersebut seramai dua ribu tiga ratus lima puluh sembilan iaitu empat puluh empat persepuluh enam peratus orang ibu tunggal" in Malay, which translate to "out of

that number two thousand three hundred and fifty nine forty four point six percent are single mothers" in English.

In Malay input text number 2, "Pada tahun 2010 jumlah pinjaman perumahan yang diluluskan oleh sistem perbankan adalah sebanyak" which translate to, "In 2010 the number of housing loans approved by the banking system was" in English. It is then normalized into "pada tahun dua ribu satu puluh jumlah pinjaman perumahan yang diluluskan oleh sistem perbankan adalah sebanyak" in Malay which is translated into English "In two thousand and ten the number of housing loans approved by the banking system was".

From input text number 3 Malay, "SOALAN 33 Dr Mansor Bin Abd Rahman minta MENTERI PERDAGANGAN ANTARABANGSA DAN INDUSTRI" which translated into English "QUESTION 33 Dr Mansor Bin Abd Rahman asked the MINISTER OF INTERNATIONAL TRADE AND INDUSTRY" was normalized into "soalan tiga puluh tiga doktor mansor bin abd rahman minta menteri perdagangan antarabangsa dan industri" in Malay and the English translation is "question thirty three doctor mansor bin abd rahman asked the minister of international trade and industry". All the input text from Table I is being normalized by converting numbers to text, lowercasing the input text, and removing any punctuation marks.

##### A. Tacotron

After the text is normalized and tokenized, 256-dimensional character embeddings are applied to Malay texts. Subsequently, the embedded text is fed into an encoder pre-net. The encoder CBHG module processes the encoder pre-net output to produce the final encoder representation that the attention module will utilize. As previously mentioned, the decoder comprises the decoder pre-net, attention RNN, decoder RNN, and CBHG (post-net CBHG). Finally, the CBHG synthesizes the linear spectrogram, and the Griffin Lim synthesizer with a power of 1.5 is used to convert it into a sound wave. Table II presents all the parameters.

##### B. Tacotron 2

In comparison to the Tacotron model, the Tacotron 2 model uses character embeddings of size 512, which are fed into a stack of three convolutional layers. The final convolutional layer's output is used as input for a single bidirectional LSTM layer to generate the encoded features for the model. The Tacotron 2 model utilizes the location-sensitive attention network, which computes location features using 32 1-D convolution filters of length 31. The decoder block includes a pre-net consisting of two fully connected layers with 256 hidden ReLU units that is followed by a stack of two unidirectional LSTM layers, each with 1024 units, and a linear projection to predict the target spectrogram frame. To enhance overall reconstruction of the output, the predicted mel spectrogram is passed through a 5-layer convolutional post-net, which predicts a residual. During inference, the model uses stop token prediction, where the concatenation of the decoder LSTM output and the attention context is projected to a scalar and passed through a sigmoid activation to predict the probability that the output sequence has completed. To synthesize the waveforms, the Griffin Lim synthesizer is used to generate sound waveforms. Unlike the Tacotron model, the

Tacotron 2 model does not employ CBHG stacks and GRU recurrent layers. All parameters can be found in Table III.

TABLE II. MALAY TACOTRON HYPER-PARAMETER

HYPER-PARAMETER NAME	HYPER-PARAMETER VALUE
Audio Parameter	number_mels=80; number_freq=1025, sample_rate=20000, frame_length_ms=50, frame_shift_ms=12.5, emphasis=0.97
Character Embedding	256-D
Encoder Parameter	Encoder Pre-net : FC-256-ReLU → Dropout(0.5) →FC-128-ReLU → Dropout(0.5) Encoder CBHG : Conv1D bank: K=16; conv-k-128-ReLU; Max pooling: stride=1, width=2; Conv1D projections=conv-3-128-ReLU→ conv-3-128-Linear; Highway net=4 layers of FC-128-ReLU; Bidirectional GRU=128 cells
Attention RNN	1-layer GRU (256 cells)
Decoder Parameter	Decoder Pre-net : FC-256-ReLU → Dropout(0.5)→FC-128-ReLU → Dropout(0.5) Decoder RNN : 2-layer residual GRU (256 cells)
Post-net CBHG	Conv1D bank: K=8, conv-k-128-ReLU; Max pooling: stride=1, width=2; Conv1D projections: conv-3-256-ReLU →conv-3-80-Linear; Highway net: 4 layers of FC-128-ReLU; Bidirectional GRU: 128 cells

TABLE III. MALAY TACOTRON 2 HYPER-PARAMETER

HYPER-PARAMETER NAME	HYPER-PARAMETER VALUE
Audio Parameter	sampling_rate=24000; n_mel_channels=80; ffilter_length=1024; hop_length=200; windows_length=800
Character Embedding	512-D
Encoder parameter	encoder_embedding_dim=512; encoder_kernel_size=5; encoder_n_convolutions=3
Attention Parameter	attention_dim=128; attention_rnn_dim=1024

Decoder parameter	n_frames_per_step=1; decoder_rnn_dim=1024; prenet_dim=256; max_decoder_steps=1000; gate_threshold=0.5; p_attention_dropout=0.1; p_decoder_dropout=0.1

### C. Training

Training of the data is conducted based on the two models, utilizing the Malay text corpus. Both models use the same data, as explained in previous sections. There are some differences in the training parameters of both models. Table IV summarizes the training parameter summaries. Tacotron 2 requires a smaller batch size than Tacotron because it employs a more complicated representation. A large batch size will cause the processing time to take longer and sometimes cause

the program to crash. From Table IV also, Tacotron 2 requires a lengthy run time with nearly the same total steps. Steps for checkpoint intervals are steps where a predicted spectrogram is generated as an output after certain steps. Fig. 3 and Fig. 4 display the alignment plot results for both models at specific checkpoint intervals.

TABLE IV. TRAINING PARAMETER DIFFERENCES

TRAINING PARAMETER	TACOTRON	TACOTRON 2
Batch Size	32	28
Total Step Run (Steps)	95850	80000
Total Hours Run (Hours)	59.42	136.33
Steps for checkpoints intervals (Steps)	150	2000

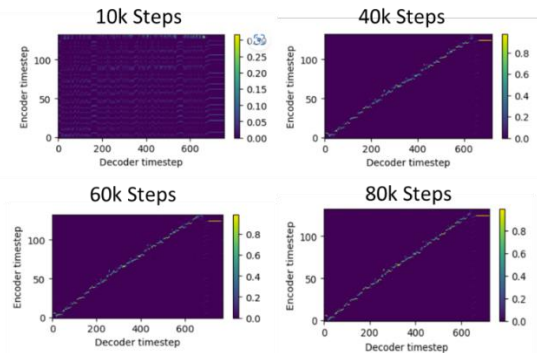

Fig. 3. Alignment for certain steps for Tacotron.

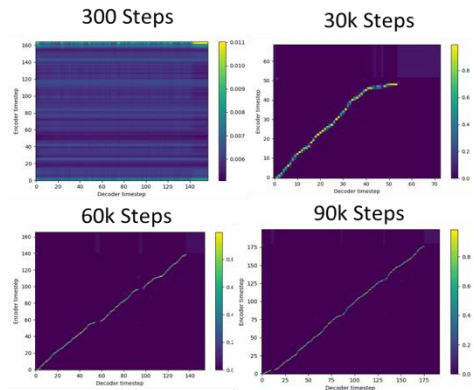

Fig. 4. Alignment for certain steps for Tacotron 2.

An alignment graph shows the visual representation of the learned attention mechanism between the input text and the output and also shows how the model aligns each input character with the corresponding output acoustic features. The graph should have a clear diagonal pattern to indicate that the model is aligning input characters with output features correctly. If it doesn't, it may be having difficulty or not being trained properly. The fig. 3 and 4 also demonstrate that the diagonal pattern on the graph does not appear until after a certain number of training steps.

## V. EVALUATION AND DISCUSSION

### A. Measurement Evaluation

To evaluate the effectiveness of the proposed method, a selection of approximately 20 Malay sentences were randomly sampled from an online news portal, as well as several sentences from Malaysian Hansard parliament speeches. These Malay sentences will then be synthesized using the Tacotron and Tacotron 2 models to get the audio speech. By using these 20 Malay sentences, an original human sound was recorded. For both synthesized models, this human voice serves as another point of comparison. The input word is taken from outside of the training data, which is why the original human voice is being used. Around 5 native speakers will then evaluate the naturalness and intelligibility of human sound, synthesized speech from Tacotron, and synthesized speech from Tacotron 2.

This experiment was based on subjective evaluations. According to [19], a MOS served as a gauge of the effectiveness for TTS, following guidance from the International Telecommunication Union (ITU-T P.85, 1994). To evaluate overall sound quality, a 5-point scale was used, with 5 being the highest quality and 1 being the lowest. Around 5 native speakers will then evaluate the naturalness and intelligibility of human sound, the synthesized speech from Tacotron, and the synthesized speech from Tacotron 2 follow the 5-point scale. To calculate the overall individual performance, the mean calculation is used to get the final answer. A simple mean calculation is shown in equation 1, where R is individual rating and N is the total number of speech output.

$$\text{Mean MOS} = \frac{\sum_{n=1}^N (R_n)}{N} \quad (1)$$

The evaluation for this experiment is based on naturalness and intelligibility. Naturalness and intelligibility are important qualities expected from a TTS system. Naturalness is how the model produces a speech that is human alike in terms of casual, emotional, and spontaneous styles of speaking. Currently, speech recordings used in TTS training typically follow formal reading styles, as pauses, repeats, changes in speed, varying emotions, and errors are not permitted [3]. However, in casual or conversational talk, humans seldom speak in a standard reading style. Intelligibility is how the model can produce speech that can be understood by everyone. Noise is one of the factors that affects the intelligibility of the model [20]. In a real-life situation, a listener is often unable to understand what another person is saying if the environment is noisy. This can lead to some information not being conveyed.

### B. Result

A subjective evaluation test was conducted to compare the method including with an original human voice in Malay speech synthesis. Fig. 5 and Fig. 6 show the results of naturalness and intelligibility for the human voice, Tacotron, and Tacotron 2.

Fig. 5. Comparison of MOS score for naturalness.

Fig. 6. Comparison of MOS score for intelligibility.

The result shows that in terms of naturalness, the Tacotron 2 model is lower compared to the Tacotron, but for intelligibility, the Tacotron 2 model has a slight improvement, though it is still considered lower compared to the Tacotron.

### C. Result and Discussion

From the result however shows that the outcome of this trial contradicts other experiments conducted in [7] for English and [13] for Myanmar language, which suggest that Tacotron 2 performance exceeded the Tacotron. But in this experiment, shows that Tacotron outperformed the Tacotron 2 model. Fig. 7, shows the comparison on the alignment graph between Tacotron and Tacotron 2. The alignment graph shows that Tacotron model diagonal pattern is marginally clearer and have a very straight diagonal pattern compared to Tacotron 2 model, and Tacotron 2 model also generate a longer decoder timesteps. From the previous explanation, a clear diagonal graph indicates that the model is aligning input characters with output features correctly.

This might be for a few reasons, one of which is that the model might not have learned the correct alignment between input text and output speech yet. Most likely, the model needs more training epochs or the hyperparameters need to be changed. Another reason might be issues with the attention mechanism. The model might be struggling to learn the appropriate alignment between the input and output sequences. Overall, the attention mechanism parameter needs to be adjusted to improve the quality of the Tacotron 2 model.

Fig. 7. Comparison alignment graph between Tacotron and Tacotron 2.

## VI. CONCLUSION

The purpose of this study is to provide an end-to-end TTS technique for the Malay language, hence contributing to the development of Malay language technology. In conclusion, this study shows that Tacotron and Tacotron 2 can both translate Malay text into speech, but the Tacotron model performs better when compared to Tacotron 2. In the future, to improve the Tacotron 2 model, some hyperparameters will need to be adjusted, especially in the attention and decoder parameter. Additionally, there could be a contemplation of the use of WaveNet as a vocoder in Tacotron 2. Given its flexibility, the WaveNet vocoder allows high user adaptability in manipulating synthesized speech to suit various scenarios, thereby enhancing overall performance. To further explore end-to-end TTS methods for the Malay language, other end to end models such as FastSpeech, Transformer TTS, and Parallel WaveGAN can be considered. This approach could provide increased flexibility in the application of end-to-end techniques for Malay language.

## ACKNOWLEDGMENT

The authors acknowledge that part of this research is supported by Universiti Kebangsaan Malaysia under GUP grant with grant number: GUP-2020-063.

**Abstract**—Artificial intelligence and deep learning algorithms have become essential fields in medical science. These algorithms help doctors detect diseases early, reduce the incidence of errors, and decrease the time required for disease diagnosis, thereby saving human lives. Deep learning models are widely used in Computer-Aided Diagnosis Systems (CAD) for the classification of various diseases, including blood cancer. Early diagnosis of blood cancer is crucial for effective treatment and saving patients' lives. Therefore, this study developed two distinct models to classify eight types of blood cancer. These types include follicular lymphoma (FL), mantle cell lymphoma (MCL), chronic lymphocytic leukemia (CLL), acute myeloid leukemia (AML), and the subtypes of acute lymphoblastic leukemia (ALL) known as early pre-B, pre-B, pro-B ALL, and benign. AML and ALL are specific classifications for human leukemia cancer, while FL, MCL, and CLL are specific classifications for lymphoma. Both models consist of different phases, including data collection, preprocessing, feature extraction techniques, and the classification process. The techniques applied in these phases are the same in both proposed models, except for the classification phase. The first model utilizes the VGG16 architecture, while the second model utilizes DenseNet-121. The results indicated that DenseNet-121 achieved a lower accuracy compared to VGG16. VGG16 exhibited excellent results, achieving an accuracy of 98.2% when classifying the eight classes. This outcome suggests that VGG16 is the most effective classifier for the utilized dataset.

**Keywords**—Deep learning; convolutional neural networks (CNNs); leukemia; lymphoma; computer-aided diagnosis systems (CAD)

## I. INTRODUCTION

According to a report by the World Health Organization (WHO), approximately 1 in 6 deaths worldwide is caused by cancer, making it the second leading cause of death globally. Among the various types of cancer, blood cancer holds significant prominence. It accounts for approximately 9% of all cancers and is now ranked as the fourth most common cancer in both men and women worldwide [1, 2]. As a result, researchers have shifted their focus towards applying artificial intelligence techniques to develop models that can assist in addressing this issue in the medical field. In the following section, we will provide a detailed description of the most prevalent types of blood cancer.

### A. Leukemia

Leukemia is a type of cancer that affects the blood cells and can occur in individuals of all ages, including children and adults [3]. It is characterized by an abnormal proliferation of immature blood cells in the bone marrow, which leads to the

replacement of healthy blood cells. In leukemia, a genetic mutation takes place in an immature blood cell, causing it to transform into a cancerous cell. These malignant cells do not function properly and multiply at a faster rate compared to normal cells, while having a shorter lifespan. Consequently, the presence of cancerous cells in the bone marrow displaces the healthy blood cells [4].

Leukemia can be categorized into two main types based on the rate of malignant cell growth. If the malignant cells grow rapidly, it is classified as acute leukemia, whereas if they grow slowly, it is classified as chronic leukemia [1]. As a result, there are four primary types of leukemia: Acute Myeloid Leukemia (AML), Acute Lymphoblastic Leukemia (ALL), Chronic Myeloid Leukemia (CML), and Chronic Lymphocytic Leukemia (CLL) [5].

- **Acute Myeloid Leukemia:** It is the most common type of acute leukemia. It occurs when the bone marrow produces abnormal blasts and immature white blood cells (WBCs). In some cases, it may also lead to the production of abnormal red blood cells (RBCs) and platelets. The symptoms of early-stage AML may resemble those of a common cold or other illnesses [6].
- **Acute Lymphoblastic Leukemia:** It is a type of cancer that primarily affects white blood cells and is commonly found in children. It is characterized by the uncontrolled growth and excessive production of immature white blood cells in the bone marrow. The symptoms of ALL, which include fatigue, weakness, and joint and bone pain, can resemble those of the flu and other common illnesses, making the diagnosis challenging. ALL is further classified into three subtypes: Early Pre-B, Pre-B, and Pro-B ALL [7, 8].
- **Chronic Myeloid Leukemia (CML):** It is a type of cancer that primarily affects white blood cells. In individuals with CML, there is uncontrolled growth of immature white blood cells, known as blast cells, in the body [4].
- **Chronic Lymphocytic Leukemia:** it is a haematological disease that affects B lymphocytes or B cells. It is more prevalent in adults and rare in children. CLL symptoms include weight loss, fever, sleep sweats, and frequent infection [6].

### B. Lymphoma

Lymphoma is a type of blood cancer that occurs due to the abnormal development of white blood cells called lymphocytes. Lymphocytes are specialized cells that circulate throughout the body via the blood and lymphatic systems, playing a crucial role in the immune response to prevent infections [9]. Lymphoma is characterized by the clonal proliferation of malignant lymphocytes, which can be either T cells or B cells. The diagnosis of different types of lymphoma is typically based on the growth pattern and cytological features of the abnormal cells observed under light microscopy using Hematoxylin and Eosin-stained tissue samples. Lymphoma is classified into three main subtypes: follicular lymphoma (FL), mantle cell lymphoma, and Chronic Lymphocytic Leukemia (CLL) [10].

As mentioned in the previous section, the most prevalent types of blood cancer include FL, MCL, CLL, AML, and ALL, which encompass Early Pre-B, Pre-B, Pro-B ALL, and benign subtypes. The objective of this study is to develop a classification model for accurately categorizing images into these different disease categories.

Blood cancer can be detected through manual counting using a hematological analyzer, which involves the classification of cells based on their morphological characteristics. However, this method is often time-consuming, labor-intensive, and expensive. Moreover, manual analysis

may yield inaccurate results in terms of leukocyte counts and classification. In order to address these challenges [9, 11], researchers have developed Computer-Aided Diagnosis (CAD) systems that utilize deep learning techniques to assist physicians in accurately identifying leukemia.

Deep learning algorithms have gained significant popularity in Computer-Aided Diagnosis (CAD) systems. Among these algorithms, the convolutional neural network (CNN) is one of the most widely used approaches. CNN consists of three main layers: the Convolutional Layer, the Pooling Layer, and the Fully Connected Layer. Illustrated in Fig. 1, a CNN can learn hierarchical representations of data by extracting more general features in the initial convolutional layers and progressively capturing more specific features in the subsequent layers. The effectiveness of CNNs in medical diagnosis has been well-established [4, 12].

This study makes several contributions to the field of blood cancer diagnosis. Firstly, an image augmentation technique is applied as a preprocessing step to enhance the quality of blood cancer images. Secondly, a classification method using two different CNN architectures is employed to distinguish between eight different classes of blood cancer that have not been used before. The performance of the model is also thoroughly analyzed and compared with existing state-of-the-art methods. Finally, mixed datasets are utilized to improve the accuracy of blood cancer classification.

Fig. 1. Convolution neural network architecture.

## II. RELATED WORK

This section presents an overview of previous research conducted on blood cancer classification, focusing on the methods and techniques employed by researchers to accurately identify and classify various types of blood cancer. These studies have made significant contributions to the development of more effective diagnostic tools and have enhanced our understanding of this complex disease.

In [4] Mañla et al. (2022) developed a CNN-based model for the classification of leukemia. They utilized a dataset consisting of 3,536 images from 18 different sources, which

were divided into four classes: healthy (1,434 images), ALL (881 images), AML (978 images), and other types (243 images). To enhance the quality of the images, the study employed data augmentation techniques. By applying multilevel and ensemble CNN architectures to the four-class scenario, the researchers achieved accuracy rates of 94.73% and 94.59%.

In [13], Amjad et al. (2018) developed a CAD for the classification ALL subtypes. The dataset utilized in their study consisted of images of ALL subtypes, including 100 images of L1, 100 images of L2, 30 images of L3, and 100 images of normal cells. The proposed system employed segmentation and

deep learning methods, utilizing the AlexNet convolutional neural network architecture. With this approach, an accuracy of 97.78% was achieved.

In [3], Sara et al. (2019) proposed an automated deep learning method utilizing a hybrid approach for distinguishing between immature leukemic blasts and normal cells. The study employed two CNN architectures, namely MobileNet and VGG16. The ISBI 2019 dataset was utilized, consisting of 7,272 images of ALL cells and 3,389 images of healthy cells. The proposed approach achieved an accuracy of 96.17%.

In [6], Nighat et al. (2020) employed the DenseNet-121 and ResNet-34 Convolutional Neural Network architectures for leukemia subtype identification. Both ResNet-34 and DenseNet-121 utilized data augmentation techniques to analyze various image patterns. The study utilized the publicly available ALL-IDB and ASH image bank datasets for leukemia analysis. After augmentation, the dataset consisted of 1,079 images for the ALL class, 1,194 images for the AML class, 840 images for the CLL class, 1,243 images for the CML class, and 1,280 images for the healthy class. The accuracy rate achieved was 99.91% for DenseNet-121 and 99.96% for ResNet-34.

In [11], Maneela et al. (2021) proposed a model for AML detection using the AlexNet and LeNet-5 Convolutional Neural Network architectures. The dataset utilized in this study comprised 4,000 images, with 1,000 images in the lymphocytes class, 1,500 images in the abnormal monocytes class, and 1,500 images in the normal monocytes class. The data was obtained from a hospital in Peshawar, Pakistan. The AlexNet model achieved an accuracy of 98.58%, while the LeNet-5 model achieved an accuracy of 96.25%.

In [1], Arjun et al. (2022) developed a model for leukemia detection utilizing machine learning and deep learning techniques. The study introduced a novel dataset consisting of 500 blood smear images, including images of normal cells, AML cells, and ALL cells. Both binary classification and three-class classification were performed in the study. The

proposed approach achieved an accuracy of 97% using VGG16 and 98% using DenseNet121, along with a support vector machine for binary classification. For the three-class classification, an accuracy of 95% was achieved using ResNet50.

In [14], Laura et al. (2021) developed a predictive model for leukemia identification. The dataset used in this study consisted of 16,450 single cells. Various CNN architectures, including VGG16, ResNet101, DenseNet121, and SENet154, were employed to evaluate the model. The best performance was achieved by SENet154 and VGG16, both achieving an accuracy of 94.6%.

In [15], Xiaoli et al. (2021) proposed a deep residual neural network model for the classification of three types of lymphoma: CLL, FL, and MCL. The dataset used in this study consisted of 374 lymphoma pathology images. The model achieved an accuracy of 98.63%.

In [16], Nadia et al. (2019) developed a deep learning model to classify lymphoma subtypes, including CLL, FL, and MCL. The ResNet-34 architecture was utilized to evaluate the model, achieving an accuracy of 95.47%. The dataset used in this study consisted of 374 lymphoma images.

In [17], Hiroaki et al. (2020) proposed an ensemble deep neural network model for classifying three types of lymphoma: FL, diffuse large B-cell lymphoma (DLBCL), and reactive lymphoid hyperplasia (RL). The dataset used in this study consisted of a total of 6,183 images. The model achieved an accuracy of 97%.

### III. PROPOSED MODEL

The goal of this study is to build a model for blood cancer classification to help doctors and physicians diagnose blood cancer in its early stages and determine treatment to save human lives. This includes three main tasks: data collection, preprocessing, and finally, classification of blood cancer images using CNN architectures. The model is shown in Fig. 2.

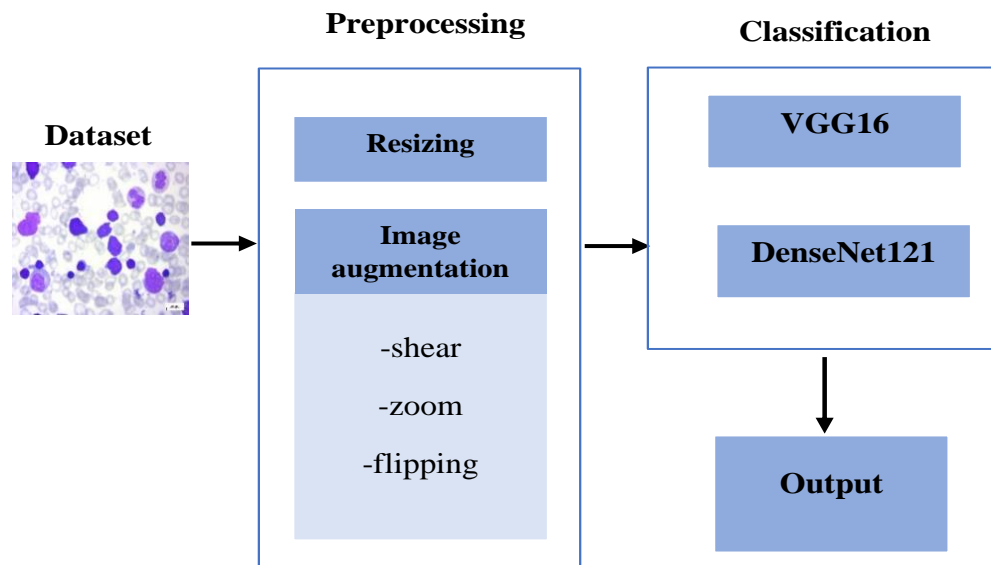

Fig. 2. Proposed model.

### A. Dataset

Due to the scarcity of medical data caused by privacy concerns, obtaining sufficient data for biomedical research can be challenging. In this study, we addressed this issue by combining three public datasets [18, 19] to create a larger and more comprehensive dataset for our blood cancer classification model. The dataset consists of 3,679 images across eight different classes. Table I provides a summary of the dataset used.

TABLE I. SUMMARY OF USED DATASET

Class	Number of images	Dataset	Image size
Benign	504	Kaggle	224 × 224
Early ALL	985		224 × 224
Pre-ALL	963		224 × 224
Pro ALL	804		224 × 224
CLL	113		1388 × 1040
FL	139		1388 × 1040
MCL	122		1388 × 1040
AML	49	ASH	960 × 720

### B. Preprocessing

We used pre-processing and augmentation techniques to improve the quality of visual information in each input image, thereby enhancing the visibility of essential structures.

1) *Resizing*: As a result of using multiple datasets with different image sizes, all input images were processed by resizing them to 224×224 to fit the input of our model.

2) *Image augmentation*: Image augmentation is utilized to train the model. It involves creating modified versions of the dataset images, thereby increasing the size of the training dataset. However, image augmentation serves a dual purpose: not only does it expand the dataset, but it also introduces variability to the data, enabling the model to generalize better to unseen data and address the issue of overfitting. Additionally, as the model is trained in slightly altered images, it becomes more robust and reliable. The preferred method of data augmentation is in-place or on-the-fly augmentation, implemented through Keras' ImageDataGenerator class [20]. This approach exposes the network to diverse variations in the dataset during each epoch of training. By creating additional versions of the original dataset images, the number of images used in each experiment is quadrupled, augmenting the data, and facilitating the classification process.

Before applying any processing, the input is rescaled by a factor known as "rescale." The original RGB coefficients of the images range from 0 to 255, which would be too high for the models to effectively learn at a standard learning rate. Therefore, the original images are rescaled by a factor of 1/255. This rescaling involves multiplying the image data by this value, resulting in image values between 0 and 1. Additionally, three image augmentation techniques are employed: shear, zoom, and flipping.

Shear is one of the image augmentation techniques employed by Keras' ImageDataGenerator, and it utilizes a shear range of 0.2. The shear angle is represented by a floating-point number, indicating the degree of shear in the anticlockwise direction.

The images are also enhanced through zooming. There are two zoom options available: zooming out of the image or zooming in on the image. The ImageDataGenerator class accepts a float value for the zoom range as input. The zoom is applied within the range [1 - zoom range, 1 + zoom range]. Alternatively, instead of providing a float number, a list with two values representing the lower and upper limits can be used [20]. When the value is less than one, the image zooms in, while any value greater than one causes the image to zoom out.

Flipping an image involves reflecting it around its vertical axis, horizontal axis, or both axes simultaneously. This technique allows users to augment the number of images in a dataset without the need for any artificial processing [20]. In this study, random horizontal flipping is used.

### C. Classification

Finally, the data was ready for the classification process. The model was trained using two CNN architecture models: VGG16 and DenseNet121. These classification architectures were implemented on Google Collaboratory.

1) *DenseNet121*: It facilitates the training of deep learning models by solving the vanishing gradient problem, increasing feature reuse, and reducing parameter usage. It has achieved progressive performance in a variety of computer vision tasks [21]. The DenseNet architecture is shown in Fig. 3.

2) *VGG16*: The VGG-16 network includes 16 convolution layers and a small receptive field of 3×3. It has a Max pooling layer of size 2×2 and 5 such layers in total. After the last Max pooling layer, there are three fully connected layer [22]. A schematic of VGG-16 architecture is illustrated in Fig. 4.

3) *Parameters*: All the model's parameters are explained, including the activation function, loss function, optimizer, and metrics.

a) *Activation function*: Another form of activation function applied in neural computing is the softmax function. It estimates the probability distribution from a vector of real numbers. The softmax function returns arrange of values between 0 and 1, with the total of the probability equal to 1[23]. Softmax is shown in Eq. 1. The softmax function is used in multiclass models to produce probabilities for each class.

$$F_{(y_i)} = \frac{e^{(y_i)}}{\sum_j e^{(y_j)}} \quad (1)$$

Where y is input vector.

b) *Loss function*: The loss function is employed to evaluate the network's effectiveness [24]. The Categorical Cross-Entropy loss, also described as softmax Cross-Entropy loss (CE), is employed in this research. It is employed in multi-class classification. the Categorical Cross-Entropy loss function is showed as in Eq. 2.

Fig. 3. DenseNet architecture.

Fig. 4. A schematic of VGG-16 architecture.

Where  $y_a$  represents the score for the positive classes in CNN.

c) *Optimizer*: In the training data, adaptive moment estimation (Adam) is used to correctly update the network weights iteratively. It employs first and second gradient descent computation to fit the learning rate parameter for each weight in the neural network, the first moment represents the mean, and the second represents the uncentered variance, The learning rate is the percentage by which weights are updated; the default learning rate is 0.001. High values accelerate learning before the rate is changed, and lower values slow learning in training [25].

d) *Evaluation metrics*: The model is evaluated based on accuracy (Acc) metrics; accuracy is a common metric used to evaluate the performance of a classification model. It measures the proportion of correct predictions made by the model compared to the total number of predictions. To calculate accuracy, we typically use a confusion matrix. A confusion matrix is a table that summarizes the performance of a classification model by showing the counts of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) predictions. Each row of the matrix represents the instances in a predicted class, while each column

represents the instances in an actual class as shown in Fig. 5. Eq. 3 illustrates accuracy function.

- True Positive (TP): The model correctly predicted instances as positive when, they were positive. These are the correctly classified positive instances.
- True Negative (TN): The model correctly predicted instances as negative when they were negative. These are the correctly classified negative instances.
- False Positive (FP): The model incorrectly predicted instances as positive when they were negative. These are the instances of the model mistakenly classified as positive.
- False Negative (FN): The model incorrectly predicted instances as negative when they were positive. These are the instances of the model mistakenly classified as negative.

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} * 100 \quad (3)$$

		Predicted value.	
		positive (P)	Negative (N)
Actual class	P	True positive (TP)	False negative (FN)
	N	False positive (FP)	True negative (TN)

Fig. 5. Confusion matrix.

#### IV. RESULT

VGG16 and DenseNet121 CNN architectures were utilized to classify 8 types of blood cancers. The models were trained for 20 epochs with a batch size of 64. The dataset comprised a total of 3,679 images, with 2,733 images allocated for training and 946 images for testing. Fig.6 displays samples of the blood cancer images. The models were evaluated using unseen data to assess their generalization capability. The accuracy of the models was measured, and the results revealed impressive accuracy rates. VGG16 achieved an accuracy of 98.2%, while DenseNet121 achieved an accuracy of 98.1%, as presented in Table II.

The plot diagram when using 20 epochs and DenseNet121 architecture is shown in Fig. 7, plot between train accuracy and validation accuracy is shown in Fig. 7(a), plot between train loss and validation loss is shown in Fig. 7(b). The plot diagram when using 20 epochs and VGG16 architecture is shown in Fig. 8, plot between train loss and validation loss is shown in

Fig. 8(a), plot between train accuracy and validation accuracy is shown in Fig. 8(b).

#### A. Comparison with the State-of-the-Art

In this section a comparison between the proposed model and the state of the art is presented as shown in Table III.

Fig. 6. Samples of the blood cancers images.

TABLE II. RESULTS OBTAINED BY VGG16 AND DENSENET121 CNN ARCHITECTURES

Model	#Of epochs	Accuracy	Batch size	Time for each epoch
VGG16	20	98.2%	64	21 s
DenseNet121	20	98.1%	64	21 s

Fig. 7. The plot diagram when using 20 epochs and DenseNet121 architecture.

Fig. 8. The plot diagram when using 20 epochs and VGG16 architecture.

TABLE III. COMPARISON BETWEEN THE PROPOSED MODEL AND THE STATE-OF-THE-ART

#	Research	Year	Model	#Classes	#Images	Accuracy
1	[4]	2022	ensemble CNN architectures	4	3,536	94.73%
2	[13]	2018	Alexnet	4	330	97.78%.

15	Proposed model	2023	VGG16	8	3,679	98.2%,
			DenseNet121			98.1%.

## V. DISCUSSION

This study has made significant progress in the field of blood cancer research by classifying eight different types of blood cancer using deep learning algorithms. Previous studies did not classify these eight types of blood cancer. Two different CNN architectures, namely VGG16 and DenseNet121, were employed for the classification process. The softmax activation function was used to calculate the probabilities of each class, ranging from 0 to 1, based on the CNN outputs. The highest probability corresponds to the predicted class for a given input. The effectiveness of the network was evaluated using the Categorical Cross-Entropy loss function, which measures the dissimilarity between the predicted probabilities and the actual target values, enabling the assessment of model performance. During the training process, the Adam optimizer was used to iteratively update the network's weights. The optimizer aims to find the optimal set of weights that minimize the loss function, thereby improving classification accuracy. The results of the classification process indicate that the VGG16 model achieved the highest accuracy among the two architectures, with a value of 98.2%. This means that the VGG16 model correctly classified 98.2% of the instances in the dataset. On the other hand, the DenseNet121 model achieved a slightly lower accuracy of 98.1%. These accuracy values suggest that both models performed exceptionally well in classifying the eight types of blood cancer, with VGG16 demonstrating slightly better performance compared to DenseNet121. However, the study encountered several challenges. Acquiring sufficient high-quality data proved to be a major hurdle as blood cancer datasets were often limited in size and lacked diversity, posing challenges in developing a robust and accurate model. Ensuring data accuracy and reliability was crucial for obtaining meaningful results. Another significant challenge was the interpretability and explainability of deep learning models. In the context of medical research, interpretability is vital for gaining insights into the underlying factors contributing to the classification.

Developing methods to explain the model's predictions and provide interpretable results was a significant undertaking. Furthermore, the study required substantial computational resources and time to train complex models on large datasets. Access to high-performance GPUs and collaboration with medical experts were essential for effective model training and evaluation. Bridging the gap between deep learning expertise and domain-specific knowledge posed additional challenges, emphasizing the need for collaboration with experts in blood cancer pathology, diagnosis, and treatment. Addressing these challenges was crucial in developing an accurate and reliable blood cancer classification model that aligns with clinical practices and aids in advancing diagnosis and treatment strategies.

## VI. CONCLUSION

This work presents the classification of blood cancer types using state-of-the-art deep learning techniques. Leukemia and lymphoma are hematological diseases and types of blood cancer that cause abnormal behavior in blood cells. In this study, we propose VGG16 and DenseNet121-based models to classify two types of leukemia and three subtypes of lymphoma and compare their performance. Data augmentation techniques are also employed to address the issue of overfitting, resulting in improved results. The proposed models are evaluated using unseen images that were not included in the training phase. The VGG16 architecture achieves the highest accuracy of 98.2%, while DenseNet121 exhibits slightly lower accuracy.

In future work, we plan to expand the classification to include other types of blood cancer, such as myeloma and chronic myeloid leukemia. Additionally, we aim to evaluate the proposed dataset using various deep learning algorithms to compare their performance in this field of research. Furthermore, an online Internet of Things (IoT) application will be developed to collect and analyze a larger volume of blood data.

# Deep Feature Fusion Network for Lane Line Segmentation in Urban Traffic Scenes

Hoanh Nguyen

Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

**Abstract**—As autonomous driving technology continues to advance at a rapid pace, the demand for precise and dependable lane detection systems has become increasingly critical. However, traditional methods often struggle with complex urban scenarios, such as crowded environments, diverse lighting conditions, unmarked lanes, curved lanes, and night-time driving. This paper presents a novel approach to lane line segmentation in urban traffic scenes with a Deep Feature Fusion Network (DFFN). The DFFN leverages the strengths of deep learning for feature extraction and fusion, aiming to enhance the accuracy and reliability of lane detection under diverse real-world conditions. To integrate multi-layer features, the DFFN employs both spatial and channel attention mechanisms in an appropriate manner. This strategy facilitates learning and predicting the relevance of each input feature during the fusion process. In addition, deformable convolution is employed in all up-sampling operations, enabling dynamic adjustment of the receptive field according to object scales and poses. The performance of DFFN is rigorously evaluated and compared with existing models, namely SCNN, ENet, and ENet-SAD, across different scenarios in the CULane dataset. Experimental results demonstrate the superior performance of DFFN across all conditions, highlighting its potential applicability in advanced driver assistance systems and autonomous driving applications.

**Keywords**—Lane line segmentation; deep learning; convolutional neural network; spatial and channel attention

## I. INTRODUCTION

As urbanization accelerates and our reliance on transportation intensifies, the need for safer and more efficient urban traffic systems is more pressing than ever. Among the numerous challenges in developing intelligent transportation systems, accurate lane line segmentation is a vital task for the functionality of autonomous driving and advanced driver-assistance systems (ADAS). By properly recognizing and predicting lane lines, these systems can better ensure the safety and efficiency of road traffic. Within the domain of computer vision and image processing, a plethora of methods have been proposed to address lane line segmentation. Traditional methods, like edge detection and Hough transform, provide some utility, but their performance can be significantly hindered under complex conditions such as variable lighting, weather, and diverse road markings. With the rise of deep learning, Convolutional Neural Networks (CNNs) have shown superior performance in various tasks including lane line segmentation [1], [2]. In recent years, a range of techniques for lane line segmentation employing Convolutional Neural Networks (CNNs) have been devised. Study [3] presents a robust method for lane detection in continuous driving scenarios, leveraging the power of deep neural networks. The

authors introduced a novel two-stage framework that first generates lane line proposals using a pixel-wise prediction model, and then refines these proposals through a sequential prediction model, leveraging temporal information between frames. Their method demonstrated impressive robustness in handling various complex scenarios and achieved notable performance on multiple benchmark datasets. Phillion [4] proposed a novel method to tackle the "long tail" problem in lane detection - the issue of detecting rare or unusual lane configurations. The approach uses a sequential prediction network that dynamically generates waypoints, thereby allowing it to adapt to a wide variety of lane shapes and configurations. In their study, Qin, Wang, and Li (2020) [5] introduced a structure-aware deep lane detection algorithm. The algorithm focuses on improving the speed and efficiency of lane detection by incorporating prior structural knowledge into a novel deep learning framework. Recently, Yoo et al. [6] proposed an end-to-end lane marker detection algorithm using a row-wise classification approach in their research. Their method transforms the challenging lane detection problem into a simpler row-wise classification task, improving both speed and accuracy of detection. Another approach [7] is to utilize a fully convolutional neural network with a novel instance segmentation head to simultaneously detect and separate different lane lines. In recent work, Abualsaud et al. [8] introduced LaneAF, a robust multi-lane detection method based on the concept of affinity fields. The proposed approach uses the affinity fields to encode relational information between different parts of the lane lines, enhancing the detection accuracy in challenging situations like close, parallel, and curvy lanes. Wang, Ren, and Qiu [9] introduced LaneNet, a real-time lane detection network designed for autonomous driving applications. LaneNet utilizes a two-branch neural network that simultaneously performs semantic segmentation for pixel-wise lane detection and instance segmentation for distinguishing between individual lane lines. In [10], Pan et al. introduced a novel concept of Spatial Convolutional Neural Networks (SCNN) that extends traditional CNNs by performing convolutions in the spatial domain. This novel SCNN framework, which treats spatial information as a type of deep information, was shown to be particularly effective in traffic scene understanding tasks, including lane line detection. Based on SCNN, Zheng et al. [11] proposed a Recurrent Feature-Shift Aggregator (ReSA) for lane detection tasks. The ReSA model uses a novel recurrent structure to shift and aggregate deep features, effectively capturing the spatial dependencies of lane pixels and thereby improving lane detection performance. Hou et al. [13] introduced a self-attention distillation strategy for developing lightweight lane

detection CNNs. The method involves training a smaller student network to mimic the attention maps of a larger, pre-trained teacher network, thereby improving the efficiency and performance of the student network. More recently, Vu et al. [14] proposed HybridNets, an end-to-end perception network for autonomous driving. HybridNets, combining multiple sub-networks tailored to different perception tasks, provides a unified architecture that can simultaneously perform various tasks, including lane line detection, while sharing learned representations. In addition to structures specifically designed for the task of lane line segmentation, some proposed methods use popular networks for general semantic segmentation such as Fully Convolutional Networks (FCN) [14], U-Net [15], SegNet [16], DeepLab v3+ [17], for the task of lane line segmentation, which also yield promising results and achieve significant outcomes.

Although the above methods show promise in lane line segmentation tasks, challenges remain due to the intricate nature of urban scenes that include varying lanes, unpredictable surrounding environments, and complicated traffic scenarios. To address these challenges, this paper presents a Deep Feature Fusion Network (DFFN) for lane line segmentation in urban traffic scenes. The core idea of the proposed method is to leverage the strength of deep learning and feature fusion to extract and combine multi-level and multi-scale features from the input images. This approach not only enhances the robustness of the network against complex conditions but also significantly improves the segmentation performance by effectively capturing both the local detailed information and the global contextual information of lane lines. The effectiveness of the proposed model has been verified through experiments on the CULane dataset.

The rest of this paper is organized as follows: Section II presents the detailed methodology of the proposed model, including the architectural design, key components, and training procedure. Section III describes the CULane dataset and the experimental setup, followed by a comprehensive analysis of the experimental results. Section IV summarizes the key contributions and highlighting the significance of the proposed model in improving the functionality and safety of autonomous driving systems and advanced driver assistance systems.

## II. METHODOLOGY

This section elaborates on the proposed DFFN structure designed for lane line segmentation in urban traffic scenes. DFFN is based on the DLA structure [18] used for the semantic segmentation task. Therefore, this section will first provide a summary of the DLA network structure, followed by a detailed explanation of the proposed modifications designed to enhance the DLA model specifically for the lane line segmentation problem.

### A. DLA Network for Semantic Segmentation

Deep Layer Aggregation is a powerful structure that has seen successful applications across a variety of computer vision tasks, including semantic segmentation. The design of DLA is based on the observation that semantic segmentation requires not only high-level semantic information but also low-level detailed information. The main aim of the DLA architecture is to effectively aggregate multi-scale and multi-level features to generate rich and detailed feature maps that are beneficial for tasks like semantic segmentation. DLA consists of two major components: a hierarchy of basic blocks and an aggregation mechanism, as shown in Fig. 1(a).

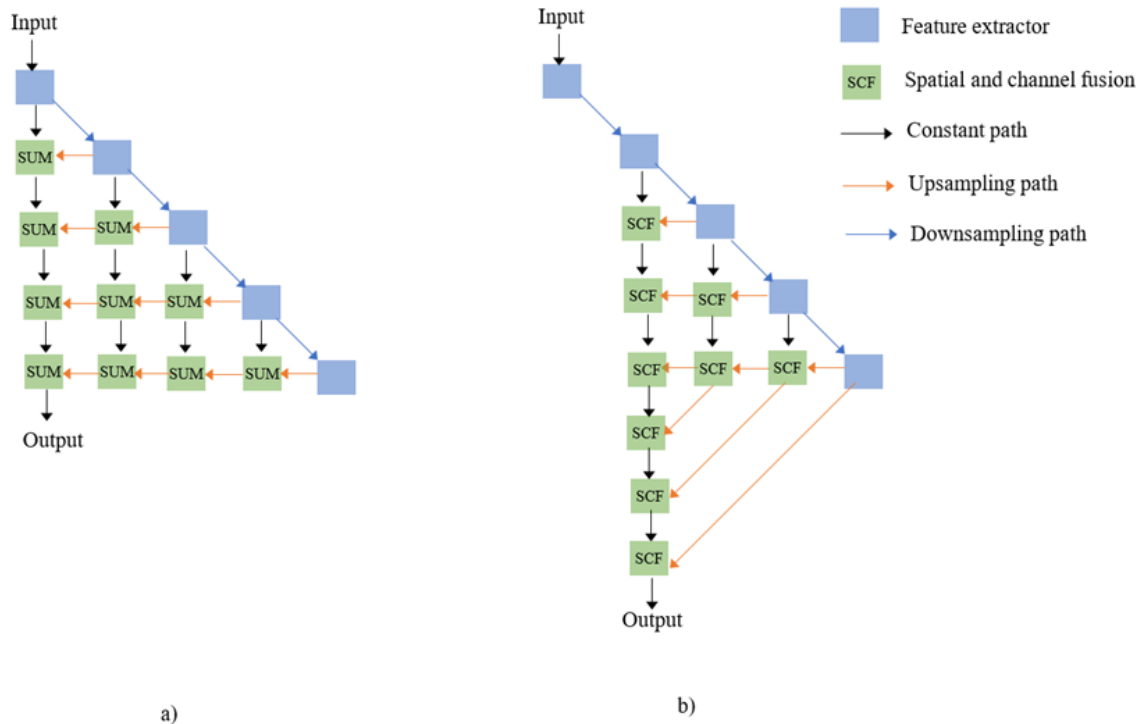

Fig. 1. The structure of original DLA (a) and the proposed DFFN (b).

1) *Hierarchy of basic blocks*: DLA adopts a hierarchical structure similar to typical convolutional networks such as ResNet [19] or ResNeXT [20], but with each level consisting of basic blocks, with each block being a small network of its own. Each basic block within the hierarchy operates at a different resolution, and the block output is a feature map of the corresponding resolution. Lower-level blocks capture fine-grained features, while higher-level blocks capture coarser but more abstract features.

2) *Aggregation mechanism*: The uniqueness of DLA lies in its aggregation mechanism. Traditional convolutional networks only use features from the highest level for prediction, which could result in a loss of detailed spatial information. DLA, however, introduces an aggregation mechanism that propagates the information from higher layers to lower layers, in a top-down manner. This aggregation allows high-level semantic features to be combined with low-level spatial features. The process begins with the highest level, where features are first processed by a  $1 \times 1$  convolution to reduce the channel dimension. Then, these features are upsampled and summed with the corresponding lower-level features. The combined features are then processed by another  $1 \times 1$  convolution before being passed to the next lower level. The aggregation mechanism allows DLA to generate rich feature maps that contain both high-level semantic information and low-level detailed information. This feature is particularly beneficial for semantic segmentation, which requires a good understanding of both the object (high-level) and the exact boundary (low-level) of each semantic class.

### B. Deep Feature Fusion Network with Spatial and Channel Fusion

Although DLA has achieved some success in semantic segmentation tasks, its performance in lane line segmentation in urban traffic scenes is greatly limited. There are several reasons to explain this. Firstly, the proportion of lane lines usually occupies a relatively small ratio in the image, and sometimes lane lines are not clearly visible. This severely restricts the accuracy of pixel-level segmentation of lane lines. Secondly, in complex environments where lane changes, changing lighting conditions, or irregular lane shapes frequently occur, the feature fusion scheme in DLA is easily affected by background noise. Inspired by attention mechanism [21], which employs channel and spatial self-attention for adaptive feature refinement to enhance the performance of convolutional networks in tasks like image classification, image captioning, and object detection, this paper designs the DFFN based on the DLA architecture for efficient lane line segmentation in urban traffic scenes. Fig. 1(b) illustrates the detailed structure of the proposed DFFN. It judiciously employs both spatial and channel attention mechanisms to learn and anticipate the significance of each input feature during the fusion process. Consequently, it amplifies lane line features from both spatial and channel dimensions, extracting effective lane line characteristics even in challenging environments. Specifically, DFFN utilizes ResNet-34 [19] as its backbone to create an optimal balance between precision and processing speed. It deviates from the traditional DLA by

integrating more skip connections between low-level and high-level features, resembling the operational structure of the Feature Pyramid Network [22]. Moreover, DFFN replaces the convolution layers in all up-sampling modules with deformable convolution, allowing for dynamic adjustments of the receptive field in accordance with object scales and orientations. This transformation not only offers flexibility but also helps mitigate alignment issues. In addition, each linear aggregation node in the original DLA structure is replaced by the spatial and channel fusion node (SCF), which is designed to compute spatial and channel attention based on the relation of the input feature maps. The next subsection will elaborate on the spatial and channel fusion design.

1) *Spatial and channel fusion*: The spatial and channel fusion is applied on two different input feature maps,  $I_S$  and  $I_L$ , where  $I_S$  is the shallower, higher resolution feature map and  $I_L$  is the deeper, lower resolution feature map, as shown in Fig. 2. Since  $I_S$  contains richer spatial information, this paper applies spatial attention operation on this feature map to enhance its spatial information. The spatial attention operation includes two  $3 \times 3$  convolution layers followed by sigmoid activation. Suppose  $I_S \in \mathbb{R}^{W \times H \times C}$ , the output of the spatial attention operation  $I'_S$  is calculated as follow:

$$I'_S = \sigma(h(I_S)) \quad (1)$$

where  $h(\cdot)$  is the convolution operation, and  $\sigma$  is the sigmoid function.

Fig. 2. Spatial and channel fusion.

On the other hand, as  $I_L$  have richer semantic representations, this paper applies channel attention operation on this feature map to improve its channel features. The channel attention operation first applies average pooling and max pooling to generate intermediate feature maps. Then, two  $1 \times 1$  convolution layers are applied in parallel to further transform these intermediate feature maps. Finally, the sigmoid activation function is used after summing the intermediate maps to generate the rich channel semantic maps. Suppose  $I_L \in \mathbb{R}^{W \times H \times C}$ , then the output of the channel attention operation  $I'_L$  is calculated as follow:

$$I'_L = \sigma(g(Avg(I_L)) + g(Max(I_L))) \quad (2)$$

After computing spatial and channel attention based on the relation of the input feature maps, this paper employs element-wise multiplication and summation to generate final enhanced feature map as follow:

$$I_O = I'_S \odot I_S + I_L \odot I'_L \quad (3)$$

Since the spatial and channel fusion module employs simple non-linear operation, it introduces negligible computation overhead.

### III. RESULTS

#### A. Dataset and Metrics

This paper employs the CULane dataset [10] to evaluate the proposed model. The CULane dataset has been utilized in various studies related to autonomous driving and advanced driver assistance systems. It's especially popular for tasks such as lane detection, semantic segmentation, and traffic scene understanding. The CULane dataset is quite large, containing around 55,000 images, and covering various scenarios with different traffic, lighting, and weather conditions. It consists of images from urban streets, highways, and rural areas captured at different times of the day. It also includes challenging driving scenarios like night driving, shadows, dazzling, and rainy or foggy conditions, thus offering a comprehensive dataset for robust model training. Each image in the CULane dataset is carefully annotated with high-quality pixel-level annotations of lane lines, including markings for straight lanes, curved lanes, and parallel lanes. This detailed annotation serves as an excellent training ground for lane segmentation models. It is worth noting that each image also contains corresponding binary lane segmentation maps, which are quite useful for model training and evaluation. The dataset is split into distinct training and testing sets, providing a reliable platform for both the development and evaluation of models. The training set contains around 88,880 images, while the test set contains approximately 34,680 images, spread across 9 different categories representing a range of driving conditions, as shown in Table I and Fig. 3. This paper carefully screened 40,000 annotated images containing lane lines in the dataset and used 70% of the filtered dataset for training. As in [10], this paper uses *F1*-measure as metric for evaluating the proposed model.

Fig. 3. Some examples for different scenarios.

TABLE I. PROPORTION OF EACH CATEGORY IN THE CULANE DATASET

Category	Proportion (%)	Resolution
Normal	27.7	590×1640
Crowded	23.4	
Dazzle light	1.4	
Shadow	2.7	
No line	11.7	
Arrow	2.6	
Curve	1.2	
Night	20.3	
Crossroad	9.0	

#### B. Experimental Results

This paper compared the performance of the proposed method against established models including SCNN [10], ENet [23], and ENet-SAD [12]. All experiments were conducted across eight distinct categories of the CULane testing set, evaluated based on *F1*-measure. The results are shown in Table II. In the Normal condition, DFFN demonstrated superior performance with an *F1* score of 70.25%, compared to SCNN (60.12%), ENet (65.62%), and ENet-SAD (67.72%). Under Crowded circumstances, the robustness of the DFFN model was notable, achieving an *F1* score of 58.71%, outperforming SCNN (45.38%), ENet (55.46), and ENet-SAD (55.81). In the Dazzle light and Shadow scenarios, DFFN continued to excel, achieving *F1* scores of 53.54% and 55.62% respectively, surpassing the scores of SCNN, ENet, and ENet-SAD. For the No line and Arrow conditions, DFFN maintained high performance levels, demonstrating impressive lane recognition capability in comparison to other models, as evidenced by the *F1* scores. In the Curve category, DFFN achieved an *F1* score of 58.80%, demonstrating superior performance in identifying and tracking curved lanes. Lastly, in the Night condition, DFFN upheld its strong performance, with an *F1* score of 58.62%, outperforming the compared models in low-light conditions. These experimental results underscore the effectiveness and robustness of the proposed DFFN method across varied traffic scenarios and lighting conditions. The consistently high *F1* scores, in comparison to other established models, suggest promising potential for DFFN in real-world applications, such as autonomous driving and advanced driver assistance systems.

Fig. 4 provides a detailed visual comparison of the performance of the proposed DFFN, SCNN, and ENet on the CULane testing images. The first column displays the original image, providing the actual scene context from the CULane testing set. The second column shows the ground truth, representing the ideal output that the models should aim to replicate. These images provide a benchmark against which the model outputs are evaluated. The third column presents the results of the proposed DFFN model. An initial visual comparison between these outputs and the ground truth may suggest the effectiveness of the DFFN in accurately segmenting lane lines under different traffic scenarios. The fourth column illustrates the output from the SCNN model. By comparing these images with the ground truth and the DFFN outputs, we can assess the performance of the SCNN in relation to both the ideal output and the proposed model. The final column depicts the results from the ENet model. Again, a comparison between these images, the ground truth, and the other model outputs helps evaluate the performance of the ENet model in various traffic conditions. A detailed examination of Fig. 4 would provide insights into the areas where the proposed DFFN outperforms or underperforms compared to the SCNN and ENet models. For example, we might observe that the DFFN model performs particularly well in crowded scenarios or shadow conditions, offering more accurate and robust lane segmentation than the comparative models. However, the DFFN might be sensitive to noise and outliers in the input data. This could result in misclassification or incomplete segmentation of lane lines, affecting the overall accuracy and reliability of the model's outputs. Addressing the

sensitivity to noise and outliers is an important challenge in lane line segmentation with deep learning models like the DFFN. Techniques such as data augmentation, robust feature

extraction, and outlier detection can be explored to improve the model's resilience to noisy input data and enhance its accuracy and reliability.

Fig. 4. Visualization of experimental results in CULane dataset of the proposed model and SCNN, ENet.

TABLE II. F1-MEASURE (%) OF DIFFERENT APPROACHES ON THE CULANE TESTING SET

Method	Category							
	Normal	Crowded	Dazzle light	Shadow	No line	Arrow	Curve	Night
SCNN [10]	60.12	45.38	37.52	41.44	36.34	45.31	44.44	41.20
ENet [23]	65.62	55.46	50.21	54.49	35.82	58.11	56.43	49.39
ENet-SAD [12]	67.72	55.81	52.91	54.51	39.06	56.94	57.91	54.12
Proposed model	70.25	58.71	53.54	55.62	39.86	59.17	58.80	58.62

#### IV. CONCLUSION

This paper introduces the Deep Feature Fusion Network (DFFN), a novel approach for lane line segmentation in complex urban traffic scenes. Based on the DLA structure, the DFFN integrates more skip connections between low-level and high-level features. In addition, each linear aggregation node in the original DLA structure is replaced by the spatial and channel fusion node to learn and predict the importance of each input feature during the fusing process. The DFFN has demonstrated its robustness in challenging scenarios, including crowded environments, varying lighting conditions, unmarked lanes, and curved paths, outperforming established models consistently. These results highlight the potential of the DFFN model in improving the functionality and safety of autonomous driving systems and advanced driver assistance systems. Despite its current performance, there is always room for improvement and optimization. Future work could focus on further enhancing the DFFN's ability to adapt to diverse environmental conditions and refining the model's capability to handle more complex and unusual lane line patterns, as well as addressing the sensitivity to noise and outliers.

**Abstract**—Skin diseases represent a variety of disorders that can affect the skin. In fact, early diagnosis plays a central role in the treatment of this type of disease. This scholarly article introduces a novel approach to classifying skin diseases by leveraging two ensemble learning techniques, encompassing multi-modal and multi-task methodologies. The proposed classifier integrates diverse information sources, including skin lesion images and patient-specific data, aiming to enhance the accuracy of disease classification. By simultaneously utilizing image input and structured data input, the multi-task functionality of the classifier enables efficient disease classification. The integration of multi-modal and multi-task techniques allows for a comprehensive analysis of skin diseases, leading to improved classification performance and a more holistic understanding of the underlying factors influencing disease diagnosis. The efficacy of the classifier was assessed using the ISIC 2018 dataset, which comprises both image and clinical information for each patient with skin diseases. The dataset used in this study comprises images of seven different types of skin diseases and their associated medical information. The findings of our proposed approach show that it outperforms traditional single-modal and single-task classifiers. The results of this study demonstrate that the proposed model attained an accuracy of 97.66% for the initial classification task (image classification). Additionally, the second classification task (clinical data classification) achieved an accuracy of 94.40%.

**Keywords**—Multi-modal approach; multi-task approach; transfer learning; deep learning; skin diseases classification

## I. INTRODUCTION

Skin diseases, also known as dermatological conditions [1], represent a diverse group of disorders that can affect the skin, hair, nails, and mucous membranes. These disorders exhibit a wide spectrum of clinical presentations, ranging from benign and self-limiting conditions [2], such as common warts and seborrheic dermatitis, to severe and debilitating conditions, such as bullous pemphigoid and cutaneous lymphoma. The classification of skin diseases is crucial for proper diagnosis, treatment, and management. Accurate and timely diagnosis allows for the initiation of appropriate therapy and can prevent the progression of the disease. Moreover, the classification of skin diseases is a challenging task [3], that requires a thorough understanding of the clinical presentation, histopathological features, and laboratory results. In addition to this, a misdiagnosis or delayed diagnosis can lead to inappropriate treatment [4], which can result in poor outcomes, increased morbidity, and increased healthcare costs. The use of Artificial

Intelligence (AI) techniques for the classification of skin lesions and other diseases, including COVID-19 [5] and diabetes diseases [6], [7], have gained increasing attention in recent years [8], due to their potential to improve diagnostic accuracy and reduce the time required for diagnosis.

AI techniques are based on the ability of algorithms to learn from data and make predictions based on that learning. These techniques can be used to analyze large amounts of data and identify patterns [9], [10], that may be difficult for human experts to discern. In the context of skin disease classification, machine learning and deep learning techniques [11], [12], can be used to analyze images of skin lesions, identify patterns in clinical data, and analyze laboratory results. The utilization of these algorithms in skin disease classification has the potential to improve diagnostic accuracy and reduce the time required for diagnosis. However, the development and implementation of AI techniques for skin disease classification [13], requires a thorough understanding of the data and the algorithms used, as well as a rigorous evaluation of their performance. Recent advancements in AI have also had a significant impact on various other fields [14]–[16].

In the field of skin disease classification, previous studies have primarily focused on using deep learning techniques. While these approaches have shown promising results, there are significant gaps that necessitate further research. One notable gap is the limited exploration of multi-modal and multi-task deep neural networks for enhanced skin disease classification. Existing studies have predominantly focused on single-modal data or single-task models, neglecting the potential benefits of integrating diverse data modalities or leveraging multiple related tasks simultaneously. By addressing this gap, our research aims to develop a transfer learning approach in the context of multi-modal and multi-task deep neural networks, enabling more comprehensive and accurate skin disease classification. This approach holds the potential to leverage the complementary information from various data modalities, such as images, genetic data, and patient history, to improve the overall classification performance. Additionally, the inclusion of multiple related tasks, such as disease severity assessment or treatment recommendation, can further enhance the diagnostic capabilities of the system. By bridging this gap and exploring the potential of multi-modal and multi-task deep neural networks, our research contributes to the advancement of skin

disease classification techniques and has practical implications for improving diagnostic accuracy and patient care.

In this study, a multi-modal, multi-task DNN classifier is used to introduce an efficient MDSS [17], [18], that can identify skin conditions in dermatoscopic pictures. The innovative idea is to combine the outputs of two artificial intelligence models based on the TL approach and DNN models [19], [20], using multi-model and multi-task techniques. To build an accurate model compared to the published approaches at the time. To improve the performance of skin disease categorization, this model has been used to integrate medical information, such as past medical history and laboratory findings, with imagery data. This research used the ISIC 2018 dataset to train and evaluate our proposed MDSS, which contains photos of seven distinct types of skin disorders. Furthermore, in addition to the photos provided, the dataset used includes critical clinical information about each image [21], such as age, gender, and location. Hence, the main objective of our article is to enhance the accuracy of skin disease classification, leading to improved diagnostic outcomes, timely interventions, and better patient care. By providing practical insights and demonstrating the applicability of our approach, we aim to empower healthcare practitioners with a reliable tool [22], that can enhance their diagnostic capabilities and positively impact patient outcomes.

This manuscript is structured as follows: A thorough examination of prior research in the domain of skin disease classification utilizing DL techniques is provided in Section II. The design and implementation of the proposed Multi-Modal and Multi-Task classifier, as well as the methodology employed, are expounded upon in Section III. The results of the experiments, including a performance assessment, are detailed in Section IV. Finally, in Section V, the conclusion of this study and potential areas for future research are outlined.

## II. RELATED WORKS

Deep learning [23], a subset of machine learning [24], has been increasingly used in the field of skin disease classification in recent years. This is due to its ability to automatically extract features [25], and patterns from large and complex datasets, such as images of skin lesions. In this section, we will review the current state-of-the-art in skin disease classification over the last few years using DL techniques. We will examine the various techniques that have been proposed in these studies, such as TL and DNNs, to compare these methods with our proposed classifier in this manuscript.

A study presented in [26], explores the use of DL techniques for the classification of skin lesions on imbalanced small datasets. The authors propose the use of a single model of DL and evaluate its performance in comparison to traditional machine learning methods and human experts. They found that this approach has the potential to improve diagnostic accuracy and reduce the time required for diagnosis, even when working with small, imbalanced datasets. However, the use of DL on imbalanced small datasets also poses challenges such as overfitting and a lack of robustness in the classifier. The authors also suggest potential directions for future research in this field to overcome these challenges, such as the development of more advanced DL architectures and

techniques and the integration of additional clinical data. The best proposed model in this study, namely RegNetY-3.2G-Drop, achieved a balanced accuracy value of 85.8% using the ISIC 2018 dataset.

A scientific study featured in [27], presents a new method for skin lesion classification using DL techniques. The proposed method, called SSD-KD, is a self-supervised, diverse knowledge distillation method that uses a lightweight model to classify skin lesions from thermoscopic images. The authors evaluate the performance of this method and show that it can achieve an accuracy of 84.6% and generalization capability even when working with a small dataset. The authors also point out that this approach is an efficient method for skin lesion classification, especially when there is a lack of labeled data. On the other hand, one of the limitations of this study is that it achieves a low level of accuracy.

A scholarly article published in [28], introduces a new technique for diagnosing malignant melanoma using DL techniques. The proposed method, called 2-HDCNN, is a two-tier hybrid dual convolutional neural network feature fusion approach that fuses multiple features from different sources to improve diagnostic accuracy. The authors of the article have evaluated the performance of this method and have found that it is able to achieve high accuracy and generalization capability on the task of malignant melanoma diagnosis, with an accuracy of 92.15%. This means that the method can accurately diagnose malignant melanoma in a high percentage of cases.

A paper appearing in [29], provides a new method for extracting and classifying skin lesion features using DL techniques. The proposed method uses regularization techniques to improve the accuracy and robustness of the model. It also uses layer-wise weight norm-based feature extraction to extract informative features from the skin lesion images. The authors evaluate the performance of this method on several datasets and show that it can achieve an accuracy of 94.42% on the ISIC 2018 dataset, 91.73% accuracy on the ISIC 2019 dataset, and 93% accuracy when evaluated on the combined dataset.

A work documented in [30], discusses a novel approach for skin lesion classification using DL techniques. The proposed method, called End-to-End Decoupled Training (E2EDT), is designed to handle the long-tailed distribution problem, which is a common issue in the skin lesion classification task. E2EDT is a robust DL method that decouples the training process into two stages: pre-training and fine-tuning. The authors evaluate the performance of this method using the ISIC 2018 dataset and show that it can achieve a balanced accuracy of 87%.

Table I presents a comprehensive overview of the reviewed studies, highlighting essential information such as the number of classes, the implemented classifiers, and the highest performance attained based on the evaluation metrics employed. This table acts as a valuable resource, providing a condensed overview of the essential findings from the literature review. By presenting this information in a concise and structured format, Table I facilitates easy reference and comparison of the different approaches and outcomes reported in the studies. This condensed representation of essential

findings promotes efficient data analysis and aids in the identification of research gaps and future directions.

TABLE I. SUMMARY OF SOME LITERATURE WORK

Ref	Datasets (Classes)	Models	Accuracy
[26]	ISIC 2017 Dataset (3)	RegNetY-3.2G-Drop	74.6%
	ISIC 2018 Dataset (7)		85.8%
	ISIC 2019 Dataset (8)		59.3%
	7-PT Dataset (5)		65.7%
[27]	ISIC 2019 Dataset (8)	SSD-KD	84.6%
[28]	ISIC-2018 Dataset (2)	2-HDCNN	92.15%
[29]	ISIC 2018 Dataset (2)	CLCM-net	94.42%
	ISIC 2019 Dataset (2)		91.73%
[30]	ISIC 2018 Dataset (7)	E2EDT	87%

In recent years, deep learning techniques have gained significant popularity for skin disease classification. However, this approach is not without limitations. One primary limitation lies in the availability of labeled data, as deep learning models necessitate large amounts of accurately labeled data for effective training. Acquiring such data, especially for rare skin diseases, can be challenging, which hinders the development and deployment of deep learning models in these cases. Another limitation pertains to the quality of the available data. The performance of deep learning models heavily relies on the quality of the input data. Poor data quality, characterized by noise, missing information, or inconsistencies, can negatively impact the model's performance, leading to overfitting and limited generalization capabilities. Furthermore, deep learning models may struggle to generalize well to unseen data, particularly when the distribution of the new data differs significantly from the training data. This limitation poses challenges in real-world scenarios where the model needs to perform accurately in diverse and previously unseen cases. Additionally, the existing literature predominantly focuses on single-modal data or single-task models, neglecting the potential advantages of incorporating multi-modal data and leveraging multi-task learning approaches. By solely considering a single data modality or a specific task, previous studies failed to exploit the complementary information present in diverse data sources, which could potentially enhance the classification performance and broaden the scope of skin disease diagnosis.

Addressing these limitations and exploring the potential of multi-modal data and multi-task learning in the context of skin disease classification is crucial to overcome the data scarcity challenge, improve generalization capabilities, and advance the state-of-the-art in this field.

### III. MATERIALS AND METHODS

#### A. Schematic of the Planned Multi-Modal and Multi-Task Classifier for Skin Disease Monitoring

In this subsection, a comprehensive approach for building a multi-modal and multi-task classifier for skin diseases is presented. The proposed framework leverages the

EfficientNetV2L network for processing the image dataset and the DNN for handling the clinical dataset. The following paragraphs provide additional details, examples, and techniques to further elucidate the process.

To initiate the classifier's development, a large dataset of skin lesion images and corresponding clinical data is collected. In this study, the ISIC 2018 dataset is specifically chosen due to its widespread utilization and its potential as a valuable resource for constructing the multi-modal and multi-task classifier. The ISIC 2018 dataset comprises a diverse range of skin lesion images along with associated clinical information, enabling the model to learn from both visual and clinical data sources. On the other hand, pre-processing of the collected data is then conducted to ensure its suitability for model training. This crucial step involves data cleaning techniques such as eliminating noise, addressing data inconsistencies, and handling missing or irrelevant information. Furthermore, techniques such as normalization can be employed to enhance the quality of the image dataset, while feature scaling methods can be applied to the clinical dataset. Following data pre-processing, the classifier extracts meaningful features from the image data and the clinical data. The image data is processed using the EfficientNet V2L network, which has demonstrated its effectiveness in image classification tasks. The network employs advanced techniques such as convolutional layers and attention mechanisms [31], [32], to capture intricate visual patterns and extract discriminative features from the skin lesion images. Similarly, the clinical data is fed into a deep neural network (DNN) architecture that is specifically designed to handle heterogeneous clinical data, extracting relevant features from patient-specific attributes, laboratory results, and other clinical information. The extracted features from both modalities are then integrated within a multi-task learning framework. This framework allows the model to simultaneously learn from both image and clinical data, leveraging the complementary information contained in each modality. A shared encoder architecture is employed to concatenate the outputs of the EfficientNet V2L network and the DNN, combining the learned representations from both modalities into a unified feature representation. This fused representation is subsequently passed through a final classifier layer, enabling the model to make accurate predictions regarding skin disease classification. To assess the performance of the proposed multi-modal and multi-task classifier, a separate test dataset is utilized. This dataset comprises skin lesion images and corresponding clinical data that were not involved in the training process. By evaluating the classifier on this independent dataset, its ability to accurately diagnose skin diseases can be quantitatively measured, providing insights into its efficacy and generalization capability.

The flowchart (Fig. 1) accompanying the text visually illustrates the different stages and processes involved in the design and implementation of the proposed multi-modal and multi-task classifier. This flowchart serves as a comprehensive guide, offering a clear and organized overview of the sequential steps encompassing data pre-processing, model construction, and model evaluation.

Fig. 1. The architecture of the proposed model.

### B. ISIC 2018 Dataset Description

The ISIC 2018 dataset is a collection of images of skin lesions, along with corresponding diagnostic information, used for research in the field of skin disease classification using AI techniques. The dataset includes over 10000 images of various skin lesions [33], including malignant melanomas, benign nevi, and other types of skin diseases. The diagnostic information provided with the images includes the diagnosis made by a dermatologist as well as other relevant clinical data. The ISIC 2018 dataset is a widely used benchmark dataset in the field of skin disease classification and is commonly used to evaluate the performance of new AI algorithms and models. As depicted in Fig. 2, several examples are presented from the ISIC 2018 dataset.

Fig. 2. The examples of the seven different classes of skin disease present in the dataset : (a) Actinic keratoses; (b) Basal cell carcinoma; (c) Benign keratosis-like lesions; (d) Dermatofibroma; (e) Melanoma; (f) Melanocytic nevi; and (g) Vascular lesions.

The dataset used in this study comprises images of 7 different types of skin diseases [34], including Actinic keratoses, Basal cell carcinoma, Benign keratosis-like lesions, Dermatofibroma, Melanoma, Melanocytic nevi, and Vascular lesions. Moreover, alongside the provided images, the dataset used encompasses essential clinical information pertaining to each picture, encompassing age, gender, localization, and Dx\_type (denoting the modality through which the skin disease was diagnosed). The dataset is divided into a training set and a test set, with 7500 images in the training set in addition to their clinical data and 2500 images in the test set with their associated medical information, respectively.

### C. Deep Learning Algorithms for Classification

*a) Multi-Modal and Multi-Task Neural Network:* A Multi-Modal and Multi-Task Neural Network is a type of DL architecture that can process and analyze multiple types of input data [35], such as images, text, and audio, simultaneously. This type of network can perform multiple tasks, such as classification and segmentation, using the same network architecture, allowing for more efficient and effective processing of data. Additionally, this type of network can improve the performance of each task [36], by leveraging the shared representations and features learned from the other tasks. This is done by sharing the weights of the network across different tasks, which can help improve the generalization of the model and reduce the need for additional training data. Overall, multi-modal, and multi-task networks are well-suited for applications where multiple types of data need to be analyzed together, such as medical imaging and clinical data. The diagram presented in Fig. 3 illustrates a multi-modal and multi-task neural network model, which is represented through its architectural components and connections.

Fig. 3. An example of a multi-modal and multi-task neural network.

*b) EfficientNet V2L Network:* EfficientNet V2L is a type of neural network architecture [37], that is designed to improve the efficiency and effectiveness of DL models. This network is an updated version of the original EfficientNet, which was designed to improve the performance of DL models while reducing their computational complexity. The V2L version of EfficientNet is specifically designed to handle large-scale image datasets, and it can achieve state-of-the-art performance on a wide range of image classification tasks. The network is characterized by its unique architecture, which includes depth-wise separable convolutions, linear bottlenecks, and efficient scaling of network depth and width. These design choices allow the network to achieve high performance while using fewer parameters than other state-of-the-art architectures. EfficientNetV2 models utilize a scaling method and a neural architecture search algorithm to optimize both the architecture and hyperparameters of the network simultaneously. These models are specifically designed for image classification tasks and come in a range of sizes, referred to as "scales." Each scale corresponds to a distinct model architecture and number of parameters, with larger scales possessing a greater number of parameters and higher accuracy. The architecture search space has been expanded to include novel operations, such as FusedMBCConv, in addition to conventional CNN operations.

*c) Deep Neural Network:* DNNs are a class of machine learning models [38], that are composed of multiple layers of artificial neurons. These layers are interconnected and process the input data through a series of mathematical computations known as activation functions. DNNs are trained to learn patterns and features in the input data, allowing them to perform tasks such as image recognition, natural language processing, and speech recognition. DNNs are known for their ability to represent complex, non-linear relationships between input and output and can often achieve state-of-the-art performance on a wide range of tasks. They are widely used in many medical fields and have become a popular tool for solving complex problems.

#### D. Confusion Matrix and Measures

A confusion matrix is a table that is often used to describe the performance of a classification algorithm, specifically in the context of medical diagnosis. In the case of skin diseases, a confusion matrix [39], would display the number of True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN) for a given diagnostic test. These values can then be used to calculate various performance measures [40], such as accuracy, precision, recall, and specificity, which can give insight into the effectiveness of the diagnostic test. The following formulas compute these metrics:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

$$\text{Recall} = \frac{TP}{FN+TP} \quad (3)$$

$$\text{Specificity} = \frac{TN}{TN+FP} \quad (4)$$

#### IV. FINDINGS AND DISCUSSION

In the current section, the primary experimental results of the scientific study are presented. Initially, the training performance of all utilized models is depicted through plots that depict the evolution of accuracy and loss over time. Furthermore, a confusion matrix is presented to provide a thorough understanding of the classification outcomes.

##### A. Implementation Platform

The present study carried out all experiments using the Python programming language and the Jupyter Lab environment. The AI models were trained on the Google Colab platform, which is a Jupyter Notebook-based cloud service for researching and training AI algorithms. The computational resources employed in this setup included a Tesla K80 GPU with 12GB of GDDR5 VRAM, an Intel Xeon Processor with two cores operating at 2.20 GHz, and 13 GB of RAM. The construction of models was facilitated through the utilization of two primary implementation libraries: Keras and Autokeras. Additionally, the Adam optimizer and cross-entropy loss

function [41], were employed for training all algorithms. Table II presents the hyperparameters used for fine-tuning the pre-trained models utilized in this research.

TABLE II. THE PARAMETERS AND FUNCTIONS UTILIZED IN THE TRAINING PROCEDURES

Network	Epochs	Batch Size	Loss Function	Optimizer	Learning Rate
Proposed Model	50	16	Categorical Cross entropy	Adam	1e-4

##### B. Experimental Results

a) *Training of DL Models Results:* The training results of the proposed multi-modal and multi-task DNN with TL were evaluated using accuracy, precision, recall, and specificity metrics. These results were also evaluated using learning curves, which showed a consistent improvement in performance as the number of training epochs increased. The learning curves also indicate that the proposed approach can effectively utilize the additional information provided by this proposed approach. The loss curve, on the other hand, shows a decrease, indicating that the model is learning and generalizing well. The convergence of both curves suggests that the proposed approach effectively leverages multi-modality and multi-task information, resulting in a robust classifier for skin disease classification. Generally, these results demonstrate the effectiveness of the proposed approach in improving the classification of skin diseases. Fig. 4 illustrates the accuracy and loss curves of the multi-modal and multi-task DNN with a TL classifier during the training phase.

b) *Testing of DL Models Results:* The effectiveness of the models was evaluated in this study using a separate set of test data that incorporated both image and clinical data inputs. The performance of the model for each class of skin disease was visualized through the generation of a confusion matrix, which subsequently informed the calculation of performance metrics. The results of the multi-class classification confusion matrix are presented in Fig. 5.

Fig. 4. Performance of the multi-modal and multi-task DNN with the TL classifier : (a) The accuracy of the model over time; (b) The decrease in loss function over time during the training phase.

Fig. 5. Confusion matrix illustrates the performance of the proposed classifier: (a) Initial classification task (image input); (b) Second classification task (clinical data input).

These matrices show that the model performed well for most of the classes, with a high number of TP and a low number of FP and FN. The confusion matrix also revealed some misclassification for a few classes, which can be further investigated to improve the performance of the model. Overall, these results demonstrate the effectiveness of the proposed

approach in classifying skin diseases. Based on the results of the matrices, it can be inferred that the proposed approach for classifying skin diseases is effective. The assessment measures for the performance of the proposed model are also outlined in Tables III and IV.

TABLE III. PERFORMANCE ANALYSIS OF THE INITIAL CLASSIFICATION TASK USING METRICS: ACCURACY, PRECISION, RECALL, AND SPECIFICITY

Class	Accuracy	Precision	Recall	Specificity
0	97.43%	56.45%	74.47%	98.16%
1	97.16%	75.86%	75.00%	98.53%
2	98.09%	86.93%	96.23%	98.31%
3	97.23%	57.89%	24.44%	99.46%
4	96.97%	96.75%	98.55%	94.17%
5	98.55%	100.00%	88.11%	100.00%
6	98.22%	45.83%	44.00%	99.13%
<b>Average</b>	<b>97.66%</b>	<b>74.25%</b>	<b>71.54%</b>	<b>98.25%</b>

TABLE IV. PERFORMANCE ANALYSIS OF THE SECOND CLASSIFICATION TASK USING METRICS: ACCURACY, PRECISION, RECALL, AND SPECIFICITY

Class	Accuracy	Precision	Recall	Specificity
0	96.27%	42.62%	55.32%	97.59%
1	92.53%	40.85%	67.44%	94.06%
2	93.67%	69.75%	71.07%	96.35%
3	95.60%	25.58%	24.44%	97.80%
4	89.87%	93.96%	89.82%	89.95%
5	95.13%	87.33%	70.81%	98.56%
6	97.73%	35.48%	44.00%	98.64%
<b>Average</b>	<b>94.40%</b>	<b>56.51%</b>	<b>60.42%</b>	<b>96.13%</b>

The tables provide numerical values for each performance metric, which allows for a quantitative assessment of the multi-task classification performances. The numerical values represent the specific performance of the model for each metric, and by comparing these values to other metrics, we can understand how well the model is performing.

### C. Discussion

A novel methodology for skin disease classification is presented that incorporates the utilization of multi-modal and multi-task classifier. The proposed classifier integrates multiple modalities of data, including visual representations of skin lesions and patient-specific characteristics, to enhance the precision of disease classification. The multi-task aspect of the classifier enables it to concurrently classify the disease through the integration of image-based inputs and structured data. The proposed approach was evaluated using the ISIC 2018 dataset, which includes both image and clinical information for patients with skin diseases. This dataset encompasses data on 7 different categories of skin diseases. Our findings indicate that the proposed model exhibited a high level of accuracy, specifically 97.66% for the primary classification task (Image classification). Furthermore, the second classification task (clinical data classification) demonstrated an accuracy of 94.40%. The results of our proposed methodology demonstrate that it surpasses traditional single-modal and single-task classifiers.

The proposed classifier for improved classification of skin diseases offers several benefits. One of the key contributions of this model is that it utilizes multiple sources of information, including images of skin lesions and patient-specific information, to improve the accuracy of disease classification. Additionally, the multi-task aspect of the classifier allows it to simultaneously classify the disease and predict its severity, providing more comprehensive information for diagnosis. The use of transfer learning techniques also allows for better performance in real-world scenarios and faster training times. While the proposed approach for improved classification of skin diseases offers many benefits, it also has some limitations. One limitation is that the proposed approach is based on a dataset of skin diseases, which means that it may not be able to generalize well to other types of skin diseases or other medical conditions. Another limitation is that the model still requires a large amount of labeled data for training, which can be challenging to obtain. Moreover, while the proposed classifier shows promising findings, it is important to be aware of these limitations and to continue researching ways to improve the model's performance and applicability. Table V presents a comparison of the proposed multi-modal and multi-task DNN with a TL classifier to other methods discussed in the literature. The table compares the performance of our system to other efforts in terms of accuracy metrics. The results show that our proposed system outperforms the other methods discussed in the literature, indicating that it is a promising approach and offers significant potential for improving skin disease classification. The superior performance exhibited by our system reinforces its viability as an advanced and effective method in the field, highlighting its potential for enhancing diagnostic accuracy and facilitating improved patient care.

TABLE V. COMPARATIVE OUTCOMES OF THE PROPOSED APPROACH WITH EARLIER STUDIES PUBLISHED IN THE LITERATURE

			94.40%

<sup>a</sup>. Multi-Modal and Multi-Task DNN with TL

### V. CONCLUSION AND PERSPECTIVES

In conclusion, this study proposed a multi-modal and multi-task DNN with TL for improved classification of skin diseases. The proposed approach utilizes multiple sources of information, including images of the skin lesions and patient-specific information, to improve the accuracy of disease classification. The classifier's ability to perform multiple tasks enables it to classify the disease by utilizing both image input and structured data input simultaneously. The results of the study demonstrate that the proposed model achieved high accuracy on the ISIC 2018 dataset, outperforming traditional single-modal and single-task classifiers.

As perspectives, there are several promising avenues for future work building upon the findings of this research. One prospective direction involves exploring additional data sources to further enhance the accuracy and robustness of the model. On the other hand, incorporating genetic data, patient history, or environmental factors could provide a more comprehensive understanding of skin diseases and enable more precise classifications. Additionally, investigating advanced techniques, such as ensemble models and the XAI technique, may improve the performance and generalization capabilities of the classification system.

**Abstract**—This study focuses on predicting and estimating possible stock assets in a favorable real-time scenario for financial markets without the involvement of outside brokers about broadcast-based trading using various performance factors and data metrics. Sample data from the Y-finance sector was assembled using API-based data series and was quite accurate and precise. Prestigious machine learning algorithmic performances for both classification and regression complexities intensify this assumption. The fallibility of stock movement leads to the production of noise and vulnerability that relate to decision-making. In earlier research investigations, fewer performance metrics were used. In this study, Dickey-Fuller testing scenarios were combined with time series volatility forecasting and the Long Short-Term Memory algorithm, which was used in a futuristic recurrent neural network setting to predict future closing prices for large businesses on the stock market. In order to analyze the root mean squared error, mean squared error, mean absolute percentage error, mean deviation, and mean absolute error, this study combined LSTM methods with ARIMA. With fewer hardware resources, the experimental scenarios were framed, and test case simulations carried out.

**Keywords**—Dickey-Fuller test case (DF-TC); recurrent neural network (RNN); root mean square error (RMSE); long short-term memory (LSTM); machine learning (ML); auto-regressive integrated moving average (ARIMA)

## I. INTRODUCTION

This study focuses on predicting and estimating possible stock assets in a favorable real-time scenario for financial markets without the involvement of outside brokers about broadcast-based trading using various performance factors and data metrics. With regard to broadcast-based trading, the main objective of this study is to predict and estimate possible stock assets in a favorable real-time scenario for the Saudi financial markets, excluding outside brokers. Sample data from the Y-finance segment was assembled into API-based data series with exactitude and sharpness. Prestigious machine learning algorithmic performances for both classification and regression complexity increase significantly. Because stock movement is fallible, noise is produced as a result, which leaves decision-making vulnerable. Fewer performance measures were used in earlier research investigations. Previous studies relied on fewer

performance metrics [6]. The focus of the study is to use comprehensive models with unique parameters to predict more precisely. Methods considered in this research are long-short-term memory (LSTM) and auto-regressive integrated moving average (ARIMA), along with various performance measures. The major contribution of this study relies on the fast execution of simulation processes with fewer hardware resources in the case of predictions with the Long Short-Term Memory Algorithm. Every researcher wishes to prototype stock prices efficiently with less noise so that stock buyers can consequently decide when to trade or invest to make a generous profit [8].

Better time series models and intricate ML models can both contribute to success. Stock values, nevertheless, are very erratic and unpredictable [7]. Overall, this indicates that there is little consistency in data patterns for estimating stock prices across an effective time horizon. On time series data, LSTM meshes [26] are effectively used for classification evaluation, computation [15], and prediction. They inherit the ability to retain data or information over various time periods and have twice as much processing power to handle data points, sequences, and series [16]. In other words, LSTM is renowned for its ability to store large amounts of data [8]. The only components used by LSTM are those referred to as gates. Prices on the stock market are nonstationary data sources. In the intraday or off-market, rising and falling movements [4] are not linear. They fluctuate and diminish in response to repository, fund, and pressure; they are remarkably predictable when coupled with a model. Evaluation of stock price prediction can demonstrate its value in advancing an investor's career and development [25]. Many investors base their choices on financial news or the opinions of fictitious financial gurus working covertly. These financial counselors participate in insider trading, misuse investor emotions, and ultimately deplete or exploit investor wealth [14]. Companies' fundamental analyses take into account a number of factors, including quarterly net profit, long-term firm growth, and market risk tolerance. This study's goal is to provide a useful prediction data flow visualization for investors to use while making short-term decisions using unprocessed mathematical data from a variety of open-source repositories [13]. It is quite

difficult to predict stock prices in a real-time setting using both theoretical and numerical issues. The hypothesis study has been carried out by numerous researchers using various performance indicators, but which can determine the success or failure of future system implementation [10] based on the profit or loss experienced by individual investors [11] over the course of their lives.

**A. Evolution of Recurrent Neural Network (RNN)**

Firstly, it is anticipated that altogether inputs and outputs are interdependent of each segment in a neural terminology. However, it is not reliable for maximum scenario such as predicting the next day stock price in a financial market. RNN tends to utilize the resources of sequential pair information. They are so called recurrent due to their performance of the same simulation for every component of a sequence pair, in which output is dependable on the previous calculations. Thus, it is known that elements have recent memory that involves knowledge-based information that has been implemented so far.

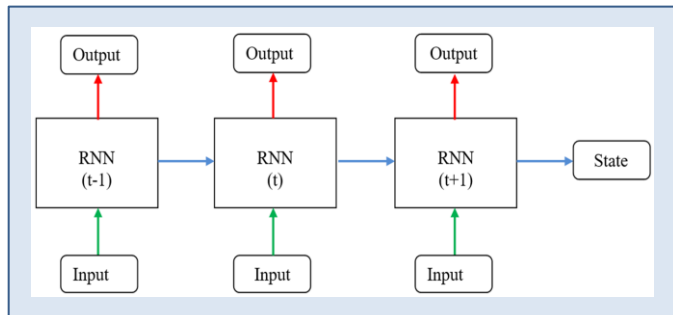

Fig. 1. Recurrent Neural Network and its states.

RNNs can make scrutinization of their internal state cell memory to compute pair of inputs in forecasting and prediction scenario. The full form of LSTM is classified as Long Short-Term Memory that comprises of three types of gates and cell state as shown in Fig. 1. LSTM has futuristic problem-solving capability and thus, it is introduced to overcome the problems inhibited by the RNN modeling [17] execution. The Fig. 2 represents the simulation depicting various sectors of Saudi stock market for ARIMA and LSTM. Undoubtedly, Input gate is activated when new piece of information is incremented into the current state of LSTM. LSTM can be implemented to elucidate Long Term interdependency [19] of variables issues in RNNs. The modules constitute of three gates namely Forget gate and next Input gate and then Output gate in the last segment. The forget gate manages what type of information has to be thrown out of memory state and responsible for take decisions related to time of remembrance. Output gate decides what to throw out of memory. Humans cannot think every time from the beginning of every problem from scratch [18].

**B. Auto-Regressive Integrated Moving Average (ARIMA) Model**

The terminology is composed of AR that stands for Auto regressive and it manipulates the dependency relationship among the observation and lagged time Observations. Integrated is responsible for operating differencing between

raw observations in order to maintain stationary state of data. Lastly, MA stands for Moving Average that anticipates the relationship of observations and residual sort of error [19]. Generally, time series consist of continuous [20] data that consist of seasonal component and cyclic component followed by trend component. During the statistical analysis of stock, it is recommended to focus on its returns which have been taken after investing in the financial market. The forecasting equation is prepared as mentioned.

The forecasting equation is prepared as follows.

$$\text{if } d=0 : y_t = Y_t \tag{1}$$

$$\text{if } d=1 : Y_t - Y_{(t-1)} \tag{2}$$

$$\text{if } d=2 : y_t = (Y_t - Y_{t-1}) - (Y_{t-1} - Y_{t-2}) = Y_t - 2Y_{t-1} + Y_{t-2} \tag{3}$$

In terms of y, the normal forecasting of ARIMA equation is as follows:

$$\hat{y}_t = \mu + \phi_1 y_{t-1} + \dots + \phi_p y_{t-p} - \theta_1 e_{t-1} - \dots - \theta_q e_{t-q} \tag{4}$$

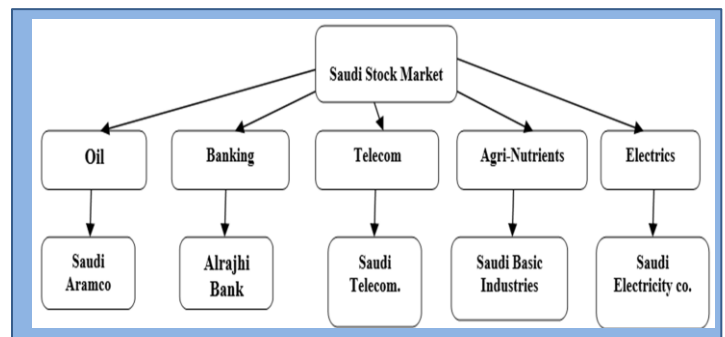

Fig. 2. Simulation depicting various sectors of Saudi stock market for ARIMA and LSTM.

In this study, Dickey-Fuller testing scenarios combined with time series volatility forecasting and the Long Short-Term Memory (LSTM) algorithm, which used in a futuristic recurrent neural network setting to predict future closing prices for large businesses on the stock market.

This article is organized in five sections: Section I included a detailed introduction about the key concepts, and Section II articulated the significant literature collectively with the background to the research work. Section III described the proposed methodology with Dickey-Fuller testing scenarios combined with time series volatility forecasting and the Long Short-Term Memory (LSTM) algorithmic sequences. The proposed methodology has integrated for simulation for different Saudi companies on the basis of ARIMA, LSTM and Agent Based Prediction. Section IV contains the experimental analysis, results, and discussions. Section V states the conclusions with achievements along with the future scope.

**II. RELATED WORK**

This section has analyzed the related study, innovations and executional scenarios of existing models and approaches. The author F. Kamalov, L. et al. (2020) compared various methods to perform prediction based on neural networks for the very forthcoming market opening value of SP 500 global indices by

focusing on its historic stock values [1]. B. B. P. Maurya, et al. (2019) explained the complexity of ML problems by using parameters such as E Ratio, Moving Average and MACD for better correctness [2]. C.C. Emioma et al. (2021) made intention to be implemented least-squares LR model for the guidance of intraday [3]. Nti IK, Adekoya AF et al. demonstrated that financial market investment decisions were 66% regarding technical analysis and further 11% and 23% were anticipating on the fundamental aspects and extended decisions 8.26% and 2.46% were dependent on combined analyses [28].

Samara A. Alves et al. (2018) focused on the Brazilian stock market and developed a decision model to compute the stock price with respect to certain technical indicators [29]. Traditional Neural Networks have few limitations for simulating the data as it is dependable on hardware structure with parallel processing. Moreover, Functioning of ANNs is so uncertain that it leads to why and how questions regarding trust build in the network. There is no determined assurance of Specific network structures; it is only possible with trial and experience. Chun-Hao Chen et al. (2020) proposed an algorithm for company-based portfolio by computing through Genetic programming algorithm and dividing the stocks into groups that can be effective for investor decisions [5]. Consequently, Traditional Neural network can work with numerical problems, but it faces performance issues while demonstrating the problem to the ANNs. The time duration of the network cannot be set, and it can be reduced to a specific value of error on a data sample that indicates training has been completed. Thus, ANNs do not give us exact results for simulation. Adaptive Neuro Fuzzy inference systems have major limitations in handling large inputs; thus, computation cost becomes very high in case of gradient learning and complex structure. Furthermore, few drawbacks are concerned with the location of the desired membership function and the curse of dimensionality [27].

Some researchers proposed neural networks, fuzzy logic control systems (FLCS) [30], genetic algorithms to analyze the stock market, medical and image based optical text recognition data [33][37][44]. Some other researchers proposed hybrid models such as neural fuzzy hybrid system [41][37][44], neural-genetic algorithm [38]. The neural fuzzy hybrid system (NFHS) operated separately. The unified NFHS utilizes the process to discover all factors from FLCS [42][45]. NFHS can correspond to exercise data produced from n-measurements of functionalities. NFHS comprises the fault figuring segment to advance the learning-training directions while the faults been unhurried, primarily membership sequences demarcated, then membership arrangements constraints stimulated. Zhao, Z., Zhou, H., Li, C., Tang, J., Zeng, Q. (2021) analysed that networks with incomplete information cannot be proposed effectively with partially familiar nodes, links and labels and their extended work is based on designing an inductive embedding model to solve real world network problems. The parameter used in ANFIS has a direct relation with computational cost [30]. In recent years, many researchers have been working diligently for this cause and experimented

over various ML algorithms to discover a prime solution in social benefit, numerous classical methods like SVM, DT, RF along with algorithms from NN family like DNN, ANN, neural fuzzy hybrid systems [39] and many others have come up with satisfactory result with some future scope [40][43]. The parameters used for evaluation are closing price, price differences, and daily return. Another research proposed automated decision making ResNet feed-forward neural network-based methodology for the medical diagnosis of diabetic retinopathy [51]. In another research integrated with the simple, multiple linear regression models [31][32][36] to generate a signal for SPY growth.

### III. METHODOLOGY

In the methodology, imported feasible libraries such as math, pandas, data reader, Sequential, Dense, LSTM are used in preliminary stage. Furthermore, Obtain the stock price using the Yahoo Finance API, then display the date in a table. Find out how many columns and rows there are in the data set. Visualize the history of closing prices while waiting. Convert a new Df to a numpy array after creating a new Df with a close column. Scale the data after obtaining the counting number of rows to train the computing model on. X\_train and Y\_train data sets should be created together with the training dataset and scaled training data set. X\_train and Y\_train should be converted to numpy arrays to transform the data into three dimensions. Build the LSTM model, compile the model and get the RMSE value. Plot the data and visualize and then show the validation and prediction price. If (Validation Price is greater than Prediction) then execute Buy Signal for the API Bridge. If (Validation Price is less than Prediction) then execute Sell Signal for the API Bridge. Set Money Management with maximum lose acceptance with proper Stop Loss at executive of each signal in API Bridge. Set Profit Target with each investment decision execution with Broker Account. Evaluate the Win ratio and Profit ratio. Repeat the process according to the Money management portfolio. The financial Market is quite a considerable at biggest challenge in statistics. Many individuals think that only technical analysis can beat it and can earn some sort of money, but reality is bit uncertain in the real time scenario as shown in the Fig. 3.

Build the LSTM model, compile the model and get the RMSE value. Plot the data and visualize and then show the validation and prediction price. Many individuals think that only technical analysis can beat it and can earn some sort of money, but reality is bit uncertain in the real time scenario as shown in the Fig. 3.

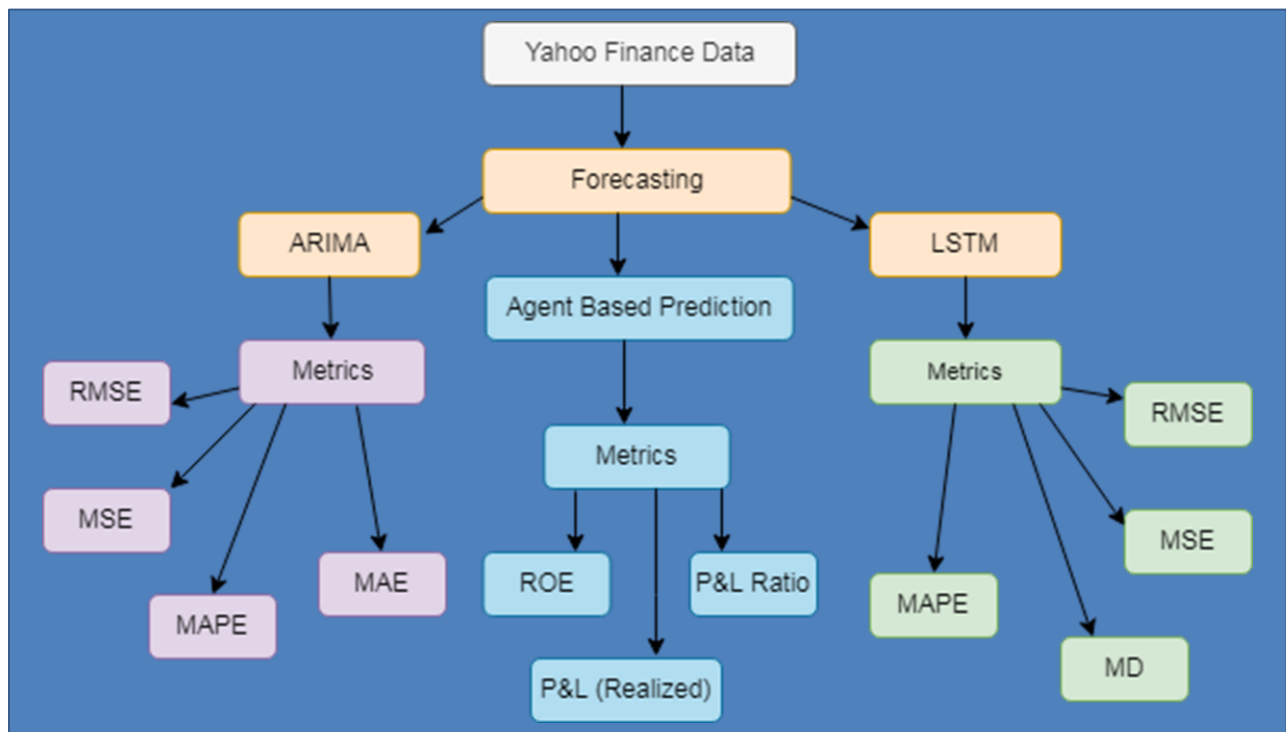

Fig. 3. Methodology for simulation for different Saudi companies on the basis of ARIMA, LSTM and agent based prediction.

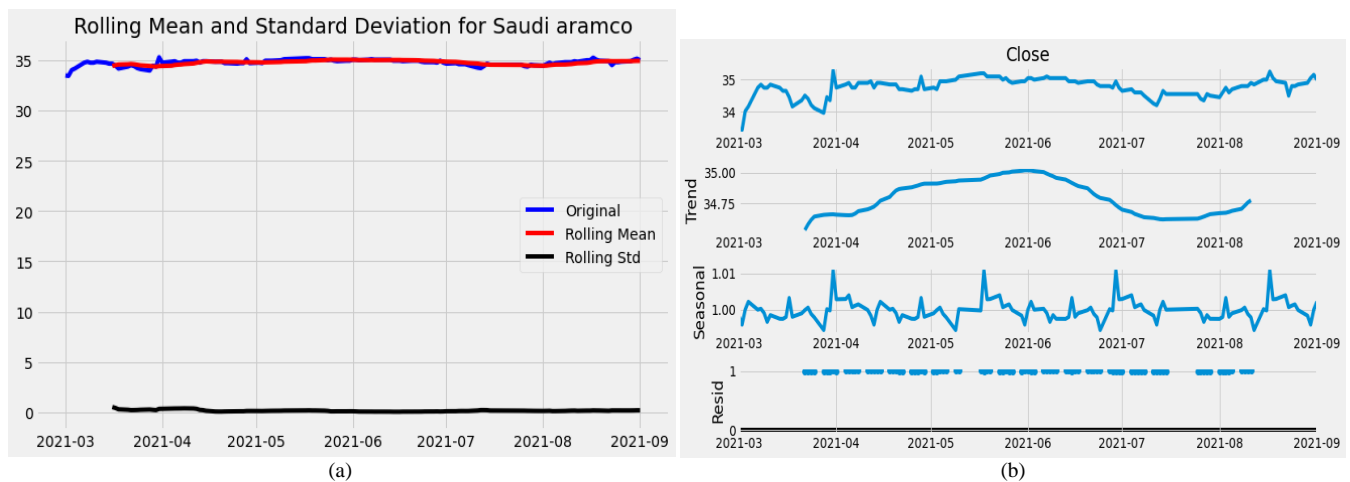

Fig. 4. (a) Test for stationary (b) Seasonal decay of Saudi Aramco.

Earlier, traditional statistics [22] models were emphasized on exponential smoothing and linear [21] prediction for ARIMA Models. Non-stationary [12] information is known as the information whose measurable properties for example the mean and standard deviation are not consistent over the long run but rather all things considered, these measurements change over the long haul. Firstly, Test for stationary and determine rolling statistics and Plot rolling. The Fig. 4(a) and 4(b) represents the test for stationary and seasonal decay of Saudi Aramco.

The tensor flow libraries are integrated in this research. Tensor flow will be utilized as a back end for LSTM model prediction of ten large cap companies listed on the Saudi stock exchange. Fig. 5 represents the forecasting of Saudi Aramco

using ARIMA model for training and predicting and Fig. 6 represents the simulation of Saudi Aramco using LSTM model. Data has been sourced from yahoo finance through API as it is continuous form of data with high precision and accuracy. The data set has been sourced online through yahoo finance API for past six Months. Furthermore, Data is fetched in terms of rows and columns [9]. The p-value of Saudi Oil Company comes out to be 0.000019. Company code for Saudi Aramco is 2222.SR and elaborates that the seasonal trend remained stable in May-2021 and showed a modest rise in August 2021. The Seasonal Trend reached its peak in August 2021 and further share price climbed down in consecutive months. Author has made sure of the installation of tensor flow libraries. Tensor flow will be utilized as a backend for LSTM model prediction of ten large cap companies listed on the Saudi stock exchange. Data has

been sourced from yahoo finance through API as it is a continuous form of data with high precision and accuracy. The data set has been sourced online through yahoo finance API for the past Six Months. Furthermore, Data is fetched in terms of rows and columns. Fig. 7(a) and 7(b) represents the test for stationary and seasonal decay of AlRajhi Bank.

Fig. 5. Forecasting of Saudi Aramco using ARIMA model for training and predicting.

Fig. 6. Simulation of Saudi Aramco using LSTM model.

In the last case chosen to stop with the occasionally differenced information, and not done an extra round of differencing. In the previous case concluded that the information was not adequately fixed and taken an extra round of differencing. Fig. 8 represents the forecasting of AlRajhi Bank using ARIMA model for training and predicting scenarios.

Biggest challenge is to find the relation between independent variables and results of stock market movement. Author has utilized specific [23] set of features including Open Price, Close Price, Date, High Price and Low Price and increment of other variables such as Volume can be considered under observation forcing the model to over-fitting and using maximum limit of memory and execution time for Signal Generation. Nevertheless, Data collected should not be in irregular form, but it should be categorized into three components [24] such as trend, seasonal and irregular variations (noise). The Table I represents the results of dickey fuller test cases. Fig. 9 represents the simulation of AlRajhi Bank using LSTM model for training and predicting scenarios.

Meanwhile, it needs to choose what will yield. This yield will be founded on cell state yet will be a sifted adaptation. To begin with, it run a sigmoid layer which chooses parts of the cell state which will yield. Then, at that point, it put the cell state through tanh (to push the qualities to be somewhere in the range of  $-1$  and  $1$ ) and increase it by the yield of the sigmoid door, so it just yields the parts chose to. Another variety is to utilize coupled neglect and information doors. Rather than independently choosing what to neglect and what new data is to be added, it settles on those choices together. It possibly fails to remember when it will include something in its place. Figure.8 corroborates the upward trend starting from April 2021 till the Middle of August 2021 and thus represents the strong bullish trend. Fig. 9 represents the clear view of reaching a peak, supports the positive slope, shows the complex understanding, and thus results in inappropriate decisions based on forecasting.

Fig. 7. (a) Test for stationary (b) Seasonal decay of AlRajhi Bank.

Fig. 8. Forecasting of AlRajhi Bank using ARIMA model for training and predicting.

TABLE I. RESULTS OF DICKEY FULLER TEST

Date	Saudi Oil Company	Sabic	Saudi Telecom Company	AlRajhi Bank	Saudi Electric

#### IV. RESULTS AND DISCUSSION

There are various Performance measures such as RMSE, MSE and MAPE which commutes the different models for better efficiency. Many Researchers have emphasized on volatility, risk-adjusted Returns, and annualized ROE. The conventional models have been extensively explored in the recent years with series of experiments with promising results in controlled environment. Mean absolute percentage error is used to check how accurate forecast system is for simulation. It works best if there are no extremes and no zeros. The Root Mean Square error is described by the famous equation:

$$MAE = \frac{\sum_{i=1}^n |y_i - x_i|}{n} \quad (5)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (6)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n}} \quad (7)$$

$$MAPE = \frac{1}{N} \sum_{i=1}^N \left| \frac{A_i - F_i}{A_i} \right| \quad (8)$$

The Table II and III represent performance evaluation of ARIMA, LSTM simulations for five Saudi large cap companies.

#### A. Performance Evaluation

Multiple Stock Implementation is an advanced system execution. Trend component is majorly responsible for the P/E ratio of the company. Oil Sector, Banking Sector, Telecom Sector, Electricity Sector, Agri-Nutrients sector are subjected to be in Neutral state and IT Sector has shown the tremendous return on investing in with six months as shown in graph above. Proposed strategy brings fruitful returns even in the downward trend of share price of the company whereas mutual funds perform in negative returns in the downward trend. Execution speed of simulation process is inversely proportional to the numbers of iterations and checkpoints. LSTM Model has outperformed in random behaviour of stock price in recent 6 months of Simulation. The Table IV represents LSTM simulation for prediction of future values for date range.

TABLE II. PERFORMANCE EVALUATION OF ARIMA SIMULATION FOR FIVE SAUDI LARGE CAP COMPANIES

Company	RMSE	MSE	MAPE	MAE

B. Agent Based Prediction

Proposed Strategy can be considered as decision support mechanism that can be used to develop both classification and somewhat regression problem solver model. Implementation of Saudi Stock Market is more like if then else condition programmatically. It can be used in series of data that involve call node and sometimes leaves that means breaking of bigger problem into smaller one to onto sub classes. Real time performance metrics illustrated the exact return over investment can be considered as total return on equity (ROE), Total profit and loss (P/L), Total Gain/loss Ratio.ROE depicts the capability of the firm to return equity investment into profits. Initially, it is recommended to calculate the variance and then get desired value of standard deviation. Total gain/Loss ratio is just like a scorecard for an active person who major objective is to maximum gains. The simplest method to calculate the volatility of a company is to evaluate the standard deviation of stock prices for specific time interval. The tradition formula for evaluation return on equity is as following equation 9, 10 and 11:

$$ROE = \frac{\text{Net Income}}{\text{Shareholder Equity}} \tag{9}$$

$$\text{Profit and Loss Ratio} = \frac{\left(\frac{\text{Total Gain}}{\text{Number of Winning Trades}}\right)}{\left(\frac{\text{Total Loss}}{\text{Number of Losing Trades}}\right)} \tag{10}$$

$$\text{Profit and Loss (Realized)} =$$

$$(\text{Average Sell Price} - \text{Average buy Price}) \times \text{Quantity} \tag{11}$$

Initially, the yfinance module must be installed in google Collaboratory. The window size has been kept as 100. Starting Money has been set to 10000 and layer size as 400 and moreover, number of iterations as 300 and checkpoints are declared as 10. Research has calibrated on historical data through Yahoo Finance Application Interface Data. Period for data is six months starting from 2 March 2021 to 2 September 2021. The Fig. 10 represents the performance for proposed strategy for Saudi telecom Co. (7010.SR).

Fig. 10. Shows performance for proposed strategy for Saudi Telecom Co. (7010.SR).

Fig. 11. Shows performance for proposed strategy for Al Moammar information systems (7200.SR).

Researchers have not used an overriding function to forcibly fetch data. Instead yfinance module is used for directly sourcing data with more precision and accuracy. Fig. 10 is concerned with the performance of the Saudi Telecom company with 3.8878 Percentage return over the initial investment of 10000 credits. Total gains reported in the simulation of strategy for the Saudi Telecom company were 388.78. Fig. 11 depicts performance for Al Moammar Information Systems with return over investments of 12.8702 percentages within 6 months and total gains are reported to be 1287.02 with respect to initial investment of 10000. Time-series anticipating models are the models that are proficient to foresee future qualities dependent on recently noticed qualities. Time-series anticipation is broadly utilized for non-stationary information. This non-stationary information (utilized as contribution to these models) is normally called time-series. The hypothesis study has been performed by various researchers using different performance measures, but it can judge success or failure of future implementation of the system depends on profit or losses faced by the individual investors in their lifetime process.

The Table V and Fig. 12 shows the comparative analysis of proposed methodology with existing approaches based on implicated methods, dependable and non-dependable parameters, time constraints, supporting data metrics and computational values. Researchers relied on neural networks, Support Vector Machines, trend indicators while computations on raw mathematical data utilized from various open-source repositories. Predicting stock values in a real time environment is a very uncertain task for both theoretical as well as numerical problems. Consequently, the company valuation depends on quarterly earnings and yearly cash flows using technical and fundamental analysis. However, it is bit risky to believe on the facts and figures released by the company to consider that a stock company has both justifiable earnings.

TABLE V. COMPARATIVE ANALYSIS OF PROPOSED METHODOLOGY WITH EXISTING APPROACHES BASED ON IMPLICATED METHODS

Author Name	Method	Prediction
Chun-Hao Chen et.al. [46]	GGA based GSP	87.8%
Gautam Srivastava et.al. [47]	SSACNN, CNNpred, SVM, NN	89%
Wen M [48] et.al.	CNN for trend-based prediction. LSTM, HMM, and ARIMA for Pattern Recognition	92.32%
Md. Mobin Akhtar et.al. [49]	LSTM, SVM, and news feature extraction.	80.3%
Pei-Yuan Zhou et.al. [50]	Relationship prediction rules	82.92 %.
Proposed Methodology	LSTM, SVR Regressor, and Linear Regressor based Hybrid simulation.	97.5 %

Fig. 12. Comparative analysis of proposed methodology with existing approaches.

The future system can be focused on multiple stock implementations that require high configuration hardware resources for concurrent execution [34][35]. A few instances of time-series incorporate the temperature esteems over the long haul, stock cost over the long haul, cost of a house over the

long haul and so forth in this way, the information is a sign (time-series) that is characterized by perceptions taken consecutively on schedule. There have been endeavors to anticipate stock costs utilizing time series investigation calculations; however, which not utilized to put down wagers in the genuine market.

## V. CONCLUSION

With regard to broadcast-based trading, this study focuses on the forecast and assessment of possible stock assets in a real-time favorable scenario for the Saudi financial markets, exclusive of external brokers. With the use of a futuristic recurrent neural network environment and the Long Short-Term Memory algorithm (LSTM), this research combined Dickey-Fuller testing scenarios, forecasted time series volatility, and anticipated the closing prices of large-cap businesses on the stock market in the future. Sample data from the Y-finance sector was assembled using API-based data series and was quite accurate and precise. In order to analyze the root mean squared error, mean squared error, mean absolute percentage error, mean deviation, and mean absolute error, this study combined LSTM methods with ARIMA. It is concluded that Aramco has demonstrated the lowest value of RSME when compared to other large-cap businesses. Various tests and simulations display validations and forecasts along with the value of the root mean square error. With fewer hardware resources, the experimental scenarios were framed, and test case simulations carried out. Using the available data, future work can be expanded to include low- or opening-price predictions for stocks. Aside from RMSE estimates, the extended work may also include other performance indicators.

International College, Krirk University, Bangkok 10220, Thailand<sup>4</sup>

**Abstract**—By expanding and innovating Michael Porter Diamond Model, a Dual-core Diamond Model is developed in this paper with innovation and openness as the core factors in consideration of the actual needs of the development of service sector in the Yangtze River Economic Belt of China. This paper establishes an evaluation indicator system of service sector competitiveness profitability to measure and evaluate the competitiveness of service sector in 11 provinces and towns in the Yangtze River Economic Belt through PCA (principal component analysis) based on the relevant information of the 11 provinces and towns mentioned above in 2015 and 2016. The research results indicate that the design of Dual-core Diamond Model is in line with the current situation and future development needs of the service sector in the Yangtze River Economic Belt, and the dual-core factors, namely, innovation and openness, have become the most important factors influencing the competitiveness of the service sector in the Yangtze River Economic Belt. Based on the model analysis results, it should propose strategies to enhance the competitiveness of the service industry in the Yangtze River Economic Belt. It needs to enhance innovation ability as well as to further expand trade in services. Firstly, encourage the growth of related industries and create a coordinated development cluster for the service sector. Second, intensify efforts in talent cultivation and build a talent system in alignment with the development of service sector. Third, improve the relevant legal system and innovate the service supervision and governance system in the service sector. Last, focus on a coordinated and integrated inter-region development.

**Keywords**—Dual-core diamond model; service sector; Yangtze river economic belt; principal component

## I. INTRODUCTION

Eleven (11) provinces and towns, including Shanghai, Jiangsu, Zhejiang, Anhui, Jiangxi, Hubei, Hunan, Chongqing, Sichuan, Yunnan, and Guizhou, are included in the Yangtze River Economic Belt. They are the most developed regions in the Yangtze River Basin, accounting for 21.4% of China's national territory area and 40% of the China's national GDP. The Yangtze River Economic Belt accounted for 44.1% of the national GDP in 2018<sup>1</sup>. The Yangtze River Economic Belt has unique potential for growth and obvious advantages in transportation, natural resources, industrial groups, human

resources and urban construction. Supporting the development of service sector is an effective strategy to facilitate the industrial innovation and transformation and enhance the industrial competitiveness in the Yangtze River Economic Belt, which is conducive to tapping into the potential of domestic demand in the upper and middle regions of the Yangtze River, forming a pattern of cooperation and interaction and mutual benefits of advantages throughout the Yangtze River's upper, middle, and lower sections, effectively reducing the regional development gap. From 2009 to 2016, the GDP of the service sector in the Yangtze River Economic Belt increased from RMB 6,283.8 billion to RMB 16,538.6 billion, accounting for 43.14% of national GDP in service sector, up from 29.08%<sup>2</sup>. Directive Opinions on Promoting the Development of Yangtze River Economic Belt Supported by the Golden Waterway, Outline of Yangtze River Economic Belt Development Plan and other plans and policies have outlined the development needs for promoting the innovative and coordinated development, transformation and improvement of service sector in Yangtze River Economic Belt.

Some scholars have started to study industrial competitiveness under the framework of Michael Porter Diamond Model. Joshi incorporated the Diamond Model to examine the competitiveness of Indian automobile industry [1]. Yonghong constructed the evaluation indicator system of competitiveness of shipbuilding industry cluster based on the Diamond Model [2]. Esen studied the competitiveness of Turkish tourism industry by comparing with the Diamond Model [3]. Zhao utilized the Diamond Model to identify and examine the variables influencing the development of China's photovoltaic industry [4]. Based on the Diamond Model, Wu analyzed and investigated the competitiveness of China's coal sector [5]. Zheng et al. and Wan identified the variables influencing the trade in services sector of China and proposed countermeasures to enhance its competitiveness based on Porter's Theory of International Competitiveness Advantage [6][7]; Gu and Xia analyzed the main factors for enhancing the competitiveness of China's cultural industry based on the Diamond Model [8]. Zhuang et al. and Chen et al. believed that the four elements of Porter's "Diamond Model" are the

<sup>1</sup><https://baike.baidu.com/item/%E9%95%BF%E6%B1%9F%E7%BB%8F%E6%B5%8E%E5%B8%A6/5453694?fr=aladdin>

<sup>2</sup>Derived from *Statistical Yearbooks* of various provinces and cities.

main factors that affect the international competitiveness of the trade in services sector of China [9][10].

Based on researches on the level of growth of service sector in the Yangtze River Economic Belt, many scholars made an effort to establish an evaluation indicator system to identify the level of growth of service sector in the Yangtze River Economic Belt. Wu et al., Qian et al. and Zheng used factor analysis to evaluate the scale, structure, potential and benefits of service sector development in the Yangtze River Economic Belt [11-13]; Liu and Yao built models to evaluate the competitiveness of productive service sector and the development of modern logistics sector in the Yangtze River Economic Belt [14][15]; Xu et al. and Yang empirically analyzed the impact of human capital, transportation, income level and other factors on the development of service sector in the Yangtze River Economic Belt [16][17]; Wu et al. empirically tested the impact of market level of growth, economic level of growth, trade in services as well as the quantity of human capital and urbanization on the overall factor productivity of service sector in Yangtze River Economic Belt [18]. Yang et al. believed that carbon emission constraints and regression in technical level have a negative impact on the overall energy effectiveness of logistics sector in the Yangtze River Economic Belt [19]. Hu et al. and Sun et al. measured the amalgamation level of service sector in the Yangtze River Economic Belt [20-22]. Jing and Wang respectively adopted the Gray Relevance Total Analysis and Symbiosis Model to study the integrated development of service sector in the Yangtze River Economic Belt [23][24].

To sum up, enhancing the competitiveness of the service industry in the Yangtze River Economic Belt can promote the integration and development of industries in the Belt, as well as enhance the international competitiveness of the Belt. Some scholars have made some explorations on industrial competitiveness based on Michael Porter Diamond Model. Today, however, with the rapid development of service sector today, the research on the competitiveness of China's service sector needs to be further deepened and strengthened. This is especially demonstrated in the fact that the choice of factors affecting the competitiveness of service sector is scattered. Many scholars choose the affecting factors directly based on Porter's "Diamond Model". The selection of indicators has a certain degree of similarity. However, this paper holds that Michael Porter Diamond Model is not applicable to all countries, and its degree of explanation with regard to the industrial competitiveness of developing countries is not sufficient. This article believes that enterprises can improve their efficiency and competitiveness through technological innovation, institutional innovation, sales channel innovation, etc. By expanding openness, actively participating in international market competition, learning advanced management experience, and introducing more advanced

knowledge and technology, we can enhance the competitiveness of enterprises. Therefore, this paper combines Michael Porter Diamond Model and the authentic circumstances and conditions of Yangtze River Economic Belt to construct a "Dual-core Diamond Model" with "innovation" and "openness" as the core factors, and proves that this model is feasible and scientific for the service sector of Yangtze River Economic Belt through empirical test evidence.

## II. THE OVERALL DEVELOPMENT OF SERVICE SECTOR IN THE YANGTZE RIVER ECONOMIC BELT

### A. The Development Scale of Service Sector in 11 Provinces and Towns in the Yangtze River Economic Belt

Development scale of service sector in the Yangtze River Economic Belt. From 2009 to 2016, the GDP contributed by service sector in 11 provinces and towns in the Yangtze River Economic Belt increased continuously (see Table I and Fig. 1), from RMB 6,283.8 billion to RMB 16,538.6 billion, at a rate of 163.19%, indicating that the service sector in the Yangtze River Economic Belt is following a desirable development trend, and its scale is expanding constantly. Although its growth rate fluctuates slightly, it holds steady at a relatively high level.

Comparative analysis on the development of service sector in 11 provinces and towns of Yangtze River Economic Belt and the overall development of service sector in China. The GDP contribution of service sector in the Yangtze River Economic Belt rose to 43.14% in 2016 from 29.08% in 2009 (see Table I and Fig. 2). The service sector in the Yangtze River Economic Belt has grown rapidly, especially in recent years. The booming knowledge-intensive modern service sector has improved the quality of service sector development and promoted the modernization and transformation of the services sector. The service sector in the Yangtze River Economic Belt holds great development potential and is a pillar for the development of China's service sector.

Development of service sector of 11 provinces and towns in Yangtze River Economic Belt. As evidenced by the 2015 and 2016 statistics (Table II), there are obvious imbalances in regional development in 11 provinces and towns in the Yangtze River Economic Belt. In terms of service sector GDP in each region, Shanghai, Zhejiang and Jiangsu, which are located in the lower reaches, ranked among the highest, while Yunnan and Guizhou provinces in the western region of China, stayed at the bottom. The service sector GDP of Shanghai, the city with the top-scale service sector was nearly four times that of Guizhou, the city with the smallest service sector scale. Anhui ranked last in the service sector productivity, which was equivalent to approximately 1/4 of the value of Shanghai.

TABLE I. GDP OF SERVICE SECTOR IN YANGTZE RIVER ECONOMIC BELT AND ITS PROPORTION IN THE GDP OF CHINA FROM 2009 TO 2016

Year	2009	2010	2011	2012	2013	2014	2015	2016
GDP of service sector in 11 provinces and towns of Yangtze River Economic Belt (In RMB 100 million)	62838	64882	89708.9	101387	116633	130088	145193	165386
Growth rate of GDP of service sector in Yangtze River Economic Belt (%)	15.25	3.15	27.68	11.52	13.07	10.34	10.40	12.21
GDP of service sector in China (In RMB 100 million)	154748	182038	216099	244822	277959	308059	346150	383365
The proportion of GDP of service sector of the Yangtze River Economic Belt to that of China	29.08	35.64	41.51	41.41	41.96	42.23	41.95	43.14

Data source: China Statistical Yearbook, and Statistical Yearbooks of various provinces and cities

Fig. 1. Service industry in 11 provinces and cities of yangtze river economic belt.

Data source: Statistical Yearbook of various province and city

Fig. 2. Proportion of GDP of service industry of the yangtze river economic belt to that of China.

### B. The Scale of Employees in the Tertiary Industry in 11 Provinces and Towns of the Yangtze River Economic Belt

Fig. 3 depicts the shifts in the number of workers in secondary and tertiary industries in 11 Yangtze River Economic Belt provinces and cities between 2008 and 2016. It is obvious that the development trend in the scale of employees in the tertiary industry was quite consistent with the trend in the production scale of service sector, which continues to rise, and the gap between the employment by the tertiary and secondary industries was widening. It is evident that the service sectors of various provinces and towns in the Yangtze River Economic Belt have better capacity in boosting employment and attracting human resources.

To sum up, the development of the service sector in the Yangtze River Economic Belt has become the powerhouse for the development of service sector in China. However, it still has certain shortcomings, such as a general lack of core technology, dependence on traditional industries in the

international market, and weak overall competitiveness in the service sector in the Yangtze River Economic Belt, especially in the middle and upper reaches of the Yangtze River. Therefore, a service sector driven by innovation will surely become a leading force behind economic development in the future. Meanwhile, with the high-quality economic development and the smooth progress in supply-side structural adjustment, the service sector in the Yangtze River Economic Belt needs to be further opened up in order to enhance economic benefits, encourage the modernization and transformation of industrial structures and raise the level of global industry competition. The efforts in the development of the service sector in the Yangtze River Economic Belt must be applied in a correct direction by seizing the emerging opportunities in global economic development and by identifying the strategies and routes that are aligned with the current development status and future development demands of the service sector in the Yangtze River Economic Belt.

TABLE II. GDP AND PRODUCTIVITY OF SERVICE SECTOR IN 11 PROVINCES AND TOWNS OF YANGTZE RIVER ECONOMIC BELT IN 2015-2016

Year	Province/city	GDP of service sector (In RMB 100 million)	Service sector productivity	Year	Province/city	GDP of service sector (In RMB 100 million)	Service sector productivity
2015	Shanghai	17274.62	20.19	2016	Hubei	14351.67	9.84
2016	Shanghai	19662.90	22.57	2015	Hunan	12796.87	8.98
2015	Jiangsu	34272.40	18.66	2016	Hunan	14631.83	10.30
2016	Jiangsu	38691.60	20.70	2015	Chongqing	7527.08	10.64
2015	Zhejiang	21341.91	14.86	2016	Chongqing	8538.43	11.46
2016	Zhejiang	24091.57	15.94	2015	Sichuan	13127.72	7.78
2015	Anhui	8602.11	5.02	2016	Sichuan	15556.29	8.99
2016	Anhui	9959.92	5.75	2015	Yunnan	6147.27	6.25
2015	Jiangxi	6559.63	6.69	2016	Yunnan	6875.50	6.78
2016	Jiangxi	7764.93	7.68	2015	Guizhou	4723.77	10.06
2015	Hubei	12819.76	9.03	2016	Guizhou	5261.01	10.39

Fig. 3. Scales of employment by the tertiary industry and the secondary industry in the yangtze river economic belt and their difference.

### III. THEORETICAL MODEL

Porter put forward the Theory of Industrial Competitiveness Advantage for the first time and established the Diamond Model, which provided a further theoretical framework and reference for evaluating industrial competitiveness by breaking through the Theory of Comparative Advantage [25]. After that, some researchers used the Diamond Model to study industrial competitiveness, and the others expanded the model. Rugman et al. expanded Michael Porter Diamond Model into the “Double-diamond Model” by integrating the actual situation in Canada [26]. Cho et al. built the “Nine-Factor Model” based on the real conditions of South Korea, and believed that this model can explain the formation of competitiveness in underdeveloped

and developing countries [27]; Moon et al. built a “Generalized Double-diamond Model” adapted to the economic development of small countries based on the “Double-diamond Model” [28]. Rui added a core factor, namely, the “ability in knowledge absorption and innovation” to Porter’s “Diamond Model” and built the “New Diamond Model” by incorporating the actual development situation of China [29]. Zhao expanded Michael Porter Diamond Model and built the “New Diamond Model” with innovation in science and technology at its core [30].

The competitiveness advantage of the service sector in the Yangtze River Economic Belt is still concentrated on the traditional field. To build a high-end industry with high value addition in the international division of labor and to maintain a

sustainable competitiveness, we must integrate independent innovation in open market competition. The Communist Party of China's 19th National Congress report makes it clear that "Innovation is the key driving factor for development." The report also suggests a number of new initiatives and targets, including to "increase the service sector's opening up scope and quicken the cultivation of new advantages in international economic cooperation and competition." At present, as the process of global economic integration continues to accelerate and competition in the international market becomes more and more extensive and fierce, China needs to further open up its market and encourages the service sector to "go global", which has become a part of China's national strategic deployment. This paper holds that the promotion of competitiveness in service sector is the key task under the "go global" strategy, as the improvement of competitiveness relies on the transfer of kinetic energy between old and new, while the key determinant of kinetic energy transformation lies in innovation. The analysis of competitiveness in service sector in Yangtze River Economic Belt by Michael Porter Diamond Model does not reflect the crucial role played by innovation and openness against the background of globalization and a knowledge-driven society. Based on this, this paper expands Michael Porter Diamond Model to build a "Dual-core Diamond Model" with "innovation" and "openness" as the core factors, in consideration of the current conditions and demands of service sector development in the Yangtze River Economic Belt (Fig. 4).

Innovation is the primary core factor. It includes

technological innovation, knowledge innovation and market innovation. Industrial innovation can facilitate product sales and product improvement, and enhance economic benefits. Therefore, the industrial innovation process is also the process of the formation and promotion of industrial competitiveness, which is the potential impetus behind the sustainable development of industrial competitiveness.

Openness is another core factor. If a country (region) opens up, its enterprises are confined to the domestic market. After opening up, this country's dominant enterprises can grow and prosper during their participation in international competition, while underdeveloped enterprises are winnowed out in the process which allows the surviving enterprises to enjoy more living space and achieve greater development. Therefore, only by encouraging the service sector to "go global" and taking part in the full-scale international division in full of labor can those enterprises get sustainable competitiveness in international competition.

Production factor is also the primary key factor. It refers to various inputs of resources needed for the development of service sector, including natural resources, knowledge resources, human resources and capital investment. Porter believes that the demands of rudimentary factors (climate, geographical location, unskilled labor, etc.) are on the decline, so is their influence on competitiveness; and that developing and putting in advanced factors (high-quality human resources, improved urbanization level) are essential for obtaining industrial competitiveness, as they have a dominant effect on the improvement of competitiveness.

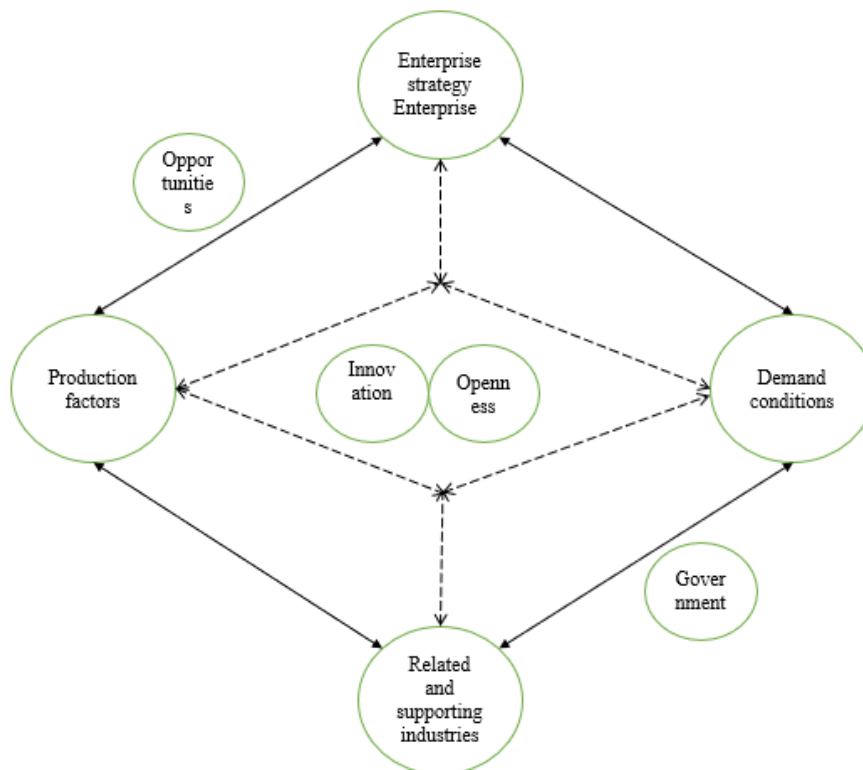

Fig. 4. Dual-core diamond model.

Demand condition is the fourth key factor. It refers to the demands for service products in a country's market. It is generally believed that the average income level of a country or the income level of the majority of its population reflects the representative demand of this country. Domestic enterprises are domestic market-oriented, so their investment, production and sales are mainly guided by domestic market demand. The size and nature of a country's market influence the scale and efficiency of production, will have a huge impact on promoting industrial development and stimulating industrial improvement and innovation, and are important factors determining whether enterprises can build up their international competitiveness.

Related and supporting industries are the also key factors, which refer to the upstream industries and complementary industries related to service sector. The competitive advantage of an industry does not stand alone, but are also correlated with related industries and they can complement each other to form stronger competitive advantages through cooperation and sharing resources; Supporting industries help downstream industries adapt to changes in market demand quickly and improve their competitive advantages. The stronger the related and supporting industries are, the more they can drive the development of the industry through inter-industry association assistance.

The quaternary key factors are enterprise strategy and enterprise structure. They refer to the choice and decisions by service enterprises in terms of objectives, management and organizational structures. In the fierce competition in the domestic market, an industry can enhance its local competitive advantage through forcing manufacturers to participate in competition in the international market, and finally enhance its international competitiveness. Therefore, if an industry is in line with the industrial competitiveness advantage of the country in terms of strategy and structure, the competitiveness of the industry will be developed accelerated and reinforced.

In addition to the above factors, there are two variables that have an impact on industrial competitiveness, namely, government and opportunity. The government directly influences the industrial competitiveness through policies, and opportunities create new possibilities for the promotion of industrial competitiveness by transforming the existing competitive environment and order. However, government and opportunity are not the decisive influencing factors of industrial competitiveness, and it is difficult to represent them with economic data, so this paper does not include them in the indicator system and quantitative economic model analysis.

#### IV. EMPIRICAL ANALYSIS

This part establishes the evaluation indicator system of competitiveness in the service sector of Yangtze River Economic Belt based on the "Dual-core Diamond Model", and applies PCA to measure and evaluate the competitiveness in the service sector of Yangtze River Economic Belt from a variety of perspectives, including innovation, openness, production variables, demand dynamics, associated and supporting industries, company strategy, and organizational structure.

#### A. Rely on the "Dual-Core Diamond Model" to Build the Evaluation Indicator System of Competitiveness in the Service Sector of Yangtze River Economic Belt

1) *Innovation*. The improvement in innovation ability facilitates the improvement in industrial productivity and competitiveness. Investment in R&D funds encourages enterprises to actively pursue scientific and technological innovation, management innovation, product innovation and market innovation, thus enhancing the development of emerging service industries. This paper makes reference to the method developed by Liu et al. (2019), where the number of patents obtained and R&D funds are adopted as indicators representing innovation ability [31]. The "number of valid inventive patents" for the current year is the number of patents obtained, and the R&D funds ratio is the ratio of R&D funds to GDP.

2) *Openness trade dependence reflects the degree of participation and dependence of a nation's economic development on the international market*. Many domestic scholars use trade dependence to measure a country's degree of openness to the global market. In this paper, export (import) dependence is selected to represent the degree of openness [32][33]. Formula: export (import) dependence = import (export) amount/GDP of a country (region).

3) *Production factors*. On the one hand, urbanization level reflects the development of infrastructures, including its transportation, information, and communication systems (region). The higher the urbanization level is, the stronger its support for the development of service sector will be. Urbanization not only facilitates the development of modern service sector, but also brings in high-end service sector and injects new impetus into urban economic development. On the other hand, the inputs of essential human resources of essence to enhancing industrial competitiveness. The service sector provides intangible products, and the service is provided by people engaged in the service sector. Therefore, the employment by the tertiary industry represents the development scale and potential of the service sector to a certain extent. In this paper, the urbanization level is selected by the method proposed by Zhuang [9], and the employment by the tertiary industry is taken into consideration to represent the production factors. Formula: urbanization level = urban population/total population.

4) *Demand conditions*. This paper draws from the practice of Mou [34], and selects per capita GDP to represent demand conditions; The per capita disposable income of urban and rural residents is chosen as the demand condition using the techniques proposed by Huang and Deng [35]. The former reflects the economic level of growth of a country (region), while the latter two reflect its purchasing power.

5) *Associated and auxiliary industries*. The secondary industry serves as the basis and starting point for the tertiary sector's growth. Without the former, there would be virtually no demand for the latter in society. The development of the tertiary sector itself determines whether it can grow into an

advantageous industry and participate in international competition. This paper selects the labor productivity of the secondary and tertiary sectors based on the practices of Zhuang [9], Lan and Dou to represent related industries and supporting industries [36]. Formula: The secondary (tertiary) industry's labor productivity is calculated by dividing the number of jobs it employs by the added value of its output.

6) *Enterprise strategy and structure*. Because of the profit-seeking nature of capital, foreign investors always choose enterprises with better development potential when

making capital investment decisions. Enterprises that attract foreign investment can not only introduce advanced hardware facilities and attract excellent human resources, but also enhance their technological level and management ability. This paper draws from the practices of Lan and Dou in selection of the overall amount of foreign direct investment to represent the enterprise strategy and structure [36].

The indicator system is established based on the factors selected above, as shown below in Table III:

TABLE III. THE EVALUATION INDICATOR SYSTEM OF COMPETITIVENESS IN THE SERVICE SECTOR OF YANGTZE RIVER ECONOMIC BELT DEVELOPED BASED ON THE "DUAL-CORE DIAMOND MODEL"

Target level	Factor level	Indicator level
The evaluation indicator system of competitiveness in the service sector of Yangtze River Economic Belt developed based on the "dual-core Diamond Model"	Innovation	X1: Invention patents
		X2: Ratio of R&D funds to local GDP
	Openness	X3: Export dependence
		X4: Import dependence
	Production factors	X5: Level of urbanization
		X6: Employment by the tertiary industry
	Demand conditions	X7: Per capita GDP
		X8: Per capita disposable income of permanent urban residents
		X9: Per capita disposable income of permanent rural residents
	Related and supporting industries	X10: Productivity of secondary industry
		X11: Productivity of tertiary industry
	Enterprise strategy and structure.	X12: Paid-up amount of foreign direct investment

### B. Data and Variables

1) *Selection and description of variables*: innovation: X1: invention patents (Nr.), X 2: ratio of R&D funds to local GDP (%); Openness: X3: export dependence, X4: import dependence; Production factors: X5: level of urbanization, X6: employment by tertiary industry; Demand conditions: X7: per capita GDP, X8: urban dwellers' per capita disposable income, X9: income available per person in remote areas; Related and supporting industries: X10: productivity of secondary industry, X11: productivity of tertiary industry; Enterprise strategy and structure: X12: paid-up amount of foreign direct investment.

2) *Data source*: In order to create two data sheets, this study chooses cross-sectional data from 11 provinces and cities in the Yangtze River Economic Belt in 2015 and 2016. Relevant indicator data come from *Statistical Yearbook* of 11 provinces and towns in Yangtze River Economic Belt and *China Statistical Yearbook*.

### C. Setting of Measurement Model

This paper evaluates the competitiveness of service sector in Yangtze River Economic Belt through Principal Component Analysis. Principal Component Analysis (PCA) is a dimension-reducing statistical method that selects a small

number of key variables from multiple variables by linear variation. The majority of the information from the original variables may still be found in principal components, and there are far fewer principal components than there were original variables.

PCA is applied on the basic data of 2015 using SPSS software, with results shown in Table IV and Table V.

Through PCA, two principal component eigenvectors are extracted. It can be seen from Table IV that the first and second principal components contribute 71.49% and 14.132% of the variance, respectively. The first two primary components' combined contribution rate is 85.622%, which contains most information and can significantly explain most variations of the original data. Therefore, the first two components are selected as comprehensive indicators in replacement of the 12 original indicators to evaluate the competitiveness of service sector in 11 provinces and towns in the Yangtze River Economic Belt.

The coefficient of each indicator in the two principal components is obtained by comparing the data of each indicator corresponding to components 1 and 2 in the composition matrix in Table V against the open square root value of eigenvalue corresponding to principal components. The principal component is expressed as follows:

TABLE IV. EIGENVALUE AND CUMULATIVE CONTRIBUTION OF VARIANCE OF THE PRINCIPAL COMPONENTS OF THE COMPETITIVENESS IN SERVICE SECTOR OF YANGTZE RIVER ECONOMIC BELT IN 2015

Component	Initial eigenvalue			Extracted quadratic sum		
	Total	Variance percentage	Cumulative percentage (%)	Total	Variance percentage	Cumulative percentage (%)
1	8.579	71.490	71.490	8.579	71.490	71.490
2	1.696	14.132	85.622	1.696	14.132	85.622
3	.715	5.955	91.577

TABLE V. COMPONENT MATRIX IN 2015

Indicator	Component	
	1	2
Invention patents (Nr.)	.911	-.160
Ratio of R&D funds to local GDP	.930	.186
Export dependence (%)	.927	-.073
Import dependence (%)	.863	-.352
Urbanization rate	.795	.317
Employment by the tertiary industry (unit: 10,000 people)	.153	.907
Per capita GDP (RMB)	.994	-.009
Per capita disposable income of permanent urban residents (RMB)	.951	-.088
Per capita disposable income of permanent rural residents (RMB)	.947	.088
Productivity of secondary industry	.516	-.563
Productivity of tertiary industry	.929	-.159
Paid-up amount of foreign direct investment (unit: 100 million dollars)	.842	.476

$$F_1 = 0.3110ZX_1 + 0.3174ZX_2 + 0.3163ZX_3 + 0.2945ZX_4 + 0.2714ZX_5 + 0.0524ZX_6 + 0.3392ZX_7 + 0.3246ZX_8 + 0.3233ZX_9 + 0.1761ZX_{10} + 0.3172ZX_{11} + 0.2876ZX_{12} \quad (1)$$

$$F_2 = -0.1228ZX_1 + 0.1426ZX_2 - 0.0560ZX_3 - 0.2701ZX_4 + 0.2436ZX_5 + 0.6961ZX_6 - 0.0067ZX_7 - 0.0678ZX_8 + 0.0673ZX_9 - 0.4325ZX_{10} - 0.1222ZX_{11} + 0.3653ZX_{12} \quad (2)$$

$$F = \frac{71.490}{85.622} F_1 + \frac{14.132}{85.622} F_2 \quad (3)$$

Wherein  $ZX_1 \dots ZX_{12}$  is the indicator value normalized by SPSS software. By applying this formula, the comprehensive scores of competitiveness in the service sector of 11 provinces and cities in the Yangtze River Economic Belt in 2015 are derived, as shown in Table VI. Table VI shows the gaps among 12 provinces and cities in terms of competitiveness of service sector.

Following the same measurement method, the comprehensive scores of competitiveness in service sector of 11 provinces and cities in the Yangtze River Economic Belt in 2016 are derived, as shown in Table VII.

TABLE VI. COMPREHENSIVE SCORES OF SERVICE SECTOR IN 11 PROVINCES AND CITIES IN 2015

Ranking	Province/city	F1	F2	F
1	Shanghai	5.2920	-0.2472	5.0448
2	Jiangsu	2.9331	0.1074	3.0404
3	Zhejiang	2.2420	0.1704	2.4124

11	Guizhou	-2.4554	-0.2852	-2.7405

#### D. Analysis of Model Results

As shown by comparing the 2015 and 2016 data, the scores and rankings of service sector's growth level among the 11 provinces and towns in the Yangtze River Economic Belt are relatively stable, indicating a healthy and robust development trend. While there are obvious gradients and gaps in the level of growth of service sector among those provinces and towns, they can be categorized into three classes. Class I include Shanghai, Jiangsu and Zhejiang, which are situated in the Yangtze River's lower reaches, Class II is composed of Chongqing, Hubei, Hunan, Anhui and Sichuan, and Class III consists of Jiangxi, Yunnan and Guizhou. It demonstrates the significant disparity between the upper, middle, and lower levels of the Yangtze River Economic Belt in terms of the development of the service sector.

It can be known from the basic data that the innovation indicator, namely, "the ratio of R&D funds to local GDP", of the regions in the lower reaches of the Yangtze River, which rank the top three, is obviously ahead of other regions. Chongqing, situated in the upper reaches of the Yangtze River and ranked above other regions in the middle and upper reaches of the Yangtze River, remains at the 4th place, because its indicators "export dependence" and "import dependence"

when compared to those other provinces and towns, are much greater. This is closely related to a series of measures implemented by Chongqing in recent years to speed up the development of inland highland for openness. Therefore, it is evident that "innovation" and "openness" are crucial factors to influence and determine the competitiveness of service sector.

#### V. RESEARCH CONCLUSIONS AND COUNTERMEASURES TO ENHANCE THE COMPETITIVENESS OF SERVICE SECTOR IN YANGTZE RIVER ECONOMIC BELT

##### A. Research Conclusions and Suggestions for further Researches in the Future

The study's findings demonstrate that there is still much room for improvement in the competitiveness of the service sector in the Yangtze River Economic Belt. The "Dual-core Diamond Model" developed and designed based on Michael Porter Diamond Model in this paper accords with the present situation and future development needs of the service sector in the Yangtze River Economic Belt. The feasibility and scientificity of the "Dual-core Diamond Model" are further verified by the evaluation indicator system of the competitiveness of the service sector in the Yangtze River Economic Belt built based on the "Dual-core Diamond

Model” and the quantitative model analysis on the 12 selected indicators. In addition, empirical analysis shows that “innovation” and “openness” have become the important factors that enhance the competitiveness of service sector in the Yangtze River Economic Belt. In this paper, the research on service sector is relatively macroscopic, Provincial level research and the research on segmented industry deserve a closer and deeper look while considering the failure to test the mechanisms by which innovation and openness affect the competitiveness of the service industry. In the future, modern service sector and high-end service sector will become the focus and key areas in the development of service sector in China, so the next step is to carry out researches on segmented modern service sector and high-end service sector to verify the mechanism transmission path of influencing factors, and focus on analyzing more responsible situations and seeking more effective ways to enhance the competitiveness of the service industry in the Yangtze River Economic Belt.

#### *B. Countermeasures for Improving the Competitiveness of Service Sector in Yangtze River Economic Belt*

Enhancing innovation ability. Continually improve the overall design and accelerate the formation of an innovative development model to serve the development of the service sector in the Yangtze River Economic Belt; continuously improving R&D and innovation capabilities, and developing outstanding products, technologies and services; further increasing R&D investment to raise the technological level; spearheading technological innovations with institutional innovations, integrating the resources of local governments, universities and research institutes, and establishing an innovation capability improvement system; attaching more importance to the significance of human resources in the middle and upper reaches of the Yangtze River, and allowing the expanding human resources to exert their potential strength and make use of late-mover advantages in the fierce international competition [37,38].

Further expanding trade in services industries. Firstly, we should introduce a scientific and reasonable competition mechanism, build an open and fair competition environment for businesses with laws and regulations, and boost service industry exports by expanding openness in service industry; Secondly, we should identify and determine the key areas of service sector, especially in the domains such as finance, medical care, education, culture, tourism and other fields. Meanwhile, we should orderly liberalize the fields of pension service, trade circulation and e-commerce, and actively promote the export of capital-intensive and technology-intensive services such as computer information services; Lastly, we should encourage the appropriate liberalization in service industry, mobilize and utilize more resources, reinforce the interconnection ties among various industries and accelerate the growth momentum under China’s significant and epoch-making “Belt and Road” Initiative. We should also strive to further realize market alignment and integration, and facilitate the process of East Asian integration by investing significant resources into the process of building a platform of multilateral cooperation for China-ASEAN in service industries, so as to incentivize more countries and regions to get involved into economic globalization. We

should make full use of both international and domestic markets to build a strong and dynamic industrial and market foundation for expanding service industry exports [39].

Encouraging the growth of interconnected industries and create a coordinated development amalgamation for the service sector. We should encourage the thorough and seamless integration of manufacturing and service industries and focus on accelerating the transformation and improvement of the logistics transportation industry in the traditional service sector and continue to tap into the enormous potential and resources of tourism and extend the industrial chains. We should also introduce corresponding preferential policies on financing and finance sector as well as industrial support policies in order to break the industrial dichotomy between manufacturing and service industries, and fully utilize cutting-edge technologies such as big data, AI, and the Internet of Things to encourage the thorough integration and coordinated expansion of manufacturing and service sectors as well as to encourage growth in the general competitiveness of the service industries.

Paying more efforts on talent cultivation and building a talent system in alignment with the development of service sector. We should carry out pilot talent training programs for service sector, introducing the relevant laws and regulations about trade services of various countries and cultivate the ability to proficiently use software and technology. We should also promote the cultivation of an entrepreneurial team proficient in international business, and accelerate the cultivation of a group of high-end talents specializing in financial insurance, cultural creativity, business consulting and other fields. We should strive for a balanced development of talents cultivation in various regions by focusing on the education and cultivation of the overall quality of non-urban population while improving the overall quality of urban population. We should promote the supply-side structural changes in the employment market for the service sector by maximizing the demographic dividends enjoyed by the Yangtze River Economic Belt, so as to conserve talents for the development of service sector and the promotion of competitiveness.

Improving the relevant legal system and innovate the service supervision and governance system in the service sector. Traditional supervision methods mainly rely on administrative power, which is difficult to adapt to the new economic modes in modern economy. Therefore, it is necessary to innovate supervision concept and enhance the flexibility and effectiveness of policies. In addition, we should make efforts to establish an early warning mechanism for service sector security; we should improve the judicial safeguard system, optimize the commercial dispute resolution system, and build a new co-governance mechanism based on integration of multi-dimensional supervision.

Focusing on coordinated and integrated inter-region development. We should highlight the radiating effect and the leading role of Shanghai, Jiangsu, Zhejiang and other regions, and actively solidify the strategic alliance of service sector among regions in the upper, middle and lower reaches of the Yangtze River Economic Belt. We should also encourage the

gradient transfer of service sector and development in industrial sector. We should transform the various resources and advantages under the opening-up policy over numerous regions and towns into the amelioration of the economy [40]. The “Belt and Road” Initiative, the plans for the development of the Yangtze River Economic Belt, and the New Western Land-sea Corridor have provided enormous potential and numerous opportunities for regions along the Yangtze River to discover a new form of opening up. Undoubtedly, inland areas may learn from the salubrious experience of economically leading areas and integrate it into their own development strategies in their efforts to reform their current system and they can definitely achieve the continuous upgrading and optimization of the development mode for opening up their industries and maximize their respective competitiveness in various fields.

#### ACKNOWLEDGMENT

# Enhancing COVID-19 Diagnosis Through a Hybrid CNN and Gray Wolf Optimizer Framework

Yechun JIN\*, Guanxiong ZHANG, Jie LI

College of Physics and Information Engineering, Cangzhou Normal University, Cangzhou 06100, Hebei, China

**Abstract**—Covid-19 is an infectious respiratory disorder brought about using a brand-new coronavirus first found in 2019. The severity of symptoms can vary from mild to life-threatening. No vaccine or specific treatment has been developed to address Covid-19. Hence the most effective preventive measure is to practice social distancing and adhere to good hygiene practices. Medical imaging and convolutional neural networks are used in Covid-19 research to quickly identify infected individuals and detect changes in the lung tissue of those infected. Convolutional neural networks can be used to analyze chest CT scans, detecting potential signs of infection like ground-glass opacities, which indicate the presence of Covid-19. This article introduces a powerful framework for classifying COVID-19 images utilizing a hybrid of CNN and an improved version of Gray Wolf Optimizer. To demonstrate the efficiency of the projected framework, it is verified on a standard dataset and compared with other methods, with results indicating its superiority over the others.

**Keywords**—Covid-19; respiratory disorder; medical imaging; convolutional neural networks; improved gray wolf algorithm

## I. INTRODUCTION

This In Wuhan, Hubei Province, China, a cluster of pneumonia cases with an undetermined reason was described in Dec. 2019. Middle East Respiratory Syndrome (MERS-CoV) and severe acute respiratory syndrome (SARS-CoV) are just two examples of the diverse diseases that can be brought on by the coronaviruses (CoV) family of viruses. Formerly undetected in people, the coronavirus illness (Covid-19) is a new type that was discovered in 2019.

The way of transmission of Covid-19 makes it a very dangerous disease. The disease can be transmitted by airborne droplets (discharges that appear invisibly when talking, sneezing, or coughing.). Medical imaging is also essential in determining the severity of COVID-19 and providing guidance for treatment. Medical imaging can be used to diagnose pneumonia.

Automated CT or X-ray analysis techniques based on artificial intelligence exist for the detection, monitoring and quantification of the coronavirus. They are used to detect infected patients from healthy individuals. At first, blood tests were taken from patients hospitalized with corona symptoms after some time, and it took 2 to 3 days to confirm their infection. It was dangerous and caused the number of patients to increase for a long time. The beginning of this decade should be marked by the coronavirus pandemic, spurring the development and advancement of various digital technologies to combat multiple diseases and clinical issues.

Machine learning, a subdivision of artificial intelligence, enables a system to gain knowledge from prior data, detect patterns, and make decisions with little human input. Examples of algorithms include logistic regression [1], SVM [2], K-means clustering [3], etc.

DL (Deep Learning) is a type of ML (machine learning) that utilizes multiple layers of computation to analyze and learn data representations, extracting features at various levels of abstraction. CNNs methods are one example of DL and are employed in various uses related to Covid-19 identification.

For example, A DL-based technique for diagnosing the Covid-10 utilizing X-ray images was offered by [4]. The researchers employed chest X-ray radiographs to identify coronavirus pneumonia in patients by utilizing five transfer learning-based convolutional neural networks, namely ResNet101, ResNet50, InceptionV3, Inception-ResNetV2, and ResNet152. Five-fold cross-validation was implemented, and three binary categorizations were established containing four groups (viral pneumonia, bacterial pneumonia, and COVID-19, normal (healthy)). Findings presented that the ResNet50 system can provide the greatest segmentation efficiency among the other 4 utilized models, according to the performance findings.

Using chest CT X-ray pictures, Aslan et al. introduced two DL methods for the automated detection of positive COVID-19 patients [5]. These suggested designs used ANN methodology to autonomously conduct lung segmentation (pre-processing) on CT images (ANN). The AlexNet architecture was included in both designs. Hence, a pre-trained application is the suggested approach. The second suggested design, meanwhile, had a combined configuration since it included a BiLSTM (Bidirectional Long Short-Term Memory) layer that also considered temporal aspects. The findings show that the suggested architecture performs very well at detecting infections. Consequently, this research contributes to previous studies with its advanced architectural design and high segmentation accuracy.

A structure for COVID-19 image segmentation that combines deep learning and metaheuristics was suggested in [6]. As a deep learning system, appropriate visual representations were learned and extracted using MobileNetV3 as the foundation for feature extraction. To reduce the dimension of the image representations and improve classification precision, the Aquila Optimizer was used as a characteristic selector and metaheuristic method. Two datasets, including CT COVID-19 and X-ray images, were applied to verify the suggested framework. The tests' findings

\*Corresponding Author.

demonstrated that the suggested framework performed well regarding segmentation precision and dimension decrease throughout the characteristic extraction and choice stage. The Aquila Optimizer feature selection algorithm demonstrated superior performance metrics than other prior approaches.

However, despite the advancements in deep learning techniques for COVID-19 identification using medical imaging, there is still a need for more efficient and accurate classification frameworks. While previous studies have demonstrated the effectiveness of convolutional neural networks (CNNs) in analyzing chest CT scans and X-ray images, there is room for improvement in terms of classification performance and computational efficiency. Furthermore, the existing literature lacks research on the utilization of hybrid models that combine CNNs with optimization algorithms to enhance the classification accuracy of COVID-19 images. Optimizers play a crucial role in fine-tuning the model parameters and improving its overall performance. Therefore, there is a gap in the literature regarding the development and evaluation of a hybrid CNN framework incorporating an improved version of the Gray Wolf Optimizer for COVID-19 image classification. Closing this gap in the research is essential as it can lead to the development of a more effective and accurate framework for identifying COVID-19 infections. Such a framework would not only assist in the timely diagnosis of the disease but also aid in monitoring the severity of the infection and providing appropriate treatment guidance. Additionally, an enhanced classification model would contribute to the efforts in containing the spread of the virus by enabling the rapid identification of infected individuals.

The approach outlined in this article for detecting and identifying covid-19 from medical photos is based on the combination of the Improved Gray Wolf Algorithm and Convolutional neural networks. There are two critical steps in this process. The photos are subjected to pre-processing in the first stage to minimize and eliminate the noise. To identify the kind of tumor through data training, the operation of segmentation and extraction of brain tumor features is performed in the second phase. This section describes the pre-processing processes, formulation of the Improved Gray Wolf Algorithm, and convolutional neural networks.

## II. PRE-PROCESSING STAGE

Category of image pre-processing is one of the most basic stages of image processing because the images that are given to the computer system mainly have noise in their pixels. These noises should be reduced as much as possible and ideally eliminated. Medical images of Covid-19 are no exception to this rule.

The noise image is considered in the form of an initial image, and after that, the noise removal operation is performed by the MFT filtering method [7]. To achieve the constituent structure and components of the images and their analysis, as well as their small and large details, the quantum MFT filtering method was considered. The output of the pre-processing step is a set of decomposed coefficients.

In this process, a set of these coefficients is randomly selected to perform the reconstruction operation. The parts used in this process consist of median filtering, Gaussian filtering, quantum matching, criterion change, single-point columns and rows, point detection and point-to-point matching. In Gaussian filtering, a Gaussian filter is applied to the image. The value of this filter is chosen by chance. This value can be 3×3 or 5×5 pixels. After performing this filtering, the median filter is utilized for the image. In the following, the total pixels are randomly multiplied by a suitable criterion. This numerical value is in the interval between 0.7 and 1.3. Once the appropriate criterion is chosen, the process of quantum adaptation must begin.

In this step, the amount of light in each part of the image is matched by the quantum processing method of the MFT filtering method. In a single-point row and column steps, pixels are determined randomly. In the point-to-point matching phase, each pixel of the decomposed coefficients is determined randomly until the new image is generated. In the last step, all row, column and diagonal points are identified by MFT filtering to reduce image noise. After completing the mentioned operation, the whole image is sorted by the unique pixel values they have. Threshold functions and active contours have two characteristics which are oscillating and wave, and they are written according to the below Equation:

$$\int_{-\infty}^0 |\psi(t)|^2 dt < \infty \quad (1)$$

where, the maximum energy in  $\psi(t)$ , which is proportional to time and changes according to it, has a time interval assigned to it, expressed according to the below formula.

$$\int_{-\infty}^0 \psi(t) dt < 0 \quad (2)$$

Considering that reducing the noise of the images is intended, its relationship is written as follows:

$$\begin{aligned} \text{Min - Noise} = & \left( \sum_{\Omega} \sqrt{1 + (\beta |\nabla l|)^2} \right) \\ & + \frac{\lambda}{2} (l - I)^2 \end{aligned} \quad (3)$$

In this equation, several parameters are involved, each serving a specific purpose in the noise reduction process:

$I$  represents the target image, which refers to the ideal or noise-free image that we aim to reconstruct or approximate.

$I$  denotes the noisy image, which is the input image that contains the noise and requires denoising.

$\nabla l$  represents the total variation of the determination period. Total variation is a measure of the image's smoothness or the amount of changes between neighboring pixels. By considering the total variation, the algorithm can effectively preserve the edges and important features while reducing noise.

$\beta$  is the balance level parameter. It controls the trade-off between noise reduction and preserving image details. Adjusting  $\beta$  allows for fine-tuning the denoising process to achieve the desired level of noise reduction while maintaining important image characteristics.

$\lambda$  is the regularization parameter, also known as the smoothing parameter. It controls the smoothness of the denoised image and balances the fidelity to the noisy input image. A higher value of  $\lambda$  promotes smoother results, while a lower value preserves more details but may not effectively suppress noise.

$\Omega$  represents the total points in the image, indicating the spatial domain over which the noise reduction process is applied.

By minimizing the expression in Equation (3), the algorithm aims to reduce the noise in the input image (I) while preserving important image details and minimizing artifacts introduced during the denoising process. This noise reduction step is essential to enhance the quality and accuracy of the COVID-19 image analysis, facilitating more reliable classification and diagnosis. Overall, incorporating the noise reduction relationship into the proposed framework contributes to improving the robustness and effectiveness of COVID-19 image classification by reducing unwanted noise and enhancing the clarity of the images.

The performance of Equation (3) is such that it always considers the edge of the corresponding image and preserves its important features. The expression  $(l - l)^2$ , which is present in Equation (3), shows the amount of verification and confirmation of the validity of the existing image during review and processing with the base image.

### III. METHODS AND TOOLS

In this investigation, the concept of DL is used to train the network. DL is a type of ML that utilizes a variety of algorithms to represent abstract concepts numerically in the form of a graph. Deep models comprised multiple layers of linear and non-linear transformations. In other words, it is based on learning to display knowledge and features in model layers, which are based on artificial neural networks that model very complex networks.

#### A. Deep Learning

Its impact has been felt in almost all scientific fields and has changed businesses and industries. Recently, deep learning method has been widely utilized in the automatic identification of COVID-19 in patients [8-9]. Since then, numerous CNN designs have been created to classify images, and it has been demonstrated that these architectures outperform humans on the same dataset [10]. In order to forecast picture class labels, connectivity loss, as well as operational parameters (e.g., convolution kernels), are learnt from peripheral images [11].

A convolutional neural network is generally comprised of input, convolution, activation, fully connected, and output layers.

1) *Convolution layer*: The convolution layer is the maximum essential layer in a CNN. It can automatically identify features of an image without the need for manual definition. This layer can be expressed mathematically as follows:

$$f(g(t)) \cong \int_{-\infty}^{\infty} f(\tau)g(t - \tau)d\tau \quad (4)$$

where, convolution is determined by taking the integral of the product of two functions after inverting and altering one of them. As stated in Equation 4,  $g(t)$  serves as the filter that is reversed and shifted across the input function  $f(\cdot)$ . The result of this intersection between  $g(\cdot)$  and  $f(\cdot)$  is the convolution value.

The "stride" parameter indicates the intervals at which the filter function traverses the input function. The stride is the distance the filter function  $g(\cdot)$  moves across  $f(\cdot)$ . Generally, after a convolution operation, the output feature map will have a reduced size compared to the inputs. To prevent this from happening and maintain the dimensions of the output map, "padding" is utilized.

2) *Activation layer*: Activation layers, which typically follow convolution layers and are nonlinear in nature, play a crucial role in the selection of neurons to be activated. The input of the activation layer is an actual number that is transformed by a nonlinear operation.

3) *Pooling layer*: Pooling layers are usually placed between convolutional layers to reduce the three-dimensional size of the demonstration and decrease the number of variables and computations in a system. A pooling layer filters out important pixels and eliminates noise from the output feature map of a convolutional layer. Furthermore, pooling layers are utilized to increase the spatial invariance of the network.

4) *Fully connected layers*: The fully associated layers, which receive the output from the characteristic extraction layers, are typically positioned at the end of the neural network. The principal objective of the Dense layer is to assess all of the characteristics generated by preceding layers and use them for classification tasks. The following is a description of this notion.

$$L = \sum_{i=1}^N \sum_{j=1}^k -D_k^j \log Z_k^j \quad (5)$$

where,  $N$  is the sample count,  $D$  describes the chosen output vector, and  $Z_k^j$  shows the actual output vector for the  $m$ th class as determined by the following formula:

$$Z_k^j = \frac{\exp(f_j)}{\sum_{j=1}^k \exp(f_j)} \quad (6)$$

The function  $L$  is developed to contain a value to raise the weights'  $\eta$  values, and this is done with the weight penalty:

$$L = \sum_{i=1}^N \sum_{j=1}^k -D_k^j \log Z_k^j + \frac{1}{2} \eta \sum_P \sum_Q \omega_{p,q}^2 \quad (7)$$

where,  $L$  describes the whole number of layers,  $K$  defines the layer  $q$  connections, and  $p$  is the connection weight. A block schematic of a typical CNN for skin cancer detection is shown in Fig. 1.

Fig. 1. The convolutional neural network's common construction.

### B. Improved Gray Wolf Algorithm

The Gray Wolf Optimization (GWO) algorithm draws inspiration from the collective behavior of gray wolves while hunting, which is a variety of Swarm Intelligence Algorithm. The wolves' location in the issue-solving area shows how the issue can be solved [12]. Gray wolves live and hunt in groups.

The wolves employ a strategic approach to hunting, first forming a perimeter around the targeted prey and gradually tightening the circle until the animal is exhausted. They begin to attack in succession, taking direction from the alpha wolf and eventually bringing down their target [13]. Gray wolves exhibit a hierarchical social structure. This hierarchy is shown in Fig. 2 and explained below:

Fig. 2. The gray wolf hierarchy.

- The alpha category ( $\alpha$ ) is known as the group leader and is responsible for making decisions about hunting. Alpha decisions apply to the entire group.
- The beta wolves ( $\beta$ ) constitute the second hierarchical class within a wolf pack and are relied upon for making decisions and performing other duties. These wolves are often called upon to assume the alpha position when the existing alpha reaches advanced age or passes away.
- The Omega wolves ( $\omega$ ) can be classified as the lowest hierarchical order in the wolf pack. This group of wolves functions similarly to a Peshmerga, requiring obedience from all other members of the pack and being the last to receive sustenance.
- Wolves which are not included in the aforementioned social structure are referred to as Delta wolves ( $\delta$ ). These wolves are subordinate to Alpha and Beta but have a higher rank than Omega.

Gray wolves surround their victim when hunting, as was already described. The following relationships are employed to model hunting:

$$\vec{D} = |\vec{C} \cdot \vec{X}_p(t) - \vec{X}(t)| \quad (8)$$

$$\vec{X}(t+1) = \vec{X}_p(t) - A \cdot D \quad (9)$$

Hence,  $t$  denotes the coefficients,  $A$  and  $C$  represent the vector of hunting position and the vector of position for the gray wolf.

$$\vec{A}Z = \vec{a} \cdot \vec{r}_1 - \vec{a} \quad (10)$$

$$\vec{c}(t + 1) = 2 \cdot \vec{r}_2 \quad (11)$$

In the above Equations,  $i$  is equal to the repetition of the algorithm. Vectors  $A$  and  $C$  are the vector coefficients of the prey location, and  $X$  is the location of the gray wolf.  $a$  is linearly decreased from 2 to 0 throughout iterations.  $\vec{r}_1$  and  $\vec{r}_2$  are accidental vectors in the interval between 0 and 1.  $X_p$  is the bait position.

It is assumed that the position of prey  $X_p$  is uncertain in the search space. Therefore, the hunting position is considered the alpha position (the best solution obtained). With this assumption, the position of the wolves is obtained by considering the hierarchy:

$$\begin{aligned} \vec{X}_1 &= \vec{X}_\alpha - \vec{A}_1 \cdot (\vec{D}_\alpha) \cdot \vec{X}_2 \\ &= \vec{X}_\beta - \vec{A}_2 \cdot (\vec{D}_\beta) \cdot \vec{X}_3 = \vec{X}_\delta - \vec{A}_1 \cdot (\vec{D}_\delta) \end{aligned} \quad (12)$$

where,

$$\begin{aligned} \vec{D}_\alpha &= |\vec{C}_1 \cdot \vec{X}_\alpha - \vec{X}| \cdot \vec{D}_\beta \\ &= |\vec{C}_2 \cdot \vec{X}_\beta - \vec{X}| \cdot \vec{D}_\delta = |\vec{C}_3 \cdot \vec{X}_\delta - \vec{X}| \end{aligned} \quad (13)$$

$$\vec{X}(t + 1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \quad (14)$$

By using these relationships, the position of the wolves is obtained in each iteration. Finally, when the stop condition is met, the algorithm ends.

In the following, the proposed improved algorithm will be presented. The gray wolf algorithm is one of the powerful optimization algorithms based on collective intelligence. But the performance of collective intelligence algorithms decreases when faced with complex cost functions [14]. Therefore, to cover this weakness, the developed gray wolf algorithm is introduced in this section. Discovery and extraction features are two fundamental pillars of efficient optimization. The meaning of exploration is to search the entire space of variables. Having this feature will make the algorithm able to explore the entire search space and avoid getting stuck in local extremes. The presence of parameter  $A$  in the gray wolf algorithm creates a balance between exploration and extraction properties.

When the parameter  $A$  is in the range  $A > 1$  or  $A < -1$ , the algorithm works in a heuristic manner, and when this parameter is in the range  $-1 < A < 1$ , the extraction property of the algorithm will increase [15]. This parameter is defined as  $\vec{A} = 2\vec{a} \cdot \vec{r}_1 - \vec{a}$  and its value depends on the value of  $a$ . In the main algorithm, the amount of this variable is equivalent to 2 at the beginning of the algorithm, and as the repetitions pass, it reaches zero value linearly. To improve the efficiency of this

algorithm, in the suggested technique, the following relationship is used to apply changes to  $a$ :

$$a = \cos\left(\frac{\pi i}{T}\right) + 1 \quad (15)$$

where,  $i$  and  $T$  represent, in turn, the iteration of the algorithm and the maximum algorithm iteration.

The values of parameter  $a$  in the proposed method in the exploration stage are larger than its values in the original method. This means increasing the power of discovery in this stage of the proposed method. On the other hand, the values of parameter  $a$  in the extraction stage are lower than those in the main algorithm. This helps to increase the convergence velocity of the improved algorithm compared to the original technique.

In addition to using Equation (15) to update the parameter, in order to improve the efficiency of the algorithm, instead of averaging the position of wolves  $\alpha$ ,  $\beta$  and  $\delta$  in Equation (14), their weighted average is used. In this way, the weight coefficient of each position is considered proportional to the inverse of the resulting cost function. Therefore, instead of using the relation (14), the following relations can be used to obtain the position in the next iteration.

$$\vec{X}(t + 1) = \frac{L_1 \vec{X}_1 + L_2 \vec{X}_2 + L_3 \vec{X}_3}{L_1 + L_2 + L_3} \quad (16)$$

where,

$$G_\alpha = \frac{1}{\text{cost}_\alpha} \quad (17)$$

$$G_\beta = \frac{1}{\text{cost}_\beta} \quad (18)$$

$$G_\delta = \frac{1}{\text{cost}_\delta} \quad (19)$$

where,  $\text{cost } t$  describes the value of the cost function of the corresponding position, and  $L_1$ ,  $L_2$ , and  $L_3$  represent three weights of the updated Equation.

### C. Optimized CNN

Different studies are conducted to improve the structure of a CNN. The application of optimization algorithms to CNNs has produced interesting results. This paper introduces a new optimized approach to optimize CNN structure. The construction of the projected CNN has been shown in Fig. 5, and the input images are 32x32 pixels in size. The proposed algorithm is clearly illustrated in Fig. 3.

For this issue, the size of the sliding window is denoted by "max", and the smallest value that can be accepted of the max-pooling minimum (which is 2 here) is labeled "min" to cut down the error of the system. It's worth mentioning that the amount of the sliding window must be less than the input data. As a result, a selection of answers has been randomly obtained.

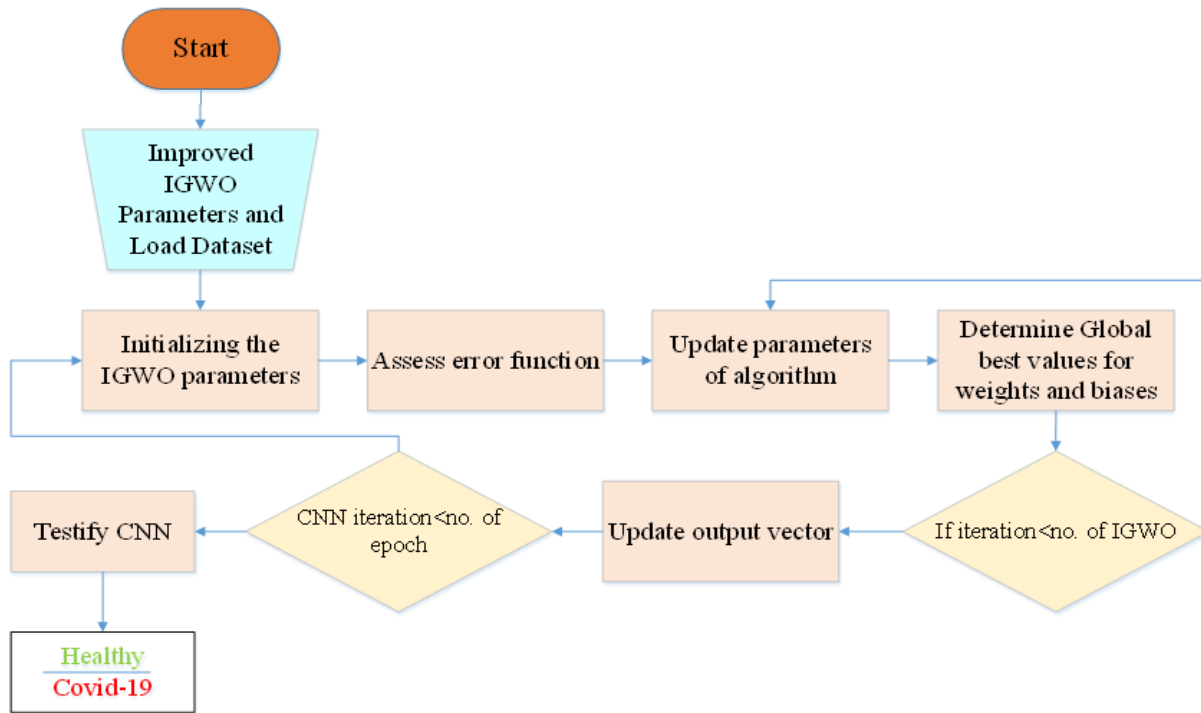

Fig. 3. Schematic representation of the suggested CNN/IGWO.

CNN training is paramount for achieving the best outcomes from layer parameters so that each layer is properly connected and identifies the image accurately. Utilizing the gradient descent algorithm to optimize the parameters of a model, such as convolution filters and fully connected layer weights, is commonplace. In particular, the latter layer plays an integral role in image classification. Thus, it is imperative to refine the training of its weight vector by utilizing an enhanced Whale Optimization Algorithm. The number of search agents should be set at fifty, and a maximum of two hundred iterations with vectors varying linearly between 0 and 2 can be applied. To minimize CNN, a fitness function should be used:

$$E = \frac{1}{T} \sum_{i=1}^{n_t} \sum_{j=1}^{n_{ol}} (D_{ji} - Z_{ji})^2 \quad (20)$$

where,  $D_{ji}$  and  $Z_{ji}$  denote the chosen output and the output amount generated by the Convolutional Neural Network (CNN), respectively, where  $n_{ol}$  and  $n_t$  represent the number of output layers and the amount of training samples, respectively.

This research utilized the half-value precision function to validate the optimized Covid-19 by accurately determining the parameters of the algorithms and applying them to a Convolutional Neural Network. Parameter initialization and evaluation of the function value were conducted, and then the Improved Gray Wolf Algorithm was utilized to update the algorithm parameters. This iterative process was repeated until termination criteria were met. The two essential CNN parameters of weights and biases were selected for optimization in accordance with this research.

$$W = [w_1, w_2, \dots, w_p]$$

$$b_n = [b_{1n}, b_{2n}, \dots, b_{Ln}] \quad (21)$$

$$A = [a_1, a_2, \dots, a_A] \quad (22)$$

$$w_n = [w_{1n}, w_{2n}, \dots, w_{Ln}] \quad (23)$$

With  $A$  denoting the whole number of agents,  $L$  specifying the whole number of layers,  $l$  representing the layer index,  $n$  representing the number of agents, and  $w_{in}$  Signifying the amount of the weight in layer  $i$ ;  $l$  ranges from 1 to  $L$  and  $n$  from 1 to  $A$ .

By employing the Improved Gray Wolf Algorithm for error minimization instead of backpropagation, we can optimize both weights and biases with ease since it does not require any backward computation.

#### IV. SIMULATION RESULTS

##### A. Dataset Explanation

The open-source repository on GitHub, run via Dr Joseph Cohen, was used to obtain 65 X-ray images of people with COVID-19 for this study[16]. The majority of the patients in this repository have severe acute respiratory syndrome (SARS), COVID-19, Middle East respiratory syndrome (MERS), or acute respiratory distress syndrome (ARDS) pneumonia. Chest X-ray Images (pneumonia) from the Kagel repository, which contains 65 standard X-ray images, have also been used [17]. Our investigation utilised a dataset composed of chest X-ray images from 65 healthy individuals and 65 patients diagnosed with COVID-19. A total of 130 images were collected and resized to 224×224 pixels. As illustrated in Fig. 4(a) and 4(b), samples of chest X-ray images of both usual and Covid-19 cases are presented.

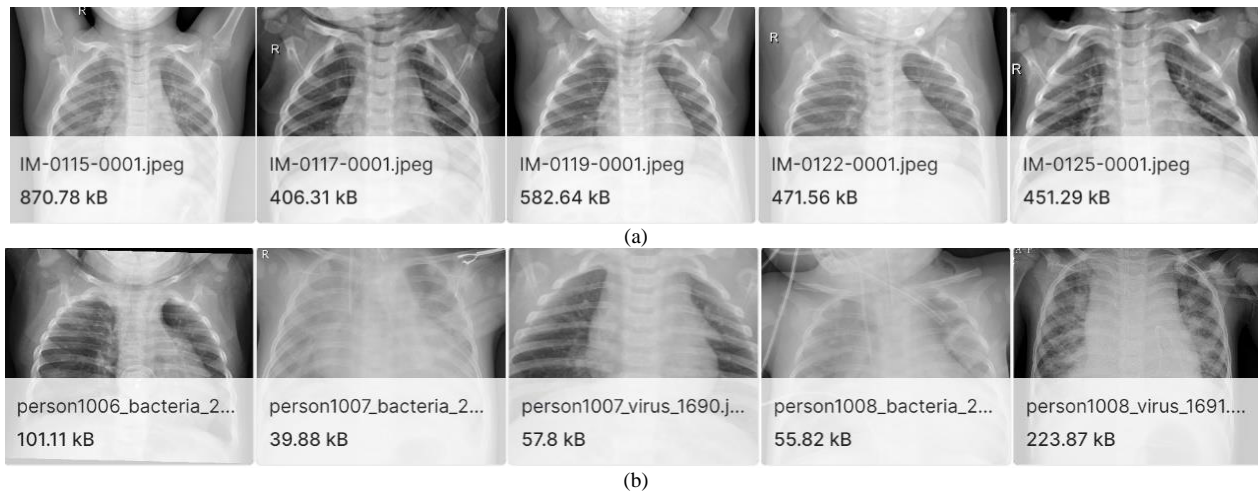

Fig. 4. Some chest X-ray image examples to (a) Normal and (b) Covid-19 cases.

### B. System Configuration

Utilizing MATLAB R2018b with 64-bit Windows, our algorithm was programmed and executed on an Intel Core i7 CPU 2.00GHz, 2.5GHz, 16GB RAM and 64-bit operating system. In addition to the variable of the competitive algorithms, we set the population size ( $N = 50$ ), maximum iterations ( $tmax = 200$ ), and 10 independent runs for each optimization problem. This ensures a reliable and effective optimization process.

The dataset was partitioned randomly into two subsets: 75% for training and 25% for testing. K-fold cross-verification was employed to validate the results, which are presented in Fig. 5 with five different values of k.

### C. Operation Criteria

The proposed system's efficiency was validated by employing five criteria for evaluating deep transfer learning models; Sensitivity, particularity, precision, and positive and negative predictive value (PPV and NPV).

$$Sensitivity (\%) = \frac{TP}{TP+FN} \quad (24)$$

$$Specificity (\%) = \frac{TN}{FP+TN} \quad (25)$$

$$Accuracy (\%) = \frac{TP+TN}{TP+FP+FN+TN} \quad (26)$$

$$PPV (\%) = \frac{TP}{TP+FP} \quad (27)$$

$$NPV (\%) = \frac{TN}{FN+TN} \quad (28)$$

Fig. 5. Visual representation of test and training data sets for five-fold cross-validation.

The percentage of examples correctly classified as positive is known as True Positive (TP), while the percentage of examples incorrectly classified as positive is known as False Positive (FP). The False Negative (FN) count corresponds to the number of examples that is falsely labeled as negative. In contrast, the True Negative (TN) count corresponds to the amount of example that is correctly declared negative. Concerning a given dataset and test model, the True Positive (TP) count denotes the amount of positive COVID-19 cases the model has accurately identified. The number of false positives (FP) is the number of normal results that were incorrectly classified as positive for COVID-19. In contrast, the number of true negatives (TN) is the number of normal results that have been correctly identified. The number of false negatives (FN) is the amount of positive COVID-19 results that are misclassified as negative.

**D. Results and Discussions**

1) *Confusion matrix and accuracy analysis:* In this investigation, chest X-ray images are utilized to forecast Covid-19 cases. The outcomes of the simulation were trained and assessed on chest X-ray images, and then, they were

compared to traditional convolutional neural networks [18] and CNN/GWO methodology. As previously explained, the k-fold cross-validation method has been used to prevent overfitting. According to the analysis of the graphs in the proposed CNN/IGWO model in fold-2, according to the graphs and the confusion matrix, it performs better. Also, in the CNN/GWO model, fold-1 performs better according to the graphs and the confusion matrix, shown in Fig. 6.

As can be observed, Fig. 6 clearly demonstrates that the proposed CNN/IGWO model outperforms the CNN/GWO model and CNN model in terms of predictive performance, as evidenced by the various metric indicators. The CNN/IGWO model astoundingly recognized COVID-19 contaminated illness (65 images) as accurate positive and ordered images (65 images) as true negative with an impressive 99 percent accuracy score upon analyzing the uncertainty matrix.

Fig. 7 and Fig. 8 reveal the remarkable improvement in precision and loss of a CNN optimized by the IGWO algorithm using the Joseph Cohen dataset, compared with CNN [18] and CNN/GWO methodology.

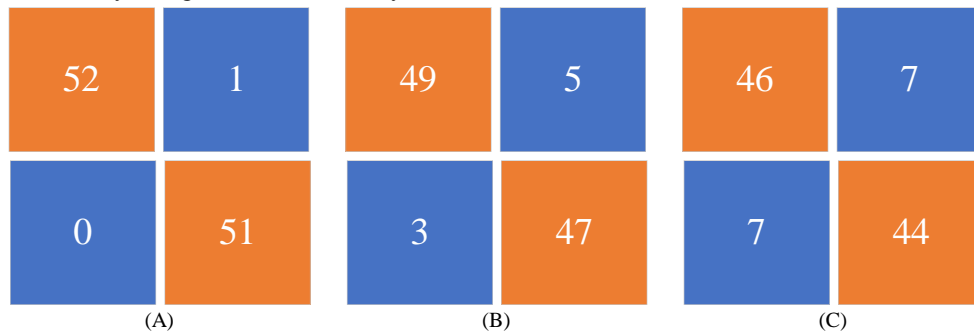

Fig. 6. Confusion matrix of (A) CNN/IGWO, (B) CNN/GWO, and (C) CNN/GWO.

Fig. 7. Accuracy value of (A) CNN/IGWO, (B) CNN/GWO, and (C) CNN/GWO.

Fig. 8. Loss value of (A) CNN/IGWO, (B) CNN/GWO, and (C) CNN/GWO.

According to the results from accuracy and loss diagrams in Fig. 7 and Fig. 8, it can be understood that the maximal the number of epochs, the more the precision of the CNN/IGWO method increases and the less the error in this model. Therefore, if we want to compare these two models in general, the CNN/IGWO model has a better performance

2) *Comparison of two models based on test data:* As mentioned before, the method was compared with standard CNN [18] and CNN/GWO methodology validation and analyzing the proposed method's efficiency. In another detailed comparison of the performance of the models, the comparison of the three methods by the test data is denoted in Table I.

We obtained 100% sensitivity and a value of 100% specificity, 86% accuracy value for the proposed which is the best performance among the methods in the CNN/IGWO model. The lowest performance is achieved by the standard CNN with of 87% sensitivity value, 86% specificity value, and 86% specificity value accuracy. As a result, the CNN/IGWO method offers an advantage over the other two models in both the training and test phases. As can be observed, the highest level of accuracy belongs to the proposed CNN/IGWO method toward the other two aforesaid methods. The results show the effect of using the IGWO algorithm on the deep learning framework.

TABLE I. ANALYZING THE EFFICACY OF COVID-19 DETECTION USING PERFORMANCE METRICS

## V. CONCLUSION

The new coronavirus (Covid-19) is an infectious agent that causes severe respiratory illness in humans. Initially identified in Wuhan, China, in late 2019, the virus has since spread worldwide. Common indications of Covid-19 infection are fever, cough, dyspnea, muscle pain, malaise, and impaired olfaction or gustation. Diagnosis can be confirmed through laboratory testing for the virus or through medical imaging techniques such as sample chest radiography and calculated tomography (CT) scans. Generally, supportive care, hydration, rest, and symptom observation are the treatments for Covid-19. Computer-aided detection (CAD) is a method employed to identify Covid-19 in clinical imaging. This entails using artificial intelligence algorithms to discover infection in X-ray, computed tomography (CT) scans, and ultrasounds. The algorithm examines the image and locates any patterns correlated with the disorder. If a pattern is observed, it is flagged as a potential suggestion of Covid-19. This approach has been beneficial for the early detection of the virus and has improved the precision of diagnosis. This paper introduces a modified convolutional optimal neural network by an Improved Gray Wolf version (IGWO) Algorithm as a new technique for the optimal analysis of COVID-19 in medical imaging. The proposed method was tested on the Joseph Cohen

dataset, and its performance was compared with that of other methods, including CNN and CNN/GWO, to demonstrate its effectiveness.

One potential future direction for further research in the field of medical imaging and disease detection is the development of a versatile and adaptable framework that can detect not only COVID-19 but also other respiratory diseases or conditions. While the focus of the current research is on COVID-19, expanding the framework to encompass a broader range of diseases would enhance its clinical utility and impact. To achieve this, researchers can explore the possibility of incorporating a wider variety of training data and expanding the dataset to include images of various respiratory diseases such as pneumonia, tuberculosis, lung cancer, and other pulmonary conditions. By training the model on a diverse dataset, it can learn to identify unique features and patterns associated with different diseases, enabling it to provide accurate and specific diagnoses.

# Automated Epileptic Seizure Detection using Improved Crystal Structure Algorithm with Stacked Autoencoder

Srikanth Cherukuvada, R. Kayalvizhi\*

Department of Networking and Communications  
School of Computing, SRM Institute of Science and Technology  
Kattankulathur, Chennai, India

**Abstract**—Epilepsy can be referred to as a neurological disorder, categorized by intractable seizures with serious consequences. To forecast such seizures, Electroencephalogram (EEG) datasets should be gathered continuously. EEG signals were recorded by using numerous electrodes fixed on the scalp that cannot be worn by patients continuously. Neurostimulators can intervene in advance and ignore the seizure rate. Its productivity is increased by using heuristics such as advanced seizure prediction. In recent times, several authors have deployed various deep learning approaches for predicting epileptic seizures, utilizing EEG signals. In this work, an Automated Epileptic Seizure Detection using Improved Crystal Structure Algorithm with Stacked Auto encoder (AESD-ICSASAE) technique has been developed. The presented AESD-ICSASAE technique executes a three-stage process. At the initial level, the AESD-ICSASAE technique applies min-max normalization approach to normalize the input data. Next, the AESD-ICSASAE technique uses ICSA based feature selection method for optimal choice of features. Finally, the SAE based classification process takes place and the hyperparameter selection process is performed by Arithmetic Optimization Algorithm (AOA). To depict the enhanced classification outcomes of the AESD-ICSASAE technique, series of experiments was made. Furthermore, the proposed method's results have been tested utilizing the CHB-MIT database, with results indicating an accuracy of 98.9%. These results validate the highest level of accuracy in seizure classification across all of the analyzed EEG data. A full set of experiments validated the AESD-ICSASAE method's enhancements.

**Keywords**—Deep learning; EEG signals; epileptic seizure detection; hyperparameter tuning; stacked autoencoders

## I. INTRODUCTION

Epilepsy is a disease of the central nervous system caused by irregularities in brain electricity [1]. Seizures occur often and often without notice, making this a diagnosis. Epilepsy manifests itself with episodes of temporarily diminished or suspended consciousness, brief periods of unconsciousness, and abrupt, severe convulsions [2]. Epilepsy has a significant effect on people's life since it may result in catastrophic events, mental decline, and restrictions on routine tasks. Patients with epilepsy would benefit more from a method to predict when they will have seizures so that they can avoid injury and begin treatment immediately [3]. In addition, it lays the way for seizure intervention mechanisms to be used to prevent impending seizures and individualized epilepsy treatment (tailored medicine with minimal side-effects). Numerous

studies have recently shown that the onset of epileptic seizures may be predicted with some degree of accuracy [4], suggesting that individuals with epilepsy might benefit from seizure prediction methods. The EEG is now the most widely used instrument for seizure detection [5]. Examining pre-seizure EEG activity for specific patterns that signal future seizures was the key challenge, and this was overcome in the reported study [6]. Epileptic seizures lead to a rapid increase in electrical disturbances in brain of patients, which is measured utilizing the EEG approach [7]. Generally, EEG signal recordings were scrutinized by neurologists for determining different levels of epilepsy such as interictal (in-between seizures), ictal (on-going seizures), post-ictal (after seizure onset period), and preictal (just before seizure onset) [8]. But this process can be time-taking, and arduous, which results in the need for automated epileptic seizure predictive mechanism. Deep learning (DL) was another pattern in this regard, which can manage the large signal dataset produced by wearable IoT sensing gadgets such as EEG headsets for epilepsy [9]. The methods depend on DL methods solve the restrictions of conventional Machine Learning (ML) methods by providing less processing duration and ability of managing big data of multichannel biomedical signals. Accordingly, such methods serve promising roles in offering real time solutions in healthcare field [10].

In this paper, an Automated Epileptic Seizure Detection using Improved Crystal Structure Algorithm with Stacked Auto encoder (AESD-ICSASAE) technique has been developed. The presented AESD-ICSASAE technique executes a three-stage process. The AESD-ICSASAE methodology begins with a min-max normalization stage to standardize the input data. After that, an ICSA-based feature selection methodology is used by the AESD-ICSASAE method to choose the best features. In the end, the SAE-based method of classification is carried out, and the AOA is the one responsible for carrying out the hyperparameter selection procedure. Multiple computations have been performed to show how the AESD-ICSASAE technique improves classification accuracy.

## A. Key Contributions

The work presented here introduces an automated system for identifying epileptic seizures termed AESD-ICSASAE. The methodology employed by the authors involves the utilization of deep learning methodologies, particularly stacked autoencoders (SAEs), for the purpose of examining EEG data.

Here we propose using the AOA to choose appropriate the hyperparameters and a modified version of the crystal structure algorithm (ICSA) to choose appropriate attributes. The AESD-ICSASAE approach greatly enhances classification accuracy, providing a possible choice for real-time seizure forecasting and tailored epilepsy therapy, according to the experimental findings.

The following outline describes how the remaining parts of this work are structured: Section II demonstrates current and significant work. The conceptual design of the proposed system is presented in Section III. Both findings and analysis of the simulations are discussed in Section IV. Challenges and limitations are discussed in Section V. The work is concluded in Section VI.

## II. RELATED WORKS

In [11], Epilepsy convulsions using EEG recordings were detected using the wavelet transform and then classified using ML algorithms as either not a seizure or a seizure. In all, 48 occurrences were selected from the collected EEG signals obtained via the CHB-MIT scalp EEG data. Hence, this data was segmented using Tuneable Q-Wavelet Transform (TQWT), and time-frequency characteristics like entropy were extracted, and temporal parameters were extracted to provide a huge dataset for accurately identifying epilepsy occurrences. Utilizing Random Forest (RF) and Support Vector Machine (SVM) classifiers, the dataset is further processed for classifying epilepsy. Jaiswal and Banka [12] proposed 2 effectual methods including Subpattern related PCA (SpPCA) and cross-subpattern correlation-related PCA (SubXPCA) includes SVM for automated seizure recognition in EEG signals. Feature extraction has been executed utilizing SubXPCA and SpPCA. Both methods explore sub pattern relation of EEG signals, which aids in making decisions.

By focusing on what makes seizures unique, Qureshi et al. [13] were able to develop a system for Epileptic Seizure Detection (ESD) that uses both traditional ML algorithms and fuzzy-based approaches. In this work, the raw input divides unknown EEG input segments into interictal and ictal groups. Bairagi and Harpale [14] introduced a novel technique, Singular Spectrum Empirical Mode Decomposition (SSEMD) for effectual categorization of Epileptic and Normal EEG Signals. For classifying EEG signals in normal and epileptic classes, high-performance ML classifiers were employed. In [15], an end-to-end ML method was modelled for recognition of epileptic seizures utilizing the pretrained deep 2D-CNN and concept of Transfer Learning (TL).

In [16], a Principal component analysis (PCA) with Genetic Algorithm (GA) related ML method can be advanced for classifying binary epileptic seizures out of EEG dataset. The presented method leverages PCA for minimizing the count of attributes for binary classification of epileptic seizures and can be implemented in the prevailing ML techniques for assessing model performance compared with more features. In this study, GA was used for tuning the hyperparameters of ML methods to detect the optimal ML method. To find the best SVM parameters for categorizing EEG recordings, Subasi et al. [17] develop a hybrid strategy for ESD using GA and Practical Swarm Optimization (PSO). SVMs are one of robust ML

approaches and were widely leveraged in several application zones. The kernel parameter's setting for SVMs in training effects the classifier accuracy. The authors employed GA- and PSO-related techniques for optimizing the SVM parameters.

The AESD-ICSASAE method represents a notable advancement over prior methodologies for the automated detection of epileptic seizures, exhibiting superior performance in multiple aspects. The approach employed involves the utilization of deep learning techniques, particularly stacked autoencoders (SAEs), to more efficiently capture intricate patterns present in EEG signals compared to conventional ML methods. The utilization of an enhanced crystal structure algorithm (ICSA) facilitates superior feature selection, thereby tackling the difficulty of discerning pertinent features from voluminous EEG datasets. Furthermore, the AOA facilitates the optimization of hyperparameter selection, thereby augmenting the efficacy of the overall model. The suggested system exhibits superiority over prior approaches due to its ability to achieve greater categorization accuracy, enhanced computational efficiency, and increased interpretability, all of which are attributed to the recent advances.

## III. THE PROPOSED MODEL

A novel AESD-ICSASAE technique for reliable ESD on EEG data was developed in this paper. The presented AESD-ICSASAE technique executes a three-stage process.

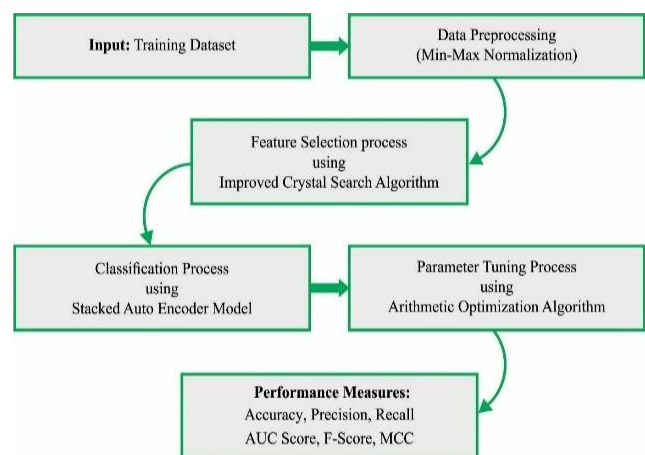

Fig. 1. Structure of the AESD-ICSASAE scheme.

As a first step, the AESD-ICSASAE method uses a min-max normalization methodology to standardize the input data. After that, an ICSA-based feature selection strategy is used by the AESD-ICSASAE method to choose the most relevant characteristics. At last, the AOA with SAE based classification process takes place. Fig. 1 represents the workflow of AESD-ICSASAE model.

### A. Data Normalization

In the beginning, the AESD-ICSASAE method utilizes a min-max normalization strategy in order to standardize the input data. The process of Min-Max normalization involves applying a linear transformation to the original dataset.  $MaxA$  and  $MinA$  represent the upper and lower bounds of attribute  $A$ , accordingly. The process of Min-Max normalization involves mapping the value of variable  $A$  to a

new value, denoted as  $v'$ , within a specified range. This is achieved by computing the difference between the  $new\_MinA$  and  $new\_MaxA$ . The threshold value for Min-Max range was fixed as  $[0,1]$

$$V' = \frac{V - \text{Min } A}{\text{Max } A - \text{Min } A} (\text{new\_Max } A - \text{new\_Min } A) + \text{new\_Min } A \quad (1)$$

### B. Feature Selection using ICSA Technique

The AESD-ICSASAE method currently employs an ICSA-based strategy for selecting features. The mathematical modeling of CSA is developed where the aim is to utilize crucial modification [18]. Now, all the candidate solutions of optimization technique are considered as a single CSA in the space. CSA counts are determined at random for the initialization of iteration purposes.

$$Cr = \begin{bmatrix} Cr_1 \\ Cr_2 \\ \vdots \\ Cr_i \\ \vdots \\ Cr_n \end{bmatrix} = \begin{bmatrix} x_1^1 & x_1^2 & \dots & x_1^j & \dots & x_1^d \\ x_2^1 & x_2^2 & \dots & x_2^j & \dots & x_2^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_i^1 & x_i^2 & \dots & x_i^j & \dots & x_i^d \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_n^1 & x_n^2 & \dots & x_n^j & \dots & x_n^d \end{bmatrix} \begin{cases} i = 1, 2, \dots, n \\ j = 1, 2, \dots, d \end{cases} \quad (2)$$

In Eq. (2),  $n$  indicates the CSA count and  $d$  designates the problem dimension. The initial location of CSA can be determined at random in the searching space as follows:

$$x_i^j(0) = x_{i,\min}^j + \xi(x_{i,\max}^j - x_{i,\min}^j), \begin{cases} i = 1, 2, \dots, n \\ j = 1, 2, \dots, d \end{cases} \quad (3)$$

Now,  $x_i^j(0)$  correspondingly represents the initial CSA position,  $x_{i,\min}^j$  and  $x_{i,\max}^j$  shows the minimal and maximal permissible values for  $j^{th}$  variable of  $i^{th}$  solution candidate and  $\xi$  indicate random number within  $[0, 1]$ . All the CSA at the corner can be assumed as the main CSA related to the concept of 'basis' in CSAlography, in which  $Cr_{main}$  is determined at random by assuming the initially made CSA. Note that arbitrary selection for every step can be determined by ignoring current  $Cr$ . The CSA with optimum formation can be determined as  $Cr_b$  while mean value of arbitrarily selected CSA is signified by  $F_c$ .

In order to upgrade the location of solution candidate in searching space, fundamental principle was deliberated:

a) Simple cubicle:

$$Cr_{new} = Cr_{old} + rCr_{main}, \quad (4)$$

b) Cubicle with the best CSAs:

$$Cr_{new} = Cr_{old} + r_1Cr_{main} + r_2Cr_b, \quad (5)$$

c) Cubicle with the mean CSAs:

$$Cr_{new} = Cr_{old} + r_1Cr_{main} + r_2F_c, \quad (6)$$

d) Cubicle with the best and mean CSAs:

$$Cr_{new} = Cr_{old} + r_1Cr_{main} + r_2Cr_b + r_3F_c, \quad (7)$$

Now, the novel location is denoted by  $Cr_{new}$ , the older location can be represented by  $c_{r_{old}}$ , and  $r$ ,  $r_1$ ,  $r_2$  and  $r_3$

denotes the random number. To provide the best possible results from the classifier, the CSO technique includes a fitness function (FF) whose values are skewed towards the positive to highlight the superiority of the candidates.

$$\text{fitness}(x_i) = \text{ClassifierErrorRate}(x_i) = \frac{\text{number of misclassified samples}}{\text{Total number of samples}} * 100 \quad (8)$$

The fitness function (FF) employed in the ICSA method was developed to have a balance between classifier accuracy (maximum) and the number of chosen features in all solutions (min) obtained by using such selected features, Eq. (9) denotes the FF for evaluating solutions.

$$\text{Fitness} = \alpha\gamma_R(D) + \beta \frac{|R|}{|C|} \quad (9)$$

Whereas  $\gamma_R(D)$  signifies the classifier error rate of presented techniques.  $|C|$  is total number of features in the dataset,  $|R|$  denotes the cardinality of the selected subset,  $\alpha$  and  $\beta$  were two parameters that match the importance of subset length and classification quality.  $\alpha \in [1, 0]$  and  $\beta = 1 - \alpha$ .

In order to create the ICSA, the chaos theory was used in the design process. The evolution of chaos exhibits regularity, nonrepeat ergodicity, and unpredictability, and it is a nonlinear process that may be sensitive to the starting state. Such attributes enable particles to hasten the convergence speed of method, escape from local optimization, and establish good spatial distribution. To participate in population initialization, chaotic series related to Tent map was employed and it can be formulated below.

$$f(x) = \begin{cases} 2x & 0 \leq x \leq 0.5 \\ 2(1-x) & 0.5 < x \leq 1 \end{cases} \quad (10)$$

The formula of Tent map afterward Bernoulli transform can be expressed:

$$f(x) = \begin{cases} 2x & 0 \leq x \leq 0.5 \\ 2x - 1 & 0.5 < x \leq 1 \end{cases} \quad (11)$$

### C. Seizure Recognition using Optimal SAE

In this work, the SAE based classification process takes place. The SAE method obtains the feature vector as input to assign appropriate class labels. AE was a kind of unsupervised learning framework which has 3 states namely input, hidden states and output [19]. The process of AE trained includes encoded and decoded parts. Fig. 2 depicts the infrastructure of SAE. The encoded part is used for mapping the input dataset to hidden demonstration and decoded part is used to regenerate input dataset in hidden demonstration. To give the unlabeled source dataset  $\{x_n\}_{n=1}^N$ , while  $x_n \in R^{m \times 1}$ ,  $h_n$  signifies hidden encoded vector analyzed in  $x_n$ , and  $\hat{x}_n$  indicates decoded vector of final state and encoder procedure can be defined in such a way:

$$h_n = f(W_1x_n + b_1) \quad (12)$$

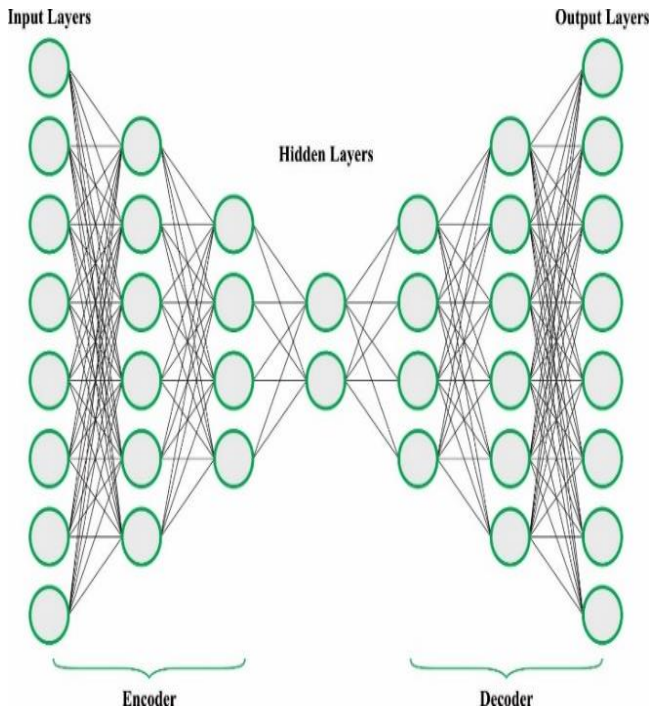

Fig. 2. Architecture of SAE.

While  $f$  represents the encoded operation,  $W_1$  stands for the weighted matrix associated with the encoded, and  $b_1$  displays the bias vector. This method of decoding may be characterized as follows:

$$\hat{x}_n = g(W_2 h_n + b_2) \quad (13)$$

The decoded perform is denoted by  $g$ , while the weighted matrix of decoding are represented by  $W_2$ , and the bias vector is denoted by  $b_2$ . To reduce the amount of inaccuracy in the reconstruction, AE's collection of variables was fine-tuned.

$$\varnothing(\theta) = \arg \min_{\theta, \theta'} \frac{1}{n} \sum_{i=1}^n L(x^i, \hat{x}^i) \quad (14)$$

While  $L$  denotes a loss function  $L(x, \hat{x}) = \|x - \hat{x}\|^2$ .

SAE uses a stacking technique to map  $n$  AEs to  $n$  hidden states using an unsupervised state-wise learning approach, before tuning using a supervised technique. Because of this, we may classify the SAE-based technique in the following ways:

- 1) The first step was to train the first AE using the input dataset to produce a feature vector;
- 2) The second phase was to use that feature vector as input for the next stage, and so on, until the process stopped.
- 3) Afterwards, all hidden states are trained, and the BP technique is used to minimize the cost function and improve the weight using labelled trained sets to achieve tuning.

Finally, the hyperparameter selection process is performed by the AOA resulting in enhanced performance. This optimization technique primarily relies on exploration and development stages [20]. The searching space for candidate solutions can be covered generally to break deadlock of method falling into search stagnation in exploration stage.

In the preliminary step of AOA's optimized approach, the sequence of potential solutions was constructed randomly.

$$X = [\chi_{N-1,1} \chi_{N,1} \chi_{2,\dots,1} \chi^1, 1 \chi_{N-1,j} \chi_{N,j} \chi_{2,j} \chi^1, j \chi_{N,n-1} \chi_{1,\dots,n-1} \chi_{N-l,n} \chi_{1,n} \chi_{N,n} \chi_{2,\dots,n}']$$

$$X = \begin{bmatrix} x_{1,1} & \dots & \dots & x_{1,j} & x_{1,n-1} & x_{1,n} \\ x_{2,1} & \dots & \dots & x_{2,j} & \dots & x_{2,n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{N-1,1} & \dots & \dots & x_{N-1,j} & \dots & x_{N-1,n} \\ x_{N,1} & \dots & \dots & x_{N,j} & x_{N,n-1} & x_{N,n} \end{bmatrix} \quad (15)$$

Before the AOA can put the optimized method into action, it must complete the searching phase based on the resultant value of the Math Optimizer Accelerated (MOA) functioning, which may be calculated using the formula below.

$$MOA(C\_Iter) = \text{Min} + C\_Iter \times \left( \frac{\text{Max} - \text{Min}}{M\_Iter} \right) \quad (16)$$

We may see the function's value after  $Iter$  iterations by looking at  $MOA(C\_Iter)$ ;  $C\_Iter$  shows the existing iteration;  $M\_Iter$  indicates the maximal iteration amount; Min and Max stand for the minimum and maximum values of the accelerated function, respectively.

The exploration phase is realized mainly by the two operators namely Division (D) and Multiplication (M). In mathematical computation, these two operators are accomplished tremendously distributing value, for the considerable amount of candidate solutions were covered. In exploration technique, the position of candidate solution can be considerably upgraded by the following expression:

$$x_{i,j}(C\_Iter + 1) = \begin{cases} \text{best}(x_j) / (MOP + \varepsilon) \times ((UB_j - LB_j) \times \mu + LB_j) & r_2 < 0.5 \\ \text{best}(x_j) \times MOP \times (UB_j - LB_j) \times \mu + LB_j & \text{otherwise} \end{cases} \quad (17)$$

Now  $\chi_{i,j}(C\_Iter + 1)$  denotes the  $j^{th}$  location of  $i^{th}$  solution in  $(C\_Iter + 1)^{th}$  iteration;  $\varepsilon$  represents the small value; The  $UB$  and  $LB$  indicate the maximum and minimum possible distances to a proposed solution;  $\mu$  is applied to regulate exploration stage that was set to 0.5.

$$MOP(C\_Iter) = 1 - \frac{C\_Iter^{\frac{1}{\alpha}}}{M\_Iter^{\frac{1}{\alpha}}} \quad (18)$$

The variable  $\alpha$  is utilized to establish the degree of effectiveness of the exploitation process during each iteration, where  $\alpha$  is assigned a value of 5. The utilization of the exploitation process is contingent upon two operators, specifically Addition (A) and Subtraction (S), which are conducive to minimizing dispersion in candidate solutions and can be implemented through extensive search techniques with a heightened likelihood of approximating the best possible solution.

$$x_{i,j}(C\_Iter + 1) = \begin{cases} \text{best}(x_j) - MOP \times ((UB_j - LB_j) \times \mu + LB_j), & r_3 < 0.5 \\ \text{best}(x_j) + MOP \times ((UB_j - LB_j) \times \mu + LB_j), & \text{otherwise} \end{cases} \quad (19)$$

**Algorithm 1:** Pseudo code for AOA

```

Populace size (N) and maximum iterations (T) are set to their
default values.
The starting position of each individual searching agent,
 $X_i(i = 1,2, \dots, N)$ 
Input values are  $\alpha, \mu, \text{Min},$  and  $\text{Max}$ 
While ( $t \leq T$ )
Assess the fitness of every search agent, Upgrade best Fitness,
 $X_b$ 
Assess the MOP
Assess the  $MOA$ 
For every search agents
If  $\text{rand} > MOA$ 
Upgrade position
Else
Upgrade position
End if
End for
                                 $t = t + 1$ 
End While
Return best Fitness,  $X_b$ 
    
```

The flexible changes between the exploration and utilization steps enable the AOA approach to finding the best answer and remain to offer a wide range of options for a broad search.

IV. RESULTS AND DISCUSSION

In this section, we verify the AESD-ICSASAE technique's experimental outcome evaluation on a dataset [21,22], of 40000 observations and two categories of classes, illustrated in Table I. The AESD-ICSASAE method has chosen a set of 7 features out of 23 features.

TABLE I. A COMPREHENSIVE OVERVIEW OF THE DATASET

Type of Classes	Total number of Observations
Seizure	20,000
NonSeizure	20,000
<b>Overall Observations</b>	<b>40,000</b>

In Fig. 3, the confusion matrices of the AESD-ICSASAE model are demonstrated. The results demonstrated that the AESD-ICSASAE model has shown accurate classification of seizure and no seizure class samples.

Table II presents the comprehensive outcomes of detecting seizures achieved by the AESD-ICSASAE approach, utilizing 60% of the Training set (TR) and 40% of the Testing set (TS) records. The AESD-ICSASAE method's brief findings for classification using 60% of the TR dataset are shown in Fig. 4. Samples belonging to the seizure and no seizure classes were correctly recognized using the AESD-ICSASAE methodology. In addition, it is noticed that the AESD-ICSASAE model at training phase has attained overall  $\text{accu}_{bal}$  of 98.70%,  $\text{prec}_n$  of 98.70%,  $\text{reca}_1$  of 98.70%,  $F_{score}$  of 98.70%,  $AUC_{score}$  of 98.70%, and MCC of 97.41%.

Fig. 3. Confusion matrix of the AESD-ICSASAE approach for the training (TR) and testing (TS) databases with a ratio of 60:40 and 70:30, respectively.

TABLE II. PRESENTS THE FINDINGS OF DETECTING SEIZURES USING THE AESD-ICSASAE APPROACH WITH A 60:40 RATIO OF TRAINING TO TESTING DATABASES

Training / Testing (60:40)						
Class	$\text{Accu}_{bal}$	$\text{Prec}_n$	$\text{Reca}_1$	$F_{score}$	Score of AUC	MCC
<b>Training Set</b>						
Seizure	98.10	99.30	98.10	98.70	98.70	97.41
NoSeizure	99.30	98.10	99.30	98.70	98.70	97.41
<b>Average:</b>	<b>98.70</b>	<b>98.70</b>	<b>98.70</b>	<b>98.70</b>	<b>98.70</b>	<b>97.41</b>
<b>Testing Set</b>

<b>Average:</b>	<b>98.66</b>	<b>98.67</b>	<b>98.66</b>	<b>98.66</b>	<b>98.66</b>	<b>97.33</b>

Fig. 4. Average outcome of AESD-ICSASAE approach under 60% of TR.

Table II presents the comprehensive outcomes of detecting seizures achieved by the AESD-ICSASAE approach, utilizing 60% of the Training set (TR) and 40% of the Testing set (TS) records. Fig. 5 presents the detailed classification outcomes of the AESD-ICSASAE method with 40% of TS database. The AESD-ICSASAE technique has properly identified the seizure and no seizure class samples. Moreover, it is visible that the AESD-ICSASAE methodology at testing phase has attained an average  $\text{accu}_{bal}$  of 98.66%,  $\text{prec}_n$  of 98.67%,  $\text{reca}_1$  of 98.66%,  $F_{score}$  of 98.66%,  $AUC_{score}$  of 98.66%, and MCC of 97.33%.

Fig. 5. Average outcome of AESD-ICSASAE approach under 40% of TS database.

Table III provides an overview of the AESD-ICSASAE method's detection findings for seizures using 70% of TR and 30% of TS datasets. The AESD-ICSASAE approach's quick classification results using 70% of the TR dataset are shown in Fig. 6. The AESD-ICSASAE technique has properly recognized the seizure and no seizure class samples. Also, it is noted that the AESD-ICSASAE method at training phase has acquired average  $accu_{bal}$  of 98.92%,  $prec_n$  of 98.93%,  $reca_l$  of 98.92%,  $F_{score}$  of 98.92%,  $AUC_{score}$  of 98.92%, and MCC of 97.85%.

TABLE III. SEIZURE DETECTION OUTCOMES OF AESD-ICSASAE APPROACH UNDER 70:30 OF TR/TS DATASET

NoSeizure	98.48	99.22	98.48	98.85	98.85	97.69
<b>Average</b>	<b>98.85</b>	<b>98.84</b>	<b>98.85</b>	<b>98.84</b>	<b>98.85</b>	<b>97.69</b>

Fig. 7 portrays brief classification outcomes of the AESD-ICSASAE methodology with 30% of TS database. The AESD-ICSASAE technique has properly identified the seizure and no seizure class samples. Additionally, it is noted that the AESD-ICSASAE technique at testing phase has achieved average  $accu_{bal}$  of 98.85%,  $prec_n$  of 98.84%,  $reca_l$  of 98.85%,  $F_{score}$  of 98.84%,  $AUC_{score}$  of 98.85%, and MCC of 97.69%.

Fig. 6. Average outcome of AESD-ICSASAE technique under 70% of TR database.

Examining the AESD-ICSASAE approach's Training Accuracy (TACC) and Validation Accuracy (VACC) for seizure detection efficiency is shown in Fig. 8. The graph shows that greater TACC and VACC values result in greater efficiency for the AESD-ICSASAE method. The AESD-ICSASAE model is clearly the most successful in terms of TACC results.

Fig. 7. Average outcome of AESD-ICSASAE approach in 30% of TS database.

Fig. 8. Depicts the TACC and VACC analyses of the AESD-ICSASAE approach.

In Fig. 9, the TLS and VLS of the AESD-ICSASAE model is put to the test in terms of their ability to identify the onset of a seizure. Based on the graph, it seems that the AESD-ICSASAE method performs better when TLS and VLS are kept to their absolute minimums. It has been shown that the AESD-ICSASAE method leads to diminished VLS results.

Fig. 9. TLS and VLS analysis of AESD-ICSASAE approach.

Fig. 10 presents the results of a clear precision-recall analysis of the AESD-ICSASAE database used to evaluate the tested methods. The results showed that the AESD-ICSASAE method improved precision-recall values across the board.

Fig. 11 displays the results of a comprehensive ROC analysis performed on the AESD-ICSASAE test database. That number meant the AESD-ICSASAE algorithm had successfully clustered together a number of different types.

Fig. 10. Precision-recall analysis of AESD-ICSASAE method.

Fig. 11. ROC curve analysis of AESD-ICSASAE method.

Finally, the AESD-ICSASAE strategy superior accuracy may be verified at the ending phase through a comparative analysis, as depicted in Table IV and Fig. 12. The depicted figure indicates that the AESD-ICSASAE approach has exhibited enhanced efficacy, achieving an accuracy of 98.92%.

TABLE IV. COMPARISON OF THE AESD-ICSASAE SYSTEMS TO ALTERNATIVE METHODOLOGIES

Methodology used	Accu <sub>y</sub> (%)
<b>AESD-ICSASAE</b>	<b>98.92%</b>
DCAE-MLP	98.17%
SVM Model	82.39%
LR Model	81.32%
ResNet-152	90.63%
Inception-V3 Model	91.89%
EESC Model	93.92%

Fig. 12. Comparative analysis of AESD-ICSASAE system with other approaches.

In contrast, the existing models such as DCAE-MLP, SVM, LR, ResNet-152, Inception-v3, and EESC models have demonstrated certainly reduced accuracy of 97.17%, 82.39%, 81.32%, 90.63%, 91.89%, and 93.92% respectively. These results assured the supremacy of the AESD-ICSASAE model on seizure detection and classification.

#### V. CHALLENGES AND LIMITATIONS OF PROPOSED WORK

There are currently a number of restrictions and difficulties in the area of automated epileptic seizure identification. Several challenges arise in the application of EEG data analysis, such as inter-individual variability, the trade-off between sensitivity and specificity, poor generalization of current methods across different datasets and patient groups, the requirement for immediate implementation with high accuracy, interpretation of deep learning models, and a lack of data for training and evaluation purposes. To surmount these obstacles, it is necessary to undertake investigation efforts that are geared towards developing the applicability of findings, minimizing erroneous positive and negative outcomes, refining instantaneous being processed, augmenting comprehensibility, and broadening the availability of varied and inclusive datasets.

#### VI. CONCLUSION

This paper presents the AESD-ICSASAE algorithm, a novel method for performing precise ESD on EEG data. The described AESD-ICSASAE method is a three-step procedure. The first step of the AESD-ICSASAE method is to normalize the input data using a min-max normalization strategy. After that, an ICSA-related feature selection procedure is used by the AESD-ICSASAE method to choose the best features. Finally, improved performance is achieved by the AOA's hyperparameter selection process and categorization of SAE-related data. Experiments were conducted to illustrate the improved classification results achieved using the AESD-ICSASAE method. The simulations covered every possible scenario, ensuring that the AESD-ICSASAE method would improve. To boost the efficiency of the AESD-ICSASAE method, a fusion system based on ensemble voting may be developed in the future.

Additionally, there exist numerous elements that could be examined in the work. Initially, an inquiry into the generalizability of the AESD-ICSASAE methodology across diverse datasets and patient cohorts would offer valuable perspectives on its potential utility above the particular dataset employed. Furthermore, conducting an analysis of comparison with established methodologies could simplify an analysis of the merits and limitations of the suggested approach. Improving the comprehensibility of the outcomes through the identification of the influential characteristics or trends could improve its medical significance. Enhancing the real-time validity of the approach could be achieved through enhancing its efficiency in computing, particularly in managing substantial amounts of EEG data. Performing verification tests on additional data sets would confirm the efficacy and dependability of the aforementioned. Ultimately, an evaluation of the viability of executing the proposed methodology in real-time will determine its practicability in facilitating prompt seizure forecasts and strategies. Incorporating considerations related to generalization, effectiveness, comprehension, productivity, verification, and real-time accessibility would enhance the effectiveness of the AESD-ICSASAE methodology.

# Evaluation of the Effects of 2D Animation on Business Law: Elements of a Valid Contract

Sarni Suhaila Rahim<sup>1\*</sup>, Hazira Saleh<sup>2</sup>, Nur Zulaiha Fadlan Faizal<sup>3</sup>, Shahril Parumo<sup>4</sup>

Fakulti Teknologi Maklumat Dan Komunikasi, Universiti Teknikal Malaysia Melaka (UTeM), 76100 Melaka, Malaysia<sup>1,3,4</sup>  
Politeknik Melaka, No. 2, Jalan PPM 10, Plaza Pandan Malim, 75250 Melaka, Malaysia<sup>2</sup>

**Abstract**—This article presents an evaluation of Business Law 2D Animation: Elements of a Valid Contract. The developed application was produced to assist business law students to understand the contents of the topic Elements of a Valid Contract. An experiment was carried out to assess the usability of the application as a learning and review material for business law students. This study comprised five major evaluation components, including learnability, usability, accessibility, functionality, and effectiveness, to investigate user involvement and satisfaction with the proposed educational learning system. To acquire user testing results, online questionnaires were issued. There was a total of 63 respondents, including multimedia experts, students, and subject matter experts. The findings of the current study revealed that the majority of respondents were pleased with the outcomes of the animation. The results may assist in improving the teaching of the topic Elements of a Valid Contract for business law students as it provides visually appealing method of learning.

**Keywords**—2D Animation; business law; elements of a valid contract; evaluation

## I. INTRODUCTION

‘Elements of a Valid Contract’ is a fundamental topic in corporate law that is essential for business law students to remember. The topic necessitates a correlation between a multitude of components and case studies, thereby making the process of understanding and retaining each element and its relevant cases difficult for students. As the topic progresses, lecturers also may encounter challenges in simplifying appropriate teaching materials.

The objective of this paper was to present a thorough evaluation of the usability of a visual animation project named ‘Business Law 2D Animation: Elements of a Valid Contract’. This animation provided simplified descriptions of the Elements of a Valid Contract to facilitate the retention of important case studies among business law students and to assist lecturers in delivering interactive and comprehensive lessons. To evaluate user involvement and satisfaction with animation as a learning platform, five evaluation components were employed. The research question of this proposed research work is how can the best intervention and teaching material for effective business law course delivery in educational setting be constructed.

It is envisaged the proposed work would assist in providing an effective teaching delivery to the students and lecturers in the form of 2D animated video. The contribution of this study is obvious as the resulting outcomes can be

capitalised as guidelines to increase an understanding and learning motivation to the business law students.

## II. LITERATURE REVIEW

Animation is a technique that involves the manipulation of figures to create the illusion of movement. Most contemporary animations are predominantly produced through computer-generated imagery, which has allowed multiple storytellers to deliver their narratives in a more creative and enjoyable manner and visual designers can expand their creativity far beyond what the world allows them to do through liveliness. In addition to presenting a novel means of expression and innovation, animation possesses a practical advantage in that the movement attracts more attention than static images [1]. Several studies in the literature have reported on the use of animation, particularly for teaching and learning purposes [2-5]. Though there are educational materials for law subjects [6-8], these products are delivered in non-interactive videos and instructional manuals, wherein multimedia elements have not been fully utilised.

The topic Elements of a Valid Contract consists of six elements, namely: (i) offer, (ii) acceptance, (iii) consideration, (iv) intention of making legal relation, (v) certainty of the contract, and (vi) capacity and legality [9]. Accordingly, the Two-dimensional (2D) Animation for Business Law: Elements of a Valid Contract [10] was developed. This application explains the elements of the topic in more accessible terms in order to help students remember relevant case studies and allow lecturers to teach students in an easier and more interactive way. Fig. 1, Fig. 2, and Fig. 3 present the screenshots of the developed Business Law 2D Animation: Elements of a Valid Contract. A comprehensive explanation of the design and development phases of the application and the comparison of the existing products with the proposed application are presented in [10]. The current study further elaborated on prior studies presented in [10] by focusing on the evaluation of the Business Law 2D Animation: Elements of a Valid Contract. This study elaborated on five evaluation components for system testing, namely: learnability, usability, accessibility, functionality, and effectiveness. Numerous researchers have explored and employed usability testing, as evidenced by the works of [11] to [19]. Usability is described as the capacity of a product or service to provide maximum satisfaction, efficiency, and effectiveness across various users [20].

### III. METHODOLOGY

The testing plan, comprising the test user, test schedule, test strategy, test implementation is elaborated in this section.

The current study was conducted on students enrolling in business law at Politeknik Melaka, Malaysia. The details of the respondents are presented in Table I. The respondents were given a link to begin the system testing by their lecturers, who were also the targeted end users of this animation. The lecturers observed the testing and assessed the content of the Business Law 2D Animation: Elements of a Valid Contract to ascertain the level of animation accuracy.

1) *Multimedia experts*: In the current study, multimedia experts evaluated the Business Law 2D Animation: Elements of a Valid Contract. Multimedia experts are those possessing expertise and competence in the field of multimedia and

information technology. In this study, multimedia experts consisted of the Chief of Technology Officer and the lecturers of multimedia courses. They conducted a system testing with an emphasis on the interface, interactivity, design, multimedia elements, and content layouts.

TABLE I. TESTING RESPONDENTS

	Multimedia Expert	Subject Matter Expert	Students
<b>General Information</b>	Lecturers in UTeM who has working experience from less than 3 years to more than 5 years	Lecturers in Politeknik Melaka who has working experience from less than 3 years to more than 5 years	Students in Politeknik Melaka age 18 to 20 years
<b>Description</b>	This testing is being done to test the technicalities of this animation in terms of multimedia principles	This testing is being done to verify the accuracies of the animation's content and provides coverage of the proposed topic.	This testing is being done to see the effectiveness of this animation.

2) *Subject matter experts*: Subject matter experts are individuals who have knowledge and expertise in a subject matter. In the current study, the subject matter experts had specialised knowledge of the Elements of a Valid Contract topic. They were lecturers of Business Law courses at Politeknik Melaka. They were given the link to the Business Law 2D Animation: Elements of a Valid Contract. They conducted a system testing to determine the content accuracy of animation and provide feedback and recommendations through a questionnaire.

3) *Business law students*: The current study focused on business law students at Politeknik Melaka. The test was administered to them through an online platform and overseen by their lecturers, who were the subject matter experts. After the system testing, student respondents were given a link to the questionnaire to facilitate the analysis.

#### A. Test Description

The test description clarifies the testing aim and projected test outcome. During the system testing, a questionnaire on user acceptance was administered to the respondents.

The respondents were required to watch the Business Law 2D Animation: Elements of a Valid Contract. They took the test using the animation link provided to them and filled out the form provided by the researchers.

#### B. Test Data

The test data of the user testing are explained in Table II, while Table III, Table IV, and Table V represent the data gathered from subject matter experts, multimedia experts, and students, respectively.

TABLE II. TEST DATA FOR USER TESTING

General Information	Number of Respondents
Lecturers in Politeknik Melaka who has working experience from less than 3 years to more than 5 years	3
Lecturers in UTeM and multimedia expert who has working experience from less than 3 years to more than 5 years	4
Students in Politeknik Melaka age 18 to 20 years	56

TABLE III. DETAILS OF SUBJECT MATTER EXPERT

No	Respondent	Position
1	Respondent 1	Principal Lecturer, Politeknik Melaka
2	Respondent 2	Law Lecturer, Politeknik Melaka
3	Respondent 3	Lecturer, Politeknik Melaka

TABLE IV. DETAILS OF MULTIMEDIA EXPERT

No	Respondent	Position
1	Respondent 1	Lecturer, FTMK UTeM
2	Respondent 2	Lecturer, FTMK UTeM
3	Respondent 3	Lecturer, FTMK UTeM
4	Respondent 4	Chief Technology Officer, SiagaX Industries (M)

TABLE V. DETAILS OF STUDENTS

Institution	Total	Age	Gender
Politeknik Melaka	56	18 – 20 years old	Male Female

#### IV. DATA ANALYSIS AND RESULTS

The current study includes diagrams and charts based on the findings of the overview and testing measures to summarise the outcomes of the system testing.

1) *Multimedia experts*: The current study involved four multimedia experts: three were lecturers in Fakulti Teknologi Maklumat dan Komunikasi (FTMK) at UTeM and one from SiagaX Industries (M). The questionnaire was administered on Google Forms and was given to multimedia experts together with as well as the Business Law 2D Animation: Elements of a Valid Contract. After they experienced the animation, they evaluated the animation in terms of functionality, learnability, and the user-interface of the animation. The data collected were then analysed and compiled into graphs.

a) *Chart of Functionality for Multimedia Experts*: Fig. 4 presents the data gathered from the functionality section. The functionality section evaluated the effectiveness of content delivery through multimedia functions. According to the test results, all experts agreed on the effectiveness of animation in terms of its functionality as it followed the principles of

multimedia. Fig. 5 shows the overall mean value for the functionality section and the number of experts who participated in this section. The data indicated that all experts agreed on the animation’s functionality and its practicality for student use.

This animation follows the principles of multimedia.  
4 responses

The graphic materials used in this animation is obtainable.  
4 responses

The transitions used in this this animation is smooth and clear.  
4 responses

The audio and narrations in this animation is clear and appropriate.  
4 responses

The content arrangements make the delivery of information more effective.  
4 responses

Fig. 4. Results of functionality by multimedia experts.

Fig. 5. Overall mean for functionality by multimedia experts.

b) *Chart of Learnability for Multimedia Experts:* As illustrated in Fig. 6, all experts agreed that the content of the animation was easy to follow despite the lack of student knowledge on the topic. More than half of the experts agreed that the audio component of the content was clear and comprehensible. However, one expert disagreed due to the presence of a narrator and accompanying background music, which intercepted the delivery of the content.

Nonetheless, all the experts agreed that the utilisation of animation positively impacted business law students and that the content was presented in a straightforward approach, thereby improving student learnability. Also, half of the experts expressed a favourable impression towards the animation's learnability. They agreed that this animation had the potential to enhance the learning efficacy of business law students.

Fig. 7 provides the overall results of the learnability section and the number of experts who participated in this test. The figure proves that the mean percentage of experts agreed that this animation helped with students' learnability as they believed that the animation could be utilised with ease by business law students.

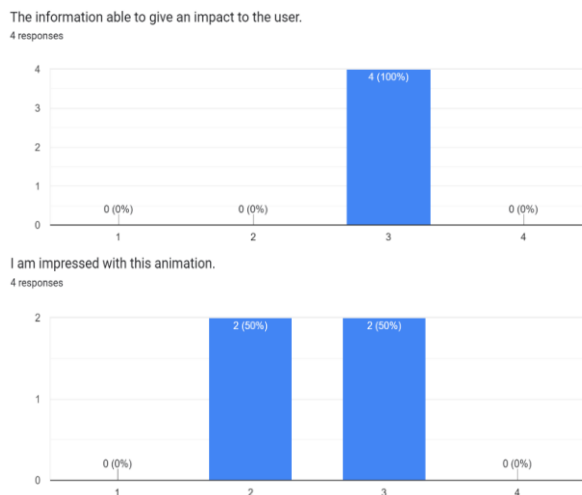

Fig. 6. Results of learnability by multimedia experts.

c) *Chart of User-Interface for Multimedia Expert:* As depicted in Fig. 8, the results of Question 1 revealed all experts agreed that the graphics and textual components used in this animation were appropriate and attractive for business law students. It was determined by over 70 per cent of experts that the colours utilised in this animation were aesthetically attractive and appropriate. The colours employed in this animation made the user interface livelier and more attractive, thereby increasing the learnability of business law students.

It is evident in Fig. 8 that all experts agreed that the multimedia forms of the animation had successfully aided learning. The use of multimedia was important to elevate the functionality of the user interface. Even though the data revealed that 50 per cent of the experts agreed that the texts were clear and comprehensible, the remaining 50 per cent perceived the animation as having poor readability. Considering that the textual components used in this animation complemented the audio narration of the content, poor text readability may result in an unclear and unintelligible user interface.

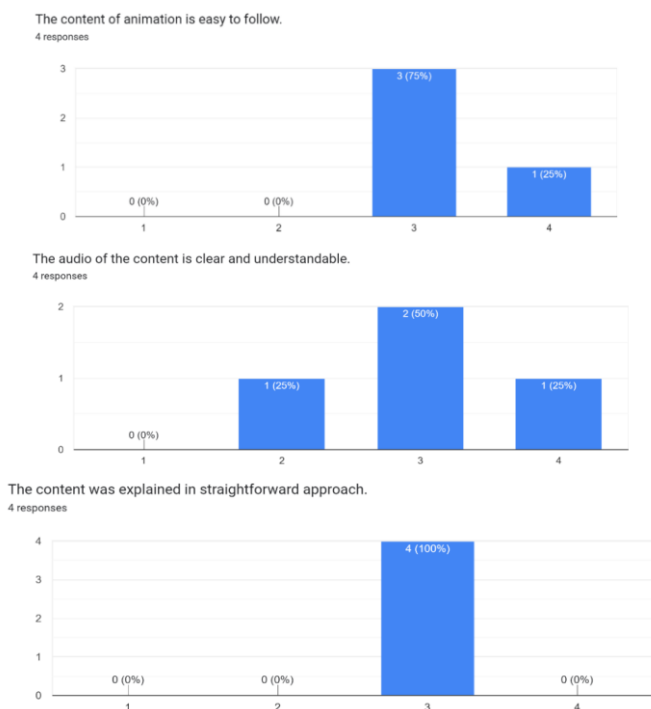

Fig. 7. Overall Mean for learnability by multimedia experts.

Nevertheless, all experts agreed that the Business Law 2D Animation: Elements of a Valid Contract was user-friendly as its user interface was appropriate and attractive. This helped business law students to better understand the Elements of a Valid Contract.

The data presented in Fig. 9 indicate significant variability in the overall mean of the user interface section. Specifically, Question 2 and Question 4 exhibited the lowest average scores among the five questions analysed. However, it was evident that a majority of the experts agreed that the user interface employed in this animation was attractive with the aid of multiple multimedia components. The interactive design and user-friendly interface of this animation facilitated the learning process of business law students.

The graphics and text used are appropriate and attractive.  
4 responses

The colors used in this animation are attractive and appropriate.  
4 responses

This animation is successfully aided with multiple multimedia forms (i.e., audio, text, images, and video).  
4 responses

Readability of text in this animation is clear and easy to understand.  
4 responses

This animation is user-friendly.  
4 responses

Fig. 8. Results of user interface by multimedia experts.

The summary responses of Multimedia Expert are presented in Table VI.

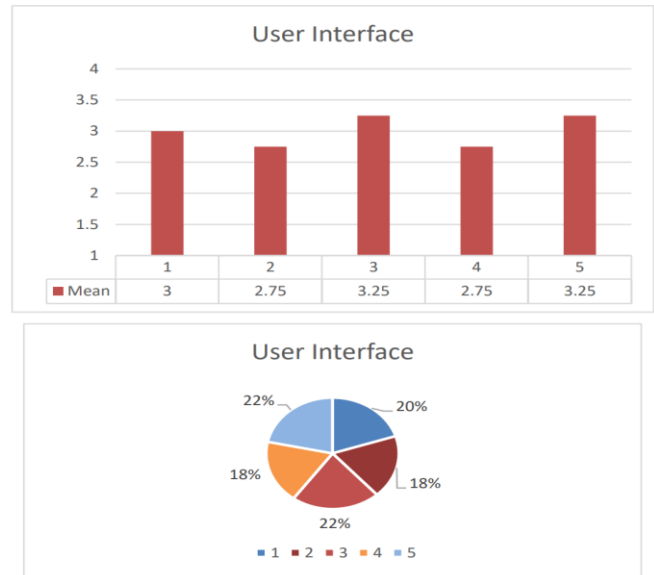

Fig. 9. Overall mean for user interface by multimedia experts.

TABLE VI. RESULT SUMMARY FOR MULTIMEDIA EXPERT

Question Type	Strongly Disagree	Disagree	Agree	Strongly Agree	Total
Functionality			80%	20%	100%
Learnability		15%	75%	10%	100%
User-Interface		15%	70%	15%	100%
<b>Total</b>		<b>10%</b>	<b>75%</b>	<b>15%</b>	<b>100%</b>

*d) Suggestion for Improvement from Multimedia Expert:*

Based on the responses from the questionnaire obtained from multimedia experts, four (4) suggestions for improvement were proposed.

- i. The character design should vary according to the different character names.
- ii. The video explanation was good and comprehensible, the graphics use was extensive, and the placements of each animation component were satisfactory. However, the multimedia components were too crowded and the colour theme used in the animation was not good enough. The selection of typeface was also unpopular.
- iii. Voice-over can be improved to engage and interact with users.
- iv. The instructional video should be accompanied by an audio or a textual introduction to explain the purpose of the video before explaining the cases.

2) *Subject matter expert:* Three respondents consisting of subject matter experts who were lecturers at Politeknik Melaka, Malaysia were involved in this testing through

interviews. The animated video and a questionnaire were given to them. After they experienced the animation, they were asked to evaluate the animated video in terms of its content, effectiveness, and flexibility. The data collected were then analysed and compiled into graphs.

a) *Chart of Content for Subject Matter Expert:* The subject matter experts evaluated the accuracy of the animation content of the 2D Animation for Business Law: Elements of a Valid Contract and whether it was in accordance with the syllabus of Elements of a Valid Contract. Based on the test results, all the experts strongly agreed on the accuracy of the content in this animation aligned with the syllabus in Elements of a Valid Contract. Also, they agreed with the narrator's explanation in this animation and that the explanation was straightforward and easy to understand. The cases used as examples for each element in the topic were also relevant and appropriate. Overall, subject matter experts agreed that the content used in this animation was accurate and precise. They believed that this animation facilitated the understanding of the content of the Elements of a Valid Contract among business law students.

b) *Chart of Effectiveness for Subject Matter Expert:* The subject matter experts evaluated the effectiveness of the animation in helping the learning of business law students and its use as teaching material. Based on the test results, all experts found this animation effective in conveying the content and serving as teaching material. For example, all subject matter experts agreed that the content layout of the animation improved the delivery, thereby being useful as teaching material.

Subject matter experts also believed that the use of this animation could help business law students improve their learning efficiency on the topic. The respondents also agreed that the use of this animation could improve student learning and may serve as revision material due to the accuracy of the content.

In short, the 2D Animation for Business Law: Elements of a Valid Contract was effective for students as well as lecturers. This was evidenced by experts agreeing that this animation may serve as revision material to facilitate the learning process of business law students, as revision material and facilitate the teaching process of lecturers, as teaching material.

c) *Chart of Flexibility for Subject Matter Expert:* In the last section, the subject matter experts evaluated the flexibility of the 2D Animation for Business Law: Elements of a Valid Contract as a new learning method. Table VII summarises the findings of the study on subject matter experts.

The experts strongly agreed that the materials used in the animation were appropriate for the topic of Elements of a Valid Contract, specifically because the materials could aid the understanding of the topic among business law students. The experts believed the animation was presented in a comprehensive and effective manner, featuring good visualisation and narration. In addition, the content arrangement of relevant cases in Elements of a Valid Contract

exhibited a satisfactory flow. The results also show that all the experts agreed on the use of this animation as their teaching material for the convenience of students in the future. This is due to the flexibility of the system being appropriate and suitable for their students.

In conclusion, all experts agree on the flexibility of the 2D Animation for Business Law: Elements of a Valid Contract, to be implemented effectively as teaching material to aid the process of delivering the content of Elements of a Valid Contract to business law students.

TABLE VII. RESULT SUMMARY FOR SUBJECT MATTER EXPERT

Question Type	Strongly Disagree	Disagree	Agree	Strongly Agree	Total
Content				100%	100%
Effectiveness			19.98%	80.02%	100%
Flexibility			13.32%	86.68%	100%
<b>Total</b>			<b>11.1%</b>	<b>88.9%</b>	<b>100%</b>

d) *Suggestion for Improvement from Subject Matter: Expert* Based on the responses from the questionnaire obtained from subject matter experts, three (3) suggestions for improvement were proposed.

- i. Each element is accompanied by separate animation, therefore enabling profound content explanation.
- ii. Add more content to the animation.
- iii. A very good effort and approach of using an interactive method to attract students to memorise cases. The video is very clear and helpful for students.

3) *Students:* The present study involved a sample of 56 respondents from Politeknik Melaka, Malaysia. The data collection method employed in this research was a questionnaire. An online questionnaire, through the Google Forms platform, was administered to the respondents along with the 2D Animation for Business Law: Elements of a Valid Contract. Upon completion of the animation testing phase, respondents evaluated the animation with regard to their preferred method, as determined by the questions posed in each of the three sections: efficiency, effectiveness, and user interface. The data collected were then analysed and compiled into graphical representations.

a) *Chart of Efficiency for Students:* This section presents the findings of the evaluation of the efficacy of the animation in terms of attractiveness, simplicity, and comprehension of the narrator's explanation. Student respondents were required to choose between two methods in this section.

According to the data presented in Fig. 10, 46 respondents (82.1 %) expressed a preference for the animation as it was a more appealing mode of learning compared to slide presentations and textbooks. This indicates that students were more interested in learning through interactive pedagogical

approaches as opposed to textbooks. A total of 75 per cent of the student respondents decided that the animation provided a simpler explanation, whereas the remaining 25 per cent disagreed. The present evidence indicates that the narrator provided a comprehensive explanation that facilitated student understanding of the Elements of a Valid Contract and the corresponding pertinent cases. A total of 43 students agreed that the content of the animation was easier to comprehend than slide presentations and textbooks. This accounted for up to 76.8 per cent of the chart. This indicated that students agreed that the animation, though more compact, provided a straightforward comprehension.

In response to the question of whether animation, slide presentation, or textbooks helped students revise the topic of Elements of a Valid Contract more effectively, 71.4 per cent of the respondents agreed animation was the most effective method. They agreed that animation was more entertaining, thereby more effective at capturing their attention while studying. Lastly, based on Fig. 11, the majority of the respondents agreed that animation helped them learn the Elements of a Valid Contract and its relevant cases more efficiently because of the proficiency of the animation in terms of content delivery and attractive graphics.

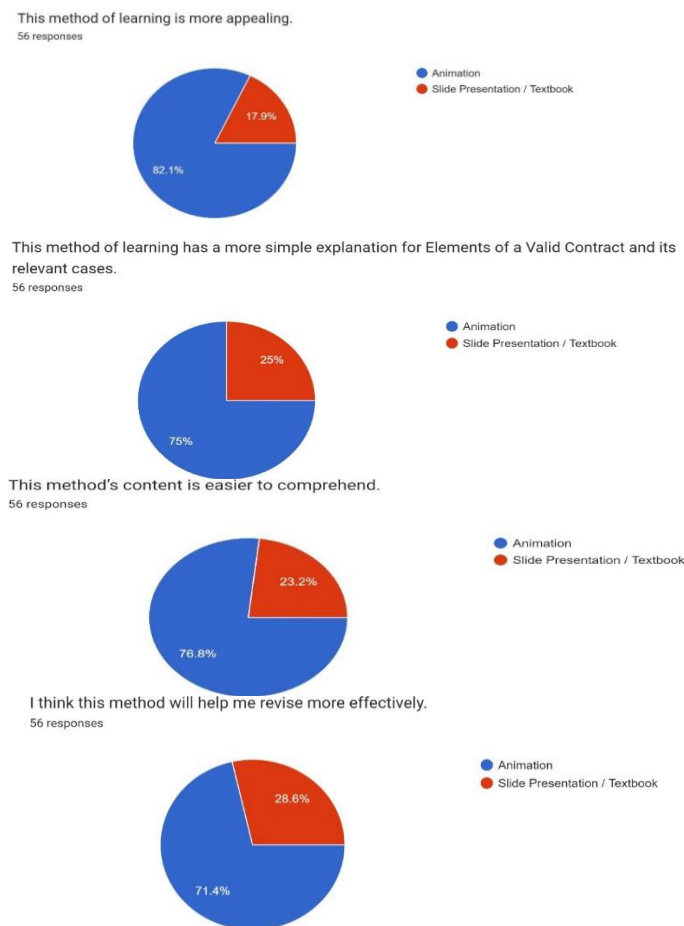

Fig. 10. Results of efficiency by students.

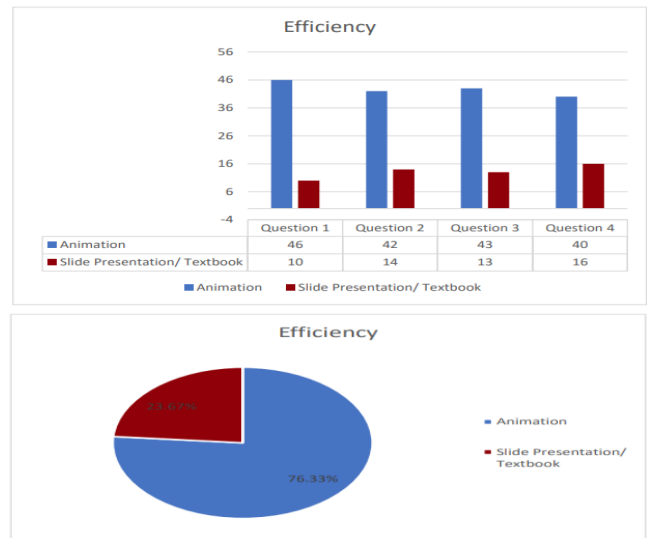

Fig. 11. Overall results of efficiency by students.

b) *Chart of Effectiveness for Students:* The respondents also evaluated the effectiveness of 2D Animation for Business Law: Elements of a Valid Contract for their learning process of Elements of a Valid Contract. They were required to choose one of two methods: (i) animation or (ii) slide presentation/textbook, in terms of approach, retrieval of information, and learning impact.

Based on Fig. 12, 73.2 per cent of the student respondents agreed that animation employed a straightforward approach to aid their understanding of the topic Elements of a Valid Contract, whereas the other 26.8 per cent agreed that same was provided by slide presentations or a textbook. Fig. 12 also demonstrated that animation assisted 71.4 per cent of student respondents in memorising the relevant cases of Elements of a Valid Contract, followed by slide presentations and textbooks with 28.8 per cent of students. It is concluded that the simple explanations provided by the narrator and the colourful graphics aid in faster memorisation.

The integrated multimedia used in animation helped 80.4 per cent of the respondents to retrieve information on the topic of Elements of a Valid Contract more effectively compared to slide presentations and textbooks. The integrated multimedia elements were believed to help users extract information more easily. Based on Fig. 12, 37 (66.1 %) respondents preferred animation as the method was more impactful because the animation facilitated their comprehension of abstract concepts and processes by making them more relatable and understandable. Nevertheless, 19 students (33.9 %) preferred slide presentations or textbooks.

Based on Fig. 13, 70 per cent of the respondents agreed that the animation made learning Elements of a Valid Contract with its relevant cases more interesting. The animation was able to help them memorise cases and assisted them in retrieving information more effectively due to its straightforward explanations.

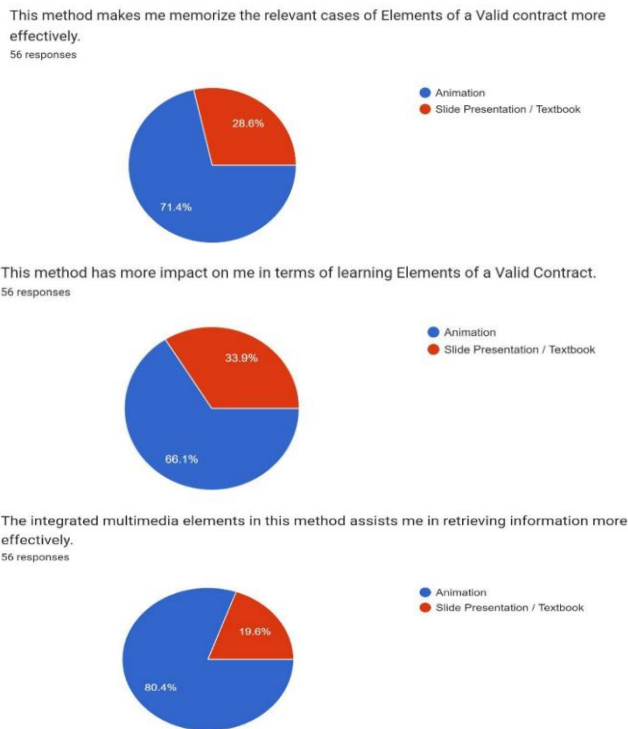

Fig. 12. Results of effectiveness by students.

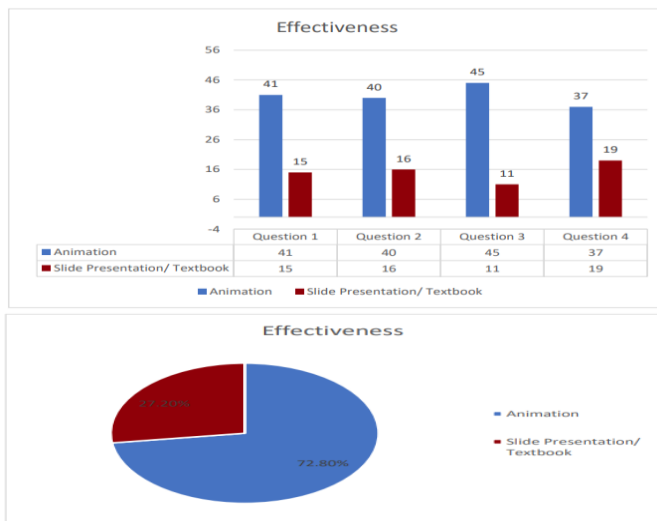

Fig. 13. Overall results of effectiveness by students.

c) *Chart of User-Interface for Students:* In the last section, student respondents evaluated the user interface of the 2D Animation for Business Law: Elements of a Valid Contract. The questions in this section required the participants to choose the interface of a learning method which was more attractive, user friendly, and piqued their interest in learning the topic Elements of a Valid Contract.

Based on Fig. 14, 73.2 per cent of the respondents chose animation as a more visually appealing and comprehensible method of learning. This was attributed to the effective use of graphics, colours, and typeface. The features also resulted in the animation to be an effective tool for capturing attention. In

addition, 82.1 per cent of student respondents agreed that the arrangement flow of relevant cases of the topic Elements of a Valid Contract in the animation provided them with a more effective way of visualising and memorising compared to reading them on slide presentations and textbooks. While the 78 cases were presented in long sentences in the conventional methods of reading, the use of graphics and concise sentences with straightforward explanations in the animation improved their visualisation, thereby enhancing the effectiveness of memorisation.

Moreover, 83.9 per cent of the student respondents agreed that animation's overall interface was more attractive in catching their attention and fostering their interest in learning the Elements of a Valid Contract. Thus, using the 2D Animation for Business Law: Elements of a Valid Contract, had the potential to aid the revision process and serve as an effective learning material. Also, 89.3 per cent of the student respondents agreed that the layout and overall graphics of the animation piqued their interest in the Elements of a Valid Contract. This is because the simple and short explanation helped them better understand the topic.

Fig. 15 shows that 80 per cent of student respondents agreed that the user interface of the 2D Animation for Business Law: Elements of a Valid Contract helped them in their learning, memorising, and revising the topic Elements of a Valid Contract better than the user interface of slide presentations and textbooks which were characterised with long sentences and lack of graphics.

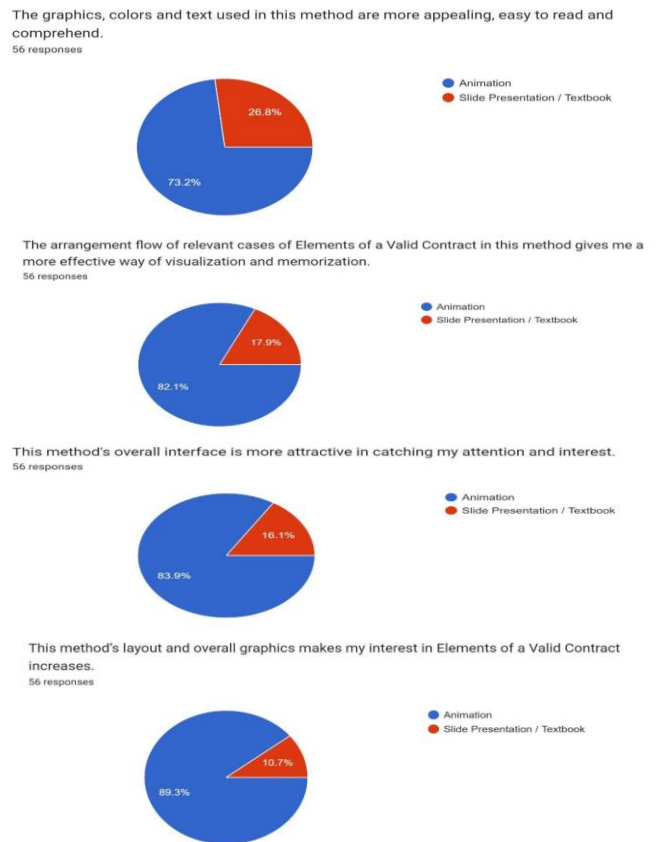

Fig. 14. Results of user interface by students.

Table VIII summarizes the testing summary for students.

TABLE VIII. RESULT SUMMARY FOR STUDENTS

Question Type	Animation	Slide presentation/ Textbook	Total
Efficiency	76.33%	23.67%	100%
Effectiveness	2.8%	27.2%	100%
User-Interface	2.13%	17.87%	100%
<b>Total</b>	<b>77.1%</b>	<b>22.9%</b>	<b>100%</b>

Fig. 15. Overall results of user interface by students.

d) *Summary for Improvement from Students:* Based on the responses from the questionnaire obtained from student respondents, two (2) suggestions for improvement were proposed.

- i. The audio was unclear in some parts of the animation.
- ii. This animation was lacking in content. It was compiled with one relevant case for each element of the topic Elements of a Valid Contract. Students preferred more pertinent examples because the animation was too brief. There should be multiple videos for each element rather than a single video compilation.

## V. DISCUSSION

One of the more significant findings to emerge from this study is the proposed application received positive feedbacks from the target users. From the testing performed, it is found that the sound quality of the 2D Animation for Business Law:

Elements of a Valid Contract should be improved as it was unclear. Also, the pace of the narration should be slowed down to improve the explanation. There should also be an interaction with users to engage them. In addition, an audio introduction should be included to explain the purpose of a video before diving into case explanations. As there are a lot of relevant cases in each element of the topic, it is expected that the videos be separated into different explainer videos. This allows for more relevant cases and explanations to be inserted for deeper explanations. Despite the extensive use of graphics in this animation, different character designs could be used for the various character names that are featured in each case to avoid the mix-up of characters.

The primary objective of this research was to improve the comprehension of business law students on the topic of Elements of a Valid Contract. The inability of many students to memorise the lengthy cases in each element of a valid contract prevented them from scoring well on their examinations. The findings of the testing indicate that the outcomes of the 2D animation may facilitate and overcome the limitation from the current work proposed by other researchers in [6-9]. The 2D Animation for Business Law: Elements of a Valid Contract was designed to enhance students' comprehension of the topic and facilitate their ability to recall pertinent cases through the use of graphics. This research also aimed to assist lecturers teaching business law by enhancing their understanding of the subject and making it easier for them to engage students during class.

## VI. CONCLUSION

The objective of this study was to evaluate the usability of animation: 2D animation for Business Law: Elements of a Valid Contract. The primary objective of the current study was to assist students in gaining a deeper understanding of the Elements of a Valid Contract topic and in memorisation of the relevant cases for each element. The animation proved to be a success as the findings indicate that the animation is engaging and trustworthy. Among the significant findings of this study is that the animation received positive feedback from the intended audiences. Such improvements are intended to facilitate the use of the 2D animation for Business Law: Elements of a Valid Contract as a resource for student review and as teaching material for lecturers. The research question of this proposed research work has been answered as the intervention of an effective teaching material for business law course delivery in educational setting has been successfully constructed. In a nutshell, the current study has demonstrated that animation facilitates students' understanding of the Elements of a Valid Contract by aiding their retention of pertinent cases, thereby reaching its objective.

## ACKNOWLEDGMENT

This research is funded by Universiti Teknikal Malaysia Melaka (UTeM) through Teaching and Learning in TVET Short-Term Research Grant (PJP/2022/FTMK/TVET/S01952). We are thankful to UTeM, Politeknik Melaka and all respondents who took part in the final survey and testing phase, and we would like to express our thoughtful appreciation to them.

**Abstract**—Machine Learning (ML) algorithms are widely used in solving classification problems. The biggest challenge of classification lies in the robustness of the ML algorithm in various dataset characteristics. Quadratic Interpolation Flower Pollination Neural Network (QIFPNN) is categorised into ML algorithm. The new QIFPNN's extraordinary capabilities are measured on binary-type datasets. This research ensures that the remarkable ability of QIFPNN also applies to non-binary datasets with balanced and unbalanced data class characteristics. Flower Pollination Neural Network (FPNN), Particle Swarm Optimisation Neural Network (PSO), and Bat Neural Network (BANN) were used as comparisons. The QIFPNN, FPNN, PSO, and BANN were used to train Multi-Layer-Perceptron (MLP). The test results on five datasets show that QIFPNN obtains an average classification accuracy higher than its comparison in three datasets with balanced and unbalanced data class characteristics. The three datasets are Iris, Wine, and Glass. The highest classification accuracy obtained by QIFPNN in the three datasets is 97.1462%, 98.6551%, and 73.1979%, respectively. Based on the F1-score test from QIFPNN, it is higher than all the comparisons in four datasets: Iris, Wine, Vertebral column, and Glass. Sequentially, 96.4599%, 98.7155%, 90.7517%, and 60.2843%. It proves that QIFPNN can also classify datasets with non-binary data types with balanced and unbalanced data class characteristics because they are more consistently tested on various datasets and are not susceptible to the influence of variations in dataset characteristics so that they can be applied to various types of data or cases.

**Keywords**—Quadratic interpolation; flower pollination algorithm; neural network; non-binary dataset; multi-layer-perceptron

## I. INTRODUCTION

The field of Machine Learning (ML) is a subsection of Artificial Intelligence (AI) [1] that allows computers to recognise patterns in data and make predictions based on that information [2,3]. Practical ML algorithms can provide precise results, even when dealing with datasets that present various real-world problems. The UCI Machine Learning Repository [4] is a database offering a range of datasets the AI community uses to evaluate ML algorithms.

ML algorithms are classifiers, meaning they can predict an unknown sample's class based on previous training data. A challenge in classifying data is the variation in dataset

characteristics, such as sample size, number of attributes, class count, sample distribution in each class, missing data, and data type. Traditional classification algorithms can sometimes be unreliable, mainly when dealing with datasets with an uneven distribution of class samples or an unbalanced class distribution [5].

Optimisation algorithms are frequently utilised to tackle optimisation problems and have had positive outcomes in optimising Machine Learning (ML) algorithms, such as Neural Networks (NN) [6]. The NN, also known as Multi-Layer Perceptron (MLP), is considered one of the most effective ways to solve classification problems in real-world scenarios [7,8]. The training process of NN involves feedforward and backward procedures. The backward procedure, in which weight adjustment occurs through the conventional gradient method, can be weak and often gets stuck at local optima [9,10]. The metaheuristic algorithm can take the place of this backward procedure. The success of these algorithms lies in their capability to explore the search space through both exploration and exploitation. Exploration involves finding various solutions in the search space, while exploitation involves finding the best solution to improve existing ones. A proper balance between exploration and exploitation can quickly lead to identifying the search space with the optimal solution [11], avoiding any wasted time in areas with insufficient solutions [12,13].

The Flower Pollination Algorithm (FPA) is a metaheuristic approach that balances exploration and exploitation by regulating global and local pollination in each iteration of the population. FPA has been extensively used in classification tasks using public datasets. For instance, in a study by Senthilnath et al. [14], FPA was used to adjust the class centre weights in Euclidean distance training and was compared to other algorithms such as Harmony Search, Bat Algorithm, Differential Evolution, Spider Monkey Optimization, Grey Wolf Optimization, Cuckoo Search, Particle Swarm Optimization, Genetic Algorithm, and K-means. The results showed that FPA performed better, with the lowest Classification Error Percentage, on all tested datasets. Additionally, FPA was applied to update the Probabilistic Neural Network (PNN) weights in classification problems and produced better results than PNN on all 11 datasets [7]. Yazid

et al. [15] used FPNN, which combines FPA and PNN, to classify heart diseases and found it to have higher accuracy than a standard backpropagation neural network based on results from four UCI datasets.

In recent research, Polly et al. [16] looked into classifying real-world swine disease cases. The dataset comprised 158 samples, 68 attributes, a binary data type, and an unbalanced data distribution in 11 classes. The Quadratic Interpolation Flower Pollination Neural Network (QIFPNN) increased accuracy by 22.40% and training speed by 7.61% compared to the Flower Pollination Neural Network (FPNN). QIFPNN is a modification of FPA where the Levy vector is replaced with a random vector based on the step length of quadratic interpolation (QI). The effectiveness of QIFPNN in increasing accuracy and speeding up training time on datasets with binary data types needs to be extended to datasets with non-binary data types. So it needs to be tested on various dataset characteristics with various data types, then compare the results with FPNN, PSONN, and BANN, which are other metaheuristic algorithms. The goal is to prove that QIFPNN can also classify datasets with non-binary data types. As a result, QIFPNN provides better classification accuracy and F1-score on datasets with non-binary data types than its comparators. It proves that QIFPNN is not susceptible to variations in dataset characteristics so that it can be applied to various data types or cases.

This research is structured as follows: in the theory section, we present the Quadratic Interpolation Flower Pollination Neural Network (QIFPNN). In the experimental setup section, we describe the dataset and parameter settings. In the results and discussion section, we present the accuracy measurement and F1-score of the QIFPNN and its comparators, followed by the conclusion section.

## II. THEORY

### A. Quadratic Interpolation Flower Pollination (QIFP)

Polly et al. [16] introduced QIFP, an improvement from FPA [17]. The improvement lies in the step vector of global pollination and the search space technique. In the first improvement, the step vector  $\gamma L$  is replaced with a quadratic interpolation step vector  $Q$ , so (1) can be written as (2).

$$x_i^{t+1} = x_i^t + \gamma L(g^* - x_i^t) \quad (1)$$

$$x_i^{t+1} = x_i^t + Q(g^* - x_i^t) \quad (2)$$

where  $x_i^t$  represents the  $i$ -th pollen in iteration  $t$ ,  $g^*$  is the best pollen,  $\gamma$  is the scaling factor, and  $L$  is the random step vector with Levy distribution. The pollen represents the solution vector.

The derivative of the polynomial quadratic function is used to get  $r^*$  which gives the minimum or maximum fitness. The illustration can be seen in Fig. 1. Next; the step vector  $Q$  is formed by:

- 1) Generate a vector  $Q$  with the normal distribution  $Q \sim N(\mu, \sigma)$ , where the mean  $\mu = r^*$ , deviation standard  $\sigma = f_i$ , and the  $f_i$  are fitness value of objective functions of  $g^*$ .
- 2) Replace the element value of the vector  $Q$  by 20% from  $d$  by using (3).

$$Q_c = \begin{cases} 0, & c=l \\ Q_c, & \text{otherwise} \end{cases} \quad (3)$$

where  $l \in \text{randi}[1, d]$ ;  $\text{randi}$  is *rand integer*,  $c=1, 2, \dots, d$  and  $d$  is the dimension of the solution vector.

Fig. 1. Illustration of a polynomial quadratic function.

The second improvement, the FPA search space is directly carried out in the natural search space  $[LbReal, UbReal]$ . The QIFP search space starts from a small search space, which is then expanded gradually. Expansion is done by:

- 1) Identify search space first:

$$[Lb, Ub]^d = [-1, 1]^d \quad (4)$$

- 2) Expanding the next search space:

$$[Lb, Ub]^d = \begin{cases} [Lb-1, Ub+1]^d & t \text{ MOD } 50 = 0 \\ [Lb, Ub]^d & \text{otherwise} \end{cases} \quad (5)$$

- 3) Repeat step 2) until  $Lb = LbReal$  and  $Ub = UbReal$ .

where the value of  $LbReal$  and  $UbReal$  has an integer type, and zero is the result of the sum of  $LbReal$  and  $UbReal$ .

### B. Quadratic Interpolation Flower Pollination Neural Network (QIFPNN)

The evaluation of weights for classification problems in MLP is to minimise the mean square error (MSE) value. In QIFPNN, QIFP is used as a weight adjustment [16]. The flowchart of QIFPNN can be seen in Fig. 2, which represents the QIFPNN algorithm. The novelty can be seen in the two rectangles marked with bold lines. The first rectangle refers to (2), while the second rectangle refers to (4) and (5).

Fig. 2. QIFPNN flowchart.

### III. EXPERIMENTAL SETUP

#### A. Dataset Description

This section briefly overviews the five UCI datasets used in the study. The datasets were divided into three parts: training, validation, and testing, with 90% of the data used for training and validation (using 10-fold cross-validation) and 10% for testing

The classification process took place in two stages:

1) *The training stage aimed to find the optimal weights and determine the length of the training process. This stage used both training and validation subsets to prevent overfitting.*

2) *In the testing stage, the weights found in the training stage were applied to the test subsets to measure classification accuracy.*

Table I displays the sample size, number of input attributes and classes, missing sample size, and data type of each dataset. Table I can be categorised into datasets with balanced data classes (Iris) and unbalanced data classes (Wine, Lung cancer, Vertebral column, Glass). The Lung cancer dataset has many input attributes but a small sample size (known as a singularity problem) [18]. The Vertebral column dataset has two classes with approximately equal amounts of data in each class. The Glass dataset has six classes with varying amounts of data in each class.

#### B. Parameter Settings

The parameters used to configure each algorithm consist of four parts, namely:

- Parameters that apply to all algorithms, including (1) the number of neurons in the hidden layer ( $hn$ ), (2) the population ( $population$ ), (3) the lower and upper bounds of the actual search space [ $LbReal, UbReal$ ], (4) the maximum iteration ( $maxIteration$ ), (5) the target

error ( $targetError$ ), (6) the limit of iterations for convergence conditions for classification accuracy ( $iterThOfCA$ );

- Parameters specific to QIFPNN and FPNN, namely the switch probability ( $p$ );
- Parameters specific to PSONN, namely the learning parameters ( $\alpha$  and  $\beta$ );
- Parameters were specific to BANN: the loudness ( $loudness$ ) and the pulse rate ( $pulseRate$ ).

The QIFPNN, FPNN, PSONN, and BANN use MLP architecture with one hidden layer by determining the number of neurons in that layer according to (6) [16]. One hidden layer can approximate any function with arbitrary accuracy [19].

$$hn = \sqrt{(si+so)+ii} \quad (6)$$

Where, respectively,  $hn$ ,  $si$ , and  $so$ , are the number of neurons in the hidden, input, and output layers, while  $ii$  is an integer set to be 1. The determination of  $ii = 1$  aims to simplify the size of the MLP architecture in order to expedite the learning process.

It is essential to control parameters in each iteration of a metaheuristic algorithm to obtain an optimal solution. However, there is no known effective strategy to produce a variety of parameters [20]. All parameters are set based on Polly et al. [16], namely population  $n=30$  [16,21], [ $LbReal, UbReal$ ] $=[-80,80]$ , maximum iteration  $maxIteration=4000$ , target error  $targetError=0.001$ , and limit of iterations for convergence conditions for classification accuracy  $iterThOfCA=700$ . Three variables control the stopping criteria:  $maxIteration$ ,  $targetError$ , and  $iterThOfCA$ . Another parameter set for QIFPNN and FPNN is switch probability  $p=0.8$  [16,17,22–24]. Specifically for PSONN, the learning parameters are  $\alpha \approx \beta \approx 2$ , while for BANN, the parameter  $loudness=0.25$  and the parameter  $pulseRate=0.5$  [25].

TABLE I. CHARACTERISTICS OF THE DATASETS

Dataset	Sample Size	Number of Input Attributes	Sample Size in Each Class	Missing Sample Size	Data Type
Iris	150	4	<ul style="list-style-type: none"> <li>Class 1 Iris Setosa = 50 data (33.3%)</li> <li>Class 2 Iris Versicolour = 50 data (33.3%)</li> <li>Class 3 Iris Virginica = 50 data (33.3%)</li> </ul>	-	Real
Wine	178	13	<ul style="list-style-type: none"> <li>Class 1 = 59 data (33.2%)</li> <li>Class 2 = 71 data (39.9%)</li> <li>Class 3 = 48 data (26.97%)</li> </ul>	-	Integer, real
Lung Cancer	27	56	<ul style="list-style-type: none"> <li>Class 1 = 8 data (29.6%)</li> <li>Class 2 = 10 data (37.04%)</li> <li>Class 3 = 9 data (33.3%)</li> </ul>	5	Integer
Vertebral Column	310	6	<ul style="list-style-type: none"> <li>Class 1 Abnormal = 210 data (67.7%)</li> <li>Class 2 Normal = 100 data (32.3%)</li> </ul>	-	Real
Glass	214	9	<ul style="list-style-type: none"> <li>Class 1 Building windows float processed = 70 data (32.7%)</li> <li>Class 2 Building windows non-float processed = 17 data (7.9%)</li> <li>Class 3 Vehicle windows float processed = 76 data (35.5%)</li> <li>Class 4 Vehicle Windows non-float processed = 0 data (0%)</li> <li>Class 5 Containers = 13 data (6.1%)</li> <li>Class 6 Tableware = 9 data (4.2%)</li> <li>Class 7 Headlamps = 29 data (13.6%)</li> </ul>	-	Real

This study set the population parameter to 30, referring to Chakraborty et al. [21], as the four datasets used in this research were also employed in their study. Furthermore, the findings of Polly et al. [16] provided additional support by utilising the same population size and yielding satisfactory solutions. The rationale for determining the parameter  $[LbReal, UbReal] = [-80, 80]$  was based on an intuitive approach to solution search techniques, starting from the smallest search space and gradually expanding it. The expansion of the search space was performed every 50 iterations, and the most extensive range of the search space,  $[-80, 80]$ , was determined by setting the maximum iteration to 4000. The target error parameter was set to 0.001 to achieve high accuracy on the training data.

The parameter  $iterThOfCA$  was set to 700 based on documented test results in Table II. The row labelled "Average Training and Validation Accuracy" shows that using the  $iterThOfCA=700$  parameter yields slightly lower accuracy than the  $iterThOfCA=1000$  and 1800 parameters. However, the difference with the highest accuracy is tiny, only 0.22. In the row labelled "Training Time," the  $iterThOfCA=700$  parameter results in a shorter time than the  $iterThOfCA=1000$  and 1800 parameters. Therefore, the  $iterThOfCA=700$  parameter is selected as the appropriate option. The switch probability parameter is set to 0.8 based on preliminary parametric studies indicating that a value of  $p=0.8$  can provide better performance for most applications [17,23,24]. Expressly, for PSONN, the learning parameters (" $\alpha$  and  $\beta$ ") are set to 2, while for BANN, the normal values for the loudness parameter are 0.25, and the pulse rate parameter is set to 0.5, following standard practices in PSONN and BANN [25].

TABLE II. THE DETERMINATION OF THE  $ITERTHOFCA$  PARAMETER WAS BASED ON THE AVERAGE TRAINING ACCURACY, VALIDATION ACCURACY, AND TRAINING TIME USING 10-FOLD CROSS-VALIDATION, CONDUCTED OVER 5 REPETITIONS

	$iterThOfCA$ Parameter		
	700	1000	1800
The average training and validation accuracies (%)	87.9191	88.0872	88.1432
The average training time (seconds)	5934.45	7497.80	10555.65

### C. Testing

The experiment measures the performance of four algorithms by evaluating their average classification accuracy and training time. The tests were repeated 20 times in each fold of the 10-fold cross-validation method, and the results were recorded as the average of these trials. Additionally, the F1-score was also calculated as part of the testing procedure.

## IV. RESULT AND DISCUSSION

The tests were conducted on five datasets, as outlined in Table I. The results of the tests, including the average of the classification accuracy and the average of the training time, are shown in Table III and Fig. 3 to 4. Table IV shows the results of the F1-score test.

As seen in Table III, the QIFPNN algorithm produced a higher average classification accuracy in the training subset

than the other algorithms for all five datasets. It includes the Iris, Wine, Lung cancer, Vertebral column, and Glass datasets with an accuracy of 98.9103%, 99.3056%, 90.7478%, 87.6424%, and 73.855%, respectively. The QIFPNN model has the lowest mean square error and does not experience premature convergence across various datasets. The F1-score further supports this in the training subset, which was higher for all five datasets, including the Iris, Wine, Lung cancer, Vertebral column, and Glass datasets, with scores of 97.7294%, 99.3488%, 90.0801%, 90.9789%, and 64.8062% respectively, as shown in Table IV.

The average classification accuracy obtained from the training, validation, and test subsets from QIFPNN is higher than all the comparisons in the three datasets, namely the Iris, Wine, and Glass datasets. The average acquisition accuracy of the classification can be seen in Table III and Fig. 3, namely 97.1462%, 98.6551%, and 73.1979%. FPNN is only higher in two datasets than all the comparisons in the Lung cancer and Vertebral column datasets, respectively 78.7861% and 87.4692%. Still, QIFPNN ranks second highest after FPNN in both datasets, with gains of 76.5826% and 87.3895%. Based on the F1-score test from QIFPNN in Table IV, it is higher than all the comparisons in the four datasets: Iris, Wine, Vertebral column, and Glass. Sequentially, 96.4599%, 98.7155%, 90.7517%, and 60.2843%. Meanwhile, FPNN is higher than all its comparisons only in the Lung cancer dataset, namely 75.3369%, but QIFPNN ranks second highest with an acquisition of 73.1106%. It proves that the QIFPNN training model is the best among all comparisons because it is more consistently tested on various datasets and is not susceptible to the influence of variations in dataset characteristics so that it can be applied to multiple other data/cases.

The average PSONN training time is faster than QIFPNN, FPNN, and BANN on three datasets, namely Iris, Vertebral column, and Glass, with values of 384.4917 seconds, 55.6039 seconds, and 678.6673 seconds. QIFPNN is faster than FPNN, BANN, and PSONN on two datasets, namely Wine and Lung Cancer, with values of 179.7063 seconds and 135.8932 seconds, which can be seen in Table III and Fig. 4. It proves that, in general, PSONN is faster than its comparators. However, QIFPNN has a speedy training time compared to the comparison specifically for datasets that experience singularity problems, such as the Lung cancer dataset. The training time is also quick for datasets like Wine, which have unbalanced data class characteristics. This fact shows that the quadratic interpolation concept accommodated by QIFPNN works very quickly in the training process for datasets with characteristics similar to those of the Lung cancer and Wine datasets.

Based on the results of classification accuracy and F1-score measurements, it can be said that the QIFPNN is suitable for classifying non-binary datasets with balanced and unbalanced data class characteristic models. The slow training time of QIFPNN on the Iris, Vertebral column, and Glass datasets is due to the QIFPNN fitness evaluation being twice the fitness evaluation of FPNN, BANN, and PSONN in each individual (flower/pollen gamete) per iteration.

	FPNN	89.7003	92.9143	89.5973	90.7373
	BANN	89.9682	91.2794	88.4099	89.8858
	PSOINN	83.1972	86.5253	83.7587	84.4937
Glass	QIFPNN	<b>64.8062</b>	55.9833	60.0634	<b>60.2843</b>
	FPNN	45.7893	48.3887	44.9519	46.3766
	BANN	41.4919	38.9253	36.9897	39.1356
	PSOINN	23.9903	27.5101	25.1203	25.5403

However, QIFPNN is faster in obtaining solutions compared to FPNN, BANN, and PSOINN on the Lung cancer and Wine dataset, so it can be explained that the quadratic interpolation concept on QIFPNN can increase the QIFPNN training speed than the levy distribution concept on FPNN, the idea of acoustic echolocation on BANN, and the concept of adjusting the trajectories of individual agents, called particles, as the piecewise paths formed by positional vectors in a quasi-stochastic manner in PSOINN in both datasets.

## V. CONCLUSION

In previous research, the new algorithm QIFPNN was tested on real-world cases involving binary data types. Findings from that study indicated that QIFPNN significantly outperformed FPNN, PSOINN, and BANN. In this study, QIFPNN was tested using five UCI datasets with variations in data characteristics, such as non-binary data types, balanced and imbalanced classes, and singularity issues. The main objective of this research was to investigate the reliability of QIFPNN in dealing with various characteristics present in these datasets. Reliability measurements used classification accuracy, F1-score, and training time as evaluation metrics. The classification accuracy measurements on the training subset consistently showed that QIFPNN outperformed all other models across all datasets, indicating that QIFPNN did not suffer from premature convergence.

Moreover, the average classification accuracy on the training, validation, and test subsets demonstrated that QIFPNN performed superiorly on three datasets: Iris, Wine, and Glass. Although on the other two datasets, QIFPNN ranked second after FPNN; the difference was marginal. Furthermore, the F1-score test results revealed that QIFPNN significantly outperformed other models on four datasets, including Iris, Wine, Vertebral column, and Glass. However, on the Lung cancer dataset, QIFPNN ranked second after FPNN with a slight difference. These findings demonstrate that QIFPNN exhibits reliable performance in handling various dataset characteristics. Based on the measurements of classification accuracy and F1-score, it can be concluded that the QIFPNN training model is a reliable choice for various dataset characteristics in different cases.

Additionally, the training time measurements indicated that PSOINN was faster on three datasets, namely Iris, Vertebral column, and Glass, while QIFPNN was faster on two datasets. In the QIFPNN algorithm, the fitness evaluation is performed twice, resulting in excessive training time consumption. We recommend improving the Q step vector by introducing an additional parameter as a multiplier factor. The aim is to enhance the performance of QIFPNN.

**Abstract**—Role-based Access Control has become the standard of practice for many organizations for restricting control on limited resources in complicated infrastructures or systems. The main objective of the role mining development is to define appropriate roles that can be applied to the specified security access policies. However, the mining scales in this kind of setting are extensive and can cause a huge load on the management of the systems. To resolve the above mentioned problems, this paper proposes a model that implements Hamming Distance approach by rearranging the existing matrix as the input data to overcome the scalability problem. The findings of the model show that the generated file size of all datasets substantially have been reduced compared to the original datasets. It has also shown that Hamming Distance technique can successfully reduce the mining scale of datasets ranging between 30% and 47% and produce better candidate roles.

**Keywords**—Role-based Access Control; role mining; hamming distance; data mining

## I. INTRODUCTION

Role mining techniques exploit the existing user-permission assignment (UPA) to define roles that are suitable to the policies of an organization. The UPA usually involves big scale of data, which usually makes role mining difficult to process. The input data should contain at least a set of users (U), permissions (P), and user permission assignment relation (UPA) which is commonly depicted in a Boolean matrix form. A number of studies, such as in [3], [4], [5] and [6], have found that pre-processing phases are significant to be implemented, especially to simplify the scalability of the UPA matrices that work as the input to the role mining process. Furthermore, the authors also have discussed that pre-processing steps can be divided into two major classes: data cleansing and data selection. Data cleansing can be defined as a method to decrease the noise that resides in the UPA matrices, while data preparation ensures that the input data is suitable to be executed by role mining algorithms.

From the perspective of RBAC, when an organization's existing UPA includes numerous permissions and users, or when the size of UPA becomes excessively large, it increases the likelihood of the UPA to contain overlapping permissions and an unnecessary number of roles. To address these challenges and to uncover roles that are of high quality and meaningful, data mining techniques, specifically clustering techniques, are required. Eventually, it can produce reliable and optimal candidate roles that would be forwarded to the next stage or phase. In addition, the migration from traditional

ACM to RBAC model usually would not result in the best RBAC states either they are too complex or not scalable enough to be passed on the next phase.

Based on the above discussion, there is a main question from RBAC's standpoint on how to overcome the scalability problem in existing system of an organization. So, the main objective of this research is to discover an approach, specifically a data mining technique in pre-processing stage, such as Hamming Distance, k-Nearest Neighbor (k-NN) or deep learning algorithm as in [7] to be implemented to rearrange the matrix to overcome the huge scale of UPA as input data to produce more scalable, optimal and accurate datasets that can be used into the next phase. Furthermore, the selection of data mining methods for this research must be suitable for binary or Boolean data type.

The output of pre-processing stage is optimal candidate roles. A candidate role in a RBAC system contains a set of permissions that is connected to a user-to-role assignment that can be visualized as a row in matrix PA, a column in matrix UA, and a user is permitted with permissions if he/she is appointed with a role that includes the designated permissions. This stage is the most meaningful process because this phase usually produces a big pool of candidate roles [4], [8], [9], therefore appropriate techniques are needed to recover optimal candidate roles by exploiting appropriate data mining techniques or heuristics algorithms.

This paper proposes an approach that can manage the conversion from traditional and existing ACM in an organization to RBAC that contains large data since the large data can be complicated and unscalable and consist of redundant data with immoderate permissions and roles. The approach has utilized data mining technique particularly Hamming Distance, prior to the role mining process that can cluster a more accurate RBAC system.

The remainder of the paper is structured as follows. Section II presents a background study of this work, specifically on clustering techniques. Section III discusses the general methodology developed for the proposed approach; Section IV elaborates the experimental results and discussion on the proposed approach; lastly Section V sums up the research with conclusion and future works.

## II. RELATED WORK

The fast growth of internet technologies has created extreme escalation of data gathering, storing, and analysis of large datasets and data mining can be described as a method to

obtain informative patterns from these datasets. One of a common data mining task that is appropriate for role mining is clustering. Generally, clustering can be expressed as a process of combining items that have the same attributes, specifically in role mining. Clustering is the act of grouping similar users and permissions to produce a common set of roles. Clustering techniques have been comprehensively reviewed in many applications, such as the pattern recognition field. According to the authors, clustering technique offers many advantages as the following features [10], [11]:

- 1) Firstly, it can be utilized as a pre-processing technique to obtain related groups within the datasets.
- 2) Secondly, it can decrease the cost that involved in data mining technology.
- 3) Thirdly, it is effective to get information regarding the properties of the datasets.

Many clustering techniques have been proposed for different datasets, and most of the conventional clustering algorithms are unsuitable for handling categorical datasets, such as in role mining. Researchers [12] have introduced a statistical method using Hamming Distance (HD) to cluster categorical datasets. In their research, HD vectors has been utilized to generate clusters for each iteration until no notable clusters can be produced. The proposed method has performed significantly better than the other algorithms. Furthermore, the application of clustering techniques in role mining has been discovered by [13], [14] and according to the authors, the dataset would be segregated into clusters based on the same characteristics that eventually would decrease size of the dataset significantly.

Moreover, the authors also have discovered, based on the simulations and analysis conducted, that the application of the Bayesian model can successfully cluster datasets that contain categorical data [15]. Most recently, [16] have effectively proposed a model to cluster categorical datasets using a mixture of distributions based on HD. Additionally, according to the authors, the role mining scales were huge that could produce results that were not easily interpreted; hence the authors have adapted the basic role mining concept into clustering problem with the application of HD to rebuild the original matrix into a compressed matrix [17].

In recent years, there has been an increasing amount of literature on role mining techniques in Role-based Access Control (RBAC). However, numerous existing role mining algorithms in RBAC do not provide any appropriate approach to overcome the huge scale of existing UPA in an organization that may contain overlapping permissions that can lead to inaccurate and too many roles that eventually overwhelmed the existing system and burdened the administrator. Researchers [18] have proposed a technique based on frequent pattern mining. However, this technique has constructed a large number of potential permission sets. Additionally, researchers [19] have discussed a feasible solution based on a constraint satisfaction problem. However, this solution still produced quite a large of number of users and permissions. Therefore, the rest of this paper will discuss on the methodology, results, and discussion on Hamming Distance approach to reduce role mining scalability.

### III. MATERIALS AND METHODS

This section presents the detailed specification of an approach or phase to restructure the huge scale of role mining input data, namely user-permission assignment (UPA), that exists in a form of Boolean matrix to produce optimal and accurate candidate roles. This approach discusses the application of data mining technique, specifically Hamming Distance (HD), to reduce the scalability of UPA input data. The process begins by grouping users with the same permissions and considering them as a user group. Then each user group can be depicted as different user clusters. The output of this process is a less complex matrix UPA.

#### A. Datasets

The dataset that has been used in this research is the benchmark access control datasets, as shown in Table I and the datasets comprise of the numbers of users  $|U|$ , the number of permissions  $|P|$ , the size of user-permission assignment  $|UPA|$ , number of roles  $|R|$  and density that can be described as the number of entries equivalent to one with the respect to its size in an unrestricted setting. The Apj dataset was acquired from the network access control rules used in Hewlett Packard (HP) and the profile was obtained from the Cisco firewalls and used to authenticate the users with the related network access [20]. Furthermore, the healthcare dataset was collected from the US Veteran's Administration [21]. Additionally, the firewall1 and firewall2 datasets were gained from Checkpoint firewalls and lastly the domino dataset came from a set of user and access profiles for a Lotus Domino server [20].

TABLE I. REAL WORLD DATASETS

Dataset	$ U $	$ P $	$ UPA $	$ R $
Apj	2044	1164	6841	453
Domino	79	231	730	20
Firewall1	365	709	31951	64
Firewall2	325	590	36428	10
Healthcare	46	46	1486	14

#### B. Measurements

This approach needs data mining technique such as Hamming Distance to rearrange the matrix to overcome the huge scale of UPA as input data to produce more scalable, optimal and accurate datasets. Moreover, the selection of data mining methods for this research must be suitable for binary or Boolean data type. For this research, the successful implementation of such technique can be determined by size of generated files and the size should be reduced (smaller size) compared to the original dataset

#### C. Hamming Distance Approach

An effective transition from a conventional access control model to a role-based model needs to define an appropriate dataset that enables to capture the security policies of an organization. The complexity of the RBAC system can be quantified by parameters such as number of roles, permissions, hierarchy size, constraints, and user-permission assignment (UPA). Although the process may seem uncomplicated to

accomplish when the roles can be defined from the beginning, for an organization with existing user-permission assignments, this procedure can be complicated to produce stable candidate roles, especially when the existing UPA contain a huge number of permissions and users. This enormous UPA may deteriorate the functionality of the RBAC system and become challenging to handle appropriately.

For a RBAC system, role mining is a method that can be implemented to cluster or group users who have the same or comparable permissions and role mining can be utilized to create various roles with these permissions. Users are commonly given roles with numerous duplicate permissions and this method can simplify the management and maintenance of RBAC system. Therefore, in order to reduce the complexity of the generated roles, it is necessary to cluster users who share the same attributes. However, implementing traditional role mining techniques resulting enormous mining scales and burdens the administration of the systems due to the miscellany of permissions and users [22].

Therefore, a pre-processing technique is needed to reduce the scalability of the UPA to produce more precise candidate roles. For this paper, basic role mining has been converted into a clustering problem using the Hamming Distance (HD) approach and basic role mining can be defined as the following:

Definition 1. Given a set of users (U), a set of permissions (PRMS), a user permission assignment (UPA), a set of roles (ROLES), a user-to-role assignment (UA), and a role-to-permission assignment (PA), 0-consistent with UPA and minimizing the number of roles, k.

Hamming Distance (HD) approach has been applied to decrease the scales of UPA. This approach can decrease the size of initial dataset by grouping users with the same permissions in the existing UPA to generate an initial set of roles. As input data of RBAC model is user-permission assignments (UPA) in a form of Boolean matrix, it can be observed that the matrix is at the same length, and it is a common practice to calculate the distance between two separate but similar length vectors applying Hamming Distance calculation. Generally, the approach to find the distance can be done by calculating the number of positions between two similar length vectors namely Distance (x, y).

#### IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section presents the results and discussion on the pre-processing model as discussed in previous sections. The algorithms have been implemented in Python 3.6 through Visual Studio Code and tested on a MacBook Air running macOS Monterey Version 12.6.1 on Apple M2 and CPU having 8 GB memory. Five real-world datasets have been widely employed in literature to evaluate the framework to analyze the performances of various unconstrained role-mining heuristics.

The effectiveness of pre-processing model that works to restructure role mining input data (UPA) that exists in the form of a Boolean matrix to produce optimum candidate roles can be demonstrated in the following subsection. The measurement that has been used is size of generated files and the size should

be reduced (smaller size) compared to the original dataset. More precisely, the size of the generated files can be expressed as clustered size that can determine how well UPA are clustered. The dataset that has been used in this research is the benchmark access control datasets, as shown in Table I and the datasets comprise of the numbers of users |U|, the number of permissions |P|, the size of user-permission assignment |UPA| and number of roles |R| in an unrestricted setting.

Fig. 1 describes the model of pre-processing approach to generate candidate roles or can be described as optimal candidate role set identification, and this model can be divided into three main steps. In the first step, rows in the original dataset have been applied with Hamming Distance formula to find a distance value between two identical length rows. Furthermore, in the second step, based on the values of Hamming Distance, the generated dataset is divided into partitions according to similar clusters of users. Lastly, the generated dataset is rearranged in the third step to produce a meaningful smaller set of users that signify each cluster. Thus, these steps can be viewed as processes that can reduce the scalability of UPA, resulting in a compressed dataset containing final candidate roles or optimal candidate to be used in the next phase.

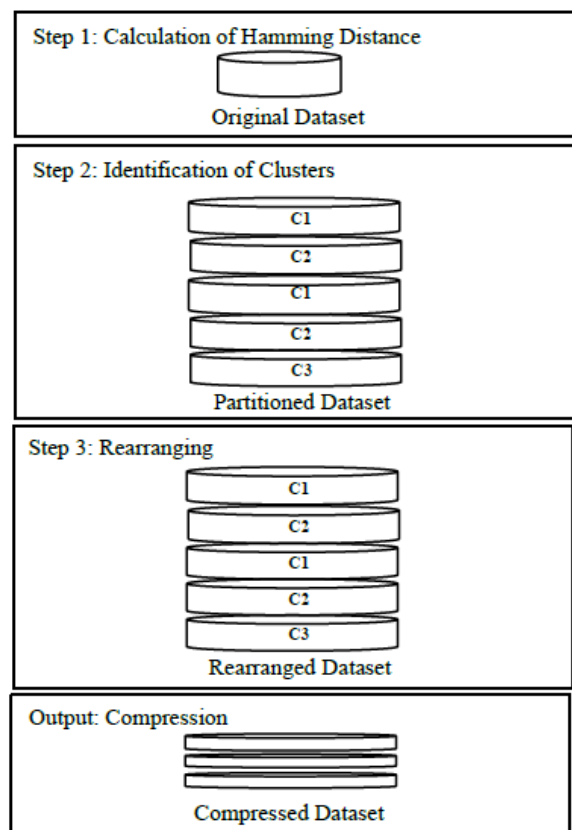

Fig. 1. Role selection and assignment phase.

Table II compares the original files size and generated files size that have been applied with Hamming Distance computation. Meanwhile, Fig. 2, Fig. 3, Fig. 4, Fig. 5 and Fig. 6 show the contrast between both sizes that are represented in form of a graph. Each graph can be designated by blue and red bar, the blue bar signifies the original file size, and

correspondingly, the red bar symbolize generated file size, which are computed by Hamming distance computation. Furthermore, Fig. 7 shows the comparison of file sizes between both original datasets and generated datasets in the directory of the computer.

TABLE II. ORIGINAL VS EXTRACTED FILES SIZE

Dataset	Original File Size	Generated File Size
Apj	144 KB	68 KB
Domino	15 KB	6 KB
Firewall1	671 KB	273 KB
Firewall2	765 KB	319 KB
Healthcare	31 KB	10 KB

Fig. 2. Initial vs. extracted file size comparison of apj dataset.

Fig. 3. Initial vs. extracted file size comparison of domino dataset.

Fig. 4. Initial vs. extracted file size comparison of firewall 1 dataset.

Fig. 5. Initial vs. extracted file size comparison of firewall 2 dataset.

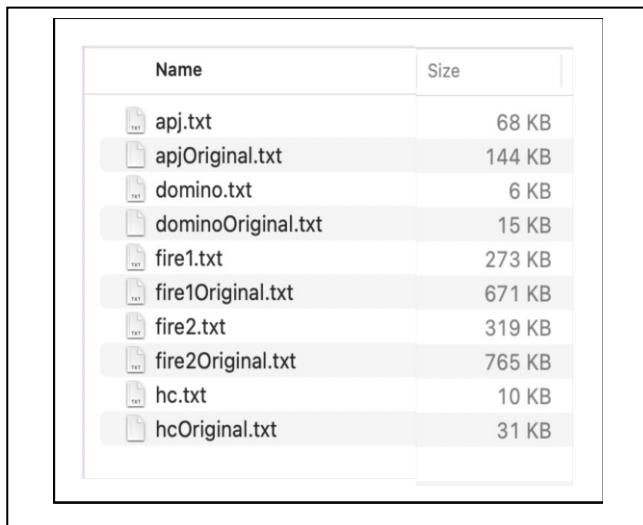

Fig. 6. Initial vs. extracted file size comparison of healthcare dataset.

Name	Size
apj.txt	68 KB
apjOriginal.txt	144 KB
domino.txt	6 KB
dominoOriginal.txt	15 KB
fire1.txt	273 KB
fire1Original.txt	671 KB
fire2.txt	319 KB
fire2Original.txt	765 KB
hc.txt	10 KB
hcOriginal.txt	31 KB

Fig. 7. Comparison of original and generated file size.

TABLE III. REDUCED FILES SIZE

Dataset	Original File Size	Generated File Size	Reduced Size (%)
Apj	144 KB	68 KB	47.2%
Domino	15 KB	6 KB	40.0%
Firewall1	671 KB	273 KB	40.7%
Firewall2	765 KB	319 KB	41.7%
Healthcare	31 KB	10 KB	32.3%

Significantly, based on Table II and Fig. 2 to Fig. 7, the generated file size of all five datasets substantially have been reduced compared to the initial or original datasets showing that Hamming Distance (HD) approach is successfully can be utilized to reduce the mining scale of datasets and eventually can produce better candidate roles. Thus, the three steps as in Fig. 1 can effectively recognize as processes that can reduce the scalability of UPA and resulting a compressed dataset that contains final candidate roles to be used in the next phase. Table III displays the percentage of reduced file size and indicates that HD enables to compress the original dataset to become a smaller generated dataset between 32% to 47%. The Apj dataset has disclosed the highest percentage of 47.2%. In the meantime, the Healthcare dataset has shown the lowest percentage of 32.3%.

## V. CONCLUSION AND FUTURE WORKS

In conclusion, the generated file size of all five datasets has been significantly reduced compared to the original using Hamming Distance approach. The process begins by grouping users that have the same permissions and considering them as a user group, and then each user group can be depicted as different user clusters. The output of this process is a less complex UPA matrix.

For future works, two directions can be considered. The first direction is to consider other possible data mining techniques to be combined with role mining technique, particularly clustering techniques that can produce more

accurate candidate role sets, and the second direction is to explore role-engineering optimization potential in other applications or environments such as in Internet of Thing (IoT) environment.

**Abstract**—In the Automated Guided Vehicle (AGV) warehouse automatic guided vehicle system, the path planning algorithm for intelligent logistics vehicles is a key factor to ensure the stable and efficient operation of the system. However, the existing planning algorithms have problems such as single designing a route and the inability to intelligently evade moving barriers. The academic community has proposed various solutions to these problems, although they have improved the efficiency and quality of path planning to some extent, they have not completely solved problems such as poor safety in planning, the high number of path inflection points, poor path smoothness, easily getting stuck in deadlocks, and have not fully considered the running cost and practical implementation difficulty of algorithms. To address these issues, the article deeply researched traditional A\* scheme and Dynamic Window Approach (DWA) technology and proposed designing a route method according to the fusion of the A\* algorithm and DWA technology. The algorithm improved the A algorithm by introducing a sub-node optimization algorithm to solve problems for instance poor global path planning safety and easy deadlock. Moreover, the algorithm reduced the amount of global route reversal locations and increased path consistency by improving the evaluation function and removing redundant points of the A algorithm. Finally, by integrating the DWA algorithm, the intelligent logistics vehicle achieved dynamic obstacle avoidance capabilities for moving objects in the real world. Our simulations-based results on MATLAB framework show that the algorithm significantly improves path smoothness, path length, path planning time, and environmental adaptability compared to traditional algorithms, and basically meets the path planning requirements of the AGV system for intelligent logistics vehicles.

**Keywords**—AGV; path planning; A\* algorithm; dynamic window approach

## I. INTRODUCTION

In recent years, with the major breakthroughs in the P.R. China-Europe Railway Express, the China-Japan-Korea Free Trade Zone, and the Belt and Road Initiative (BRI) in Pakistan, China's flagship economic corridor economy has ushered in new development, and at the same time stimulated the rapid growth of the logistics industry. According to statistics from relevant departments, the total volume of China's logistics industry in 2022 will reach 347.6 trillion, a year-on-year increase of 3.4% [1]. At the same time, due to the continuous development of Artificial Intelligence (AI), warehouse-

automated guided vehicles (automated guided vehicles, AGV) are commonly utilized in warehousing and distribution, logistics distribution, and other industries [2]. But at this stage, the AGV control system has a single path planning and fixed-point pickup, and cannot dynamically avoid dynamic obstacles [3]. The dynamic path planning of the AGV control system needs further research.

At present, many experts and scholars put forward different solutions. J Borenstein's team proposes a virtual stand that considers the dynamic behavior of fast-moving robots and solves the local minimum trap problem. Hao W's team used neural networks for path planning [4]. Chang et al. presented the SPEA2 method into the genetic algorithm to distribute the fitness of the population individuals and realized the balance of path smoothness, path length, and path difficulty [5], Xiong Lijun et al. introduced the initial grid transfer rule and changed the information The method of updating elements, deleting redundant nodes, DWA algorithm [6] for the design for regional paths and other methods can improve the rate of integration of the ant colony algorithm, the smoothness of the planned path, and the safety and reliability. Performance indicators such as smoothness, safety, and reliability are improved compared with traditional algorithms [7]. The K Dan team proposed the A\* algorithm for the first time [8]. Yang Guihua and others adopted the method of cleaning the Close list to optimize the total quantity of vertices in the route that the A\* method designed [9], while Yang Mingliang and others tried to integrate the A\* algorithm and The DWA algorithm into achieves the global optimality of the planned route via avoiding obstacles the objective is to arrive [10]. Although the above method has improved the efficiency and quality of path planning to a certain extent, it has not completely solved the problems of too many vertices in the path planning, is not smooth, and is easy to fall into a deadlock, and has not considered the cost of algorithm operation and the difficulty of the actual implementation. Focusing on the real-world issues of adaptive obstacle-resistant routing for stored robotics, this study suggests a route modeling technique utilizing DWA and the typical A\* technique.

The main contribution of this research work is as follows:

1) *Firstly*, the problems of the A\* algorithm such as long search time, readily prone to global optimal, traversing obstacle vertices, and insufficient path smoothness are improved; a

\*Corresponding Author.

globally optimal path is planned, and then combined with DWA to analyze the dynamic obstacle part.

2) *Secondly*, we create an adjacent adaptive obstacle-avoiding route to arrive at the desired route.

3) *Finally*, we conduct three sets of comparative computer simulations to verify that the method which is suggested performs superior to the traditional algorithm and the existing improved algorithm in both stationary and dynamic settings where the obstacle movement direction is known and unknown superiority.

The paper is structured into several sections. Section I introduces the field of automated guided vehicles for guided vehicle systems. Section II provides an environment model construction. Section III presents the basic algorithm. Section IV leads to the improved safety and reliability of the improved A\* algorithm. Section V focuses on simulation-based experimental results. Finally, Section VI concludes this research work and stipulates future research directions in Section VII.

## II. ENVIRONMENT MODEL CONSTRUCTION

As shown in Fig. 1, the grid map is used to construct the virtual working environment map of the robot. In this two-dimensional map, the black grids represent obstacles, respectively S1, S2, ..., Sn, and the white grids represent no obstacles, while Point N and Point T represent the beginning and ending points, respectively. The serial numbers of grids are 1, 2, 3... from bottom to top and from left to right. What needs to be paid is that a distinct identification and associated two-dimensional dimensions are assigned for every grid, and the conversion method is the following:

$$\begin{cases} x_i = (\text{mod}(i, MM) - 0.5) * \beta \\ y_i = (NN + 0.5 - \text{rup}(20 - i/NN)) * \beta \end{cases} \quad (1)$$

Among them,  $x_i$  and  $y_i$  are the coordinates of the  $i$ -th grid in the two-dimensional graph;  $\beta$  represents the unit length of the grid;  $\text{mod}$  represents rounding;  $MM$  and  $NN$  are the grids in the row direction and column direction of the grid respectively number;  $\text{rup}$  is a custom function, representing rounding up.

Fig. 1. Grid map of robot working environment.

## III. BASIC ALGORITHM

### A. Traditional A\* Algorithm

The shortest route among the two locations is determined by the most common methods are the Dijkstra algorithm [11] and A\* algorithm. Compared with the Dijkstra algorithm, the A\* method predicts the projected utility from the present location to the objective position in addition to recording the utility of getting to the beginning place. It has the advantages of faster speed and higher efficiency. It is a heuristic depth-first algorithm [12]. The assessing parameter of the conventional A\* method is typical:

$$f(n) = g(n) + h(n) \quad \# \quad (2)$$

Among them,  $f(n)$  depicts the car's assessment process in its present grid,  $g(n)$  indicates the actual utility value of the mobile robot from the initialing dot to the current dot, and  $h(n)$  denotes the heuristic performance [13], Euler distance was employed as the heuristic in the research [14].

$$H(n) = \sqrt{(N1_x - N2_x)^2 + (N1_y - N2_y)^2} \quad \# \quad (3)$$

The A\* technique's pathfinding strategy is displayed in the following Fig. 2:

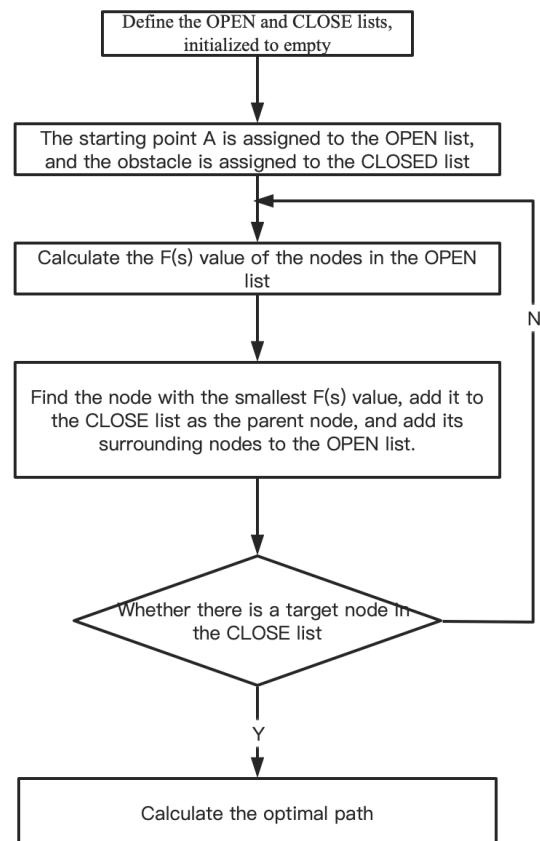

Fig. 2. A\* Algorithm flow chart.

Step 1: Open the list and close the initial transmission of the list.

Step 2: Fill out the unfilled list with the initial location, then get the set of surrounding points and add it to the open list, and then the beginning spot should be taken off the list that is vacant and added to the closing condition of the closed list.

Step 3: Judging whether these surrounding point sets are already in the open list or not, then update the F and father points of these points and add them to the open list; if they are, then update G, F, and father points.

Among them, G stands for the utility associated with relocating initialing point A to a certain grid tile,

F represents the prediction function value of the point, and its value is equal to G+H, and H refers to the anticipated utility of moving from the specified square to the final result, that is, the utility of the heuristic function.

Step 4: then obtain the surrounding point set, find the point with the smallest F from the surrounding point set, then remove the point that finds the smallest F from the open list, and add it to the closed list.

Step 5: judge whether the opening list is empty, if it is empty, it means that the path does not exist, if it is not empty, execute Sep3 in a loop.

Step 6: If the objective grid is in the "open list", it means that the route has been identified, the algorithm ends, and the path planning is completed.

The classic A\* algorithm has some issues, as the information mentioned shows:

1) The planned path is rough, and the inflection point is too close to static obstacles, so it cannot be directly applied to the movement of smart cars in real life.

2) It can only run in a static environment. When the working environment changes, it still plans the path according to the environmental grid map before modification, resulting in the existence of theory and failure of practice, and even causing safety hazards.

### B. Dynamic Programming (DWA) Algorithm

To address the drawbacks of the confusing decision-making introduced by the A\* technique, which only focuses on the path to the destination, and overlooks the impact of dynamic barriers on the performing route's track on the vehicle's route selection, the DWA (dynamic window technique) algorithm is a more suitable solution plan [15].

The fundamental idea is to collect different sets of rates in the velocity domain (v, w), and model the course of these velocities over a predetermined amount of time, and the rating function should be used to assess these motions, and decide on the corresponding optimal trajectory (v, w) Drive the robot to move[16].

There are three main steps in the operation of the algorithm, specifically:

1) *Smart car kinematics model*: As shown in Fig. 3, the smart car belongs to omnidirectional movement. In the robot coordinate system, there is the speed  $V_x$  in the X direction and the speed  $V_y$  in the Y direction [17]. The relationship between the position and speed at time t and time  $t + \Delta t$  is as follows:

$$\begin{bmatrix} x(t + \Delta t) \\ y(t + \Delta t) \\ V_x(t + \Delta t) \\ V_y(t + \Delta t) \\ \theta(t + \Delta t) \\ \omega(t + \Delta t) \end{bmatrix} = \begin{bmatrix} x(t) + V_x(t) * \cos(\theta(t)) * \Delta t - V_y(t) * \sin(\theta(t)) * \Delta t \\ y(t) + V_x(t) * \sin(\theta(t)) * \Delta t + V_y(t) * \cos(\theta(t)) * \Delta t \\ V_x(t) + \alpha_x(t) * \Delta t \\ V_y(t) + \alpha_y(t) * \Delta t \\ \theta(t) + \omega(t) * \Delta t \\ \omega(t) + \alpha(t) * \Delta t \end{bmatrix} \# \quad (4)$$

It is especially pointed out that this model has two coordinate systems - the world coordinate system and the smart car coordinate system.

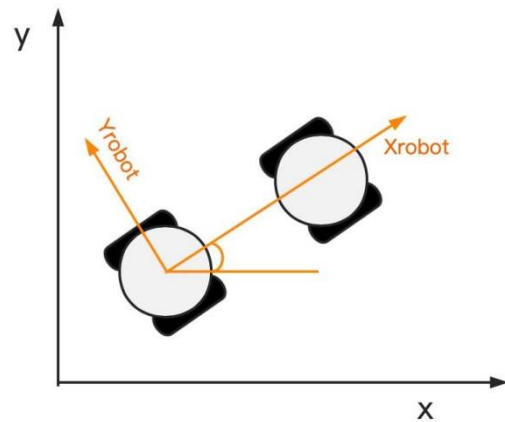

Fig. 3. Kinematics model of the smart car.

$V_x(t)$  and  $V_y(t)$  in the above formula refer to the speed of the smart car in the x and y directions in the smart car coordinate system respectively.

2) *Velocity space of the smart car*: Theoretically speaking, the acceleration of the smart car should reach the maximum value that the machine motor can bear in an instant from the moment it stops to the start of acceleration, but in the actual environment, the car is limited by various factors, mainly including the following aspects:

a) *The smart vehicle's velocity is its only constraint*:  $V_s$  represents the range of vector speeds the vehicle is capable of which is affected by angular velocity and linear velocity:

$$V_s = \{(v, \omega) | v \in [v_{min}, v_{max}] \wedge \omega \in [\omega_{min}, \omega_{max}]\} \# \quad (5)$$

b) *The moving trolley is affected by its own motor performance*: In the actual operating environment, subject to cost and safety considerations, the acceleration of the car has a range limit, and the maximum acceleration and deceleration will take a certain amount of time to reach. The expressions are as follows:

$$V_d = \{(v, \omega) | v \in [v_c - v_b * \Delta t, v_c + v_b * \Delta t] \wedge \omega \in [\omega_c - \omega_b * \Delta t, \omega_c + \omega_b * \Delta t]\} \# \quad (6)$$

c) *The mobile car is affected by obstacles:* To make the car stop before it hits an obstacle and avoid damage to goods and property, the car should satisfy the following expression under the premise of maximum deceleration:

$$V_a = \left\{ (v, \omega) \left| \begin{array}{l} v \leq \sqrt{2 \text{dist}(s, \omega) v_b \wedge} \\ \omega \leq \sqrt{2 \text{dist}(s, \omega) \omega_b} \end{array} \right. \right\} \# \quad (7)$$

Among them, distance (s, w) shows the quickest path between the vehicle and the obstruction.

After the speed of the car passes through the three restrictions, the speed space will return to a certain extent, and it will change according to the changes in the linear velocity, angular velocity, and acceleration of the motor. This is the dynamic window of the car's movement [18], When the conditions are met, a sample of the speed space of the car, and the speed range in Fig. 4, below will be obtained:

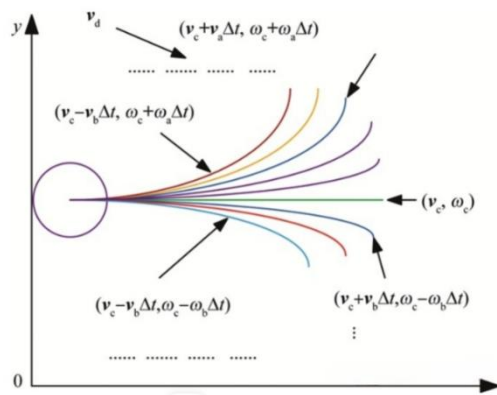

Fig. 4. Smart car speed range map [19].

3) *Evaluation function:* In general, the following is the evaluation process:

$$G(v, \omega) = \sigma \left( \alpha * \text{heading}(v, \omega) + \beta * \text{dist}(v, \omega) + \gamma * \text{vel}(v, \omega) \right) \# \quad (8)$$

Among them, heading (v, w) is the azimuth evaluation function: assess the angle between the intended location and the car's final route, given the present selected velocity; the main meaning of distance (v, w) is that the car is in the predicted. The final destination of the route is placed relative to the closest constraints on the map, and sample sites that are nearby the barrier are penalized to guarantee the car is able to prevent it and lessen the likelihood that it would collide with it; vel (v, w) is the current car, promoting the vehicle will help it swiftly reach its aim [20],  $\alpha$ ,  $\beta$ ,  $\gamma$  are the weights, and  $\sigma$  is the smoothing coefficient, which is generally 1.

After obtaining a variety of trajectories through the above methods, the current optimal speed and the best trajectory are selected through the evaluation function, to drive the car to avoid obstacles as much as possible. But this method has the blindness and randomness of path selection.

#### IV. IMPROVED A\* ALGORITHM

##### A. Improve Safety and Reliability

Although the traditional A\* scheme contains several benefits fast speed and global routing in path routing, it has the disadvantages of a large turning range, many trajectory polylines, and the initial path of turning to being close to obstacles. The following Fig. 5 shows the domain algorithm of the traditional A\* scheme for routing:

Fig. 5. Schematic diagram of the domain of the A\* algorithm.

From the analysis in Fig. 5, we know that the reason for the insufficient uniformity of the planned route is that the type A\* technology adopts one 3\*3 domain algorithm, leading to the turning range of the smart car. This causes the issue that the planned car path is insufficient near static barriers.

To fix the challenge, the improved A\* scheme needs to adopt a sub-node optimization algorithm in the route. Its core is to select an appropriate method to remove redundant nodes according to obstacles at different positions, to prevent the phenomenon in which the car traverses obliquely through the apex of obstacles and ensure that the car Safe distance from obstacles.

As shown in Table I, sub-nodes 1, 3, 5, and 7 are divided into X-type nodes, and sub-nodes 2, 4, 6, and 8 are divided into N-type nodes. According to the division method, the selection method of the sub-node optimization algorithm is:

TABLE I. SUB-NODE OPTIMIZATION ALGORITHM

Obstacle node type	Handling measures	The number of remaining child nodes
X	do not deal	8
N	removes two child nodes adjacent to the obstacle child node	6

##### B. Path Smoothness Optimization

After adopting the above-mentioned sub-node optimization algorithm, although the phenomenon of obliquely crossing the obstacle vertex can be avoided, it also strengthens another shortcoming of the A\* algorithm - the problem that the path is not smooth and the path length is not optimal. In order to solve

this problem, the improved A\* algorithm adopts the method of twice smoothness optimization.

1) *The first smoothness optimization:* The first smoothness optimization is achieved by improving the evaluation function of the A\* algorithm. By increasing the weight value of  $h(n)$  to increase the evaluation value  $G$  of the correct node, the algorithm selects a child node closer to the end position. The function expression is as follows:

$$f(n) = g(n) + \left(1 + \frac{r}{R}\right)h(n) \quad (9)$$

Where  $r$  is the space between the beginning position and the goal point, where  $R$  is the value between the present and objective locations.

2) *The second smoothness optimization:* When the classical A\* algorithm plans the path, there will be several redundant connections in enormous amounts, which will increase the length of the path and make the result not the optimal solution. Therefore, the A\* algorithm for the second smoothness improvement adopts two methods to remove redundant nodes:

a) Remove collinear nodes, such as five nodes  $N_4$ ,  $N_5$ ,  $N_6$ ,  $N_7$ , and  $N_8$  belong to collinear nodes, then the child nodes of  $N_3$ . The next step should be to change to the node with obstacles in the first domain of the collinear node, that is,  $N_8$ .

b) Eliminate the right-angle inflection point, when the next two steps of the parent node  $N_i$  are still in the domain of the parent node, it is determined that the path planning is in progress. There is a right-angle inflection point. Currently, whether the child node of the domain union of the three parent nodes is an obstacle is judged. If not, the next hop of  $N_i$  is changed to  $N_{i+2}$  instead of  $N_{i+1}$ . After two path smoothness optimizations, the path planning demonstration diagram of A\* is shown in Fig. 6.

Fig. 6. A\* path planning.

### C. Integrated Obstacle Avoidance Strategy

Based on the above improvement scheme, the 9\*9 improved A\* algorithm incorporates the DWA algorithm, the A\* algorithm is used for global path planning, a reference route is provided for DWA, and points are selected for local obstacle avoidance path planning, which solves the problem of the DWA algorithm. The blindness and randomness of the path selection realize the optimal combination of the shortest path and dynamic obstacle avoidance. At the same time, in order to

ensure the path smoothness of the car at the turning point, and to ensure that the smart car can slow down in advance when encountering obstacles or turning, so as to ensure the safety of the goods and the optimization of the path length, the improved algorithm proposes a The new DWA evaluation algorithm based on the globally optimal path, its expression is as follows:

$$G(v, \omega) = \sigma(\alpha * heading(v, \omega) + \beta * dist(v, \omega) + \gamma * vel(v, \omega)) + \eta * Yheading(v, \omega, G_i) \quad (10)$$

In the formula,  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\sigma$ , and  $\eta$  are weighted, and  $\sigma$  is a smoothing coefficient, usually, its value is 1. Heading () is the azimuth evaluation function, distance () measures the separation between the course of motion and the obstruction, vel () is the evaluating process, Y heading () is the deviation function from the sub-target point to the end of the path, where  $G_i$  represents the current car The subgoal point closest to the global planning path. Therefore, this paper implements a global path planning algorithm that integrates obstacle avoidance, avoids the blindness and randomness of the classical DWA algorithm at the beginning of path selection, and effectively ensures the global route is followed in the best possible way by cutting the path's width and design time, Superiority.

## V. SIMULATION-BASED EXPERIMENTAL RESULTS

To assess how well the enhanced technique performs and verify the feasibility of the algorithm, the algorithm validity verification experiment and the algorithm comparison verification experiment were carried out. Both experiments were carried out on the Matlab R2023a simulation platform, the computer operating system version is MacOS 11, the processor is Intel Core i7-4870HQ, and the memory is 16G. In the comparative experiment, two map environments were constructed, and the size, shape, and number of obstacles of different environments were different. By setting up different environments, the performance of the proposed improved planning algorithm is analyzed and verified in terms of path length, path smoothness, running time, and obstacle avoidance ability.

### A. Improved A\* Algorithm Verification

To verify the advantages of the improved A\* algorithm in path smoothness, pathfinding efficiency, and security, this paper simulates different environments on Matlab, namely a simple environment (10\*10 grid map) and a complex environment (20\*20 grid map), where "  $\Delta$  " identifies the beginning and "  $\circ$  " identifies the finding. Compared with the simple environment, the number of map environments and obstacles has doubled in complex environments, and the number of searchable sub-nodes has expanded by 4 times. It can effectively evaluate the performance of the upgraded A\* technique. A\* algorithm shows in Fig. 7.

Fig. 7 and Fig. 8 shows that the enhanced A\* algorithm can prevent too many vertices in the path planning process, and then plan a route with a shorter path length and a higher path smoothness. Fig. 9 and Fig. 10, we can see that the improved algorithm called A\* will identify a shorter route in fewer seconds in a complex environment, which is obviously better than the traditional A\* algorithm. The direction energy parameters of path planning for different algorithms in two

different environments are shown in Table II, and the data are recorded with two decimal places:

Fig. 7. Path planning of the traditional A\* algorithm in a simple environment.

Fig. 8. Path planning of the improved A\* algorithm in a simple environment.

Fig. 9. Path planning of traditional A\* algorithm in a complex environment.

Fig. 10. Path planning of the improved A\* algorithm in complex environments.

TABLE II. PARAMETERS OF PATH PLANNING IN DIFFERENT ENVIRONMENTS

		<i>Path length</i>	<i>Vertices</i>	<i>Planning time</i>
<b>Simple environment</b>	Traditional A* algorithm	18.00	10	7.69
	Improved A* algorithm	14.83	5	5.48
<b>Complex environment</b>	Traditional A* algorithm	38.00	16	22.89
	Improved A* algorithm	29.85	10	11.03

From this, we can see that in comparison to the typical A\* algorithm, the enhanced A\* method has a comprehensive reduction in the number of breakpoints by 44%, a comprehensive reduction in path length by 17.18%, and a comprehensive reduction in planning time by 14.68%. The enhanced A\* method performs quite well regarding route length and roughness.

B. Fusion Obstacle Avoidance Function Verification

The A\* technique's minimization evaluation has to be verified for different obstacles after integrating the obstacle avoidance ability. Construct a simulation environment 3, which is a 20\*20 grid map containing movable obstacles, represented by yellow squares, whose moving coordinates are ([14, 7], [14, 11]), and contains several Unknown static obstacles represented by gray squares. Numerous factors have an impact on the efficacy as well as the efficiency of the enhanced routing technique. The experimental environment parameter settings are shown in Table III:

TABLE III. EXPERIMENTAL ENVIRONMENT PARAMETER SETTINGS

Parameter type value	
<b>Direction angle <math>\alpha</math></b>	0.05
<b>Static distance <math>\beta</math></b>	0.2
<b>Dynamic Distance <math>\gamma</math></b>	0.3
<b>Smoothing factor <math>\sigma</math></b>	1
<b>Offset term <math>\eta</math></b>	0.1

The following figure displays the experiment's findings:

Fig. 11. Path planning of the fusion obstacle avoidance ability A\* algorithm.

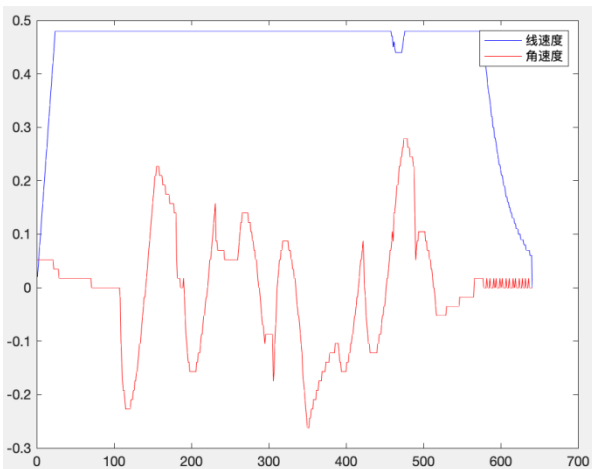

Fig. 12. The speed change diagram of the smart car.

Fig. 13. The attitude angle change diagram of the smart car.

Through the analysis of Fig. 11, 12, and 13, we can conclude that for static obstacles that appear on the global planning path, when the distance between the smart car and the obstacle exceeds the calibration value, the car can change the angular velocity, thereby affecting the attitude angle. Realize

automatic obstacle avoidance. When facing a dynamic obstacle, the car slows down, changes the angular velocity value, and greatly changes the attitude angle, so as not to more violent collision with the unstable obstruction. The route routing efficiency metrics for the A\* approach when combined with the DWA technique is shown in Table IV.

TABLE IV. PATH PLANNING COMPARISON TABLE

	Number of inflection points	Path length	Planning time
Global planning path	1	29.85	11.28
Final path	0	38.60	60.50

From this, it is evident that, compared with the global route diagram drawn via the improved A\* algorithm, the path integrated with the DWA algorithm has a higher smoothness and is more suitable for the actual production and living environment when the path length is not much different. The path realizes the optimal global path and excellent obstacle avoidance ability of the intelligent logistics vehicle.

### C. Improved Algorithm Compared with Other Algorithms

The ancient route technique known as the "ant colonies program" was created by summarizing how ants forage in the wild [21-27]. The selection basis is that the shorter route has higher pheromone concentration along the route, which guides other ants to forage along the route and forms positive feedback to obtain the shortest route to find food. The ant colony algorithm can also provide global route scheduling for the fusion algorithm. The path planning of the ant colony algorithm in a complex setting (environment 2) is shown in Fig. 14:

Fig. 14. Ant colony algorithm planning global path.

The path planning comparison table is shown in Table V:

TABLE V. PATH PLANNING COMPARISON TABLE OF IMPROVED A\* ALGORITHM AND ANT COLONY ALGORITHM

	Path length	Vertices	Planning time
Improved A* algorithm	29.85	10	11.03
Ant Colony Algorithm	32.04	9	12.08

From the above Table V, we can analyze that throughout the procedure of developing a global route, the ant colony scheme has the disadvantages of obliquely crossing the obstacle vertices, insufficient smoothness of the intended route, and long path length. By comparison, the high smoothness and low route size of the enhanced A\* algorithm in global scheduling is proved again.

## VI. CONCLUSION AND FUTURE WORK

Focusing on dynamic obstacle-avoiding route scheduling problems for storing robotics, the study put forward an A\* route scheduling algorithm integrated with the DWA obstacle avoidance algorithm. Fitting greatly optimizes the path smoothness and path length of the global path planning, and realizes planning a better route in a shorter time. By integrating the DWA algorithm, it realizes automatic avoidance of static and dynamic obstacles on the planned path, improves the flexibility and the method's effectiveness at finding results in complex environments, and makes up for the shortcomings of the A\* algorithm that cannot achieve dynamic obstacle avoidance.

Through MATLAB simulation experimental results, the efficacy of the enhanced method suggested in this investigation is verified in terms of route smoothness and the capacity to prevent obstacles. However, the more advanced method still has the problems of long planning time and poor adaptive proficiency of the integration technique. These are the routes for further research on the path planning of smart cars.

## VII. FUTURE WORK DIRECTIONS

In our future research work, we elaborate on an efficient global planning algorithm that can be designed and can be real-time used in different real-world environments and achieve the good goal of reducing the planning time by 80% based on the current method.

## VIII. FUNDING STATEMENT

This research is supported by the Shandong Provincial Undergraduate Teaching Reform Project (Grant Number: Z2021450) & the Shandong Provincial Natural Science Foundation of P.R China (Grant Number: ZR2020QF069).

## ACKNOWLEDGMENT

The authors are grateful to the anonymous referees for their insightful comments and suggestions and Chinese authors are also very thankful to Mohammad Ali Jinnah University (MAJU), Karachi, Sindh, Pakistan who supported us in this research work.

## CONFLICTS OF INTEREST

The authors declare that they have no conflicts of interest to report regarding the present research paper.

# Advances in Machine Learning and Explainable Artificial Intelligence for Depression Prediction

Haewon Byeon

Department of Medical Big Data, College of AI Convergence, Inje University,  
Gimhae 50834, Gyeongsangnamdo, South Korea

**Abstract**—There is a growing interest in applying AI technology in the field of mental health, particularly as an alternative to complement the limitations of human analysis, judgment, and accessibility in mental health assessments and treatments. The current mental health treatment service faces a gap in which individuals who need help are not receiving it due to negative perceptions of mental health treatment, lack of professional manpower, and physical accessibility limitations. To overcome these difficulties, there is a growing need for a new approach, and AI technology is being explored as a potential solution. Explainable artificial intelligence (X-AI) with both accuracy and interpretability technology can help improve the accuracy of expert decision-making, increase the accessibility of mental health services, and solve the psychological problems of high-risk groups of depression. In this review, we examine the current use of X-AI technology in mental health assessments for depression. As a result of reviewing 6 studies that used X-AI to discriminate high-risk groups of depression, various algorithms such as SHAP (SHapley Additive exPlanations) and Local Interpretable Model-Agnostic Explanation (LIME) were used for predicting depression. In the field of psychiatry, such as predicting depression, it is crucial to ensure AI prediction justifications are clear and transparent. Therefore, ensuring interpretability of AI models will be important in future research.

**Keywords**—*Depression; LIME; Explainable artificial intelligence; Machine learning; SHAP*

## I. INTRODUCTION

Artificial Intelligence (AI) refers to computer technology that mimics human intelligence by using logical methods to reason, learn, and make decisions. With the advancement of AI technologies such as machine learning, deep learning, and natural language processing, this technology is being applied not only in professional fields but also in our daily lives. For instance, virtual assistants such as Apple's Siri, Samsung's Bixby, and Google's Assistant use natural language processing technology to provide convenience to our lives [1].

There is a growing interest in applying AI technology in the field of mental health, particularly as an alternative to complement the limitations of human analysis, judgment, and accessibility in mental health assessments and treatments [2,3]. Traditional mental health assessments rely heavily on the subjective self-reports and interviews of patients, leading to potential inaccuracies in expert decision-making [4,5]. The misdiagnosis rate of mental health conditions (e.g. bipolar disorder) can be as high as 55~76% [6,7], even among experts

who have difficulty grasping the symptoms and information not reported by the patient.

The current mental health treatment service faces a gap where people who need help do not receive it due to negative perceptions of mental health treatment, lack of professional manpower and physical accessibility limitations [8,9,10]. There is a growing need for a new approach to overcome these difficulties, and AI technology is being explored as a potential solution.

In particular, explainable artificial intelligence (X-AI) with both accuracy and interpretability technology can help improve the accuracy of expert decision-making, increase the accessibility of mental health services, and solve the psychological problems of high-risk groups of depression [11]. In this mini-review, we examine the current use of X-AI technology in mental health assessments for depression. Additionally, we discuss the measures and limitations of applying AI to mental health services.

## II. MATERIALS AND METHODS

### A. Artificial Intelligence and Machine Learning in Depressive Disorder

Depressive Disorder is a severe psychiatric disorder that results in functional impairment [12]. Currently, the diagnosis of depressive disorder relies on the identification of a minimum number of core symptoms that cause functional impairment over a certain period of time [12]. However, this symptom-based approach can lead to diagnostic discrepancies and make it challenging to interpret the results of additional studies, such as genetic studies, neuroimaging studies, and postmortem studies.

The early detection and diagnosis of subtle clinical signs in depressive disorder require highly skilled professionals working in specialized mental health services. Hence, using more objective and reliable techniques, such as neuroimaging techniques, can aid in early detection. Machine learning has the potential to make accurate diagnoses and predict the response to treatment, beyond the conventional method of comparative analysis between a patient group and a normal control group.

Artificial intelligence was first introduced at the Dartmouth Conference in 1956 by Professor John McCarthy of Dartmouth University in the US [13]. At the technological level, it refers to Narrow Artificial Intelligence (NAI), which can perform certain tasks with better-than-human capabilities [14]. Machine

learning is a specific approach to implementing AI, in which a computer learns how to perform a task through an algorithm, rather than having specific decision criteria inputted directly by humans. In this process, defining appropriate features is critical to machine learning, and various algorithms, such as the Support Vector Machine, Gaussian Process Classifier, Linear Discriminant Analysis, and Decision Tree are used.

Deep learning, a branch of machine learning, goes further by using given data as input [15]. This end-to-end machine learning reduces errors that can occur due to human intervention, but the quality and quantity of data provided for learning is becoming increasingly important [13]. Therefore, obtaining high quality data for AI learning is becoming more important than the algorithms used.

**B. Advances in Machine Learning in Neuroimaging**

Brain imaging studies can be classified into structural and functional studies. Various studies have reported the use of machine learning techniques to predict the onset of depression. Conventional structural brain imaging studies, which compare patients with major depressive disorder (MDD) and healthy controls, often use T1-weighted images, which provide high contrast between gray matter and white matter, allowing for more accurate viewing of gray matter regions that make up the cortex. However, MDD is a complex disorder with diverse symptoms, and neuroanatomical abnormalities in MDD are not limited to morphological changes in a single local area. T2-weighted imaging and diffusion tensor images are other neuroimaging techniques used to study structure. Meanwhile, functional aspects can be studied using fMRI (functional Magnetic Resonance Imaging). There are various methods used in fMRI research to predict the diagnosis of depression, such as task-related fMRI and resting fMRI. However, studies [16,17,18] on discrimination of depression using neuroimaging techniques have shown accuracy errors that vary based on sample size. Flint et al. (2021)[16] found that a study with a small sample size (n = 20) demonstrated higher accuracy than one with a medium sample size (n = 100), while a study with a large sample size (n = 1,868) showed an accuracy of only 61%. The authors emphasized the importance of considering the impact of test set size on systematic misestimation and why an overestimation effect may occur. Therefore, researchers should not disregard their models solely based on low training data, instead they should test the models on a larger set of data to assess its performance if it exhibits good results.

**C. Advances in Machine Learning in Psychological Assessment**

Depression is diagnosed through a structured interview, which sets it apart from many other diseases. The Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (published by the American Psychiatric Association)[19] provides diagnostic criteria that are widely used across the globe. These criteria are updated periodically by the APA. One of the main features of these criteria is that they rely solely on interviews with patients and psychological assessments. For instance, Table I displays the diagnostic criteria for major depressive disorder.

TABLE I. INSTANCE OF CRITERIA FOR MAJOR DEPRESSIVE DISORDER IN THE DSM-5

Criteria	
A	If five (or more) of the following symptoms persist for two consecutive weeks and show a change from previous functional status, at least one of the symptoms must be (1) depressed mood or (2) loss of interest or pleasure. Note that symptoms due to other apparent medical conditions should not be included
1	Depressed mood most of the day and nearly every day, subjectively reported (e.g., feeling sad, empty, or hopeless) or objectively observed (e.g., tearing); note that in children and adolescents, it may present as irritable mood.
2	Significantly diminished interest or pleasure in almost all of the usual activities nearly every day.
3	Significant weight loss (e.g., weight change of 5% or more in one month) or weight gain, or decrease or increase in appetite almost every day, without weight control; note that in children, weight gain should not exceed expectations.
4	Insomnia or hypersomnia nearly every day.
5	Psychomotor agitation or retardation nearly every day, observed objectively, not just subjective feelings of restlessness or stagnation.
6	Fatigue or loss of energy nearly every day.
7	Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) almost every day, not just remorse or guilt.
8	Decreased ability to think or concentrate, or indecisiveness nearly every day, either subjectively or objectively observable.
9	Recurrent thoughts of death (not just fear of dying), recurrent suicidal thoughts without a specific plan, or a suicide attempt or specific plan to commit suicide.

This definition of major depressive disorder makes it difficult to properly differentiate whether someone is exaggerating their symptoms using these criteria or, conversely, minimizing symptoms to avoid social stigma and prejudice as a person with a mental illness [12]. Furthermore, many risk indicators for depression have been presented through numerous studies so far, but no single risk indicator can accurately diagnose or classify depression [20,21]. This is because depression is not caused by a single factor but develops through various genetic and environmental interactions. Therefore, in order to diagnose depression clearly, it is necessary to consider the importance and influence of various risk factors in one model, which should include not only the results of face-to-face counseling but also various environmental and biological results. To overcome these limitations, several studies [22,23,24] have attempted to predict depressive disorder using machine learning.

**D. Limitations of Machine Learning in Diagnosis**

Studies on machine learning in the diagnosis of depressive disorder [22,23,24] have been ongoing for more than 10 years, and accuracy, sensitivity, and specificity are used to evaluate these models. Accuracy has been reported to range from the high 60% to the mid-80%, while sensitivity and specificity have been reported to be in the high 70-80% range. However, when applying machine learning theories to actual clinical practice, several problems arise that prevent its application, such as the heterogeneity of various image data, which arises from data collection, acquisition parameters, and post-processing methods. This makes it challenging to generalize the results to other data and compare.

**E. Advancement of Decision Tree-based Ensemble Model Techniques for Depression Prediction and SHAP**

As a result of the efforts of many researchers to create ML models with high accuracy and reproducibility over the past decade, ML models have evolved into ensemble and boosting models, as follows.

**F. Random Forest**

The random forest algorithm is a machine learning methodology that predicts by deriving several decision tree algorithms. The decision tree algorithm is an analysis technique that models relationships and rules of data and does not require assumptions of linearity, normality, and equal variance [25]. Random forest derives several such decision trees and synthesizes the results. Random forest randomly selects training data and independent variables when creating each decision tree to make predictions. Although individual accuracy may be low, all decision trees are aggregated and predicted. It has the advantage of increasing accuracy and stability because it performs side-by-side measurement [26]. In other words, the random forest randomly selects N independent variables and creates T decision tree algorithms that randomly select data and use the most derived value or average value as the predicted value based on the majority rule. The concept of a random forest is illustrated in Fig. 1.

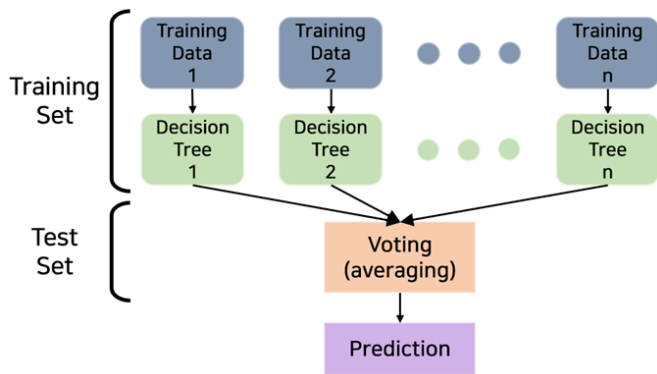

Fig. 1. The concept of a random forest.

**G. Extreme Gradient Boosting: XGBoost**

The boosting technique is an ensemble technique that creates a weak learner using initial sample data and iteratively adds new learners in the direction of reducing the error of the learning result. In particular, gradient boosting is an algorithm that continues to add new models that predict the residuals of previous learners [27]. However, it has the disadvantage of slow learning and overfitting. XGBoost is an algorithm that compensates for these drawbacks. The concept of XGBoost is shown in Fig. 2.

Introduced by Tianqi Chen in August 2016, XGBoost is a decision tree-based machine learning algorithm that uses a gradient boosting structure. It creates an optimized model that prevents overfitting while minimizing training loss through parallel processing, missing value processing, and regularization [28].

Fig. 2. The concept of XGBoost.

**H. Light Gradient Boosting Machine: LightGBM**

LightGBM is a fast and efficient GBDT (Gradient Boosting Decision Tree)-based algorithm designed by Microsoft MSRA (Microsoft Research Lab Asia) in 2016 [29]. Existing GBDT-based algorithms have a problem in that they do not perform well in large amounts of high-dimensional data because they have to scan all of the data to evaluate the information gain for all possible split points. Here, information gain refers to better discriminating data by selecting a certain attribute. LightGBM solved the problem by introducing two techniques, Gradient-based One-Side Sampling (GOSS) and Exclusive FeatureBundling (EFB) techniques.

In GBDT, data attributes with large gradients play a larger role in information gain. Therefore, GOSS is a technology that maintains data attributes with a large gradient and randomly removes data attributes with a small gradient with a certain probability. EFB is a technique for grouping mutually exclusive variables according to the characteristics of a sparse variable space to reduce the number of variables [30]. In other words, LightGBM uses this technology to reduce usage and achieve fast training speed. The concept of LightGBM is illustrated in Fig. 3.

Fig. 3. The concept of LightGBM.

**I. Categorical Boosting: CatBoost**

The CatBoost algorithm is an ordered boosting technique that focuses on preprocessing categorical variables and solving overfitting problems [31]. Unlike conventional boosting models that sequentially learn all residual errors, ordered boosting creates a model by calculating residual errors with some data. After that, the technique calculates the residual error of the remaining data through the corresponding model.

In addition, overfitting is prevented by mixing the order of data through random permutation in sequential boosting. The CatBoost algorithm improves training speed through variable combinations that combine variables with the same information gain. Furthermore, unlike other ensemble algorithms that use Grid Search or Randomized Search to find the optimal hyperparameter, it optimizes the initial hyperparameter value, so the parameter adjustment procedure is unnecessary.

### J. Explainable Artificial Intelligence (XAI)

Explainable artificial intelligence (XAI) refers to helping users understand the results by explaining the outcomes predicted by artificial intelligence. This makes it possible to identify the main factors influencing the result, understand the basis of the decision based on the prediction result of the machine learning model, and provide an intuitive explanation that humans can comprehend about the prediction result [32].

### K. Local Interpretable Model-Agnostic Explanation (LIME)

LIME is a technique that uses combinations of masking or non-masking of superpixels, which are regions of interest in an image that contain important information. The goal is to create an interpretable model that checks the importance of each superpixel in the prediction of a black box model. For example, if an image is classified as a frog, LIME can help us understand why by cutting the image into explanatory units and creating multiple masked and non-masked versions of each unit. We then input these images into the black box model to determine the probability that each one is classified as a frog.

To interpret the results, we train a surrogate model that takes the number of masking cases as input values and the corresponding probabilities as output values. This model can show intuitive results and requires fewer resources than other techniques. Additionally, LIME is model-agnostic, which means it can be applied regardless of the machine learning model used.

However, LIME has some disadvantages. One is that the method used to determine the decision boundary of the model is non-deterministic, meaning that the output value may be different each time it is called. Another is that since LIME only considers one data point at a time, it may not provide a complete explanation of the entire model. The concept of LIME is shown in Fig. 4.

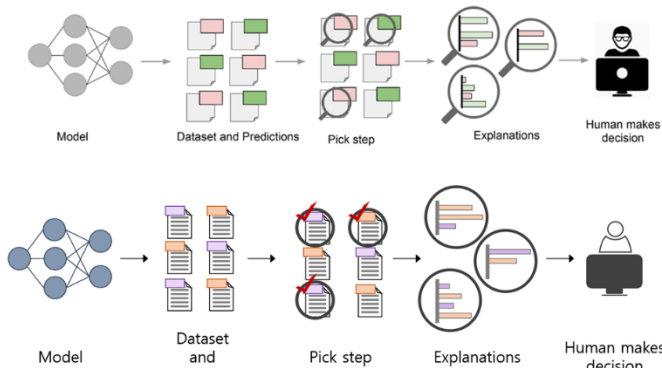

Fig. 4. The concept of LIME.

### L. Shapley Additive exPlanations (SHAP)

SHAP is an algorithm based on Shapley Values from game theory used to describe the output of a machine learning model. The Shapley value is a value obtained through the average change according to the presence or absence of a variable after constructing a combination of several variables to determine the importance of one variable [33]. An explainable model is created based on the training data and the learned model, and the Shapley value, which expresses the influence on the prediction result in terms of direction and magnitude, is calculated for the newly input data. Through this, the technique explains the contribution that the input variable has on the output value of the learned model.

Existing feature importance techniques use a permutation method to measure the effect of a variable on a model. This method has the advantage of high computational speed, but results may be distorted when variables are dependent on each other. Also, the negative (-) influence cannot be calculated, so the value of a specific variable may be set higher than its actual influence. On the other hand, the SHAP technique considers the possibility that variables affect each other and can calculate the negative (-) influence. Although it has the disadvantage of being slow, it can be seen as measuring the influence more accurately than the variable importance method [34]. The concept of SHAP is shown in Fig. 5.

Fig. 5. The concept of SHAP.

### M. Studies of Predicting Depression based on XAI

Explainable machine learning is a relatively new field that aims to make machine learning models and their decisions more understandable and transparent. This is especially important when making decisions that could negatively impact people's lives, such as diagnosing depression. Several studies have reported that depression was predicted using SHAP, one of the techniques of X-AI (Table II). For instance, Matthew et al. (2021)[35] propose a framework for explainable machine learning called SHAP (SHapley Additive exPlanations) that can identify depressive symptoms from social media posts. SHAP is a method that assigns importance values to each feature in a model based on how much they contribute to the prediction. The framework uses natural language processing and sentiment analysis to extract features and provide explanations for the predictions. The authors assessed the model's performance on a held-out test set and found an AUC of 0.73 (sensitivity: 0.66, specificity: 0.7) and 0.67 (sensitivity: 0.55, specificity: 0.7) for GAD and MDD, respectively. Additionally, the authors used advanced techniques such as SHAP values to illuminate which features had the greatest impact on prediction for each disease.

TABLE II. SUMMARY OF X-AI STUDIES

Article	Data	Models /Algorithms	Results
Nguyen and Byeon (2022)[32]	36,000 depression participants over 60 years old	Deep neural network, LIME	Accuracy=89.92%, Precision=93.55%, Recall=97.32%
Matthew et al. (2021)[35]	4,184 undergraduate students	Natural language processing, sentiment analysis, SHAP	GAD: AUC=0.73 (sensitivity: 0.66, specificity: 0.7) MDD: AUC=0.67 (sensitivity: 0.55, specificity: 0.7)
Hueniken et al. (2021)[36]	Canadian adults (aged $\geq 18$ years, N=6021) who completed web-based surveys	Random forest, gradient boosting, support vector machine, and neural network, SHAP	Average accuracy of 85% and 88% 3 most important items predicting elevated emotional distress: increased worries about finances (SHAP=0.17), worries about getting COVID-19 (SHAP=0.17), and younger age (SHAP=0.13)
Amit et al. (2021)[37]	266,544 UK women who gave birth between 2000 and 2017	Gradient tree boosting algorithm based on SHAP	Postpartum depression: AUC=0.805 to 0.844 Sensitivity=0.72 to 0.76 Specificity=0.80
Hochman et al. (2021)[38]	A nationwide longitudinal cohort that included 214,359 births between January 2008 and December 2015	Gradient-boosted decision tree algorithm	Postpartum depression AUC=0.712 Sensitivity=0.349 Specificity of 0.905
Uddin et al. (2022)[39]	Large text-based dataset from a public Norwegian information website: ung.no. (11,807 and 21,470 posts of different length)	LSTM (Long Short-Term Memory), RNN (Recurrent Neural Network), LIME	Depression Accuracy=84.2%

### III. RESULTS AND DISCUSSION

Hueniken et al. (2021) [36] used machine learning methods to identify factors associated with anxiety and depression among Canadian adults during 8 months of the COVID-19 pandemic. The study analyzed data from repeated cross-sectional surveys conducted by Statistics Canada between May 2020 and December 2020, involving 6,021 respondents. Authors applied four machine learning algorithms (random forest, gradient boosting, support vector machine, and neural network) to predict anxiety and depression scores based on demographic, economic, lifestyle, and health risk variables [36]. Authors found that machine learning models performed well in predicting anxiety and depression scores, with an

average accuracy of 85% and 88%, respectively [36]. Authors also identified several important predictors of anxiety and depression, including age, gender, income level, employment status, physical activity level, chronic conditions, and perceived health risk related to COVID-19 infection or vaccination.

The study by Amit et al. (2021)[37] aimed to predict the risk of postpartum depression (PPD) using machine learning and electronic health records (EHR) data from primary care. PPD is a common disorder that affects mothers and their newborns. The study used data from 266,544 UK women who gave birth between 2000 and 2017 and had at least one visit to their primary care physician within a year after delivery. The machine learning algorithm used in this study was a gradient tree boosting algorithm based on SHAP. According to the findings, incorporating EHR-based forecasting with EPDS score enhanced the area under the receiver operating characteristic curve (AUC) from 0.805 to 0.844, as well as increased the sensitivity from 0.72 to 0.76 while retaining a specificity of 0.80. The study demonstrates the feasibility and value of using SHAP-based machine learning and EHR data for estimating PPD risk and improving screening and early intervention.

Hochman et al. (2021) [38] conducted a study to create and validate a model using machine learning to predict postpartum depression (PPD). The research analyzed data from a national cohort of Israeli women who gave birth between 2008 and 2015 and had a psychiatric diagnosis or prescription within a year after delivery. EHR-derived sociodemographic, clinical, and obstetric features were used with a gradient-boosted decision tree algorithm to develop the prediction model. The model's accuracy was assessed in the validation set, achieving an AUC of 0.712, with a sensitivity of 0.349 and a specificity of 0.905 at the 90th percentile risk threshold. The model identified PPDs more than three times higher than the overall set, with positive and negative predictive values of 0.074 and 0.985, respectively. The study revealed that both recognized (e.g., past depression) and less-recognized (differing patterns of blood tests) PPD risk factors were strong predictors in the model. The research demonstrated the usefulness of machine learning-based models in predicting PPD using large-scale cohort data with high accuracy.

Several studies [32, 39] have developed X-AI models to predict depression using LIME. Uddin et al. (2022) [39] developed an interpretable machine learning model that can predict depression from multi-modal data, such as speech, text, and facial expressions. The model used attention mechanisms and feature importance scores to provide insights into the factors influencing depression. Furthermore, as the attributes utilized by the system are grounded on the probable indications of depression, the system could produce purposeful justifications of the verdicts from machine learning algorithms through the use of an interpretable artificial intelligence technique named LIME. The accuracy of the developed depression prediction model was 84.2%.

Nguyen and Byeon (2022) [32] utilized a deep neural network (DNN) model to make predictions about depression in elderly individuals during the pandemic. They focused on

social factors related to stress, health status, daily changes, and physical distancing as potential predictors. To obtain data, they used the 2020 Community Health Survey of the Republic of Korea, which included more than 97,000 participants over 60 years old. After cleansing the data, the DNN model was trained on information from over 36,000 participants and 22 variables. The researchers also integrated the DNN model with a LIME-based model to make the predictions more explainable. The study found that the model achieved an accuracy of 89.92% and had high precision (93.55%) and recall (97.32%) scores, indicating its effectiveness. The researchers highlighted the potential of this explanatory DNN model in identifying elderly patients who require early treatment due to the increased likelihood of depression caused by the pandemic.

Taken together, X-AI such as SHAP and LIME have been reported to be effective in predicting depression in several previous studies. However, the predictive performance of machine learning techniques varies across studies due to differences in data imbalance (particularly in the Y variable), the nature of the features incorporated in the model, and how the outcome variable is measured. Therefore, while some studies have shown that X-AI-based machine learning algorithms perform well, additional studies are continually needed to verify the predictive performance of each algorithm since the results cannot be generalized to all data types.

#### IV. CONCLUSION

Models that are easy to interpret often have simple structures and lower accuracy, while models that are difficult to interpret typically have more complex structures and higher accuracy. In various fields, researchers are conducting studies to apply X-AI to models to ensure interpretability while using powerful learning algorithms with excellent predictive performance. In order to introduce AI into sensitive decisions such as medical diagnoses, and to support medical professionals in their decision-making, sufficient justification for AI results needs to be established. Particularly in the field of psychiatry, such as the prediction of depression, it is crucial to ensure that the justifications for AI predictions are clear and transparent. Therefore, ensuring the interpretability of AI models will be important in future research.

**Abstract**—Object detection has experienced a surge in interest due to its relevance in video analysis and image interpretation. Traditional object detection approaches relied on handcrafted features and shallow trainable algorithms, which limited their performance. However, the advancement of Deep learning (DL) has provided more powerful tools that can extract semantic, high-level, and deep features, addressing the shortcomings of previous systems. Deep Learning-based object detection models differ regarding network architecture, training techniques, and optimization functions. In this study, common generic designs for object detection and various modifications and tips to enhance detection performance have been investigated. Furthermore, future directions in object detection research, including advancements in Neural Network-based learning systems and the challenges have been discussed. In addition, comparative analysis based on performance parameters of various versions of YOLO approach for multiple object detection has been presented.

**Keywords**—Deep learning; neural networks; object detection; YOLO

## I. INTRODUCTION

Object detection involves the process of identifying the location of objects within an image (object localization) and assigning each object to its corresponding class (object classification) [1]. Commonly utilized techniques for object detection include frame difference, background subtraction, optical flow, and Hough transform [2], but they have limitations regarding accurate object detection. On the other hand, object recognition focuses on determining the presence of a specific object in visual data and often involves feature extraction [3].

Nowadays, object detection is applied in various fields such as face detection [4][5], mask detection for COVID-19 compliance [6], railway signal detection [7], and multiple object tracking for counting purposes. Many object detection methods are being developed from many years. Researchers are trying to come up with new methods which will be stable and give accurate results irrespective of the data size. The emergence of popular algorithms for object detection included R-CNN, Fast R-CNN, and Faster R-CNN. R-CNN was initially slow due to its inability to share processing, requiring a ConvNet forward pass for each proposed object [8]. To address this, spatial pyramid pooling networks (SPPNets) were introduced to accelerate R-CNN by enabling computation sharing. Subsequently, Fast R-CNN was developed, training the deep VGG16 network nine times faster than R-CNN, achieving a significantly faster testing speed (213 times faster), and higher Mean Average Precision (MAP) [9] applications requiring fast

and accurate object detection [10-13]. YOLO9000, an extension of YOLO, employs joint optimization of detection and classification to identify over 9000 object types in real time. This approach combines data from diverse sources such as ImageNet [14], [15] and COCO [16] using joint optimization techniques and Word Tree [17]. YOLO9000 significantly bridges the dataset size gap between detection and classification. [18]. YOLOv3, a combination of Darknet-19 and residual network technology, features 53 convolutional layers known as Darknet-53. YOLOv3 performs comparable to SSD variations regarding COCO's average mean average precision measure but is three times faster [19].

Real-time object detection functions enable widespread and cost-effective utilization of standard Graphics Processing Units (GPUs). While the most accurate neural networks currently available cannot operate in real-time and require multiple GPUs for training, YOLOv4 addresses these challenges. YOLOv4 is designed to run efficiently on a standard GPU in production systems, optimizing parallel calculations rather than relying solely on low computation volume theoretical indicators [20], [21]. This paper comprehensively reviews various object detection models and their evolutionary advancements. Due to the availability of lots of object detection algorithms, the question arises which is the better and most suitable for handling complex data and giving high accuracy.

The main objective of this study is to presents a detailed analysis of multiple object detection techniques using deep learning. The study is organized as follows: Section I provides introduction; Section II describes the related work. Experimental work is described in Section III. The results are analyzed and discussed in Section IV. Section V presents the conclusion of the article.

## II. RELATED WORK

In this section, the existing work based on multiple object detection techniques using deep learning has been reviewed [28]. On making a comparative study of YOLOv5 models' performance based on [31], [33], it has been observed that using YOLOv5 for object detection has gained significant popularity across diverse applications. In a prior study by P. Mishra et al., YOLOv5 was successfully employed to identify objects for agricultural monitoring [34]. The research showcased the proficiency of YOLOv5 in accurately detecting various elements such as crops, weeds, and other objects on large-scale agricultural landscapes. Another study by S. Gupta et al. utilized YOLOv5 for real-time object detection in surveillance videos, showing its efficiency and accuracy in

detecting multiple object classes [35]. These studies highlight the successful application of YOLOv5 in different domains even in detecting the more minor objects findings in the automobiles for which the YOLO5 [36] developed series

achieved a very good accuracy, indicating its versatility and performance. The network architecture and overview of YOLOv5 is shown in Fig. 1 and 2, respectively.

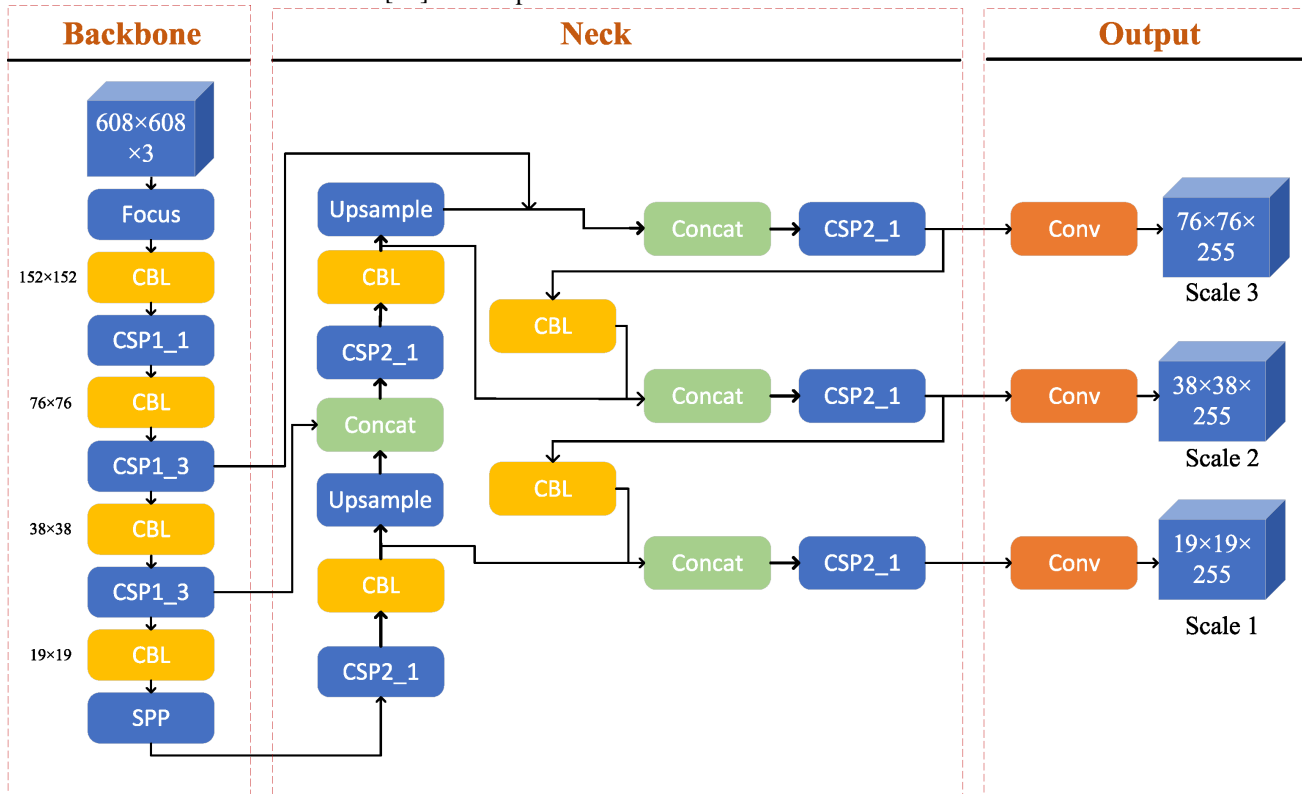

Fig. 1. The network architecture of YOLOv5. [25].

### Overview of YOLOv5

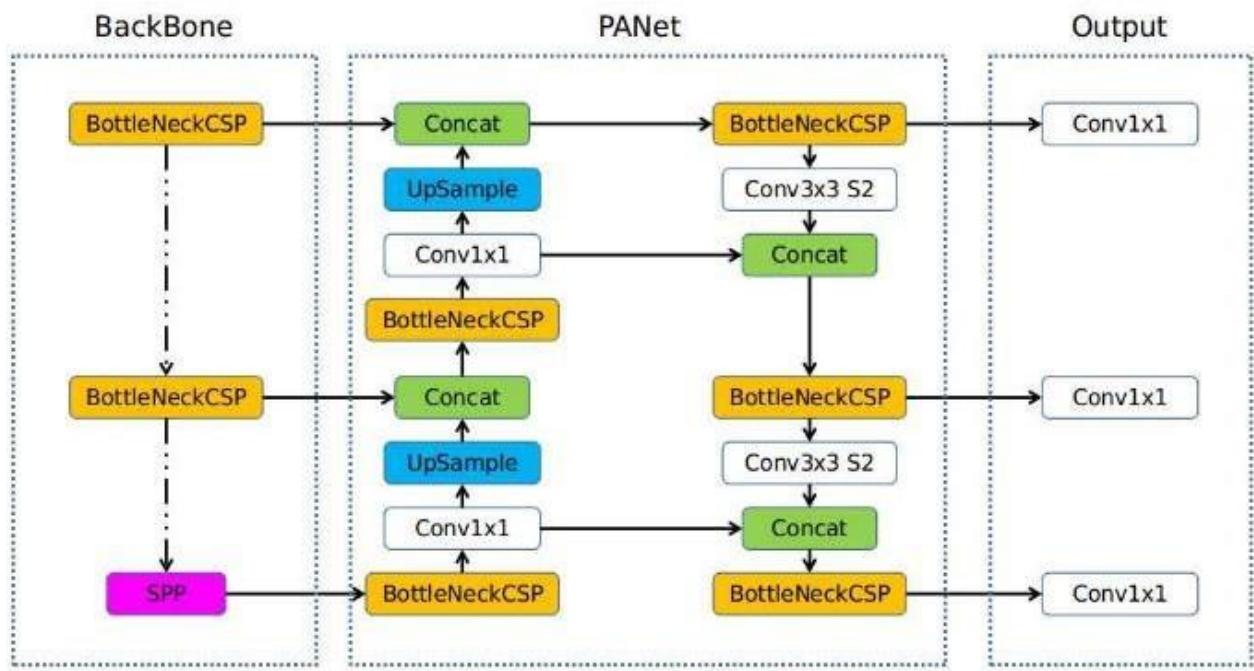

Fig. 2. The overview of YOLOv5. [26].

Data Annotation and Model Training with Roboflow, has been extensively used for data annotation and model training in various computer vision projects. In a study by L. Chen et al., Roboflow was employed to annotate images and train a YOLOv5 model for traffic sign detection [37]. The researchers leveraged the capabilities of Roboflow to generate accurate bounding box annotations, resulting in an exact and efficient traffic sign detection system. Additionally, a study by M. Rodriguez et al. utilized Roboflow for annotating medical images and training a YOLOv5-based model to detect abnormalities in lung X-rays [38]. These examples demonstrate the successful integration of Roboflow in diverse applications, emphasizing its role in facilitating data annotation and model training pipelines and in medical one of its standard applications, is detecting the Lung nodule using YOLO5 [39].

**Object Detection in Unconstrained Environments:** Object detection in unconstrained environments has been a challenging task. Previous work has leveraged YOLOv5 and Roboflow to address this challenge. In a study, YOLOv5 was used for Outdoor Navigation System for Visually Impaired People [40], [41]. Combining YOLOv5's real-time detection capabilities and Roboflow's efficient data annotation and model training workflow enabled accurate and timely object detection in dynamic environments. This work demonstrates the potential of using YOLOv5 and Roboflow in real-world scenarios with complex backgrounds and varying lighting conditions.

**Object Detection for Robotics Applications:** YOLOv5 and Roboflow have also found applications in robotics. In a research project by A. Kumar et al., YOLOv5 and Roboflow were employed for object detection in an autonomous drone system [42]. The combination of YOLOv5's fast inference speed and Roboflow's annotation capabilities allowed the drone to detect and track objects in real time, enabling autonomous navigation and interaction with the environment. This study showcases the integration of YOLOv5 and Roboflow in robotics applications, highlighting their potential for enhancing situational awareness and decision-making capabilities. These examples demonstrate the successful utilization of YOLOv5 and Roboflow in various domains, including aerial monitoring, surveillance, unconstrained environments, and robotics. The combination of YOLOv5's real-time object detection capabilities and Roboflow's annotation and model training platform has proven effective in achieving accurate and efficient object detection systems. With the improvement of the YOLOv5 framework, YOLOv6 has been developed for which a customized quantization method is introduced. The latest version of YOLOv6s demonstrates improved mean Average Precision (MAP) compared to all previous iterations of YOLOv5. Additionally, it achieves approximately twice the inference speed [43]. Roboflow for annotation and data management has streamlined the preprocessing stage, ensuring the availability of adequately labeled training data for training object detection system. This has significantly contributed to the development process by expediting the annotation process and allowing more focus on the algorithmic aspects of the system. Furthermore, keeping up-to-date with the latest research papers in the field of object detection, including YOLOv7 [44], [55].

**Deep Learning-based Object Detection:** Deep learning has revolutionized the field of computer vision, enabling highly accurate object detection. The seminal work by R. Girshick et al. introduced the R-CNN (Region-based Convolutional Neural Networks) framework [45], laying the foundation for subsequent advancements. Numerous variants, such as Fast R-CNN [46], Faster R-CNN [47], and Mask R-CNN [48], have been proposed to improve detection accuracy and processing speed. These methods have significantly influenced the development of stick-based object detection system. **Single-Shot Object Detection:** Single-shot object detection algorithms have gained popularity due to their real-time processing capabilities. Among them, YOLO family of models [49] has achieved remarkable performance. YOLO models detect objects in a single pass through the Neural Network, making them suitable for resource-constrained environments. It can be observed from literature that YOLO effectively used for object detection.

**Mobile object detection** aims to enable object detection on mobile devices with limited computational resources. MobileNet [50], is a lightweight deep neural network architecture specifically designed for mobile applications. Its efficient design and small memory footprint make it ideal for real-time object detection on low-power devices. The concepts underlying MobileNet have influenced the development of stick-based object detection system. Contextual object detection methods utilize contextual information to improve detection accuracy. Context R-CNN [51] incorporates context reasoning into the detection pipeline, leveraging the relationship between objects and their surrounding context. Stick-based object detection system also considers contextual cues to enhance object identification and classification.

**Focal Loss for Dense Object Detection:** They claim that the main barrier stopping one-stage object detectors from outperforming top-performing, two-stage techniques, including Faster R-CNN versions, is class imbalance. They developed the focused loss, which adds a modulating term to the cross-entropy loss, to focus learning on challenging examples and de-weight the many obvious negatives [52] and PointRCNN [53]. These methods leverage multi-scale feature MAPs and anchor-based strategies to improve detection performance in challenging scenarios. Stick-based object detection system integrates similar strategies to handle unconstrained environments effectively.

**Sensor-Based Object Detection:** Object detection approaches based on sensors use data captured by diverse sensors, including LiDAR, radar, and cameras, to identify and track objects. LiDAR-based methods, such as Point RCNN [54] and PIXOR [55], leverage 3D point cloud data for accurate object localization. Although primarily based on visual information, stick-based object detection systems can benefit from incorporating sensor fusion techniques to enhance detection accuracy.

### III. METHODOLOGY

The methodology below explains the object detection process using the base model as YOLOv5. Fig. 3 depicted the block diagram of object detection procedure.

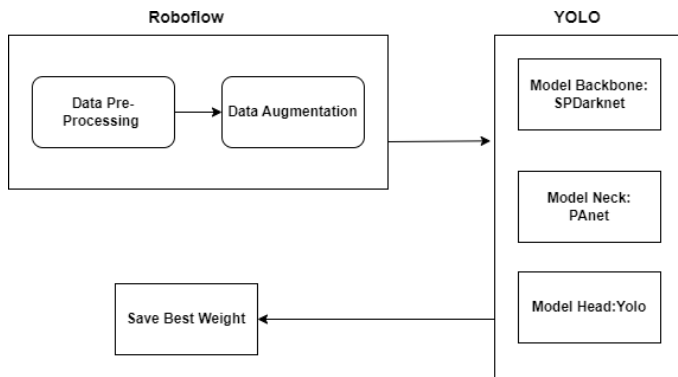

Fig. 3. Block diagram of object detection system.

#### A. Preprocessing

Roboflow has been used for Data preprocessing and data augmentation.

- It provides a platform for better data collection, pre-processing, and model training techniques.
- It can handle a variety of different annotation formats.
- The pre-processing of data includes resizing, image orientations, contrasting, and data augmentations.
- There are choices for model deployment and visualization, spanning the whole state-of-the-art.

1) *Noise*: Adding noise to a hazy photograph might help it to stand out. The picture seems to be made up of white and black dots when "salt and pepper noise" is applied.

2) *Crop*: An area of the image is picked, cropped, and resized to its original size.

3) *Flip*: Horizontally and vertically; the picture is flipped: The pixels are rearranged while the picture's characteristics are preserved when the image is flipped.

4) *Rotation*: The picture is rotated by a degree ranging from 0 to 360 degrees. Each rotated image will be different in the model. Each rotated image will be different in the model. The picture's brightness changes, resulting in a darker or brighter image. This technique allows the model to recognize photos in various illumination situations.

5) *Blur*: The image quality will vary because photographs come from various sources. Some images will be of outstanding quality, while others will undoubtedly be of terrible quality. In these circumstances, blur the original photographs, making model more resistant to the image quality used in the test data.

6) *Shear*: Shearing is rotating an image along a central axis to add or remove discriminating points. Typically, it is used to magnify images so that computers may understand how different viewpoints affect how things are perceived.

7) *Bounding boxes*: Bounding boxes are rectangles defining the boundaries of photograph items. Bounding boxes can be annotated in a variety of ways. The bounding box coordinates are represented differently in each format [22].

8) *Exposure*: Exposure refers to the quantity of light that

reaches your camera's sensor over some time, resulting in visual data. It could be a second or several hours.

9) *Model Utilized*: Three main vital parts of YOLOv5 are as follows:

a) *Model Backbone*: Model Backbone's primary goal is to extract essential features from an image. In YOLOv5, the CSPNet [23] backbone is used to extract a wealth of valuable characteristics from an input image.

b) *Model Neck*: Model Neck is preferable while developing feature strategies. Models can generalize their object marking and scaling using feature extractions. Recognizing the same object in various scales, marks, and shapes is helpful. The neck in YOLOv5 uses PANet to build feature pyramids.

c) *Model Head*: In YOLO, the detection process incorporates the Head component of the model, responsible for the final stage. Following the application of anchor boxes to the extracted features, the Head component further contributes to the detection process. Generated output vectors represent the final results of the detection process. The heads of the YOLOv5 models follow a similar structure to those found in the v3 and v4 versions. YOLOv4 is the superior architecture from this perspective. It's worth mentioning that YOLOv4 is trained in the Ultralytics YOLOv3 repository (rather than the Darknet), which includes most of the training changes in the YOLOv5 repository, resulting in MAP increases.

YOLOv5 has notably impacted by transitioning the Darknet research framework to the PyTorch framework. The Darknet framework, predominantly coded in C, offers meticulous control over the network's operations. Developed in the C language, Darknet grants extensive control over network activities. This low-level control is beneficial for research in several aspects. However, incorporating new research findings becomes more challenging as each addition requires custom gradient computations [24].

#### B. Data Augmentation Approach

While training the batch YOLOv5 use a data loader that helps add data online with each set. Data loader performs scaling, mosaic augmentation, and color space. Mosaic data augmentation, for example, mixes four photos into four random-ratio tiles. Mosaic augmentation allows the model to learn to deal with "small object problems" in which the smaller items are not detected correctly compared to more significant objects. Thus, it is an effective method for object detection identification benchmark. It's not worth experimenting with the set of augmentations to maximize performance on a specific work that is wrathful. Pre-trained models abound in YOLOv5. The trade-off between model size and inference time separates them. The received picture is first run through the YOLOv5 algorithm. The real-time snapshot in this study is partitioned into matrix grids. The image may be divided into any number of grids as the image complexity changes. After the photos have been divided, each grid holding the item undergoes classification and localization. All of the grids are given a confidence score. Depending on whether the item is spotted or not, the confidence score and the bounding box for each grid will alter. Training techniques are just as crucial as the final performance of an

object detection system while being less talked about. Data augmentation alters the base training data to expose the model to more semantic variance than the training set alone.

#### IV. EXPERIMENTAL WORK

The procedure for the experiment began with the collection of data, followed by the training of the YOLO network, and finally the testing of the output with test photos. The network was designed to detect 106 class labels and performed annotations [27] of all the images of data. A sample dataset of multi-object detection and category-wise objects in the available dataset are shown in Fig. 4 and 5, respectively.

In the dataset, augmentation is performed and improved model performance which helped to increase the size and help to generalize the model. A function is lost. IOU is a popular target detection index. It is utilized to assess the positive and negative samples and, in most anchor, -based approaches to calculate the distance between the expected and actual locations.

The research paper introduces a proposed regression positioning loss, which considers multiple factors including

overlapping, area, center point distance, and aspect ratio. These factors play a vital role in calculating the loss for regression positioning and are deemed crucial in the proposed approach.

1) *Network output analysis:* The output must be viewed as a feature MAP or a vector onto which the features are being Mapped. If  $N$  = no of bounding boxes and  $C$  = no of classes the detector can detect, these  $N$  bounding boxes detect various objects. Fig. 6 graphs are the training loss and validation loss graphs auto-generated by Roboflow software. These graphs show the change in the loss function over training epochs or iterations. The training loss graph displays the loss on the training data, while the validation loss graph shows the loss on a separate validation dataset. These graphs help monitor the model's learning progress and identify potential overfitting or under fitting. Fig. 7 shows results obtained. Table I displays the accuracy percentages obtained for various class labels. It is evident that the swivel chair achieves the highest accuracy, while the class label exhibits the lowest accuracy when compared to the other class labels.

Fig. 4. Sample dataset of multi-object detection.

Fig. 5. Category-wise objects in the dataset.

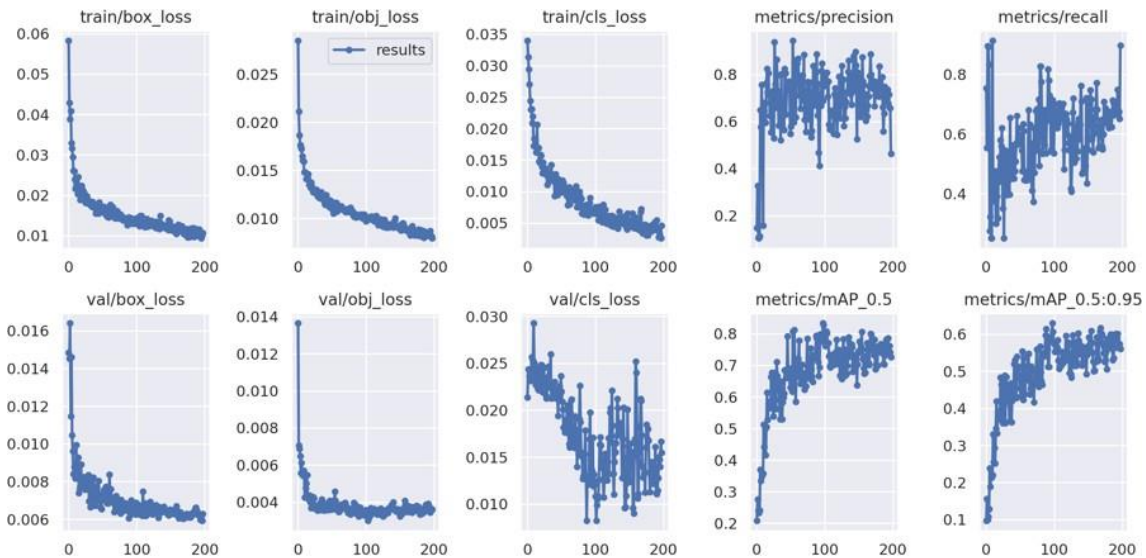

Fig. 6. Graph of performance parameter.

TABLE I. ACCURACIES OBTAINED FOR OUR DATASET CLASS LABELS

Class Labels	Accuracies
Swivel Chair	98%
Bed	95.3%
Cat	83.8%
Ambulance	79.2%
Man	76.5%
Dog	76.1%
Bus	74.2%

Fig. 7. Obtained results.

The existing research work on the comparisons of the object detection algorithm have been reviewed and presented. The comparison of various YOLO models and their accuracies is presented in Fig. 9. The test time is reduced by 15.6% compared to YOLOv3 due to YOLOv4's various improvements, which lead to the best detection results, as demonstrated above. Despite having fewer training

parameters than the YOLOv3-tiny model, the YOLOv4-tiny model's detection results are nonetheless accurate, are subpar. The detection effect is the worst of the models, only achieving 50.06%. The SPP module causes the YOLOv3-SPP3 model's performance to be slightly better than the YOLOv3 but noticeably worse than the YOLOv4. Fig. 8 depicts the YOLO classification loss, the loss compares the predicted class probabilities with the ground truth labels for each object in the image, the loss is being compared between YOLO and Faster R-CNN. Faster R-CNN is better than YOLOv5 in terms of accuracy with approximately 10 times higher inference rate [29]. This optimization occurs by utilizing backpropagation and gradient descent techniques to update the network parameters. To achieve optimal performance, the weights assigned to each loss component can be adjusted to balance their contributions within the overall loss function. Comparative analysis of various YOLO versions for rural road, urban road, and highways image dataset of sample size 120000, 124000, 150000 respectively [30] the Yolov3 has good precession with bad recall and F measure, and with low mAP, FPS. On the other hand, YOLOv4 and YOLOv5 have stable scores in terms of precision and MAP. YOLOv5 outperforms in terms of speed of the algorithm, and precision as compared to YOLOv3, and YOLOv4 [30]. The comparative analysis of YOLO versions for urban road dataset is provided in Fig. 9.

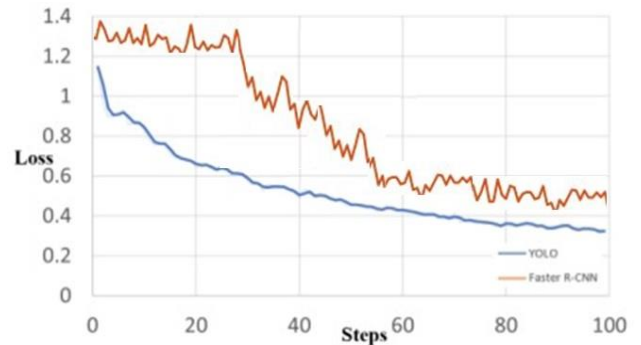

Fig. 8. YOLO classification loss.

Fig. 9. Comparative analysis of YOLO versions.

In 2021 YOLO series was extended by introducing Yolox [32]. The series continues and the above of the mentioned models were created. Each model in the table above underwent 300 iterations of training. With the help of the ultralytics library's autobatch function, the micro groups' sizes were calculated. The YOLOv5s model's training took the least time. YOLOv5x training took the longest, lasting approximately nine hours, and was completed in under an hour. A comparative study of YOLOv5 is presented in Table II.

TABLE II. COMPARATIVE STUDY OF YOLOV5 VERSIONS DURING THE TESTING

Models	MAP	FPS	Parameters (M)	Test Time(s)
YOLOv3	76.55	35	61.5	122.23
YOLOv3-tiny	62.5	134	8.7	28.14
YOLOv3-SPP3	76.87	40	63.9	128.19
YOLOv4	87.48	72	27.6	103.86
YOLOv4-tiny	50.06	252	7.2	18.41

## V. CONCLUSION

In this study object detection algorithms and systems are analyzed based on their accuracy and the speed of detecting objects. It also observed that the accuracy and speed of object detection algorithms are improving daily. Fast R-CNN is an enhanced version of R-CNN that incorporates a selective search for generating Regions of Interest. In contrast, Faster R-CNN utilizes a Regional Proposal Network (RPN), contributing to its superior performance compared to Fast R-CNN. But the Faster R-CNN algorithm required many passes to extract all the objects from the single frame; this is where Single Shot Detector (SSD) came into the picture. Till the time when YOLO was not developed SSD was considered to be the best. YOLOv5 was designed in such a way that it can detect small objects also, especially in autonomous vehicles. Additionally, leveraging Roboflow for annotation and data management has streamlined the preprocessing stage, ensuring the availability of adequately

labeled training data for training object detection system. In a nutshell, YOLOv5 is a faster, more scalable, and lighter model compared to other competitors. In future work, it is very useful in IOT, or mobile-based detection, like objecting detecting sticks for blind people, sign language detectors, etc. YOLOv7 is a faster, but heavier model, hence can be used in robotics, satellite imaging, and other related things.

Research Scholar, Department of CSE, Koneru Lakshmaiah Education Foundation, Hyderabad, India<sup>1</sup>  
Professor, Department of CSE, Koneru Lakshmaiah Education Foundation, Hyderabad, India<sup>2</sup>

**Abstract**—The Internet of Things (IoT) connects different sensors, devices, applications, databases, services, and people, bringing improvements to various aspects of our lives, such as cities, agriculture, finance, and healthcare. However, guaranteeing the safety and confidentiality of IoT data which has become rich in its quality requires careful preparation and awareness. Machine learning techniques are used to predict different types of cyber-attacks, including denial of service (DoS), botnet attacks, malicious operations, unauthorized control, data probing, surveillance, scanning, and incorrect setups. In this study, for improving security of IoT data, a method called Deep Stack Encoder Neural Network to predict botnet attacks by using N-BaIoT bench mark dataset is employed. In this study a new framework is introduced which will improve the performance of prediction rate to 94.5%. To evaluate the performance of this method assessment criteria are adopted like accuracy, precision, recall, and F1 score, comparing it with other models. From the optimizers of Adam, Adagrad and Adadelta, Adam optimizer gave the highest accuracy with relu activation function.

**Keywords**—Internet of things; botnet attacks; neural network methods; N-BaIoT; deep stack encoder; Adam optimizer; Adagrad optimizer; Adadelta optimizer; activation function

## I. INTRODUCTION

The Internet of Things is developed by wireless sensor networks. Through the Internet of Things, people can connect the physical world with the online world. With the rapid development of integrated circuit technology and wireless communication technology, engineers have been able to create IoT nodes that are very inexpensive and have both signal acquisition, data processing, and wireless communication capabilities [1].

The Internet of Things (IoT) is a network that connects assorted devices to the web through a definite protocol, facilitating data sharing, intelligent identification, tracking, placement, management, and monitoring. While the traditional perception of IoT revolves around a network of physical objects, the internet now encompasses a wide range of devices, including household appliances, smartphones, vehicles, toys, cameras, medical devices, advanced frameworks, individuals, animals, and buildings. These interconnected devices communicate and exchange data according to predetermined protocols.

The IoT's use in the industrial sector is supposed to increase output, efficiency, and security of industrial

processes, according to the industry 4.0 vision. In essence, the IoT refers primarily to the effective application of the IoT in industrial operations. The architecture of the IoT can be summed up in four layers. In the industrial sector, the Internet of Things (IoT) architecture comprises of multiple layers: physical, network, middleware, and application. The physical layer encompasses various physical equipment, sensors, mobile and computer devices, as well as other monitoring and automated devices. The network layer encompasses diverse communication networks such as machine-to-machine interfaces, cellular networks, and wireless sensor networks. The middleware layer includes cloud storage, application programming interfaces (APIs), and web services, which facilitate communication between the network layer and the application layer. Finally, at the topmost layer, the application layer enables a wide range of industrial processes and services, including robots, smart factories, smart buildings, smart healthcare, smart vehicles, and more.

IoT systems are made up of interconnected computing devices that can be mechanical, electronic, or any other type of object. For Internet of Things (IoT) systems, it is essential that each device has a unique identifier and the capability to transmit data above a network without relying on human-to-human or human-to-computer interaction. To connect with multiple devices or objects, IoT systems utilize distinctive network address schemes. Unfortunately, a significant number of IoT devices connected to the Internet lack sufficient security measures due to resource constraints, rendering them susceptible to cyberattacks. Yet, the majority of IoT systems run independently across unreliable network connections and the Internet, which exposes the network to cyberattacks. Security concerns need to be resolved as soon as possible given network attacks and cyber threats vs. the bright future of IoT systems.

An IoT network's, Network Intrusion Detection System (NIDS) keeps track of all internet traffic passing through the devices. It acts as a protective barrier that can identify threats and safeguard the network against unauthorized users and malicious attacks. The main defense against network intrusion and other threats in modern computer networks is NIDS. IoT devices are constrained by their physical counterparts' energy consumption, memory capacity, and computational power. Hence, it is nearly difficult to utilize conventional signature-based intrusion detection systems on these devices. Large datasets are frequently needed for signature-based NIDS in

order to build reliable detection systems for IoT. The resources of IoT devices must be taken into account when restructuring traditional signature-based NIDS.

In any communication network, the IoT is exposed to various kinds of vulnerabilities and security threats. In particular, security is a critical challenge for the IoT development, as it constitutes an extended version of the conventional unsecured Internet model and combines multiple technologies such as Wireless Sensor Networks (WSNs), optics networks, mobile broadband, and 2G/3G communication networks. Each of the aforementioned technologies is prone to various security risks.[2].

It is anticipated that IoT applications and technologies would advance beyond anything that is conceivable. Unfortunately, IoT technology development is still in its infancy and has not reached its full security protection maturity. IoT software developers' update management issues and non-uniform manufacturing standards are two security challenges faced by IoT systems. Critical challenges include the physical management of security concerns and users' ignorance as a result of their ignorance of security issues related to IoT devices. The network and surroundings of IoT systems must also be protected, in addition to using encryption techniques to secure data transmission.

However, the nature of the resource limitations prevents the use of conventional network security mechanisms in IoT systems. Due to the IoT system applications' quick development and widespread adoption, several network attacks have also surfaced. The number of assaults will increase as IoT use cases develop. Being aware of the substantial increase in cyber-threats within the IoT system significantly mitigates the probability of network security breaches and data compromises.

Some examples of the most prevalent attacks launched against IoT systems include:

#### A. Denial of Service (DoS)

Due to enormous cyberattacks IoT systems or network resources become unreachable to the intended authorized users. The purpose of these attacks is to temporarily or permanently interrupt the services provided by a host IoT system.

#### B. Distributed Denial-of-Service (DDoS)

A distributed DDoS attack is a malicious network attack that interrupts systematic traffic and network services. It involves overwhelming the target or neighboring infrastructure with a disproportionate volume of network traffic. DDoS attacks are effective when attackers exploit various compromised systems to produce a huge volume of traffic in the network. IoT systems or other devices which are the part of the network can also be targeted with these attacks.

#### C. Marai Botnet Attack

Cybercriminals employ the software known as Mirai to turn networked devices into remotely controlled robots in a catholic scale network as a part of botnet. It primarily targets internet consumer electronics, including IP cameras and

routers for the house. Mirai was frequently used as an initiator in attacks like DoS/DDoS.

#### D. Sybil Attack

Peer-to-peer networks are susceptible to Sybil attacks. A Sybil attack alters the identity of the IoT device to generate numerous anonymous identities and use an excessive amount of power. It was given that name in honor of Sybil, who wrote the book Sybil, in which a lady coping with dissociative identity disorder. An IoT device in a network that uses several identities frequently compromises reputation systems' allowed network access. Attacks using Sybil take use of this vulnerability in the IoT system network to launch initial attacks.

Since 2007 AI-based threats have been arisen as a significant trouble to the Internet of Things (IoT). These attacks, driven by artificial intelligence, present a greater danger compared to traditional human-focused attacks. Cybercriminals now leverage AI-powered tools that are faster, scalable, and more efficient, posing a serious challenge to the IoT ecosystem. The nature of AI-based assaults, with their increased volume, automation, and customization, makes them difficult to counter, despite sharing certain characteristics and strategies with traditional IoT hazards.

Further down, reader can see the literature survey which talks about the previous works and findings, followed by the proposed work and methodology, which covers about the information regarding the dataset, clean up and pre-processing techniques of the data, modules and tools used in the proposed work and libraries used for implementation of the proposed work, in succession there are algorithm which explains the detailed flow of the project from pre-processing to results and system architecture explaining the structure of the proposed work.

## II. LITERATURE REVIEW

The proliferation of the Internet of Things (IoT) has observed significant progress, making it vulnerable to cyberattacks targeting IoT devices. Safeguarding these devices to give security has become a crucial priority in order to mitigate potential risks. Among the various types of attacks, botnet attacks pose a severe and pervasive threat to IoT devices. One vulnerability lies in stationary IoT devices, as they often lack the necessary memory and computational capacity required for robust security measures. Moreover, several current systems are dedicated to enhancing security by identifying unfamiliar patterns within IoT networks [3].

The fundamental concept behind the Internet of Things (IoT) is to unite smart devices to the web, enabling seamless communication between physical objects and various entities like servers and mobile devices. The IoT has made its way into every sphere of life, spanning homes, industries, healthcare, automotive, and sensors. Consequently, the proliferation of vulnerabilities within IoT security poses severe risks to user safety and property [4].

The Internet of Things (IoT) industry flourishes; it has a significant rise in the diversity and abundance of IoT devices. These devices find widespread application in areas such as

smart homes, wearable technology, manufacturing, automotive, and healthcare, and other domains related to daily life. However, this rapid expansion also leads to a continuous emergence of security vulnerabilities in IoT devices. The escalating number of security vulnerabilities poses substantial risks to the privacy and property of users [5].

We have in-depth analysis of detection and prevention methodologies for various security attacks aimed at IoT systems. It is specifically aimed at software developers, researchers, and professionals working in the field of Internet of Things, who desire a comprehensive understanding of the strategies employed to detect and mitigate these attacks. Each item in the list is accompanied by a concise description and references that readers can refer for more detailed information [6].

The Industrial Internet of Things (IIoT) encompasses a wide range of elements, including sensors, machinery, industrial applications, databases, services, and workforce, which collectively contribute to various aspects of lives such as smarter cities, agriculture, and e-healthcare. While IIoT and consumer IoT share certain similarities, distinct cybersecurity measures are implemented for each network. Unlike consumer IoT, which is typically utilized by individual users for specific purposes, IIoT solutions are often integrated into larger operational systems. [7].

IoT-enabled devices have found applications in both industrial and commercial sectors, offering businesses a competitive edge over their rivals. However, the widespread use of interconnected smart devices has led to heightened concerns regarding privacy and data breaches. These concerns have disrupted workflow, activities, and network services within enterprises. To safeguard their organizational assets and ensure uninterrupted services, professionals must proactively address these risks by implementing comprehensive security protocols and policies [8].

One area that has received limited attention in previous literature is the vulnerability of routing protocol for low power and lossy networks to attacks. To address this issue, the author of this study proposed an artificial neural network (ANN) model for detecting decreasing rank attacks. The results showcased an impressive accuracy rate exceeding 97% and demonstrated strong performance across various tests conducted on the held-out testing dataset. These findings indicate the model's efficacy in terms of accuracy, precision, detection probabilities, false-positive rate, false-negative rate, and other relevant metrics [9].

The scientific community has shown considerable interest in the Internet of Things (IoT). The potential compromise of these devices by malicious individuals not only jeopardizes privacy but also poses significant risks to critical assets. Consequently, the detection and prevention of unique attacks within the IoT ecosystem are of utmost importance. In this study, the author introduces a novel threat detection system that integrates development and operations frameworks. In the initial phase, data from each application is processed by incorporating statistical and higher-order statistical features alongside the existing ones [10].

The integration of the Internet into corporate processes through IoT platforms becomes more prevalent, the need for stable and efficient connections becomes increasingly important. The authors of the article introduce a comprehensive automated intrusion detection system that focuses on enhancing Fog security and addressing cyber-attacks. The proposed model utilizes multi-layered recurrent neural networks that are specifically designed for deployment in Fog computing environments, which are situated in close proximity to end-users and IoT devices. Given that intrusion detection systems are among the key remedies employed for IoT security, it is common to adopt multiple strategies simultaneously. RNN and other neural networks can be effectively employed to analyze data and provide protection against cyber threats, offering layered defense mechanisms [11].

Employing machine learning within an IoT gateway helps protect the system in order to address the issues of securing IoT devices. They examine the use of Artificial Neural Networks in a gateway to detect anomalies in data transmitted from edge devices and are persuaded that this method can improve IoT system security. Security has been regarded as one of the weaker aspects in IoT during its growth. There are various hurdles to implementing security inside an IoT network, including system heterogeneity and the sheer number of devices that must be addressed [12].

All information processing systems now include a fundamental component for the detection of cyberattacks, and once an attack is identified, it might be possible to stop it or lessen its effects. In this study, the focus is on developing a straightforward detector to identify specific Botnet attacks on IoT systems. The proposed approach involves utilizing a learning recurrent random neural network (RNN), which offers advantages in terms of its compact 12-neuron recurrent architecture and low computational requirements, making it well-suited for edge devices. The RNN is trained offline using a simplified gradient descent technique, resulting in high detection rates of approximately 96% while maintaining minimal false alarm rates [13].

Security plays a critical role in nearly implemented or ongoing IoT applications. The widespread adoption of IoT is rapidly expanding and infiltrating various industries. While current networking technologies offer support for many IoT applications, certain applications demand more robust security measures from the underlying technologies they rely on. Looking ahead, IoT devices will not only be connected to the internet and local devices but will also have the capability to directly communicate with other devices across the internet [14].

The present era is characterized by an extensive deployment of IoT systems that generate vast amounts of data, and the detection of anomalies is a crucial aspect of every such system. These anomalies may indicate resource depletion in an industrial environment, unforeseen issues at an aerospace platform, or unusual performance of medical devices, among others. Hence, the ability to identify anomalies can have any monitoring system's overall performance is significantly impacted. The dataset in this

context includes several forms of threats, such as DoS/DDoS, Botnet, Brute Force, Web Attack, Infiltration, and Port Scan, that could potentially cause an IoT system to fail [15].

The number of Internet-connected devices, such as cameras, embedded machines, sensors, and many others that comprise the IoT, is rapidly increasing. By 2025, as projected by the International Data Corporation (IDC), the number of interconnected IoT devices is estimated to reach 41.6 billion. DL-based security mechanisms are heterogeneity tolerant since they can learn diverse features from unstructured data on their own. They can also be utilized to distinguish novel mutated threats from their older incarnations; thus, the security mechanism does not necessitate a patch on IoT devices on a regular basis [16].

The applications of IoT are expansive and continuously expanding, covering a wide range of areas such as public security, infrastructure development, connected healthcare, smart homes, cities, grids, and wearables. However, with such widespread use comes the risk of various attacks, including those aimed at denying service or taking control of the network. Among these, DDoS attacks pose a significant threat to IoT systems, as they involve many attackers from different locations overwhelming the network. To combat this, the author suggests using SDN and recurrent neural networks for DDoS detection and IoT security [17].

As the usage of IoT devices becomes increasingly widespread, network attacks have grown in frequency and severity. Denial of Service (DoS) and Distributed Denial of Service (DDoS) attacks have emerged as common types of threats targeting IoT networks. Traditional security measures like firewalls and intrusion detection systems are insufficient when it comes to detecting complex DoS and DDoS attacks. This is because they rely on static predefined rules to differentiate between normal and malicious network traffic [18].

The Internet has evolved from being a useful research tool for academic institutions to becoming an essential utility, comparable to gas, water, and electricity. However, as with any valuable resource, there is a risk of crime intended to exploit the technology illegally or to impede others from using it. The interconnectedness of the Internet makes it vulnerable to attacks from anywhere in the world, making cybersecurity a crucial concern. According to the latest survey conducted in 2015, security breaches are increasing [19].

This passage delves into an in-depth exploratory study that examines the obstacles associated with integrating these technologies into a cohesive system. The integration is affected by various challenges including security, scalability, accountability, and issues related to communication trust. The successful and effective integration of these technologies can accelerate the digital transformation of market, companies and the development of new business models [20].

The advent of the Internet of Things (IoT) has transformed the traditional way of living by introducing a sophisticated way of life. IoT has brought about numerous innovations such as smart homes, smart cities, pollution control, energy conservation, smart transportation, and smart industries.

Numerous important studies and research have been carried out to develop technology through IoT [21].

Copious IoT devices are presently available for use, many of which are extensively used in various services and are vulnerable to cyber-attacks. Cyber-attacks targeting IoT devices do not only affect the devices themselves. Since IoT devices are usually connected to other systems and appliances, they become entry points for hackers to gain access to anything connecting them [22].

The Internet of Things (IoT) has given rise to world of limitless opportunities for applications across many facets of society, but it also comes with several difficulties. Security and privacy are two such issues. To address this issue, incorporating security measures into the hardware of IoT devices beyond standard procedures is a potential solution [23]. A few examples of the devices are laptops, cell phones, tablets, washing machines, etc. IOT is a vast network of linked "things." The devices each have a microchip that connects them all. These microchips monitor their environment and report back to both humans and the network. The best feature of IOT is that every physical object may connect with one another and is reachable over the internet. Many devices are linked to the internet as a result of cheap internet access [24].

A method of identifying the neuron's structure and the optimal activation function of stacked autoencoders has been proposed for dimension reduction to minimize mean square error loss. A total of eight different neuronal structures of auto encoders and six activation functions are used to accomplish this. As a result, the optimal structure is 68-50-30-58-60 when viewed from the perspective of the mean squared loss function. As far as computational time and classification metric (97.4%) are concerned, the ELU is with negligible difference in the best activation function. It has been stated in [25] that this study will assist the defenders in selecting the activation method. In [26] it is recommended that activation and loss functions that may be useful to defenders. By using the CICIDS 2017 dataset, the effect of these functions is evaluated with an SVM-RBF classifier.

In [27] a model has been advocated by using semi-supervised Deep Learning, specifically Semi-supervised GAN (SGAN), for detecting botnet attacks on the N-BaIoT benchmark dataset is interesting. It appears that the approach has achieved high accuracy for binary classification (99.89%) and a decent accuracy for multiclass classification (59%). Semi-supervised learning techniques can be useful when labeled data is limited or unavailable. By leveraging both labeled and unlabeled data, semi-supervised models can learn from the available labeled data while utilizing the unlabeled data to improve the model's performance.

### III. PROPOSED WORK

In this work, the main concentration is on increasing the accuracy even for multi class classification by using autoencoders and also by considering confidentiality, availability, integrity, and privacy as they are more specific security needs, which are frequently referred to as security attributes. The technology tries to reduce latency and improve reliability while data is transmitted across the network. In

order to identify attacked data in the IoT context, this system makes use of the reputation model. In this proposed model Adam optimizer and Average subtraction-based optimizer are used which increases accuracy as compared to existing models. To make sure in terms of the security in the Internet of Things, it is crucial to accurately identify the interconnected devices. This involves employing a technology that can automate three key functions related to IoT security, specifically for device identification and discovery. IoT devices on the network are automatically and continuously detected, profiled, and categorized. Also it keeps a running list of the gadgets.

**A. Data-Set Collection**

For this study, the dataset which is used contains 10 lakhs of rows and 115 columns. This dataset was taken from [28]. It has many rows and columns and tried to include all the types of possible botnet attacks. The dataset which is used is N-BaIoT. The N-BaIoT dataset is a state-of-the-art and exceedingly refined assemblage of data that holds the capacity to revolutionize research within the realm of Internet of Things (IoT).

Table I gives brief information about IoT devices which have been used in two different botnet with their model names in the dataset considered. This dataset encompasses an extensive array of sensor readings and significant metrics, delivering a comprehensive and meticulous overview of the condition and conduct of IoT devices in authentic, real-life surroundings. The ongoing study undertakes an exhaustive exploration of the intricate and exceptionally advanced N-BaIoT dataset, encompassing an astonishing 7,062,606 records of network traffic, comprising both malevolent and benign activities.

The Table II depicts different IoT botnets which consists of various types of attacks and have been collected from a simulated organizational context. Last two columns of the specified dataset are the output columns which tells us whether the IOT devices are attacked or not and the category of the attack. The proposed model is checking whether the IOT devices undergone by botnet attacks or not and even specify the type of attack.

The graphs which are depicted for Marai and Bashlite bonnets (Fig. 1 and 2 respectively) consist of various types of attacks in individual botnets. These attacks are harmful as the complete network will be in the control of botmaster, the attacks which have been discussed, occur may be due to the sensitivity of IoT devices in the network [29]. The pursued dataset contains two types of Botnets and each one of it contains five different malwares and number of each has been depicted in the figures.

TABLE I. DEVICES IN N-BAIOT DATASET WITH MODEL NAMES

Types of devices with their model names
Danmini_Doorbell
Ecobee_Thermostat
Ennio_Doorbell

Fig. 2. Distribution of different attacks in Bashlite botnet.

### B. Normalization

Normalization is an adequate preprocessing technique which has various normalization methods as well. The study [30] uses min max normalization for intrusion detection in the network to identify malwares; however Z-score normalization is one good option. Z-score normalization, also known as standardization, is a method used to transform the values of a feature in a dataset to have a mean ( $\mu$ ) of 0 and a standard deviation ( $\sigma$ ) of 1. The transformation is performed while from each value is subtracted from the mean of the feature, and then dividing by the standard deviation. The transformed feature is then referred to as a standard score or a Z-score (eq 1). This normalization method is commonly used in machine learning and data preprocessing to ensure that all features are on a similar scale and to reduce the impact of outliers. Hence, the normalization technique is used to normalize the data given in the dataset and also by standardizing the features, it can also improve the numerical stability and convergence speed of some machine learning algorithms. Comparing to the other normalization techniques named min-max normalization, long scaling and clipping, and BCNF. Z-Score normalization gave highest accuracy.

$$Z - score(X) = \frac{(X-\mu)}{\sigma} \quad (1)$$

### C. Feature Selection using Information Gain

Information gain is a feature selection method used in machine learning to rank the importance of features based on the reduction of entropy in the data. In decision tree learning, information gain is used as a criterion for splitting the data based on the features. The entropy of a set of samples represents the amount of uncertainty or randomness in the data. By selecting features with high information gain, the entropy of the data is reduced, leading to a more predictable and accurate model. The idea is to select features that provide the most information about the target variable, by measuring the reduction in entropy after splitting the data based on each feature. Information gain for feature selection has been used which is a simple and effective feature selection method that can be used in various machine learning algorithms, especially decision trees and decision tree-based ensemble methods. Let  $F$  be the set of selected features then,

$$F = \operatorname{argmax}(\operatorname{InfoGain}(X_i, Y)): X_i \in X \quad (2)$$

### D. Data Processing

For data processing One Hot Encoder is used, which is a data transformation technique used in machine learning and data analysis. The process involves transforming categorical variables into a format that is compatible with machine learning algorithms. In one hot encoding, each unique categorical value in a column is converted into a binary vector of 0s and 1s. For example, if a categorical column has three possible values "A", "B", and "C", the one hot encoding process would convert this column into three binary columns: one for "A", one for "B", and one for "C". If a row had the value "B" in the original column, then the "B" column would have a 1 in that row and the other two columns would have 0s. So for converting strings into numerical values One Hot Encoder was used for machine learning algorithms.

## IV. METHODOLOGY

The architecture represented in the diagram (Fig. 3) is a deep stack encoder, consisting of numerous layers that are arranged on top of each other. This design allows the model to learn hierarchical representations by gradually extracting complex features from the input data. Before feeding the data into the encoder, a feature selection process is performed using information gain. Out of the original 115 features, 58 features are nominated based on their relevance and prominence to the task at hand. This choice helps to reduce the dimensionality of the input and emphasis on the most informative features. To optimize the model's parameters and improve the efficiency of training, different optimizers are employed. Precisely, the optimizers used in this work include Adam, Adagrad, and Adadelata. These optimizers regulate the weights and biases of the model throughout training, with the goal of lessening the loss function and taming the model's performance.

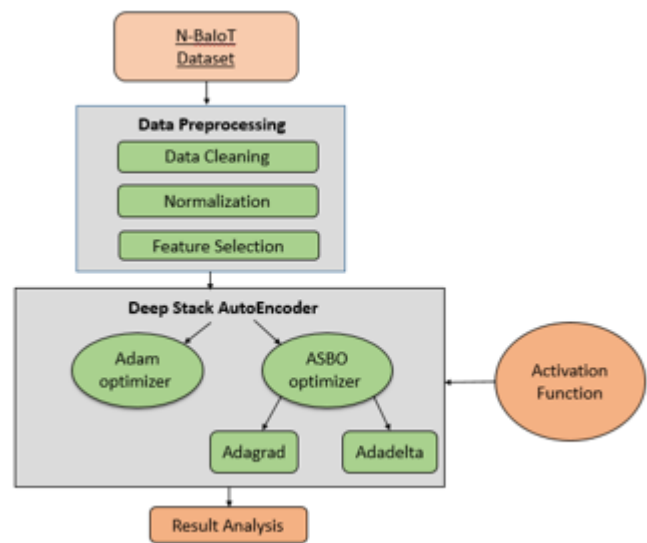

Fig. 3. Workflow diagram of proposed methodology.

The special choice of activation function is one more important factor in the model design. In this case, Rectified Linear Units (ReLU) are used as the activation function for both the input and hidden layers. ReLU activation is known for its ease and effectiveness in supporting the model to learn intricate nonlinear relationships in the data. For the output layer, the softmax activation function is employed which is commonly used in multi-class classification tasks as it converts the output values into a probability distribution over diverse classes, enabling the elucidation of the final predictions. By deploying these design choices, such as feature selection, diverse optimizers, and apposite activation functions, the model targets to attain superior performance and acquire better-quality outcomes for the specified task.

### A. Deep Stack Auto Encoder

Deep Stack Encoder is also known as stacked autoencoders, which are used in unsupervised learning. Stacked autoencoders consist of multiple layers of autoencoder neural networks. An autoencoder is a type of neural network that is trained to encode and then decode input

data, such that the output is as close as possible to the original input. By stacking multiple layers of autoencoders on top of each other, each layer learns to encode the input data in a more abstract and compressed way, with the final output being a low-dimensional representation of the input data. So Deep Stack Auto Encoder is used to encode and then decode the data. The model is having two types of optimizers, Adam Optimizer and Average Subtraction based Optimizer.

### B. Neural Network Using Adam Optimizer

Adam (Adaptive Moment Estimation) is an optimization algorithm widely used for training deep learning models, specifically neural networks. It combines the strengths of two popular optimization algorithms, namely RMSProp and Momentum. The algorithm computes a weighted average of previous gradients and squared gradients to adapt the learning rate on a per-parameter basis, as depicted in equation (2). This capability allows the algorithm to assign different learning rates to individual parameters, resulting in faster convergence and often superior performance compared to other optimization algorithms. The application of the Adam optimizer is done in present study, specifically focusing on two parameters,  $Y_1$  and  $Y_2$ . The present model comprises one input layer, three hidden layers, and one output layer. To utilize the Adam optimizer effectively, Tensor Flow and Keras libraries are imported. Finally, the network is compiled to prepare it for further processing.

$$\theta_t = \theta_{t-1} - \alpha * m_t / (\text{sqrt}(v_t) + \text{epsilon}) \quad (3)$$

where,  $\theta_t$  is the parameter vector,  $\alpha$  is the learning rate,  $m_t$  &  $v_t$  are the first and second momentum updates.

### C. Neural Network using Average Subtraction Based Optimizer

Average subtraction based optimizers are a class of optimization algorithms for training neural networks. They are called average subtraction based because they subtract the moving average of the gradient from the current gradient in order to update the weights. This helps to reduce the variance of the gradient and stabilize the training process.

One of the most well-known average subtraction based optimizers is the Adagrad optimizer. Adagrad updates the learning rate for each weight in the network based on the historical gradient, with a larger learning rate for weights (shown in Eq. 3) with a smaller historical gradient and a smaller learning at optimizer to adapt to the characteristics of each weight and reduces the risk of oscillations or stagnation during training. Another example of average subtraction based optimizers is the Adadelta optimizer, which extends the idea of Adagrad by using the average of the squared gradient instead of the gradient itself. Adadelta also includes a decay factor to reduce the impact of historical gradients over time shown in Eq. 4. Here average subtraction for two parameters  $Y_1$  and  $Y_2$  was done. In this model, there is a input layer, a hidden layers and a output layer. And for this adadelta optimizer TensorFlow, keras were imported.

$$\beta_t = \beta / \text{sqrt}(G_t + \text{epsilon}) \quad (4)$$

where  $\beta_t$  is the initial learning rate, epsilon is a small constant to prevent division by zero and  $G_t$  is the gradient.

$$E[\delta_w]_t = \rho * E[\delta_w]_{t-1} + (1 - \rho) * \delta_w^2 \quad (5)$$

where  $\rho$  is a decay rate that controls the contribution of past gradients to the moving average.

### D. Pandas

It is software package for the Python programming language that is used to manage and evaluate data. It is used in particular for huge calculations or bigger data; it has additionally Numpy in it. To perform operations on data files such as csv, pandas library is used. The `pd.read_csv()` feature is utilized to import and analyse the data stored in a csv file. Additionally, to make accessing data easier, names are given to each column and store them in an index list.

## V. ALGORITHM

Algorithm: Deep Stack Encoder with Feature Selection, Adam, Adagrad, and Adadelta Optimization.

1. Load the dataset (D) and store as matrix X with dimensions (n\_samples, n\_features) and vector Y with dimensions (n\_samples,).
2. Normalize the input features of X using Z-Score normalization.

$$Z - \text{score}(X) = \frac{(X - \mu)}{\sigma}$$

3. Perform feature (F) selection using Information Gain,

$$F = \text{argmax}(\text{InfoGain}(X_i, Y)): X_i \in X$$

4. Build three neural network models using Adam, AdaGrad, and Adadelta optimizers, and store them as  $M_1$ ,  $M_2$ , and  $M_3$  respectively.
5. for  $M_i$  in Models do
6. Train dataset  $D_{train}$  using the selected features F as input features and  $Y_{train}$  as output labels.
7. Predict the output labels for the test dataset  $D_{test}$  using the trained model and the selected features F as input features and store the predicted output labels as  $Y_{pred(i)}$ .
8. Calculate the performance metrics for each model  $M_i$  using the true output labels  $Y_{true}$  and predicted output labels  $Y_{pred}$ .
9. End
10. Output the performance metrics for all three models, METRICS ( $M_1$ ), METRICS ( $M_2$ ), and METRICS ( $M_3$ ).

Once the dataset have been loaded that consists of 115 columns where it is very huge and for which there is a need to decrease the number of columns. This can be achieved through feature selection by selecting top features by adapting information gain. Then normalize the data points by inheriting Z-score normalization and then construct three neural network models  $M_1$ ,  $M_2$  and  $M_3$  with three different optimizers Adam, Adagrad and Adadelta. Split the pre-processed dataset into two major division in ratio of 7:3 for training and testing

respectively and predict the output labels. Finally calculate the efficiencies by considering performance metrics.

### VI. SYSTEM ARCHITECTURE

System architecture is a pictorial depiction of all the components that come at a place to procedure the complete system. The architecture of the model is shown in Fig. 4, which also lists all the plans, tools, processes, and other components. Using the provided data set, leveraging the given dataset, two optimization techniques are employed, namely Adam and average subtraction-based optimizers, to enhance the dataset's performance and determine the accuracy of the model. By utilizing these optimizers, the aim is to fine-tune the dataset and achieve improved results. The proposed approach follows a sequential flow for attack prediction. It begins with the user loading the dataset, followed by data preprocessing to prepare the data for analysis. Feature selection techniques, such as information gain, are applied to identify 58 relevant features from the original set. When a user provides input, such as network logs or suspicious activity patterns, the deployed model processes the data and generates predictions regarding the likelihood or classification of an attack. This approach combines dataset loading, data preprocessing, feature selection, model training, deployment, and user input to expedite accurate attack predictions.

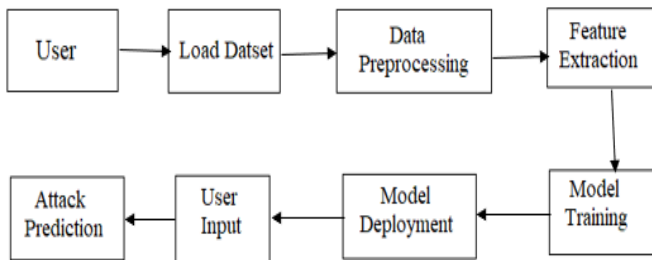

Fig. 4. System architecture.

### VII. EXPERIMENTAL RESULTS

Three different types of optimizers are used in the present neural network models, the results are as follows:

Accuracy, recall, precision, and F1-score metrics were considered to test the system for detection of botnet attacks. The equations are defined as follows:

Accuracy: It is the proportion of correct predictions made by the model out of all predictions. It is usually expressed as a percentage.

$$Accuracy = (TP + TN) / (TP + TN + FP + FN)$$

Where TP: True Positives, TN: True Negatives, FP: False Positives, FN: False Negatives.

Precision: It measures how many of the predicted positive instances are positive. It is a useful metric when the cost of false positives is high.

$$Precision = TP / (TP + FP)$$

Recall: It measures the ability of a model to identify all positive samples correctly. A high recall indicates that the model is good at identifying positive samples, while a low

recall suggests that the model is missing some of the positive samples.

$$Recall = TP / (TP + FN)$$

F1 Score: It is a metric used in binary classification problems, which is the harmonic mean of precision and recall. It takes both precision and recall into account to provide a balanced evaluation of the model's performance.

$$F1\ Score = 2 * (Precision * Recall) / (Precision + Recall)$$

TABLE III. COMPARISON TABLE FOR MODEL EVALUATION WITH MATRICS

	Existing Model	Feed Forward Adam	Adagrad	Adadelta
Accuracy	90.88	94.5	89.9	87.1
Precision	93	96.3	87	84.4
F1 Score	88	96.2	86.3	81.6
Recall	91	97.5	86.5	82.3

In the above table, Table III the performance of an existing model is assessed along with three optimization algorithms, to be precise Adam, Adagrad, and Adadelta, based on accuracy, precision, F1 score and recall metrics. The observation from the comparative study concluded that Adam outstripped the others in terms of accuracy, precision, F1 score and recall. It has been accomplished well with respect to overall performance and to facilitate the rightly classified instances. It is precisely vital to make a note that these results are definite to the considered dataset and may differ according to the type of the data and the job at hand.

Fig. 5. Comparative graph for precision, recall, f1 score

In credit to adaptive learning rate of Adam optimizer projects higher results where it regulates the learning rate for each parameter during the training session. This adaptive nature guarantees that the model defined converges efficiently without overrunning or getting stuck in local optima. Fig. 5 is the comparative graph which depicts Adam optimizer grander performance in terms of precision, recall, and F1 score when compared to Adagrad and Adadelta.

Fig. 6. Comparative graph for accuracy (%).

The major aim of this comparative graph which has been portrayed in Fig. 6 is used to appraise the performance of three optimizers-Adam, Adagrad and Adadelta. The fallouts of the analysis exhibits the Adam optimizer efficiency when compared with other two. The visual graph presented embodies x-axis with optimizer names and y-axis with accuracies with a bar graph. The bar for Adam optimizer stood above all the other optimizers signifying its efficiency.

Fig. 7. Comparative graph for time complexity.

The time complexity of a neural network model is influenced by various factors, including the number of layers, the number of neurons in each layer, the type of activation function utilized, the number of training epochs, and the size of the input data. Typically, the time complexity of a neural network model can be expressed as  $O(N^3)$ , where  $N$  represents the number of neurons in the largest layer. The time taken to get the results for Adam, Adagrad, Adadelta are 53.63 sec, 68.52 sec and 65.32 sec (see Fig. 7). When there is a need for quick and superior results, commissioning the Adam optimizer is extremely recommended when it is related with other optimizers mentioned.

## VIII. CONCLUSION AND FUTURE ENHANCEMENT

In this work, the use of different kinds of optimizers named Adam optimizer, average subtraction based optimizer which contains Adagrad optimizer and Adadelta optimizer was done. These are the parts of deep stack encoder. Adam optimizer gave the accuracy of 94.56, Adagrad gave the accuracy of 89.95, and Adadelta gave the accuracy of 87.17. From the experimental results we conclude that Adam optimizer is the most accurate optimizer and less time taking. For future intensifications, we can change the number of hidden layers and number of neurons in input, output and hidden layers to increase accuracy further. As in here, there is only use of one input, one hidden and one output layers. The change in the number of layers can be multiple combinations which will bring significant difference in the results. The number of activation functions can change the future results.

# Behavior Intention of Chronic Illness Patients in Malaysia to Use IoT-based Healthcare Services

Huda Hussein Mohamad Jawad<sup>1</sup>, Zainuddin Bin Hassan<sup>2</sup>, Bilal Bahaa Zaidan<sup>3</sup>

College of Information and Communications Technology Universiti Tenaga Nasional, Jalan IKRAM-UNITEN, 43000 Kajang, Selangor, Malaysia<sup>1,2</sup>  
Future Technology Research Center, National Yunlin University of Science and Technology, 123 University Road, Sect, Douliou, Yunlin 64002, Taiwan<sup>3</sup>

**Abstract**—The Internet of Things (IoT) has emerged as a trend in the healthcare industry to develop innovative solutions that enhance patient outcomes and operational efficiency. Healthcare has become more accessible, affordable, and efficient to sensors, wearables, and health monitors. The healthcare industry's adoption of the Internet of Things is lagging behind other sectors despite its many benefits. This study aims to investigate the extent to which chronic patients in Malaysia are using healthcare services made possible by the Internet of Things. To that end, this study proposes a unified framework to examine how these highlighted factors affect Behavioral Intention (BI) with regard to adopting IoT healthcare services. The innovation here is in bringing together three distinct theories: i) the Technology-Organization-Environment Framework (TOE), which is a framework for understanding how companies adopt new technologies; ii) the Unified Theory of Acceptance and Use of Technology (UTAUT); and iii) the Social Exchange Theory (SE). Patients in Malaysia who are coping with long-term health issues were surveyed online. This study also employs SPSS and Smart Partial Least Square (Smart PLS) for data analysis. Eleven hypothesized predictive components have been investigated. The results showed that chronic illness patients' BI towards adopting IoT solutions was considerably impacted by both individual and technological factors and related aspects. The impact of BI on Use Behaviour (UB) also showed similar outcomes. Moreover, trust somewhat mediates the impact of both individual and technological factors on BI. The findings of this investigation will be beneficial to policymakers and suppliers of healthcare in that country. Additionally, the patients and their family members would gain benefits from the study due to the fact that the delivery of comprehensive treatment, especially in the field of chronic disease management, will be improved through IoT-healthcare services. The Internet of Things will also let medical staff function remotely and professionally.

**Keywords**—Internet of things; IoT; chronic disease; adoption theories; adoption

## I. INTRODUCTION

Chronic diseases have become one of the most important problems of the twenty-first century. It is considered a very serious global, national, and individual health problem. Globally, in 2019, they were responsible for nearly 42 million deaths (Global Burden of Disease Collaborative Network 2020) [1]. This proportion has increased over time, from 67% of deaths worldwide in 2010 to 74% in 2019 (Global Burden of Disease Collaborative Network 2020). Although the COVID-

19 pandemic led to a considerable number of deaths due to communicable diseases in 2020 (WHO 2020) [1][2] Chronic diseases are generally defined as conditions that last for at least 1 year and require ongoing medical attention or limitation of daily living activities; approximately one in three adults is affected by multiple chronic conditions (MCCs), such as cardiovascular diseases, cancer, and diabetes.[2]. Their social and economic consequences can impact people's quality of life. Chronic conditions are becoming increasingly common and are a priority for action in the health sector [1].

In contrast, healthcare costs have been a significant global concern. The rising costs of healthcare can be attributed to various factors, including an aging population, an increase in chronic diseases, and costly administrative and technology expenses. These issues are being addressed by implementing more efficient healthcare models and investing in new technologies to improve patient outcomes and reduce costs.

In the previous decade, IoT has experienced exponential growth and revolutionized the application of technology in the healthcare industry [1]. It offers cutting-edge technology and services that enable communication between any two Internet-connected objects [2]. The Internet of Things (IoT) is being used by both nations and businesses to boost their competitiveness [2, 3].

No one has been able to agree on a single, comprehensive definition of the IoT. Researchers, however, use the term "Internet of Things" to refer to an online network of physical items [2-4]. The healthcare industry is slow to adopt IoT despite its many advantages [5]. In spite of the growing popularity of IoT healthcare services, there is a lack of data and research on how customers and patients are adapting to these technologies. The absence of information on users' opinions regarding the utilization and implementation of IoT in the healthcare system is notable. [6], Malaysia is no exception, especially for patients with chronic diseases.

The healthcare industry has indeed been slow in adopting IoT technologies, and a lack of a systemic approach could be a contributing factor. Despite ongoing efforts to promote the adoption of IoT in healthcare, other factors such as data privacy and security concerns, as well as the cost of implementing these technologies, remain challenges that need to be addressed [7]. Most current studies in Malaysia and elsewhere ignore the importance of human factors and social context in favor of studying the underlying technology,

components, and services. Regarding the matter at hand, it is important to clarify the definition of service. The term refers to any devices, applications, or services offered by a smart healthcare provider that is related to the diagnosis, monitoring, prevention, or treatment of human disease or the assessment or care of human health. [8]. To achieve successful adoption of IoT healthcare services, it is important to consider the user's perspective [9]. Hence, it is crucial to examine the factors that lead to the low adoption of smart healthcare services from the patients' perspective. Despite the various benefits of this approach, patients have concerns at both individual and technological levels, as outlined below:

1) At the individual level, users may find it challenging to comprehend IoT and may not be aware of its potential benefits for their daily lives [5, 10, 11].

2) At the technological level, patient data sensitivity involves concerns about security and privacy during the collection and transfer of data [12, 13].

Although the Internet of Things is still a relatively new technology, most research on the Internet of Things has been conducted in mature economies, with limited studies in developing and emerging markets. The healthcare sector is one of the many industries that have adopted IoT lately.

Prior studies have proposed several hypotheses to elucidate the reasons behind the low adoption of the Internet of Things (IoT). Understanding these predictors can help improve the explanatory power of IoT models and ultimately address the issue of low adoption [14-16]. Davis's concept, the technology acceptance model (TAM), is one of the most popular in use today. Venkatesh's research has shown that while the Technology Acceptance Model (TAM) can explain a significant portion of the variation in technology acceptance, it has limitations in predicting adoption rates. Venkatesh subsequently developed the Unified Theory of Acceptance and Use of Technology (UTAUT), which expands on TAM and other models to provide a more comprehensive understanding of technology adoption. UTAUT can explain up to 69% of the variance in technology adoption, making it a valuable tool for researchers and practitioners seeking to understand and promote technology adoption [17].

However, UTAUT and other models such as the Technology Acceptance Model (TAM) have been criticized for their emphasis on individual aspects and generalizations in predicting the adoption of new technologies. Nonetheless, these models provide a useful starting point for comprehending technology adoption and can be supplemented with other factors, such as organizational culture, social influence, and technical factors, to develop a more complete comprehension of technology adoption [17].

While individual variables are crucial, the properties of the technology itself, such as its security, privacy, and accessibility, can significantly influence its adoption rates. These factors can make or break the chances of a technology being adopted [17, 18]. Recent research has demonstrated that combining two or more theories can improve the ability to explain technology acceptance [19]. In light of this recommendation, the present investigation synthesizes the

UTAUT, an individual-based paradigm, with the TOE, a multi-perspective framework to identify the factors that encourage Malaysians with chronic diseases to use the Internet of Things (IoT) for their healthcare. The contributions of this study are:

1) Analysis of previous works to determine and investigate the behavior intention of chronic patients toward using IoT healthcare services.

2) Combining the UTAUT, TOE, and Social Exchange Theory to better understand IoT adoption in healthcare services.

3) Structural equation modeling (SEM) is deployed including the Smart Partial Least Square (Smart PLS) as part of the analysis process.

The paper is organized as follows: Section II shows the literature review including the related works. Section III presents the research framework and hypothesis. The methodology is shown in Section IV. All the results are presented and discussed in Section V; Section VI concludes the work, and finally, the limitation and future work are presented in Section VII.

## II. LITERATURE REVIEW

This section provides background on the use of IoT in healthcare and its relevant information. It also presents a theoretical background to show the main focus of previous studies related to IoT in the healthcare sector and discusses existing frameworks and models related to the study in detail. Additionally, a summary of related works is presented, addressing and contrasting them to highlight the gap in existing research that this work is addressing and to show the difference between previous works and this work.

### A. IoT in Healthcare

IoT in healthcare refers to the integration of internet-connected devices and sensors with healthcare systems to gather, monitor, and analyze patient data in real-time [20, 21]. The use of IoT modules in the healthcare sector has led to the emergence of "smart healthcare," which aims to improve patient outcomes and healthcare services through the use of technology. The adoption of IoT is expected to continue to grow in the coming years. Providing quality healthcare at an affordable cost is one of the most pressing societal and economic issues facing many nations today [22]. In some nations, healthcare expenditures are projected to reach 20-30% of GDP by 2050 [23]. Combining devices and technology reduces operating expenses and enhances the quality of healthcare services, making cost savings a key advantage of IoT healthcare innovation [24-26]. In light of the fact that increasing expenses will have a significant impact on patients' quality of life, this is particularly essential [22, 27].

At the moment, IoT is mostly used in healthcare for patient tracking through remote devices, data gathering, instantaneous transfer, and full network accessibility. It also paves the way for machine-to-machine data exchange, interoperability, and the analysis and exchange of crucial information. In the field of medical diagnostics, IoT has been essential as a result of moving the emphasis away from the hospital and onto the patient and their residence.

Consequently, IoT has reduced healthcare system costs and the incidence of risky errors, particularly for patients with disabilities and chronic diseases. [28-30]. According to the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP), chronic disease refers to a long-term health condition that persists over an extended period, typically lasting for three months or more. These diseases generally do not have a definitive cure and often require ongoing medical management to control symptoms and prevent further complications. They can impact various aspects of a person's life, including physical functioning, mental well-being, and overall quality of life [31].

In the United States, chronic diseases account for a disproportionate share of deaths and disabilities. Hypertension, cardiovascular disease, and diabetes mellitus are all examples of common chronic disorders. Despite the lack of a cure, most chronic diseases can be managed in various ways to lessen the severity of symptoms or slow their course [32]. Chronic illnesses are the leading worldwide cause of mortality and disability [33], so much so that they have been dubbed the "silent global epidemic". As reported by the WHO, diabetes has become one of the primary contributing factors to premature illness and death in many countries, including Malaysia. As shown in Fig. 1, Malaysia's Ministry of Health Malaysia (2019) depicts that Malaysia occupies the first spot in terms of mortality rates among the population aged between 20 and 79 globally.

Fig. 1. Rate of death in Asian countries.

Several scholarly investigations have proposed that adopting Internet of Things (IoT) healthcare services could be the solution for improved monitoring and healthcare delivery to patients with chronic illnesses [6, 34, 35]. In this manner, the Internet of Things (IoT) could be used to improve patients' quality of life by reducing the stress placed on their loved ones and hospital visits. In light of this, prior research in Malaysia focused mainly on the development of smart homes, or specific information about Internet of Things deployment in sectors such as healthcare and industry [36-38]. However, it was hypothesized that individual and technological factors were responsible due to the poor rate of adoption of IoT, particularly among those suffering from chronic diseases in Malaysia [33].

### B. Technical Review

A variety of authors have reviewed this topic, with different perspectives on the role that various factors play in enabling IoT in healthcare. Three major categories of factors are

identified and discussed based on their significance to the success of the implementation of IoT in healthcare, such as factors related to the systems, factors related to individuals (end users), and other factors related to infrastructure and environments, as shown in Fig. 2.

Fig. 2. Most related factor to enables IoT in healthcare.

1) *Factors related to the system:* It refers to the factors that impact a system's capacity to accomplish its intended purpose. These aspects are considered critical to the success or smooth functioning of Internet of Things services, such as big data, security and privacy, technological requirements, connectivity, and availability, and they represent the system factors required for a connected IoT in a healthcare context. Each of these elements is described briefly in the sections that follow.

a) *Big data:* The phrase "big data" is used to refer to a huge amount of data that exceeds the capacity of traditional storage and processing methods [39]. This deluge of information may be assembled or fragmented. How to reliably and securely acquire and retain data in systems has been a major topic of study in recent years [28, 40], as well as the means through which to preserve a strong level of integrity [25, 28]. How the system would handle a large amount of healthcare data collected from a variety of sensors was the topic of several studies [33]. Several studies voiced concerns about the speed and analysis of massive volumes of data [21, 40, 41] following data collection and processing [42, 43], data management [2, 44], and data monitoring. These potential difficulties must be addressed in order to assure the availability, dependability, and correctness of big data [28, 45] and to aid decision-makers in making sound decisions [43, 46].

*b) Security and privacy:* Both "security" and "privacy," which concentrate on data security, are related concepts. Security is mainly concerned with preventing unauthorized access to the system's data or information, whereas privacy relates to the protection of personally identifiable information. These words work better with modern healthcare software to protect patients' personal information [9, 24, 47]. Security risks, data breaches, insecure devices, and wearability are just some of the potential security and privacy issues that have been the subject of several studies [2, 4, 27, 48-50]. Data security and patient privacy must be prioritized for the longevity of any smart healthcare system [21, 51, 52].

*c) Technical requirements:* Besides the necessary basics, we should consider technical requirements [53, 54] leaks from energy storage systems and batteries [20, 55], low power consumption in operation [22, 56], leveraging IoT endpoints for use in intelligent decision-making, and power usage [50, 57-62] to improve communications and store information quickly [63]. Smart hospitals rely on connections to upload patient data, link medical equipment, and react fast (via sensors) [64]. Researchers focus on network connections and data transmission reliability [60, 65, 66] and handle problems like traffic [67]. Other studies improve service quality and performance [9, 60, 68].

*d) Enhance system performance:* Numerous aspects of the healthcare system are of interest to the authors in order to improve service quality in a timely and accurate manner. [40, 69], such as raising people's consciousness about the need to use medical equipment regularly, dealing with delays in responses or problems in latency [60, 70], and keeping up a high rate of data transfer quality [63, 71], also decreasing packet loss, determining the relationship between ICT and healthcare, and how ICT can help an individual [67]. Patients also get the best healthcare applications [20, 58, 65]. Some research has recommended early detection using improved monitoring systems [45, 72, 73] such as hypertension and blood pressure, and a deep learning-based vocal pathology detector to identify false main users [41, 74]. Rural healthcare should be egalitarian [40, 75]. Maintaining current technology and creating a smart healthcare engineering course to interest students [76, 77].

*2) Factors related to the individual:* Providers of healthcare must guarantee that user requirements and perspectives are prioritized. Several of the reviewed studies highlighted user problems and concerns, such as system performance, ease of use, accessibility to healthcare services, reliability of IoT devices, high cost, and trust [64, 78]. Thus, IoT aims to lower patients' expense burden by reducing hospital and clinic visits while providing precise and effective healthcare [22]. Most research has focused on these issues [73, 74]. Some have attempted to make smart gadgets and communication technology for remote monitoring systems more affordable [50, 56]. Thus, the notion of a "smart stone" has been embraced by some academics as a means of reducing elderly citizens' issues using mobile devices and tablets by limiting the system's involvement with the user [27]. This

approach was also utilized to determine the primary elements impacting senior people's adoption of smart gadgets for health care [5]. IoT healthcare's major problem is user uptake. To determine the most important elements affecting technology adoption, researchers must dig deep [29].

*3) Other factors:* Some researchers have reported additional issues, particularly in terms of external influences [3], traditions, laws, and ordinance platforms [45, 75], healthcare information systems that use social media, and how they can improve patient care [50, 79], and the benefit of working in the healthcare industry for a long time [80]. An increase in the senior population is a direct result of the correlation between healthcare system improvements and a longer lifetime duration. Physical incapacity, long-term illness, and technological headaches are just a few of the difficulties that the elderly face [29].

### C. Theoretical Review

In the study of how people embrace new technologies, there are eight prominent models, theories, and frameworks. UTAUT is the newest model available. TAM, however, is the standard. However, these two paradigms have been panned by healthcare experts for being overly simplistic and narrow in their concentration on the individual. Yet, the technological side, which is more concerned with technology's potential and public opinion of it, is rarely incorporated.

The TOE is an integrative paradigm that seeks to address this shortcoming from a variety of angles. It involves elements of technology, management, and ecology. Once again, the TOE is inadequate for the separate facets of technological diffusion.

Researchers have suggested that combined theories are able to explain the variation in adoption [81]. Few studies combined more than one theory to better explain the rise of the IoT [82]. Therefore, this study merges the TOE and UTAUT. The social exchange theory can be used to account for contextual factors like customer trust in service providers, which will boost the proposed model's ability to explain observed phenomena (SE).

*1) Existing frameworks and models of IoT:* The theory of reasoned action is a foundational concept in the history of technology adoption (TRA). Fishman and Ajzen created TRA [83]. According to the theory's central tenet, people's actions are driven by their attitudes and internalized values. Ajzen recognized the theory's flaws and developed the Theory of Planned Behavior (TPB) [84] by combining attitude, subjective norms, and perceived behavioral control. Davis combined TRA and TPB to create the TAM model [85].

According to research, UTAUT and TAM are commonly used models for measuring people's willingness to adopt new technologies, but they have been criticized for being too simplistic and narrow in focus. Meanwhile, the TOE framework, which includes elements from technology, organization, and natural phenomena, is considered more holistic but still lacks key components for effective technological integration. Therefore, combining the TOE and UTAUT models is necessary to gather data on both individual and technological aspects. By including the contextual variable

of trust, the proposed model's explanatory power can also be enhanced.

TABLE I. SUMMARIZES THE DIFFERENCES AND SIMILARITIES BETWEEN SEVERAL THEORIES AND MODELS OF TECHNOLOGICAL ACCEPTANCE

Theory/ Model	Explained variance
1- Theory of Reasoned Action (TRA)	0.36
2- TAM	0.54
3- Motivation Model (MM)	0.38
4- Theory of Planned Behavior (TPB)	0.47
5- Combined Technology Acceptance Model and Theory of Planned Behavior (C-TAM-TPB)	0.39
6- Model of PC Utilization (MPCU)	0.47
7- Innovation Diffusion Theory (IDT)	0.40
8- Social Cognitive Theory (SCT)	0.36
9- Unified Theory of Acceptance and Use of Technology (UTAUT)	0.69

According to the social exchange theory, people are more likely to adopt an innovation when they trust specific individuals or groups promoting it and when they believe that the benefits outweigh the risks and costs associated with its use are less [86, 87]. As a result, establishing and maintaining trust in the adoption of new technology is essential for promoting positive attitudes and behaviours toward innovation [64].

In previous studies, a combination of more than one theory was also investigated such as a study, that combined TAM and IDT to predict the adoption of IoT by users [32]. Before combining TAM, TRA, and TPB to foretell IoT adoption, Rahimi studied each one separately, and the results demonstrated that IoT adoption can be largely explained by three theories, or previously unconsidered constructs could be added to existing theories [82].

2) *Discussion of related work:* This section discusses and summarizes all the related works to IoT adoption studies; Table II shows the research gap and limitations found in the literature.

TABLE II. A SUMMARY OF RELATED WORKS

PA is a more significant factor in determining PEOU among males than females, according to the findings. Men are more affected by issues of appearance, privacy concerns, and feeling insecure than women.</p>

From the literature, it is obvious that the number of experimental studies is greater than the number of theoretical studies, which seems logical given that a good service must be provided to patients by developing an efficient healthcare system to deliver the best customer service. After ensuring that the service is worthwhile enough, we turn to theoretical studies to examine the intention of people to adopt these services in their daily lives, as well as highlight the users' concerns about these services to give a clear indication to the providers to put more effort into providing a better experience with IoT healthcare services.

It can be seen from Table II that the number of studies pertaining to the adoption of IoT in the healthcare sector is limited. Most previous studies adopted an experimental rather than empirical approach. As can be seen in the summary table (Table I), the empirical, quantitative, and adoption studies are focused on the factors or predictors of IoT adoption among users. Most of the studies employed TAM to explain the behaviour toward adopting IoT.

Among these studies, perceived ease of use (PEOU) and perceived usefulness (PU) were found to be critical for the adoption of IoT [20]. Similar findings were derived in the study of Liu who indicated that social norms, trust, as well as PEOU and PU were the predictors of IoT adoption [32]. Rahimi deployed TAM and also reported that PEOU and PU were critical for the adoption of IoT, along with TAM the researcher also examined the validity of TRA and TPB [82]. Studies using TAM were also conducted by many researchers [90, 91]. The empirical studies also deployed other theories of technology adoption, such as UTAUT. In a study by Pal, the UTAUT model was applied along with variables such as anxiety, trust, and cost to understand the adoption of IoT by the elderly in four Asian countries [5]. The findings showed that the variables of UTAUT along with trust and cost were important predictors of IoT adoption among the elderly population. Meanwhile, Meri used the theory of reasoned action (TRA) to predict the adoption of IoT [89]. Previous research has shown that several different theories often work together. In Liu's research, for instance, TAM and IDT were coupled to anticipate user adoption of the internet of things

[32]. Rahimi tested TAM, TRA, and TPB individually and then combined them to predict IoT adoption [82].

In conclusion, theoretical studies in the area of IoT adoption in healthcare are still limited, and there is a need to go in-depth due to its importance in providing distinguished healthcare services for patients. This can contribute to reducing the number of deaths and improving overall healthcare outcomes. Furthermore, findings revealed that a combination of more than two theories is needed to develop a comprehensive model that captures the complex nature of IoT healthcare service adoption.

### III. RESEARCH FRAMEWORK AND HYPOTHESIS

IoT adoption among patients with chronic diseases is a topic of increasing interest in the healthcare industry. In Malaysia, where chronic diseases are prevalent, understanding the factors that predict IoT adoption is crucial. This research aims to explore these factors using the Unified Theory of Acceptance and Use of Technology (UTAUT), the Technology-Organization-Environment (TOE) framework, and the social exchange theory. According to UTAUT, individual factors such as performance expectancy, effort expectancy, and social influence play a significant role in predicting IoT adoption.

IoT adoption is also affected by technological factors such as security, privacy, and availability. Due to the sensitive nature of health data, security concerns arise, while privacy concerns refer to the preservation of users' personal information for the availability of Internet of Things devices and their associated services.

Facilitating conditions, which are a component of UTAUT, are also crucial IoT adoption predictors. These conditions pertain to the infrastructure and resources necessary for the effective use of IoT devices. For instance, the availability of dependable internet connectivity and technical support can have a significant impact on the adoption decisions of end consumers.

According to social exchange theory, trust is a crucial mediator for predicting IoT adoption. Patients with chronic

diseases may be hesitant to implement IoT devices out of concern for the technology's dependability and precision.

Having confidence in the technology and its purveyors can help mitigate these concerns and boost adoption rates.

Fig. 3. The research framework.

According to UTAUT, there are moderating factors, such as gender and experience. We will use gender and chronic disease patient experience as moderating factors in this investigation. Fig. 3 illustrates the research framework used in this study.

#### A. Individual Factors

Performance expectancy (PE), effort expectancy (EE), and social influence (SI) are considered individual factors in the context of IoT adoption. Previous studies have shown that these factors have a significant positive effect on the intention to adopt IoT [92]. Based on this, it is expected that individual factors will also have a positive and significant impact on IoT healthcare service adoption in this study. Thus, it is hypothesized that:

H1: Individual variables influence positively the BI to adopt IoT-healthcare services by patients with chronic diseases.

1) *Performance Expectancy (PE)*: The term "performance expectancy" refers to the degree to which a person feels that using a certain piece of technology will assist them in doing their duties in a manner that is both more effective and efficient [93]. In the context of the Internet of Things (IoT), this term refers to the extent to which an individual believes that making use of IoT devices will improve their overall performance when carrying out a given set of responsibilities. According to Venkatesh's findings, PE has been identified as the most influential factor in determining an individual's behavioural intention (BI) toward technology adoption. This was reported in reference [93]. According to Pai and Huang PE impairs the ability of BI to utilize health information systems [43].

Carlsson revealed that performance expectations have a direct positive effect on an individual's intention to use mobile devices. This means that if an individual believes that using a mobile device will help them perform their tasks more efficiently and effectively, they are more likely to have the intention to use it [94]. The greater the PE, the more likely it is that mobile health services will be embraced, according to experimental studies [95]. Therefore, the following hypothesis was put up for this investigation:

H1a: PE has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

2) *Effort Expectancy (EE)*: The ease of use (or EE) of a system is defined as "the degree of simplicity" [96]. Researchers have found that EE has a substantial effect on users' propensity to embrace a health information system. Clinical support for decision systems, mobile health monitoring systems, and e-health solutions accessible via smartphones are all examples, and portable well-being has all been shown to be positively influenced by EE [17, 95]. Pal found that effort expectancy has a major impact on the adoption Internet of Things in healthcare [5]. Hence it entails that:

H1b: EE has a positive effect on the BI for chronic disease patients to utilize IoT-healthcare services.

3) *Social Influence (SI)*: "How important it is to other people that you accept the new technology" [93] is how social influence is defined as it relates to technology adoption. Liu concludes that SI is a crucial factor and has a significant effect

on the spread of mobile medical services. Pal also looked into how peer pressure affects the uptake of smart homes to improve the health of the elderly [5]. Literature reviews have found a similar pattern: people are more inclined to adopt new technology when they see other people using it, too [97]. It is hypothesized in this investigation that individuals with chronic diseases will be influenced to accept and use IoT-healthcare services:

H1c: SI has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

### B. Technological Factors

The TOE relies heavily on technological aspects. Their impact on the spread of various technologies has been the subject of several studies. According to Lian's research, technological factors have a significant effect on cloud computing's uptake in Taiwan [101]. Cloud computing adoption in the public sector has been the subject of several studies, including one by Polyviou and Pouloudi [107], who showed that technological characteristics were significant predictors of cloud adoption among public sector personnel. In India, cloud computing has been slow to catch on, according to research by Gangwar [90]. Thus, it is hypothesized in this study that technical factors will have a beneficial impact proceeding the behavioural intention of Malaysians with persistent illness to implement IoT healthcare. Accordingly, it is assumed:

H2: Technological factors have a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

1) *Security*: The healthcare industry is facing serious security challenges. Without adequate safeguards, billions of sensitive medical files are kept on unprotected servers. Concerns regarding the safety of patient data and infrastructure have grown in tandem with the prevalence of ransomware attacks. In the present study, we define security as the confidence that patients with chronic diseases have in IoT healthcare services as safe places to save and share their personal information [98]. Security was introduced as a technological aspect by Lian, Senyo, and Alkhatir [92, 99, 100]. So, this research takes into account security as a factor of the technological factors. Numerous studies have looked into how people's perceptions of risk influence their decisions about whether or not to adopt new technology. According to Junqi's research, [75] security concerns significantly affect whether or not a healthcare system is adopted. It is hypothesized as:

H2a: Security has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

2) *Privacy*: When it comes to the use of IoT devices in healthcare, privacy is a key problem. Medical devices such as (but not limited to) pacemakers, insulin engines, and individual monitors are frequently used in hospitals to keep tabs on patients' vital signs. In order to exchange data, these gadgets join a wireless network. Multiple hackers have broken through these systems as of late, taking the information for their end. If patients find out later that their doctors are using Internet of

Things devices on them, they may feel violated. The term "privacy" refers to "the extent to which individuals with chronic diseases perceive that their personal information is secure" [98]. Researchers have taken privacy into account as a technological aspect in the spread of cutting-edge tools in a variety of contexts. For the Internet of Things to be widely used in healthcare, researchers have shown that protecting patients' personal information is crucial [2, 52, 101]. Hence, it is assumed that:

H2b: Privacy has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

3) *Availability*: Availability, which is one of the sub-constructs of technological factors, is the perception of how much personalized and uninterrupted connection and communication an individual has with other individuals and networks through ubiquitous technology [94]. Lack of internet connectivity is one of the main barriers to utilizing telehealth/telemedicine, as 68% of health care professionals reported this as their top concern in adopting these new technologies [17]. When formulating the TOE model, Tornatzky and Fleischer took into account accessibility to technology as a technological component [102]. Pathinarupothi, who noted that availability is vital for remote monitoring, and impacts the amount to which users are ready to embrace IoT, is one of the researchers that looked at how accessibility affected IoT uptake [69]. The willingness of users to employ the Internet of Things is affected by factors such as availability. According to research in the field of technology adoption, such as the Phaphoom study, availability is crucial for the spread of cloud computing [103]. Positive findings on the impact of availability on BI to use IoT by Malaysians with chronic diseases are anticipated in this research. So, the following is postulated:

H2c: Availability has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

4) *Facilitating Condition (FC)*: The variable "FC" is one of the constructs of the Unified Theory of Acceptance and Use of Technology (UTAUT). "FC" stands for "facilitating conditions," which refers to "the extent to which a user believes that an organizational and technical infrastructure exists to support the system's use" [104]. The FC was directly related to the employment of cutting-edge technology by the researchers that deployed UTAUT [93, 105, 106]. The extent to which a user is pleased with and finds value in an IT application has been shown in other research to be a major predictor of that user's intention to involve with new technologies [107]. Consequently, if the FC for a new system is high, it's likely that its users will be pleased with it and want to keep using it. Academic technology adoption was found to be significantly influenced by FC [106]. As a result, it stands to reason that FC has a significant impact on patients' propensity to engage in IoT-based healthcare services. Then, it is theorized as:

H2d: FC has a positive effect on the BI for chronic disease patients to adopt IoT-healthcare services.

### C. Behavioural Intention (BI) and Use Behaviour

Is a catch-all phrase covering research into how people engage with and make use of technological systems. From marketing to the law, BI has found a home in many industries. Yet, the field is most commonly associated with the study of human-machine interactions in the social sciences. A definition of BI is the extent to which a person has deliberated over whether or not to engage in a particular course of action in the future [106]. Individual's subjective evaluation of whether or not they should engage in the desired behavior (UB) [93]. Individuals' subjective evaluation of whether or not they should engage in the desired behavior (UB) [93]. Most earlier models of technology acquisition such as TAM and UTAUT have connected the BI to the UB [85, 93]. Gao observed a substantial correlation between BI and UB in their research [106]. Many investigations [108-110] have found the same thing. Therefore, in this study, it is hypothesized as:

H3: BI has a significant effect on the actual use of adopt IoT healthcare services by chronic disease patients.

### D. Mediating Role of Trust

Patients with chronic conditions who have faith in the integrity of IoT-healthcare services are said to have "high levels of trust" [98]. Users were more likely to adopt new technologies when they had a positive impression of the companies providing those services [111]. Lansing and Sunyaev concluded, using a classification system based on how trust plays out in trying out new gear, that trust was underappreciated in this context and that the variable trust mediated the relationship between the factors of success of acquisition and utilization goals [112]. Ghazizadeh, Lee, and Boyle used trust as an intermediary among PEOU, helpfulness, and BI [113]. The conclusions revealed that trust completely mediated the consequence of PEOU on BI.

According to Social Exchange Theory, trust is a critical aspect that might impact an individual's desire to employ technology in healthcare. As stated in previous studies, patients who have trust in IoT healthcare technology are more likely to use, learn from, and realize its advantages. Furthermore, a trust may influence how individual and technological factors influence an individual's behavioural intention to adopt new technology. The research hypothesis is that trust will play a mediating role in the relationship between individual and technological factors and patients' behavioral intention (BI) to adopt Internet of Things (IoT) healthcare services. In other words, the study proposes that trust will act as a link between these factors and patients' willingness to use technology in healthcare. It is theorized as follows:

H4a: Trust mediates the effect of individual factors on BI to adopt IoT-healthcare service by chronic disease patients. H4b: Trust mediates the effect of technological factors on BI to adopt IoT-healthcare service by chronic disease patients.

### E. Moderating Effect of Gender and Experience

Recent research has examined the impact of gender and experience on the relationship between UTAUT constructs and

people's intentions to use technology. The results suggest that gender and experience can have a significant influence on people's attitudes towards technology, and should be taken into account when introducing new technological solutions [93]. Another point should be highlighted that the user's background and familiarity with the internet, computers, and other forms of information technology is another important factor to consider when introducing new technology solutions. The Unified Theory of Acceptance and Use of Technology (UTAUT) has also recognized that people are more likely to use technology when they have a high level of familiarity with it. This suggests that prior experience with technology can influence people's attitudes toward new technology and may impact their willingness to adopt it.

Rezvani used gender and professional experience to moderators the relationships between TAM and privacy and connectedness. [38]. The findings showed that these two characteristics affected the perceived utility (PU), perceived ease of use (PEOU), privacy, and desire to use IoT. Based on the UTAUT paradigm, this study hypothesizes that gender and experience affect the connection between individual and technological factors and patients' adoption of IoT. Accordingly, the following is hypothesized:

H5a: Gender moderates the effect of individual factors and technological factors on the BI to adopt IoT-healthcare service by chronic disease patients.

H5b: Experience moderates the effect of individual factors and technological factors on the BI to adopt IoT-healthcare service by chronic disease patients.

## IV. METHODOLOGY

### A. Population and Sample Size

This section describes the characteristics of the participants included in this research, how they were selected as well as the study's sample size.

1) *Population*: The population is described as "the entire group of people, events, or things that can be observed or measured." [114]. This definition is quite wide and might include anything from individual people to entire societies. Other researchers defined population as "the intended group that shares similar characteristics with the group in which the researcher wishes to generalize the research findings" [64]. When collecting data, it is important to choose the population carefully to ensure collecting relevant and reliable data. In the current research, the population of this study is patients suffering from chronic diseases in Malaysia. Presently, there are no specific statistics that reflect the number of patients with chronic diseases in Malaysia. However, the prevalence of chronic illnesses such as diabetes, hypertension, and heart disease is increasing among patients in Malaysia.

This study focuses on the Klang Valley area given that it is an urban area with the highest population in Malaysia amounting to 8.4 million people according to the World population review. Approximately 1.2 million of these patients are estimated to have one or more chronic conditions according to the Ministry of Health, Malaysia.

2) *Sampling*: The sample size is defined as “a process of selecting a number of individuals from a population to be tested or studied” [115]. The selection of a target population is critical to ensure that the sample is representative of the larger population of interest [114]. According to the Ministry of Health, about 1,000,000 Malaysians with chronic conditions live in the Klang Valley. SEM data analysis requires a sample size of 100–200 [116]. Kline said that SEM samples are typically 200 [117]. According to Krejcie and Morgan [118] and Sekaran [114], 384 respondents are a substantial and acceptable sample for this study's population.

### B. Questionnaire Design

A standardized, closed-ended questionnaire was used to compile information for this investigation. The variables are measured in accordance with standards established by earlier research into the spread of IoT healthcare services. There are three sections in this questionnaire as it is shown in Fig. 4:

- 1) The first section explains the purpose of the questions.
- 2) The second section collects demographic data from respondents, such as age, gender, usage of IoT services, familiarity with IoT, expertise with IoT, and whether they have any chronic diseases.
- 3) The third section contains items designed to measure technological and individual characteristics, as well as research variables like behavioral intention, trust, and actual usage behavior.

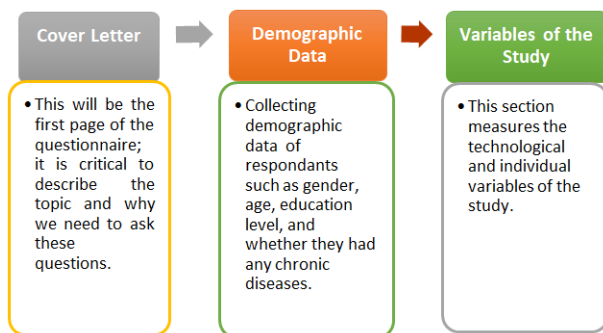

Fig. 4. The questionnaire sections.

Items are graded on a 5-point Likert scale, with 1 representing strongly disagreeing and 5 representing strongly agreeing. Compared to seven- and ten-point Likert scales [119–121], Likert scales are utilized because they have been found to be more accurate in gauging respondents' thoughts and feelings. The "closed-ended" nature of these questions makes them easier to answer than open-ended questions that ask respondents to describe how they feel about an issue or topic. These types of questions also increase the reliability of the data and make it easier to analyze the data and interpret the results [122].

### C. Preliminary Test

After the questionnaire was designed, and before collecting actual data, it was crucial to conduct a preliminary test to ensure that the questions were appropriate, to obtain accurate results [123]. Particularly if the questions of the questionnaire

were adopted from earlier studies, there is a need to modify the questions in a way to fit the new purpose of the research. As it has been done in this investigation were the questionnaire adopted from previous studies [124–126].

Pre-test and pilot studies were conducted in this study. The purpose of this test is to determine errors and ambiguity, make sure that questions are clear enough and understood by respondents, as well as identify any technical problems that may prevent the results from being reliable and accurate [64, 114].

### D. Data Collection Procedures

Several approaches can be used for collecting data via surveys in research studies, including online and mail surveys, telephone interviews, face-to-face interviews, and drop-off surveys [114]. The present study aligns with previous research that investigated the adoption of IoT in healthcare and deployed a survey approach to collect the data due to the cost-effectiveness, convenience, and time of the studies [15, 38, 90]. Surveys also enable researchers to collect a large number of responses in a relatively short period [114]. Given that the data collection process occurred during the lockdown of COVID-19, an online survey may be the best option, as it allows patients to complete the survey at a time that is convenient for them and reduces the amount of contact between the patient and the researcher during that period. respondents who met the inclusion criteria were selected to complete the questionnaire. An online questionnaire was deployed for the data collection.

Among the initial 384, we received 252 valid responses. As Kline stated that SEM responses more than 200 are satisfactory [117], such results are regarded adequate. SPSS 24.0 and Smart PLS 3.3 are used to analyze the data. Missing values, outliers, normality, and multicollinearity checks are all part of SPSS's preliminary analysis. The measurement type and the structural version are both a part of the main analysis conducted using Smart PLS.

## V. RESULTS

### A. Descriptive Information

The respondent descriptions and variables for the study are included here. The former was reported in terms of frequencies and percentages, while the latter was represented statistically by means of each variable. The level of education, gender, age, chronic illness, frequency of use, and method of accessing IoT healthcare of the respondents are shown in Table III.

Factors and their associated descriptions are shown in Table IV. The average score for performance expectation (PE) was 3.29, indicating that most respondents agreed with the items used to calculate PE. The majority of respondents moderately agreed with the items evaluating effort expectancy (EE), as seen by its mean score of 3.39. Similar results for social impact could be shown (SI). The degree of individual-related elements had an overall mean score of 3.31. All of the factors taken into account under individual-related aspects in this study were moderately supported by respondents, it may be concluded.

TABLE III. DESCRIPTIVE INFORMATION OF RESPONDENTS

	Label	Frequency	Percent
Education	Less than high school	4	1.6
	High School or Less	21	8.3
	Diploma	93	36.9
	Bachelor	120	47.6
	Master	10	4.0
	PhD	4	1.6
Gender	Male	157	62.3
	Female	95	37.7
Age	18-30 years	10	4.0
	31-40 years	41	16.3
	41-50 years	88	34.9
	51-60 years	113	44.8
Chronic disease	Yes	252	100.0
Usage of IoT healthcare services	Yes	79	31.4
	No	173	68.6
Tool to access IoT healthcare services	Smartphone	39	15.5
	Devices in the house	19	7.5
	Wearable devices	21	8.4
	Not using	173	68.6

Table V lists the four dimensions of the level of technologically related factors: security, privacy, availability, and facilitating conditions. Security, privacy, availability, and facilitation conditions have comparable mean scores of 3.20, 3.18, 3.38, and 2.96. A substantial level of agreement with the

associated items or measures was determined in this study to be a mean score greater than 2.5. In light of this, the majority of respondents showed moderate agreement with all of the technologically linked criteria examined in this study. This is mirrored in Table IV's total mean score, which is 3.18.

TABLE IV. DESCRIPTIVE STATISTICS OF INDIVIDUAL FACTORS

Code	Mean	Std. Deviation	Level
PE1	3.34	.983	Moderate
PE2	3.25	.935	Moderate
PE3	3.29	.898	Moderate
PE4	3.28	.920	Moderate
Performance expectancy	3.29	-	Moderate
EE1	3.26	1.038	Moderate
EE2	3.49	.998	Moderate
EE3	3.42	1.036	Moderate
EE4	3.39	.999	Moderate
Effort expectancy	3.39	-	Moderate
SI1	3.41	.931	Moderate
SI2	3.15	.996	Moderate
SI3	3.17	1.193	Moderate
Social influence	3.24	-	Moderate
Overall mean score	3.31	-	Moderate

TABLE V. TECHNOLOGY-RELATED FACTOR DESCRIPTIONS

Code	Mean	Std. Deviation	Level
SC1	3.21	.986	Moderate
SC2	3.22	1.000	Moderate
SC3	3.18	.985	Moderate
Security	3.20	-	Moderate

FC3	2.96	1.011	Moderate
FC4	2.95	1.066	Moderate
Facilitating conditions	2.96	-	Moderate
Overall mean score	3.18	-	Moderate

The trust-related descriptive data are shown in Table VI. As a result, the overall average is 3.33, suggesting a moderate degree of agreement with the trust-measuring statements.

According to Table VII, the overall average grade for that behavioral intention (BI) is 3.30. All items used to gauge BI

severity have received moderate agreement from participants, as indicated by the mean score being larger than 2.50.

Table VIII displays the outcomes for the frequency of use. The majority of respondents only somewhat agreed with the assertions pertaining to real behavior, as indicated by the mean score of 3.41 for actual behavior (AB).

TABLE VI. DESCRIPTIVE STATISTICS OF TRUST

Code	Mean	Std. Deviation	Level
TRT1	3.27	.952	Moderate
TRT2	3.44	1.030	Moderate
TRT3	3.29	.952	Moderate
TRT4	3.32	1.172	Moderate
The overall mean of trust	3.33	-	Moderate

AB4	3.67	1.156	Moderate
Overall Mean	3.41	-	Moderate

B. Structural Equation Modeling

Structural Equation Modeling (SEM) is a statistical method for analyzing the relationships between multiple variables [127]. SEM can be used for a variety of purposes, including testing theoretical models, investigating complex relationships between variables, and examining causal relationships [128]. Some of the advantages of SEM include its ability to handle multiple variables, account for measurement errors, and test complex models. Additionally, SEM allows researchers to test both direct and indirect effects between variables, making it a powerful tool for hypothesis testing and theory development [129]. The structural equation model assessment is divided into two models. The first model is the first-order variables while the second model is the second-order variables. The steps of assessing the SEM-PLS are shown in Fig. 5. By using SEM, researchers can gain valuable insights into the factors influencing the behavioral intention of chronic disease patients to adopt IoT-healthcare services in Malaysia.

Fig. 5. Steps of assessing SEM-PLS.

1) *Measurement model assessment:* First-Order Measurement Model Assessment of SEM evaluates a structural equation model where all variables are measured by a single indicator, while Second-Order Measurement Model Assessment evaluates a structural equation model where one or more latent variables are themselves measured by other latent variables. Both assessments involve examining the reliability and validity of the measures used to operationalize the latent variables in the model to ensure that the measurement model provides a good fit to the data and accurately reflects the underlying constructs of interest [129, 130].

The finalized measurement model of this study is presented in Fig. 6, comprising the main constructs (1) individual-related factors (second order) and their dimension, performance expectancy, effort expectancy, and social influence (first order), and (2) technological-related factors (second order) and its dimension, which consist of the first-order variables; availability, security, privacy, and facilitating conditions. The factor loadings of the items on their respective variables and the loading of the first order on the second order are also presented.

Fig. 6. Measurement mode.

2) *Structural model:* The structural model is used to test hypotheses about the relationships among the variables and to estimate the strength and direction of those relationships [131]. The assessment of the structural model involved four criteria: R-square, Q-square, F-square, and the path coefficient. By integrating both the structural and measurement models, structural equation modeling provides a comprehensive analysis of the relationships among latent variables and their corresponding indicators.

C. Result of Hypotheses Testing

All three types of hypotheses—direct effect, mediating effect, and moderating effect—were examined here. Following Hair [74], all hypotheses were tested using a p-value of less than 0.05 and a bootstrapping sample size of at least 5,000. The direct effect hypotheses are summarized in Table IX.

The first hypothesis (H1) and its three components (H1a), (H1b), and (H1c) predicted the impact of personally relevant factors on behavioural intent. With p-values smaller than .05, the results showed that both performance expectation and social influence had a substantial direct impact on BI.

TABLE IX. THE OUTCOME OF THE TESTS OF THE HYPOTHESES

H	Factors	B	Std.	T-value	P Values	Significant
H1	Individual Related factors -> BI	0.238	0.082	3.032	0.002	Yes
H1a	Performance Expectancy -> BI	0.158	0.072	2.180	0.016	Yes
H1b	Effort Expectancy -> BI	0.043	0.057	0.752	0.230	No
H1c	Social Influence -> BI	0.153	0.072	2.121	0.019	Yes
H2	Technological related factors -> BI	0.454	0.072	6.288	0.000	Yes
H2a	Security -> BI	0.199	0.064	3.119	0.001	Yes
H2b	Privacy -> BI	0.042	0.063	0.665	0.253	No
H2c	Availability -> BI	0.107	0.055	1.971	0.045	Yes
H2d	Facilitating Condition -BI	0.238	0.054	4.400	0.000	Yes
H3	Behavioural Intention ->AB	0.620	0.047	13.217	0.000	Yes

H1, H1a, and H1c are all supported by this level of evidence ( $p < 0.05$ ). Since the expected effect of effort on BI was not statistically significant, H1b cannot be true. The second hypothesis claimed that technological factors, including security (H2a), privacy (H2b), availability (H2c), and facilitating conditions (H2d), had a major impact on behavioral intention. The p-values for security, availability, and enabling conditions were less than 0.05, implying that hypotheses H2, H2a, H2c, and H2d are accepted. Yet, the impact of privacy on BI proved insignificant, leading to the rejection of H2b. The impact of BI on user habits is substantial for H3 with a p-value of just under 0.05. As a result, H4 is supported.

Trust can mediate the relationship between different factors and people's behavioral intention (BI) to use technology. Specifically, the direct effect of trust as a mediator is significant, meaning that trust plays an important role in shaping people's attitudes toward technology. The indirect effect of technological-related factors via trust on BI is also significant, indicating that people are more likely to use technology when they trust it and perceive it as reliable. Similarly, the effect of individual-related factors on BI through trust as a mediator is also significant, suggesting- that people's personal characteristics and beliefs can impact their trust in technology, which in turn influences their intention to use it.

The results indicate that education plays a moderating role in this relationship, meaning that it can influence the strength of the association between individual/ technological - related factors and BI.

#### D. Discussion of Hypotheses Testing

The study found that individual factors, specifically performance expectancy (PE) and social influence (SI), significantly affected the patients' behavior intention (BI) towards adopting these services. The results are consistent with previous studies, suggesting that these factors are crucial in determining patients' willingness to adopt IoT healthcare services. While EE has an insignificant effect on BI, The explanation for this finding is that patients may only anticipate the benefits of these services without fully understanding the effort required to participate in them, in addition, since many individuals have grown accustomed to using contemporary gadgets in their daily lives, it has become easier for them to adapt to new technologies.

The second main hypothesis proposed that technological-related factors have a significant impact on BI, and the results indicated that these factors do have a significant effect on patients' BI. The findings suggest that technological factors are crucial in determining patients' willingness to use IoT healthcare services. This indicated that an increase in the level of technological-related factors will cause an increase in BI toward using IoT healthcare services among these patients. The results of the hypotheses testing revealed that security, availability, and facilitating conditions have a positive and significant impact on the BI, except for the privacy factor. The insignificant effect of privacy on chronic disease patients' behavioral intention (BI) towards adopting IoT healthcare services, may be due to patients' understanding of the difficulties in sharing their information with a third-party. This understanding may be attributed to Malaysia's local laws that protect patients' privacy, which could have influenced patients' willingness to use IoT healthcare services.

According to the third hypothesis, BI has a significant impact on the UB of IoT healthcare services among chronic disease patients. The findings indicated that BI is an important driver of UB.

The fourth hypothesis was related to the mediating effect of trust between individual and technological-related factors and chronic disease patients' BI towards using IoT healthcare services. The findings of the mediating analysis reflected that trust partially mediated the effect of individual-related factors on BI toward IoT adoption. Likewise, trust mediated the effect of technological-related factors on BI in facilitating IoT usage among chronic disease patients. This indicates that trust in the service providers can explain part of the relationship between individual and technological-related factors and BI.

The last hypothesis of this study predicted that gender and experience moderate the effect of individual and technological factors on BI towards using IoT by chronic disease patients. The findings indicated that the prediction was untrue. Gender did not moderate the effect of individual factors on BI nor the effect of technological factors on BI towards the use of IoT by chronic disease patients.

A possible explanation of the insignificant moderating effect of gender is the fact that the IT knowledge level among the patients was similar among male and female patients. In addition, the IoT is easy to use by both genders. In terms of experience or education, this study proposed that education

will moderate the effects of individual and technological-related factors on BI towards using IoT by chronic disease patients. The findings showed that this assumption is true.

## VI. CONCLUSION

The ultimate goal of this research is to examine the factors that influence patients' behavioral intention toward IoT adoption when dealing with chronic illnesses. The study found that patients who were provided with more information about their illness and believed that IoT devices could improve their quality of life were more likely to adopt IoT healthcare services in the form of wearable devices.

To enhance the model's explanatory capacity and originality, the investigation combined the UTAUT and TOE models with SET. The researchers used structured equation modeling (SEM) methods to test the integrated model on a group of Malaysians with chronic illnesses.

The study's findings indicate that individual factors and their dimensions, such as performance expectancy (PE) and social influence (SI), had a significant impact on chronic disease patients' behavior intention (BI) towards IoT healthcare services adoption in Malaysia. These results align with previous studies. The study also observed similar outcomes for technological-related factors and their dimensions, including security, availability, and facilitating conditions. Additionally, the effect of BI on UB was significant. Trust partially mediated the effect of individual and technological-related factors on BI, while education played a moderating role in the latter relationship.

This research is unique in the current literature on the Internet of Things (IoT) because it was undertaken in Malaysia. This study explored a number of hypotheses to shed light on what influences IoT adoption among Malaysians with chronic illnesses, as opposed to the narrower focus of TAM in other studies. Understanding the possibility of implementing IoT healthcare services in Malaysia Legislators and suppliers in the healthcare system are going to find the study results quite helpful. Patients and their loved ones would benefit from this research since the widespread implementation of IoT healthcare services will improve the quality and efficiency with which chronic disease management is handled. Meanwhile, healthcare workers will benefit from this study as well, since the IoT will facilitate the remote performance of their duties.

## VII. LIMITATIONS AND FUTURE WORK

Several limitations should be highlighted in this investigation. Patients with long-term illnesses were the focus of this research. This means that the results only apply to people who have a chronic illness. In light of this, it has been proposed that scientists increase the size of the sample numbers, such as those with mild diseases and frequent hospital visitors. This research looked into the use of Internet of Things healthcare services by people living with chronic diseases in Klang Valley, Malaysia. Researchers may therefore suggest conducting a global study with patients from diverse nations would allow for an additional thorough international comparison of results, as the current study's findings are specific to this demographic.

In this research, we looked at how gender and level of experience/education can act as moderators. There is a lack of information about how these factors influence users' decisions to use IoT, so more research will be needed to better understand the underlying relationships. Some of the observed associations between the studied variables and trust can be attributed to the role of trust as a mediator. To better operationalize trust in online interactions, in service delivery, and in healthcare settings, it is advised that future research investigate the possible role of this characteristic.

In this work, UTAUT, TOE, and SET were integrated to form a model for examining the research aspects. In subsequent works, a similar method could be utilized to more adequately illustrate the aforementioned IoT adoption variation. For instance, the combination of TAM and DOI or TAM and TPB or TAM, TOE, and DOI can be deployed to examine their power in explaining the adoption of IoT or other technologies.

**Abstract**—This study used the activity theory model to determine the dynamic difficulty adjustment of serious-game based on synthetic fog. The difference in difficulty levels was generated in a 3-dimensional game environment with changes determined by applying varying fog thickness. The activity theory model in serious-games aims to facilitate development analysis in terms of learning content, the equipment used, and the resulting in-game action. The difficulty levels vary according to the player's ability because the game is expected to reduce boredom and frustration. Furthermore, this study simulated scenarios of various conditions, scores, time remaining, and the lives of synthetic players. The experimental results showed that the system can change the game environment with different fog thicknesses according to synthetic player parameters.

**Keywords**—Dynamic difficulty adjustment; serious-game; activity theory model; synthetic fog; synthetic player

## I. INTRODUCTION

One of the most significant challenges in successful teaching is preparing a suitable learning environment [1]. Several studies have shown that appropriate teaching methods are usually active, engaging, goal-oriented, [2] generate spontaneous random feedback, and provide solutions to challenges [2], [3]. The last two characteristics are also possessed through instructional content when playing games embedded in a computer [4]. Scientifically, this category of game is called a serious game [5], and it aids in making the learning process more interesting, fun, comfortable, effective, improves learning performance, student's skills, and behavior [5], [6].

This research aims to change the habits, ways of thinking, views, increase knowledge, and train the soft skills of serious-game players. It also increases engagement, extrinsic and intrinsic motivation, creates awareness, and analyzes games developed to focus on a particular lesson, which can be played in the classroom or at home.

Carvalho et al. [7], [8] proposed a scheme to analyze and evaluate various student experiences with learning material for later aggregation and study. According to Callaghan et al. [9], the serious-game view is complex and covers three principal activities, namely gaming, learning, and instructional, comprising the student and the teacher. The game consists of basic supplementary attempts or resources obtained from the teacher.

The Activity Theory Model Serious-Game [10] (ATMSG) method [8] comprises four analytical phases. In the first stage, the teacher explains the critical tasks relevant to the system action and defines the course and theme. The second stage establishes a sequence as a map to help define the game's core elements and provide an initial point for determining the interlinked aspects of the system framework. In the third stage, the trainer describes elements relevant to each node of the game [11] order. While in the last phase, the teacher collects suitable acts, resources, and targets that equally belong to the game order. After completing the phase, the trainer has a summary of the play structure, knowledge, and didactic components, as well as their application.

However, some weaknesses are associated with the serious game, such as difficulty in playing, which sometimes frustrates the players. To overcome these weaknesses, the player must achieve a state of "flow" [12][13], which is usually characterized by sustained concentration and increased achievement. Several studies proposed Dynamic Difficulty Adjustment (DDA) [14]–[19], a mechanism to dynamically maintain a game's difficulty level [20]–[22] to ensure an increase in user's interest.

The mechanism of dynamic difficulty adjustment starts with processing data from players and enemies in the game and changing the difficulty level [23]–[26] based on the player's skill. The attributes of both parties are usually changed to dynamic, and the more skilled the player, the greater the possibility of the system limiting resources and the harder it will be to beat the enemies. However, when the player suffers defeat, the game will provide weaker enemies and abundant resources [27].

Several studies have examined DDA in games, such as computer-controlled players [27], and inferred difficulty curves from real-time data [28]. These studies developed automatic difficulty selection [29], applied appropriate difficulty based on player information [30], determined the effect of difficulty setting on trust players [31], and produced dynamic game content based on evidence-centred design [32]. However, this study will adopt simpler and faster techniques [32] by using a dynamic value to adjust the game's difficulty level.

This study proposes the automatic DDA based on synthetic fog setting to reduce players' visibility. Artificial fog

technique is widely used to measure fog removal techniques from natural images [33]–[36]. Nevertheless, artificial fog is more used to produce difficulty when playing games, adding a mysterious experience and increasing tension. This technique has not been previously used in preliminary studies to determine difficulty level because artificial fog is an art without any standards. Moreover, the in-game synthetic fog only serves as a compliment.

A synthetic agent [37][38]–[41] was used to determine the serious-game [42] dynamic difficulty levels that should be achieved based on the final target scenarios, which is modified at each level.

## II. RELATED WORKS

A study conducted in 2015 [43] proposed setting the difficulty of the enemy character, which can change their nature and behaviour, based on the game player's ability. It only focused on changes in the conduct of the enemy's character with the difficulty setting method completed [44] using an evolutionary algorithm. Lach [45] used an adaptive evolutionary algorithm to regulate non-player characters' behaviour. These approaches do not provide details of the framework used for the serious-game foundation.

Callaghan proposed using a serious-game framework based on activity models [8] to integrate analytical techniques in engineering lessons in 2018 [9]. However, the approach taken does not consider adaptive difficulty management.

Another research article [30] proposed using a fuzzy coordinator for dynamic difficulty setting in commercial games applied to bots. Although the study described the behaviour of smart bots, which have a variety of capabilities, it was not applied in serious games.

A dynamic process was used by [29] to determine the difficulty setting in video games without stating the use of methods and parameters set dynamically at each level. The report by [28] also proposed a dynamic difficulty setting, for puzzle games, using a rating system. Preliminary studies [28], [29] have not implemented the serious-game strategy because they do not use machine learning methods.

A previous study by [32] proposed a dynamic difficulty setting in game-based learning using the ECD framework to design and assign each student's competency. A dynamic difficulty setting was designed by changing the non-player character's attributes that can balance the abilities of students who are playing dynamically. The study focused on educational content questions without considering the game environment setting. It also introduced the ECD framework for dynamic difficulty management [32], focusing on mathematics using standard Indonesian student exams. These studies focused on the evidence used as a reference to process dynamics more accurately and effectively.

The study by [27] proposes creating an enemy using the dynamic difficulty setting and applying it to the business content. The dynamic difficulty setting handles two strategies, namely enemies who can decide strategies and provide threats

to players, who are expected to be more involved in the game.

An architecture was proposed in [46] to produce enemy formations in a procedurally two-dimensional game. This was carried out to determine the variable difficulty curve and enemy variation used to design an appropriate difficulty setting based on the fitness function calculation [47]. The study by [46] presented the dynamic difficulty adjustment with a skill chain and ranking system used to balance the game's difficulty. Their discussion suggested that the skill chain can be useful for getting players to complete a higher number of tasks with a greater difficulty level.

Studies on the dynamic difficulty setting of the serious game are challenging to explore. To date, no system has been proposed, using the concept of the activity theory model [9], irrespective of its numerous advantages and convenience in developing and analyzing the learning strategies of the games.

Meanwhile, the serious-game dynamic difficulty setting system with the activity theory model has a more detailed division and is more suitable for an educational game. Several studies have discussed the dynamic difficulty settings [27][48][47] aimed at enemy characters capable of deciding strategic behaviour and producing appropriate attack formations. It also uses skill chains to produce balance by providing several missions with a higher level of difficulty. However, this present study aims to design a dynamic difficulty management system which uses the activity theory model to determine environmental changes and the difficulty level of the serious game. This process is carried out by applying synthetic agents as substitutes for players to facilitate analysis. The contributions of this research are described in the following paragraphs.

First, a dynamic difficulty adjustment is proposed in the activity theory model of the serious-game. The system reads the player's parameters' initial value and then re-reads it after the player receives an award. Based on reading this second parameter, the system can dynamically adjust the difficulty level. Furthermore, it changes player and game parameters, saved in the settings log, to produce a new level of play. In this study, the virtual environment system can interact with players.

Second, the change in difficulty is designed using the artificial fog model, where the thickness can be calculated according to a heterogeneous distribution. This artificial haze can prevent players from recognizing objects that must be collected as part of the learning mission that must be achieved. Third, synthetic agents can be used to test the system for difficulty level changes, making it easier to analyze and more comfortable to fix.

Several sections of this research describe the development, testing, and analysis of file systems. Section III discusses the introduction to the dynamic difficulty adjustment, the activity theory serious-game model, the dynamic difficulty adjustment model, the artificial fog model and the application of synthetic agents. Furthermore, the experimental results and the discussion are shown in Section IV, while Section V concludes the research.

### III. DYNAMIC DIFFICULTY ADJUSTMENT

The dynamic difficulty adjustment process was carried out using parameters at an entry-level. When players increase or decrease a specific parameter, they have new values, which add to the old one to create a new parameter. Therefore, from new parameters, the game starts a new level, which splits its parameters into HVHL and LVHL. HVHL represents higher value parameters used to determine health and score. A player with high health and score is tagged better; hence the difficulty level should be adjusted. LVHL reflects a parameter that indicates a better player for a higher value [32]. This parameter is increased when the player solves a game problem quickly. Table I shows the game's parameters. Curriculum and the Education Unit Level Curriculum[49], as shown in Table II.

Compute each parameter's value by determining the skill value ( $efF_i$ ), which is determined using equation (1). It calculates the player's performance, which is dependent on the current achievement parameter ( $F_{val_i}$ ), the maximum ( $F_{max_i}$ ), and the minimum ( $F_{min_i}$ ) values.

Measure the overall player value and enemy's skill to specify the total amount ( $ef$ ), the player or opponents abilities using equation (2). Equation (2) includes the weight of each parameter. The value serves as the significance of a parameter used to define the players' performance, as shown in Table III. For a detailed explanation, please refer to [14]–[19].

$$efF_i = \begin{cases} \frac{F_{val_i} - F_{min_i}}{F_{max_i} - F_{min_i}} & \text{for HVHL} \\ \frac{F_{max_i} - F_{val_i}}{F_{max_i} - F_{min_i}} & \text{for LVHL} \end{cases} \quad (1)$$

$$ef = \frac{\sum_{i=1}^n (efF_i * weight_i)}{\sum_{i=1}^n weight_i} \quad (2)$$

Analyze the skill values of the player and the opponent ( $diff\ ef$ ) to determine whether the change is necessary using equation (3). The  $efp$  and denotes the player's and the enemy's skill value, which is measured using equation (2).

$$diff\ ef = > p_{lim} * efp \quad (3)$$

Compute the arrangement value and replace the opponent parameters. The game parameters are modified using equations (4) and (5).

$$adj\ Fi = \begin{cases} diff\ ef * (F_{max_i} - F_{min_i}) & \text{for HVHL} \\ -diff\ ef * (F_{max_i} - F_{min_i}) & \text{for LVHL} \end{cases} \quad (4)$$

$$F_{val_{0,i}} = \begin{cases} F_{val_{old_{0,i}}} + adjF_i & \text{for } efp > efo \\ F_{val_{old_{0,i}}} - adjF_i & \text{for } efp < efo \end{cases} \quad (5)$$

$adj\ Fi$  and  $F_{val_{0,i}}$  denote the appropriate value and current modification values of the players. This indicates that the device lowers the skills of players' previous opponent and attributes  $F_{val_{0,i}}$  for them to beat the enemy more efficiently. The method is continuously used until the players have solved all problems or their health points equal zero.

#### A. Activity Theory Model Serious-Game

The gameplay consists of 6 steps, as shown in Fig. 1. In phase 1, the player is asked to take action by customizing the avatar or choosing the model after entering the game through its configuration section. Furthermore, in phase, players learn how to play and assess the game based on the activity model. In phase 3, they face the choice to choose a new mission or continue with the old one. When players select a new task, they play a puzzle, and when they decide not to select a new mission, the game system provides suggestions. The puzzle played in phase 4 consists of the tool in the form of tiles. The game's goal is to visualize the changes in the value achieved. Students perform tasks to fulfil missions, overcome challenges to remember knowledge, and focus on work.

Furthermore, in phase 5, the game awards added values to determine additional player abilities and other bonuses. After receiving the award, players face another challenge, which is an opportunity to increase the rewards they have received until the maximum value is achieved. There are three sides of players on the activity theory model, namely the play, learning, and intrinsic instruction. The player seeks help to learn the game interface using a pre-installed tutorial. From a learning point of view, the player analyzes the device provided by the game in the form of suggestions. The intrinsic instruction process enables the player to demonstrate and provide the player with learning instructions. Game systems assess, measure performance, and give feedback to players. Phase 6 evaluates, appreciates and improves the performance [5], [9], [46], [50]–[52].

TABLE I. GAME'S PARAMETERS

Subject	Group's Parameter	Process	Game's Parameter
Player	HVHL	Number of correct answers	Score
	LVHL	The time to fix the task	Action Time
Enemy	HVHL	Enemy knack to break the problem with distinct form of query	Strength
	LVHL	knack to resolve matter in restricted time	Velocity

TABLE II. HIGHEST AND LOWEST VALUE OF EACH PARAMETER

No.	Attribute in-game	Value	
		Highest Value/Fmax	Lowest Value/Fmin
1.	Score	100	45
2.	Action Time	210	0
3.	Strength	100	45
4.	Velocity	250	0

TABLE III. PARAMETER'S WEIGHT

Parameter	Weight
Score/Strength	0.8765
Action Time/Velocity	0.1235

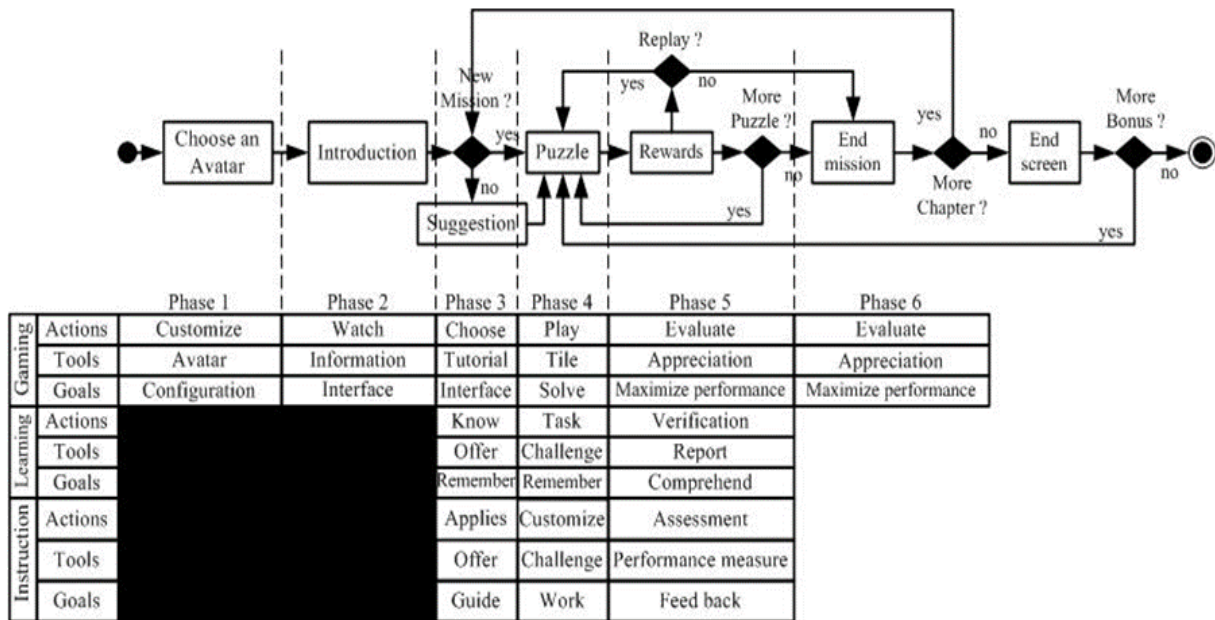

Fig. 1. Phases of Gameplay.

**B. Dynamic Difficulty Adjustment Model**

The process applied when the player successfully answers the question is analyzed in the dynamic difficulty adjustment model. There are four main processes in the application of FDDACP method in the game, these include 1) Collect Enemy's and Player's Attributes, 2) Adjust Level of Difficulty, 3) Change Enemy's and Player Attributes and 4) Save changes in Log. This process is shown in Fig. 2 [32].

**C. Dynamic Difficulty Adjustment Model in Activity Theory Model Serious Game**

Fig. 3 shows the mechanism of implementing the dynamic difficulty system in a serious game. This process is applied when the player fulfils the associated task. The proposed method in this research comprises the following six stages.

- 1) Read the initial parameter value of the player. This mechanism collects the entire parameter value before the player starts the game.
- 2) Player puzzle. After several times, the player receives the rewards, and the system reads the parameter value. This step processed the parameter value provided by the reward step and used it as input for the system adjustment method.

3) Adjust level using dynamic difficulty adjustment processes the parameter value provided by the 2<sup>nd</sup> step and calculates it to determine the mechanism.

4) The change of the player's parameter is carried out based on the adjustment value. For instance, if players are about to lose, the game gives them more time to answer the next question in peace.

5) Save Log Settings. This method saves the process of change in the game to see where the student needs change.

6) Create a new level. The change value is stored in the Log function to generate a new level.

When the player asks questions in the game, all processes above are completed. The next question will change the parameter as long as the player is safe.

**D. Synthetic Fog Model**

The use of synthetic foggy imagery aims to facilitate the creation of three-dimensional fog in a game. Therefore, changes can be made more measurable to reduce manufacturing time. The standard size of the PSNR and SSIM index is used to facilitate evaluation and comparison and a more detailed explanation can be seen in the reference [36][34]. Fig. 4 shows a different fog environment.

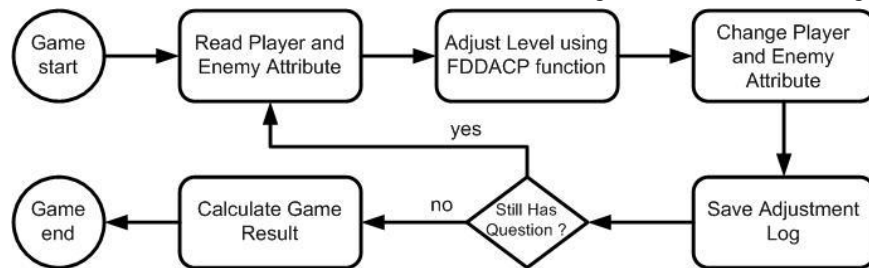

Fig. 2. Dynamic difficulty adjustment model.

#### IV. RESULT AND DISCUSSION

##### A. Dynamic Difficulty Calculation

The results obtained from equations (1) to (6) are shown in Table IV. It comprises two scenarios, namely the enemy is lower and higher than the player. Therefore, for the first case, the parameter power was 1 (HVHL), and the speed was 100 (LVHL). This means that when the player reaches a score and time-act of 10 and 43, the game system will change, and in the next stage, the enemy's parameters increase hence the power and speed become 8.88 and 96.65. When the player's achievement is almost the same, the score becomes ten, and the time-act 40, hence the power parameter increases to 9.32, while the speed drops to 93.31.

Furthermore, in 2<sup>nd</sup> scenario, the enemy was higher with power and speed value of 15 and 30, while the player's achievement remained the same as in the previous scenario, at a score and time-act of ten and 43. When the power decreased to 13.62 and speed increased to 30.76, with the player's score, time-act, power and speed parameters of 10, 40, 10.08, and

32.11.

##### B. Synthetic Fog

This research used the score, time remaining, and player life parameters to determine the opponent's function in the game system. At the beginning of the game, players were not allowed to fight their opponents, but against time, score, and life, known as HVHL. The time remaining and the player's health are denoted with LVHL. The DDA changes the fog's thickness to hinder players from fulfilling the mission given. The fog used in this study is synthetic [36][34], as shown in Table V. Therefore, the thinner the fog, the lower the difficulty level generated, and the thicker the fog, the harder it becomes.

The haze is divided into ten parts, as shown in Table V. It starts from level 0 to 9, which denotes dense to extremely clear. In the game, fog level 0 (thick) means it is the most challenging, and 9 (extremely clear) denotes easy, as shown in Table VI.

TABLE IV. EXAMPLE OF THE GAME SCENARIO

Scenario 1 <sup>st</sup>				Scenario 2 <sup>nd</sup>			
Enemy = Low				Enemy = High			
HVHL	LVHL	HVHL	LVHL	HVHL	LVHL	HVHL	LVHL
Score	Time-act	Power (enemy)	Speed (enemy)	Score	Time-act	Power (enemy)	Speed (enemy)
10	43	1	100	10	43	15	30
10	40	8.88	96.65	10	40	13.62	30.76
		9.32	93.31			10.08	32.11

TABLE V. DIVISION OF FOG IN INTERNATIONAL VISIBILITY [36][34]

Haze level	Haze	Visibility
0	Dense fog	<50 m
1	Thick fog	50 - 200 m
2	Moderate fog	200 – 500 m
3	Light fog	500 m – 1 km
4	Thin fog	1 km – 2 km
5	Haze	2 km – 4 km
6	Light haze	4 km – 10 km
7	Clear	10 km – 20 km
8	Very clear	20 km – 20 km
9	Extremely clear	>50 km

TABLE VI. FOG/HAZE TYPE FOR EACH LEVEL IN THE GAME

Game level	Fog/Haze type
Level 1	Extremely clear
Level 2	Very clear
Level 3	Clear
Level 4	Light haze
Level 5	Haze
Level 6	Thin fog
Level 7	Light fog
Level 8	Moderate fog
Level 9	Thick fog
Level 10	Dense fog

### C. Game Screenshot

The proposed game is shown in Fig. 5, where Fig. 5(a) is a screen belonging to the synthetic player, which comprises the time remaining, the achieved and target scores, the game difficulty level, and the synthetic player's life. Fig. 5(b) is the mission the synthetic player needs to complete, while Fig. 5(c) is the object to avoid. If the task can be accomplished, points will be added, while a decrease in the synthetic player's life is obtained when the object is held.

Fig. 6(a) and 6(b) represent the game's 3<sup>rd</sup> and 4<sup>th</sup> levels. The mission and object positions that must be avoided are visible in both figures. Fig. 7(a) and 7(b) show the 3<sup>rd</sup> and 5<sup>th</sup> levels of the game and its conditions. A thicker haze surrounds the game environment compared to Fig. 6(b). In Fig. 7(b), the mission positions to be reached and the objects to be avoided are increasingly invisible due to the thick fog.

Fig. 8(a) shows the 3<sup>rd</sup> level of the game, as illustrated in Fig. 6(a) and 7(a) It also shows the mission positions and objects to avoid. Meanwhile, Fig. 8(b) shows the condition when the game reaches the 9<sup>th</sup> level. Apart from the mission and invisibility of the objects to be avoided, the trees in front of the synthetic player also start to disappear.

### D. Dynamic Difficulty Level Selection

The selection of dynamic difficulty levels is shown in

Table VII. It indicates several different parameters owned by a synthetic player, such as score, student time, life, and health of the synthetic player. The following column shows changes in the level of difficulty with and without using DDA. The scoring parameter, remaining time and life of 12, 63 and 27 are shown in the third row. According to the settings based on DDA, with and without the game, levels are 3 and 2. The challenge increases with greater excitement when the player is at level 3.

Furthermore, when the score level drops on the scenario 4<sup>th</sup> to 10, the DDA will set the game level back to level 2. In contrast, in the settings without using the game level is increased to level 3 because it will undoubtedly cause players to feel frustrated and easily bored with the game.

Another example is seen in scenarios 7 to 10 in yellow highlight, where the setting with and without DDA determines the difficulty level to be 7 and 5 in green highlight, respectively. When the synthetic player score increases to 49 in red highlight, the setting uses DDA of the difficulty level rises to 8 in magenta highlight. Furthermore, the synthetic player score increases to 52 and 54 with the rise in the difficulty level to 10.

This is different from the difficulty level settings without DDA because when the synthetic player score is 35, the game system without DDA determines the difficulty level at 5 in green highlight. When synthetic player's score increase to 49, 52, and 54, the game difficulty level is suddenly raised to level 10 shown in grey highlight, which will lead to a sudden rise, frustrating the player and making them more reluctant to continue the game.

The phenomena in Table VII are graphically visualized, as shown in Fig. 9. The graph shows that the increase in the difficulty level using DDA is progressing, as indicated by the purple line.

A synthetic player is used to provide the advantage of testing many times without worrying about boredom. Fig. 10 is an experimental visualization of 10 repetitions, where each experiment is carried out 1,000 times to determine the difficulty/gameplay change.

TABLE VII. THE GAME LEVEL SELECTION COMPARISON

Scenario	Input Parameter			Game Level	
	Score	Time Remain	Player Life	DDA	without DDA
1	2	70	10	1	1
2	4	66	28	1	1
3	12	63	27	3	2
4	10	47	35	2	3
5	14	42	38	3	3
6	26	36	31	4	4
7	35	28	38	7	5
8	49	25	40	8	10
9	52	11	50	9	10
10	54	9	65	10	10

E. Comparison

This study produces a dynamic difficulty adjustment system applied to a serious game based on the activity theory model for educational material in 3D format. It differs in characteristics compared to the application of DDA in other studies. Table VIII shows these differences in detail with reference [32] to students and determining what has changed in enemy behaviour without implementing the serious-game model of activity theory. This is in accordance with the study by [27] on applying DDA in business and in-game. The study [48] is a study that focuses on setting up enemy formations in the 2-dimensional role play game genre. Adjustments are made based on variable difficulty curves and enemy variations of the fitness function. Preliminary study by [47] implements DDA using a ranking system to balance gameplay. When compared with the four studies, this research has similar characteristics [32]. However, the advantage of environmental changes resulting from DDA is applied in a serious-game-based activity theory model and tested using a synthetic player.

TABLE VIII. DIFFERENCE IN CHARACTERISTICS COMPARED TO THE APPLICATION OF DDA IN OTHER STUDIES.

V. CONCLUSION

In conclusion, this study proposed a dynamic difficulty setting system to overcome boredom and frustration when playing educational games. The game format selected is serious-game with an activity theory model, which details each goal into instruction, learning, and games. The serious-game comprises the same scope, namely action, equipment, and targets, making it easier to design a serious-game for specific and precise educational needs.

At the experimental stage, the serious-game system building was combined with a dynamic difficulty setting to obtain the players' abilities and skills. Furthermore, the limited visibility at different levels of difficulty led to the proposal of a 3D serious-game, which does not need the process of determining the characters in the early stages of the game. Designing a serious game for education determines the dynamic difficulty setting and educational content. The experimental results showed that the game system created can adjust the game environment smoothly.

Compared to previous studies, the system in this study has the advantage of using a serious-game model that focuses on improving student knowledge, involving smooth environmental changes, and avoiding competition with enemy characters. Besides, the proposed system is also able to follow the abilities of players who are not always the same.

Our next study is to add educational material settings for different player achievements. So not only setting the fog thickness but also considering the setting of educational materials. And we added artificial intelligence to make the changes more subtle.

ACKNOWLEDGMENT

We express our deepest gratitude to all leaders and laboratory assistants and Multimedia Laboratory in the Informatic Engineering, Faculty of Science and Technology, UIN Maulana Malik Ibrahim, Malang.

**Abstract**—Breast cancer is the leading cause of mortality in women worldwide. One of the biggest challenges for physicians and technological support systems is early detection, because it is easier to treat and establish curative treatments. Currently, assistive technology systems use images to detect patterns of behavior with respect to patients who have been found to have some type of cancer. This work aims to identify and classify breast cancer using deep learning models and convolutional neural networks (CNN) with transfer learning. For the breast cancer detection process, 7803 real images with benign and malignant labels were used, which were provided by BreakHis on the Kaggle platform. The convolutional basis (parameters) of pre-trained models VGG16, VGG19, Resnet-50 and Inception-V3 were used. The TensorFlow framework, keras and Python libraries were also used to retrain the parameters of the models proposed for this study. Metrics such as accuracy, error ratio, precision, recall and f1-score were used to evaluate the models. The results show that the models based on VGG16, VGG19 ResNet-50 and Inception-V3 obtain an accuracy of 88%, 86%, 97% and 96% respectively, recall of 84%, 82%, 96% and 96% respectively, in addition to f1-score of 86%, 83%, 96% and 95% respectively. It is concluded that the model that shows the best results is Resnet-50, obtaining high results in all the metrics considered, although it should be noted that the Inception-V3 model achieves very similar results in relation to Resnet-50, in all the metrics. In addition, these two models exceed the 95% threshold of correct results.

## I. INTRODUCTION

Breast cancer is the second most common cancer in women globally with more than 2.2 million cases in 2020. Breast cancer is the leading cause of mortality in women worldwide, as it is estimated that, in 2020, this carcinoma killed about 685 000 women [1]. This can be classified according to its histological basis into in situ and invasive carcinoma. Regarding the diagnosis of this disease, the evidence recommends that women over 40 years of age should undergo a screening mammogram every two years at the latest [2]. Mammography is the most used technique for the diagnosis of breast cancer; however, this test usually requires other ancillary tests to accurately determine the status of the tumor, among which are ultrasound [3] and tissue sampling [4]. Therapeutic treatment consists of debulking surgery, radiotherapy, endocrine targeted therapy and chemotherapy [5]. Among the surgical interventions, segmental mastectomy has proven to be effective in the treatment of tumors detected at early ages,

especially when combined with the use of radiotherapy [6]. From these interventions, a sufficiently representative tissue sample is also obtained to perform the histopathological studies necessary for the determination of the benign or malignant nature of the tumor, which is why these images are used for the work. The main problem is how to identify and classify breast cancer using deep learning models. Also, as specific problems we have What kind of models can be applied? How to evaluate each of the models for the proposed case?

This paper presents four CNN models that can discover the features in the images, such as edges and corners to detect the type of breast cancer from biopsies, which can be used by medical centers to detect carcinoma in their patients. The four deep CNN models were programmed to classify the images into two types: benign and malignant. The CNN-based transfer learning models used for this research work are: VGG16, VGG19, ResNet50, and Inceptionv3, these models were programmed with the database hosted in Kaggle. The four CNN models seek to diagnose the type of breast carcinoma from histological breast images. It should be noted that the models used do not have the same number of depth layers, nor programming architecture, so the results are different in terms of accuracy. The objective of this work is to identify and classify breast cancer using Transfer Learning.

This paper is organized in the following order: In Section II a review of related works was performed, in Section III the methodology used for training the models is synthesized, in Section IV the results after experimentation are presented in addition to the discussion and in Section V the paper is concluded.

## II. RELATED WORK

In recent years, the concept of CNN has started to be used in fields such as medicine. This is because since their introduction they have presented very good results in image processing, as stated by LeCun in [7], [8].

The capacity of CNNs in image processing has led researchers to start using them in the classification of histological images, as is the case of [9], where they carried out a work for the classification between benignity and malignancy of images obtained from breast tumors in a Brazilian laboratory, a model with AlexNet architecture was trained using four different strategies to deal with the high resolution of the images presented; obtaining results close to 85% in all strategies. Among the results of the work, an accuracy of 89.6

+/- 6.5% stands out. In a different work it can be observed that the applications expand to other medical fields, as is the case of [10] where a model based on the Inception V3 architecture is trained to detect the stress of a person based on thermal images of points of interest of the head. The results obtained were good, reaching an accuracy of 88% when 5 stress classes were used, but 97% when these 5 classes were divided into 2 with the labels "No stress" (classes 1 and 2) and "Stress" (classes 3, 4 and 5). The authors, in [11] developed a CNN model to segment the various types of breast abnormalities, based on the pretrained ResNet 50 model, achieving a recognition rate of 88%. Similarly, in [12] used 3 CNN models, Inception V3, Inception-ResNet V2 and ResNet-101, to predict whether patients with primary breast cancer will metastasize, based on their ultrasound images, the results were compared with the performance of 5 radiologists, having positive results in the two tests performed, in A and B with an area under the receiver operating characteristic curve (AUC) of 0.9 and 0.89, a sensitivity of 82% and 85% and a specificity of 0.79% and 72%, respectively. Another study by in [13] implemented a method to classify breast cancer into benign and malignant based on a CNN, AlexNet. The results obtained show that AlexNet obtained an accuracy greater than 99%, superior to existing algorithms.

The following Table I summarizes the results obtained by the authors described in the previous points.

In [14] used a new advanced methodology that develops machine learning algorithms, such as deep learning algorithms, to accurately classify breast cancer. Deep learning algorithms are fully automatic in learning, feature extraction and classification and are suitable for all images, from natural images to medical images. The authors used a deep convolutional neural network, AlexNet, to classify breast cancer in mammography images. The performance of the proposed convolutional network structure they evaluated and compared with existing algorithms. In [15], four convolutional neural network (CNN) models were proposed for pneumonia detection in chest radio-graphs. They were trained to classify radiographs into two types: normal and pneumonia, using multiple convolutional layers. The models used in this work are pre-trained: VGG16, VGG19, ResNet50 and InceptionV3. The metrics used to evaluate the results are accuracy, recall and F1 score. The results showed that the Inceptionv3 model performed the best with 72.9% accuracy, 93.7% recall and 72.9% F1 score. 72.9% accuracy, 93.7% recall and 82% F1 score. This shows that CNN models are suitable for detecting pneumonia with high accuracy.

TABLE I. SUMMARY OF MODEL PERFORMANCE METRICS ACCORDING TO AUTHORS

Authors	Accuracy	Error rate	Other indicators
Fabiol, O. Luiz, P. Caroline and H. Laurent [10]	85% 88.9%	--6.5	-
S. T. Ahmed and S. M. Kadhem [11]	88% - 97%	-	-
Maleika, B. Nazmeen, D. Wasiimah, N. Shaista, G. Xiaohong, Sinha GR [12]	88%	-	-

### III. METHODOLOGY

This section details the procedure or methodology used for training and fitting CNN-based models from data acquisition to validation (evaluation) of results. Fig. 1 summarizes the 8-step process for model fitting, and subsequently the evaluation of the fit or generalization using data that the model has not seen (data test). This process starts with the data source, is ingested into the work environment for division into training and test data, followed by a normalization phase, then images are generated from the existing ones with the data augmentation technique, then transfer learning and fine tuning are applied to create models adapted to the case, then goes the training and adjustment, then metrics are used for model evaluation and model validation, if the model exceeds the threshold the final model is obtained otherwise it returns to the phase of pre-trained models for application of fine tuning until the model is valid.

#### A. Data Source

The breast cancer histopathology images acquired from patients have been obtained from the Kaggle platform, whose main source and original publication was provided by "Laboratory of Vision, Robotics and Imaging (VRI)" at the following link <https://web.inf.ufpr.br/vri/databases/breast-cancer-histopathological-database-breakhis/>, where there are two folders, one for each class, the first one for benign type images and the other one for malignant type images. The data source provides 7803 histopathology images obtained from the platform mentioned in the previous point, such images are provided in two types, 2479 images correspond to benign type and 5324 are of malignant type, in Fig. 2 a sample can be observed.

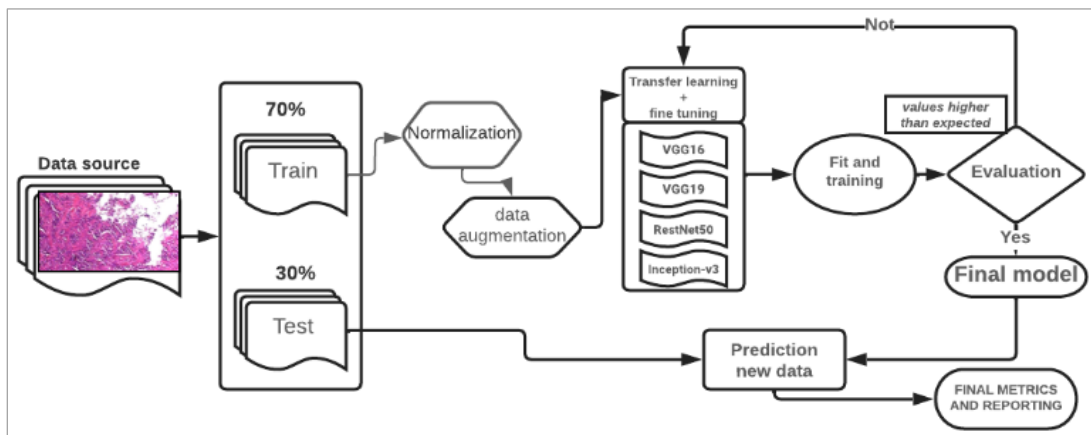

Fig. 1. Flow diagram corresponding to the phases of the silver-plated system.

Fig. 2. Sample histopathology images obtained from the source.

### B. Data Train and Test

Once the images have been ingested, they have been divided into training and test data, the criterion is 70% to train the models and 30% to evaluate results, this will allow determining the generalization of the models.

### C. Normalization

The original images go through a normalization process, to avoid problems at the time of training [16][17], the criterion used is the division 1 between the maximum value of the pixels, for the case 1/255, which gives values between the range of 0 and 1.

### D. Data Augmentation

The objective of data augmentation is to generate more images from the existing ones [18][19], the criteria used are: random rotations of 25 degrees, increase and decrease of width and height corresponding to 0.15 of the original size, random zoom of 20%, points outside the input limits by the "reflect" method and randomly flip the inputs horizontally, in Fig. 3 an example of a particular image and the result of five transformations can be observed.

Fig. 3. Results of data augmentation transformation for the images under study.

### E. Transfer Learning and Fine Tuning

Transfer learning is a method where previously trained models are used and applied to a particular case, for this study we have used models trained with a set of data provided by the "ImageNet" contests and that have been shared by the keras library [20][21], the models correspond to VGG16, VGG19, Resnet 50 and Inception V3. Such models were trained with 1.4 million photographs as input and 1000 image classes as output, among which vehicles, plants, animals, etc. stand out. The description of the models is detailed in the following points:

1) *VGG16*: The architecture of this neural network model stands out for using 3x3 convolution kernels, smaller than the previous models, in addition to max-pooling layers of a size of 2x2 [22]. The input size of the network is 224x224. At the output of the convolution layers, we have 3 layers of neurons formed by 4096 the first 2 and 1000 the last one, which presents a SoftMax activation function to determine the image class. Fig. 4 represents the architecture for this study.

Fig. 4. VGG16-based model for breast cancer staging.

2) *VGG19*: The architecture of this neural network is like that of VGG16, where the difference in number represents the number of convolutional and dense layers in each model, which, in this case, would be 19 [23], Fig. 5 shows the architecture for this research.

Fig. 5. VGG19-based model for breast cancer staging.

3) *ResNet50*: Convolutional neural network with 50 layers deep. These layers are ordered starting with one of a 7x7 convolution kernel, a 2x2 max-pooling [24], 9 layers repeating 3 times a sequence of 3x3. 64, 1x1,64 and 1x1,256, 12 layers repeating 4 times a sequence of 1x1,128, 3x3,128, and 1x1,512, 18 layers repeating 6 times a sequence consisting of 1x1,256, 3x3,256 and 1x1,1024 and completes the 50 layers with 3 repetitions of a sequence of 1x1,512, 3x3,512 and 1x1,2048. From this the average-pooling layers are used, in Fig. 6 the model used for the case is represented.

Fig. 6. ResNet 50-based model for breast cancer classification.

4) *Inceptionv3*: This is the third version of a neural network with 48 layers deep, unlike the VGG architectures, it requires considerably less computational power, but still provides reliable results. The size of the network image input is 299 x 299. Fig. 7 shows the synthesized process for the case.

Fig. 7. Inception V3 model for breast cancer staging.

Fine tuning is the method that allows to adapt the results when using a pre-trained model, since such models had a different or similar task to the one being studied. For this case of this study whose output is of two classes, in which you want to evaluate whether an image corresponds to benign or malignant type, it is used import the original models without considering the fully connected layer, then the convolutional layer is retained, the fully connected layer is added and the output of two classes.

A convolutional neural network model has the first layer corresponding to the convolutional layer, it is a block where most of the computations occur, given by a set of convolutional filters each of which allows to detect certain characteristics of the images. For example, 1) Pooling operation: it allows to simplify the output of the results of the convolution operation by decreasing the subsampling rate, thus reducing the number of parameters that the network needs to learn. There are several types of subsampling, for this study Max-Pooling is used; 2) Flatten layer: allows to add a flat layer where the spatial dimensions of the input collapse in the dimension of the channel, this procedure is used in this pooling and prior to the fully connected layer; 3) Fully connected: in this stage all the input neurons (flattened) are connected to each neuron of the output layer. The main objective of this fully connected layer is to carry out a kind of clustering of the information that has been obtained so far, which will be used in subsequent calculations for the final classification; 4) Evaluation: for the evaluation of the different models, multiple evaluation measures are used to assess the performance of a Deep learning model. Its objective is to verify the accuracy of the generalization of a model on new data. Different metrics such

as confusion matrix, accuracy, precision, recall, F1-Score, etc. are used to evaluate the models.

#### F. Evaluation Model

Multiple evaluation measures are used to assess the performance of a deep learning model for the evaluation of different models. Their objective is to verify the accuracy of the generalization of a model on new data.

#### G. Matriz De Confusión

The confusion matrix is a matrix representation that allows to compare the results of the predictions and the actual data of the target class. Each predicted value gives as correct or incorrect result, this depends on the coincidence with the correct value:

True Positive (TP): The predicted value when compared to the stored value is correct.

True Negative (TN): The predicted value when compared to the stored value is not correct.

False Positive (FP): Predicted value is positive when compared to the stored value is negative.

False Negative (FN): The predicted value is negative and when compared to the stored value is positive.

#### H. Accuracy

This is the total percentage of items correctly classified [25].

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN}$$

##### a) Error Rate

This is the total percentage of incorrectly classified items.

$$Error\ rate = \frac{FP + FN}{TP + FP + FN + TN}$$

##### b) Precision

The number of items that have been properly recognized as positive out of a total number of items recognized as positive [25].

$$Precision = \frac{TP}{TP + FP}$$

##### c) Recall

The metric allows reporting on the rate of true positives [25].

$$Recall = \frac{TP}{TP + FN}$$

##### d) F1-Score

This metric combines precision and recall obtaining a much more objective value.

$$F1 = 1 * \frac{(Recall * precision)}{Recall + precision}$$

## IV. RESULTS AND DISCUSSION

The results obtained following the proposed methodology are synthesized in this section, from the division between training data (70%) and test data (30%) of the 7803 original images. The number of epochs for each of the models was a maximum of 20 and the parameters for the activation function "relu" for the hidden layers and for the output "Sigmoid" were used, to reduce the overfitting restricted to the deactivation of 30% of neurons in each layer (dropoud=0.30), the learning rate of 0.001 and the stochastic downward gradient optimizer with momentum, for the training of the models with the adaptation detailed in the previous point, GPU was used for the processing and adjustment of the model. Fig. 8 shows the results and the evolution of the Loss and accuracy for the VGG16 model, clearly there is a significant change in the first epochs of the training process, in relation to the Loss, this decreases drastically in the first two epochs, from then on there is a slow decrease, with respect to the accuracy, until epoch 10 there was a good increase and from then on there is no significant improvement and even has to fall into a problem of overfitting.

From the model fit, the test data was used to predict using the model and make a comparison between the expected output results and the given prediction, a summary through the confusion matrix is shown in Fig. 9.

The results show that of the correct or positive true predictions, 1487 correspond to 63.52% of the total and 569 true negative predictions, representing 24.31% of the total; the incorrect predictions, with respect to false positives, were 201 images and false negatives correspond to 84 images.

Fig. 8. Evolution of results loss and accuracy of the training process - Model VGG16.

Fig. 9. Confusion matrix of the VGG16 model.

With respect to the training results of the VGG19 model, they show that as the number of epochs increases the error decreases and the accuracy increases, this change can be seen with greater force until the second epoch, in advance the change is slow and even approaching epoch 20 the values begin to differ between the training and test data. Once the model has been fitted with the training data, the test data is used to predict and evaluate how well it generalizes to new cases.

Regarding the third model ResNet50, it shows the evolution of the error function during the training process, the model starts with high variability between the training versus test data, from the eighth epoch the process stabilizes; regarding the accuracy it increases significantly until the eighth epoch, thereafter no significant change is observed.

Finally, the Inception V3 model shows the improvement in the two metrics clearly distinguished, regarding Loss in the first epochs decreases drastically and even in the fifth epoch the results are more stable or homogeneous, as you increase the epochs these results improve the accuracy between training and test data is very close, the model fit metrics finally corroborate this perspective (further shown below).

After fitting the models and using the prediction test data to evaluate the accuracy of each model, Table II summarizes the performance measures for each model, with the metrics accuracy, error-rate, precision, recall and f1-score.

TABLE II. SUMMARY PERFORMANCE METRICS OF THE MODELS PROPOSED FOR BREAST CANCER PREDICTION

Modelo	Accuracy	Error rate	Presicion	Recall	f1-score
VGG16	0.88	0.12	0.88	0.84	0.86
VGG19	0.86	0.14	0.86	0.82	0.83
ResNet 50	0.97	0.03	0.96	0.96	0.96
Inception V3	0.96	0.04	0.96	0.95	0.95

The results indicate that there is a significant correlation with related work, the findings of this paper are discussed below with relevant research highlighting similarities and differences. For example, the ResNet-50 model achieved an accuracy of 97%, this result is consistent with that achieved in papers [9] and [12], in which CNN was used to classify breast cancer abnormalities, achieving a performance of 75% and 83%, respectively. Also, the Inception-v3 model achieved a very significant performance of 96%, higher than that achieved in the work [13], where they used this model to predict lymph node metastasis from images, achieving an accuracy of 85%, 73% specificity and 73% sensitivity. The VGG16 model also achieved satisfactory results in terms of 88% accuracy. However, this model, achieved a better performance in [14], reaching 95.70% accuracy in tumor detection in monograph images and the VGG19 model in this work achieved a

performance of 86% accuracy, higher than that achieved in [15], where it reached 72% pressure in pneumonia detection through transfer learning with CNN. Artificial intelligence, specifically neural networks, have contributed significantly to the clinical field, models such as ResNet50 and Inception-v3, are great and efficient predictors in this field of health, and in this work have been classified as the best models in performance and accuracy, to identify and classify breast cancer using transfer learning page.

## V. CONCLUSIONS

This work by using deep learning models allowed retraining and adaptation for the correct classification of benign or malignant cancer from real histopathology images, four models based on VGG16, VGG19, ResNet 50 and Inception V3 were considered, and a retraining process was carried out using GPU for faster convergence, once the models were adjusted, the result evaluation process was carried out with test data. The model that achieves the best performance is ResNet 50, with 97% of correctly classified cases, although the model based on Inception V3 has a value of 96%, statistically there would be no significant difference (at 95% confidence), the model that has the lowest performance is based on VGG19 with 86%. Individually for the prediction of the positive classes that are positive, the models based on ResNet 50 and Inception v3 obtain equal scores with 96% of the cases. Regarding the positive values that have been correctly classified the model based on ResNet 50 obtains the highest value corresponding to 96 % equal to the f1-score. It is followed by the Inception v3 model with 1% below these results; statistically there would be no significant difference. The work shows a suitable methodology for the retraining of Deep learning models, the results are encouraging, the model based on ResNet 50 and Inception v3 exceeds the threshold of 90% for the classification of breast cancer of the case raised.

# Zero-Watermarking for Medical Images Based on Regions of Interest Detection using K-Means Clustering and Discrete Fourier Transform

Rodrigo Eduardo Arevalo-Ancona, Manuel Cedillo-Hernandez  
SEPI-ESIME Culhuacan, Instituto Politecnico Nacional, Mexico city, Mexico

**Abstract**—Watermarking schemes ensure digital image security and copyright protection to prevent unauthorized distribution. Zero-watermarking methods do not modify the image. This characteristic is a requirement in some tasks that need image integrity, such as medical images. Zero-watermarking methods obtain specific features for the master share construction to protect the digital image. This paper proposed a zero-watermarking scheme based on K-means clustering for ROI detection to obtain specific features. The K-means algorithm classifies the data according to the proximity of the generated clusters. K-means clustering is applied for image segmentation to identify ROI and detect areas that contain important information from the image. Therefore, the Discrete Fourier Transform (DFT) is applied to the ROI features, using the high frequencies to increase its robustness against geometric attacks. In addition, an edge detection based on the Sobel operator is applied for the QR code creation. This type of watermark avoids errors in watermark detection and increases the robustness of the watermark system. The master share creation is based on an XOR logic operation between extracted features from the selected ROI and the watermark. This method focuses on the protection of the image despite it being tampered with. Many proposed schemes focus on protection against advanced image processing attacks. The experiments demonstrate that the presented algorithm is robust against geometric and advanced signal-processing attacks. The DFT coefficients from the extracted ROI features increase the efficiency and robustness.

**Keywords**—Zero-watermark; ROI detection; machine learning; k-means; image security; copyright protection

## I. INTRODUCTION

In recent years, the advances in communication technologies and multimedia file sharing through different digital systems have increased related to the conditions generated by the COVID-19 pandemic. In addition, the images transmitted through different communication channels may contain sensitive information [1]. For this reason, technology for digital image protection, authentication and copyright protection is a requirement. One technology that has attracted the attention of researchers is the watermarking systems, which provide security, copyright protection, or certify digital images [2].

The protection of medical images has become a relevant task in recent years since there has been an increase in remote medical consultations. Therefore, medical images carried out

the patient's data which is an essential requirement. For this reason, watermarking systems are a solution to this problem.

Traditional embedding algorithms imperceptibly embed ownership information into the host image to ensure the copyright, consequently, the signal is recovered from the watermarked image [3], [4], [5]. Traditional watermarking methods embed a signal with ownership information into a host image [4], [5]. This process distorted the image and modified its information. However, this process can generate some distortion generating a wrong image analysis. An example is the one proposed by Juarez-Sandoval et al. [3]. They present a method of imperceptible-visible watermarking. A homogeneous region is detected by the variance of the values in the pixels, followed by the just noticeable difference (JND), which represents the maximum luminance variation. The JND identifies the most appropriate area in the image to embed the binary watermark. Guanghai and Hao [6] used the Arnold transform to encrypt the watermark. On the other hand, they applied the Wavelet Transform based on the Mallat decomposition, representing the coefficients of the low-pass and high-pass filters, thus adjusting the intensity of the watermark to the pixel variations. To avoid distortions in the images, Zero-watermarking techniques are developed, these schemes do not embed information into the digital data. Instead, zero-watermarking used specific features from the image, and the watermark to create a master share (a feature matrix) without losing the host image quality. The master share is unique for each image.

Region of interest (ROI) detection on images identifies specific areas with relevant information for its analysis and features extraction that belongs to the selected region [7], [8]. On the other hand, regions of non-interest (RONI) generally used related features to the background [9], [10]. ROI methods are used in watermarking algorithms to make the embedding and detection process of the watermark signal more efficient since it takes advantage of the detected features that are unique for each ROI. Zhang et al. [11] developed a watermarking system by inserting the signal into the RONI of medical images. They applied the Discrete Wavelet Transform (DWT) and added two bits in each frequency sub-band obtained (low, medium, high). Next, the Otsu algorithm identifies the RONI, and then the detected ROI is encrypted with a hashing algorithm to combine it with the patient's information. In [12] Qi et al. proposed two factors to select the ROI by detecting variations, especially in the case of medium frequencies. Subsequently, the visual effect factor (VEF) determines the

region of watermark embedding. Lampezhev et al. [13], proposed a K-means segmentation for ROI detection on medical diagnosis. Therefore, a fuzzy clustering evaluation criterion was applied to select specific features from the image to determine the statistical data required for making decisions in applied medicine.

Medical image watermarking schemes divide the image into ROI and RONI for signal embedding. In addition, the ROI and RONI segmentation can be modified easily by the software. As a solution, zero-watermarking systems generate lossless protection in the image quality being more efficient. In zero-watermarking algorithms, the signal is not embedded into the base image [14], [15]. Extracted features from the image are fuzzed with the watermark related to the owner's information for the creation of the master share. These associations are stored and provide continuous protection [16]. In addition, the main advantage of this algorithm is the generated robustness.

Khafaga *et al.* presented in [17] a descriptor based on multi-channel Gaussian-Hermite moments of fractional order for feature extraction to create a vector with the most robust features and used the 1D Chebyshev chaotic map to scramble the watermark and increase its security. Finally, it is performed an XOR operation for the master share creation. Xing, Li, and Liang created a zero-watermarking scheme [18]. The Discrete Cosine Transform (DCT) is applied to high-frequency coefficients obtained from the Discrete Fourier Transform (DFT). The coefficient matrix is extracted from the left corner and has the same size as the watermark. The Arnold Transform scrambles the watermark to increase the security of the system. Thus, the coefficient matrix and the scrambled watermark are fuzzed for the master share generation.

ROI detection-based algorithms have a relevant role in zero-watermarking systems, as it identifies unique features from each image [15]. The extracted features create the master share serving for identification, protection, authentication, and certification of the digital image against misuse [19], [20]. Fang et al. in [21] present a watermarking scheme that detects specific areas in medical images by extracting the SIFT descriptors. Therefore, they apply the Bandelet Transform for pixel change detection. Thus, the Discrete Cosine Transform (DCT) is applied to generate more robustness against geometric attacks. The Arnold Transform increases watermark security. Finally, the watermark and the ROI features are combined. Gong et al. [22] applied a Residual-DenseNet to obtain a feature vector of the image, then the logistic map creates a Chaotic matrix and generates the feature matrix through a logical XOR operation, which is stored to verify the image. In [23] Hosny and Darwish applied Multi-channel Fractional-order Gegenbauer moments of color images to obtain the ROI-related features of the image and form the feature vector, which is combined with the watermark to generate image protection.

This paper proposes a zero-watermarking scheme-based detection of regions of interest using K-means clustering. Therefore, the DFT is used to obtain high frequencies to create a feature matrix. The features remain without distortions if the image has been tampered with. Thus, the process of the

watermark construction used the Sobel filter to obtain the image edges. Finally, the master share is created by fuzzing the watermark and the feature matrix.

The k-means algorithm provides robustness to the presented method, generating an image segmentation based on features clustering for the ROI detection. The main advantage of this technique is the ROI detection which remains without modifying the pixel values used for the master share generation and detection even if the image has been tampered with. On the other hand, the DFT makes the system more efficient, even though some geometric or advanced image processing attacks are applied to the image by an unauthorized user. High frequencies do not change despite image manipulation. The master share provides continuous copyright protection and image certification.

The main contributions of this paper are:

- K-means ROI detection and DFT-based feature extraction increase the robustness of the watermark system.
- ROI detection creates a feature matrix related to the image. These features are not modified when advanced signal processing is applied to the image.
- K-means clustering is applied for image segmentation to identify ROI and image patterns for the identification of areas with important infrastructures from the image.
- The DFT coefficients generate unique invariant features against geometric attacks.
- The extracted features for the master share construction are unique and generate a lossless watermarking system, which does not distort or modify the image, allowing its analysis for a correct diagnosis.
- This method focuses on the protection of the image despite it being tampered with. Many proposed schemes focus on protection against advanced image processing attacks.

The rest of the paper is organized as follows. Section II provides the background of study. Section III presents the proposed method. Section IV provides the experimental results, and Section V concludes this paper.

## II. BACKGROUND

This paper proposed a zero-watermarking scheme based on K-means clustering for ROI detection. ROI detection increases the efficiency of feature detection and extraction. Furthermore, high-frequency coefficients of the DFT provide robustness against geometric attacks, where the selected features do not change.

### A. K-Means Clustering for Image Segmentation

Image segmentation analyzes the image and identifies ROI with useful detected features [24]. ROI detection may determine the areas which must be tampered avoiding their use for feature extraction to create the master share [25]. ROIs have areas with relevant information. In the case of medical images, this information is vital for analysis for a correct and

efficient diagnosis, so they should not be modified or distorted and thus not affect the patient's diagnosis.

Unsupervised learning refers to a kind of machine learning where there are no labels or the output is not known, like the clustering algorithms [26], this technique is like classification methods since it divides the data into groups called clusters.

Fig. 1. Example of K-means image segmentation: A) Original image B) K-means segmented image, C) ROI detection.

Clustering techniques separate the data by associating points into different classes. K-means is one of the most used clustering algorithms, due to its implementations which consist of an iterative algorithm that assigns the data to a specific cluster based on the Euclidean distance (1) from an arbitrary centroid ( $\eta$ ).

$$\min(E(\eta) = \sqrt{\sum_{i=1}^n (p_i - \eta_i)^2}) \quad (1)$$

where  $p$  is the data point, and subsequently the centroids are realigned to the mean of the assigned clusters ( $S$ ) on each iteration (2) [27], [28].

$$\frac{\delta E}{\delta \eta} = \mathbf{0} \rightarrow \eta_{i+1} = \frac{1}{S} \sum p \quad (2)$$

K-means is a popular algorithm because is easy to understand and implement and it can be used in many tasks. One of the disadvantages is that the number of centroids must be set before the initialization. K-means algorithm clusters the pixels for image segmentation and pattern recognition for ROI detection [29], [30]. The clustering technique detects interest points on the image for pattern recognition using different centroids [31]. K-means segmentation detects ROI to determine the most important features from the image to obtain better results for pattern recognition and feature extraction in zero-watermarking algorithms [32] (Fig. 1). Segmentation methods recognize ROI if an attack is applied to the image the feature points may change. Furthermore, DFT coefficients improve feature detection due to their properties which make the frequency coefficients from the selected area invariant to geometric attacks.

### B. 2D Discrete Fourier Transform

The Discrete Fourier Transform (DFT) (3) makes a representation of the space domain image into the frequency domain, providing robustness against geometric attacks (scaling, cropping, translation, rotation) [33].

$$F(u, v) = \frac{1}{\sqrt{M}\sqrt{N}} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} I(x, y) e^{-j2\pi(\frac{xu}{M} + \frac{yv}{N})} \quad (3)$$

The Fourier Spectrum (4) (Fig. 2) describes frequency coefficients. The DFT has a real value (Re) and an imaginary value (Im).

$$|F(u, v)| = \sqrt{(\text{Re}\{F(u, v)\})^2 + (\text{Im}\{F(u, v)\})^2} \quad (4)$$

Phase (5) describes the symmetry of the signal.

$$\theta = \tan^{-1}\left(\frac{-\text{Im}\{F(u, v)\}}{\text{Re}\{F(u, v)\}}\right) \quad (5)$$

The magnitudes in (4) and (5) make a polar representation of the DFT (6).

$$F(u, v) = |F(u, v)| e^{-j\theta uv} \quad (6)$$

The DFT has the properties of linearity, scale, translation, symmetry, rotation, and cropping (sampling). Consequently, the DFT improves the performance and efficiency of the presented method.

Fig. 2. A) Original image, B) DFT 2D matrix from the image.

### III. PROPOSED ZERO-WATERMARKING SCHEME

This paper presents a zero-watermarking scheme, focusing on the master share generation aimed to protect digital images. K-means algorithm detects image ROI for feature extraction (Fig. 3).

The selected features from the ROI are robust against image processing attacks. The DFT makes a robust zero-watermarking algorithm, and high-frequencies coefficients are used for master share creation.

Fig. 3. Master share generation.

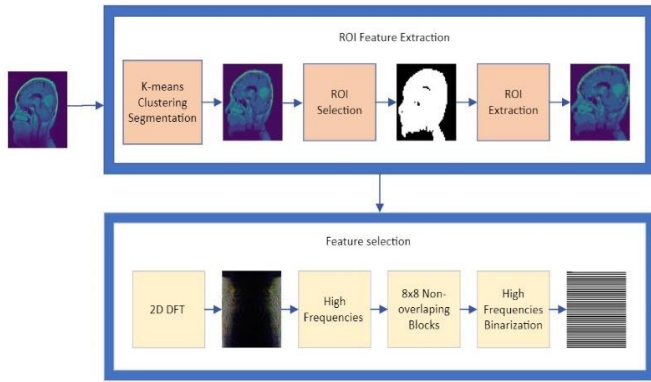

Fig. 4. Features extraction.

The DFT properties increase the robustness against geometric attacks. The master share provides copyright protection and image security.

### C. Region of Interest Feature Extraction

The master share generation (Fig. 4) is based on K-means ROI detection which provides robustness against advanced image processing attacks since the selected features do not change. In addition, combining ROI detection and DFT increases the robustness of the watermark system. Consequently, this method improves the performance and efficiency of the presented method.

The idea of the K-means implementation is to detect the main ROI from the medical image to extract the main image features. To improve the robustness of the watermark the ROI are eliminated. Therefore, the DFT is applied to the new image matrix to obtain the high-frequency coefficients and increase the robustness against geometric attacks. DFT domain correlated patterns to improve the image details. In addition, the matrix with the DFT coefficients is divided into non-overlapping 8x8 blocks for its binarization for the master share construction, using the mean value as a threshold (Fig. 4). In addition, the DFT coefficients are sorted from the higher to lower frequencies, and a matrix with a size of 160 x 160 is created.

### D. Watermark Construction

The watermark is unique for each image using the characteristics from the image. Generating this type of watermark avoids conflicts in the detection stage and increases the system's robustness. Therefore, it becomes a useful method for image security and copyright protection. The watermark generation process consists of the patient's information encrypted in a QR code with an image of the edge detection with the Sobel filter on the QR code center (Fig. 5).

QR codes are modules in which the patient's information can be stored, as well as their doctor, or redirect the user to their electronic file. On the other hand, QR codes can be detected by different devices, such as cell phones, computers, or tablets regardless of a loss of information.

Fig. 5. Watermark generation.

In addition, these types of identification codes are quickly accessible, facilitating the identification of patients. Therefore, the QR codes can be used as a watermark for images.

The features from the edge detection reduce the watermark retrieval error and avoid ambiguity since the watermark is unique for each image. Furthermore, edge detection identifies key points from the image and applies them for image protection. In addition, the watermark is resized to a matrix of 52 x 52. These features increased the efficiency of the zero-watermarking scheme.

### E. Master Share Generation

The master share is the element that provides the image security, certifies it, and protects the copyright protection, and must be stored in an external device. The master share (MS) is generated by fuzzing the image's unique features (imf) with the constructed watermark (Ws) with an XOR ( $\oplus$ ) logic operation (7). The image features are stables and invariants as a requirement.

$$MS = imf \oplus Ws \quad (7)$$

The master share (Fig. 6) is unique for each image and is created for the efficient protection of the digital image.

### F. Master Share Detection

In the detection phase (Fig 7.), the ownership authentication is validated verifying the image and certifying its authenticity. The generated master share and the unique features reveal the watermark. The watermark is detected by applying the logical XOR operation between the image features and the stored master share corresponding to the original image.

The watermark is recovered using the extracted features and the Master Share, this procedure is described as follows.

Fig. 6. A) Constructed watermark, B) Master share.

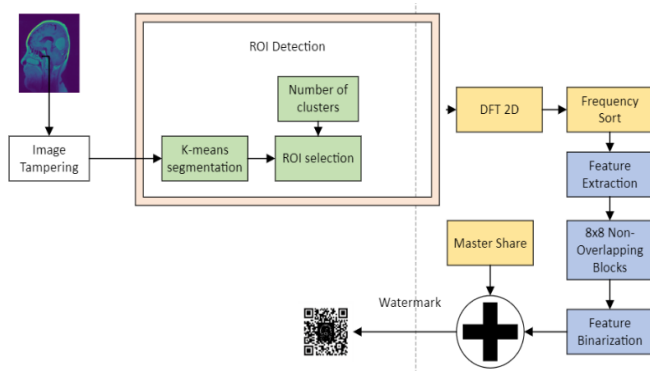

Fig. 7. Master share detection.

Step 1: The image is segmented using the K-means clustering algorithm for the localization of the regions of interest.

Step 2: The DFT high-frequency coefficients are obtained.

Step 3: The extracted features are binarized.

Step 4: It is applied an XOR operation between the binarized sequence and the Master Share.

Step 5: The watermark is recovered, and it is verified.

#### IV. EXPERIMENTAL RESULTS

Many experiments were realized to evaluate the performance of the proposed algorithm. The testing image database contains 708 images with a size of 512 X 512. In addition, the watermark is 160 x 160. The dataset was obtained from [34].

Some advanced image processing (blurring, median filter, gaussian filter, denoising, jpeg compression) and geometric attacks (rotation, scale, translation, cropping) were performed to evaluate the zero-watermarking scheme.

As an evaluation metric the bit error rate (BER) (8) is used to measure the detected bit errors between the watermark ( $W$ ) and the retrieved watermark ( $W'$ ). A low BER indicates stronger watermark robustness [16].

$$BER = \frac{\text{Error bits}}{M \times N} \quad (8)$$

In addition, the normalized cross-correlation (NCC) (9) evaluates the similarity between the watermark and the extracted watermark [19].

TABLE I. GEOMETRIC ATTACKS ROBUSTNESS TEST

Attack	BER	NCC	Attack	BER	NCC
No attack	0.0058	0.9944	Bottom left crop	0.0077	0.9929
Radom rotation	0.0091	0.9900	Upper right crop	0.0055	0.9941
Roll translation 150	0.0064	0.9942	Center crop	0.0072	0.9931
Scale	0.0053	0.9945	Translation	0.0095	0.9904

TABLE II. ADVANCED IMAGE PROCESSING ATTACKS ROBUSTNESS TEST

Attack	BER	NCC	Attack	BER	NCC
JPEG 90	0.0041	0.9958	Scale and blurring	0.0094	0.9900
JPEG 70	0.0053	0.9950	Gaussian filter	0.0041	0.9955
JPEG 30	0.0061	0.9941	Scale and Gaussian filter	0.0071	0.9929
Gaussian noise	0.0060	0.9930	Denoising	0.0062	0.9939
Scale and Gaussian noise	0.0054	0.9945	Median filter	0.0052	0.9946
Blurring	0.0070	0.9923	Scale and median filter	0.0056	0.9947

$$NCC = \frac{\sum W(i,j) \oplus W'(i,j)}{M \times N} \quad (9)$$

where  $m$  and  $n$  are the dimensions of the watermark.

Table I and Table II demonstrate the robustness of the proposed zero-watermarking scheme. The BER and NCC metrics ensure the effectiveness of the algorithm.

The BER value is closer to 0, indicating that the recovered watermark has a low error. The NCC is closer to 1, showing a great similarity between the detected watermark and the embedded watermark.

TABLE III. RETRIEVED WATERMARK AGAINST DIFFERENT TAMPERING ATTACKS

Tampere d Image	Watermar k	Retrieved Watermar k	Tampere d Image	Watermar k	Retrieved Watermar k
No attack			Roll translation		
Center crop			Rotation		
Median filter			Scale 170 x 170		
JPEG 30			Gaussian noise		

Fig. 8. Bit error rate for different numbers of clusters.

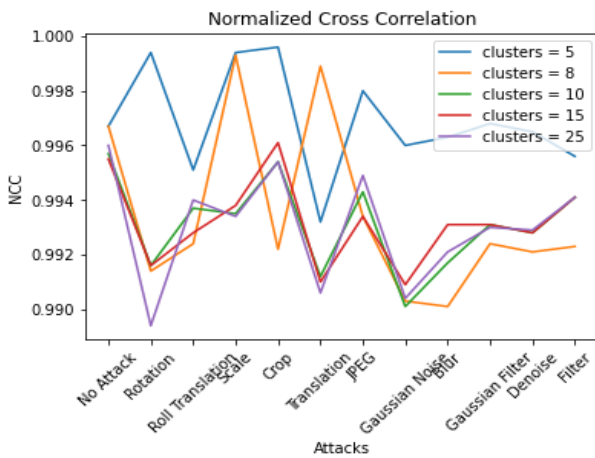

Fig. 9. Normalized cross correlation for a different number of clusters.

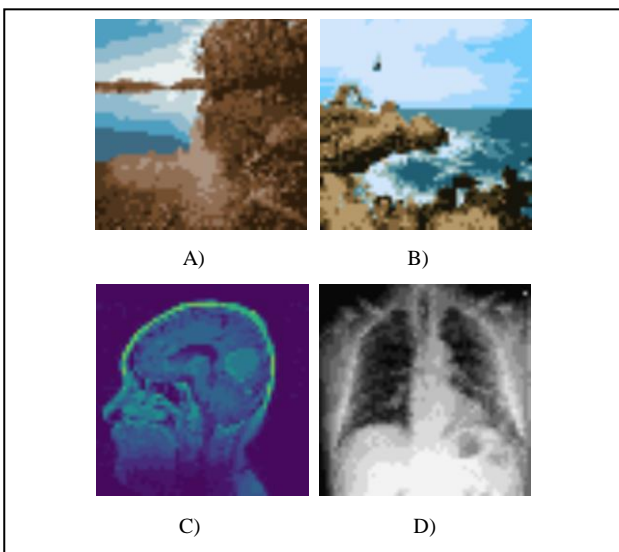

Fig. 10. ROI detection with different number of clusters for different images and tasks.

Table III shows the efficiency of the watermark detection stage and the robustness of the proposed method. The retrieved

watermark is very similar to the original watermark, which can be seen in Table I and Table II. The efficiency of the zero-watermarking scheme is similar regardless of the selected clusters.

Fig. 8 shows the variations on the BER with different numbers of clusters against different advanced image processing attacks and geometric attacks. Fig. 9 demonstrates mage certification stage recovers a similar retrieved watermark to the original watermark. Hence the selection of clusters will depend on the task and the image type. Since the selection of ROI will depend on the requirements of the application of the watermarking system. ROI selection may be necessary to determine a zone with user-specified characteristics for master share creation, as in Fig. 10.

The proposed algorithm is compared with other ROI zero-watermarking lossless algorithms. The comparison of our proposed zero-watermarking scheme with other schemes (Zhang et al. [35], Huang et al. [36], Cheng et al. [37], Zhou et al. [38] and Jing et al. [39]) was made in terms of the following aspects: 1) robustness against geometric attacks (no attack, rotation, translation, scale, crop). 2) Robustness against (blurring, noise addition, and JPEG 30 compression). 3) The BER is used for the analysis of the recovered watermark. 4) To evaluate its similarity with the original watermark, the NCC was used. 5). For a fair comparison, the same dataset is used and the same conditions from the experimental environment. In addition, some of the authors from the comparison schemes increased the robustness of their algorithms, this can be observed in the variations from the BER values and the similarity measures that they presented. The results are in Fig. 11 and Fig. 12.

The proposed method presents a better performance against different geometric and advanced image processing attacks.

The high-frequency coefficients from the DFT provide robustness against geometric attacks and the ROI detection increases the efficiency against advanced image processing attacks.

Fig. 11. Bit error rate comparative.

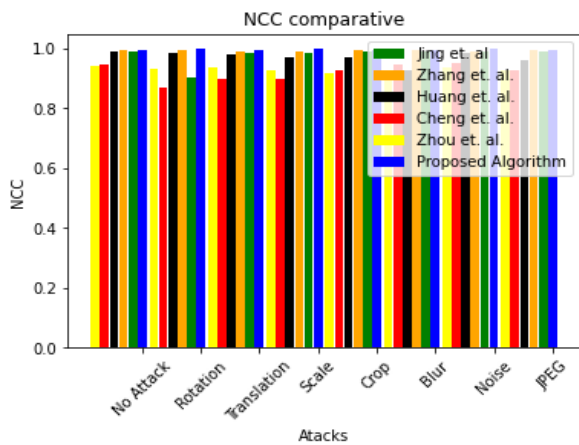

Fig. 12. Normalized cross correlation comparative.

The method presented in this paper better satisfies the lossless requirements and provides robustness against the different geometric and advanced image processing attacks (Table I and Table II). Comparing our method with other zero-watermarking has a better performance. The recovered watermark can be easily distinguished and provides security for copyright protection related to digital images. On the other hand, the features related to the image as a watermark provide an effective protection system.

#### V. CONCLUSIONS

In this paper, a zero-watermarking algorithm is presented based on ROI detection for image certification and authentication. The results demonstrate the robustness of the zero-watermarking system and the similarity of the retrieved watermark, generating continuous image protection, verification, authentication, and certification. On the other hand, the features related to the image as a watermark increases image security. Moreover, the ROI detection based on K-means generated a better performance of the zero-watermarking system. The results show a minimum loss on the watermark recovery. The use of different ROI areas does not significantly modify the results obtained, however, when using a greater number of clusters, the processing time increases.

In future work, the use of a specific ROI for the extraction of the characteristics is proposed. The user can focus on image analysis to perform artificial intelligence tasks related to robotics and computer vision. The system would generate a verification method for images related to security areas and avoid their misuse. In the same way, image databases could be generated for various tasks with protection and a system for user verification.

#### ACKNOWLEDGMENT

The authors thank the Instituto Politécnico Nacional (IPN), as well as the Consejo Nacional de Humanidades, Ciencia y Tecnología (CONHACYT) for the support provided during the realization of this research.

# Kalman Filter-based Signal Processing for Robot Target Tracking

Baofu Gong

Library, Criminal Investigation Police University of China, Shenyang, 110854, China

**Abstract**—In the field of computer vision, the signal tracking of moving objects is a highly representative problem. Therefore, how to accurately and quickly track the target unit has become the focus of the research. Based on this, a Cam Shift algorithm improved by Kalman filtering algorithm is introduced to realize fast tracking of moving targets. This method uses the prediction function of the Kalman filter to predict the moving target of the next frame, transforms the global search problem into a local search problem, and improves the real-time performance. The experimental results show that, in the case of complete occlusion, the trajectory of the unimproved algorithm will deviate compared with the actual trajectory of the improved trajectory tracking curve, but the improved algorithm has no trajectory deviation. The error of the improved algorithm is about 4%, while the maximum error of the unimproved algorithm is about 90%. The improved algorithm reached the expected target accuracy after 110 and 78 trainings in X and Y coordinates, respectively, while the CamShift algorithm without Kalman filtering still failed to reach the expected error after 200 trainings in X and Y coordinates. This indicates that the performance of the improved CamShift algorithm based on Kalman filter has been greatly improved. In conclusion, the improved algorithm proposed in this study is highly practical.

**Keywords**—Motion target tracking; Kalman filter; CamShift algorithm; occlusion processing

## I. INTRODUCTION

The research object of moving target tracking is video sequence, or image sequence, which refers to the spatial-temporal changes of the moving target in the whole sled [1], such as the appearance and disappearance of the target, the position, size and shape of the target, etc. [2]. It is caused by the presence of illumination changes, background interference, shadows, camera jitter, and occlusion between moving signals. Therefore, it is necessary to process the video image sequence [3]. The research on tracking technology of moving targets in the sequence image is to organically combine image processing, automatic control, information science and other technologies to form a fast detection of moving targets from the image information, and to extract the location information of the target for real to ground tracking [4]. Vision is the most important organ of human perception, and it is the main way for humans to obtain external information. With the rapid development of information technology in the 21st century [5], the demand for multimedia information is increasing, and computer vision technology is gradually becoming a hot spot in today's computer research [6]. Computer vision is a comprehensive and interdisciplinary discipline involving numerous aspects such as image processing, intelligent pattern recognition, artificial intelligence, automatic control, and

neural networks [7]. Research in computer vision aims to enable computers to sense and understand the external environment, so that they can simulate human vision [8]. Motion target tracking is an important topic in the field of computer vision [9], which focuses on detecting, locating and tracking targets in video frames, obtaining the motion characteristics of the targets, and further processing and analyzing them to achieve higher-level tasks [10]. Based on this, the research aims to propose a Kalman filter-based signal processing algorithm for robot target tracking. The second part is a review of the current status of domestic and international research on Kalman filter-based robot target tracking signal processing algorithms. The third part is the pre-processing of sound signals and the construction of a model for a neural network-based smart home interactive speech fuzzy enhancement algorithm, and the fourth part is the performance analysis of Kalman filter-based robot target tracking signal processing applications.

In this study, Kalman filter algorithm is used to improve CamShift algorithm, and a robot model based on wheel incomplete constraint is proposed, which is taken as a marker column. In the real robot test, the object motion model based on the velocity model is established based on the odometer motion model and the linear characteristics as the background. Finally, the experimental results are analyzed to verify the accuracy of the model tracking ping pong ball. This study chose this algorithm because in the field of computer vision, signal tracking of moving objects is a representative problem, and how to accurately and quickly track target units has become a focus of research. Compared to other algorithms, this algorithm is improved by the Kalman filter, which can use the prediction function to predict the moving target of the next frame, transforming the global search problem into a local search problem, and improving real-time performance. The experimental results show that compared to the unimproved algorithm, the improved algorithm has higher accuracy, smaller error, and no problem of trajectory deviation. Therefore, this algorithm exhibits superiority in moving object tracking. The main contribution of this study is to propose a robot target tracking signal processing algorithm based on a Kalman filter, which can effectively avoid the impact of factors such as lighting changes, background interference, shadows, camera shake, and motion signals on moving target tracking. Compared with other methods, the algorithm in this study has higher real-time performance and accuracy, and can better adapt to different environments and scenarios. In addition, this study also proposed a robot model marked by incomplete wheel constraints, and established an object motion model based on velocity model, providing a more complete and

accurate description for robot target tracking. In the experiment, this study also conducted tests on table tennis movement, and verified the accuracy and practicality of the model tracking table tennis through the analysis of the experimental results. In summary, the innovation and practicality of this study can provide new ideas and methods for the research and application of robot target tracking.

## II. RELATED WORK

The reason why motion target tracking techniques have evolved and developed so well is by no means a one-off and has been explored in depth in recent years to advance the field. By integrating the extended Kalman filter (EKF) and direction-of-arrival (DOA) based geolocation into a factor graph (FG) framework, Cheng et al. [11] proposed a new location tracking algorithm. The study also proposed the use of a predicted Cramer-Rao lower bound (P-CRLB) to dynamically estimate the observation error variance, exhibiting more robust tracking performance than methods using only a fixed mean variance approximation. By considering the uncertainty of the network and the target A reliable sensor selection method with, Anvaripour et al. [12] proposed an updated traceless Kalman filter (U2KF) to achieve effective tracking of the target through sensor selection, and the results of the study verified the effectiveness and practicality of the proposed scheme. Wang et al. [13] proposed how to unify the coordinate system and data when using multiple sensors for tracking case and data pre-processing. Then, the method of combining fuzzy sets with a novel trajectory optimization method based on the extended Kalman filter (EKF) and nested probabilistic numerical linguistic information (NPN-EKFTO) is investigated and the feasibility of their method is verified with a study case of unknown maneuvering target trajectory optimization in Sichuan Province. Zhou et al. [14] proposed to study the target and pursuit satellite approach operation between the target and the pursuing satellite for the positional tracking control problem, and proposed an updated controller which has better adaptive capability for the initial estimation of inertial parameters as this updated controller estimates the pursuer's inertial parameters through UKF, and finally numerical simulations are given to prove the effectiveness of the proposed controller. Zhao et al. [15] proposed a new adaptive square root volumetric joint probabilistic data association (ASRCJPDA) and constructed a virtual vehicle target tracking scenario in PreScan software to better simulate real traffic conditions. The simulation of the target tracking example showed the effectiveness and superiority of the method.

Shmaliy et al. [16] modified the KF and unbiased finite impulse response (UFIR) filters using a backward Eulerian (BE) method for models with colored measurement noise (CMN). This method is more suitable for systems without feedback. The study showed that the equivalence of the KF algorithm was demonstrated analytically and confirmed by simulations, giving numerical examples of target tracking and providing visual object tracking for experimental validation, demonstrating the high efficiency of the designed algorithm in CMN removal. Yang et al. [17] proposed a novel and effective method to investigate further applications of algebraic filtering processing, including Gaussian filtering for background removal and extended Kalman filtering for target prediction, to

maintain the advantage of real-time tracking. Blair [18] found that when tracking maneuvering targets using a near-isovelocity (NCV) Kalman filter with discrete white noise acceleration, the choice of process noise variance is complicated by the fact that process noise errors are modeled as white Gaussian and target maneuvers are deterministic or highly deterministic. The study provided information on the use of the NCV Kalman filter for the NCV. Bhat et al. [19] proposed a particle filter-based tracking algorithm to track targets in vivid and complex environments in video, based on the similarity between features extracted from the target and possible candidate features in consecutive frames, using a particle filter algorithm to build the target's trajectory. For the color distribution model, Bhattacharya coefficient is used as a similarity metric, and the nearest neighbor distance ratio is used for matching the corresponding feature points in the KAZE algorithm. The study shows that the performance of the proposed tracking scheme is significantly better than contemporary feature-based iterative target tracking methods. Fraser and Ulrich [20] solved the NEO spacecraft formation mission by designing two unique adaptive extended Kalman filter algorithms for relative navigation problem. The proposed adaptive Kalman filter approach uses maximum likelihood estimation techniques to derive analytical adaptation laws. The study shows that the proposed adaptive navigation algorithm is significantly more robust in filtering initialisation errors, dynamics modeling defects and measurement noise.

The research on robot target tracking signal processing based on Kalman filtering by domestic and foreign scholars shows that there are more studies on Kalman filtering tracking, but there are relatively few studies on the fusion and optimisation of Kalman filtering and CamShift algorithms to achieve signal processing for robot target tracking and signal recognition of obscured targets. Thus, this study focuses on the fusion of Kalman filtering and CamShift algorithms for robotic target tracking signal processing, which improves the recognition rate compared to a single algorithm and also significantly enhances the recognition of occluded targets during motion.

## III. DEVELOPMENT OF A KALMAN FILTER-BASED APPROACH TO ROBOT TARGET TRACKING SIGNAL PROCESSING

### A. Development of a Mathematical Model for Robot Target Tracking Signal Processing based on Kalman Filtering

In order to accurately determine the specific position of a moving object at each time to achieve the purpose of tracking, the object being tracked can be extracted from the feature points, which can be a simple geometric figure, a three-dimensional point, or the centre of a solid, so that the analysis of a target is transformed into the analysis of data from certain specific points. Since the study takes the observation information acquired by the camera about a moving object as angular information, the equation for the observation of a moving object is shown by Equation (1).

$$\beta = \arctan\left(\frac{x}{y}\right) + \omega = h(x, y) + \omega \quad (1)$$

In Equation (1),  $x$  and  $y$  are the positions of the target points in the  $x$  and  $y$  directions of the coordinate axes, and  $\omega$  is the observed noise with a mean value of 0 and a mean variance of  $\sigma_\beta^2$ . In order to determine the information about the direction of movement, i.e. the position and velocity of the object, to make the state vector  $s(t)$ , the state at the moment of  $t$  is shown in Equation (2), and the noise effect is shown in Equation (3).

$$s(t) = \begin{pmatrix} x \\ y \\ v_x \\ v_y \end{pmatrix} \quad (2)$$

$$\dot{s}(t) = Fs(t) + W \quad (3)$$

In Equation (3),  $F = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$  is its constant

coefficient matrix and  $W$  is its dynamic noise. Since the observations of camera observation are obtained from each frame, Equation (3) is discretized as shown in Equations (4) and (5).

$$s_k = F_T s_{k-1} + W_{k-1} \quad (4)$$

$$F_T = e^{FT} = \begin{bmatrix} 1 & 0 & T & 0 \\ 0 & 1 & 0 & T \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (5)$$

In Equations (4) and (5),  $T$  is the sampling period, and  $W$  is the noise at the  $K$  sampling. After linear discretization, the observed equation of state is shown in Equations (6) and (7).

$$Z_K = H_K s_K + V_K \quad (6)$$

$$H_K = \left[ \frac{y}{x^2 + y^2}, \frac{-x}{x^2 + y^2}, 0, 0 \right] |_{S_{k/K-1}} \quad (7)$$

In Equations (6) and (7),  $V_K$  is the noise of the system at the time of  $K$  sampling and  $H_K$  is its coefficient matrix.

$X_w$  Theand  $Y_w$  axes in an arbitrarily set world coordinate system are parallel to the image coordinate system  $x$  and  $y$  axes respectively, so that the  $X_w$  and  $Y_w$  axes are parallel to the pixel coordinate system  $u$  and  $v$  axes respectively. At this point the robot is moving horizontally, so the coordinates of the  $Z_w$  axis do not change and therefore the coordinates of the  $Z_w$  axis can be ignored for the purposes of the study. In addition, the camera model on the robot is a pinhole model, which is made according to the principle of transmission projection, in a

plane parallel to the  $X_w O Y_w$  plane, by which the angle can be observed. This angle signal is then transmitted to the Kalman filter module to estimate the position of the tracking target.

### B. Establishment of A Kalman Filter-based Signal Processing Method for Robot Target Tracking

Image signal pre-processing work is crucial in the robot target tracking process, based on this, the image pre-processing, can effectively remove noise, reduce the effect on the subsequent processing, improve the accuracy of the detection algorithm, image pre-processing techniques include color image filtering, color image grayscale and binarization, image post-processing is mainly to eliminate interference to the image, thus obtaining a satisfactory image. The post-processing of the image is the elimination of interference to obtain a satisfactory image. Post-processing of video images is the study of mathematical morphological operations and histogram conversion of images. The acquisition, input and processing of images generate noise at every step of the process. Noise can lead to degradation and blurring of the image quality and seriously affect the important characteristics of the image, which causes increased difficulty in the analysis and understanding of the image, especially in the image acquisition and input process. Therefore, the role of noise suppression is particularly prominent [21]. The specific steps are shown in Fig. 1.

Fig. 1. Image preprocessing steps diagram.

Gaussian filtering is a smooth linear filter and the weight of the template is taken into account when selecting the Gaussian function. The algorithm can effectively filter Gaussian noise, and it is particularly effective in normal conditions. The two-dimensional Gaussian function is shown in Equation (8).

$$h(x,y) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (8)$$

In Equation (8), the amplitude of the Gaussian filter is determined by the parameter  $\sigma$ . Rotational symmetry is an important property in a two-dimensional Gaussian function that ensures that the filter is equally smooth in all directions. In addition, an important property of the Gaussian function is that the Gaussian function is a single function and the Gaussian filter is essentially a weighted average filter, which can be expressed as shown in Equation (9).

$$g(x,y) = \sum_{m=-K}^K \sum_{n=-L}^L W(m,n) f(x+m,y+n) \quad (9)$$

In Equation (9),  $W(m,n)$  is its weighting factor and the viewport of the Gaussian filter is  $(2K+1) \times (2L+1)$ . Mean

filtering is essentially a process where the target pixels are first set as a template (the template is the removal of the target pixels and consists of 8 pixels) and the mean of the pixels in the template is replaced with the target pixels again, as shown in Equation (10).

$$g(x, y) = \frac{1}{(2K + 1)(2L + 1)} \sum_{m=x-K}^{x+K} \sum_{n=y-L}^{y+L} f(x, y) \quad (10)$$

Grayscale binarization refers to setting the grayscale value of the pixels of the original grayscale image to 0 or 255, and converting the grayscale image into a black and white image with only all white. Choosing a suitable threshold that can convert 256 different grayscale images into a binary image, the obtained binarized image still has good local features and overall features. The pixels in the grayscale image are divided into all black or all white according to the set threshold. The selection of a suitable threshold is an important step in this process. The set threshold can be used to segment the target from the background when detecting moving objects, and the processing of the grey-scale image binarisation is shown in Equation (11).

$$g(x, y) = \begin{cases} 1, & f(x, y) \geq \tau \\ 0, & f(x, y) \leq \tau \end{cases} \quad (11)$$

In Equation (11),  $f(x, y)$  represents the greyscale value of  $(x, y)$  in the initial grayscale image and  $g(x, y)$  represents the greyscale value of the pixel  $(x, y)$  after conversion to a binary image. First, a suitable threshold  $\tau$  is set, which is compared to  $\tau$ . The pixel is white if its grey value is greater than the threshold  $\tau$  and black if it is below the threshold  $\tau$ . Fig. 2 shows the difference between the original table tennis image before and after the grey-scale binarisation pre-processing.

Fig. 2(a) shows the original image of table tennis, and Fig. 2(b) is the image obtained after gray binarization. Image gray binarization means that the gray value of each pixel in the pixel matrix of the image is 0 (black) or 255 (white), that is, the effect of the entire image is only black and white, and the gray value range of the image after binarization is 0 or 255.

Kalman filtering (Kalman) it is an algorithm for minimum variance estimation of a dynamic system state sequence based on an a priori model describing the random variables in the dynamic system, and then a system of KF equations to obtain a best estimate of the target state based on global information in real time. Kalman filtering algorithm includes both state model and observation model [22], as shown in Equations (12) and (13).

$$X_k = A_k X_{k-1} + B_k W_k \quad (12)$$

$$Z_k = H_k X_k + V_k \quad (13)$$

(a) The original image.

(b) Image after grayscale binarization.

Fig. 2. Comparison of table tennis before and after greyscale binarization.

In Equations (12) and (13),  $X_k$  is the  $n \times 1$  dimensional state vector matrix;  $A_k$  is the  $n \times n$  dimensional state transfer matrix;  $B_k$  is its input matrix;  $W_k$  is a random vector of dynamic disturbances (white noise);  $Q$  is the covariance;  $Z_k$  is the  $m \times 1$  dimensional observation vector set;  $H_k$  is the  $m \times n$  dimensional observation coefficient matrix, and  $V_k$  is the observation noise vector in the covariance dimension  $R$ . Based on the above model, the Kalman filter can be divided into two categories, one for algorithmic forecasting and the other for correction of subsequent observations. The detailed process of the algorithm is as follows [23]. Firstly, the state prediction equation of the algorithm is shown in Equation (14).

$$X_k = A_k X_{k-1} + B_k U_k \quad (14)$$

The error covariance forecast equation and the updated Kalman gain factors are shown in Equations (15) and (16).

$$P_k = A P_{k-1} A^T + Q \quad (15)$$

$$K_k = P_k H^T (H P_k H^T + R)^{-1} \quad (16)$$

The covariance correction equation for its state correction and error is shown in Equations (17) and (18).

$$X_k = X_k + X_k(Z_k - HX_k) \quad (17)$$

$$P_k = (I - K_k H)P_k \quad (18)$$

Fig. 3. Block diagram of Kalman filter for stochastic linear discrete system.

Fig. 3 is a block diagram of the Kalman filter for the stochastic linear discrete system (Kalman) obtained from Equations (14) and (17), with the observed variable as the input signal and the resulting optimal estimate as its output signal. Tracking process using Kalman filter: Kalman filter uses the observed value to estimate the motion state. The process is divided into two steps: prediction and update. The prediction part is responsible for estimating the state of the next moment by using the current state and error covariance, and obtaining a priori estimate; the update section is responsible for feedback, taking the new actual observations into account with the prior estimates to obtain a posteriori estimate. After each completion of prediction and update, the priori estimate of the next moment is predicted by the posterior estimate, and the above steps are repeated. The Kalman filter Recursion is the principle. It directly acts on all previous data to estimate the current state value. Thus, Kalman filter is very easy to implement, which is also one of the significant advantages of Kalman filter.

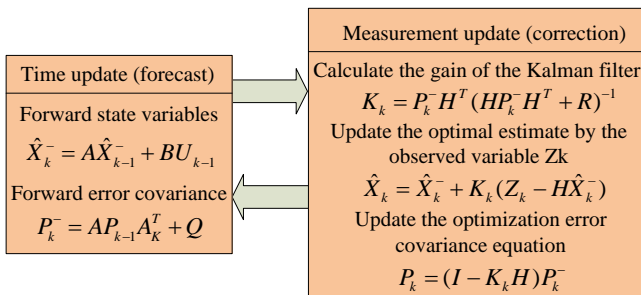

Fig. 4. Kalman filter algorithm flow chart.

On this basis, the posterior estimate derived from the system observation equation and the time update equation is used as the next a priori estimate, which is iterated. The Kalman filter has a recursive repetitive feature that makes it highly time-sensitive, and on this basis, the current state can be recursively estimated from the observed variables and the posterior estimate of the previous point only [24]. The Kalman filter approach can be illustrated in Fig. 4, which divides the Kalman filter into two parts, the measurement update and the time update. In this case, the covariance of the errors can be

calculated separately, with  $\hat{X}_{k-1}$  and  $P_{k-1}$  as their initial estimates. From the theory of Kalman filtering, it was found that when tracking a moving object, the position of the moving object in the next frame can be accurately predicted to reduce the search distance. In the case of partial occlusion, the object can be tracked quickly and accurately, and the algorithm is simple and convenient to enable real-time tracking of the target. The traditional Camshift algorithm is an expansion of the Meanshift algorithm and is currently the most widely used tracking method. This method uses a colour histogram to obtain a color probability distribution which changes as the object moves, allowing the object to be tracked using the change in color probability distribution. The method mainly consists of transforming the sequence image in RGB color space into HSV space and using the H component as the color histogram, so that the size of the random distribution can be visualised. In addition, the inverse projection method is used to obtain the color probability distribution map. In fact the color probability distribution map is a grey scale image. By finding the zero order distance and first order spacing, the distance between the centre of the viewport and the shape centre can be found, so that the essence of the Camshift algorithm is to perform Meanshift operations on each frame to track the target object by repeated iterations [25]. The probability curve of the CamShift algorithm is obtained through an inverted histogram. For the convenience of the study, a normalisation method is prescribed for the histogram, as shown in Equation (19).

$$q = \{q(u)\}_{u=1,2,\dots,m} \quad (19)$$

In Equation (19), the eigenvalues of  $\sum_{u=1}^m q(u) = 1$ ;  $u$  refers to indicators of a rectangle in the histogram;  $m$  is the number of its rectangles, and the probability value of its  $u$ -th square is shown in Equation (20).

$$q(u) = \frac{1}{n} \sum_{(x,y) \in R_m} \delta[c(R(x,y)) - u] \quad (20)$$

In Equation (20),  $R(x,y)$  is the image function of the image block  $R_m$ ;  $n$  is the number of its pixels;  $(x,y)$  is the value of the pixels, expressed in coordinates, and  $\delta(\square)$  is the Kronecker function;  $R$  has the following relationship with the corresponding pixels of its image block  $I$  of the same size, as shown in Equation (21).

$$I(x,y) = \sum_{u=1}^m q(u) \delta[c(R(x,y)) - u] \quad (21)$$

In Equation (21),  $R(x,y)$  is the image function of the image block  $R$  and the image block  $I$ . It is a mono which has a glow between [0,1] and must be linear in the range [0,226] in order to meet the display requirements. Both the MeanShift and CamShift algorithms use iterative operations on the weight map in the tracking frame to achieve tracking of objects, but their methods are. MeanShift assigns a weight to each pixel  $\sqrt{q_u / p_u} \cdot q_u$  and  $p_u$  are the current pixel values in the target

model and the corresponding probabilities in the candidate patterns, while CamShift assigns a weighting factor to each pixel  $q_u$ . Based on the calculation of the target size and colour probability distribution, the centre of mass and size of the moving object in the current frame is found and a circular frame is used to target the moving object. Fig. 5 shows the flow chart of the CamShift tracking algorithm.

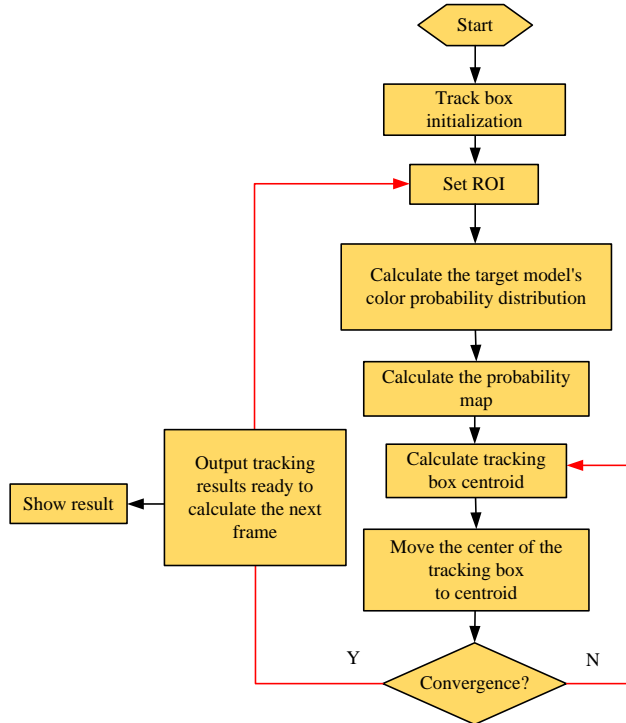

Fig. 5. CamShift tracking algorithm flowchart.

CamShift algorithm can achieve fast tracking of the object and meet the real-time demand. Its specific steps are as follows, the first step is to initialize the size and position of the search window, and the algorithm can be done automatically based on the object detection. The second step is to obtain the probability distribution of the color in the search box. The third step is to set the region of interest (ROI), based on the current object position, size and the maximum of a single frame motion distance. The fourth step is to solve for the centre of mass of the search square using the MeanShift algorithm. The fifth step is to cross out the position of the object if the distance between the centre point and the centre of mass is below a certain threshold. Otherwise, return to the fourth step. The sixth step is to perform adaptive calculations for the orientation and size of the tracked object. As the CamShift motion target tracking algorithm lacks a motion prediction module, the combination of Camshift and Kalman filtering allows the position of the moving object to be effectively estimated using the Kalman filter when the target is partially occluded, the targets are interfering with each other, the target is moving too fast and the tracking fails due to background interference in the approach. The  $Z_k$  obtained from the iterations of the algorithm has a great influence in the Kalman filter, thus affecting the prediction of the Kalman filter.

#### IV. PERFORMANCE ANALYSIS OF KALMAN FILTERING BASED ROBOT TARGET TRACKING SIGNAL PROCESSING APPLICATIONS

The experiment adopted 28 frames per second, 360\*240 resolution of rolling ping-pong image video. The processor is Intel(R) Core(TM) i5-8250 CPU@1.60GHz, and the memory is 8GB. The OpenCV library is used to detect and track the extracted objects. In order to test the performance of the research algorithm, the study designed a robot to track the motion of table tennis. Based on this, a wheel-based non-complete constraint robot model was proposed and used as a marker column. In the physical robot experiments, based on the odometer motion model and taking the linear characteristics as the background, the object motion model based on the velocity model was established. First, the robot starts with the pre-processing of the captured table tennis images. By pre-processing the images, the method effectively removes noise from the images and reduces the impact on subsequent processing, as shown in Fig. 6.

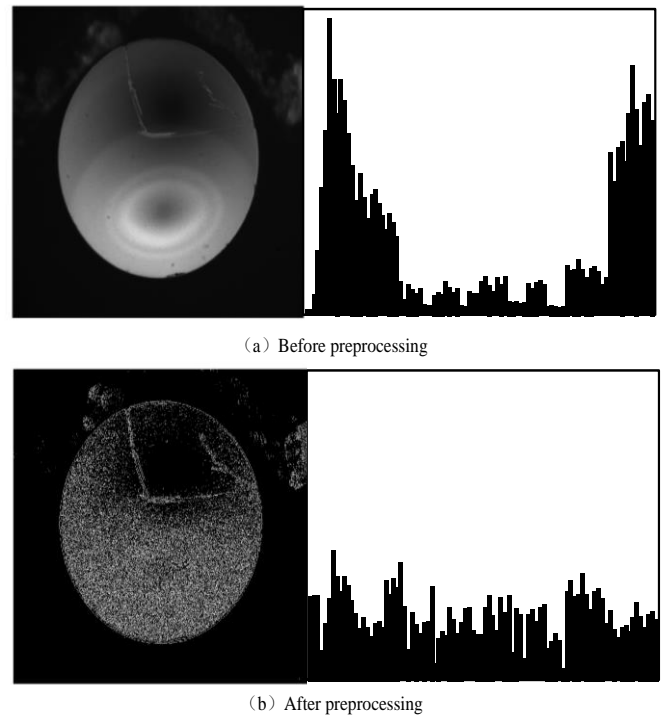

Fig. 6. Comparison of the effect before and after preprocessing the collected table tennis image signal.

As can be seen in Fig. 6, the histogram of the table tennis image signal captured by the robot changes significantly after pre-processing, which makes the grey intervals of the image larger and more uniform. This increases the contrast and makes the details in the image clearer, eliminating individual noise points to achieve the enhancement effect. Some images have the disadvantage of higher contrast due to factors such as lighting, blurring the details, and comparative suppression of irrelevant grey areas to bring out relevant objects or grey areas. The algorithm proposed in the study explores whether the improved CamShift algorithm based on Kalman filtering can effectively solve the problem of robot tracking of target motion

trajectories when moving objects are heavily obscured. 28 frames per second video with 360\*240 resolution of a rolling table tennis ball image was chosen for this experiment. The actual motion trajectory and robot tracking of the target trajectory are shown in Fig. 7.

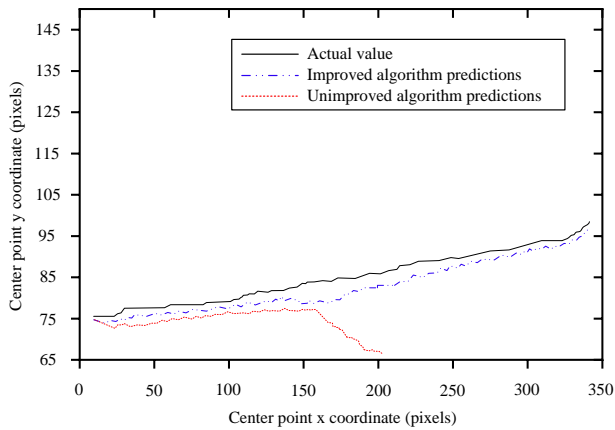

Fig. 7. Comparison of trajectory tracking of occluded table tennis balls before and after the improvement of Kalman filter algorithm.

It is evident from Fig. 7 that the target trajectory signal tracking graphs for the algorithm improved by Kalman filtering and the algorithm not improved by Kalman filtering are compared with the true values of the target. The graph shows that after encountering complete occlusion, the ping pong ball trajectory deviates from the true trajectory under the unimproved algorithm, while the corrected algorithm shows no track deviation with its improved by Kalman filtering. The bullseye coordinates of the CamShift algorithm for target unit tracking are shown in Table I.

TABLE I. THE COORDINATES OF THE TARGET CENTER POINT BEFORE AND AFTER THE IMPROVEMENT OF THE TRACKING ALGORITHM

Frame number	Target real coordinates	Real coordinates before algorithm improvement	The real coordinates after the algorithm is improved	Algorithms must be improved error
Frame 7	(100, 74)	(99, 67)	(99, 72)	3.98
Frame 11	(148, 78)	(148, 69)	(143, 75)	4.56
Frame 15	(189, 89)	(181, 56)	(183, 62)	23.66
Frame 18	(208, 84)	(183, 56)	(208, 79)	34.02
Frame 23	(258, 94)	(183, 54)	(246, 88)	90.95

Table I shows the relative error between the improved central position and the actual position during tracking, namely the relative absolute deviation between the two points. It can be seen that the target signal coordinates of Frames 7, 11, 15, 18 and 23 are selected in the research. When the target is blocked, the tracking accuracy of the improved algorithm based on Kalman filtering is greatly improved. The improved method

can ensure its tracking accuracy, and its iteration time comparison is shown in Fig. 8.

Fig. 8. The variation of the target X, Y coordinate error with time.

Fig. 8 clearly shows that the algorithm improved by Kalman filtering achieves the expected target accuracy after 110 and 78 training cycles for X and Y coordinates respectively, while the CamShift algorithm without Kalman filtering does not reach the expected error after 200 training cycles for both X and Y coordinates, indicating that its training effect is poor. This shows that the CamShift algorithm with Kalman filtering has better performance and can reach the intended training accuracy in a very short period of time.

Fig. 9. Comparison of the accuracy of the algorithm before and after the improvement.

As can be seen from Fig. 9, the initial value of the CamShift algorithm improved by Kalman filtering increases

with the number of iterations of the model, and its correctness gradually stabilizes when the number of iterations of the model reaches a certain level. After stabilization, the accuracy of the model constructed by the improved CamShift algorithm based on Kalman filter was 99.69%. After 200 iterations, the improved algorithm showed a qualitative improvement in its performance over the previous algorithm, perhaps due to the combination of CamShift and Kalman filter. As a result, the targets were partially occluded, interfered each other, and moved too fast in approaching background interference caused by tracking failure. The position of the moving object can be effectively estimated using the Kalman filter, which affects the prediction of the Kalman filter. Table tennis tracking images are shown in Fig. 10.

Fig. 10. Table tennis trajectory tracking image.

As can be seen from Fig. 10, the improved Kalman filtering algorithm proposed in this study has an excellent tracking effect on table tennis, with the confidence interval reaching 99%. In the frame 10, the coordinates of table tennis are determined as (356.8, 42.3), and its track tracking effect is excellent, without trajectory deviation and other phenomena. Therefore, the algorithm proposed in this study has excellent practicability.

## V. RESULTS AND DISCUSSION

The results of this study indicate that the signal processing algorithm for robot target tracking based on Kalman filter has great application potential in solving the difficult problems in moving target tracking. This algorithm achieves fast tracking of moving targets by tracking and predicting target signals, with higher real-time performance and accuracy. In addition, the adaptive ability and robustness of the algorithm have also been well verified. The experimental results show that the improved Kalman filter algorithm can quickly and accurately capture targets when they are occluded, making the tracking of the target continuous and stable, thereby solving the error when the target is occluded in global search and improving real-time performance. Therefore, this algorithm can be widely applied in fields such as robot target tracking, video surveillance, and intelligent transportation.

In addition, this study also has certain reference value for the establishment of robot models. By establishing a robot model marked by incomplete wheel constraints and establishing an object motion model based on the velocity model, a more complete and accurate description of robot target tracking is provided, and it also provides a certain reference for research in other robot application fields.

It should be pointed out that although this study has achieved good results in experimental results, it still needs to be adjusted and optimized according to specific situations in practical applications. At present, research methods have certain limitations in solving the problem of target occlusion. Although the improved Kalman filtering algorithm can quickly and accurately capture targets, if the target is completely occluded, the algorithm still has errors. In addition, the performance of the algorithm may also be affected by specific environments and scenarios, and needs to be adjusted and improved. Therefore, in future research, it is necessary to further improve the robustness and adaptability of the algorithm to cope with more complex practical situations. At present, research has implemented a robot target tracking signal processing algorithm based on Kalman filter, and has achieved good results in experimental results. This algorithm can quickly and accurately capture moving targets, with higher real-time and accuracy, and solves the error of target occlusion in global search. There are two aspects to the unfinished work: on the one hand, adjustments and improvements are made to different environments and scenarios to improve the robustness and adaptability of the algorithm. On the other hand, it is necessary to further improve the real-time and accuracy of the algorithm to cope with more complex practical situations. Therefore, in future research, it is necessary to further optimize and improve algorithms to meet the needs of different scenarios, and explore new methods to improve the performance and practicality of algorithms.

## VI. CONCLUSION

Moving target tracking is an important research direction in computer vision. This paper introduces the principle of Kalman filter algorithm and CamShift algorithm. Kalman filter technology is used to realize target tracking, which makes up for the loss of Camshift algorithm in target tracking. In the case that the target is seriously blocked, the algorithm can capture the target quickly and accurately, and make the tracking of the target continuous and stable, with good adaptive ability and robustness. The research shows that the contrast of the target signal is improved after the preprocessing. The enhancement effect is achieved, and the single noise point is eliminated. By comparing the tracking curve of the target track signal of the improved Kalman filtering algorithm with the real motion curve of the target, it can be seen that, when the target meets the complete occlusion, the ping pong track under the unimproved algorithm deviates from the real track, while the improved algorithm almost coincides with the target motion track. The algorithm improved by Kalman filtering reached the expected accuracy in X and Y coordinates after 110 and 78 training times respectively, while the algorithm without Kalman filtering still did not reach the expected error in X and Y coordinates after 200 training times. The accuracy of the model based on the improved algorithm of Kalman filter is 99.69%. After 200 iterations, the performance of the improved algorithm is significantly improved compared with the previous algorithm, indicating that the proposed robot target tracking signal processing algorithm based on Kalman filter has strong practical significance. This method realizes the fast tracking of moving target, solves the error when the target is blocked in the global search, transforms the global search

problem into the local search problem, and improves the real-time performance.

# Vehicle Path Planning Based on Gradient Statistical Mutation Quantum Genetic Algorithm

Hui Li, Huiping Qin, Zi'ao Han, Kai Lu

School of Computer and Information Engineering, Harbin University of Commerce Harbin, China

**Abstract**—In the field of vehicle path planning, traditional intelligent optimization algorithms have the disadvantages of slow convergence, poor stability and a tendency to fall into local extremes. Therefore, a gradient statistical mutation quantum genetic algorithm (GSM-QGA) is proposed. Based on the dynamic rotation angle adjustment by the chromosome fitness value, the quantum rotation gate adjustment strategy is improved by introducing the idea of gradient descent. According to the statistical properties of chromosomal change trends, the gradient-based mutation operator is designed to realize the mutation operation. The shortest path is used as the metric to build the vehicle path planning model, and the effectiveness of the modified algorithm in vehicle path planning is demonstrated by simulation experiments. Compared with other optimization algorithms, the path length planned by the improved algorithm is shorter and the search stability is better. The algorithm can be effectively controlled to fall into local optimums.

**Keywords**—Quantum genetic algorithm; path planning; gradient descent; adaptive mutation operator; quantum rotation gate

## I. INTRODUCTION

With the continuous development of artificial intelligence, automation technology [1] has shown strong applicability. Autonomous vehicles have become the future direction of the vehicular sector. Its core is autonomous driving technology. Autonomous driving technologies mainly include environment sensing, path planning, behavioral decision-making, and tracking control. Path planning [2] [3], as one of the key aspects of autonomous driving technology, has become a hot research topic in the field of autonomous driving. It has important value in engineering applications [4]. Path planning is mainly to plan a drivable path avoiding obstacles from the starting point to the target one based on the road environment [5]. Planning the shortest path is an NP-hard problem [6]. Thus, the path planning problem has high computational complexity. From the development of path planning algorithms, there are traditional algorithms represented by Dijkstra's algorithm [7], A\* algorithm [8], artificial potential field (APF) method [9], and dynamic window algorithm (DWA) [10]. As well as genetic algorithm (GA) [11], ant colony optimization (ACO) [12], and particle swarm optimization (PSO) [13] are as the representative of intelligent optimization algorithms. The high computational cost of traditional algorithms makes it difficult to further improve the efficiency of path search, leading to a gradual decline in utilization [14].

ZHU [7] studied the path planning problem considering intersection properties and proposed a reverse labeling Dijkstra

algorithm (RLDA) with minimizing travel time from the origin to the terminus as the optimization objective. The RLDA algorithm has low polynomial time complexity. The convergence efficiency and computational speed of the proposed algorithm are improved. LI [8] introduced a bidirectional alternating search strategy in the A\* algorithm and weighted the heuristic function with an exponential decay to improve the search efficiency of the algorithm. In addition, a path node filtering function was introduced to effectively reduce the turning angle. LI [15] proposed a path planning method combining an APF and a dynamic enhanced fireworks algorithm for autonomous vehicles. This real-time path planning method effectively improved smoothness and safety of paths. Hou [16] proposed an enhanced ant colony algorithm with a communication mechanism for path planning, which accelerates the integration of historical paths through direct communication between individuals, and improved the path selection rules and heuristic functions to increase the convergence speed and search efficiency. LIU [17] proposed a path planning method based on the improved gray wolf algorithm, introducing interference factors and dynamic weights based on the lion optimization algorithm to avoid the loss of diversity. However, the ability to jump out of the local optimum needs to be enhanced. Kumar [18] proposed a path planning method combining artificial bee colony and evolutionary planning algorithms, using an artificial bee colony algorithm to perform an initial search based on an improved strategy, followed by an evolutionary algorithm to refine the obtained feasible paths and reduce the search cost. Martinez [19] proposed the integration of an autonomous motion planning strategy for a differential robot. It combined the PSO with a Proportional-Integral-Derivative controller to ensure the stability of a differential robot path planning in complex environments.

Intelligent optimization algorithms have become one of the mainstream methods for solving path planning problems due to their better search capabilities and higher computational efficiency compared to traditional path planning algorithms. The GA has stronger global search capabilities than other intelligent optimization algorithms, as well as the ability to easily extend other algorithms. Although genetic algorithms have the above characteristics, there is a problem with early convergence [20] [21] due to high chromosome similarity in the later stages. In response to the GA problem, many researchers have proposed different modified algorithms. HE [22] proposed a GA to improve the fitness function. It added the knowledge in the problem domain as guiding information to the search process of the algorithm and took full advantage

of the trend of the function to improve the convergence rate of the algorithm. XU [11] introduced a disaster strategy and a dynamic mutation operator embedded in the A\* algorithm into the GA to reduce prematureness and improve the local search ability of the algorithm at later stages. The fitness function with multiple constraints enhanced the smoothness of the planned path. However, the initialization of the population with each catastrophe reduces the computational efficiency. ZHANG [23] proposed a hybrid initialized genetic algorithm, where a portion of individuals use a greedy algorithm to acquire paths, introducing deletion operations and reversal operations to prevent the algorithm from falling into local optimums.

The quantum genetic algorithm [24] (QGA) is an emerging intelligent optimization algorithm arising from the GA combined with the quantum computing. Depending on the superposition and entanglement of quantum states, quantum coding and quantum rotation gate update operations are introduced to enable better population diversity and convergence speed of the QGA compared to the GA. However, the QGA mainly relies on the quantum rotation gate for population updating. When solving combinatorial optimization problems [25] [26], it has problems such as low stability, poor convergence, and difficulty in jumping out of local optimums. In recent years, researchers have proposed many improvement strategies. WANG [27] introduced the quantum NOT gate mutation and quantum catastrophe operation and proposed an adaptive rotation angle strategy based on genetic algebra. However, the quantum NOT gate mutation operation is prone to population turbulence, and the randomness of the quantum catastrophe operation may cause the algorithm to fail to converge. XIAO [28] introduced the grouping optimization strategy of hybrid frog-jumping algorithm to divide the population and given the acceptance probability of feasible solutions using simulated annealing reception criterion. The search probability is somewhat improved. ZHANG [29] proposed an adaptive rotation angle strategy based on fitness-based values, and also introduced a quantum NOT gate mutation operation. CHENG [30] proposed an improved double-linked quantum genetic algorithm that uses an inverse sine function to construct the corner step function. The search accuracy of the algorithm is improved.

In this paper, we propose a vehicle path planning method based on a gradient statistical mutation quantum genetic algorithm. A dynamically adjusted quantum rotation gate strategy is used to improve the convergence of the algorithm and the stability of the global search by introducing the idea of gradient descent based on dynamically adjusting the rotation angle according to the fitness value of the chromosomes. Based on the statistical properties of the trend of chromosome change, the mutation operator is designed to implement the mutation operation instead of the quantum NOT gate. An adaptive mutation strategy based on the quantum bit probability density is proposed to improve the ability of the algorithm to jump out of the local optimum. The effectiveness of the proposed algorithm is demonstrated through experimental analysis of path planning simulations.

The rest of the paper is structured as follows: In Section II, the vehicle path planning problem is formulated and the cost function for path planning is described. In Section III, the main

steps of QGA are introduced and the principles of chromosome update and mutation operations in the GSM-QGA are presented. The GSM-QGA is applied to path planning. Section IV presents the simulation of global path planning for vehicles using the GSM-QGA.

## II. PROBLEM STATEMENT

For the vehicle path planning problem, the main objective in this paper is to obtain a feasible path with the shortest distance based on avoiding static obstacles.

### A. Assumptions

The following assumptions are made:

- The vehicle moves from the starting point to the target one in a finite plane space at a uniform speed.
- The shape and size of obstacles and their geographic locations never vary during vehicle movement.
- The vehicle can be considered a mass point concerning static obstacles in the environment map [31].

### B. Cost Function of Path Planning

The path planning mainly considers safety and path cost. In this work, the shortest path is used as the path cost in vehicle path planning. To facilitate the computation of path planning, a sequence of spatial location points is often used to represent the travel path of a vehicle, and this representation needs to only take into account the feasibility of each spatial location point. Therefore, two cost functions are constructed: The path point cost function (*point\_fit*) and the path cost function (*way\_fit*). The path point quantum state updating is determined with *point\_fit*, and the path selection is determined based on *way\_fit*. The Euclidean distance is used to construct *point\_fit* [32]. The cost of a path can be estimated by calculating the sum of distances from its points to both the original position and the goal one. Notably, the smaller such the distance is, the lower the overall cost will be.

$$\min \text{point\_fit} = \sqrt{(x_{ir} - x_s)^2 + (y_{ir} - y_s)^2} + \sqrt{(x_{ir} - x_g)^2 + (y_{ir} - y_g)^2} \quad (1)$$

Where  $(x_{ir}, y_{ir})$  denotes the coordinates of the  $r$ th path point in the  $i$ th drivable path.  $(x_s, y_s)$  indicates the coordinates of the starting point.  $(x_g, y_g)$  indicates the coordinates of the target one.

To calculate the total path length of all path points connected in sequence, *way\_fit* is defined as follows.

$$\min \text{way\_fit} = \sum_{r=1}^{M-1} \sqrt{(x_{ir} - x_{ir+1})^2 + (y_r - y_{ir+1})^2} \quad (2)$$

Where  $M$  is the number of all path points in a feasible path.

## III. OPTIMIZATION ALGORITHM

In path planning problems, an improved algorithm is needed for problems where the QGA is not sufficiently stable and tends to fall into a local minima or maxima. In this section, the GSM-QGA for vehicle path planning will be introduced. The key process of the QGA will be described. Principles of

chromosome updating and mutation operations in the GSM-QGA are presented along with the vehicle path planning process.

### A. Quantum Genetic Algorithm

A quantum bit (qubit) is the smallest information unit of a quantum computer. In a two-state quantum system, the state of a qubit can be described as [33].

$$|\varphi\rangle = \alpha|0\rangle + \beta|1\rangle \quad (3)$$

Where the state of a qubit  $|\varphi\rangle$  is the superposition of uncertainty between the state of qubit  $|0\rangle$  and qubit  $|1\rangle$ .  $\alpha$  and  $\beta$  are the probability amplitudes. They satisfy the normalization conditions as follows [33].

$$|\alpha|^2 + |\beta|^2 = 1 \quad (4)$$

The use of qubit coding for population initialization enables the inclusion of complex population information at a small population size. An initialized quantum population is represented as follows.

$$Q(0) = \{q_i(0)\}, (i = 1, 2, \dots, m) \quad (5)$$

Where  $m$  is the population size. An individual is defined by one chromosome, denoted as  $q_i(0)$ . In addition,  $q_i(0)$  is represented as a feasible solution too. Its coded form is expressed as follows.

$$q_i(0) = \left| \begin{array}{cccc} \alpha_{i1}^1(0) & \alpha_{i1}^2(0) & \dots & \alpha_{i1}^k(0) \dots \alpha_{im}^1(0) & \alpha_{im}^2(0) & \dots & \alpha_{im}^k(0) \\ \beta_{i1}^1(0) & \beta_{i1}^2(0) & \dots & \beta_{i1}^k(0) \dots \beta_{im}^1(0) & \beta_{im}^2(0) & \dots & \beta_{im}^k(0) \end{array} \right| \quad (6)$$

Where  $q_i(0)$  denotes the  $i$ th individual in the initialized population.  $n$  is the number of gene points contained in a feasible solution, and  $k$  is the number of qubits contained in gene coding. When the population is initialized, in order to ensure the equilibrium of the population distribution, the probability magnitude of each qubit in an individual is expressed as (7).

$$\alpha_{ir}^j(0) = \beta_{ir}^j(0) = \frac{1}{\sqrt{2}} \quad (7)$$

Where  $i = 1, 2, \dots, m$ ;  $r = 1, 2, \dots, n$ ;  $j = 1, 2, \dots, k$ .

QGA uses a quantum rotation gate to update the probability amplitude of the qubit in order to search for the optimal solution of the problem. The quantum rotation gate is commonly adapted as follows [34].

$$U(\theta) = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \quad (8)$$

Where  $\theta$  is the rotation angle, obtained by looking up the table.

The updated state  $|\varphi'\rangle$  is denoted as

$$|\varphi'\rangle = \begin{bmatrix} \alpha' \\ \beta' \end{bmatrix} = U(\theta) \times |\varphi\rangle = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \quad (9)$$

Where  $\alpha'$  and  $\beta'$  denote the probability magnitudes after updating of states  $|0\rangle$  and  $|1\rangle$ .

Fig. 1. The Update Of Qubits Probability Amplitudes.

In the two-state quantum system, the update of qubits probability amplitudes is shown in Fig. 1. The probability amplitudes of qubits are taken with continuity. In this way, the QGA has continuous spatial search capability.

### B. Gradient Statistical Mutation Quantum Genetic Algorithm

1) Adaptive quantum rotation gate: The rotation angle of the quantum rotation gate plays a key role in chromosome renewal. The size and direction of  $\theta$  determine the speed and direction of individual evolution. In the QGA,  $\theta$  is obtained by looking up the table. This approach does not give a basis for the choice of rotation angle depending on the specific problem to be solved. Moreover,  $\theta$  obtained in this way fails to consider not only the differences between chromosomes in the population, but also the trends in the search points. In the GSM-QGA, differences between different chromosomes in a population of the same generation are taken into account, and trends in chromosomal gene points between populations of different generations are considered to influence population evolution. In this paper, we relate the magnitude of the rotation angle to the chromosome fitness value. At the same time, the idea of gradient descent was introduced to study the trend of chromosomal gene points. Thus, a strategy for adaptive adjustment of the rotation angle is proposed as follows.

$$\theta_{ir}^j = -\text{sgn}(A) \theta_0 \exp\left(a \frac{|fit_{best} - fit_i|}{fit_{best}} + (a-1) \frac{|\nabla f(X_{ir}) - \nabla f_{rmin}|}{\nabla f_{rmax} - \nabla f_{rmin}}\right) \quad (10)$$

$$\nabla f_{rmax} = \max \left\{ \left| \frac{\partial f(X_i)}{\partial X_{ir}} \right| \right\} (i = 1, 2, L, m) \quad (11)$$

$$\nabla f_{rmin} = \min \left\{ \left| \frac{\partial f(X_i)}{\partial X_{ir}} \right| \right\} (i = 1, 2, L, m) \quad (12)$$

Where  $\theta_{ir}^j$  denotes the rotation angle of the  $j$ th qubit in the  $r$ th gene point of the  $i$ th chromosome.  $-\text{sgn}(A)$  indicates the

direction of rotation angle.  $\theta_0$  denotes the initial rotation angle step. The weight  $a \in (0,1)$  is used to reflect the effect of fitness function values and gene point gradients on the degree of chromosome evolution.  $fit_i$  is the fitness value of the  $i$ th chromosome in the current generation.  $\nabla f(X_{ir})$  is the gradient at the  $r$ th gene point of the  $i$ th chromosome.  $\nabla f_{r,\min}$  and  $\nabla f_{r,\max}$  are the minimum and maximum values of the gradient at the  $r$ th gene point in the current population.  $A$  is

$$A = \begin{bmatrix} \alpha_0 & \alpha_1 \\ \beta_0 & \beta_1 \end{bmatrix} \quad (13)$$

Where  $(\alpha_0, \beta_0)^T$  is the probability amplitude of the corresponding qubit in the current optimal chromosome and  $(\alpha_1, \beta_1)^T$  is the probability amplitude of the corresponding qubit in the current chromosome.

The direction of the rotation angle is chosen as follows: When  $A \neq 0$ , the direction of the rotation angle is  $-\text{sgn}(A)$ ; when  $A = 0$ , the direction is chosen randomly [35].

The dynamic adjustment strategy of a quantum rotation gate considers both the fitness values of chromosomes and the trends of chromosome loci. When the chromosome fitness value is far from the optimal chromosome and the quantum position gradient changes weekly, the rotation angle is increased to expedite convergence. Conversely, in order to prevent missing the optimal chromosome, the rotation angle must be diminished, thereby enhancing both the speed of convergence in the algorithm and the stability of the global search.

2) *Quantum mutation*: Despite the strong global search capability of the QGA, it is easy to get trapped in local optima by updating the population only through a single quantum rotation gate. Therefore, a certain perturbation operation is needed to reduce the occurrence of "premature" population. Improved QGA [36] usually uses the quantum NOT gate to perform variation on the probability magnitudes of individual qubits in the population, which can avoid the local optimum to a certain extent. When a chromosome performing the mutation is very close to the optimal chromosome, the quantum NOT gate mutation will cause the reversal of the direction of qubit update, which may cause the population turbulence and the loss of excellent chromosome information. In addition, this operator fails to consider the effect of chromosomal information contained in the population and perturbative factors such as external environment on chromosomal gene mutations, resulting in a lack of population perception.

Therefore, in this paper, we propose a mutation operator that includes the past information of individuals in the population. It enables the quantum mutation operation to impose reasonable perturbations during population evolution to avoid premature convergence of the population. Genetic information decreases with increasing number of generations,

and current chromosomal gene points are most affected by paternal chromosomes. As a result, we only consider the effect of paternal chromosomes on the current chromosomal gene point. The gradient ( $\nabla Z_{ir}$ ) of statistical past chromosomal gene point fitness values is expressed as (14).

$$\nabla Z_{ir} = \nabla f(X_{ir}) + o(\nabla f(X_{ir})) \quad (14)$$

Where  $o(\nabla f(X_{ir}))$  is the higher order infinitesimal of the gradient of the offspring and parent.

The probability density function is designed according to the trend of chromosomal gene points as follows.

$$f(\nabla Z_{ir}) = \sum_l b_{l1} \exp\left(-((\nabla Z_{ir} - b_{l2}) / b_{l3})^2\right) \quad (15)$$

Where  $b_{l1}$ ,  $b_{l2}$  and  $b_{l3}$  are Gaussian mixture distribution parameters, respectively.

Transforming (15) into a probability distribution function as follows.

$$F(\nabla Z_{ir}) = \sum_l b_{l1} \int_{-\infty}^{\nabla Z_{ir}} \exp\left(-((\nabla Z_{ir} - b_{l2}) / b_{l3})^2\right) \quad (16)$$

The mutation operation is performed on the qubit probability amplitude, and the probability distribution of the qubit gradient is used as the mutation operator.

$$\begin{cases} \alpha_{ir}^j(t) = \sqrt{1 - F(\nabla Z_{ir})} \\ \beta_{ir}^j(t) = \sqrt{1 - \alpha_{ir}^j(t)^2} \end{cases} \quad (17)$$

Where  $\alpha_{ir}^j(t)$  and  $\beta_{ir}^j(t)$  denote the probability amplitude of the state  $|0\rangle$  and  $|1\rangle$  at the  $j$ th gene point of the  $r$ th chromosome in the  $t$ th generation, separately.

In addition, a reasonable mutation probability is beneficial for improving diversity and stability of population evolution. Thus, according to the evolutionary trend of chromosomes in the population, an adaptive mutation mechanism based on the qubit probability density is proposed as follows: The mutation probability of the current qubit is determined based on the gradient of gene points. When chromosome evolution is relatively "flat", a large perturbation probability is given to make chromosomes jump out of the local optimum and increase population diversity. On the contrary, a small perturbation probability is given to avoid destroying individuals with good genes and to improve the stability of the population. Random selection of qubits in an individual based on adaptive mutation probability is used to apply mutation operations. The adaptive mutation probability ( $p_m$ ) is expressed as:

$$\begin{aligned} p_m &= P(\nabla Z \geq \nabla Z_{ir}) \\ &= 1 - F(\nabla Z_{ir}) \\ &= 1 - \sum_l b_{l1} \int_{-\infty}^{\nabla Z_{ir}} \exp\left(-((\nabla Z_{ir} - b_{l2}) / b_{l3})^2\right) \end{aligned} \quad (18)$$

The flowchart of the GSM-QGA is shown in Fig. 2.

Fig. 2. The flowchart of the GSM-QGA

### C. Vehicle Path Planning Based on Gradient Statistical Mutation Quantum Genetic Algorithm

To plan a vehicle path based on the GSM-QGA, the path is first encoded, where path points on the same parallel line are encoded with qubits in a grid map. Then, the quantum encoded path points are arranged to form a feasible path, which constitutes a chromosome. The encoding form of the chromosome is shown in Fig. 3.

Fig. 3. Chromosome coding

Fitness values at the path points are discretize. Thus, the gradient of path points in the chromosome is represented using the first-order difference between two adjacent generations as follows.

$$\nabla f_{r \max} = \max \left\{ \left| f \left[ X_{ir} (t-1) \right] - f \left[ X_{ir} (t) \right] \right| \right\} \quad (19)$$

$$\nabla f_{r \min} = \min \left\{ \left| f \left[ X_{ir} (t-1) \right] - f \left[ X_{ir} (t) \right] \right| \right\} \quad (20)$$

Where  $i = 1, 2, L, m$ .

By statistically analyzing the gradient information of path points in past chromosomes, we obtain parameter values of formula (15).

$$\left( b_1 \ b_2 \ b_3 \right)^T = \begin{bmatrix} 0.7521 & 0.1421 & 0.1519 & -0.6852 & 0.04352 \\ 0.5204 & 2.072 & 0.1908 & 0.4204 & 5.743 \\ 0.9951 & 2.126 & 0.6099 & 1.01 & 2.565 \end{bmatrix} \quad (21)$$

Here are the steps of vehicle path planning based on the GSM-QGA.

Step 1: The environmental map construction. Building a grid map based on a known planning space.

Step 2: Initial parameters configuration and the population initialization. The population size ( $popsiz$ ) is  $m$ . The number of genetic generations is  $t$  and the initial value of the rotation angle is  $\theta_0$ . The starting point and ending one must be defined prior to initialization. After quantum encoding of path points, the initialized population ( $Q(0)$ ) is generated. All probability amplitudes of path point qubits in the primitive chromosome are represented by  $\alpha_{ir}^j(0) = \beta_{ir}^j(0) = 1/\sqrt{2}$ .

Step 3: Initial qubits collapse. All  $Q(0)$  undergo measurement, causing their respective qubits to collapse into a predetermined state ( $p(0)$ ). The resulting  $p(0)$  set of collapsed qubits represents the desired path points for the vehicle.

Step 4: Initial path adaptation evaluation.  $point\_fit_r(0)$  and  $way\_fit_r(0)$  are computed.  $way\_fit_r(0)$  in the population are compared, and the chromosome indicating the current shortest path ( $q_{best}$ ) and its corresponding fitness value ( $way\_fit_{best}$ ) are recorded.

Step 5: Qubits collapse. All  $Q(t)$  undergo measurement, causing their respective qubits to collapse into a predetermined state ( $p(t)$ ).

Step 6: Path adaptation evaluation.  $point\_fit_r(t)$  and  $way\_fit_r(t)$  are calculated, as well as  $\nabla f(X_{ir})$ .  $way\_fit_r(t)$  in the population are compared, and the chromosome that represents the current  $q_{best}$  and its corresponding  $way\_fit_{best}$  are recorded.

Step 7: The quantum rotation gate adaptive updating.  $\theta_{ir}^j$  is obtained by (10) to (13), and the chromosome is updated adaptively using a quantum rotation gate.

Step 8: Quantum mutation operation.  $p_m$  is determined by an adaptive mutation mechanism. Qubits in a chromosome are chosen randomly by  $p_m$ , and an adaptive mutation operator is used to apply mutation operations to these qubits.

Step 9: Determine if the maximum number of iterations or convergence condition is satisfied. If it is satisfied, the algorithm ends and the shortest path is output. Otherwise, the number of iterations  $t = t + 1$ , and return to step 4.

#### IV. RESULTS AND DISCUSSION

This section presents a vehicle path planning simulation based on the GSM-QGA aimed at demonstrating its effectiveness in this field. In this paper, we explore vehicle path planning within an industrial park, which is set against an area of  $1 \times 10^6$  m<sup>2</sup>. The environment map was generated by adopting the grid approach consisting of splitting the industrial park into grids that measure 0.05 km in length, forming a total of  $20 \times 20$  grids. White grids represent traversable areas for vehicles, whereas black grids indicate obstructions. The starting point of the vehicle is situated at the coordinate (1, 1) and denoted with a pentagram, whereas the destination is marked using a similar symbol at coordinate (20, 20). Finally, initialization parameters were established. The maximum number of genetic generations is  $t = 50$ . The population sizes of the GA are  $popsiz = 20$  and  $popsiz = 100$ . The crossover probability and mutation probability of the GA are  $p_c = 0.8$  and  $p_m = 0.1$ . The population size of the QGA is  $popsiz = 20$ . The population size for the Quantum Genetic Algorithm of quantum NOT gate mutation (N-QGA) is  $popsiz = 20$ . The mutation probability of the N-QGA is  $p_m = 0.1$ . The population size of the GSM-QGA proposed in this paper is  $popsiz = 20$ . The initial rotation angle of the GSM-QGA is  $\theta_0 = 0.1\pi$ . The solution accuracy and convergence speed of these four algorithms are compared to verify the performance of our algorithm in path planning.

Since these algorithms have a certain degree of search randomness, we count the results gathered from five runs of each algorithm, as displayed in Table I. “Length of path” in the Table I indicates the path distance from the start point to the target one. “Number of iterations” in Table I expresses the number of generations for population update when converging to the optimal solution. “Optimum path length”, “Worst path length”, and “Average path length” in Table I represent the minimum, maximum, and average values of the path distance among the five runs of the algorithm, respectively. With the condition of keeping population sizes and iteration times constant, as can be seen visually in Fig. 4 and Fig. 9, When the population size is small, the paths planned by the GA are too long and the optimal paths obtained differ significantly each time. The difference between the optimal path and the worst path is 0.3415 km. The GA converges slowly, with an average number of 32 iterations, and is easily trapped in a local optimum. By increasing the population size to 100, the GA method yields improved path length and convergence speed. The optimal path length is 1.5899 km. However, it is clear from Fig. 5 that there is still significant redundancy in the path distance. While both the QGA and the N-QGA are capable of further optimizing the path distance, it can be shown from Fig. 6 and Fig. 7 that the searched paths still vary considerably and the stability of the algorithm is not good. The difference between the optimal path and the worst path is 0.1475 km and 0.1293 km, respectively. As shown in Fig. 11 and Fig. 12, the overall convergence speed still requires further enhancement. As illustrated in Fig. 8 and Fig. 13, the GMS-QGA proposed in

this paper can break away from local optimization. The obtained optimal path is 1.5485 km and an average number of iterations is 15.8. Meanwhile, the results obtained from 5 runs confirm the good stability of the algorithm. The difference between the optimal path and the worst path is only 0.0586 km.

Fig. 14 and Fig. 15 provide a more intuitive comparison of the four path planning algorithms in terms of solution accuracy and convergence speed. Evidently, the GA exhibits slow convergence and susceptibility to premature optimization. Its planned paths exhibit a higher degree of redundancy. The QGA converges in the 18th iteration with an optimal path of 1.5889 km. While it converges quickly, it struggles to break away from local optima. By leveraging mutation operators based on the quantum NOT gate's local perturbation, the N-QGA effectively escapes local optima. It obtains an optimal path of 1.5485 km. However, the magnitude of its mutations is large, which can easily lead to population turbulence. The N-QGA has slow convergence and poor algorithmic stability. In contrast, the GSM-QGA updates quantum coding path points using adaptive quantum rotation gate, exhibiting faster path convergence. The optimal path of 1.5485 km is obtained by the 16th iteration. Furthermore, through a mutation operator and variation strategy designed based on past path data, this algorithm can better perturb the path planning process while mitigating premature optimization, thereby achieving shorter planned path distances. The average path obtained by GSM-QGA is 1.56608 km. From the calculation of the data in Table I, compared to the other three algorithms, the GSM-QGA averages 10.26%, 7.06%, 5.52%, and 2.99% reduction in length while increasing the average speed of convergence by 50.63%, 46.98%, 32.48%, and 26.85%, all while maintaining superior algorithm stability.

## V. CONCLUSION

In the vehicle path planning problem, the path planning method based on a gradient statistical mutation quantum genetic algorithm was proposed for the problems that GA is prone to early maturation and slow convergence.

In this paper, we proposed a dynamic adjustment strategy for a quantum rotation gate that considered both the chromosome fitness values and the trend of gene point changes. The convergence speed of the algorithm and the stability of the search for superiority are improved. Moreover, based on the statistical properties of the trend of chromosome change, a mutation operator was designed, and an adaptive mutation strategy based on the qubit probability density was proposed to effectively control the algorithm into a local optimum. Simulation results reveal the superiority of our GSM-QGA over GA, QGA and N-QGA: the average path length is reduced by 10.26%, 7.06%, 5.52%, and 2.99%; the average convergence speed increases by 50.63%, 46.98%, 32.48%, and 26.85%, respectively. The GSM-QGA has advantages over GA, QGA and N-QGA in terms of path length, convergence speed and algorithm stability. The effectiveness of the GSM-QGA in path planning is demonstrated.

Future work includes further extension of the algorithm in combination with other algorithms for application to more complex traffic environments. On the other hand, an attempt is made to design a new quantum gate as a transition matrix for population updating to address the problem that the quantum

rotation gate has a finite range of rotation angles in the high-dimensional space.

**Abstract**—The enormous amounts of data produced in the healthcare sector are managed and analyzed with the help of Apache Spark, an open-source distributed computing system. This case study examines how Spark is utilized in the healthcare industry to produce data-driven innovations and enhance patient care. The report gives a general introduction of Spark's architecture, advantages, and healthcare use cases, such as managing electronic health records, predictive analytics for disease outbreaks, individualized medicine, medical image analysis, and remote patient monitoring. Additionally, it contains several case studies that highlight Spark's effects on lowering hospital readmission rates, detecting sepsis earlier, enhancing cancer research and therapy, and speeding up drug discovery. The report also identifies obstacles with data security and privacy, scalability and infrastructure, data integration and quality, labor and skills shortages, and other aspects of employing Spark in healthcare. Spark has overcome these obstacles by enabling efficient data-driven decision-making processes and enhancing patient outcomes, revolutionizing healthcare solutions. Additionally, the study looks at potential future advancements in healthcare, including the use of Spark with AI and ML, real-time analytics, the Internet of Medical Things (IoMT), enhanced interoperability and data sharing, and ethical standards. In conclusion, healthcare businesses can fully utilize Spark to transform their data into actionable insights that will enhance patient care and boost the efficiency of healthcare systems.

**Keywords**—Apache spark; healthcare; patient; styling; predictive analysis

## I. INTRODUCTION

Information has always been essential for stimulating innovation and improving organizational efficiency by optimizing existing procedures. As a result, gathering data has become crucial to every organization. This information can be used to predict future events and present trends. Authors have used technological improvements to produce and collect data across many facets of life, including social interactions, science, employment, and health, understanding of this potential has risen. Existing literature demonstrates that there is a situation described as a "data deluge", when there is an abundance of data. Although technological breakthroughs have made it possible for humans to produce previously unheard-of amounts of data, it is getting harder to do so with currently available technologies. As a result, the term "big data" was created to denote massive, difficult-to-manage datasets. It is necessary to devise creative ways to organize and glean valuable insights from this data to meet society's demands now and in the future. The requirement for efficient data management is especially critical in the healthcare

industry. Healthcare organizations are producing data at an astonishing rate, similar to other industries, which presents both potential and challenges. Big data is effective in healthcare, ultimately enhancing patient care and fostering innovation within the sector by creating unique methods to handle and analyze this data [1]. Data generation in the healthcare industry has increased unprecedentedly due to developments in medical technology, electronic health records (EHRs), and wearable technology. Big Data has become a potent instrument for revolutionizing health care and spurring industry innovation [2]. This in-depth analysis explores big data's ramifications, difficulties, and opportunities in healthcare, emphasizing how it has completely changed several facets of the industry. The enormous amount, diversity, velocity, authenticity, and value of the healthcare industry's data define big data. This information comes from various sources, including clinical trials, wearable sensor data, patient records, medical imaging, and genomic data. Healthcare workers can process and analyze this data to derive valuable insights, resulting in enhanced diagnosis, personalized therapies, and better patient outcomes using sophisticated analytics, machine learning, and artificial intelligence approaches [3]. This in-depth analysis explores Apache Spark's contribution to the advancement of healthcare through its powerful data processing and analytics capabilities. Apache Spark is an open-source distributed computing platform.

The problems posed by Big Data in healthcare can now be effectively addressed thanks to Apache Spark. Its tremendous capacity for handling massive amounts of data, support for several computer languages, and interoperability with various data sources have made it a valuable tool for researchers and healthcare practitioners. Spark is appropriate for various healthcare applications because of its fault-tolerance and in-memory computing capabilities, allowing quick, scalable, and reliable data processing [4]. This case study provides an in-depth study of Apache Spark's multifarious effects on the healthcare sector. It also examines some of its applications in population health management, genomics, personalized medicine, and medical imaging analysis. The evaluation also examines the difficulties and restrictions of using Spark in the healthcare industry, such as data security issues, privacy worries, and the requirement for qualified employees. The evaluation also discusses technological developments and integrations, including machine learning libraries, cloud-based deployment choices, and seamless connection with other big data tools and platforms, that have aided Spark's acceptance in the healthcare industry. This review encourages additional research and development by thoroughly understanding

Apache Spark's potential in the healthcare industry, ultimately assisting in developing a more effective, data-driven healthcare system.

The rapid technological improvements and the rising amount of data being produced have recently caused a substantial transformation in the healthcare sector. Due to the complexity of this data flood, organizations now need creative and effective data management solutions to help them deal with it. With its strong capabilities for data processing and analysis, Apache Spark has emerged as a key tool in tackling these issues. This study paper's introduction lays the groundwork for a thorough investigation of the many aspects of Apache Spark's influence on healthcare.

The background of big data in healthcare is established at the outset, along with any consequences for innovation and patient care. The qualities of healthcare data are then explored, emphasizing their volume, diversity, velocity, authenticity, and worth as well as the potential advantages of utilizing these data through sophisticated analytics, machine learning, and artificial intelligence techniques. The relevance of Apache Spark in tackling the problems caused by big data in healthcare is then highlighted in the introduction. It highlights how the platform is an excellent choice for a variety of healthcare applications because to its fault tolerance, in-memory computing capabilities, scalability, and support for numerous programming languages.

The introduction then goes over a few of the specific uses of Apache Spark in the medical field, including population health management, genomics, customized medicine, and medical image analysis. These instances highlight Apache Spark's potential to transform several facets of healthcare, resulting in better patient outcomes and more effective healthcare systems. The introduction clearly addresses the difficulties and restrictions of using Apache Spark in healthcare environments, such as the necessity for trained employees and worries about data security and privacy.

It emphasizes the significance of continuing research and development to address these issues and utilize Apache Spark's advantages in the healthcare industry. The introduction also emphasizes how critical it is to keep up with new technological developments and integrations that facilitate the use of Apache Spark in the healthcare industry. Examples include machine learning libraries, cloud-based deployment options, and seamless integration with other big data tools and platforms. This research paper intends to contribute to the development of a more efficient, data-driven healthcare system that benefits patients, healthcare providers, and stakeholders by recognizing and utilizing Apache Spark's potential in healthcare.

The study is organized as follows: Section I provides a literature review on problem formulation and various existing methodologies; Section II describes the digitization of healthcare and spark, Section III explains the apache spark in medical imaging analysis. Section IV talks about apache spark in genomics research while Section V discusses apache spark in population health management. Technological advancements and integrations are presented in Section VI, challenges and limitations of implementing apache spark in

healthcare, future researches and development, conclusion described in Section VII, VIII, and IX, respectively.

## II. DIGITIZATION OF HEALTHCARE AND SPARK

Electronic Medical Record (EMR), like electronic health records (EHRs), store typical clinical and medical data gathered from patients. Medical practice management software (MPMs), electronic health records (EHRs), electronic medical records (EMRs), personal health records (PHRs), and other healthcare data elements have the potential to improve healthcare quality, service effectiveness, and cost management while lowering medical errors [5]. Spark in healthcare includes information obtained from payer-provider relationships (such as EMRs, prescription drug records, and insurance records), genomics-driven research (such as genotyping and gene expression data), and the network of connected Internet of Things (IoT) devices.

Early in the twenty-first century, EHR adoption was modest but has significantly increased since 2009 [6]. Healthcare data management and use now depend more and more on information technology. Developing and deploying wellness monitoring devices and related software capable of producing warnings and sharing patient health data with pertinent healthcare professionals have gained traction, particularly in forming real-time biomedical and health monitoring systems. These devices generate vast amounts of data that can be analyzed to offer real-time clinical or medical care. Apache Spark architecture is shown in Fig. 1.

### A. Management of Electronic Health Records (EHRs)

By making it possible for healthcare practitioners to efficiently store, retrieve, and share patient information, electronic health records (EHRs) play a critical role in contemporary healthcare. However, real-time access requirements and the sheer amount and variety of EHR data present significant challenges for data processing and storage. With its distributed data processing and analytics characteristics that enable more effective handling of huge datasets, Apache Spark has become a potent tool for EHR management. Healthcare businesses may enhance interoperability and data exchange by utilizing Spark, enabling improved collaboration amongst many stakeholders. A number of case studies show how the deployment of Apache Spark has improved EHR management.

### B. Disease Outbreak Predictive Analytics

To preserve the public's health and ensure the effective use of healthcare resources, illness outbreak predictions and prevention are essential. More precise predictions of disease outbreaks may be made by the integration of data from many sources, including social media, public health records, and environmental factors. Apache Spark is an effective solution for predictive analytics in this situation due to its real-time analytics and pattern identification capabilities. Healthcare organizations can improve the precision and speed of outbreak predictions by combining Spark with machine learning techniques. Numerous case studies demonstrate how Apache Spark has been used to predict disease outbreaks, reducing their impact.

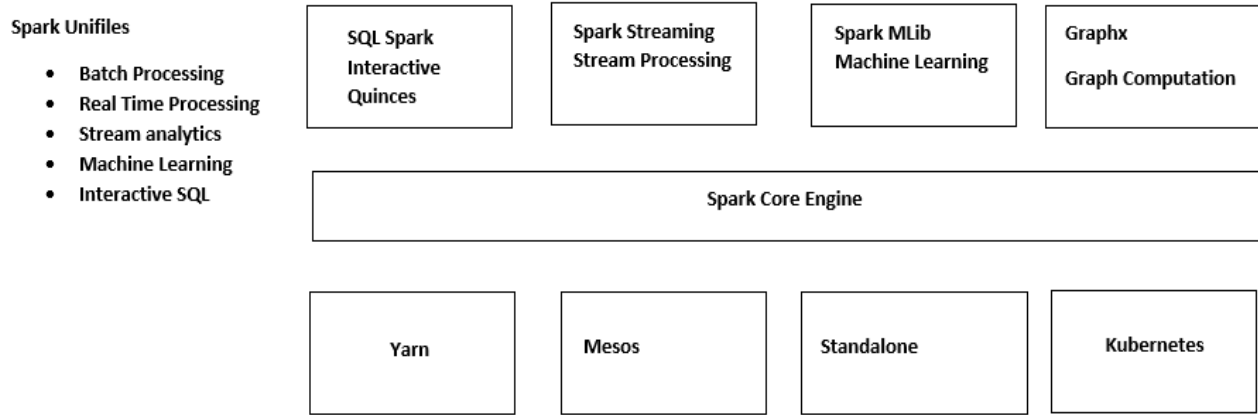

Fig. 1. Apache spark architecture.

### C. Genetics and Personalized Medicine

The idea of personalized medicine tries to customize medicines and treatments based on a person's genetic profile, potentially allowing for more precise and successful interventions.

However, the generation of enormous amounts of complex data in the field of genomics poses difficulties for processing, analysis, and integration. Because it makes it possible to handle large-scale genomic investigations and variant analysis effectively, Apache Spark has proven to be invaluable in genomics research. Numerous case studies show how the use of Apache Spark has significantly improved personalized medicine, which has ultimately improved patient outcomes.

### D. Analysis of Medical Imaging

Medical imaging, which includes procedures like X-rays, MRIs, and CT scans, is an essential diagnostic tool in the healthcare industry. Healthcare workers face difficult problems because of the growing volume of medical imaging data and the requirement for swift and precise interpretation. Through distributed image processing and integration with deep learning frameworks for advanced image recognition, Apache Spark has the potential to revolutionize the analysis of medical imaging. These capabilities result in more accurate diagnosis & quicker treatment choices. The effects of Apache Spark-based medical imaging analysis on patient care and clinical effectiveness are demonstrated in case studies.

### E. Telemedicine and Remote Patient Monitoring

Healthcare providers can now monitor patients' health and give care remotely thanks to telemedicine and remote patient monitoring, which have grown in popularity in recent years. Challenges in this area include the necessity for real-time analytics and the growing volume of data produced by remote monitoring devices. By providing real-time data processing and analytics for remote patient monitoring, improving the standard of care, and enabling predictive analytics to foresee potential health risks, Apache Spark can address these challenges. Numerous case studies highlight Apache Spark's potential to enhance patient outcomes and optimize healthcare

delivery by showcasing its positive effects on telemedicine and remote patient monitoring systems.

### III. APACHE SPARK IN MEDICAL IMAGING ANALYSIS

An essential advancement in the healthcare sector has been using Apache Spark for medical imaging analysis. Spark, a powerful distributed computing platform, has played a crucial role in overcoming the difficulties of processing and analyzing substantial image datasets. This part explores Apache Spark's effects on medical imaging analysis, demonstrating how it could be used to speed up diagnosis and enhance patient care [7].

Medical imaging analysis is looking at different imaging data types, including MRI, CT scans, and X-rays, to spot patterns and anomalies that can indicate illnesses or other abnormalities. The complexity and volume of medical imaging data are increasing, necessitating the employment of powerful processing and analysis systems that can effectively manage massive datasets [8]. Because of its distinctive features, such as in-memory computation, fault tolerance, and scalability, Apache Spark is the perfect tool for analyzing medical images. Healthcare professionals and researchers can use Spark to speed up the processing and analysis of massive imaging datasets, resulting in faster and more accurate diagnoses. Furthermore, Spark can be easily integrated into current healthcare workflows because of its compatibility with a wide range of data sources and programming languages. Developing sophisticated algorithms for image classification, segmentation, and feature extraction is also made possible by its machine-learning libraries, further boosting the diagnostic capabilities of medical imaging analysis [9]. The use of Apache Spark for medical imaging analysis has the potential to significantly impact the healthcare sector by accelerating the diagnostic process and eventually enhancing patient care. The use of powerful tools like Spark is becoming increasingly essential to preserving the efficiency and quality of medical diagnostics as the volume and complexity of medical imaging data continue to increase. Fig. 2 depicted the workflow of big data analytics, using analytical pipelines.

Fig. 2. Workflow of big data analytics, using analytical pipelines to obtain smarter and healthcare options.

#### A. Hospital Readmission Reduction

Reducing hospital readmissions is one of Apache Spark's healthcare success stories. Not only do high readmission rates affect patient outcomes, but they also raise the price of healthcare. Healthcare businesses have been able to pinpoint trends and risk factors related to hospital readmissions by using Apache Spark to analyze EHR data, demographic data, and other pertinent elements. Spark provides predictive modelling with the integration of machine learning algorithms, assisting healthcare practitioners in identifying high-risk patients and implementing targeted treatments to lower readmission rates. Following the adoption of Apache Spark-based analytics, several hospitals have reported noticeably lower readmission rates, which has improved patient care and decreased healthcare costs.

#### B. Early Detection of Sepsis

If sepsis is not promptly identified and treated, it can result in organ failure and death. Sepsis is a condition that can be fatal and is brought on by the body's reaction to infection. Real-time analysis of vital signs, laboratory findings, and other clinical data has been made possible using Apache Spark, which has been crucial in the early detection of sepsis. Spark can assist medical professionals in spotting early indicators of sepsis and starting prompt interventions by processing this data using machine learning algorithms. Several case studies show how Apache Spark works well for early sepsis detection, which lowers mortality rates and improves patient outcomes.

#### C. Cancer Research and Treatment Optimization

Cancer research and therapy optimization have benefited greatly from Apache Spark. For both researchers and physicians, the complexity of cancer and the enormous amount of genetic, proteomic, and clinical data related to it provide considerable obstacles. The rapid processing and analysis of massive datasets with Apache Spark has made it possible to

identify cancer biomarkers, subtypes, and prospective therapeutic targets more effectively. Additionally, Spark has made it easier to create individualized treatment plans that maximize the effectiveness of cancer therapies while minimizing side effects by integrating with machine learning and AI technologies. Numerous success stories in cancer research and treatment planning demonstrate Apache Spark's revolutionary effects in this field.

#### D. Accelerating Drug Discovery

Drug discovery is often a time-consuming, expensive, and complicated process. By enabling quick analysis of enormous amounts of data from numerous sources, such as genomic, proteomic, and chemical databases, Apache Spark has become an important tool in speeding up drug discovery. Researchers can more effectively identify prospective medication candidates and forecast their efficacy and safety by using Spark's sophisticated analytics capabilities. Additionally, the use of machine learning and AI approaches streamlines the drug discovery process by enabling more precise predictions of drug-target interactions. Numerous case studies demonstrate how Apache Spark has been successfully used to speed up drug discovery, resulting in the development of new treatments more quickly and better patient care.

### IV. APACHE SPARK IN GENOMICS RESEARCH

Precision medicine has undergone a sea change due to the adoption of Apache Spark in genomics research. Spark, a cutting-edge distributed computing platform, has proven to have an extraordinary ability to overcome the difficulties in processing and analyzing big genomic datasets. This section examines the influence of Apache Spark on genomics research, focusing on its potential to promote personalized medicine and provide fresh discoveries. Genomic research analyses enormous genomic datasets to find genetic differences and connections with certain diseases or disorders [10]. Because of

the size and complexity of genomic data, it is essential to deploy robust processing and analysis methods that can effectively handle massive datasets. Because of Apache Spark's unique capabilities, including in-memory computation, fault tolerance, and scalability, genomics research can benefit from its use. Researchers may quickly process and analyze massive genomic datasets using Spark, leading to the discovery of new information about the genetic relationships between diverse diseases [11].

Additionally, Spark's flexibility with numerous data sources and programming languages enables easy integration into current processes for genomics research. Its machine-learning libraries also make it easier to create complex genetic data analysis algorithms, which advances our understanding of the connections between genes and illness [12]. In conclusion, by maximizing the potential of massive genomic data, the use of Apache Spark in genomics research holds enormous promise for developing personalized medicine. The use of reliable tools like Spark is crucial for advancing genomic breakthroughs and the advancement of precision medicine as the volume and complexity of data keeps growing. programs by allowing data-driven decision-making and enhancing general population health and well-being. Adopting powerful technologies like Spark becomes increasingly essential for optimizing public health initiatives and resource allocation as the volume and complexity of population health data continue to increase [15].

#### V. APACHE SPARK IN POPULATION HEALTH MANAGEMENT

Public health projects have significantly benefited from the use of Apache Spark in the field of population health management. Spark, a state-of-the-art distributed computing platform, provides exceptional capabilities for overcoming the difficulties in processing and analyzing massive datasets important to population health. Authors discuss Apache Spark's effects on population health management, highlighting its potential to promote data-driven decision-making and enhance the results of public health initiatives. Assessment of large datasets is required for population health management to comprehend patterns, trends, and health determinants in each population. This information is essential for guiding public health policies, resource allocation, and preventive measures.

Population health data are complicated and extensive; powerful processing and analytic technologies that effectively manage massive datasets are essential [13]. Apache Spark is the perfect choice for population health management thanks to its distinctive capabilities, including in-memory processing, fault tolerance, and scalability. By using Spark, academics and public health practitioners can expedite the processing and analysis of large datasets [14], allowing for discovering health trends and patterns that guide evidence-based decision-making. Additionally, Spark can be easily integrated into current population health management workflows due to its compatibility with various data sources and computer

languages. Its machine learning libraries also enable the construction of sophisticated population health data analysis algorithms, which advance knowledge of the variables affecting public health outcomes. In conclusion, using Apache Spark in population health management can profoundly influence public health.

#### VI. TECHNOLOGICAL ADVANCEMENTS AND INTEGRATIONS

The growing use of Apache Spark in the healthcare sector can be ascribed to several technology developments and integrations that have improved its functionality and industry compatibility. To facilitate data-driven innovations and better patient care, this part outlines significant advancements, such as machine learning libraries, that have aided in the broad adoption of Spark in healthcare settings. Spark's robust machine learning libraries, including MLlib, are one of the main factors influencing its growth in the healthcare industry. These libraries offer a complete set of tools and methods for jobs, including dimensionality reduction, clustering, regression, and classification. By utilizing these resources, healthcare workers and academics can create complex models for forecasting patient outcomes, spotting illness patterns, and comprehending the connections between numerous health parameters [16]. Integration of machine learning with spark is shown in Fig. 3.

Additionally, Spark can be easily integrated into current healthcare workflows thanks to its compatibility with a wide range of computer languages, including Python, Java, Scala, and R. This adaptability lowers adoption hurdles by enabling healthcare organizations to use Spark without having to redesign their current infrastructure. Cloud-based deployment possibilities have also assisted Spark in healthcare. These choices offer scalable, on-demand computing resources that are simple to modify to meet the organization's demands. Healthcare organizations that deal with variable data quantities and need quick data processing capabilities would benefit from this flexibility.

Apache Spark's acceptance in the healthcare industry has been aided by its ability to connect with other big data tools and platforms, like Hadoop and NoSQL databases. Due to Spark's powerful processing and analytics capabilities, healthcare organizations can utilize their current investments in extensive data infrastructure [17]. In conclusion, many technological developments and integrations have significantly promoted Apache Spark's use in the healthcare industry. Spark has established itself as a versatile and essential tool for healthcare organizations looking to harness the potential of big data for enhancing patient care and fostering innovation. This is due to Spark's powerful machine learning libraries, compatibility with numerous programming languages, cloud-based deployment options, and seamless integration with other big data tools. ML-based variant spark for genomic variants are shown in Fig. 4.

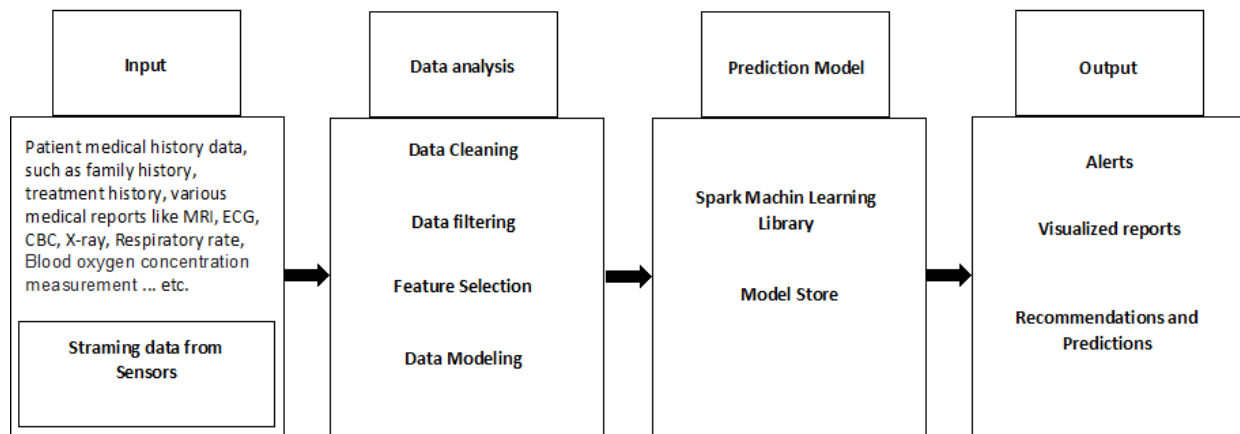

Fig. 3. ML framework for spark.

Fig. 4. Variant Spark (ML Framework for Genomic Variants).

#### A. Integration with Artificial Intelligence and ML

Integrating Apache Spark with AI and ML technologies will be more and more important as healthcare adopts big data. More sophisticated analytics, enhanced pattern recognition, and predictive capacities will be made possible by this convergence, further increasing patient care, and streamlining healthcare procedures. Future advancements in AI and ML algorithms will open new avenues for innovation and support the healthcare sector's ongoing transformation, especially when combined with Spark's distributed computing capabilities.

#### B. Real-time Analytics and Internet of Medical Things (IoMT)

The interconnected network of medical equipment, sensors, and applications that gather and distribute healthcare data is known as the Internet of Medical Things (IoMT). Real-time analytics will be more crucial in healthcare as IoMT is more adopted. Apache Spark is an essential tool for maximizing the potential of IoMT because of its capacity for real-time data processing and analysis. The combination of Apache Spark with edge computing and real-time data streaming systems will probably lead to future developments in IoMT, giving healthcare practitioners more effective and timely insights and improving patient care.

#### C. Enhanced Interoperability and Data Sharing

Data sharing and interoperability are essential elements of a data-driven healthcare environment. Apache Spark's role in improving interoperability and facilitating data exchange across many stakeholders will become even more important as it continues to gain traction in the healthcare industry. Future advancements in data standards, APIs, & data sharing protocols will make it possible to integrate Apache Spark with other healthcare systems more easily, enhancing collaboration and enabling more thorough analyses of healthcare data.

#### D. Ethical Considerations and Guidelines

Ethics relating to data privacy, security, and fairness will become more important as healthcare organizations use big data technologies like Apache Spark more frequently. To ensure the ethical use of new technologies in healthcare, it will be crucial to create and abide by ethical standards for data use, analysis, and sharing. The development of industry best practices and legislative frameworks that address these moral questions may be a future trend, encouraging a more open and accountable approach to healthcare data analytics. Healthcare businesses can increase trust with patients and stakeholders by addressing these ethical issues, assuring the sustainable and ethical use of big data technologies like Apache Spark

## VII. CHALLENGES AND LIMITATIONS OF IMPLEMENTING APACHE SPARK IN HEALTHCARE

While Apache Spark has shown much promise for revolutionizing healthcare through sophisticated data processing and analytics, it also has some issues and restrictions that must be resolved for successful adoption. This section covers the main issues with Spark's adoption in the healthcare industry, such as data security, privacy issues, and the need for qualified employees, and looks at potential solutions [18].

Spark implementation in the healthcare industry must take data security seriously because healthcare data is frequently sensitive and governed by strong privacy laws. Compliance with regulatory standards, such as HIPAA, necessitates careful handling and preserving Spark data processing. Organizations must implement robust security features, including encryption, access limits, and audit trails, to protect the sensitive data handled and analyzed [19]. Spark adoption raises privacy issues as well in the healthcare industry. When analyzing healthcare data, a fine line must be drawn between gaining insightful knowledge and protecting patient privacy. To safeguard patient privacy while enabling valuable data analysis, it is necessary to create robust anonymization techniques and data handling protocols [20].

The need for qualified employees with skills in both technical and domain-specific understanding of the healthcare industry presents another difficulty in deploying Spark in the healthcare sector. A lack of such people may hamper Spark's efficient adoption and integration into healthcare workflows. Organizations might invest in training and educational activities to create staff skilled in Spark and healthcare subject knowledge to close this skills gap. Even though Apache Spark presents the healthcare sector with several prospects for innovation and advancement, obstacles connected to data security, privacy issues, and the lack of competent labor must be carefully reviewed and resolved. Healthcare organizations can successfully utilize Apache Spark's promise while minimizing the dangers and difficulties involved by implementing extensive security measures, reliable data handling methods, and investments in workforce development.

### A. Data Security and Privacy Concerns

Despite Apache Spark's many advantages in the healthcare industry, privacy and data security issues continue to be major obstacles. Strong security measures are required to safeguard patient information due to the sensitive nature of healthcare data and strict rules like HIPAA in the US. When using distributed data processing systems like Apache Spark, it might be difficult to ensure data encryption, safe access management, and privacy standards compliance. Healthcare companies must address these issues by putting in place suitable security safeguards and regularly reviewing and upgrading their data security plans.

### B. Scalability and Infrastructure Constraints

Even though Apache Spark is scalable, healthcare companies could encounter infrastructure limitations that prevent them from taking full advantage of the technology's potential. A distributed computing environment can be

resource-intensive to deploy and manage, necessitating hefty hardware, networking, and storage expenditures. It may be difficult for smaller healthcare companies, in particular, to scale their infrastructure to meet the rising needs of big data processing. Organizations may want to use cloud-based solutions that provide scalable, managed infrastructure for Apache Spark deployment to lessen the impact of these limitations. Various Performance Interferences in Apache Spark are discussed in [21].

### C. Data Integration and Quality Issues

Integrating data from disparate sources and ensuring data quality are crucial aspects of leveraging big data in healthcare. Apache Spark's ability to process and analyze data from various sources is a significant advantage, but it also presents challenges in terms of data integration and quality. Healthcare organizations must contend with issues such as data inconsistency, missing values, and duplication. Ensuring data quality and integration requires robust data governance processes, including data cleansing, validation, and standardization. Implementing these processes can be time-consuming and complex, but they are essential for deriving meaningful insights from healthcare data.

### D. Skills Gap and Workforce Challenges

A skilled staff that can manage and efficiently use the technology is necessary for Apache Spark to be adopted in the healthcare industry. However, the healthcare industry suffers from a severe skills gap, with a dearth of experts in big data technology, machine learning, and advanced analytics. Healthcare firms must engage in training and development programs to create internal knowledge in Apache Spark and comparable technologies to solve this obstacle. Fostering partnerships with academic institutions, research facilities, and business associates can also aid in closing the skills gap and spur innovation in healthcare data analytics.

### E. Future Challenges

The ability to unearth priceless insights from big data and improve patient care has made Apache Spark a disruptive force in the healthcare industry. Healthcare organizations can successfully incorporate Spark into their workflows by overcoming the accompanying difficulties and constraints, opening up new possibilities for innovation and data-driven advancements in the healthcare industry. This study report concludes by highlighting Apache Spark's substantial contribution to the advancement of patient care and data-driven innovations in the healthcare industry. The following is a summary of the major findings:

- Due to its distributed computing capabilities, fault-tolerance, and in-memory processing characteristics, Apache Spark has become a potent tool for managing and Analysing large- scale healthcare data.
- Personalized medicine, genomics, medical image analysis, and remote patient monitoring are just a few of the many uses for Apache Spark in the healthcare industry. Other uses include EHR management, predictive analytics for disease outbreaks, and genomics.

- The early diagnosis of sepsis, improved cancer research and treatment, decreased hospital readmissions, and accelerated drug discovery are just a few of the success stories that demonstrate Apache Spark's disruptive potential in the healthcare industry.
- Despite the many advantages, there are still difficulties and restrictions in using Apache Spark in the healthcare industry. These include issues with data security and privacy, scalability and infrastructure, data integration and quality, and a skills gap in the workforce.
- The integration of Apache Spark with AI and ML, real-time analytics and IoMT, improved interoperability and data sharing, and the introduction of ethical concerns and norms are future trends and prospects in the healthcare sector.

Apache Spark can change the healthcare sector by solving the issues and constraints and utilizing upcoming trends and possibilities, which will ultimately result in improved patient care and more effective healthcare delivery.

### VIII. FUTURE WORK

Several proposals for upcoming research and development will help Apache Spark's adoption and use as it continues to have an impact on the healthcare sector:

- Create and improve Apache Spark-based algorithms for use cases particular to the healthcare industry: Algorithms' effectiveness and uptake can be greatly increased by customizing them to meet the specific objectives and challenges of the healthcare industry. To address issues unique to the healthcare industry, such as forecasting illness progression, streamlining treatment regimens, and evaluating intricate medical data, researchers should concentrate on creating and improving Spark-based algorithms.
- Examine unique Apache Spark applications in the healthcare industry: Investigating novel Apache Spark applications in the healthcare industry can result in creative solutions and advancements in patient care. Future studies should investigate topics like preventive care, rare diseases, and mental health because these are all areas where big data analytics may make a significant difference.
- Encourage cross-disciplinary cooperation: Promoting cross-disciplinary cooperation among researchers, engineers, data scientists, and healthcare practitioners can spur creativity and hasten the creation of Apache Spark-based healthcare solutions. Collaborations between healthcare practitioners, business, and academics can help to share resources, exchange knowledge, and create best practices.
- Improve data privacy and security measures: Future research should concentrate on establishing cutting-edge methods for safeguarding sensitive patient data within Apache Spark and other big data platforms, as these issues continue to be major hurdles in the healthcare industry. Federated learning, homomorphic

encryption, and differential privacy are a few examples of these strategies that can assist assure compliance with rules while facilitating useful data analysis.

- Examine the ethical implications of big data use in healthcare: As Apache Spark and other big data technologies are being used in healthcare, it is important to recognize and address the ethical implications. Future studies should investigate the moral issues around data ownership, privacy, justice, and openness, and they should also establish standards and best practices for the ethical application of big data in healthcare.
- Make a concerted effort to educate and cultivate a workforce skilled in Apache Spark and comparable technologies to close the skills gap in healthcare data analytics. To create curricula, training programs, and continuing education opportunities that advance expertise in big data analytics and promote a culture of data-driven decision-making in healthcare, educational institutions, industry partners, and medical institutions should work together. Focusing on these suggestions will help researchers, healthcare providers, and industry partners realize Apache Spark's full potential in the healthcare sector, resulting in better patient outcomes, more effective healthcare delivery, and greater innovation overall.

### IX. CONCLUSION

Apache Spark's adoption in the healthcare industry has shown incredible promise for fostering innovation, enhancing patient care, and enabling data-driven decision-making. Healthcare organizations can handle the problems caused by the complexity and volume of healthcare data by utilizing Spark's powerful processing capabilities, scalability, and machine learning frameworks. Applications of Spark in population health management, genomics research, and medical imaging analysis have shown how it has the potential to revolutionize many different facets of the sector. However, to successfully implement Spark in the healthcare industry, it is vital to solve critical issues, including data security, privacy concerns, and the need for qualified staff. Healthcare organizations need to have robust security protocols in place to safeguard sensitive data and guarantee regulatory compliance to use Spark's advantages. A culture of continuous learning and workforce development investments can also assist in closing the skills gap and give healthcare personnel the know-how they need to utilize Spark fully.

# Weight Optimization Based on Firefly Algorithm for Analogy-based Effort Estimation

Ayman Jalal AlMutlaq, Dayang N. A. Jawawi, Adila Firdaus Binti Arbain  
Department of Software Engineering-School of Computing-Faculty of Engineering,  
Universiti Teknologi Malaysia, Johor Bahru, Malaysia

**Abstract**—Proper cost estimation is one of the vital tasks that must be achieved for software project development. Owing to the complexity and uncertainties of the software development process, this task is ambiguous and difficult. Recently, analogy-based estimation (ABE) has become one of the popular approaches in this field due to its effectiveness and practicability in comparing completed projects and new projects in estimating the development effort. However, in spite of its many achievements, this method is not capable to guarantee accurate estimation confronting the complex relation between independent features and software effort. In such a case, the performance of the ABE can be improved by efficient feature weighting. This study introduces an enhanced software estimation method by integrating the firefly algorithm (FA) with the ABE method for improving software development effort estimation (SDEE). The proposed model can provide accurate identification of similar projects by optimising the performances of the similarity function in the estimation process in which the most relevant weights are assigned to project features for obtaining the more accurate estimates. A series of experiments were carried out using six real-world datasets. The results based on the statistical analysis showed that the integration of the FA and ABE significantly outperformed the existing analogy-based approaches especially for the ISBSG dataset.

**Keywords**—Analogy-based estimation; firefly algorithm; software cost estimation; weight optimization

## I. INTRODUCTION

Software development effort is considered one of the most significant measures estimated in the software projects owing to the fact that planning, developing, and all other vital processes of the project largely rely on correct estimation of the development effort [1]. Accurate estimation of software development metrics has become a critical issue for researchers in recent years in the software project management field [2-4]. The unstable nature of software project requirements, related hardware platforms, and the continuous change in software development frameworks complicate the process of estimation [5, 6]. Uncertain and insufficient available information to be used in equations, relations, formulas, and so on, become a major problem confronted by researchers in this field [4, 7].

Recently, analogy-based estimation has been found by many researchers as the most adaptable technique in software effort estimation [8, 9]. Analogy Based Estimation (ABE) can be defined as the selection of the previously completed projects similar in nature to the target project and deriving effort estimation based on these selected projects [10, 11]. Although the analogy-based estimation method is a simple and

straightforward process, the process is extremely difficult due to the non-normality of software development data. [12]. Generally, the non-normality of software projects is the major issue that affects all comparison based approaches including the analogy based estimation method [13-15]. To address these issues thereby improving the estimation performance, appropriate weights of project attributes are evaluated in several research works [16, 17]. The weighting process is affected by irrelevant and complex projects and those projects that are out of the overall trend of the dataset [18, 19].

Various project attributes must be taken into consideration in the weighting process, compatible with principles of software engineering [20-22]. The inaccurate software development effort will result from attributes that are given the same weight even though they have different level of influence on estimation accuracy [23]. However, determining attribute weights used in the similarity function is a challenging issue in the ABE methods. Optimization, intensive search, and correlation analysis are the most prominent methods for attribute weighting. Correlation analysis tries to figure out the degree of dependency between software effort and other project attributes [24-26]. Intensive search applies in-depth search to determine the best subset of attributes [17, 27, 28]. Generally, the optimization methods tend to enhance the attribute weighting or feature selection in the ABE similarity function component [3, 29, 30].

Essentially, the majority of literature optimization approaches are motivated by nature, for example particle swarm optimization (PSO) which imitates fish schooling behaviour and bird flocking, ant Colony Optimization which imitates the ants' behaviour and the artificial Bee Colony (ABC) technique which mimics the bees' behaviour in searching for diet [31, 32]. Recently, the firefly algorithm (FA) which imitates some tropic firefly swarms has been introduced as a new metaheuristic algorithm [33]. Essentially, fireflies tend to be attracted to each other with higher intensity. This technique is typically different from other algorithms such as PSO and the Artificial Bee Colony (ABC). As such the FA can have two benefits: automatic regrouping and local attractions. As the intensity of light changes with distance, depending on the absorbing factor, the attraction between fireflies can be global or local, and therefore all global and local manners will be visited. Additionally, fireflies can also sub-divide and hence reorganize into sub-groups as neighbouring attraction is stronger than distant attraction; therefore it could be likely that each sub-group will group around a local mode [33-35]. This

behaviour particularly helps the FA to be fit for the optimization problem.

Comparative studies revealed that the FA algorithm is very promising and could outperform many state-of-the-art optimization techniques like PSO and GA [36], and Artificial Bee Colony ABC [37]. Therefore, inspired by the above motivations among others, this research attempt to integrate FA with the ABE method to better optimize feature weights for improving the software development effort estimation. The main goal of this study is to improve the ABE model by optimizing the feature weights. To our knowledge, no research investigation has been conducted on the impact of FA on feature weighting for the ABE model.

Rest of the paper is organized as follow. Section II explains research background. The related work of the study is presented in Section III. The detail of the proposed work is described in Section IV. The experimental design is elaborated in Section V. Results and discussion of the study is detailed in Section VI. Section VII presents statistical analysis of the proposed model compared to related models. Section VIII concludes this research study.

## II. BACKGROUND

This section presents the background of the FABE model. We first discuss the concept of analogy-based estimation, which includes different steps of the ABE process. Further, each analogy estimation metric is described, which includes the similarity function and the solution function. Finally, in this section, the concept of the Firefly algorithm is also presented.

### A. Analogy-Based Estimation (ABE)

The ABE method was initiated as a substitute for algorithmic-based software development effort estimation. In this technique, software project estimation is carried out by comparison with earlier accomplished projects and identifying the most similar projects to the board projects [38]. Owing to its suitability, the analogy-based estimation method has been popularly applied for software development in several studies. Essentially, ABE comprises four main modules, namely, historical dataset, K-nearest neighbours, similarity function, and solution function. More specifically, the ABE process is made up of steps as follows:

- Historical data creation through artificial or real datasets.
- Acquisition of new project features in a consistent manner with previous datasets.
- Applying predetermined similarity functions for example the Euclidean function to retrieve projects similar to the new projects.
- Predefined solution function is used to determine the new project's cost.

A similarity function is used in ABE for estimating the resemblance between two projects based on their feature comparison [38]. There are different similarity functions which include Manhattan similarity (MS) and the Euclidean similarity (ES). The Euclidean distance (ED) is the most popular

similarity function which particularly involves distance between particular points. The similarity function is commonly used in optimization problems where distances are compared. MS is another popular similarity function in which the normal distance of Euclidean space is substituted by a new measurement where the distance between the locations is the sum of their coordinate's differences. These metrics are popularly applied for measuring the similarity in ABE. The nature of the projects at the normality level and the dataset can considerably affect the performance of similarity functions. ES function is shown in Equation 1:

$$Sim(p, p') = \frac{1}{\sqrt{\sum_{i=1}^n w_i Dis(f_i f'_i) + \delta}} \quad (1)$$

$$Dis(f_i f'_i) = \begin{cases} (f_i - f'_i)^2 & \text{if } f_i \text{ and } f'_i \text{ are numerical or ordinal} \\ 0 & \text{if } f_i \text{ and } f'_i \text{ are nominal and } f_i = f'_i \\ 1 & \text{if } f_i \text{ and } f'_i \text{ are nominal and } f_i \neq f'_i \end{cases} \quad (2)$$

Where,  $w_i$  is the weight (which ranges between 0 and 1), allocated to each feature,  $p$ , and  $p'$  are the projects.  $f_i$  and  $f'_i$  represents the  $i$ th feature of each project,  $\delta$  is used to gain a nonzero result and  $n$  represents the number of features.

The MS representation is like the ES formula, but it calculates the complete difference between features. The mathematical representation of the MS function can be given as:

$$Sim(p, p') = \frac{1}{\left[ \sum_{i=1}^n w_i Dis(f_i f'_i) + \delta \right]} \quad (3)$$

$$Dis(f_i f'_i) = \begin{cases} |f_i - f'_i| & \text{if } f_i \text{ and } f'_i \text{ are numerical or ordinal} \\ 0 & \text{if } f_i \text{ and } f'_i \text{ are nominal and } f_i = f'_i \\ 1 & \text{if } f_i \text{ and } f'_i \text{ are nominal and } f_i \neq f'_i \end{cases} \quad (4)$$

After identifying the K most similar projects, it would be possible to calculate the target project's effort based upon the selected features or attributes. The commonly used solution function include the Closest Analogy (CA) [11], the inverse weighted mean (IWM) [39], the average, and median of the most similar projects [40]. Mean is the average of effort for  $K > 1$  while median is considered as effort median for similar projects with  $K > 2$ . In practice, Equation 5 adjusts the proportion of each project by using Inverse Weighted Mean (IWM).

$$C_p = \sum_{k=1}^K \frac{Sim(p, p')}{\sum_{i=1}^n Sim(p, p')} C_{p_k} \quad (5)$$

Where  $p$ , and  $p_k$  represents the new projects and the most similar  $k$ th project, respectively.  $C_{p_k}$  demonstrates the value of effort of  $k$ th  $p_k$  and  $K$  denotes the total number of the projects.

### B. Firefly Algorithm

Yang developed the Firefly algorithm (FA) which reflects the characteristic flashing behaviour of fireflies [33]. Firefly algorithm comes with three assumptions: i) fireflies are unisexual: fireflies could attract each other irrespective of their gender. ii) The degree of attraction of fireflies is proportional

to the brightness and both are inversely proportional to distance. If there are no brighter fireflies then fireflies will have random movement. iii) Firefly brightness is dependent on the objective function. In FA, fireflies show up in a swarm to resolve a particular optimization task through brightness which is identified by the fitness function, and movements of low brightness fireflies to high brightness which is determined by attractiveness.

In FA, the attraction between the flies involves two aspects; the various light intensities and the modeling of attraction. For a particular firefly at position  $X'$  brightness  $I$  is given as  $I(X') \propto f(x)$  while attraction  $\beta$  is proportional to the flies and is associated with the distance  $R_{i,j}$  among fireflies  $i$  and  $j$ . Equation (6) demonstrates the inverse square of intensity  $I(r)$  in which  $I_0$  denotes the intensity of light from the source.

$$I(r) = I_0 e^{-\gamma r^2} \quad (6)$$

Supposing an absorption factor of the environment  $\gamma$ , intensity is given in Equation 7 in which  $I_0$  is the original intensity.

$$I(r) = \frac{I_0}{1+\gamma r^2} \quad (7)$$

Essentially, the ED is given in Equation 8, which signifies the distance between a firefly at position  $X_i$  and another at position  $X_j$ . Where  $X_{jk}$  is the  $k^{\text{th}}$  constituent of the spatial coordinate  $X_i$

$$R_{i,j} = \|x_i - x_j\| = \sqrt{\sum_{k=1}^d (x_{i,k} - x_{j,k})^2} \quad (8)$$

A firefly  $i$  attracts a brighter one  $j$  as demonstrated in Eq. 9 in which attraction can be given by  $\beta e^{-\gamma_{i,j}^2} (x_i - x_j)$ , and  $\alpha \left[ \text{rand} - \frac{1}{2} \right]$  denotes the randomness based on the randomization parameter  $\alpha$ .

$$x_i = x_i + \beta e^{-\gamma_{i,j}^2} (x_i - x_j) + \alpha \left[ \text{rand} - \frac{1}{2} \right] \quad (9)$$

Additionally, variations of attractiveness are controlled by  $\gamma$  which in turn influences the behavior and convergence speed of FA.

### III. RELATED WORK

For the past years, several research works have been employed by different researchers to apply weighting techniques for improving ABE. One of these methods is using correlation coefficient analysis which is considered for feature selection and weighting in terms of software development effort estimation (SDEE) [41, 42]. In this case, project features with weak correlation are considered the low features and are assigned low weights while the features with higher correlation are given the higher weight and considered the most similar. The project features with no correlation are removed from the set of historical projects.

Weighting-based methods, known as Rough Set Analysis have been proposed for feature selection to better enhance the ABE performance [17, 43, 44]. In rough set analysis, feature dependency analysis generates several sub-sets of features

named classes [45]. The most similar features are obtained by considering the intersection of all the classes. The frequency of attributes in reducts, the number of attributes in a core set, and the frequency of presence of attributes in decision rules are used to build the weighting model in the rough set technique. Another non-algorithmic method for estimation is Gray Theory (GT) in which gray depicts the fuzzy process, where the white and black represent known and unknown information respectively [45]. It is a statistical technique for finding the similarity degree by comparing two projects' features. Since it also uses a comparison technique, it was employed to enhance the ABE performances [46, 47]. One of the vital aspects of ABE is the solution function since it greatly influences the estimation performance's correctness. According to various studies, several attempts have been made to adjust expressions as the solution function to enhance performance [15, 48-50].

Over many years, to modify the feature weighting of the software estimation model, several optimization techniques have been introduced. The genetic algorithm (GA) is considered widely used optimization techniques for feature weights computation in the ABE. Huang and Chiu [51] utilized Genetic Algorithm to identify the best parameters in their defined non-linear/linear equation(s). The parameters involved in equations were determined as an improvement in the ABE's performances. There has been a combination of various methods with a Genetic Algorithm for enhancing accuracy of estimation model such as the Gray Relational Similarity (GRS) method [46], regression techniques [52], and also linear adjustment [15]. For example, Bardsiri, et al. [12, 53] integrates Genetic Algorithms with fuzzy logic and artificial Neural Network, to develop a localized effort estimation process.

PSO has also been applied in many studies for improving the software development effort estimation. For example, Sheta, et al. [54, 55], Lin, and Tzeng [55] utilized the PSO technique to enhance the performances of the COCOMO estimation technique. In some scenarios, PSO has been shown to be more computationally efficient than GA [56]. Wu et al. applied the PSO algorithm for feature weight optimization in the predefined similarity measure of the software estimation approach [57]. Liu, et al. used PSO to reduce errors during the training phase and enhance estimation [58]. Azzeh, et al. [2] utilized the PSO algorithm to identify the optimum decision variable where the trade-off between several evaluation metrics is illustrated. Differential evolution have been used for feature weight optimization in ABE [23]. ABC has also been applied for the ABE optimization and indicated to outperform the PSO method [3]. Bardsiri, et al. integrated PSO with simulated annealing (SA) for feature weight optimization in ABE model [59]. Ferrucci, et al. [60] conducted a research on the influence of the fitness function. They showed that the model performance could be enhanced by choosing suitable and optimized performance measures. Essentially, the optimization of the fitness functions performs an important impact in estimation due to the complexity of software project.

#### IV. THE PROPOSED FA-BASED OPTIMIZATION FOR ANALOGY BASED ESTIMATION (FABE)

In the proposed approach, the FA is integrated with the ABE model for improving the estimation accuracy. Adaptability and Flexibility are two important properties of the FA which make it capable to mitigate the issue of the vagueness and complexity of software project attributes [33, 61]. Essentially, the main purpose of the FA is to identify the most suitable feature weights that are to be used in the similarity function. Weights are allocated for parameter optimization to enhance the ABE performance. The system architectures of the training and testing of the proposed approach are illustrated in Fig. 1 and Fig. 2 respectively, whereas Algorithm 2 shows the Pseudo-code of FABE.

##### A. Training Stage

Fig. 1 illustrates the training phase architecture of the FABE approach. In the training stage, historical project data is utilized for predicting the efforts of the training dataset.

In this stage, the model adjusts the weights of features based on the FA in the Analogy-based Estimation similarity function. The dependent feature is the development effort; all others are considered independent features. In the training phase all available dataset projects are divided into (basic, train, test) subsets. For model construction in training stage basic and training subsets are used. For model evaluation in testing stage the basic and test subsets are involved. Training projects are compared with basic projects to find suitable weights and also testing projects are compared with basic for performance evaluation. A project is taken away from the training set and applied to the similarity function as a new project that is to be determined.

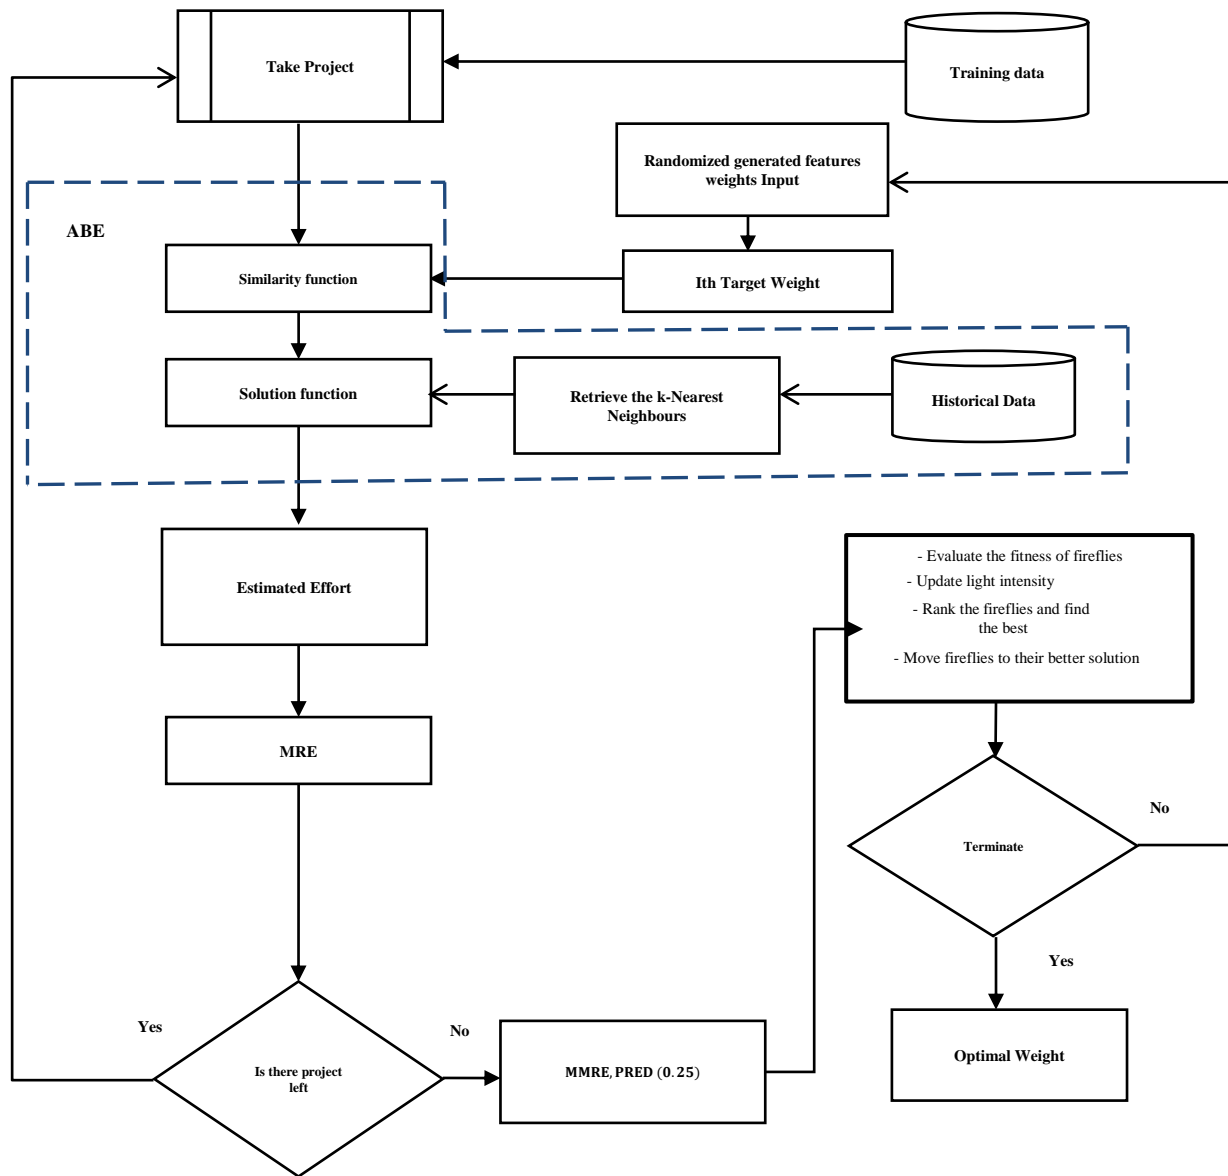

Fig. 1. Training stage.

### Algorithm 1: FABLE Algorithm

**Inputs :**

$f(.)$  objective function  $f(x)$

□ randomized parameter

□□ attraction coefficient

□ Light Absorption Coefficient

**POP** population Size

Step 1: Initialize the population of  $n$  fireflies.

Step 2: new project is selected form training dataset, and the remaining others projects are processed by ABE as historical projects.

Step 3: FABLE feature weight parameter vector is encoded for the training project.

Step 4: weight vector of range  $[0, 1]$  is generated randomly.

Step 5: The training project similarity metric is evaluated for the weight vector selected randomly from pop.

Step 6: From the historical dataset obtain  $K$  closest analogies used in ABE, and then predict effort value of the training project using different solution functions.

Step 7: Until all training cases are treated with the same identical random weight vector (created for the first training case) repeat steps 2-6.

Step 8: MRE for each individual is calculated based on the objective function.

Step 9: Training projects set accuracy metrics (MMRE, PRED (0.25)) are evaluated.

Step 10: The Evolution step // Given that stopping criteria is not fulfilled.

Step 10.1: Evaluate the fitness of fireflies using objective function

Step 10.2: Update light intensity of the fireflies

Step 10.3: Rank the fireflies and find the best

Step 10.4: Move fireflies to their better solution

Step 10.5: Go to step 12 if the stopping criteria have been met. (maximum number of iterations)

Step 11: Go to Step 10.

Step 12: EXIT.

**Output: The best Candidate solution with the optimal weight vector is chosen for the following Testing Stage.**

The FA algorithm assigns weights to the independent features used in the similarity function. The considered project is compared with the basic projects based on the Equation (1). The most similar projects are discriminated by the similarity function to the removed project and take them to the solution function, and the MRE is calculated. This procedure is continued until all training projects are estimated. In the next step, the error and prediction performances MMRE and PRED (0.25) are calculated for a training group based on the MRE values. Reduce the value of MMRE and increases PRED (0.25) are the main goal of any estimation method which motivates this study to Fine-tune FA for MMRE value minimization.

The weights are recorded to be used in the testing stage if the termination requirements are met; otherwise, the FA updates the weights taking into account the obtained performance parameters. The similarity function is given new weights, and all computations are carried out once more for the training projects. Until the termination criteria are met, this process is continued. The training phase of the model is shown in Fig. 1. There are two rounds in the training phase, as shown in the image, with the first one having to do with calculating the MMRE for training projects and the second one having to do with adjusting weights using the FA approach.

### B. Testing Stage

The primary purpose of this phase will be to assess the model's performance using hypothetical projects. Basic and testing projects are used as the inputs for the similarity function at this stage to examine how the suggested model performs. Additionally, the training stage's optimized weights are used to modify the similarity function. A project is separated from testing projects, as was done in the training stage, and then put up against basic projects through similarity function. Most resemble projects to the removed project are chosen and forwarded to predefined solution function. The amount of MRE is calculated after estimating the effort. This procedure is repetitive for all testing projects and, eventually, the value of MMRE and PRED are calculated. Fig. 2 illustrates the test phase of the proposed model. As previously mentioned, the project feature weights proposed by FA are produced to help the ABE accurately estimate the training projects effort as possible.

Fig. 2. Testing phase.

The ABE uses basic projects in this instance for comparison reason. Thus, two thirds of the current projects available in the given dataset (basic and training subsets) are utilized to obtain possible best weights, and the rest of the projects available are treated as a test set. To achieve the required precision, FA randomly produces the weights and modifies them over the iterations.

In the suggested approach, feature weighting is done thereby helping the ABE in producing better performances. The ideal set of feature weight vectors could differ from one execution run to the next because FA is a dynamic process that generates variable weights at each iteration. As a result, the weight allocated to a feature cannot be taken as the feature's importance but rather as a component that ABE must use.

### V. EXPERIMENTAL DESIGN

The experimental strategy employed in this study is presented in the following section. First, the datasets used for the experiment to evaluate the accuracy of the proposed FABLE

technique are described, then the performance evaluation metrics. Further in this section, the process involved in the experimental setup, as well as the validation method, is explained and presented.

#### A. Dataset Description

To evaluate the performances of the proposed model, we employ six different datasets, namely, Desharnais, Maxwell, COMMMO, China, NASA, and International Software Benchmarking Standard Group (ISBSG) The Desharnais dataset contains Canadian projects. China dataset is based on Chinese software projects. United States software projects are contained in Cocomo81 and Nasa93 datasets. The Maxwell dataset is constructed based on of Finnish banking projects. Dejaeger et al. [62] claimed to group dataset to categories such as size, development, project data, and environment features. The Statistics of the datasets are given in Table I. Datasets effort values skewness is up to 6.6 [62, 63] Indicating asymmetrically distributed of effort for each dataset which is a thread for accurate estimation models.

International Software Benchmarking Standard Group (ISBSG) is established Australia software based non-commercial organization, which gathers data on software projects from numerous countries globally [64]. In this study ISBSG Release 11 dataset is employed. 5052 completed software projects detailed information have been collected. Software projects data collected from 24 countries are exist in the historical dataset. Majority of projects origin are come from USA with 30.7% percentage of all dataset, followed by Japan with 16.7%, Australia 15.9%, and Finland with 10.2%.

#### B. Cross Validation

The performance evaluation will typically be rather optimistic if the model accuracy is calculated based upon that projects that are used during the implementation phase.

As the errors will always be small, it might result in a biased model evaluation for estimating accuracy [56]. Thus, to better evaluate the model accuracy, a cross-validation approach is applied, which splits the entire dataset into several train and test sets. The results of datasets that are utilized during model construction are contained in the training sets. In testing stage, unseen datasets are utilized for evaluating the accuracy and the performance of all training and testing sets are merged for cross-validation. In this research, we used a three-fold cross-validation method for proposed model performance evaluation as illustrated in Table II.

As can be seen from Table II, six different arrangements can be considered for the model. Where S1, S2, and S3 are the three subsets randomly selected from the set of all projects as basic, training and testing sets accordingly. The sets involve the similar number of projects. At each fold, evaluation measure is calculated for two different arrangements, and the mean is considered as the result of that fold. Finally the accuracy is determined based on the mean of results computed from all three stages.

TABLE I. DATASETS USED IN EXPEREMENTS

Dataset	Projects count	Features	Unit	Max	Min	Mean	Median
Maxwell	62	27	Hours	63,694	583	8223.2	5189.5
Nasa93	18	3	Months	138.3	5	49.47	26.5
Cocomo81	63	17	Months	11,400	6	686	98
Desharnais	77	12	Hours	23,940	546	5046	3647
China	499	18	Hours	54,620	26	3921	1829

TABLE II. ILASTRATION OF CROSS-VALIDATION

S			
S1	S2	S3	
Possible arrangements			
	Basic set	Train set	Test set
Fold 1	Set – 1	Set – 2	Set – 3
	Set – 1	Set – 3	Set – 2
Fold 2	Set – 2	Set – 1	Set – 3
	Set – 2	Set – 3	Set – 1
Fold 3	Set – 3	Set – 2	Set – 1
	Set – 3	Set – 1	Set – 2

#### C. Evaluation Metrics

Several metrics have been used by different studies for evaluating the performance of the comparison-based software estimation method. Accordingly, the most widely used measures include Relative Error (RE), Mean Relative Error (MRE), Percentage of Prediction (PRED) and Mean Magnitude of Relative Error (MMRE). The mathematical representation of these metrics can be given as follows:

$$RE = \frac{\text{estimated} - \text{Actual}}{\text{Actual}} \quad (10)$$

$$MRE = \frac{|\text{Estimated} - \text{Actual}|}{\text{Actual}} \quad (11)$$

$$MMRE = \sum \frac{MRE}{N} \quad (12)$$

$$PRED(X) = \frac{A}{N} \quad (13)$$

$$AE = \text{Estimated} - \text{Actual} \quad (14)$$

$$EF = \frac{PRED(25)}{1 + MMRE} \quad (15)$$

$$SA = 1 - \frac{MAR}{MAR_{p_0}} \quad (16)$$

$$\Delta = \frac{MAR - \overline{MAR}_{p_0}}{s_{p_0}} \quad (17)$$

Projects with  $MRE \geq X$  ( $X$  is usually reserved at 0.25) is denoted as  $PRED(X)$  as shown in Equation 6 and 7 where  $N$  denote the number of projects. Increase  $PRED$  and decrease  $MMRE$  is the main target of all software development effort estimation models, accordingly Araújo, et al. [65] proposed Evaluation Function (EF) measure that combined both  $MMRE$  and  $PRED$  in equation 9 to improve accuracy evaluation for software prediction model.  $MRE$  considered as a biased performance metric since its produce asymmetric distribution [22, 66].  $MMRE$  and  $PRED$  both are derived from  $MRE$  they are also considered as biased performance measure.

Mean Absolute Error (MAE) produced non-symmetric distribution on other side. Equation 8 and 9 shows how MAE can be calculated. Because of non-standardized residual MAE is difficult to interpret. SA was introduced by [22] it can be calculated by Equation 10 (in large number of runs the mean of random guessing is denoted as Mean Absolute Residual (MAR<sub>po</sub>) ) which is enhanced by [67] and used later to estimates effect size as seen in Equation 11 (sample standard deviation for the random guessing is denoted as S<sub>po</sub> ). Reliability of the estimation model can be measured by SA as if the prediction model is stated as useful. SA negative values are not acceptable while zero value shows that the estimation model is unreliable. Effect size ( $\Delta$ ) evaluates the estimation results and the effectiveness of the mode is compared with random guessing. ( $\Delta$ ) categorizes values in small (0.2), medium (0.5) and large (0.8). If the value is equal or greater than to 0.5 the results is considered as favourable [2, 22].

### VI. EXPERIMENTAL RESULTS AND DISCUSSION

As stated earlier, the ABE technique uses three control parameters, including similarity function, solution function and K-nearest neighbour. In the experiment of this research, ED is adopted for similarity function. Median and mean, are considered as the solution function to compute the estimation values. This section presents the performance results of the proposed Fabe model. We first present the experimental results in terms of the MMRE, MdmRE, and PRED based on the different control parameters, namely, Similarity, KNN, and solution function then the later the SA results. Further, the comparison results of the proposed model with existing methods are presented later in the section.

The proposed Fabe model performance is compared and validated with commonly ABE weighting variants techniques, namely traditionally ABE, feature weighting with Genetic Algorithm in ABE (GAABE) [51] , feature weighting with Particle Swarm Optimization in ABE (PSOABE) [53], feature weighting with Differential evolution in ABE (DABE) [23], feature weight optimization with Bee colony optimization in ABE (BABE) [3], these estimation models are trained with historical data and algorithmic settings are tuned automatically.

#### A. Performance of the Proposed Model

Training quality estimation results are extremely affected by data pre-processing before main model execution started. In this study all the independent features were normalized in range (0 to 1) to produce same effect on software effort dependent feature. For the experimentation of the proposed Fabe approach, we first investigate the possibility of getting the best settings of the model. To this end, we use different evaluation metrics namely (MMRE, MdmRE, PRED, and SA) on two different datasets which include Desharnais and Maxwell datasets. Also to assess the effect of the similarity function, the Euclidian similarity metric is employed. The results of the different values of the KNN (from 1 to 5) alongside respective solution function (Median, Inverse Weighted Mean, and Mean) metrics are recorded and shown in Table III to Table VI accordingly. Thus, in this section, the experimental results are presented and discussed. The main purpose of the experiment was to obtain the appropriate ABE

configuration for the proposed model based on the different parameters (k value, similarity Metric, solution function).

Table III and Table IV demonstrate the simulation results of the Fabe technique on the Desharnais and Maxwell datasets indicating various combinations of the key model parameters, such as KNN, similarity function, and solution function, respectively. From the results, it can be observed that the K value at 3 and Mean solution function are the most suitable setting as computed for both MMRE , MdmRE in the training and testing stage of the model on all the datasets, namely, Desharnais and Maxwell.

TABLE III. PERFORMANCE ON DESHARNAIS DATASET

Similarity	K	Solution	Training		Testing	
			MMRE	PRED	MMRE	PRED
Euclidean	1	Closest	0.015	0.685	0.056	0.889
	2	Inverse	0.051	0.127	0.089	0.201
		Mean	0.011	0.115	0.015	0.199
	3	Inverse	0.051	0.185	0.089	0.291
		Mean	0.033	0.131	0.017	0.299
		Median	0.059	0.115	0.021	0.289
	4	Inverse	0.051	0.245	0.089	0.381
		Mean	0.033	0.169	0.054	0.321
		Median	0.044	0.190	0.031	0.377
	5	Inverse	0.051	0.282	0.089	0.480
		Mean	0.049	0.245	0.081	0.488
		Median	0.081	0.245	0.055	0.452

TABLE IV. PERFORMANCE ON MAXWELL DATASET

Similarity	K	Solution	Training		Testing	
			MMRE	PRED	MMRE	PRED
Euclidean	1	Closest	0.041	0.701	0.019	0.095
	2	Inverse	0.059	0.542	0.049	0.091
		Mean	0.084	0.052	0.045	0.081
	3	Inverse	0.059	0.085	0.049	0.302
		Mean	0.044	0.059	0.070	0.069
		Median	0.061	0.042	0.081	0.089
	4	Inverse	0.059	0.117	0.049	0.181
		Mean	0.062	0.082	0.304	0.145
		Median	0.044	0.067	0.480	0.163
	5	Inverse	0.059	0.155	0.049	0.158
		Mean	0.040	0.077	0.271	0.104
		Median	0.039	0.086	0.220	0.126

However, the PRED (0.25) metric test performances showed that the most appropriate ABE setting for both these datasets was K=3 and the “Inverse Weighted Mean” solution function. Thus to further confirm the best configuration of the model thereby obtaining better performance, we also investigate evaluation for another performance measure SA on the Desharnais and Maxwell datasets.

Table V and Table VI demonstrate the SA results of the Euclidean similarity function for the K=3, K=4, and K=5 on the Desharnais and Maxwell datasets respectively concerning

both testing and training stage of the proposed model. The results were evaluated against, maximum, minimum, average, and standard deviation for the SA. Table V demonstrates the SA values for Desharnais datasets. From results analysis, it can be concluded that best values of the SA as maximum and average in the training stage fall at K=3, with values of 95.120 and 39.899 respectively. Likewise based on testing stage, the more suitable values happened at K=3 with an average and maximum value of 63.436 and 93.688 respectively.

The SA results for the Maxwell datasets are demonstrated in Table VI. From observed results, it could be realized that the best performance in the training stage is at K=3 with the value of the Average SA and Maximum SA being 51.955 and 95.900 respectively. Similarly, based on testing stage, the most appropriate performance was observed at K=3 and the maximum and average values of 96.938 and 52.923 respectively. It should be noted that in the experiment, K = 1 and K=2 were not considered for comparison since at these values all solutions functions were not covered. Eventually, we also conducted a simulation study on SA for Maxwell and Desharnais datasets to further support investigation of solution function best suited for the ideal value of K. SA was chosen as a guideline principle for further results analysis in order to its generalization capability.

Table VII and Table VIII demonstrate the SA results on three solution functions, namely, Inverse Weighted Mean,

Median, and Mean on the Desharnais and Maxwell datasets indicating the respective maximum, minimum, average, and standard deviation of the SA respectively. Table VII shows the Minimum, Minimum, Standard Deviation, and Average of the SA of solution function (median, mean, and inverse weighted mean) for the Desharnais dataset. From the results, it can be observed the average and maximum SA values were recorded to be 35.027 and 56.445 respectively for the “mean” as a solution function. Similarly, Table VIII shows lists of the maximum, minimum, average, and standard deviation of SA for the “mean”, median, and inverse solution functions for the Maxwell dataset. The results show that the average and optimal maximum SA values were reported to be 65.157 and 98.019, respectively, for the “mean” solution function. Based on the reported results in this section it was concluded that the most appropriate setting of the ABE is the “Mean “as a solution function and K=3.

### B. Discussion

In this section the performance of the proposed FABE was validated and compared with the state-of-the-art ABE models, namely, traditional Analogy-Based Effort (ABE), GA-based ABE, PSO-ABE, and BABE (Bee Colony-based), and Differential Evolution in ABE(DABE). All estimation methods were adjusted automatically using historical datasets and the algorithm parameters.

TABLE V. SA RESULTS ON DESHARNAIS DATASET

K	Training				Testing			
	Max. SA	Min. SA	Avg.SA	Std.SA	Max. SA	Min. SA	Avg.SA	Std.SA
3	95.120	13.026	39.899	18.113	93.688	36.185	63.436	25.571

TABLE IX. PRECISIONS VALUES FOR FRIEDMAN STATISTICAL ANALYSIS TEST

Estimation Models	Datasets					
	China	Cocomo81	Nasa93	Maxwell	Desharnais	ISBSG
ABE	12.493	24.531	11.488	13.411	13.235	41.27
GAABE	86.196	91.812	90.324	88.423	89.332	51.638
BABE	97.621	99.201	94.982	84.18	84.205	68.82
DABE	96.509	98.94	94.234	84.91	83.66	65.09
PSOABE	92.88	88.016	93.01	83.63	88.854	56.08
FABE	98.426	99.711	95.009	85.661	85.012	71.803

Table IX shows the SA comparison results of the proposed FABE model with the existing approaches on six datasets namely Desharnais, Maxwell, Nasa93, China, and ISBSG based on the “Mean” solution function and K=3 Euclidian similarity. The SA values of FABE model for training and testing on Cocomo81, Nasa93 and China are (97.005, 99.711), (96.752, 95.009) and (96.973, 98.426) respectively. The  $\Delta$  values for this proposed model on each dataset are as, Cocomo81 (Training:0.234,Testing: 0.129), China (Training:0.219 ,Testing: 0.209) ,and Nasa93 (Training:0.251,Testing:0.159). From the detailed comparison results, it can be observed that the proposed FABE approach outperforms existing models.

87% against GABE, DABE, PSOABE, BABE and traditional ABE respectively. It presented a percentage decrease of 5% and 3% against GABE and PSOABE respectively on desharnais dataset, whereas showed an improvement of 1%, 2%, and 72% against BABE, DABE and traditional ABE. In Maxwell dataset, FABE presented 2%, 2%, 1% and 72% improvement against DABE, PSOABE and traditional ABE respectively whereas it presented a percentage decrease of 3% against GABE. For ISBSG that considered the largest among all given datasets, it presented 20%, 6%, 16%, 3% and 30% against GABE, DABE, PSOABE, BABE and traditional ABE respectively, which is considered as significant improvement.

It can be concluded from result analysis that the size and type of dataset affect weight optimization techniques performance on ABE model. In the ISBSG dataset FABE outperformed existing optimization weight techniques significantly on the selected software projects for ABE model. Statistical analysis to validate FABE model performance is performed since results on different datasets are various.

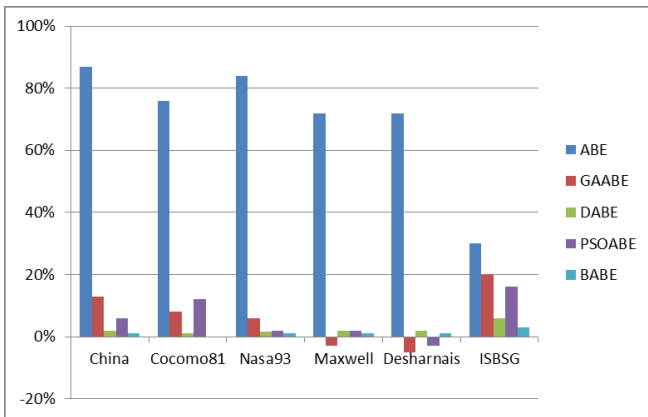

Fig. 3. FABE percentage of improvement against existing models.

TABLE X. FABE PERCENTAGE OF IMPROVEMENT

	ABE	GAABE	DABE	PSOABE	BABE
Cocomo81	76%	8%	1%	12%	0%
Maxwell	72%	-3%	2%	2%	1%
China	87%	13%	2%	6%	1%
Desharnais	72%	-5%	2%	-3%	1%
Nasa93	84%	6%	1.5%	2%	1%
ISBSG	30%	20%	6%	16%	3%

Fig. 3 and Table X demonstrate the average improvements achieved by the proposed FABE model compared to the existing models. For example in Cocomo81 dataset, it presented 8%, 1%, 12%, and 76% against GABE, DABE, PSOABE and traditional ABE. It presented 6%, 1.5%, 2%, 1% and 84% against GABE, DABE, PSOABE, BABE and traditional ABE respectively on Nasa93 dataset. For Cocomo81 dataset FABE performance is found at par BABE. In China, it presented improvements of 13%, 2%, 6%, 1% and

## VII. STATISTICAL PERFORMANCE EVALUATION

Statistical analysis is very important in finding the appropriateness of one technique to another. From the discussion in the previous section, it is obvious that the FABE approach provides the best results compared to the compared methods but now using statistical analysis this will be further confirmed. In this research owing to the fact that software engineering datasets have an issue such that each sub-population has non-contact variance, we employed nonparametric test for the analysis. A null hypothesis would be specified prior performing the test. This determines the differences or equality among the results of the models and enables alternative hypotheses to support the opposite condition to be assessed.

The null hypothesis is denoted as  $H_0$ , and the alternative hypothesis is represented as  $H_n$ . This test can be used to reject the hypothesis at a particular of significance level  $\alpha$ . The p-value is indicated with this level, which represents achieve probability at least as high as expected while null hypothesis is valid. It is recommended to apply p-value instead of  $\alpha$  since it can estimate results significantly (as p value is small this show strong validation against null hypothesis) [68]. Non-parametric tests can be classified into multiple comparisons like Friedman test and pair wise like Wilcoxon Signed test, in case of experiment that considers more than two algorithms or models it is recommended to use multiple comparisons test [69, 70]. In this case, the following hypothesis is considered:

$H_0$ : All feature weight optimization prediction models are equivalent on ABE.

To test the null hypothesis, we employed the Friedman test that is stated by Demšar[70] and García, et al [71]. For Friedman test, initially, original results transformed into ranks each model according to each dataset. Best model value is assigned rank 1; second-best one is assigned rank 2 and so on. Accordingly, we assign ranks  $r_j^i$ , to the  $j$ th of  $k$  models on the  $i$ th of  $N$  data sets based on their accuracy. The Friedman statistic ( $F_f$ ) can be given by equation.

$$F_f = \frac{(N-1)\chi_F^2}{N(K-1)-\chi_F^2} \quad (18)$$

Whereas is Chi-Square value is given by  $\chi_F^2$  in equation.

$$\chi_F^2 = \frac{12N}{K(K+1)} \left[ \sum_j R_j^2 - \frac{k(k+1)^2}{4} \right] \quad (19)$$

The Degree of Freedom (DF) is equal to  $K-1$ , in this performed experiments, value of  $K=6$  and so the value of  $DF=5$ . The sigma value of  $\chi_F^2$  in related studies is considered as 0.01 or less. Based on Chi-square table the value of  $\chi_F^2$  should be greater than 15.086. Friedman test statistic is presented in Table XII. Chi-Square value computed as 19.714, which allows the null hypothesis to be rejected. For each model test ranks are presented in Table XIII and also descriptive statistics of Friedman Test presented in Table XI.

The worst and best-performance model can be identified after the null hypothesis is rejected. From Table XIII which represents mean ranks best-worst performance information can be derived. It can be concluding from Table XIII that FAFE is performing best model followed by BABE. The lowest ranked model among comparative models is ABE.

TABLE XI. DESCRIPTIVE STATISTIC OF FRIDMAN TEST

Model	N	Mean	Std. Deviation	Minimum	Maximum	Percentiles		
						25th	50th	75th
ABE	6	19.40467	11.737169	11.488	41.270	12.24175	13.32300	28.71575

FABE	5.50

### VIII. CONCLUSION

In this research, we proposed a weight optimization method for analogy-based estimation based on the firefly algorithm (FA). An estimation model is built and assessed during the training and testing phases of the suggested framework. FA considers all potential weights and chooses those that will produce the more accurate estimations. By giving project features the most suitable weights, the ABE method's comparison process quality was enhanced. Six datasets were used to test the accuracy of the proposed approach and a cross-validation method was used to calculate the performance metrics for the MMRE, PRED (0.25), MdmRE, SA, and Size

Measure. The positive outcomes demonstrated that the suggested model can greatly improve the accuracy of estimations based on different metrics. The effectiveness of the proposed FAFE technique was demonstrated in all datasets when the obtained results were contrasted with six widely used estimating models. The combination of FA and ABE resulted in a high-performance model for estimating software development effort, according to the findings from the datasets. In future work we intended to combine existing technique in this study with missing data imputation models to pursue for furthermore improvement on estimation accuracy.

**Abstract**—Hierarchical and identity-based encryption (HIBE) is very valuable and widely used in many occasions. In the Internet of Things based on cloud services, efficient HIBE is likely to be applied to cloud service scenarios for the limited computing ability of some terminal devices. What's more, because of the insecurity of cryptographic systems caused by side channel attacks, the design of leakage resilient cryptographic scheme has attracted more and more cryptography researchers' attention. In this study, an efficient leakage resilient HIBE is constructed. (1) In essence, this given scheme contains a hierarchical ID-based key encapsulation system. By using the extractor to act on the encapsulated symmetric key, this proposed scheme may resist the disclosure for the symmetric key due to side channel attacks. The relative leakage ratio of the encapsulated key is close to 1. (2) We also construct a hierarchical identity-based hash proof system that provides the security of our scheme. The proposed scheme can not only resist side channel attacks, but also has short public key parameters and computational efficiency, which is very suitable for applications in the Internet of Things environment. (3) There is no limit to the hierarchy depth of the system, and only the maximum hierarchy length is required to be given when the system is initialized.

**Keywords**—Identity-based encryption; side channel attack; hash proof system; composite order group

## I. INTRODUCTION

The hierarchical identity based encryption (HIBE) scheme has many practical applications. Pavithran et al. [1] constructed a blockchain structure with privacy protection suitable for the Internet of Things (IoT) through HIBE. Their scheme is very suitable for some terminal devices with limited computing resources. The practicability of the scheme is demonstrated through the traffic radar speed measurement system. Fan et al. [2] constructed an efficient data protection scheme of Message Queuing Telemetry Transport (MQTT) through HIBE. MQTT is widely used for the transmission and communication.

The researches [3] and [4] all gave HIBE schemes in the random oracle model. The given scheme in the study [3] does not affect the security of the system due to the hierarchy depth. Based on Bilinear Diffie Hellman (BDH) assumption, HIBE against collusion attack is given in the study [3].

The research [4] introduced the concept of HIBE and security. A concrete two-layer HIBE scheme is given. The upper layer is completely collusion-resistant, while the lower

layer is only partially collusion-resistant. Based on BDH assumption, the security of the scheme is proved in the random oracle model.

The study [5] proposed HIBE which is not affected by the depth of hierarchy, and the key length and decryption cost are fixed. The ciphertext is fixed to three elements, and decryption requires only two bilinear map operations.

The research [6] gave HIBE that is not affected by the depth of hierarchy, and the ciphertext of the proposed scheme has a shorter length. Through the dual system encryption technology, they obtained the full security of the scheme based on the three static assumptions of the composite order group.

The dual system encryption technology is also considered in the research [7], but they constructed secure schemes in prime order groups. In particular, they presented new randomization and parameter-hiding techniques in prime-order groups.

Considering the efficiency of HIBE, the authors in [8] presented an efficient HIBE scheme. This study fully considered the effect of the system parameters, and improved the existing scheme by appropriately reducing unnecessary parameters.

Although there are some leakage resilient (LR) encryption schemes, there are few efficient LR encryption schemes. There are usually two types of means to solve efficiency problems. First, by properly optimizing parameter settings and removing unnecessary parameters, one may obtain an efficient scheme. Second, the scheme in the composite order group is transformed into the scheme in the prime order group. In this research, we will reduce the parameters appropriately by removing unnecessary parameters, so as to achieve the goal of high efficiency. This research constructs an efficient hierarchical identity based LR encryption scheme.

In this research, an efficient leakage resilient encryption scheme is explored. Through the use of extractor technology we obtain leakage resilient encryption scheme. Through the appropriate reduction of parameters we improve the efficiency of the system. Through the hash proof system we prove the security of the given system. This research provides an efficient leakage-resilient hierarchical identity-based encryption scheme that can resist almost all leakage of the encapsulated symmetric key. The relative leakage ratio of the encapsulated key is close to 1.

Other sections are arranged as follows. Section II gives the related works and our research motivation. Section III gives some necessary preparatory knowledge. Section IV gives the concrete scheme. Safety proof and leakage performance analysis are given in Section V. Section VI gives the performance comparison. The conclusion is given in Section VII.

## II. RELATED WORKS

In the research [9], a new HIBE with the maximum hierarchy depth was proposed. When the system is initialized, the maximum hierarchy depth should be given. Considering the absolute trust of the root PKG and the incomplete trust of the sub PKG, it is impossible to delegate a private key for the next layer without the keys of other layers. In this way, the burden of key escrow is reduced.

Jiang et al. [10] presented a secure HIBE against chosen plaintext attacks (CPA). Using lattice theory, its CPA security is proved through learning with errors (LWE) theory. Making an additional point, an efficient HIBE is also proposed against adaptive chosen-ciphertext attacks (CCA). This scheme's security is provided through the shortcut vector problem (SVP) difficult assumption under random oracle model.

Emura et al. [11] has built an efficient HIBE through key isolation technology. They proposed a scheme called key-insulated HIBE (HKIBE). First, the pairing based HKIBE was constructed through the  $k$ -linear assumption under the standard model. Furthermore, they also gave a method to construct efficient HKIBE from general HIBE.

The study [12] gave a revocable identity-based (RIB) and authenticated key exchange (AKE). The scheme has these functions of decentralization and private key revocation. In addition, the general method of constructing hierarchical RIB-AKE from a hierarchical RIB key encapsulation mechanism is also given.

The authors [13] provided a functional encryption based on inner product under public key cryptosystem. When decryption is in progress, the decryptor's identity can be specified and this receiver's identity may be hierarchical. They also gave an experimental result to explain that their presented scheme has certain application value.

Langrehr and Pan [14] presented two adaptive and tight secure HIBE schemes. It is mainly constructed through Matrix Diffie-Hellman assumptions.

In order to resist quantum attacks, this study [15] constructed three hierarchical identity-based (HIB) schemes in the networks which can tolerate time delays. Through the lattice based LWE hypothesis, this study [15] proposed an HIB key agreement scheme, an HIB key update scheme and a non-interactive HIB key agreement scheme.

To avoid key exposure, this research [16] put forward the key isolated encryption technology. Shikata et al. [16] gave a hierarchical key insulated encryption scheme in the standard model.

The study [17] constructed the unbounded HIBE through double system groups and gave an example. This proposed

scheme has shorter ciphertext and private key and has higher computational efficiency.

Zhang et al. [18] constructed anonymous HIBE in prime order groups. Its main advantage is that the private key and ciphertext are fixed in size.

The research [19] gave a CPA secure HIB broadcast encryption. This given scheme is based on prime order group which has high efficiency of computing. Then, the CPA secure scheme was converted to CCA secure scheme by one-time signature.

Some schemes have explored efficiency, such as the schemes [8, 11]. However, these schemes do not take into account the impact of side channel attacks, which may lead to the insecurity of the cryptographic systems.

### A. Side Channel Attacks

In recent years, many side channel attacks have been discovered. The authors [20] made a study on the power analysis of pairing based cryptography implementation. The specific attack towards pairing cryptography scheme was given. Aiming at the typical lightweight encryption scheme LBlock, Weng et al. [21] presented an improved key differential analysis attack. The authors in [22] identified the keys by sound characteristics, and applied this attack to PIN pads. Chen et al. [23] exploited an attack in which an attacker may gain system's secret information from observing this timing and other characteristics of the cryptographic system.

Many researchers engage in leakage resilient (LR) cryptography research, and have constructed some encryption schemes with leakage resilience, such as LR public key encryption schemes [24, 25], LR identity-based encryption schemes [26, 27, 28, 29], LR attribute-based encryption schemes [30, 31, 32], LR certificate based encryption scheme [33, 34, 35], and leakage resilient certificateless encryption scheme [36, 37].

### B. Our Motivations and Contributions

Inspired by the researches [6, 8], this study explores efficient encryption scheme in leakage resilient cryptography. An efficient HIBE with leakage resilience (LR-HIBE) is constructed.

First, the presented scheme has the function of resisting private key disclosure. By using the extractor, the given scheme may resist the leakage for the encapsulated symmetric key. It can resist the leakage of almost the entire encapsulated symmetric key.

Secondly, the presented scheme improves the overall performance of the system by reasonably reducing the parameters. Our scheme has less public key parameters. In addition, it greatly improves the efficiency of private key generation, private key delegation and encryption.

Furthermore, our scheme has good practicability and can greatly share the burden for the root private key generation center. The hierarchical function of the scheme enables the system to delegate private keys layer by layer. For example, we use Fig. 1 to show the information management system about Suqian University. Suqian University is the root. Those

colleges are the secondary nodes. These departments are the tertiary node, and the counselor or teacher is the leaf node. Let U represent the university. Let C represent the college. Let D represent the department. Let T represent the teacher. A member with the identity (Suqian University: School of Information Engineering) can delegate a private key to a member whose identity is (Suqian University: School of Information Engineering: Department of Software Engineering). However, he cannot delegate the private key to a member of (School: School of Management: Department of Accounting).

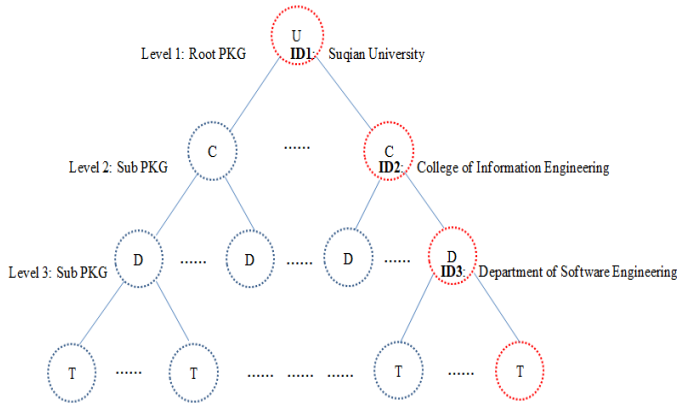

Fig. 1. The hierarchy of the information management system of Suqian University.

### III. PRELIMINARIES

#### A. Bilinear Groups with Composite Order

The research [38] gave the definitions about bilinear groups with composite order (BG-CO). Let  $\Psi$  to denote a BG-CO generation algorithm, which inputs the safety parameter  $\lambda$ , and outputs a BG-CO  $\Omega = \{N = v_1 v_2 v_3, G_1, G_2, e\}$ , where  $v_1, v_2$ , and  $v_3$  are three different primes ( $\text{Log}(v_1) = \text{Log}(v_2) = \text{Log}(v_3)$ ),  $G_1$  is cyclic group with order  $N$  and  $G_2$  is cyclic groups with order  $N$ .  $e$  is a bilinear mapping which satisfies the following two conditions.

1) Bilinearity.

$$\forall g_1, h_1 \in G_1, a, b \in Z_N, e(g_1^a, h_1^b) = e(g_1, h_1)^{ab}$$

2) Non-degenerability.  $\exists g_1 \in G_1$  such that  $e(g_1, g_1) \notin 1_{G_2}$ .

Furthermore, it is required that the operations in groups  $G_1$  and  $G_2$  are computable in terms of the polynomial time about the security parameter  $\lambda$ . We use  $G_{v_1}, G_{v_2}$  and  $G_{v_3}$  to denote these subgroups in the group  $G_1$  whose order is  $v_1, v_2$  and  $v_3$  respectively. In particular, when  $d_i \in G_{v_i}$  and  $d_j \in G_{v_j}$

( $i \neq j$ ),  $e(d_i, d_j)$  is the identity for  $G_2$ . For example, supposing that  $d_1 \in G_{v_1}, d_2 \in G_{v_2}$  and  $p$  is a generator for  $G_1$ , then  $p^{v_1 v_2}$  derives  $G_{v_3}$ ,  $p^{v_1 v_3}$  derives  $G_{v_2}$ ,  $p^{v_2 v_3}$  derives  $G_{v_1}$ . In this way, we can find  $\alpha_1, \alpha_2$  such that  $d_1 = (p^{v_2 v_3})^{\alpha_1}$  and  $d_2 = (p^{v_1 v_3})^{\alpha_2}$ . So,  $e(d_1, d_2) = e(p^{v_2 v_3 \alpha_1}, p^{v_1 v_3 \alpha_2}) = e(p^{\alpha_1}, p^{v_3 \alpha_2})^{v_1 v_2 v_3} = 1$ . The  $G_{v_1}, G_{v_2}$  and  $G_{v_3}$  are orthogonal.

Three complexity assumptions are given here, which is going to be employed in the security proof.

We let  $G_{v_1 v_2}$  to express a subgroup with order  $v_1 v_2$ . Other uses are similar.

Hypothesis 1. Given a composite order bilinear group generation algorithm  $\Psi$  and the distribution as follows.

$$\begin{aligned} \Omega &= (N = v_1 v_2 v_3, G_1, G_2, e) \xleftarrow{R} \Psi, \\ g_1 &\xleftarrow{R} G_{v_1}, X_3 \xleftarrow{R} G_{v_3}, \\ W &= (\Omega, g_1, X_3), \\ T_1 &\xleftarrow{R} G_{v_1 v_2}, T_2 \xleftarrow{R} G_{v_1}. \end{aligned}$$

This advantage that one algorithm  $A$  breaks hypothesis 1 is defined as  $\text{Adv}_{1, \Psi, A}(\lambda) := |\Pr[A(W, T_1) = 1] - \Pr[A(W, T_2) = 1]|$ .

According to the study [6], it is said that the algorithm  $\Psi$  satisfies hypothesis 1, if the advantage  $\text{Adv}_{1, \Psi, A}(\lambda)$  obtained by any probability polynomial adversary is negligible.

Hypothesis 2. Given a composite order bilinear group generation algorithm  $\Psi$  and the distribution as follows.

$$\begin{aligned} \Omega &= (N = v_1 v_2 v_3, G_1, G_2, e) \xleftarrow{R} \Psi, \\ g_1, X_1 &\xleftarrow{R} G_{v_1}, X_2, Y_2 \xleftarrow{R} G_{v_2}, X_3, Y_3 \xleftarrow{R} G_{v_3}, \\ W &= (\Omega, g_1, X_1 X_2, X_3, Y_2 Y_3), \\ T_1 &\xleftarrow{R} G_1, T_2 \xleftarrow{R} G_{v_1 v_3}. \end{aligned}$$

This advantage that one algorithm  $A$  breaks hypothesis 2 is defined as  $\text{Adv}_{2, \Psi, A}(\lambda) := |\Pr[A(W, T_1) = 1] - \Pr[A(W, T_2) = 1]|$ .

According to the research [6], it is said that the algorithm  $\Psi$  satisfies hypothesis 2, if the advantage  $\text{Adv}_{2, \Psi, A}(\lambda)$  obtained by any probability polynomial adversary is negligible.

Hypothesis 3. Given a composite order bilinear group generation algorithm  $\Psi$  and the distribution as follows.

$$\begin{aligned} \Omega &= (N = v_1 v_2 v_3, G_1, G_2, e) \leftarrow^R \Psi, \alpha, s \leftarrow^R Z_N, \\ g_1 &\leftarrow^R G_{v_1}, X_2, Y_2, Z_2 \leftarrow^R G_{v_2}, X_3 \leftarrow^R G_{v_3}, \\ W &= (\Omega, g_1, g_1^\alpha X_2, X_3, g_1^s Y_2, Z_2), \\ T_1 &\leftarrow^R e(g_1, g_1)^{\alpha s}, T_2 \leftarrow^R G_2. \end{aligned}$$

This advantage that one algorithm  $A$  breaks hypothesis 3 is defined as  $Adv3_{\Psi,A}(\lambda) := |\Pr[A(W, T_1) = 1] - \Pr[A(W, T_2) = 1]|$ .

According to the research [6], it is said that the algorithm  $\Psi$  satisfies hypothesis 3, if the advantage  $Adv3_{\Psi,A}(\lambda)$  obtained by any probability polynomial adversary is negligible.

### B. Binary Extractor

This statistical distance about two random variables  $P$  and  $Q$  is defined as:

$$STDS = \frac{1}{2} \sum_{\theta \in \Xi} |\Pr(P = \theta) - \Pr(Q = \theta)| \quad . \quad \text{This}$$

minimum entropy for a random variable  $P$  is defined as:  $H_\infty(P) = -\text{Log}(\max_p \Pr(P = p))$ .

The extractor [39]. We call a function  $\text{Ext}: \{0, 1\}^n \times \{0, 1\}^r \rightarrow \{0, 1\}^m$  as  $(k, \varepsilon)$  strong extractor as long as it meets the conditions. Suppose that  $U$  is the uniform distribution over  $\{0, 1\}^m$  and  $V$  is the uniform distribution over  $\{0, 1\}^r$ . If  $A \in \{0, 1\}^n$  and  $H_\infty(A) > k$ , we can get that  $STDS((\text{Ext}(A, V), V), (U, V)) \leq \varepsilon$ , where  $\varepsilon$  is a negligible value.

**Conclusion 1** [40]. If  $P$ ,  $Q$  and  $R$  are three random variables, and  $Q$  contains  $2^\xi$  value where  $\xi$  is an integer which is used to express the upper bound of leakage, we get  $\tilde{H}_\infty(P | (Q, R)) \geq \tilde{H}_\infty(P | R) - \xi$ .

### C. Hierarchical Identity-Based Hash Proof System

Inspired by the literature [40, 41, 42], we constructed a hierarchical identity-based hash proof system (HIB-HPS). The HIB-HPS includes the following algorithms: Setup, KeyG, Delegate, Encap, Encap\*, and Decap.

**Setup.** This algorithm inputs a security parameter  $\lambda$ . It generates the public key parameter  $PK$  and the master private key  $MK$ .  $\text{Setup}(\lambda) \rightarrow PK, MK$ .

**KeyG.** This algorithm inputs  $MK$  and an identity vector  $\vec{I}$ . It gives the private key  $SK_{\vec{I}}$ .  $\text{KeyG}(MK, \vec{I}) \rightarrow SK_{\vec{I}}$ .

**Delegate.** This algorithm takes an identity vector  $\vec{I}$  with depth  $i$  and an identity  $ID_{i+1}$  as the input. It produces the private key  $SK_{\vec{I}:ID_{i+1}}$  for this identity vector  $\vec{I}:ID_{i+1}$  with depth  $i+1$ .  $\text{Delegate}(PK, SK_{\vec{I}}, ID_{i+1}) \rightarrow SK_{\vec{I}:ID_{i+1}}$ .

**Encap.** This algorithm inputs  $PK$  and  $\vec{I}$ . It generates  $(C, k)$ .  $C$  expresses a correct ciphertext.  $k$  expresses an encapsulated key.  $\text{Encap}(PK, \vec{I}) \rightarrow (C, k)$ .

**Encap\*.** This algorithm inputs  $PK$  and  $\vec{I}$ . It obtains an invalid ciphertext  $C$ . This algorithm is only used for the security proof.  $\text{Encap}^*(PK, \vec{I}) \rightarrow C$ .

**Decap.** The algorithm inputs  $PK$ ,  $C$  and a private key  $SK_{\vec{I}}$ . It produces an encapsulated key  $k$ .  $\text{Decap}(PK, SK_{\vec{I}}, C) \rightarrow k$ .

HIB-HPS has the three characteristics as follows.

1) Correctness

$$\begin{aligned} \Pr[k \neq k' | \text{Encap}(PK, \vec{I}) \rightarrow (C, k), \\ \text{Decap}(PK, SK_{\vec{I}}, C) \rightarrow k'] < \varepsilon, \end{aligned}$$

which means that the decapsulation algorithm are almost always right to obtain the encapsulation key. That is, if the encapsulation algorithm is used to obtain ciphertext  $C$  and the encapsulated key  $k$ , then the probability of the encapsulated key  $k$  obtained by the de encapsulation algorithm is  $1 - \varepsilon$  ( $\varepsilon$  is a negligible value).

2) Indistinguishability between the valid and invalid ciphertext.

Given a private key  $SK_{\vec{I}}$ , the ciphertext gained by the **Encap** algorithm is indistinguishable from the ciphertext generated by an invalid **Encap\*** algorithm.

The indistinguishability is reflected by the next game which is played by an attacker  $A$  and a challenger  $C$ .

### Game<sub>Real</sub>

**Initialize.**  $C$  revokes the algorithm **Setup** to gain the public parameter  $PK$ . Let  $S$  denote the private key created by the challenger but not given to the attacker. The  $S$  is null at the beginning, i.e.  $S = \phi$ .

**Phase 1.**  $\mathcal{A}$  carries on the private key creation inquiry ( $\square - Create$ ), private key delegation inquiry ( $\square - Delegate$ ), and private key inquiry ( $\square - SK$ ).

$\square - Create$ .  $\mathcal{A}$  gives one identity vector  $\vec{I}$ .  $\mathcal{C}$  calls the **KeyG** algorithm to obtain a private key and adds it in  $\mathcal{S}$ .  $\mathcal{C}$  only sends  $\mathcal{A}$  a reference about the private key, not this private key itself.

$\square - Delegate$ .  $\mathcal{A}$  gives a private key  $SK_{\vec{I}}$  in  $\mathcal{S}$  and an identity  $ID$ .  $\mathcal{C}$  connects  $ID$  and  $\vec{I}$  to obtain  $\vec{I} : ID$ . Then,  $\mathcal{C}$  generates a corresponding private key by calling the private key delegation algorithm.  $\mathcal{C}$  only sends  $\mathcal{A}$  a reference about the private key, not this private key itself.

$\square - SK$ .  $\mathcal{A}$  selects a specific element in  $\mathcal{S}$ .  $\mathcal{C}$  sends the private key to  $\mathcal{A}$ . Then,  $\mathcal{C}$  deletes it out of  $\mathcal{S}$ . As for the private key,  $\mathcal{A}$  will no longer do the query  $\square - Delegate$ .

**Challenge.**  $\mathcal{A}$  gives  $\mathcal{C}$  a challenge identity vector  $\vec{I}^*$ . The restriction is that none of its prefix vectors has been inquired in phase 1.  $\mathcal{C}$  randomly selects  $\nu \in \{0, 1\}$ .

If  $\nu = 0$ , the challenger calculates  $Encap(PK, \vec{I}) \rightarrow (C, k)$ .

If  $\nu = 1$ , the challenger calculates  $Encap^*(PK, \vec{I}) \rightarrow C$ .

The challenger sends the ciphertext  $C$  to the adversary.

**Phase 2.** It is similar with phase 1. The basic limitation is that any inquired identity vector cannot be a prefix of  $\vec{I}^*$ .

**Guess.** This adversary outputs a guess  $\nu'$  about  $\nu$ . If  $\nu = \nu'$ ,  $\mathcal{A}$  wins the game. This adversary's advantages are defined as  $Game_{Real}Adv_A(\lambda) = |\Pr[\mathcal{A} \text{ wins}] - \frac{1}{2}|$ . We

have  $Game_{Real}Adv_A(\lambda) \leq \epsilon$ .

3) Smoothness

If  $C \leftarrow Encap^*(PK, \vec{I})$ ,  $k \leftarrow Decap(PK, SK_{\vec{I}}, C)$  and  $k' \leftarrow U$  ( $U$  is a uniform distribution), it can be get that  $STDS((C, k), (C, k')) \leq \epsilon$ .

#### IV. THE PROPOSED LR-HIBE SCHEME

A leakage-resistant and hierarchical identity-based encryption (LR-HIBE) scheme is given in this paper. The ciphertext is compressed to constant group elements and the private key can be re randomized by completely depending on the private key delegation algorithm. By BG-CO, we designs our the scheme. This private key is randomized by  $G_{v_3} \cdot G_{v_2}$

is not used for the real system, but only as a semi-functional form.

**Setup.** This algorithm chooses a BG-CO  $G_1$  and  $N = v_1 v_2 v_3$ , where  $v_1, v_2$  and  $v_3$  are different primes with the equal length. Let  $\ell$  indicate the maximum depth for LR-HIBE. It randomly selects  $g_1, h_1, u_1 \in G_{v_1}, X_3 \in G_{v_3}$  and  $\alpha, \beta \in Z_N$ . This public parameter is  $PK = \{g_1, h_1, u_1, X_3, e(g_1, g_1)^\alpha, e(g_1, g_1)^\beta\}$ . The master key is  $MK = (g_1^\alpha, g_1^\beta)$ .

**KeyG.** It randomly selects  $r, t \in Z_N$  and  $R_3, R'_3, R''_3 \in G_{v_3}$ . It takes the public parameter and one identity vector  $(ID_1, \dots, ID_j)$  as input. It sets the private key:  $K_1 = g_1^r R_3, K_2 = g_1^\alpha g_1^{-\beta t} (u_1^{ID_1 + \dots + ID_j} h_1)^r R'_3, K_3 = t, E = u_1^r R''_3$ .

**Delegate.** Given this private key  $K'_1, K'_2, E'$  for an identity vector  $(ID_1, \dots, ID_j)$  and an identity  $ID_{j+1}$ , this algorithm generates one private key based on this identity vector  $(ID_1, \dots, ID_j, ID_{j+1})$ . It randomly selects  $r', t' \in Z_N$  and  $\tilde{R}_3, \tilde{R}'_3, \tilde{R}''_3 \in G_{p_3}$  and gives the private key:

$$K_1 = K'_1 g_1^{r'} \tilde{R}_3,$$

$$K_2 = K'_2 g_1^{-\beta t'} (u_1^{ID_1 + \dots + ID_j} h_1)^{r'} (E')^{ID_{j+1}} u_1^{r' ID_{j+1}} \tilde{R}'_3,$$

$$K_3 = t', E = E' u_1^{r'} \tilde{R}''_3.$$

The new private key is completely randomized.

**Encrypt.** Given one message  $M$  and an identity vector  $(ID_1, \dots, ID_j)$ , this algorithm randomly selects  $s, d \in Z_N$ . It computes the ciphertext:

$$C_0 = M \cdot Ext(e(g_1, g_1)^{\alpha s}, d), C_1 = (u_1^{ID_1 + \dots + ID_j} h_1)^s,$$

$$C_2 = g_1^s, C_3 = e(g_1, g_1)^{\beta s}, C_4 = d$$

**Decrypt.** If one identity vector corresponding to a private key is just a prefix of  $(ID_1, \dots, ID_j)$ , this algorithm runs the delegation algorithm to generate an identity vector corresponding to the ciphertext. Otherwise, when the private key and ciphertext for the identity vector  $(ID_1, \dots, ID_j)$ , this algorithm gets the message as follows.

$$\begin{aligned} \frac{e(K_2, C_2)}{e(K_1, C_1)} C_3^{K_3} &= \frac{e(g_1^\alpha g_1^{-\beta t} (u_1^{ID_1+\dots+ID_j} h_1)^r R_3', g_1^s)}{e(g_1^r R_3, (u_1^{ID_1+\dots+ID_j} h_1)^s)} e(g_1, g_1)^{\beta s t} \\ &= \frac{e(g_1, g_1)^{\alpha s} e(u_1^{ID_1+\dots+ID_j} h_1, g_1)^{rs}}{e(g_1, u_1^{ID_1+\dots+ID_j} h_1)^{rs}} \\ &= e(g_1, g_1)^{\alpha s} \end{aligned}$$

$$\begin{aligned} C_0 \oplus Ext(e(g_1, g_1)^{\alpha s}, C_4) \\ = M \oplus Ext(e(g_1, g_1)^{\alpha s}, d) \oplus Ext(e(g_1, g_1)^{\alpha s}, d) = M \end{aligned}$$

The security of our scheme can be obtained through the next game  $\text{Game}_{Real}$  which is played by the attacker and the challenger.

$\text{Game}_{Real}$ .

**Initialize.** The challenger  $C$  runs the algorithm **Setup** to generate the public parameter  $PK$  for the attacker  $A$ . Let  $S$  denote the private key created by the challenger but not given to the attacker. The  $S$  is null at the beginning, i.e.,  $S = \phi$ .

**Phase 1.**  $A$  can ask these oracles  $\square - Create$ ,  $\square - Delegate$ ,  $\square - SK$ , and leakage query ( $\square - LK$ ).

$\square - Create$ .  $A$  gives one identity vector  $\vec{I}$ .  $C$  calls the **KeyG** algorithm to obtain a private key and adds it in  $S$ .  $C$  only sends  $A$  a reference about the private key, not this private key itself.

$\square - Delegate$ .  $A$  gives a private key  $SK_{\vec{I}}$  in  $S$  and an identity  $ID$ .  $C$  connects  $ID$  and  $\vec{I}$  to obtain  $\vec{I} : ID$ . Then,  $C$  generates a corresponding private key by calling the private key delegation algorithm.  $C$  only sends  $A$  a reference about the private key, not this private key itself.

$\square - SK$ .  $A$  selects a specific element in  $S$ .  $C$  sends the private key to  $A$ . Then,  $C$  deletes it out of  $S$ . As for the private,  $A$  will no longer do the query  $\square - Delegate$ .

$\square - LK$ . Given a private key  $SK_{\vec{I}}$  for one identity vector  $\vec{I}$ ,  $A$  can adaptively select the leakage function  $f(\cdot)$ .  $C$  returns  $f(SK_{\vec{I}})$  to  $A$ . This output length for  $f(SK_{\vec{I}})$  is recorded as  $\xi$ .

**Challenge.** The adversary gives  $C$  two challenge messages  $M_0$  and  $M_1$ , and one identity vector  $\vec{I}^*$ . This identity vector must meet the condition that none of its prefix

vectors is queried at phase 1.  $C$  randomly selects  $\nu \in \{0, 1\}$ , calculates the ciphertext  $M_\nu$  and sends it to  $A$ .

**Phase 2.** It is similar to phase 1. The extra constraint is that any inquired identity vector cannot be a prefix about  $\vec{I}^*$ .

**Guess.**  $A$  outputs a guess  $\nu'$  about  $\nu$ . If  $\nu = \nu'$ ,  $A$  wins.

If any probability polynomial time adversary can only achieve negligible advantages in the game  $\text{Game}_{Real}$ , the given **LR-HIBE** is secure.

This proposed scheme is divided into two aspects. The first aspect is the proof of security. The second aspect is the analysis of leakage resilience. The details are given in the next section.

## V. SAFETY PROOF AND LEAKAGE RESILIENCE ANALYSIS

In general, the system presented in this study can be constructed through two steps. The first step is a key encapsulation algorithm (KEA), and the second step is to combine the extractor with the key encapsulation algorithm to construct our scheme. First, we prove that this KEA can constitute a hash proof system, which proves the security of our scheme. Then, by combining this obtained hash proof system with the extractor we get the proposed scheme. Thus, the leakage resilience performance can be analyzed according to the characteristics of the extractor.

### A. Safety Proof

The presented LR-HIBE includes a key encapsulation algorithm. This key encapsulation algorithm is as follows.

**Setup.** This algorithm is identical with **Setup** algorithm of LR-HIBE.

**KeyG.** This algorithm is identical with **KeyG** algorithm of LR-HIBE.

**Delegate.** It is identical with **Delegate** algorithm of LR-HIBE.

**Encap.**  $Encap(PK, \vec{I}) \rightarrow (C, k)$ . This algorithm inputs this public parameter  $PK$  and one identity vector  $\vec{I} = (ID_1, \dots, ID_j)$ , and randomly selects  $s \in Z_N$ . It outputs an invalid ciphertext  $C = (C_1, C_2, C_3) = ((u_1^{ID_1+\dots+ID_j} h_1)^s, g_1^s, e(g_1, g_1)^{\beta s})$ .

The encapsulated key is  $k = e(g_1, g_1)^{\alpha s}$ .

**Encap\*.**  $Encap^*(PK, \vec{I}) \rightarrow C$ . It inputs  $PK$  and one identity vector  $\vec{I}$  and randomly selects  $s, s' \in Z_N$ . It outputs an invalid ciphertext.

$$C = (C_1, C_2, C_3) = ((u_1^{ID_1+\dots+ID_j} h_1)^s, g_1^s, e(g_1, g_1)^{\beta s'})$$

This algorithm is only used for the security proof.

**Decap.**  $Decap(PK, SK_{\bar{T}}, C) \rightarrow k$ . The algorithm inputs the ciphertext  $C$  and one private key  $SK_{\bar{T}}$ . It generates the encapsulated key  $k = \frac{e(K_2, C_2)}{e(K_1, C_1)} C_3^{K_3}$ .

We will prove that the key encapsulation algorithm is an HIB-HPS.

Proof.

1) *Correctness*: The decapsulation of a valid ciphertext is as follows.

$$\begin{aligned} \frac{e(K_2, C_2)}{e(K_1, C_1)} C_3^{K_3} &= \frac{e(g_1^\alpha g_1^{-\beta t} (u_1^{ID_1+\dots+ID_j} h_1)^r R_3^s, g_1^s)}{e(g_1^r R_3, (u_1^{ID_1+\dots+ID_j} h_1)^s)} e(g_1, g_1)^{\beta s t} \\ &= \frac{e(g_1, g_1)^{\alpha s} e(u_1^{ID_1+\dots+ID_j} h_1, g_1)^{rs}}{e(g_1, u_1^{ID_1+\dots+ID_j} h_1)^{rs}} \\ &= e(g_1, g_1)^{\alpha s} \end{aligned}$$

So the correctness is established.

2) *Smoothness*: The decapsulation of an invalid ciphertext is as follows.

$$\begin{aligned} \frac{e(K_2, C_2)}{e(K_1, C_1)} C_3^{K_3} &= \frac{e(g_1^\alpha g_1^{-\beta t} (u_1^{ID_1+\dots+ID_j} h_1)^r R_3^s, g_1^s)}{e(g_1^r R_3, (u_1^{ID_1+\dots+ID_j} h_1)^s)} e(g_1, g_1)^{\beta s' t} \\ &= \frac{e(g_1, g_1)^{\alpha s} e(u_1^{ID_1+\dots+ID_j} h_1, g_1)^{rs}}{e(g_1, u_1^{ID_1+\dots+ID_j} h_1)^{rs}} e(g_1, g_1)^{\beta(s'-s)t} \\ &= e(g_1, g_1)^{\alpha s} e(g_1, g_1)^{\beta(s'-s)t} \end{aligned}$$

Because  $s$  and  $s'$  are randomly selected,  $e(g, g)^{\alpha s} e(g, g)^{\beta(s'-s)t}$  is evenly distributed in  $G_T$ . Thus, the smoothness is proved.

3) *The indistinguishability between the valid and invalid ciphertext*: First, we give the semi functional (SF) ciphertext and SF private key. They only play a role in proof.

**SF ciphertext.** Suppose that  $g_2$  is a generator for  $G_{v_2}$ . Given the normal ciphertext  $C_1, C_2, C_3$ , this algorithm randomly selects  $x, z_c \in \mathbb{Z}_N$  and sets semi functional ciphertext  $C_1' = C_1 g_2^{xz_c}, C_2' = C_2 g_2^x, C_3' = C_3$ .

**SF private key.** First, this algorithm gains one normal private key  $K_1, K_2, K_3, E$ . Then, it randomly selects  $\gamma, z_k, z \in \mathbb{Z}_N$ . It computes SF private key  $K_1' = K_1 g_2^\gamma, K_2' = K_2 g_2^{\gamma z_k}, K_3' = K_3, E' = E g_2^{\gamma z}$ .

When an SF private key decrypts an SF ciphertext, we have

$$\begin{aligned} \frac{e(K_2', C_2')}{e(K_1', C_1')} C_3^{K_3'} &= \frac{e(K_2 g_2^{\gamma z_k}, C_2 g_2^x)}{e(K_1 g_2^\gamma, C_1 g_2^{xz_c})} C_3^{K_3} \\ &= \frac{e(K_2, C_2)}{e(K_1, C_1)} C_3^{K_3} \frac{e(g_2^{\gamma z_k}, g_2^x)}{e(g_2^\gamma, g_2^{xz_c})} \\ &= e(g_1, g_1)^{\alpha s} \frac{e(g_2^{\gamma z_k}, g_2^x)}{e(g_2^\gamma, g_2^{xz_c})} = e(g_1, g_1)^{\alpha s} e(g_2, g_2)^{xy(z_k - z_c)} \end{aligned}$$

It has an extra item  $e(g_2, g_2)^{xy(z_k - z_c)}$ . When  $z_c = z_k$ , the decryption is correct. We call the semi functional private key a nominal SF private key.

This indiscernibility between the valid and invalid ciphertext can be achieved by constructing these games.  $\text{Game}_{Real}$  is a real security game. The ciphertext is generated by a valid encapsulation algorithm and is normal.  $\text{Game}_{Real'}$  is similar to  $\text{Game}_{Real}$ , but for all private key queries it generates the private key by calling the **KeyG** algorithm instead of using a delegation algorithm.  $\text{Game}_{Restricted}$  is similar to  $\text{Game}_{Real'}$ , but an attacker cannot ask for such one identity that is the prefix for a challenge identity mode  $p_2$ . Similar restrictions are set forth below. Let  $q$  indicate this number about inquiries.

$\text{Game}_i (i \in [0, q])$ . It is similar to  $\text{Game}_{Restricted}$ . The difference is that this ciphertext sent to an adversary is one SF ciphertext. These forward  $i$  private keys are SF ones. These rearward private keys are normal ones. In  $\text{Game}_0$ , only this ciphertext is SF form. In  $\text{Game}_q$ , this challenge ciphertext is SF one and every private key is SF one.

$\text{Game}_{Semi}$ . It is similar to  $\text{Game}_q$ . The difference is that this challenge ciphertext is an SF invalid one which is generated by an invalid encapsulation algorithm.

$\text{Game}'_i (i \in [0, q])$ . This game and  $\text{Game}_i$  are similar. The difference is that this ciphertext is generated by **Encap\*** algorithm. For  $\text{Game}'_0$ , every private key is normal, and this ciphertext is SF and invalid. For  $\text{Game}'_q$ , all private keys except the first  $i$  queries are semi functional. This ciphertext is also SF and invalid.

$\text{Game}_{Final}$ . This game and  $\text{Game}_{Real}$  are similar. The only difference is  $C$  chooses one normal and invalid ciphertext to  $A$ , i.e. he selects  $\nu = 1$ .

The following 7 lemmas prove the indiscernibility of this series of games.

**Lemma 1.** For every  $A$ ,  $\text{Game}_{\text{Real}} \text{Adv}_A = \text{Game}_{\text{Real}} \text{Adv}_A$ .

**Proof.** No matter a private key is generated by this private key delegation algorithm or by this private key generation algorithm, their distributions are identical. In the view of the adversary, they are not fundamentally different.

**Lemma 2.** If there is an adversary  $A$  that makes  $\text{Game}_{\text{Real}} \text{Adv}_A - \text{Game}_{\text{Restricted}} \text{Adv}_A = \varepsilon$ , we may construct an algorithm  $C$  to destroy hypothesis 2 with more than  $\frac{\varepsilon}{2}$  advantages.

**Proof.** Given  $g_1, X_1, X_2, X_3, Y_2, Y_3$ ,  $C$  and  $A$  simulate  $\text{Game}_{\text{Real}}$ .  $A$  can generate identity vector  $ID$  and  $ID^*$  over  $\varepsilon$  probability under the conditions that  $ID \neq ID^* \pmod N$  and  $(ID - ID^*)$  is divided by  $v_2$ .  $C$  obtains one nontrivial factor for  $N$  by calculating  $x = \text{gcd}(ID - ID^*, N)$ . Let  $y = \frac{N}{x}$ . Because  $x$  is divided by  $v_2$  and  $N = xy = v_1 v_2 v_3$ . There are three cases.

- (1)  $x$  or  $y$  is  $v_1$ . Another one is  $v_2 v_3$ .
- (2)  $x$  or  $y$  is  $v_2$ . Another one is  $v_1 v_3$ .
- (3)  $x$  or  $y$  is  $v_3$ . Another one is  $v_1 v_2$ .

For case 1,  $C$  determines which of  $x$  and  $y$  is the identity element through judging which of  $(Y_2 Y_3)^x$  and  $(Y_2 Y_3)^y$  is the identity element. In general, it can be assumed that  $x = v_1$  and  $y = v_2 v_3$ .  $C$  determines whether  $T$  contains  $G_{v_2}$  part through testing whether  $e(T^x, X_1 X_2)$  is an identity element. If not,  $T$  has the  $G_{v_2}$  composition.

For case 2,  $C$  tests which of  $(X_1 X_2)^x$  and  $(X_1 X_2)^y$  is the identity element. If none of them is the identity element and it is not case 1, it is case 2.  $C$  determines which of  $x$  and  $y$  is  $v_1 v_3$  through testing which of  $g_1^x$  and  $g_1^y$  is an identity element. In general, it can be assumed that  $x = v_2$  and  $y = v_1 v_3$ .  $C$  determines whether  $T$  contains  $G_{v_2}$  part through testing whether  $T^y$  is an identity element. If  $T^y$  is an identity element,  $T \in G_{v_1 v_3}$ . If not,  $T$  has the  $G_{v_2}$  composition ( $T \in G_1$ ).

If case 1 and case 2 do not hold, case 3 holds. By detecting which of  $X_3^x$  and  $X_3^y$  is the identity element,  $C$  determines which of  $x$  and  $y$  is  $v_3$ . Without losing generality, it can be assumed that  $x = v_3$ .  $C$  determines whether  $T$  contains  $G_{v_2}$  part through judging whether  $e(T^x, Y_2 Y_3)$  is an identity element. If not,  $T$  contains  $G_{v_2}$  composition. Thus, the algorithm  $B$  destroys hypothesis 2 with more than  $\frac{\varepsilon}{2}$  advantages.

**Lemma 3.** If there exists an algorithm  $A$  who makes  $\text{Game}_{\text{Restricted}} \text{Adv}_A - \text{Game}_0 \text{Adv}_A = \varepsilon$ . We may construct an algorithm  $C$  to destroy hypothesis 1 with more than  $\frac{\varepsilon}{2}$  advantages.

**Proof.** Given  $g_1, X_3, T$ ,  $C$  simulates the  $\text{Game}_{\text{Restricted}}$  or  $\text{Game}_0$  with  $A$ .  $C$  randomly selects  $\alpha, a, b \in \mathbb{Z}_N$ , and sets  $u_1 = g_1^a$  and  $h_1 = g_1^b$ .  $C$  sends the public parameter  $\{N, g_1, h_1, u_1, e(g_1, g_1)^\alpha\}$  to  $A$ . When  $C$  is requested to provide a private key corresponding to the identity vector  $\vec{I}_j = (ID_1, \dots, ID_j)$ , he randomly selects  $r, t, t', w, v \in \mathbb{Z}_N$ , and calculates:  $K_1 = g_1^r X_3^t, K_2 = g_1^\alpha (u_1^{ID_1 + \dots + ID_j} h_1)^r X_3^w, K_3 = t', E = u_1^r X_3^v$ .  $C$  generates the normal ciphertext  $C = (C_1, C_2, C_3) = (T^{a(ID_1^* + \dots + ID_j^*) + b}, T, e(T, g_1)^\beta)$ .

This implies that  $g_1^s$  is a part for  $T$ . If  $T \in G_{v_1 v_2}$ , this is an SF ciphertext, where  $z_c = a(ID_1^* + \dots + ID_j^*) + b$ .  $A$  simulates  $\text{Game}_0$ . If  $T \in G_{v_1}$ , this is a normal ciphertext.  $A$  simulates  $\text{Game}_{\text{Restricted}}$ . Thus, the algorithm  $C$  destroys hypothesis 1 with more than  $\frac{\varepsilon}{2}$  advantages.

**Lemma 4.** If there exists an algorithm  $A$  who makes  $\text{Game}_{i-1} \text{Adv}_A - \text{Game}_i \text{Adv}_A = \varepsilon$ . We may construct an algorithm  $C$  to destroy hypothesis 2 with more than  $\frac{\varepsilon}{q}$  advantages.

**Proof.** The algorithm  $C$  needs to select an identity vector to create an SF private key.  $C$  does not know the challenge identity vector before the challenge phase, so  $C$  randomly

selects one as the challenge identity vector. The probability of success is  $\frac{1}{q}$ . Given  $g_1, X_1X_2, X_3, Y_2Y_3$  and  $T$ ,  $C$  randomly selects  $\alpha, a, b \in Z_N$ .  $C$  obtains the public parameters  $u_1 = g_1^a, h_1 = g_1^b, e(g_1, g_1)^\alpha$  and sends them to  $A$ . When  $A$  queries a private key of the  $p^{th}$  ( $p < i$ ) identity vector  $(ID_1, \dots, ID_j)$ ,  $C$  generates an SF private key.  $C$  randomly selects  $r, z, t, t', v \in Z_N$ .  $C$  computes  $K_1 = g_1^r (Y_2Y_3)^t, K_2 = g_1^\alpha (u_1^{ID_1+\dots+ID_j} h_1)^r (Y_2Y_3)^z, K_3 = t', E = u_1^r (Y_2Y_3)^v$ . This is an SF private key, where  $g_2^z = Y_2^t$ .

When  $p > i$ ,  $C$  calls the normal **KeyG** generation algorithm to achieve a normal private key.

In order to generate the private key of the  $p^{th}$  identity vector  $(ID_1, \dots, ID_j)$ ,  $C$  sets  $z_c = a(ID_1^* + \dots + ID_j^*) + b$ .  $C$  randomly selects  $w_k, w \in Z_N$ , and calculates  $K_1 = T, K_2 = g_1^\alpha T^{z_c} X_3^{w_k}, K_3 = t', E = T^a X_3^w$ .

Supposing that  $T \in G_{v_1v_3}$ , this private key is normal, where  $g_1^r$  is equal to this  $G_{v_1}$  part about  $T$ . If  $T \in G_1$ , this is an SF private key.

**Challenge.**  $A$  selects an identity vector  $ID^* = (ID_1^*, \dots, ID_j^*)$  and gives it to  $C$ .  $C$  terminates if  $C$  cannot guess the private key correctly. Otherwise,  $C$  calculates the ciphertext as follows:  $(C_1, C_2, C_3) = ((X_1X_2)^{a(ID_1^*+\dots+ID_j^*)+b}, X_1X_2, e(X_1X_2, g_1)^\beta)$ , where  $g_1^s = X_1$  and  $z_k = a(ID_1^* + \dots + ID_j^*) + b$ . Since the  $i^{th}$  identity is not the prefix about  $ID^*$  modulo  $v_2$ ,  $z_c$  and  $z_k$  are randomly distributed in  $A$ 's view. This relationship of  $z_c$  and  $z_k$  is crucial. When  $C$  tests whether the  $i^{th}$  private key is semi functional, he creates an SF ciphertext about  $ID^*$ , and decrypts it. Regardless of whether this  $i^{th}$  private key is semi functional, decryption can always succeed for  $z_c = z_k$ . In fact, this is equivalent to creating a nominal semi functional private key.

If  $T \in G_{v_1v_3}$ ,  $C$  simulates  $Game_{i-1}$  correctly. If  $T \in G_1$ ,  $C$  simulates  $Game_i$  correctly. Thus,  $C$  destroys hypothesis

2 with more than  $\frac{\epsilon}{q}$  advantages.

**Lemma 5.** Supposing that there exists an algorithm  $A$  that makes  $Game_q Adv_A - Game_{Semi} Adv_A = \epsilon$ . We may construct one algorithm  $C$  to destroy hypothesis 3 with more than  $\frac{\epsilon}{q}$  advantages.

**Proof.** Given  $g_1, g_1^\beta X_2, X_3, g_1^s Y_2, Z_2, T$ ,  $C$  randomly selects  $\alpha, a, b, t^*, \tilde{\alpha} \in Z_N$  such that  $\alpha = t^* \beta + \tilde{\alpha}$  and sets the public parameters

$$u_1 = g_1^a, h_1 = g_1^b, e(g_1, g_1)^\beta = e(g_1 X_2, g_1)^\beta, \\ e(g_1, g_1)^\alpha = (e(g_1, g_1)^\beta)^{t^*} e(g_1, g_1)^{\tilde{\alpha}},$$

and sends them to  $A$ .

When  $A$  queries the private key of the identity vector  $(ID_1, \dots, ID_j)$ ,  $C$  randomly selects one to generate an SF private key for  $C$  is not aware of the challenge identity vector. The probability of success is  $\frac{1}{q}$ .  $C$  selects

$c, r, t, z, z', w, w' \in Z_N$  at random and computes

$$K_1 = g_1^r Z_2^z X_3^t, K_2 = (g_1^\beta X_2)^i g_1^{\tilde{\alpha}} (u_1^{ID_1+\dots+ID_j} h_1)^r X_3^w Z_2^c, \\ K_3 = t^* - \tilde{t}, E = u_1^r Z_2^{z'} X_3^{w'}.$$

It is a properly distributed SF private key, where  $(g_1^\beta)^i g_1^{\tilde{\alpha}} = g_1^\alpha g_1^{-\beta K_3}$ .

$A$  selects the challenge identity vector  $ID^* = (ID_1^*, \dots, ID_j^*)$  and gives it to  $C$ .  $C$  selects  $r, t, w, z, w' \in Z_N$  at random and generates a properly distributed normal private key

$$K_1^* = g_1^r X_3^t, K_2^* = g_1^{\tilde{\alpha}} (u_1^{(ID_1^*+\dots+ID_j^*)} h_1)^r X_3^w, \\ K_3^* = t^*, E = u_1^r Z_2^{z'} X_3^{w'}.$$

$A$  gives  $C$   $ID^* = (ID_1^*, \dots, ID_j^*)$ .  $C$  gives the ciphertext  $(C_1, C_2, C_3) = ((g_1^s Y_2)^{a(ID_1^*+\dots+ID_j^*)+b}, g_1^s Y_2, T)$  to  $A$ , Let  $z_c = a(ID_1^* + \dots + ID_j^*) + b$ .  $z_c$  is modulo  $v_2$  and  $u_1 = g_1^a$  and  $h_1 = g_1^b$  are some elements of  $G_{v_1}$ . If  $\alpha, a, b \in Z_N$  are selected randomly,  $\alpha, a, b \in Z_N$  modulo  $N$  is not related to  $z_c = a(ID_1^* + \dots + ID_j^*) + b$  modulo  $v_2$ .

In the event that  $T = e(g_1, g_1)^{as}$ , this ciphertext is a properly distributed SF ciphertext. In the event that  $T \in G_2$ , this is an SF ciphertext about one random message. So, the algorithm C destroys hypothesis 3 with more than  $\frac{\epsilon}{q}$  advantages.

**Lemma 6.** Supposing that there exists an algorithm A that makes  $\text{Game}_i' \text{Adv}_A - \text{Game}_{i-1}' \text{Adv}_A = \epsilon$ . We may construct one algorithm C to destroy hypothesis 2 with more than  $\frac{\epsilon}{2}$  advantages.

**Proof.** This process of proof is similar to that of Lemma 4.

**Lemma 7.** Supposing that there exists an algorithm A that makes  $\text{Game}_1' \text{Adv}_A - \text{Game}_{Final} \text{Adv}_A = \epsilon$ . We may construct one algorithm C to destroy hypothesis 3 with more than  $\frac{\epsilon}{2}$  advantages.

**Proof.** This process of proof is similar to that of Lemma 5.

**Theorem 1.** If hypothesis 1, hypothesis 2 and hypothesis 3 are true, the valid ciphertext and invalid ciphertext are indistinguishable.

**Proof.** The maximum advantages obtained by the adversary in hypothesis 1, hypothesis 2 and hypothesis 3 are respectively denoted by  $\epsilon_1, \epsilon_2$  and  $\epsilon_3$ .

According to the above 7 lemmas, the difference between the advantages of adversary A in the above different games are:

$$\text{Game}_{\text{Real}} \text{Adv}_A - \text{Game}_{\text{Restricted}} \text{Adv}_A \leq \epsilon_2,$$

$$\text{Game}_{\text{Restricted}} \text{Adv}_A - \text{Game}_0 \text{Adv}_A \leq \epsilon_1,$$

$$\text{Game}_{i-1} \text{Adv}_A - \text{Game}_i \text{Adv}_A \leq q\epsilon_2,$$

$$\text{Game}_q \text{Adv}_A - \text{Game}_{\text{Semi}} \text{Adv}_A \leq q\epsilon_3,$$

$$\text{Game}_i' \text{Adv}_A - \text{Game}_{i-1}' \text{Adv}_A \leq q\epsilon_2,$$

$$\text{Game}_1' \text{Adv}_A - \text{Game}_{\text{Final}} \text{Adv}_A \leq q\epsilon_3,$$

From the above inequality, we can get.

$$\begin{aligned} & \text{Game}_{\text{Real}} \text{Adv}_A - \text{Game}_{\text{Final}} \text{Adv}_A \\ & \leq \epsilon_2 + \epsilon_1 + 2q(q-1)\epsilon_2 + 2q\epsilon_3 \end{aligned}$$

Because the above equation is a polynomial about  $q$ , any adversary's advantage can be ignored.

### B. Performance Analysis about Leakage Resilience

Based on the key encapsulation algorithms: Setup, KeyG, Delegate, Encap, Encap\*, and Decap, our LR-HIBE scheme is constructed. The encapsulated key space has  $\text{Log}(p_1)$  elements. We use a  $(\text{Log}(p_1) - \text{Leak}, \epsilon)$  strong extractor  $\text{Ext} : \{0, 1\}^{\text{Log}(p_1) - \text{Leak}} \times \{0, 1\}^r \rightarrow \{0, 1\}^{\text{Log}(p_1)}$ . The obtained LR-HIBE has the same algorithm as the key encapsulation algorithms: Setup, KeyG, Delegate. The encryption and decryption algorithms are as follows.

**Encrypt:**  $\text{Encrypt}(PK, M, \vec{I}) \rightarrow CT$ . This algorithm calls  $\text{Encap}(PK, \vec{I}) \rightarrow (C, k)$ , randomly selects a seed  $s^*$  of the extractor and sets  $C_0 = \text{Ext}(k, s^*) \oplus M$ . This algorithm generates a ciphertext  $CT = (C_0, s^*, C)$ , where  $C = (C_1, C_2, C_3)$ .

**Decrypt:**  $\text{Decrypt}(PK, CT, SK_{\vec{I}}) \rightarrow M$ . It takes  $PK$ ,  $CT$  and  $SK_{\vec{I}}$  as the input, where  $CT = (C_0, s^*, C)$  and  $k = \text{Decap}(C, SK_{\vec{I}})$ . It outputs the message  $M = \text{Ext}(k, s^*) \oplus C_0$ . The decryption can succeed as long as the identity vector used in decryption is the same as the identity vector used by this encryption.

**Theorem 2.** If there is a key encapsulation algorithm as defined in section 4.1. By the above transformation we can get LR-HIBE (that is, the scheme given in this paper). This relative leakage ratio about the encapsulated key of this given LR-HIBE is close to 1.

**Proof.** Let  $\text{View}$  represent the view (all random variables) that A sees when there is no leakage, we have  $\tilde{H}_{\infty}(A|\text{View}) = \text{Log}N$ . The encapsulated key length is  $\text{Log}N$ . When there is a leakage query, adversary A can obtain  $\xi$  bits information which is regarded as  $\text{Leak}$ , that is,  $\text{Leak}$  has  $2^{\xi}$  values. According to conclusion 1 we get  $\tilde{H}_{\infty}(A|\text{Leak}, \text{View}) \geq \tilde{H}_{\infty}(A|\text{View}) - \xi = \text{Log}N - \xi$ . Therefore, as long as the extractor is  $(\text{Log}N - \xi, \epsilon)$  strong,  $\text{SD}((\text{Ext}(k, s^*), s^*, \text{Leak}, \text{View}), (U, s^*, \text{Leak}, \text{View})) \leq \epsilon$ , where U is uniformly distributed. As long as the performance of the extractor is good enough, this leakage amount  $\xi$  for an encapsulated key is close to  $\text{Log}N$ . So the distance of  $C_0 = \text{Ext}(k, s^*) \oplus M$  and the uniform distribution is  $\epsilon$ . Thus, this statistical distance about two ciphertexts is no more than  $2\epsilon$ . Consequently, no PPT adversary may make a distinction between two challenge ciphertexts over more than  $2\epsilon$  advantage. This relative leakage ratio is  $\rho = \text{Leak} / \text{Log}N \approx \text{Log}N / \text{Log}N = 1$ .

Theorem 2 is proved.

## VI. PERFORMANCE COMPARISONS AND EXPERIMENTAL SIMULATION

Some comparisons between this study and several related researches [6, 8] are given in Table I. LR stands for leakage resilience.  $|G_{v_1}|$  and  $|G_{v_3}|$  represent the element length of the subgroup  $G_{p_1}$  and  $G_{p_3}$ , respectively. E indicates exponential operation in the group.

We make some comparisons about leakage resilience, public key length, private key generation and encryption cost. Our scheme has the same public key length, private key generation, private key delegation, and encryption costs as [8]. This public key in our scheme is much smaller than that given in [6], which greatly reduces the network communication burden. Since the number of system layers in a hierarchy can generally reach ten or more, the computation cost of our scheme for private key generation and private key delegation is much lower than that of the scheme [6]. When the number of layers is little, the encryption cost of our scheme is basically the same as theirs, but when the number of layers gradually increases, our encryption calculation operation is obviously better than that given in [6].

TABLE I. SOME COMPARISONS BETWEEN OUR SCHEME AND SEVERAL RELATED SCHEMES [6, 8]

	[8]	[6]	Ours
LR	No	No	Yes
Public Key Size	$3 G_{v_1}  +  G_{v_3} $	$(l+2) G_{v_1}  +  G_{v_3} $	$3 G_{v_1}  +  G_{v_3} $
Private Key Generation	$5E$	$(l+3)E$	$5E$
Private Key Delegation	$6E$	$(l+3)E$	$6E$
Encryption	$4E$	$(j+3)E$	$4E$

In addition to the performance comparisons, we also give the experimental simulation.

The experimental platform is a PC with 64 bit operating system Windows 10, 3.40 GHz main frequency, 8.00G RAM and Intel (R) Core (TM) i7-6700 CPU. Based on Java Pairing Based Cryptography Library 2.0.0 [43], we use Eclipse 4.4.1 for simulation software. A 160 bit composite order elliptic curve  $y^2 = x^3 + x$  is selected for our experiment. The private key generation time is 0.125 seconds, the private key delegation time is 0.150 seconds, and the encryption time is 0.100 seconds.

## VII. CONCLUSIONS

We propose a hierarchal and efficient identity-based encryption scheme. This given scheme may resist the bounded leakage for this encapsulated key. By using dual system encryption combined with hash proof system, the security proof can be achieved. The leakage resilient function is realized by using extractor technology. The relative leakage ratio of the encapsulated key is close to 1.

The features of this scheme are as follows.

- 1) There is no limit to the hierarchy depth of the system, and only the maximum hierarchy length is required to be given when the system is initialized.
- 2) The system has the performance of resisting the leakage of encapsulated symmetric keys, and the relative leakage rate of encapsulated symmetric keys can almost reach 1.
- 3) The system is efficient, because unnecessary parameters are appropriately reduced.

The scheme in this study is constructed in composite order groups, and the computational cost may be slightly higher than that is constructed in prime order groups. In the future, we will start to consider how to construct an LR encryption scheme in prime order groups.

Attribute based encryption is a generalization of identity based encryption and has good applications. How to construct efficient and leakage resilient attribute based encryption is worth further study.

**Abstract**—Image highlight plays a major role in different interactive media and computer vision technology such as image fragmentation, recognition and matching. The original data will be unclear if the image contains highlights. Moreover, it may reduce the robustness in non-transparent as well as glassy objects and also it reduces accuracy. Hence, the removal of highlights is an extremely crucial thing in the dome of digital image enhancement. This is to develop the enhancement of the texture in imageries, and video analytics. Several state-of-art methods are used for removing highlights; but they face some difficulties like insufficient efficacy, accuracy and producing less datasets. To overcome this issue, this paper proposes an optimized GAN technology. The Enhanced Grey Wolf Optimization (EGWO) technique is employed for feature selection process. Generative Adversarial Network is a machine learning (ML) algorithm. Here, two neural networks that will compete among themselves to produce better calculations. The algorithm generates realistic data, especially images, with great practical results. The investigational outcome reveals that the future algorithm has the ability to verify and eliminate the illumination spotlight in the image so that real details can be obtained from the image. The effectiveness of the proposed work can be proved by comparing the proposed optimized GAN with other existing models in highlight removal task. The comparison outcome gives better accuracy with 99.91% compared to previous existing methods.

**Keywords**—*Highlight detection; optimization; specular highlight detection; GAN*

## I. INTRODUCTION

Image spotlight is a mutual factor in this physical biosphere, frequently an illumination is produced when the light contacts the material surface [1]. The highlights can easily damage the quality of the target image owing to the combined effect of the sunlight and the target's surface's physical characteristics. The flow and strength of the illumination will be determined by objective's category and

dye, and also the reservation among the external area and the source of light [2]. Due to these highlights, the brightness of the image will be reduced in a sliding window and it frequently causes some unwanted discontinuities in the diffused part of the object [3]. Moreover, it will not provide true details of the image. To overcome this difficulty, a highlight removal method is introduced. The elimination of image spotlight is a major difficulty in supercomputer illustrations, computer visualization, and so on. Meanwhile, it delivers valuable info for some solicitations [4]. Because of two motivations. Firstly, it is necessary to find out the direction from where the light will be reflected. Secondly, eliminating the consequence from high spot will have the ability to improve the execution of various visualization tasks, like object recognition, essential image disintegration, and tracing.

Nevertheless, various methods have been recommended to find and repair specular reflection affected areas that rely on the evaluation of fixed images [5]. Due to this, the specular highlight may use high-level contextual cues to reduce uncertainty in areas with transformer module, thereafter the detection and correction of specular highlights from transmissive materials are more challenging and not forthright, especially when the geometry of the object is unknown. Therefore, the highlighted extracted method includes multi-scale data to identify regions with various level of highlight intensity. The estimated intensity ratio of the previous highlight removal method is used to relate the modifications among the diffused and specular replication modules then it enables the elimination of spotlights from a sole image. Hence, the standardized weighting mechanism is used to reinstate the fringe pattern in the illuminated zone whereas the highlight removal cannot be consistent between images from different viewpoints [6].

The occurrence of high spot drives a thoughtful influence on numerous features of invention. The furthestmost mutual influence is that the spotlight will convey sound and intrusion to the new image, thus the specularly on all images will be reduced, and it creates a new region with an aware of highlight image creation model [7]. Once associated with the translation tasks of additional image, the image that containing the spotlight and the dispersed image will display a heavy amount of resemblance. These resemblances in them are equal, and are different only in rare emphasized zones and gives unfortunate outcomes in argumentative workout. Hence, to carry out the issue occurred by the resemblance, an autoencoder is placed in front of the attention component, where the replication intensity of each pixel in the highlighted images is predicted by highlighted concentration cover [8].

The active rank of an image can be obtained from various ideas of image detector and the active rank is defined as the proportion among the minimum and major value that are recorded or depicted on the display [9]. Capturing image sequences with different exposure periods, provides a well-exposure all through the object surface to deal with the issue of consequent saturation. Thus, certain circumstances or expectations have the capability of enabling content analysis-based solutions. The picture element analysis based on later methods can be considered as the shiniest pixels as the high spot, that disposed to untrue recognition of spotlight and the regions with unclear white regions are developed under chromaticity analysis. Hence, the solicitation of vigorous detecting approaches cannot safe the renovated info in the current highlighted regions as the bright illumination is returned in the reflective path instead of sprinkling towards the instrument.

Projecting uniformity image patterns onto the surface underlying featureless objects has traditionally been used as a reconstruction technique to get remote sensing data. But specular reflection creates highlights, projection over these areas could result in saturation of the image through overuse [10]. The features of the estimated design continue to pose multiple problems, which have been discovered to influence the outcomes of the reconstruction. Under photometric calculations, the connection amongst the image illumination and exterior depth are used to enable this renovation. Even so, it is an under-confined difficulty; expectations are computed stronger for the features of the dispersed replications. To handle specular surfaces, a reflectance model is introduced. It describes the bond among the replicated brightness and exterior depth under an orthographic camera estimation hypothesis.

In the field of image synthesis, the Generative Adversarial Network(GAN) already has tremendous success [11]. The GAN's aim is to evaluate a set of training examples to discover the probability distribution. Generative Adversarial Network has the capability to create new examples from the estimated probability distribution. To eliminate the highlights, this paper offers a novel based GAN method for dealing with problems. In other words, the removal of specular highlights is an image-to-image transformation among the diffuse area and the highlighted area.

The key contribution of the paper is briefed as follows:

- At first, images with heavy quantity of highlights are collected and handled in this process.
- Moreover, the impulsive noise that exists in the grey scale image can be filtered by the Wavelet Decomposition Anisotropic Filter (WDAF).
- The segmentation process employed in this paper is K-means clustering and is utilized to find the groups in the unlabelled data.
- The feature selection process is carried out by the Enhanced Grey Wolf Optimization (EGWO) process to improve the hunting strategy of the wolves.
- Feature extraction process is done by Gray-Level Co-Occurrence Matrix (GLCM) algorithm; this will reduce the unwanted data from the dataset.
- The Generative Adversarial Networks (GAN) is used to notice the emphasized area from the image.
- Finally, the highlights in the image can be eliminated by Structure texture layering Algorithm
- The concluded method's success has been recognized and contrasted to other approaches to prove its better in accuracy and efficacy.

The remaining of this study is divided into the resulting sections as follows: Section II exposes the relevant works are done from a thorough analysis. Problem statement is discussed in Section III. The particulars of EGWO-GAN explored in Section IV. Under Section V, the outcomes of the experiment are reviewed and provided exactly. Section VI is the conclusion of the paper.

## II. RELATED WORKS

Su et al. [6] discussed that the Lightweight optimization technique is employed for eliminating the issues in multi-view digital image. The highlights can be removed by assumptioning the estimation of illumination chromaticity, and it carries out the orthogonal subspace projection. The method provides a practical feature which doesn't requires image reflectance priors. A Ground truth dataset is employed to establish the demonstration of the process. The paper reveals that the accuracy and robustness is more effective when compared to the existing method. The paper doesn't explain that how a single phased image could be taken from multi view facial images.

The removal of specular spotlight in colour images play a title role to enable numerous hypermedia and supercomputer visualization tasks revealed by Wu et al. (2022). Here the details of the Ground truth illuminated images are furnished and the images that photographed are real world objects. The dataset used here is Paired Specular Diffuse (PSD) dataset. Here an organic lattice is used to deteriorate the illumination in the assumed sole image and it uses GAN network Without requiring an explicit assessment the network functions the consideration mechanism to represent the mapping relationship among the diffused area and the illuminated area.

The detection result of the specular highlight will be lesser. High specular and specular on metal materials are not explained in this paper.

Under computer vision technology the Non-destructive surveying mechanism strictly improved the investigation of fresh fruit quality revealed by Hao, Zhao, and Peng [12]. During image acquisition specular highlight easily affects the fruit that has soft surface and small texture. The illuminated highlight that appears on the body of fruit will strongly affect the standard inspection. To solve this issue, a specular spotlight removing mechanism is used and it's founded on the basis of multi-band polarization imaging technique. The image at real time is realized first by developing a new multiband polarization imager. Secondly, a combined multi-band-polarization habitual vector is utilized to check whether the illuminated highlight was removed. Then the illuminated highlight was removed by separating ergodic least-squares combined with a Max-Min multi-band-polarization strategy. At last, the missed particulars are retrieved by chromaticity consistency. The suggested method will eliminate the spotlight strongly and gives an improved exchange among precision and complexity when compared to the existing method. The paper doesn't give a brief explanation about strong picture quality and unbiased estimation indexes.

Fu et al. [1] states that the highlight detection is the basic and difficult task in today's image processing field. Recent method provides a clear result by practicing two processes on artificial training facts in a controlled mode for detecting and removing highlights. A novel network is used to remove the illumination spotlight. Then a dataset with 16K real image is introduced first to reject the domain area among artificial preparation prototypes and actual investigation images and also for helping the learning-based methods. Investigation result declares that the future work is faraway enhanced than the previous technique. The study does not explain about the highlight colour evaluation model. ElMasry, Gou, and Al-Rejaie [13] disclosed that the illumination or highlight trouble arose in radiometric images, the reflecting variation will be obtained from its real value, and it hides severe problems in food products or detect heavy negative issues may cause breakdown in the investigation and verification processed. According to a non-repetitive model, the multicolour dispersion type and Principal Component Analysis (PCA) were identified and removed by specular highlight objects. The method gives effective results on hyperspectral and multispectral images; it strongly reduces the oddity and effectively increases the excellency in the illuminated data. The investigational outcomes give that the suggested technique along with PSNR will give better results. The robustness is not explained briefly here.

The specular highlight spotting and elimination are the main difficulties in computer vision technology and image visualization said by Wu et al. [14]. Deep learning model is used as the proposed method here to find and deteriorate the specular spotlight in a sole image. The specular highlight is verified using encoder and decoder web. Unet-Transformer network is used to remove highlights. Spotlight investigation pattern is used as a cloak to train the rejected work. Both the networks can be guided in a powerful mode. The feature

texture is poor here. The result should become more effective in public benchmark and real-world images when compared with previous method. The study about dataset is not discussed here. Huang, Hu, and Wang [15] disclosed that a novel uniformity framework method is introduced here to detect and remove highlights in pretended images, facial images, verbal images and organic images. Three main components are used. They are spotlighting characteristic ejected component, spotlight coarse rejected component, and spotlight filter rejection component. The spotlighting characteristic ejected component will divide the highlighted and non-highlighted image from the real image. Then the removed spotlighted image is re-obtained from spotlight coarse rejected component and the spotlight filter rejection component is gained by contextual spotlight attention mechanisms. The proposed work will gain better visual effects. The facts about real textures are not explained clearly here.

The organized bright prediction is broadly employed in 3D outline dimension revealed by [16]. Here the fringe surface is covered completely and huge reflective surfaces are affected by uneven spotlights. A polarization-based algorithm, is introduced to solve uneven illumination. By using this algorithm, the SNR of the polarized image is developed and the spotlights are removed. The centralized weighting algorithm is used to resave the surface knowledge in highlighted domain. The project result proves that the SNR of polarization figure is developed with the help of the proposed algorithm. The result proves that the fringe module is restored. The study does not explain about the saturated components. Modern high spot elimination procedures couldn't semantically distinguish among all-white or near-white resources on the external face of smooth liquor bottles discussed by Guo et al. [17]. The latest spotlight elimination processes grounded under deep learning process and it will deficit resistance in system design, ensure issues with complex training, and have inadequate objective relevance. They consequently do some jobs with less efficiency because they are unable to find and delete highlights in some tiny sample highlighted datasets. Hence, this study suggests a quick highlight removal technique that combines U2-Net and LaMa. The U2-Net is applied in the beginning of the process to detect problems. Lama is used as the core. The model is easy, efficient and simple to carry out. This proposed work provides good results than the previous method. The study about flexibility is not explained here.

Xia et al.[18] state that the specular highlights caused by laparoscopes may produces wrong visual observations, audio restoration and image fragmentation in medical and normal images. The removal of illumination from a sole image is more essential because both the normal and medical images are located in amorphous regions. Therefore, a global optimization technique grounded on a dichromatic reflection model is suggested towards controlling these issues from a sole image. The future work comprises two methods for the removal of spotlights from the image. One is for calculating the spreading of pigmentation to precise the shade and congestion in the illuminated areas and the other one uses complex optimization with double generalisation to compute

diffused and specular replication coefficients. According to the experimental findings the suggested method eliminates the illuminations from the natural and endoscopic images. A stereo reconstruction application that uses a dataset presents that the highlight reduction method may removes the RMSD of the exterior renovation truthfulness from 1.10mm to 0.69mm.

The highlight removal methods calculate and group the illuminated chromaticity value to extract diffused and specular replication constituents on or after a solitary image established under the dichromatic reproduction model said by Souza et al. in [19]. Whereas these methods can produce results that are visually appealing, their clustering algorithms either have poor setup and are too costly to perform in actual time. In this study, a high-grade of pixel grouping algorithm is proposed to eradicate the high spot from the sole image. In existing methodology, the max and min values of all the pixels are calculated. In order to suggest a successful pixel clustering method, the dissemination arrangement of those standards in a max-min chromaticity universe is examined by pseudo specular free image. In order to differentiate among diffuse and specular components, the intensity ratio is estimated for each cluster. To apply the method on CPU and GPU frameworks an optimization technique is suggested. When using only the CPU, the investigational outcomes shows that the proposed method is not only faster than the state-of-the-art method but also more accurate. Therefore, the existing previous technique can eliminate specular highpoints from a 4K image with a resolution of 3840 by 2160 in just 24 milliseconds when using the GPU.

One of the supreme essential study questions in supercomputer visualization and computer graphics is how to eliminate specular highlights from an image discussed by Fu et al. in [20]. Several techniques have been established but they generally won't operate fit for actual images because of the attendance of composite resources, solid shades, rich textures, constrictions, and hue enlightenment, among other factors. This paper introduces an original spotlight reduction mechanism to eliminate the highlights. The technique is constructed on two findings: (i) the specular highlights are frequently small and thin in dissemination; and (ii) the enduring turgid images can be characterized by an undeviating amalgamation. An optimization framework is created for the observation of the turgid and illuminated images from a sole image. The diffusion mechanisms are restored by boosting the sparseness of the encrypting factors via the L0 norm. According to the illumination definition, the additive colour mixing theory, the encrypting factors and the illumination that focuses to non-negativity. Extensive researches on a variety of images have proven the efficacy of the future work and its advantage above the earlier approaches.

Facemask spotlight elimination methods object to increase image eminence and simplify responsibilities like surface reconstruction and verification by removing the specular highlight from facial images said by Z. Wang et al [21]. However, earlier learning-based methods frequently fails when applied to images from the real world because their simulations are frequently qualified on combined artificial or test site images owing to the necessity of combined

preparation information. As an alternative to these techniques, the spotlight elimination system is suggested, which is performed on an artificial dataset then finetuned on the unpaired rough imageries. To accomplish this, a spotlight cover supervision training method is proposed that allows Generative Adversarial Networks (GANs) to train a highlight removal network utilising real-world image. In spite of the fact, nearly every image is taken in the rough embrace under certain areas, have found that even small areas without highlights can deliver valuable info for the process of removing illumination. This stimulates to create a region-based discriminator that can differentiate between the highs and lows in a facemask image and habit it to improve the originator. According to the experimentations, the approach yields result that are of a higher calibre than those produced by contemporary highlight removal methods.

### III. PROBLEM STATEMENT

Lightweight Optimization (LWO) based on machine learning technique that clears the problems in the earlier studies and it is used for identifying and graphing the highlights in the image [6]. It will not provide correct data because the computational complexity is poor here and this will affect the image quality. It will reduce the network parameters and computational complexity. Therefore, for achieving clear and good results machine learning (ML) based Generative Adversarial Network (GAN) is used. For removing the highlights from the image and to provide higher accuracy and better complexity, an Enhanced Grey Wolf Optimization (EGWO) method is utilized here and it will also reproduce the behaviour of grey wolves in a helpful way.

### IV. METHODOLOGY

The planned technique is charted in Fig. 1. Enhanced Grey Wolf Optimization based Generative Adversarial Networks is utilized for this process. There are many datasets presented and they are used for training and testing purpose and this process uses Kaggle dataset to discuss about the data and to find the accurate coding for the data etc., The images that contain highlights are exposed to pre-processing technique to reduce the noise in the image. Similarly, the recognized EGWO-GAN method is utilized to label the image high spot and its classifications. Moreover, it is utilized to achieve a greater accuracy worth. Henceforth the accepted method considers and then it labels the highlights in the image.

#### A. Data Collection

The dataset used for the testing and training process is Kaggle dataset. Approximately 10,000 dataset imageries with high spots have remained together and castoff in this research. From that image 50% (5000) of imageries were selected for training data and 50% (5000) of imageries were selected for testing data [22]. It holds 48-by-48-pixel grayscale images. The pixel section comprises a string in each picture. The training group covers 28,709 representations. The test group covers 3,589 representations.

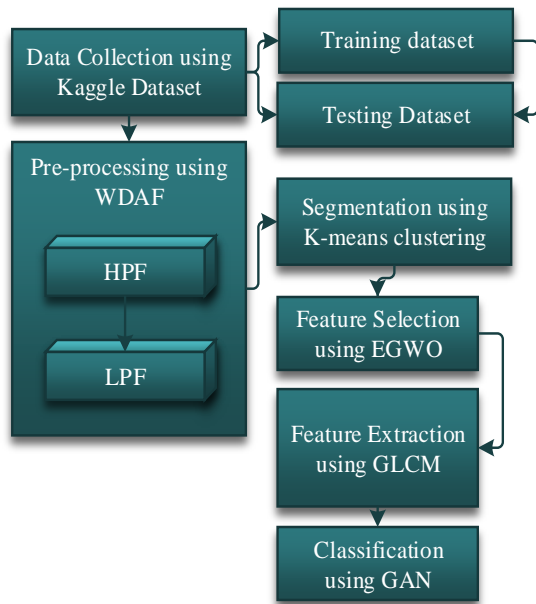

Fig. 1. Proposed EGWO-GAN technique

### B. Pre-processing

Lately, filtering by image reinforcements has increased the importance for noise elimination [23]. Though, to verify the reflected region in the image, a pre-processing technique has been introduced. Pre-processing will reduce the noise in the image. Some appearance of accidental symbols and unevenness in radiance and hue of the appearance is titled as noise. It is very important to remove the noise because the noise in the image will affect the quality of the image. So many filters are used to remove noise. Under this study, Wavelet Decomposition Anisotropic Filter (WDAF) is used for decreasing or eliminating the impulsive noise from the grey scale images. The filter is very effective in identifying peak noises from the image. The functionality, time complexity, and relative performance of these filters are compared for better performance. Henceforth, the attained noiseless images are applied in the EGWO-GAN model to eliminate the high spot from the image.

The difficulty in discrete time is given in Eqn. (1),

$$m[k] \times n[k] = \sum_{y=-\infty}^{\infty} m[y]n[k - y] \quad (1)$$

where,  $m[k]$  and  $n[y]$  are denoted as the illustrations of the intake image, while  $n[k]$  and  $n[k - y]$  is denoted as the illustrations of compulsion reaction.

Alteration of wavelet breakdown to high and low pass indications is assumed in Eqn. (2) and Eqn. (3),

$$jhigh[y] = \sum_k m[k] h[2y - k] \quad (2)$$

$$jlow[y] = \sum_k m[k] n[2y - k] \quad (3)$$

where,  $jhigh[y]$  and  $jlow[y]$  are the illustrations of the outlet gestures,  $h$  is represented as the half band high pass filter and  $n$  is represented as the half band low pass filter.

The divergence function is given in Eqn. (4) and the anisotropic function is given in Eqn. (5),

$$\partial gi(x, y; k) \partial h = div[f(x, y; k) \nabla gi(x, y; k), \quad (4)$$

$$n(k) = \frac{1}{1+(f/\lambda)^2}, \quad (5)$$

$div$  is denoted as the divergence operator,  $gi$  is represented as the diffusion coefficient,  $g(x, y)$  is noted as the image with coordinates  $(x, y)$  at period  $k$ ,  $\nabla$  is a inclined operator,  $k = |\nabla g|$  and  $\lambda$  is the inception of inclination magnitude.

The conservative anisotropic filter presents a stairway result to strained images, so, the dispersion constant to the conservative anisotropic dissemination filter has been introduced in Eqn. (6),

$$EAD = div[f(x, y; k) \nabla gi(x, y; k) \times \left[ 1 - \frac{1}{1+exp(-g(p^2 * p_0^2) - \alpha(\frac{p_0^2}{p^2}))} \right] \quad (6)$$

Finally, WDAF is given in Eqn. (7),

$$W_{WDAF} = jhigh[y] + jlow[y] + EAD \quad (7)$$

### C. Segmentation using K-means Clustering

A segmentation mask is formed for all samples, it structures the similar ellipse with white colour on a black background [24]. Numerous investigation instructions consume advanced segmentation methods under the basis of grey scale image. The present work will utilize the potential of colour image segmentation approach using K-means (KMC) clustering algorithm. This procedure is used for removing the entirely highlight affected areas.

The process of converting unidentified dataset information into various cluster particles is the main aim of the K-means clustering procedure [25]. This will solve the problems that coming under clustering or data science. The main importance of this clustering is that it will give a guarantee to convergence. It will give a smooth starting to the directions of the centroids. This algorithm figures the centroids and repeats till finding the correct centroid. It will simplify the clusters with different shapes and sizes.

The highlighted image that contains the spatial coordinates to resolve  $i*j$ , then the images should be assembled to form the  $k$ -clusters. Consider  $h(i, j)$  as the information pixel and  $P_k$  is specified as the function that focuses the group of the  $k$ -cluster. The K-means clustering algorithm has some of the following procedures and are given step by step [26],

Step 1: The centre and the cluster  $K$  must be determined.

Step 2: The Euclidean distance  $E_d$  is specified for every pixel and is expressed in the Eqn. (8).

$$E_d = ||h(i, j) - P_k|| \quad (8)$$

Step 3: All the pixels are allocated to the centre point under the basis of  $E_d$ .

Step 4: By ensuing the task assigned to all the pixels, the new centre positions are re-computed by Eqn. (9)

$$Pk = \frac{1}{k} \sum_{j \in Pk} \sum_{i \in Pk} h(i, j) \quad (9)$$

Step 5: Repeat the procedure till the condition met.

This algorithm possesses some difficulties because it has several more characteristic processes. The voluntary option for the initial centroid is more important for the clustering process. When the necessary centroid is psyche-assuredly selected, some different outcomes are produced for the centres that are necessary for the clustering. To achieve the wanted separation, important centres should be chosen exactly. When using K-means clustering, the computational complex eminence must be taken into attention whether it has infinite quantity of data parts, numerous groups and quantity of sequences. The usage of K-means clustering algorithm for the separation of image frequently comes under the basis of topographies. The outcome of the process of removing highlight is secluded into K-numbers that is used by the soul. The major difficulty of this method is if the dimension of K grows, the method will slog against us. As a consequence, if the sections grow bigger, it is more difficult to discover the affected parts. If the valuation of K reduces, it will speed the mixture of some regions that have undesirable influence on the exactness of image parting.

#### D. Feature Extraction using GLCM

The procedure of converting initial facts obsessed by arithmetical characteristics may be treated although maintaining the evidence in the unique form is recognized as feature extraction. Features are elements of information that are pertinent for dealing with particular applications and for illustrating important aspects of pictures [27]. When compared to machine learning, it produces superior results. Feature extraction helps in reducing the redundant data from the dataset. This paper uses a Gray-Level Co-Occurrence Matrix (GLCM) for the feature extraction process.

Under feature extraction, the foundation data is transformed into arithmetical topographies deprived of constructing any changes in the odd datasets and its characteristics is based on its pixel. For eliminating the statistical texture feature from the image, it uses some functions like correlation, energy, homogeneity, contrast, entropy, etc. are estimated as second-order image individualities.

1) *Correlation*: Correlation value designates the resemblance of texture of the image in two orthogonal directions specifically the horizontal and vertical directions. It is given in Eqn. (10),

$$C_{\text{correlation}} = \sum_{x,y=0}^{K-1} M_{xy} \frac{(x-\mu)(y-\mu)}{\sigma^2} \quad (10)$$

2) *Energy*: Energy is well-defined as the summation of squares with grayscale standards that are frequently higher and require unreliable concentrated values in images. It is given in Eqn. (11),

$$\text{Energy} = \sum_{x,y=0}^{K-1} (M_{xy})^2 \quad (11)$$

3) *Homogeneity*: It defines the likeness of pixels. The value of GLCM medium of consistent copy is given as 1. The

GLCM medium should be very stumpy to get least altered image texture. The homogeneity is given in Eqn. (12),

$$\text{Homogeneity} = \sum_{x,y=0}^{K-1} \frac{M_{xy}}{1+(x-y)^2} \quad (12)$$

4) *Contrast*: Features are hand-me-down to extent the resident dissimilarity of an image, and it is forecasted to be small in the even concentrated values. The creative image's entire grayscale content is then estimated in Eqn. (13),

$$\text{Contrast} = \sum_{x,y=0}^{K-1} M_{xy} (x-y)^2 \quad (13)$$

5) *Entropy*: The randomness of the image will be calculated by entropy and it will produce lower entropy values. It is given in Eqn. (14)

$$\text{Entropy} = \sum_{x,y=0}^{K-1} -\ln(M_{xy}) M_{xy} \quad (14)$$

#### E. Feature Selection using Grey Wolf Optimization

While emerging an analytical model the input variables are reduced by feature selection process. The number of input variables is lowered by this process while creating an analytical model. In certain cases, while dropping the computational cost and contribution variable of the model, the execution process will be improved. The recognition of highlights in the image has been executed by a method known as Enhanced Grey Wolf Optimization (EGWO). Its standard is to make a replica of the behaviour of grey wolves to quest in a supportive method. The EGWO will improve efficiency and accuracy. EGWO is dissimilar as of others in conditions of traditional arrangement [28]. The most informative features are chosen using the EGWO. The EGWO is meant for resolving universal enhancement and engineering design complications. Thus, the method undergoes two major changes to the EGWO. Firstly, the intelligent initialization phase, which creates the population by using the data since the filter-based method. Secondly, the implementation of the Extreme Learning Machine is used as the vile sorter to deal with the greater difficulty [29].

GWO is scalable, adaptable and simple to use. In the framework of search process, the algorithm gains a balance between utilization and investigation that generates an outstanding resolution [30]. Engineers and scientists who work in a variety of disciplines have consequently grown fascinated towards the GWO. When compared to other optimization techniques GWO is the strongest and fastest algorithm.

The GWO algorithm follows the grey wolf's group dynamics and hunting tactics. The four wolf varieties that make up the leadership sequence are  $\alpha$  (the acceptable),  $\beta$  (the second-fittest),  $\delta$  (the third-fittest), and  $\Omega$  (the left particulars of the aspirant resolutions). The procedure additionally includes three primary killing techniques of pursuing, encircling, and hitting targets.

Grey wolves enclose their prey and trudge during hunting; this is identified in the following Eqn. (15),

$$\vec{A} = |\vec{F} \cdot \vec{Y}_k(u) - Y(u)|$$

$$Y^{\rightarrow}(u + 1) = (Y_k)^{\rightarrow}(u) - C^{\rightarrow} \cdot A^{\rightarrow} \quad (15)$$

The subsequent connections are used to alter the geographical positions of different wolves that search using data from alpha, beta, and delta under Eqns. (16), (17) and (18),

$$\left. \begin{aligned} \vec{A}_\alpha &= |\vec{F}1 \cdot \vec{Y}_\alpha - \vec{Y}| \\ \vec{A}_\beta &= |\vec{F}2 \cdot \vec{Y}_\beta - \vec{Y}| \\ \vec{A}_\delta &= |\vec{F}3 \cdot \vec{Y}_\delta - \vec{Y}| \end{aligned} \right\} \quad (16)$$

$$\left. \begin{aligned} \vec{Y}_1 &= \vec{Y}_\alpha - \vec{C}_1 \cdot \vec{A}_\alpha \\ \vec{Y}_2 &= \vec{Y}_\beta - \vec{C}_2 \cdot \vec{A}_\beta \\ \vec{Y}_3 &= \vec{Y}_\delta - \vec{C}_3 \cdot \vec{A}_\delta \end{aligned} \right\} \quad (17)$$

$$\vec{Y}(u + 1) = \frac{\vec{Y}_1 + \vec{Y}_2 + \vec{Y}_3}{3} \quad (18)$$

Where,

u signifies the present repetition.

$\vec{A}$  displays the moment path.

$\vec{Y}_k$  designates prey's spot path.

$\vec{C}$  and  $\vec{F}$  are represented as the co-efficient vectors.

$\vec{Y}$  denotes the grey wolf's spot path.

The subscripts  $\alpha, \beta, \delta$  denote the alpha, beta and delta wolves. Therefore, to finish the quest with ending attack. The last violence is demonstrated by lowering the  $\vec{a}$  standards since 2 to zero.  $\vec{A}$  is an arbitrary value in the series of  $-2\vec{a}$  and  $2\vec{a}$ . Decreasing  $\vec{a}$  would also reduce  $\vec{A}$ . The wolves get closer to the prey if  $|\vec{A}| < 1$ . The grey wolves will keep an eye on the leader wolf and they will separate individually to find and attack their prey.

Number of Wolves (NW) and the Generation Number (NG) are the two most important factors assigned by the GWO technique. Where NW actually characterizes the purpose assessments in all group, and every group characterizes the conclusion movement of a wolf. The sum of Objective Function Evaluations (OFEs) will be equal to NG increased by NW. The determination of OFEs is indicated in Eqn. (19),

$$OFEs = N_W \times N_G \quad (19)$$

#### F. Detection of Highlights using GAN

Generative Adversarial Networks (GANs) ensured realized outcomes in image handling, and they are more prevalent in commercial and also in intellectual worlds [31]. GAN is a useful tool to instruct a particular reproductive prototype, thus the confrontational exercise among the originator and differentiator has the capability of generating realistic images. One essential presentation of GANs is model-to-model transformation. It may be implemented to a vast number of responsibilities, especially design transmission and image resolution. Further highlight removal method is included to demonstrate the legitimacy of the method. Deep illustrations can be learned without training material using generative adversarial networks (GANs). The co-existence of a generator and a discriminator that work against every adversarial process is the basic tenet of GAN. The generator intends for the distribution of the instances it produces to match that of the training set. By examining such examples and determining whether they are genuine or artificial, the discriminator learns using conventional supervised learning techniques. The originator needs to absorb how the models are taken from similar dissemination data in order to produce synthetic data that can't be distinguished from actual data [32].

An unsystematic illustration is taken from hidden place x that acts as the generator's input. The differentiator reorganizes the originator's output G(x) using a model of actual distribution. Even though the differentiator gives the importance of supplemental commitments, it will verify that the given principles are fake or genuine. In order to reduce the utility of  $\log(1 - D(G(x)))$ , the generator is trained. This instructs the generator to create pictures as the discriminator can't verify the fake in it (i.e.,  $D(G(x)) \approx 1$ ). To increase the likelihood that it will correctly distinguish between the real models ( $D(y)$ ) and the made-up models ( $D(G(x))$ ), the differentiator is additionally taught how to create the function  $\log(D(y)) + \log(1 - D(G(x)))$ . The above image explains about the architecture of Generative Adversarial Network. Various datasets are given as the input image here. After some predictions the highlights in the images will be removed. Fig. 2 shows the Architectural diagram of the Generative Adversarial Network.

Fig. 2. Architectural diagram of generative adversarial network.

1) *Creation of artificial data using GAN*: The generator and discriminator are designed as multiple perceptions with layers in the initial GAN structure. The procedure continues by picking a fixed-length vector at random from the Gaussian distribution. The generator then receives vector as input, and it acts as an arbitrary seed for the generative process. A data distribution has been projected into the vector space, also known as the tucked space. The GAN will enable the originator to investigate how a quantified inactive galaxy allocates consequence to fundamentals, how to allow it to accept new concepts from the inactive space for the contribution, and how it creates new output from the input that is already available. The Contribution blast is also auxiliary to the originator because it enables the GAN to produce an extensive range of samples commencing various locations within the target distributions and the algorithm permits the GAN to produce a broad range of data. The discriminator functions as a classifier and forecasts as a binary class label for an unidentified model from either the originator or actual preparation data. The training module is determined as follows in Eqn. (20),

$$\min_G \max_D K(D, G) = E_{y \sim Q_{data}(y)} [\log(D(y))] + E_{x \sim Q_x(x)} [\log(1 - D(G(x)))] \quad (20)$$

Here,

x is denoted as the input of the image.

D is the represented as the Discriminator.

G is the generator.

E is the Expectation operator.

y is denoted as the real samples.

#### G. Elimination of Highlight using Structure Texture Layering Algorithm

After the detection of highlights, it can be removed using a highlight removing technique. This paper uses Structure texture layering algorithm to eradicate the high spot from a sole image [33]. An integrated mechanism is conveyed simultaneously to tackle the removal of reflection and artifact destruction. Here, the unique input image is divided into two strata, namely, the structure and the texture layer. Any image can be considered as contrasted and nested collection of dark and light objects it only appears in a particular range of resolution is defined as the structure. Whereas, the brightness intensity of the pixels spatial fluctuation is used to determine the texture. The modification amongst the input image and the x and its structured layer  $x_S$  is calculated using the Eqn. (21). The formulation used for the total variant image restoration is based on the relative total dissimilarity measurements and a soul object generates the illusion of eradicating the texture stratum from the image is given in Eqn. (22)

$$x_T = x - x_S \quad (21)$$

$$\min_S \sum_k ||S_k - x_k||^2 + \lambda \left( \frac{\sigma_i(k)}{\delta_i(k) + \epsilon} + \frac{\sigma_j(k)}{\delta_j(k) + \epsilon} \right) \quad (22)$$

Where,

x is the input image.

$x_T$  is the texture layer.

$x_S$  is the structure layer.

S is the structure image.

K is the 2D pixel.

$(S_k - x_k)^2$  is used to define the structure that is comparable to those of the input image.

$\sigma_{i(k)}$  and  $\sigma_{j(k)}$  is strong-minded as the windowed total variation in i and j direction from the pixel k

$\delta_{i(k)}$  and  $\delta_{j(k)}$  is determined as the windowed inherent variations

$\lambda$  is denoted as the weight

The algorithm of EGWO-GAN is given below and followed by that the flow diagram of the proposed EGWO-GAN is shown in Fig. 3.

## V. RESULT AND DISCUSSION

The proposed method has been examined by some datasets. The Enhanced Grey Wolf Optimization based Generative Adversarial Network is utilized to eliminate the highlights in the image. The input image is taken and pre-processed using WDAF. Then, the segmentation process is done by k-means clustering process. Then the feature is extracted using GLCM. After that the feature selection is done by GWO. After that the highlighted part is detected using GAN. Finally, the highlight spectral is removed using structure texture layering algorithm.

Fig. 4. Initial input image.

Fig. 5. Processed output image.

Fig. 4 shows the initial input image with specular highlights and Fig. 5 shows the processed highlight detected image.

The planned method can be compared using some parameters like Accuracy, Precision, Recall, F1-score.

#### A. Performance Metrics Evaluation

1) *Accuracy*: The accuracy may be defined as the proportion of properly classified illustrations. Accuracy is expressed in Eqn. (23),

$$\text{Accuracy} = \frac{T_{\text{Positive}} + T_{\text{Negative}}}{T_{\text{Positive}} + T_{\text{Negative}} + F_{\text{Positive}} + F_{\text{Negative}}} \quad (23)$$

2) *Precision*: The ratio of suitable examples between the obtained incidences is known as precision or positive prediction value. Precision is computed from Eqn. (24),

$$\text{Precision} = \frac{T_{\text{Positive}}}{T_{\text{Positive}} + F_{\text{Positive}}} \quad (24)$$

3) *Recall*: The proportion of the applicable occurrences that is returned is termed as recall or sensitivity. Recall is uttered in Eqn. (25),

$$\text{Recall} = \frac{T_{\text{Positive}}}{T_{\text{Positive}} + F_{\text{Negative}}} \quad (25)$$

4) *F1-score*: The weighted average of the image augmentation measurements, compared between 0 and 1 is used to estimate the score function. It is signified in Eqn. (26),

$$\text{F1 - score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (26)$$

Table I and Fig. 6 show the comparison and performance evaluation of Accuracy, Precision, Recall and FI-score. When comparing those parameters with the following three existing methods, i) Exemplar-based inpainting algorithm ii) Intrinsic image layer separation method iii) Computer aided diagnosis algorithm, the proposed EGWO-GAN algorithm produces greater accuracy (99.91%), greater precision (97.92%), greater recall (97%) and greater score function (96.5%).

TABLE I. COMPARISON TABLE OF ACCURACY, PRECISION, RECALL, FI-SCORE

Method	Accuracy (%)	Precision (%)	Recall (%)	FI-score (%)
Exemplar-based inpainting algorithm [34]	98.49	75.75	88.69	81.71
Intrinsic image layer separation method [35]	99	59	71	64
Computer aided diagnosis algorithm [36]	90.6	92.8	86.7	89.7
Proposed EGWO-GAN algorithm	99.91	97.92	97	96.5

Fig. 6. Performance comparison chart for Accuracy, Precision, Recall and FI-score.

## B. Discussion

Comparing the suggested EGWO-GAN approach the previously used highlight removal techniques like Exemplar-based inpainting algorithm, Intrinsic image layer separation, Computer aided diagnosis algorithm in Table I results in greater efficiency. The accuracy of the Enhanced GWO based Generative Adversarial Network is higher than that of the performance measured using EGWO and GAN separately. By using this EGWO-GAN model the accuracy level reached is 99.91%. This indicates that the EGWO based GAN will reduce the highlights from the hyper spectral image.

Table I inclines the evaluation outcomes of different algorithms that are based under the Kaggle dataset. When comparing with various approaches the value of Accuracy, Precision, Recall and FI-score in the planned techniques illustrate healthier results. When comparing the accuracy of the proposed method with [35]'s accuracy, the planned method is (0.91%) higher than [35] and lower than [36]. Then, the planned method is better in precision of about (5.12%) when compared to [36]'s precision and the precision is less than [35]. Furthermore, the recall of the proposed method is very much higher (8.31%) than [34]'s recall and lower than [35]. The score function of the proposed method also provides (7.5%) higher score function than that of [36] and provides lesser score function than that of [35].

In this work, K-means clustering is cast-off for the separation process. It will convert the nameless dataset information into various cluster elements. When comparing to the previous techniques, the highlights cannot be removed easily because the hyperspectral images contain heavy noisy particles and the exact particulars are also unclear. The parameters of accuracy, precision, recall and score function of the suggested method gives healthier outcomes than the existing approaches. This will also provide greater efficiency.

## VI. CONCLUSION AND FUTURE WORK

Image processing is one of the latest resources in the domain of hyperspectral photography. But in some circumstances the images will be unspecified due to noise. Therefore, to classify, identify and to divide the planned technique highlight removal process is emphasized. Various datasets are used to detect highlight in the image. To remove the unwanted noise from the hyperspectral images a Wavelet Decomposition Anisotropic Filter (WDAF) is used in the pre-processing stage. Then the Gray-Level Co-Occurrence Matrix (GLCM) in the feature extraction process will determines exactly how frequently a combination of pixels with a particular value appears in the image while defining an image's characteristics. Moreover, the proposed method, Enhanced Grey Wolf Optimization based on the Generative Adversarial Network (EGWO-GAN) is employed to separate the highlighted spots from the hyperspectral images. Improved recognition and estimated accuracy also investigated using this EGWO-GAN process. Then the highlighted region is removed using Structure texture layering algorithm. Finally, the estimated accurateness of the technique was found to be 99.5% and the efficacy of this method is enhanced by the Generative Adversarial Network (GAN) that is based under the machine learning (ML) process.

# Developing a Security Policy for the Use of CCTV in the Northern Border University

Ahmad Alshammari

Department of Computer Sciences-Faculty of Computing and Information Technology,  
Northern Border University, Rafha, Kingdom of Saudi Arabia

**Abstract**—The use of closed-circuit television (CCTV) in universities is a challenging task due to global strong opposition to its implementation at education institutions. The ministry of higher education of Kingdom of Saudi Arabia (KSA) has initiated a plan for monitoring educational institutes across the Kingdom. Therefore, this paper proposes a new framework for developing a comprehensive security policy for using CCTV in the Northern Border University, which streamlines the implementation, usage, and securing of the CCTV footage contents. In this regard, a new policy was developed combining the principles of activity theory, international standards, and design science methodology. It considered six key elements from both theoretical and practical perspectives, namely government rules, technical aspects, training, security requirements, users, and legal issues. Based on them, a standard 12-principal policy was developed; to help organizations easily implement and evaluate the developed policy and secure the contents, the principles were classified into three categories: performance, security, and policy management. The findings showed that the implementation of the policy developed in this study not only improved the security measures of the university, but also built trust among the stakeholders due to the high internal security and effective evaluation of the surveillance system.

**Keywords**—Closed circuit television; security policy; surveillance; educational institutes

## I. INTRODUCTION

Numerous social issues are happening in the world today, including crime, robbery, and intrusion. Anyone can become a target of a crime at any time, whether it be against their body, property, or even life. Different crime-preventive strategies are developed to minimize its effects. In this regard, one of the most extensively adopted technologies is CCTV surveillance systems [1]. People are experiencing various technological developments in contemporary society, such as the use of CCTV systems in crime avoidance and public wakefulness. Most people actually trust that CCTV systems can secure them because if criminals feel that they are being viewed, they will not hazard their lives to pledge crimes or other unusual acts [2]. The fast identification and, in some cases, prevention and disruption of crime are two common objectives of all CCTV monitoring systems. The existence of a CCTV monitoring system, according to [3], instills confidence in people and lowers their crime-related anxiety. Additionally, CCTV systems offer practical corporate management tools that can be used to safeguard employees and encourage health and security efforts [4]. They also facilitate the process of inquiries, provide investigators with vital sources of evidence, and help to prove

individuals' innocence or guiltiness [5]. Furthermore, these systems can be useful in workplaces with unsuitable working conditions for production and control management. A great deal of information could be archived and studied when required.

A CCTV system can be created to match any installation situation, whether it is inside or outside, extremely visible or completely hidden, static or mobile depending on the recording position [6]. With a total of 5.9 million cameras (out of which 750,000 are placed in critical spaces like hospitals and schools), the United Kingdom (UK) is a country with one of the highest numbers of CCTV systems deployed worldwide, putting its nation the maximum-viewed one with roughly one camera for each 11 people. Airports, schools, streets, parking lots, and shopping malls all have these cameras installed. This technology's primary goal is to keep an eye on actions and prevent problems in numerous areas of individuals' lives and activities [7]. For instance, it is predicted that all state schools in the UK have operational CCTV systems to reduce violence and illegal activities [8]. CCTV cameras in educational institutions give parents and guardians the assurance that overall child safety and security is being taken seriously. Considering that a CCTV system is constantly watching its surroundings, it is one of the best applications to identify potentially risky and hazardous circumstances. In the past few years, numerous studies have been carried out in this area to identify such potentially dangerous scenarios. For instance, [9] developed a method for automatically identifying an attempted theft. The study [10] also used the CCTV network to automatically identify fires in buildings and in high-risk regions. In addition, police can use CCTV networks to identify automobiles on the road that are either stolen or have a history of criminal behavior [11]. This study aims to critically evaluate the existing studies in this domain and explore how CCTV can safeguard the students and employees' lives and working environments in the Northern Border University (NBU), Saudi Arabia. As a result, the deployment of CCTV systems in NBU is discussed from legal, cultural, religious, traditional, and technological aspects.

The situation of the CCTV deployment in a university in Saudi Arabia seems to be an important research topic from both the cultural/social and scientific viewpoints, considering what has been discussed above. On the other side, the educational institutes of the country seem to be in urgent need of more CCTV systems deployment. Social and cultural factors, especially those related to education, must be carefully considered by policymakers in order to achieve a more

balanced and successful plan. Overall, the analysis on the installation of CCTV systems in a university is innovative from both technological and social perspectives, and the conclusions could be beneficial to all educational institutes with comparable social and cultural frameworks. To achieve this goal, this paper makes multifold contributions: first, developing a new security policy containing 12 principles for using CCTV in NBU by combining the activity theory, international standards, and design science methodology; and second, categorizing the principles into three groups to be easily implemented and applicable to different educational institutes. The research paper identifies a research gap in the area of CCTV surveillance systems in educational institutions, specifically focusing on the case of Saudi Arabia. While the paper provides a comprehensive analysis of the challenges and policy recommendations for implementing CCTV systems in the Northern Border University, there is a need for further research to explore the actual effectiveness and impact of these systems on enhancing safety and security in educational settings. Additionally, future studies could investigate the perceptions, attitudes, and experiences of students, teachers, and other stakeholders regarding the use of CCTV surveillance in educational institutions, as well as its potential implications on privacy and ethical considerations. Understanding these aspects would contribute to a more nuanced understanding of the benefits and potential drawbacks of CCTV systems in the Saudi Arabian context and beyond.

The rest of the paper is organized as follows: the next section discusses the related work, followed by research methodology in Section III. Then, Section IV discusses not only the implementation of the CCTV policy, but also the practical, theoretical, and legal challenges of the policy. Next, Section V describes how the developed policy was implemented in the NBU clinic. Section VI presents the findings and discussions. Finally, the paper concludes in Section 6.

## II. RELATED WORK

As stated earlier, the literature evaluation must consider a wide range of criteria that typically play a part in CCTV deployment to achieve the study's objectives. In particular, it is important to carefully study topics such as the crime hindrance component of CCTV deployment, permissible and ethical concerns, technological limitations, and cultural and religious contexts. The purpose of installing security cameras in homes, offices, schools, and other locations is a significant query presented in this study. By using a security system, businesses may be able to protect their assets from theft and other crimes by using a solution that could be comparable to the necessity for health insurance when the person is correct. In parking lots [12], in small enterprises [13], on buses [14], in public locations [14], as well as for security and criminal detection, CCTV systems have been a popular tool for ensuring protection against unwelcome situations. Note that CCTV systems are not regarded as an innovative approach to preventing crime. Since most CCTV systems established by the government only cover and monitor public areas, they are unable to prevent physical and sexual attacks committed in private spaces; they are, rather, well known to function in open spaces. CCTV cameras in such areas have a reputation for

detecting and identifying less serious crimes such as sudden heated arguments between people. But the police usually take a very long time to respond to these incidents, and these persons are only arrested much later [15]. The success of CCTV surveillance depends heavily on the human component when it comes to its deployment. When the most modern and efficient technology is considered, surveillance systems must be taken into consideration as well. This is exactly the case when the system depends on automatic non-human workers [16]. Because of the significance of operator attentiveness and the fact that the produced CCTV models overlook the perceptual cognitive activities associated to the operator's visual monitoring, it is understandable why many CCTV models do not function as predicted. Regardless of whether you are in favor of or opposed to the use of CCTV, the validity of such a surveillance system is a continuous concern. In a number of instances, according to [17], the personal freedoms of residents have been violated in favor of the installation of CCTV systems, which have been shown to be ineffectual at reducing crime [18]. A straightforward TV monitor created by Walter Bruch and deployed in 1942 in Germany to safeguard and keep an eye on the notorious V-2 rockets is thought to be the earliest known use of the CCTV technology. However, the technique was not accepted and employed on marketable grounds in the USA until 1949 [19]. These straightforward systems were primarily implemented in sensitive and logistical military locations, but they have since been shown to be quite useful for securing both companies and public areas. To retain the data acquired, crude reel-to-reel recording devices were subsequently devised in the late 1950s for the earlier versions of these cameras that had no recording capabilities. Manually switching the magnetic tapes turned out to be a time-consuming and expensive process. The widespread availability of video cassette recordings in the middle of the 1970s, which was swiftly merged into surveillance systems and provided a new application for the cameras, can be said to have been a significant development in the history of CCTV systems. With this technology, the cameras could be installed and left to operate independently, allowing reviewers to later evaluate the material captured. This technique had a drawback because the tapes needed to be replaced frequently or rewritten. Multiplexing and digital video recording, which emerged in the 1990s, made it possible to integrate and display video signals from various CCTVs on a single monitor. This development improved the effectiveness of CCTV systems and contributed to an increase in their appeal in virtually all sorts of businesses and public spaces. Additionally, since the turn of the millennium, digital technology has advanced enough to allow digital video recorders (DVRs) to replace VCRs, simplifying and improving the usability of CCTV systems [20]. To quickly identify and maybe prevent crime and disruption is a common objective of all CCTV monitoring systems. There have also been assertions that the mere presence of a CCTV monitoring system serves to reassure the people and serve as a deterrent, lowering their fear of crime [21]. CCTV systems also offer useful corporate management features, which may be used to safeguard employees and assist health and safety programs [22]. Additionally, it aids in investigations, gives authorities an important source of evidence, and can exonerate those who are not responsible [23].

Additionally, it can be useful in workplaces with unsuitable working conditions for production and control management. Data gathered by CCTV allows for the storage and later evaluation of all information. A CCTV system can be made to match any installation situation, whether it is indoor or outdoor, visible, or hidden, static or mobile, depending on the recording position. There are 5.9 million cameras in the UK alone, with 750,000 of those cameras placed in sensitive locations including schools and hospitals. This works out to around one camera for every 11 residents of the country. These cameras are set up in parking lots, roadways, airports, schools, and retail centers. This technology's primary goal is to keep an eye on behavior and prevent problems in numerous spheres of a person's life and activities [23]. According to estimates, all state schools in the UK have CCTV systems in place to deter

crime and illegal behavior [8]. CCTV camera installations at educational facilities give parents and guardians the peace of mind that the general security and protection of their children is being taken seriously. A CCTV system's best application would be to identify potentially hurtful and risky conditions because it is constantly watching its surroundings. In the past few decades, numerous research projects in this area have been carried out in an effort to identify such potentially dangerous scenarios. The research [9] for instance, suggested a system that would automatically identify an armed burglary. The study [10] used the CCTV network in a similar way to use automatic fire detection in buildings and high-risk regions. Police can also employ CCTV networks to detect automobiles on the road that are either looted or have a history of illegal activity [24]. Table I summarizes the key literature.

TABLE I. SUMMARY OF THE LITERATURE REVIEWED IN THIS STUDY

Author and year	Title	Framework	Findings
[25]	Security and the Political Economy of International Migration	A security paradigm analyzing policy development through a case-study approach	Policymaking in the United States, Germany, France, and Great Britain, four leading industrial states
[26]	Redrawing the line: Borders and security in the twenty-first century	Framework to monitor border security	Attempts to limit territorial access and border security
[27]	Airport screening, surveillance, and social sorting: Canadian responses to 9/11 in context	Framework to monitor airport conditions	The creation of a coordinated plan under the new Canadian Air Transport Security Authority, together with the use of Advanced Passenger Information (API) and the Passenger Name Record (PNR) as tools for tracing travelers (CATSA)
[28]	Security is coming home: Rethinking scale and constructing resilience in the global urban response to terrorist risk	Monitoring urban security to minimize terrorists' attacks	Worldwide urban resilience to terrorism threat
[29]	Surveillance, security and social sorting: emerging research priorities	Surveillance and security measures for social sorting	This framework has been examined and criticized for its impact on governance in general and civil liberties in particular.
[30]	China on the edge: China's border provinces and Chinese security policy	Security policy for Chinese frontiers border.	As a result, the country developed a security policy, a minority policy, and a border management policy.
[31]	European foreign and security policy: states, power, institutions, and American hegemony	European foreign and security policy	The actual making of foreign policy in institutions for security.
[32]	Using a deep convolutional neural network and surveillance cameras, scalable flood level trend tracking	Framework for Flooding control in Urban areas	This method is flexible and can be used in situations such as floods and different surveillance camera models without requiring on-site camera calibration.
[33]	Integrating the procedures of reporting port security incidents and the follow-up investigation to build a national maritime security policy: a case study in Mexico	National maritime security policy	To enhance port security measures in urban countries to report incident and follow the investigation
[34]	Pedestrian detection for advanced driver assistance systems using deep learning algorithms	To recognize pedestrian for advanced driver assistance systems using CNN	This technique is used in many applications such as surveillance. Advanced robotics, intelligent vehicles, advanced drivers Assistive Systems (ADAS)
[35]	The Making of Post-Socialist Citizens in South Korea?: The Case of Border Crossers from North Korea	Border Security from North Korea	Aims to capture the complex process through which former socialist North Koreans are remade as South Koreans.
[36]	An analysis of video Surveillance technology	Automated monitoring systems using cameras to monitor their surroundings.	The qualities, benefits, and drawbacks of various existing surveillance systems were compared, and the results are given in this study.
[37]	Geopolitics of security and surveillance in Nepal and Afghanistan: A comparative analysis	A comparative analysis for security and surveillance	Security logic presents specific racial and gender bodies as suspects and examines how individuals inhabiting these spaces experience, understand, and challenge these security regimes.
[38]	Assessment of Trans-Border Surveillance Strategies on National Security at Isebania, Migori County, Kenya	Framework for Border Surveillance Strategies on National Security	The purpose of this document is to provide a framework for implementing border surveillance strategies related to national security. Research has shown that modern and effective methods have been found to be effective and are recommended by researchers. There is a need for the country to adopt technology at its borders as well as deploy skilled personnel to manage it at the right time as soon as possible.

Despite the extensive literature on security policies related to CCTV systems, there has been very little research on issues with educational institutes in Arabic countries. In addition, to the best of our knowledge, no study has addressed yet the security policy for using CCTV systems in Arab Education institutes. Therefore, in this paper, we propose a framework for developing a security policy in this regard.

### III. RESEARCH METHODOLOGY

The policy development for CCTV implementation has three main issues: first, people do not like to see their movements are recorded; second, sharing of this information in case of investigation, and third, every organization has its own distinguished organizational structure. This paper aims to propose a policy that can resolve all the above issues. Therefore, a combination of activity theory, international standards, and design science methodology is used to develop a new CCTV policy for NBU.

Fig. 1 presents the recommended structure for the CCTV policy of NBU. This paradigm emphasizes six key elements from both theoretical and practical standpoints. These locations serve as the overall perimeter and purview of the CCTV implementation within the NBU specifically, as well as throughout the kingdom's educational institutions generally.

#### A. Placement and Application of CCTV

This should be presented considering the theoretical concerns regarding the deployment and use of CCTV surveillance systems at NBU, as well as delicate subjects such as cultural and religious considerations.

#### B. Security and Risk Management

This will discuss several security issues and risk management concerns pertaining to CCTV surveillance in educational settings.

#### C. Legal Issues

The significance and necessity of the legal framework for CCTV surveillance systems will be covered in this article. This has proven to be a difficult task, particularly considering the religious and cultural foundations of Saudi Arabia's educational institutions. This section also contains legal paperwork from both the national and international levels in support of the deployment and implementation of CCTV systems.

Fig. 1. Key elements from the practical and theoretical perspectives for the Northern Border University CCTV policy.

#### D. Technical Aspects

Technology limitations may be a factor in the difficulties that may arise with the implementation and deployment of CCTV surveillance systems in NBU. This section aims to pinpoint the areas where technical limitations can have a negative suggest the deployment of successful CCTV systems and to suggest methods in which technological development might significantly reduce these limitations.

#### E. Staff Developmental Training

This section tries to emphasize the significance of effective and practical training programs and the pertinent education needed to build a sizable workforce that is trained and accountable for supporting CCTV management. The proper certification obtained through education and training can increase employee productivity and knowledge of the delicate challenges associated with monitoring and controlling CCTV footage and evidence.

#### F. Governmental Rules and Policies about the Surveillance

The Saudi Arabia government is expected to develop a reasonable and practical set of policies for the placement, installation, and administration of CCTV surveillance systems in order to produce effective and efficient systems of surveillance in a university. This section discusses pertinent issues about the Saudi government's CCTV system protocol.

Considering these six key elements, the CCTV policy for the NBU is advised. The organizational structure and university culture provides the basis for these elements. All these elements collectively provide a standardization for the CCTV policy applicable to NBU. The working framework for the policy development is presented in Fig. 2.

Fig. 2. Framework for the developing security policy for using CCTV in NBU.

### IV. IMPLEMENTATION OF THE CCTV POLICY

This section provides the details related to the implementation and evaluation of developed CCTV policy. The practical and theoretical implications are also discussed in this section. In addition, the legal and ethical challenges are explained in this section.

#### A. Practical Implications of the CCTV Policy

There are two key issues that merit consideration when assessing the practical elements and ramifications of CCTV surveillance system deployment. The first is how CCTV deployment will be designed and developed in the future according to cultural, legal, and other sociopolitical factors. Secondly, how to implement the CCTV.

1) *Design facets of development:* The installation of CCTV surveillance systems in Saudi Arabia has so far raised questions regarding their efficacy and financial usefulness. Although there is often hostility to its placement in public locations, the popular perception of its potential to reduce crime may be favorable. Advanced technology and a culture with strong cultural and religious boundaries are a delicate combination that requires careful consideration. The government of the Kingdom of Saudi Arabia has so far managed to deal with difficult regimes. Modern technology has made it possible to install sophisticated cameras in public areas. Additionally, the deployment of mobile CCTV surveillance will be made much simpler soon when drone technology is fully standardized because considerations regarding camera placement would no longer be necessary. However, it appears that there is more at stake than just the technological feasibility and economic limitations of CCTV surveillance systems. As previously noted, the layout of CCTV surveillance and its upcoming development plans must closely follow the issues presented below:

- Considering the findings, several techniques must be used to combat the problem of misuse in surveillance. The first requirement is that ethical and management obligations and responsibilities are included in the staff's education and awareness programs. Second, hiring and educating more female employees can make a big difference in this circumstance. Finally, as the results of the literature review demonstrated, there were few and poor supervision hours and weekly frequency of all recorded films. It is the responsibility of the project manager or risk manager to ensure that there is an increase in service quality and supervision frequency to lessen the possibility of employee exploitation.
- According to the literature, 42.3% of highly educated individuals oppose the use of CCTV surveillance system. Thus, spreading correct and unambiguous information about CCTV technology and its possible advantages can greatly lower worry about CCTV.
- Concerns about protection and security, particularly those related to the incidence of crimes and thefts. The government has previously been successful in similar safety and security measures simply as the public recognized that the security risk was considerably bigger than other hazards related to CCTV controlling.

2) *CCTV development and governance:* Saudi Arabia is still developing the installation and use of CCTV cameras, but some common practices have been developed to effectively manage the technology. In the case of a new technology like CCTV, the arrival of regulation is closely tied to the process of technological dispersal (Wood & Webster, 2009). CCTV surveillance systems in Saudi Arabia are mostly based on UK and European standards, but a set of local regulations based on cultural and traditional values of the population is needed, especially for educational institutions.

The main goal of governance is managing various initiatives and activities efficiently and fairly; in other words, acting responsibly and being accountable and transparent. Policymakers shall adhere to all governmental policies and guidelines regarding the process of implementing and deploying a CCTV surveillance system at NBU. The deployment process should be documented at every stage, highlighting the regions that will be impacted and outlining the actual costs and advantages of the placement. Such paperwork must also outline certain potential upcoming developments, their advantages and disadvantages, and the procedures for their control. The public must have access to these documents and be able to comment on them.

NBU should work to create a center of excellence for the CCTV investigation protocol. The implementation and ongoing management of all CCTV systems at the institution must be completely under the control of this center. As previously stated, this center needs a respectable budget to carry out its delicate work of instructing students, offering training courses for staff, estimating the correct costs and paybacks of any deployment task, gauging the projects' actual efficacy, and lastly gathering and collecting valuable statistics for the calculation of threats and doubt arising from new projects in the future.

#### *B. Theoretical Implication of the CCTV Policy*

After being launched and executed, the project should be regularly validated. Conducting regular surveys of the participants is the finest method of project validation. Therefore, it is advised that a regular survey of students, instructors, and technical personnel be carried out. The outcomes will assess the efficiency of all 12 principles of CCTV surveillance. The policies, infrastructure, and training will all be updated as necessary to reflect the findings and results in the services.

#### *C. Legal and Ethical Challenges of the CCTV Policy*

The widespread use of CCTV has always prompted certain moral and legal concerns. Additionally, the widespread misuse of CCTV footage and the absence of ethical guidelines around "dumb" CCTV surveillance have both been shown in many instances. As a result, it is only reasonable to say that the broad adoption of such CCTV systems would not be supported by the entire populace and would be closely scrutinized in terms of how the data gathered by CCTV. The current legal framework for the control of CCTV data is relatively constrained and largely focused on data protection laws, which are not the best fit for CCTV data. In a similar vein, the evolution of Japanese data security has demonstrated that CCTV is subject to very lax data security regulations. Despite the fact that CCTV installations are becoming more and more common in Japan (placed in public, semi-public, and even semi-private spaces such as office cafeteria areas), this issue is still not seen to be a problem and is not adequately regulated [39]. Strict rules and regulatory measures are now both required and desirable since the number of CCTV systems in public locations throughout the world has been increasing exponentially. Regulators will be less effective if a nation is not committed to protecting privacy and does not have the institutional safeguards to safeguard it [18]. In essence, according to [18], CCTV surveillance has

changed the notion of privacy, which has made the job of regulators and attorneys in most European nations more difficult. By doing a comparable assessment on data privacy and legislation in Africa, [40] demonstrated how underdeveloped the continent is at the moment. The study has concluded that because of Africa's lack of self-governing experiences, its collectivism culture, and its solid religious heritage, the continent continues to lag far behind the legal status of Europe in terms of the implementation and effective use of CCTV cameras in open places. This is done by considering issues such as data privacy policies, culture, and religion. Other ethical concerns with CCTV surveillance include the lack of reciprocal eyes, which occurs when the subject of the monitoring is unaware that he or she is being watched and/or who is doing so. Data are compiled with an increase in interest from unauthorized parties, hence exacerbating the privacy problems as smart CCTV systems with facial detection are implemented.

### V. IMPLEMENTATION OF DEVELOPED POLICY IN THE NBU CLINIC

The developed CCTV policy can be implemented for several fields of NBU. For example, a CCTV was installed for the NBU clinic to monitor and record the patients. The purpose of implementing the CCTV Policy for the clinic of BNU is to ensure the safety and security of both patients and staff at the clinic. This policy outlines the measures that will be taken to ensure the security of the clinic, including the installation and use of CCTV cameras and video recording systems. These measures will help to deter any criminal activity and provide a safe environment for both patients and staff. Additionally, the policy will ensure that the clinic is compliant with all relevant laws and regulations. Fig. 3 shows the details and implementation of the CCTV policy for the NBU clinic.

<b>Policy statement</b>	<ul style="list-style-type: none"> <li>This policy will cover the CCTV surveillance system in the NBU clinic. It will ensure a fair and secure use and implementation of the CCTV. This policy will cover all the equipment, software, technical staff, users, authentication, authorization, and any other issues related to the CCTV surveillance system in the NBU clinic.</li> </ul>
<b>Users</b>	<ul style="list-style-type: none"> <li>This policy will cover the use of the CCTV surveillance system. It will ensure the rights and authentication of the users. It will also distinguish among the manager, authorized users, and patients in the clinic.</li> </ul>
<b>Management and Maintenance</b>	<ul style="list-style-type: none"> <li>It will be the responsibility of the authorized technical team to manage the security of the CCTV system, its maintenance, and 24/7 availability. They will also ensure the backup, recovery, and availability of the data at the time of need.</li> </ul>
<b>Training</b>	<ul style="list-style-type: none"> <li>The NBU managers will make the arrangement to provide necessary training to the users of the CCTV surveillance system, managers, IT staff, and other relevant personnel.</li> </ul>
<b>Policy Update</b>	<ul style="list-style-type: none"> <li>The management of NBU will review the NBU clinic surveillance system time to time and will make necessary modifications according to changing requirements.</li> </ul>

### VI. FINDINGS AND DISCUSSION

To protect kids, the Saudi Arabian Ministry of Education reportedly declared that 33,000 schools across the country would soon have CCTV camera systems installed. This initiative's primary goal is to encourage a culture of safety and security among instructors and pupils as well as among the private security guards who might be employed to enforce safety standards. Additionally, there are 5 million students and 700,000 teachers in Saudi Arabia, who are carrying out their jobs in their institutes. If these measures are successful, this will significantly increase the personal safety and security of one-third of Saudi students and teachers. The installation of CCTV surveillance systems is therefore highly wanted in Saudi Arabia due to the country's developing infrastructure and industry.

However, most evaluations have produced ambiguous and conflicting conclusions when taking into account the situation studies of CCTV efficiency in the United State and European countries [41] [42]. However, in brief, as most academics have argued, the issue of whether CCTV systems might be useful should be taken into account in conjunction with a wide range of social, cultural, legal, economic, and religious aspects influencing our recent existence [43] CCTVs are expected to be installed in Saudi Arabia's most significant regions, including educational institutions.

The NBU is advised that in the short-term certain norms of conduct should be adopted by the personnel who are engaged in all aspects of CCTV surveillance. As a result, the 12 guiding principles listed below are ideal places to start when it comes to establishing CCTV surveillance at NBU in the first place. In Fig. 4, these principles are classified and summarized in a way that is easy to understand.

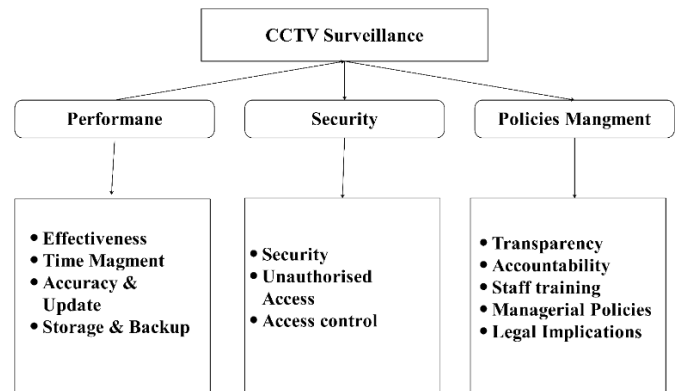

Fig. 4. Categorization of the key principles for implementing, securing, and evaluating the policy.

- **Effectiveness:** To protect the public, CCTV surveillance cameras should be deployed as effectively as possible to promote public safety and law enforcement.
- **Time Management:** A CCTV surveillance camera system must only ever be used for a specific purpose with the legal intent to deter crime.
- **Accuracy and Updates:** An accurate and current database should be used to support any surveillance camera system.

- Storage and backup: Images and other types of information should only be kept for a specific amount of time before being deleted entirely.
- Security: It is important to carefully assess and reevaluate on a regular basis how using a surveillance camera system may indirectly affect people and their privacy.
- Unauthorized Access: Images and data from surveillance cameras should be saved private and safe to prevent unwanted access and usage.
- Access Control: Any access to saved data should be controlled, and stored data should only be disclosed when it is required for a specific purpose or for rule execution.
- Transparency: When deploying a surveillance camera system, transparency must always be practiced regardless of any individual or private gain.
- Accountability: There must be clear accountability for all activities employing surveillance camera systems, including the collection, saving, and utilization of images and data.
- Trained Staff: CCTV system operators should be fully trained and qualified in order to handle technical, operational, and competency standards relevant to a system.
- Managerial Policies: Before using and deploying CCTV cameras, managers or supervisors have a responsibility to provide clear rules, regulations, and procedures.
- Legal Implication: To guarantee that all legal requirements are properly followed in practice, a regular review and auditing mechanism should be in place. This policy is developed by considering the requirement of the security management team. All the factors from design stage to the implementation and evaluation stages are considered in this policy. To make the implementation process easier, a comprehensive list of principles is categorized into three categories. These categories cover the different actors from top management to security staff. This policy is applicable to NBU as well as any educational institutes governed by the Ministry of Higher Education in KSA. The policy is critically analyzed and evaluated to check the social challenges, security measurements, authorization, and the roles offered to the human actors. Thus, the categorized principles will help the organizations to implement the policy for implementation of CCTV systems in their environment.
- Upon analyzing the findings and engaging in thorough discussions, it becomes evident that there is a need to address the identified research gap in the field of CCTV surveillance systems. While previous studies have explored the effectiveness of such systems in various contexts, there remains a lack of comprehensive understanding and evaluation of their performance, particularly in the specific setting of educational institutions. Therefore, this research aims to bridge this gap by providing a detailed analysis of the implementation and impact of CCTV surveillance systems in Saudi Arabian schools. By investigating the challenges, benefits, and implications associated with their deployment, this study offers valuable insights into enhancing the safety and security measures in educational environments. The findings shed light on the unique considerations and potential improvements required to ensure the successful implementation and operation of CCTV systems in schools, thereby advancing the state-of-the-art in this domain.

## VII. CONCLUSION AND FUTURE WORK

In this paper, the authors evaluated different challenges in implementing the CCTV surveillance system, in general, and KSA. According to the guidelines of the Ministry of Higher Education of the Kingdom, a detailed CCTV policy was advised in this study for the Northern Border University keeping in view all the challenges of the sharia, culture, and educational institute requirements. The policy also considered the requirements of the key stakeholders as well as the students and staff members. The policy was made based on the standard principles that were categorized into three classes: performance, security, and policy management. In the security section, the aim was to maximize the benefits of the surveillance system and, at the same time, ensure data security. If this policy is implemented in all its aspects, it will not only ensure the university's safety, but also build trust in the stakeholders. Exploring emerging technologies, such as machine learning and video analytics, can also be a promising area for future research to enhance the capabilities of CCTV surveillance. Furthermore, investigating the long-term effects of CCTV implementation, including any unintended consequences or potential privacy concerns, would contribute to a more holistic understanding of its implications. Lastly, considering the perspectives of various stakeholders, such as students, teachers, parents, and policymakers, can provide valuable insights into the acceptance and effectiveness of CCTV surveillance in educational environments. These future research directions will contribute to the ongoing development and improvement of CCTV systems in educational institutes.

# Enhanced Gravitational Search Algorithm Based on Improved Convergence Strategy

Norlina Mohd Sabri<sup>1\*</sup>, Ummu Fatimah Mohd Bahrin<sup>2</sup>, Mazidah Puteh<sup>3</sup>

College of Computing-Informatics and Media,  
Universiti Teknologi MARA Cawangan Terengganu, Kampus Kuala Terengganu, Malaysia

**Abstract**—Gravitational search algorithm (GSA) is one of the metaheuristic algorithms that has been popularly implemented in solving various optimization problems. The algorithm could perform better in highly nonlinear and complex optimization problems. However, GSA has also been reported to have a weak local search ability and slow searching speed to achieve its convergence. This research proposes two new parameters in order to improve GSA's convergence strategy by improving its exploration and exploitation capabilities. The parameters are the mass ratio and distance ratio parameters. The mass ratio parameter is related to the exploration strategy, while the distance ratio parameter is related to the exploitation strategy of the enhanced GSA (eGSA). These two parameters are expected to create a good balance between the exploration and the exploitation strategies in eGSA. There are seven benchmark functions that have been tested on eGSA. The results have shown that eGSA has been able to produce good performance in the minimization of fitness values and execution times, compared with two other GSA variants. The testing results have shown that the enhancements made to GSA have successfully improved the algorithm's convergence strategy. The improved convergence has also been able to improve the algorithm's solution quality and the processing time. It is expected that eGSA could be applied in many fields and solve various optimization problems efficiently.

**Keywords**—Enhanced gravitational search algorithm; variant; improved convergence; exploration; exploitation

## I. INTRODUCTION

Gravitational Search Algorithm (GSA) is a physics based metaheuristic algorithm which has been adapted to solve various optimization problems. The algorithm has been one of the popular optimization algorithms that has been adopted by the researchers [1]. GSA has been reported to have the capability to solve highly nonlinear and complex engineering optimization problems effectively [2-4]. Based on literatures, GSA has demonstrated better performance in solving optimization problems such as for constrained, unconstrained, continuous, discrete and multi objective optimizations [5, 6]. The algorithm has produced better performance than the other well-known algorithms such as Particle Swarm Optimization (PSO) and Genetic Algorithm (GA) in solving various optimization problems [5, 7, 8].

Among of the advantages of GSA are such as simple concept, less control parameters and able to balance the exploration and exploitation in the optimization [9-12]. The exploration capability is related to the ability of the algorithm to expand the search space for good solutions. Algorithms must use exploration strategies at the beginning to avoid trapping in

the local optimum. Exploitation in the metaheuristics is related to the convergence strategy or the ability to find the near optimal solution among good solutions. The strategies to achieve convergence are different for each of the algorithms. An optimal result is determined by the good balance between the exploration and exploitation capabilities.

As for GSA, the algorithm's exploitation characteristic has been reported to produce longer execution time to reach the optimal solution [13, 14]. The presence of agents with heavier masses at the end of run has contributed to longer computational time needed for the algorithm to reach the optimal solution. It has been reported that GSA suffers long computational time compared to other well-known algorithms. Based on literatures, the original GSA has been reported to have a poor local search ability and slow searching speed in the last iteration. The particles tend to get stuck in the local optima in the last stage of iterations. Due to the problem, the swarm cannot converge to the optimal point even though the particles could cluster to a small domain [15-17]. The algorithm requires more time to reach the optimal solution due to the presence of heavier masses at the end of run [18, 19].

Based on the reported problems, GSA has been suffering from the weak exploitation in certain problem domains. Due to the weakness, many enhancements and modifications have been done to GSA in order to improve its performance. Various GSA variants have been designed in order to improve its convergence rate, computational time and the solution quality. Some of the variants have focused on the modifications of the behavior of GSA by introducing new parameters or functions to the algorithm's structure. Among of the previously introduced parameters are Levy flight operator and disruption operator [20,21]. The Levy flight operator is designed to avoid the premature convergence, while the disruption operator improves the exploration and exploitation abilities of GSA. The other concepts are the adaptation of clustering method, stochastic local neighborhood search, chaos theory and natural selection rules [22-25]. These concepts have been introduced to reduce the complexity and computation of GSA and to avoid from local optima. The concepts which are related to physics theory such as astrophysics, mass dispersed gravity and wave function have also been introduced to the standard GSA in order to improve the algorithm's performance [26, 27, 21]. These modifications could enhance the global searching capability of GSA and also help the agent to escape from local optima.

The previous enhancements have considered the balance between the exploration and exploitation capabilities of the

algorithm to achieve efficient searches. The good balance of the exploration and exploitation capabilities could be achieved by assigning the specific parameters or operators to the algorithm to produce specific capabilities [21]. Based on literatures, there are many additional parameters that have been introduced such as the escape velocity operator to improve the velocity [28], differential factor parameter to balance the global and local searches [29], chaotic perturbation operator to improve the exploitation [24] and disruption operator to avoid weaker agents [21]. GSA tends to get stuck in the last iteration after performing well at the beginning. Due to the problem, there is a need to add new operators into GSA in order to increase its efficiency in solving nonlinear optimization problems [30]. Hence, this research is proposing the enhancement of GSA with the introduction of mass ratio parameter and distance ratio parameter to the algorithm. The mass ratio parameter is designed to improve the exploration strategy, while the distance ratio parameter is designed to improve the exploitation strategy. The objective of the research is to improve the convergence of GSA by improving both of the exploration and exploitation capabilities of the algorithm. In this research, the original structure of GSA is modified to further improve its performance. The new parameters have been designed based on the basis that the parameters should be able to select only better agents as the active agents for the calculation of forces, while improving the exploration and exploitation capabilities. It is expected that this proposed convergence strategy could improve GSA in obtaining better optimal solution and improve its computational time.

This paper is organized into several sections. The earlier sections present the introduction and overview of GSA. The later sections explains the enhancements of GSA, the benchmark testing, results of the analyses and discussion. Finally the paper is summarized through the conclusion of the research.

## II. LITERATURE REVIEW

### A. Gravitational Search Algorithm (GSA)

Gravitational Search Algorithm (GSA) was developed by Rashedi et al. in 2009, which was based on Newton's law of gravity and law of motion [31]. In Newton's law of gravity, the force between two objects is directly proportional to the product of their masses and inversely proportional to the square of the distance between the objects. The second law of motion states that when a force is applied to an object, the acceleration is depending on the force and the mass. GSA is represented by agents, which carry their own masses in the search space. The following steps show the basic procedures of GSA:

- 1) *Randomized initialization.*
- 2) *Fitness evaluation of agents.*
- 3) *Update  $G(t)$ ,  $best(t)$ ,  $worst(t)$  and  $M_i(t)$  for  $i = 1, 2, \dots, N$ .*
- 4) *Calculation of the total force in different directions.*
- 5) *Calculation of acceleration and velocity.*
- 6) *Updating agents' position.*
- 7) *Repeat steps 2 to 6 until the stopping criterion is reached.*

Based on the GSA procedures, the first step is the random initialization of the population of agents. The fitness values of the agents are evaluated in the second step. In the third step, the gravitational constant  $G(t)$  is updated based on the time execution, while the agents' masses, best and worst of the population are evaluated. In the fourth step, based on the evaluations, the total force in different direction of agents is calculated. The total force value leads to the updates of the acceleration and velocity of an agent as in the fifth step. Equation (1) and (2) show the computation of the acceleration  $a$  and the velocity  $v$  respectively. The acceleration  $a$  of an agent at iteration  $t$  is calculated based on the total force,  $F_i^d(t)$  and mass,  $M_{ii}(t)$  as shown by (1). In the sixth step, the position value  $x$  of an agent is calculated based on (3) after the velocity value  $v$  has been obtained. After the maximum iteration has been reached, the execution would stop and return the optimal solution. In GSA, the biggest mass corresponds to the optimal solution while its position is the solution to the problem.

$$a_i^d(t) = F_i^d(t) / M_{ii}(t) \quad (1)$$

$$v_i^d(t+1) = \text{rand}_i \times v_i^d(t) + a_i^d(t) \quad (2)$$

$$x_i^d(t+1) = x_i^d(t) + v_i^d(t+1) \quad (3)$$

## III. METHODOLOGY

### A. Enhancements of GSA

GSA has widely been improved since its introduction in 2009. Over the years, various GSA variants have been designed in order to improve its performance. The significant contributions in GSA have been focusing on improving the convergence rate, reducing computational efforts and improving the solution quality. Based on the previous studies on the improvement of GSA, the enhancements could be categorized into two approaches. One of the approaches is the modifications of the behavior of GSA by introducing new parameters or functions to GSA structure, while another approach is the hybridization of GSA with other intelligent techniques.

In this research, the exploration and the exploitation strategy of GSA is studied to overcome its convergence issues and improve the execution time. There are two new parameters that have been designed in the enhancements, namely mass ratio and distance ratio parameters. The mass ratio parameter is related to the exploration strategy, while the distance ratio parameter is related to the exploitation strategy of the enhanced GSA (eGSA).

### B. Mass Ratio Parameter

The first enhancement of eGSA is the introduction of the mass ratio parameter, which is aimed to reduce the number of active agents in the search space. Based on the original concept of GSA, only  $K_{best}$  agents should attract other agents to improve the algorithm's performance [31].  $K_{best}$  agents are the set of agents with better fitness values and bigger masses. In GSA, only  $K_{best}$  agents should apply forces to the others to control the exploration and exploitation capabilities of the algorithm. This research is proposing a mass ratio parameter to select the set of  $K_{best}$  agents in the search space. Based on the parameter, only agents with bigger masses will become active

in attracting the other masses in the search space. The formula for the mass ratio parameter is shown in (4).

$$\text{Mass Ratio} = M_i / M_{\text{best}} \quad (4)$$

where:

$M_i$  = mass of an agent

$M_{\text{best}}$  = biggest mass in the search space

Based on (4), the mass ratio of an agent is obtained by dividing its mass with the biggest mass in the search space. The set of *Kbest* agents is the agents with mass ratio values in the interval [0.1, 1.0]. These *Kbest* agents would apply forces with each other within the given mass ratio values. This mass ratio approach is introduced to control the search for good candidate solutions in the search space based on the ratio of the biggest mass. Fig. 1 shows the concept of mass ratio approach among the agents. This approach is applying exploration at the beginning when all of the *Kbest* agents apply forces to each other. However, since *Kbest* is a function of time, its initial value of  $K_0$  will decrease linearly with lapse of time. By the end of the iteration, there will be only one *Kbest* agent that applies force to the others. By the end of the iteration, exploitation is obtained by the decrement of the *Kbest* agents in the forces attractions. This mechanism could improve the exploration strategy as only the good solutions would be considered, eliminating the worse ones. The global search efficiency of GSA could be improved by selecting only better masses for the accumulation of forces. This approach could attain the good coordination between exploration and exploitation capabilities as the exploration would fade out when the exploitation starts to fade in.

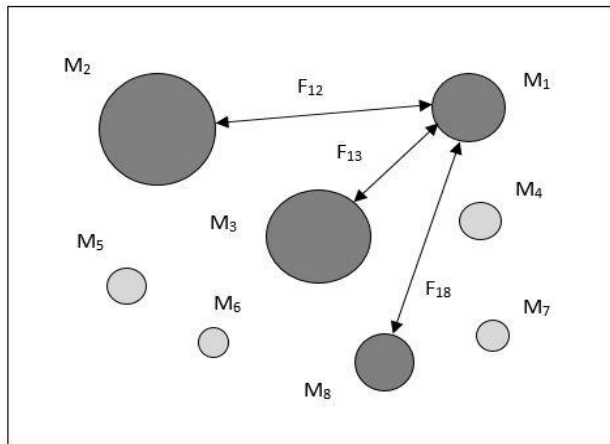

Fig. 1. Only agents with bigger masses apply forces to each other in eGSA.

### C. Distance Ratio Parameter

The second enhancement of eGSA is the introduction of the distance ratio parameter. This enhancement is inspired by the reported GSA's local search weakness [32]. This second enhancement is based on the distance factor in the accumulation of forces between the agents. Based on the gravitational force formula as seen in the (5), the forces between two agents ( $F_{12}$ ) are directly proportional to the gravitational constant,  $G$  and their masses ( $M_1$  and  $M_2$ ). The forces are indirectly proportional to their distance ( $R_2$ ).

$$F_{12} = GM_1M_2 / R^2 \quad (5)$$

Based on (5), the force between the two agents ( $M_1$  and  $M_2$ ) would be higher when the distance between them is smaller. This formula has shown that an agent would have more attraction with other agents which are in shorter distances. Furthermore, the law of motion has stated that the force is directly proportional to the acceleration of the object. Equation (6) shows the acceleration,  $a$ , of an object is directly proportional to its force,  $F$  and indirectly proportional to its mass,  $m$ . Based on the equation, the smaller force would generate lower acceleration and vice versa.

$$a = F/M \quad (6)$$

In GSA, the acceleration is necessary to determine the velocity of an agent. Equation (2) has shown the formula for the velocity of the next iteration of an agent,  $v_i(t+1)$  that is significantly influenced by the acceleration,  $a_i(t)$ . Based on (2), the low acceleration value would result in the lower velocity of an agent. Due to the lower velocity, the agent would continue their search in the bad area which would contribute to the decreased of the optimization result. Since the acceleration is depending on the force and the force is depending on the distance, the agents that are far away in the search space would generate lower velocities. The  $rand_i$  is a uniform random variable which is in the interval of between 0 and 1. The purpose of the random number is to give a randomized characteristic to the search.

In this research, since the agents have already been selected through the mass ratio approach, the active agents in the search space are only the ones with the bigger masses. These agents are more efficient, have higher attractions and move slower than other lighter agents [31]. In order to help the agents to search the space more locally, the distance ratio parameter is introduced. Based on this parameter, only agents in shorter distance are selected for the accumulation of forces between agents. The accumulated force would be used to calculate the acceleration which would determine the velocity and position of an agent. The formula for the distance ratio is as shown in (7).

$$\text{Distance Ratio} = D_{ij} / D_{i,\text{max}} \quad (7)$$

where:

$D_{i,j}$  = distance of an agent from other agent.

$D_{i,\text{max}}$  = the farthest distance with an agent.

Equation (7) has shown that the distance ratio is obtained by dividing the distance of an agent from another agent with the distance of the farthest agent in the search space. The distance of the farthest agent changes with each agent in the search space. In this research, the distance ratio is set in the interval of [0.1, 1.0]. The distance ratio approach is adapted into GSA in order to speed up the process of obtaining the forces between agents while improving the quality of solution. This approach would select agents in shorter distances depending on the ratio setting and this would help the algorithm to search the space more locally. This distance ratio parameter is introduced to help in the search for optimal solution or global optima more efficiently. Based on the

literature, GSA requires more time to reach the optimal solution due to the presence of heavier masses at the end of run [33]. This approach would reduce the number of agents to be considered in the determination of the optimal solution at the end of run, hence could improve the algorithm's local search efficiency and is expected to improve the execution time.

#### D. Procedural Steps of eGSA

This section provides a more detailed description on the procedural steps of the enhanced GSA (eGSA) by showing the formula in each step of the algorithm. There are altogether 10 steps involved in order to obtain the final optimal result in each execution. The steps of the standard GSA has been briefly described in the earlier section. In eGSA, the concept of the algorithm is still based on the standard GSA, but with the additional enhancements to its structure. In the procedure, Step 4 to Step 7 is the new enhancement in eGSA. The following shows the procedural steps of eGSA:

Step 1: Agents initialization.

Step 2: Fitness evaluation, best and worst fitness computations.

Step 3: Gravitational constant ( $G$ ) computation.

Step 4: Agent's Mass ( $M_i$ ) and  $M_{best}$  computations.

Step 5: Selection of  $Kbest$  agents based on mass ratio parameter.

Step 6: Farthest distance,  $D_{i,max}$  computation.

Step 7: Selection of agents based on distance ratio parameter.

Step 8: Accelerations of agents' computation based on total forces.

Step 9: Velocities and positions of agents' computation.

Step 10: Repeat steps 2 to 9.

The first step of eGSA is the agents' initialization in the search space. Equation (8) shows the first step of GSA which is to initialize the positions of the  $N$  number of agents.

$$X_i = (x_i^1, \dots, x_i^d, \dots, x_i^k), \text{ for } i=1, 2, \dots, N. \quad (8)$$

Based on (8),  $x_i^d$  represents the positions of the  $i^{th}$  agent in the  $d^{th}$  dimension, while  $k$  is the space dimension.

The second step covers the computation of fitness evaluation for each agent, which led to the determination of the best and worst fitness among the agents. For example, the minimization function of GSA is selected. Equation (9) and (10) show the formula for the minimization problem.

$$\text{best}(t) = \min \text{fit}_j(t) \quad (9)$$

$$j \in \{1, \dots, N\}$$

$$\text{worst}(t) = \max \text{fit}_j(t) \quad (10)$$

$$j \in \{1, \dots, N\}$$

Based on (9) and (10), the  $\text{fit}_j(t)$  represents the fitness value of the  $j^{th}$  agent at iteration  $t$ ,  $\text{best}(t)$  and  $\text{worst}(t)$  represents the best and worst fitness at iteration  $t$ .

In the third step, the gravitational constant ( $G$ ) is computed. Equation (11) shows the formula to calculate  $G$ , which is computed at iteration  $t$  [34].

$$G(t) = G_0 e^{-\alpha t/T} \quad (11)$$

Based on (12),  $G_0$  and  $\alpha$  have to be initialized at the beginning and will be reduced with time to control the search accuracy. The  $T$  is the total number of iterations.

The fourth step is the computation of the agents' masses. In the theoretical physics, there are actually three kinds of masses that have been identified. The masses are the active gravitational mass, passive gravitational mass and the inertial mass. In GSA, the active, passive and inertia masses of an agent are considered to be equal based on the theory of the general relativity [32]. Based on (12),  $M_{ai}$  and  $M_{pi}$  are the active and passive gravitational masses respectively, while  $M_{ii}$  is the inertia mass of the  $i^{th}$  agent. Equation (12) shows that the three masses are actually equal. Equation (13) shows that the mass for each agent is calculated based on the worst and best fitness at the iteration  $t$ . Each of the mass  $i$  is then updated based on the other masses  $j$  as shown in the equation (14).

$$M_{ai} = M_{pi} = M_{ii} = M_i, \quad i = 1, 2, \dots, N. \quad (12)$$

$$m_i(t) = \frac{\text{fit}_i(t) - \text{worst}(t)}{\text{best}(t) - \text{worst}(t)}$$

$$m_i(t) = \text{fit}_i(t) - \text{worst}(t) / \text{best}(t) - \text{worst}(t) \quad (13)$$

$$M_i(t) = \frac{m_i(t)}{\sum_{j=1}^N m_j(t)}$$

$$M_i(t) = m_i(t) / \sum_{j=1}^N m_j(t) \quad (14)$$

In this step, the calculation of masses for each of the agents has led to the determination of the best mass,  $M_{best}$ . In order to apply the mass ratio parameter, the determination of  $M_{best}$  has to be done in this step.

In the fifth step, the  $Kbest$  agents are selected based on the mass ratio parameter as shown in (4). Based on the mass ratio approach, only  $Kbest$  agents would become active and apply forces with each other in the search space. The sixth step is the calculation of the farthest distance,  $D_{i,max}$  among the  $Kbest$  agents. This step is necessary in order to apply the distance ratio parameter in the next step.

The seventh step applies the other new distance approach parameter. In step 7, the active agents would be selected again based on the distance ratio parameter as shown in (7). Based on the distance ratio approach, only agents with shorter distances are selected for the calculation of forces between the agents.

The eighth step covers the calculation for the acceleration of agents. Before the calculation of the acceleration, the value for  $F_{ij}^d(t)$  has to be computed based on (15). Based on (15),  $F_{ij}^d(t)$  is the force acting on agent  $i$  from agent  $j$  at  $d^{th}$  dimension and  $t^{th}$  iteration.  $R_{ij}(t)$  is the Euclidian distance between two agents  $i$  and  $j$  at iteration  $t$ .  $G(t)$  is the computed

gravitational constant at the same iteration while  $\epsilon$  is a small constant.

$$F_{ij}^d(t) = G(t) \cdot (M_{pi}(t) \times M_{aj}(t) / R_{ij}(t) + \epsilon) \cdot (x_j^d(t) - x_i^d(t)) \quad (15)$$

After the calculation of  $F_{ij}^d(t)$ , only then the total force that acts on the  $i^{th}$  agent,  $F_i^d(t)$  could be calculated based on (16). The total forces are calculated based on all of the agents that have been selected after the implementation of the distance ratio parameter.

$$F_i^d(t) = \sum_{j \in Kbest, j \neq i} rand_j F_{ij}^d(t) \quad (16)$$

The acceleration of the  $i^{th}$  agents at iteration  $t$  could be computed as already shown in (1). The ninth step covers the calculations for the velocity,  $v_i$  and position,  $x_i$  of each agent. The velocity and the position of the agents at the next iteration ( $t+1$ ) are computed based on (2) and (3) respectively. The  $rand_i$  is the random variable in the interval [0,1] which would give the randomized characteristic to the search.

The final step is to repeat the step 2 to step 9 until the iterations reach the maximum limit. The best fitness value at the final iteration is computed as the global fitness while the position of the corresponding agent is computed as the global solution of this problem.

Based on these enhancements, the new flowchart for eGSA is shown in Fig. 2. The highlighted parts in the Fig. 2 show the enhancement that has been implemented in eGSA.

### E. Benchmark Functions Testing

The enhanced GSA (eGSA) has been tested with seven benchmark test functions in order to validate its capabilities. The selected functions are the commonly used benchmark functions that have been applied to test the performance of an optimization algorithm [31, 35, 36]. The function names, their mathematical representations, characteristics and the search spaces are given in Table I.

TABLE I. BENCHMARK FUNCTIONS APPLIED IN THE EXPERIMENTS

Function Name	Mathematical Representation	Characteristic	Search Space
Sphere	$F_1(X) = \sum_{i=1}^n x_i^2$	Unimodal	$[-100,100]^n$
Schwefel 2.21	$F_2(X) = \max \{ x_i , 1 \leq i \leq n\}$	Unimodal	$[-100,100]^n$
Step	$F_3(X) = \sum_{i=1}^n ([x_i + 0.5])^2$	Unimodal	$[-100,100]^n$
Quartic Noise	$F_4(X) = \sum_{i=1}^n i x_i^4 + random[0,1]$	Unimodal	$[-.28,1.28]^n$
Rosenbrock	$F_5(X) = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2) + (x_i - 1)^2]$	Multimodal	$[-30,30]^n$
Schwefel 2.26	$F_6(X) = \sum_{i=1}^n -x_i \sin(\sqrt{ x_i })$	Multimodal	$[-500,500]^n$
Rastrigin	$F_7(X) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]$	Multimodal	$[-12.5,12]^n$

\* n = dimension

Based on Table I, four of the functions are the unimodal functions while another three are the multimodal functions. The unimodal functions are the functions with only one single local minima and are commonly applied to test the convergence rate of a search. As for the multimodal, the functions have many local minima and are commonly applied

to test the ability of the algorithm to escape from the local optima. The final result in the multimodal function is important as it shows the ability of an algorithm to find the global optima. In this benchmark testing, eGSA has been compared with another two modified or variants of GSA algorithms. The other two variants of GSA algorithms have been selected based on their almost similar concepts for enhancement with eGSA. Both of the algorithms have also been based on the distance of agents for their points of change in the GSA's structure. The comparison algorithms are the Improved GSA (IGSA) and Hybrid Gravitational Search with Lévy Flight (HGSLF) [37, 38]. The IGSA has been based on the disruption phenomena in the outerspace, where a star of the system could disrupt other objects under the influence of its gravitational force. In the IGSA algorithm, an agent is disrupted if the ratio of the distance between its mass and the neighbouring mass to its distance from the best solution is smaller than a specified threshold. As for the Lévy flight operator, it is applied to one of the mass if the distance between the two masses have become very near and both of them are not good solutions in the search space.

The parameter settings for each of the algorithm have been provided in the Table II to Table IV respectively. Based on the tables, the standard GSA parameters are the gravitational initial value, alpha and epsilon. The value of  $G_o$  and  $\alpha$  determine the convergence speed and help to balance the exploration and exploitation of GSA [39]. As for the epsilon,  $\epsilon$ , it helps in the updating strategy of GSA. The other parameter settings are for the new introduced parameters, which are the mass ratio and distance ratio for eGSA, the constant operator  $\theta$  and small value  $\rho$  for IGSA and the threshold constant  $\xi$  for HGSLF. These new parameters would determine the exploration or exploitation capabilities of the algorithms respectively.

TABLE II. PARAMETER SETTING FOR EGSA

Parameter	Value
Gravitational initial value, $G_o$	100
Alpha, $\alpha$	20
Epsilon, $\epsilon$	0.00001
Mass ratio	0.1
Distance ratio	0.9

TABLE III. PARAMETER SETTING FOR IGSA

Parameter	Value
Gravitational initial value, $G_o$	100
Alpha, $\alpha$	20
Epsilon, $\epsilon$	0.0001
$\theta$ (constant operator)	100
$\rho$ (small value)	$10^{-16}$

TABLE IV. PARAMETER SETTING FOR HGSLF

Parameter	Value
Gravitational initial value, $G_o$	100
Alpha, $\alpha$	20
Epsilon, $\epsilon$	0.0001
$\xi$ (threshold constant)	$10^{-3}$

#### IV. RESULT AND DISCUSSION

The experimental results in this research have been divided into the fitness values and processing times evaluations. These performance measurements have been evaluated based on the statistical analyses.

##### A. Fitness Values

This section provides the fitness value analyses from the results of the benchmark testing between eGSA and the other two comparison algorithms, IGSA and HGSLF. In the benchmark functions testing, each of the dimension of the function is 30 ( $n=30$ ), the population size is 50 ( $N=50$ ) and the maximum iteration ( $t_{max}$ ) has been set to 1000. Based on Table I, the minimum values ( $f_{opt}$ ) for all of the 7 functions are 0, except for  $F_6$  which has a minimum value of  $-418.9829 \times n$ . The minimization results of the benchmark functions testing for each of the algorithm are shown in the following Table V. The best, worst and the mean fitness of the solutions, which have been averaged over 30 runs have been recorded in the table.

Based on Table V, the performance of eGSA is acceptable in all of the seven functions. Based on the overall results, eGSA is able to minimize the unimodal and multimodal functions. The mean fitness values for  $F_1$  (0.4822) and  $F_2$  (0) have been able to reach 0, while for  $F_3$  (6.6875),  $F_4$  (4.2713)

and  $F_5$  (1.7320), the mean fitness values are almost reaching 0 values. For  $F_6$  and  $F_7$ , these multimodal functions have many local optima and are difficult to optimize. However, eGSA has been able to minimize the functions and the results are satisfying. Based on Table V, the overall results show that the performance of eGSA is better than IGSA and HGSLF in almost all of the functions.

TABLE V. MINIMIZATION RESULTS OF BENCHMARK FUNCTIONS

Test Function		eGSA	IGSA	HGSLF
F1	Best	0.0191	20224.06	16124.47
	Worst	1.4021	28298.42	24884.73
	Mean	0.4822	24072.19	20618.17
F2	Best	0	0	0
	Worst	0	0	0
	Mean	0	0	0
F3	Best	6.0192	78.2867	17771.13
	Worst	7.5000	306.7619	22977.62
	Mean	6.6875	147.2939	20447.29
F4	Best	1.3216	72.7237	69.0424
	Worst	7.7193	137.6973	85.0527
	Mean	4.2713	104.4885	78.1088
F5	Best	0.2022	305.2722	472.9982
	Worst	3.4489	342.4960	613.2155
	Mean	1.7320	324.3189	538.8112
F6	Best	-3360.7363	-2598.1066	-3937.7373
	Worst	-2852.5944	-2187.7641	-3586.5394
	Mean	-3150.2839	-2396.7062	-3780.7486
F7	Best	270.7417	378.7011	379.4766
	Worst	293.9898	445.3634	391.2795
	Mean	278.5284	414.4412	385.0295

The performance of eGSA, IGSA and HGSLF for the minimizations of the unimodal functions  $F_1$  to  $F_4$  have been illustrated in Fig. 3 to Fig. 6. The figures show that eGSA is able to minimize and is able to converge with better mean fitness values compared to the other algorithms. As for IGSA and HGSLF, the algorithms still have been able to minimize and converge with larger values in most of the functions. However, IGSA has not been able to further minimize the results in  $F_1$  and  $F_4$ . This is due to the decrement of the values in the minimization that have been very small, which is in decimal point values. In the early iteration of IGSA, most of the agents have been disrupted and their position values have been changed to become much smaller due to the multiplication with the  $D$  value.

In this research, the algorithms have been coded using Java for experimental purposes. Java has some limitations such as limited floating point representation and the random numbers are generated based on the pseudorandom numbers. The initial seeding of the population is important as it would affect the final results. However, the HGSLF is still able to minimize most of the benchmark functions. In this research, it is the IGSA that has difficulties in the function minimizations, most probably due to its more complex additional structure and also due to Java limitation in the floating point representation.

Fig. 3. Performance of the algorithms in the minimization of F1.

Fig. 4. Performance of the algorithms in the minimization of F2.

Fig. 5. Performance of the algorithms in the minimization of F3.

As for the multimodal functions, the performance results have been illustrated from Fig. 7 to Fig. 9. Fig. 7 shows that all of the algorithms have been able to minimize and obtain the  $f_{min}$  values of 0 for function F5. Fig. 8 and Fig. 9 show that for functions F6 and F7, eGSA and HGSLF have been able to minimize and have obtained acceptable mean fitness values. However, IGSA is unable to further minimize as it tends to trap in the local optima as shown in the F6 and F7 results. In this experimental study, it is difficult for IGSA to search for the global optimum in the minimization of the F6 and F7

functions. This is also due to the very small decrement values in the minimization of the functions.

In this experimental study, the results of IGSA and HGSLF were not as good as that had been previously reported. The reported previous results have been tested using Matlab which has limitless floating point numbers. However, in this research, Java has been selected and used for experimental purposes compared to the standard Matlab tool. Java is also a popular, powerful and robust programming language that has been implemented in various applications. This research has shown that Java could also be used for the minimization of test functions for optimization problems.

Fig. 9. Performance of the algorithms in the minimization of F7

### B. Processing Times

This section provides the processing times taken by eGSA, IGSA and HGSLF to minimize all of the seven benchmarks functions in this experimental study. Table VI shows the processing times for the seven benchmark test functions.

TABLE VI. PROCESSING TIMES FOR BENCHMARK TEST FUNCTIONS (MS)

Test Function		eGSA	IGSA	HGSLF
F1	Min	671	3686	2215
	Max	814	3809	5042
	Mean	<b>732</b>	3745	3489.75
F2	Min	239	2883	2711
	Max	433	4435	4582
	Mean	<b>314.40</b>	3780	3543.25
F3	Min	615	3836	2702
	Max	650	3926	4618
	Mean	<b>633.67</b>	3871.25	3542.25
F4	Min	609	2448	4088
	Max	689	2576	6197
	Mean	<b>646.25</b>	2489	5280.75
F5	Min	800	3726	2873
	Max	994	4031	5353
	Mean	<b>898.33</b>	3866	3891.25
F6	Min	4707	4566	3932
	Max	5749	6095	4763
	Mean	5304.20	5242.75	<b>4328.50</b>
F7	Min	3822	3975	3885
	Max	4283	6021	5537
	Mean	<b>3979</b>	4845	4508.33

Based on Table VI, the mean processing times of eGSA for most of the functions, except F6, have been the lowest compared to the other 2 algorithms. These faster processing times have been due to the eGSA concept which is to reduce the number of active agents in the search space. In eGSA, the active agents would be selected initially based on the mass ratio and then would further be selected based on the distance ratio. Table VII shows the average number of active agents in eGSA over the 30 runs after the mass ratio and distance ratio parameters have been applied in the search space. Based on the table, it could be seen that the number of active agents have

been reduced from the initial number of 50 after the mass ratio parameter have been applied. These active agents are the agents with bigger masses and represent good solutions in the search space. This mass ratio has been applied to improve the exploration of good solutions in the search space. In order to further improve the solution quality and the processing times, the active agents are further selected for the accumulation of forces between agents. Thus, the number of active agents would further be decreased after the implementation of the distance ratio parameter. This distance ratio parameter has been applied to improve the exploitation capability of eGSA. Based on the distance ratio, only the neighboring agents within the specified ratio would be selected for the accumulation of forces.

TABLE VII. AVERAGE NUMBER OF ACTIVE AGENTS BASED ON eGSA CONCEPT

	F1	F2	F3	F4	F5	F6	F7
Mass ratio	11	21	10	23	18	23	25
Distance ratio	8	16	7	20	14	19	21

As for IGSA and HGSLF, the number of active agents in the search space would not be reduced. Based on their respective concepts, only the positions of the related agents would be changed in the search space. Thus, the processing times of both of the algorithms would not be reduced in this functions minimizations. In both of the algorithms, the position changes have been designed in order to further improve especially in the exploration capabilities of the algorithms.

### C. Discussion

In the benchmark function testing, eGSA has been able to minimize and produce acceptable results. Based on the testing, the proposed enhancements have been able to improve the algorithm's convergence strategy. In the minimization results, the mean fitnesses of eGSA in almost all of the test functions are better than IGSA and HGSLF. The execution time of eGSA are also lesser than the other two variants in all of the test functions testing. This shows that the introduction of the two new parameters has been able to improve on the exploration and exploitation capabilities of the algorithm [30]. The mass ratio parameter would improve the exploration, in which the algorithm would select only the good solutions based on the mass ratio in the search space and eliminate the weaker solutions. After the exploration, the distance ratio parameter would take over to improve the exploitation capability of the algorithm. Based on the distance ratio, only the nearest agents would be selected in finding the optimal solution. Due to this approach, the search space would become smaller in scale and the algorithm would be inclined to search more locally [31]. These two parameters are expected to create a good balance between the exploration and the exploitation strategies in the enhanced algorithm. It is expected that the enhanced GSA (eGSA) could achieve both the efficient global and local searches in order to improve its convergence to optimal solution. This would help in obtaining better solution quality and reduce the execution time in solving real world optimization problems.

## V. CONCLUSION

This paper has discussed on the improvement of GSA convergence strategy, which is based on the two enhancements. The first enhancement is to assign *Kbest* agents based on the mass ratio parameter. This approach could filter and reduce the number of active agents in the search space. The second enhancement is the implementation of the distance ratio parameter to select only the nearest agents for the accumulation of forces among the *Kbest* agents. This second approach would reselect the agents based on the distance in order to further improve the execution time and also improve the solution quality.

The contribution of the research is the introduction of a new variant of GSA, namely enhanced GSA (eGSA) which could improve the algorithm's convergence strategy. Improved convergence strategy is expected to improve the performance of GSA in terms of its solution quality and computational time. In this research, eGSA has been designed mainly to reduce the number of active agents for the accumulation of the gravitational forces. The mass ratio and distance ratio operators have been designed to select only the bigger masses which represent the best solutions in the search space. It is expected that eGSA could improve the exploration and exploitation capabilities compared to the standard GSA and other variants. Significantly, eGSA has been able to perform better than two other GSA variants in the benchmark testing. The conclusion that could be derived based on the testing results is that the enhancement made to GSA has been successfully improve the algorithm's convergence, thus improving its solution quality and the processing time. The enhancements in the exploration and exploitation strategies of eGSA has enabled the algorithm to produce better results. The benchmark function testing results have shown that eGSA could produce good performance in solving minimization problems.

In future, the research on the enhancements or modifications of GSA would continue to expand as GSA has increasingly gained attentions due to its acceptable performance in solving various optimization problems. Besides, currently there are various real world optimization problems that need to be explored and solved using metaheuristics approaches.

## ACKNOWLEDGMENT

Special gratitude goes to Universiti Teknologi MARA Cawangan Terengganu for the continuous support given to the advancement of research and publication in the university. This research is funded under the UiTM Geran Penyelidikan Myra Lepas PHD (600-RMC/GPM LPHD 5/3 (068/2021).

**Abstract**—Unified Modeling Language (UML) activity diagrams are derived from use case diagrams. It becomes essential to incorporate security features and maintain consistency in the diagrams during analysis phase of Software Development Life Cycle (SDLC). As part of current software development practices, software security must be a constant effort. The activity diagrams are used to model business process. The detailed analysis of activity diagram is done. The challenge lies in viewing the main activity diagram from attacker's perspective and providing defense mechanism to mitigate the attacks. This paper presents an extension of the activity diagram named SecUML3Activity to provide security with Object Constraint Language (OCL) constraints using Five Primary Security Input Validation Attributes (FPSIVA) parameters for input validation. It also proposed three security color code notations and stereotypes in activity diagrams. White color is used to represent activity diagram in normal state. Red color in dotted line is used to represent attack activity components. Blue color with double line is used to represent the defensive activity components. The defense mechanism algorithm against SQL Injection (SQLI) attack, Cross Site Scripting (XSS) attack, DoS/DDoS attack, access validation attack is provided. The mapping of Secure 3-Use Case diagram with SecUML3Activity diagram is done through mathematical modeling.

**Keywords**—Unified modeling language; activity diagram; object constraint language; SQL injection; use case diagram

## I. INTRODUCTION

Unified modeling language (UML) is a visual language rather than a programming language to help software developers. It is used to build real-time systems and shows visual representation of the behavior and structure of the system in software development [3]. UML modeling can be done with the help of tools like StarUML, Microsoft Visio, ArgoUML, MagicDraw, BOUML, Visual Paradigm and the like [24]. UML or Object Constraint Language (OCL) is used in designing financial systems where incorporation of security is a primary concern.

Activity diagram is used to show the diagrammatic flow of events taking place in a use case diagram. It shows the dynamic behavior of a system like control flow and object flow from one action to another which is one of the main UML modeling techniques [1][4]. It is used to model security requirements in the business processes, modeling parallel and concurrent flows in an actual system and illustrate the scenario of detailing complex use cases [2][7][25].

In earlier work, Colored Petri Net (CPN) has been proposed to ensure consistency between use cases and activity diagrams [26][27][28]. Jurjens proposed UMLsec to specify security information during the development of security critical systems and provided tool-support for formal security verification using security scenarios into a system design [33]. UMLsec employs use case diagrams to capture security requirements. UMLsec defines 21 stereotypes to represent fair exchange, non-repudiation, role-based access control, secure communication link, confidentiality, integrity, authenticity, freshness of a message, secure information flow among components, and guarded access. Some stereotypes also have associated tags and constraints.

The foundation of secure SRS is consideration of security requirements to mitigate severe vulnerabilities mentioned in the vulnerability databases [15]. Secure SRS considers security requirements like input validation, multi-factor authentication to enhance UML use case, class and state transition diagrams [4][5]. In this paper, we proposed security stereotypes, colored notations to distinguish main activity diagram from attackers' activity diagram and defensive activity diagram. FPSIVA parameters based on OCL constraints are used to provide defense mechanisms in activity diagram and mitigate vulnerability in the analysis phase of SDLC. These stereotypes help developers to build functionalities carefully and flawlessly during the implementation process. Also, defense mechanism algorithms are proposed in this research work to build secure activity diagrams. The consistency between UML diagrams is maintained through relationship between proposed SecUML3Activity diagram and Secure 3-Use Case diagram proposed by authors in earlier work [2].

The paper is organized as follows. Section II describes a detailed literature survey of activity diagram, notations to draw activity diagram, relationship of activity diagram with use case diagram. Section III covers the proposed secure activity diagram: SecUML3Activity with security color notations and stereotypes using FPSIVA parameters, and defense mechanism algorithm. Section IV is used for result and discussion related to this work. Section V concludes the paper and gives direction to the future work.

## II. LITERATURE SURVEY

UML diagrams are used to visualize various perspectives of the software system. Since they are dependent on each other, the consistency between the diagrams is desired in earlier phases of SDLC. In comparison to static modeling, consistency is a more delicate issue in dynamic modeling. Non-compliance

of consistency among these diagrams lead to errors being introduced during software development and make it vulnerable to attacks like SQLI, XSS, DoS/ DDoS attack and access validation attack [12][13]. Relational Language for Advanced Security (ReAlSec) is a security engineering tool to find security threats [31]. A specification cannot be fully represented by a UML diagram on its own. Consequently, the dynamic diagrams would require a common notation among them. The external behavior of the systems to be built is meant to be expressed using use case diagrams and activity diagrams. Activity diagrams are used to show the dynamic behavior aspect of a given system by modeling data flow [1][2][18].

The Object Constraint Language (OCL) is a declarative language and forms part of the UML standard and plays a crucial role in the analysis phase of SDLC. It is an expression language used to describe constraints and other modeling artifacts that cannot be stated using conventional grammatical notations [4][28]. OCL constraint is acting as a restriction on a model to ensure consistency. Although it is designed at the class level, its semantics are applied at the object level [1][3][9][10][29]. The security of activity diagrams can be enhanced using OCL [2][4].

Activity diagrams are basically used to represent flow of events used in use case diagrams, modeling complex requirements and implementation details [11][26]. These diagrams look like data flow diagrams (DFDs) in structured analysis (SA), However, DFDs in SA are used for capturing, analyzing, and documenting requirements. They are best suited for modeling parallel and concurrent flows in an actual system. The activity can be explained as an operation of the system [6][7]. Due to the richer constructs, it offers, such as concurrency, split, and synchronization, the UML activity diagram has been utilized in process modeling and workflow modeling [20]. They have a significance in software testing [10][17][30]. They are divided into two kinds such as atomic activity diagram and compound activity diagram based on sub activity state. Managing the compound activity diagram is a significant problem when creating test cases [1].

#### A. Analysis of UML Activity Diagram

Some definitions of the activity diagram can be presented in a formal manner.

1) Activity diagram (AD) is a tuple consisting of –

$$AD = (N, E, C, R)$$

where  $N, E, C, R$  are a finite set of activity nodes, directed edges, containment and flow relationship between the nodes or containments respectively.

Activity nodes consist of action nodes  $N_a$ , object nodes  $N_o$  and control nodes  $N_c$ .

$$N = N_a \cup N_o \cup N_c$$

Directed edges are a finite set of edges.

$$E = \{e_1, e_2, e_3, e_n\}$$

$C$  contains graphical elements for containment and it is formally defined as a tuple consisting of activities, interruptible regions, exception handlers, expansion regions.

$$C = (Activities, IR, EH, ER)$$

The flow relationship  $R$  is explained as follows.

$$R \subseteq (N \vee C) \times E \times (N \vee C)$$

The control node consists of given disjoint sets as below.

$$N_c = I \cup D \cup M \cup P \cup J \cup F$$

where  $I, D, M, P, J$  and  $F$  are finite sets of initial nodes, decision/branch, merge, forks, joins and final nodes that cover activity final and flow final nodes. So,  $F$  can be denoted as  $F = F_a \cup F_f$ , where  $F_a$  is a finite set of activity final nodes and  $F_f$  is a finite set of flow final nodes. And  $F$  are finite sets of initial nodes, decision/branch, merge, forks, joins and final nodes that cover activity final and flow final nodes [19].

2) Activity diagram (AD) is a tuple consisting of –

$$D = (A, T, F, C, aI, aF)$$

where  $A, T, F, C, aI, aF$  are a finite set of activity states, completion transitions, guard conditions, flow relationship, initial activity state and final activity state respectively and described as below.

$$A = \{a_1, a_2, \dots, a_m\}$$

$$T = \{t_1, t_2, \dots, t_n\}$$

$$C = \{c_1, c_2, \dots, c_n\}$$

$$F \subseteq (A \times T \times C) \cup (T \times C \times A)$$

$$aI \in A$$

$$aF \in A$$

There is only one transition  $t$  such that  $(aI, t, a) \in F$ , and  $(a, t', aI) \notin F$  or  $(aF, t', a) \notin F$  for any  $t', a$ . The activity diagram is used to represent composite activities. Each activity node is handled individually and treats concurrent activities as an interleaving sequence of activities [17][18].

3) Since every use case *useCase* gets converted to activity diagram, the complete set of all activity diagrams  $AD$  contains many  $ad_{useCase}$ .

$$ad_{useCase} \in AD$$

As each activity diagram consists of initial node, activity nodes and activity partitions,

$$AD = \{IN, AN, AP\}$$

where,  $IN$  denotes the initial node. Every activity diagram must have an initial node.

$$IN_{useCase} \in IN$$

$AN$  denotes the activity node. There may be zero or more activity nodes in an activity diagram.

$$AN_{useCase} \in AN$$

$AP$  denotes the activity partitions. There may be zero or more activity partitions in an activity diagram.

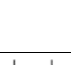

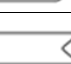

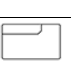

$$AP_{useCase} \in AP$$

### B. Activity Diagram Notations

The graphical notations are used for modeling activity diagrams including nodes and edges. The diagrams must ensure their semantics to conform to the UML activities metamodel [6][8]. The activity diagram notations are shown in Table I.

TABLE I. ACTIVITY DIAGRAM NOTATIONS

Element	Symbol	Description
Start		Start symbol in activity diagrams is used to indicate the start of a process or workflow.
Activity		It outlines the tasks that participate in a modeled process. It serves as the foundation of an activity diagram.
Connector		It indicates the directional flow or control flow of the activity. After a step in an activity is complete, the flow is continued by an outgoing arrow. A step in an activity is initiated by an incoming arrow.
Joint/Synchronization bar		Two ongoing tasks get combined and reintroduce them to a flow in which only one task is carried out at once.
Fork		Two concurrent operations are split from one main flow of activity.
Decision		Minimum two paths diverge at a decision and users get to view options. This symbol indicates the branching or merging of various flows.
Send signal		It conveys to a receiving activity that a signal is being sent.
Receive signal		It shows that an event has been accepted. Flow that comes from this action is completed once the event is received.
Option loop		It gives the designer the ability to depict a repeating sequence inside the loop symbol.
Flow final		It denotes the end of a particular process flow. The end of a process should be done with a flow final symbol.
Condition text	[Condition]	The developer comes to know under what condition an activity flow should split off in that direction.
End		It denotes the finish of an activity and the end of all process flows.

### C. Relationship of Activity Diagram with use Case Diagram

A systematic mapping of activity diagram with use case Diagram is described below [22][23][26][27][28].

Rule 1: Every use case must be represented by at least one activity diagram, else there will be inconsistency leading to fault in software development.

$$\exists useCase \in UseCase_{sysModel}: \exists AD_{useCase} AD_{sysModel}$$

Rule 2: An actor in a use case must be an activity partition in the corresponding activity diagram.

$$\exists actor, (assoc(actor, UseCase), \exists ap \in AP_{useCase})$$

Rule 3: Let use case diagrams UC1 includes UC2 where UC1 is the including use case and UC2 is included use case. Then event flows of both UC1 and UC2 must be specified in

the activity diagram. The action node in UC1 should refer to the activity diagram specifying use case UC2.

$$include = (including, included) \in Include$$

$$where\ including, included \in UseCase : act_{included} \in ACT_{including}$$

Rule 4: Every flow of event mentioned in the use case description or implied therein needs to be described in detail in the related event of the activity diagram. This rule is only applicable if the use case is further described in the activity diagram.

Rule 5: The event in the use case diagram has a one-to-one mapping with an action/activity state in the corresponding activity diagram.

### D. Object Constraint Language (OCL)

OCL is a formal specification language that can be used to define expressions and constraints on object-oriented models and other object modeling artifacts. IBM created the Object Constraint Language in 1995. It was initially used as a business engineering language, but it was later incorporated into the Unified Modelling Language (UML) as a formal specification language. Starting with version 1.1, OCL was included in the official OMG (Object Management Group) standard for UML. It enables programmers to communicate restrictions and guidelines that control the organization and operation of software systems. OCL 2.0 is the latest version as of September 2021. OCL is a powerful language with built-in capabilities for iterating over collections of objects, finding the value of an item, and navigating across a group of related objects. Primitive types such as Integer, Real, Boolean, and String, as well as Collections types such as Set, Bag, ordered set, and Sequence, are included in OCL's predefined standard library [14]. OCL can be used in many ways. For any expression over a UML model, it can be used as a query language to specify invariants on classes and types in the class model, type invariants for stereotypes, pre- and post-conditions on operations and methods, guards, target (sets) for messages and actions, constraints on operations, and derivation rules for attributes [3][4]. As each OCL expression has a type, it is considered as a typed language [4].

An activity diagram becomes more comprehensible when it is modeled using UML notations. To non-technical individuals, such as a client, the pictorial depiction makes knowledge transfer simple. However, there can be certain discrepancies in the diagrams if a programmer uses them as a reference when building implementation code. For instance, it's possible that the diagram doesn't show the beginning values for some characteristics or doesn't clearly indicate the limitations. In these circumstances, it is impossible for the programmer to develop the entire program without consulting the required specification or other documentation. OCL aids in the improvement of the UML diagrams and, as a result, writes the complete code for the same [4].

1) **INVARIANT**: It is a constraint that specifies a condition that must always hold true for a particular class or a set of objects. Invariants are used to define the integrity rules of a system and ensure the consistency of the data.

*Example-*  
*context Person*

*inv: self.age > 0 and self.age < 120*

A "Person" class that has an invariant specified on it. According to the invariant, a person's age must be more than 0 and less than 120. By doing this, it is ensured that a person's age is within a suitable range and that inaccurate or unrealistic figures are avoided.

Invariants are typically expressed in the context of a class and use the keyword "context" followed by the class name. The "self" keyword refers to the instance of the class on which the invariant is being evaluated. In this case, "self.age" points to the age of the Person object.

2) **PRE-CONDITIONS:** In OCL, preconditions and postconditions are used to define the conditions that must hold true before and after an operation or method is executed, respectively. They help define the expected behavior and constraints associated with an operation.

*Syntax*

*context <classifier>: <operation> (<parameters>)*

*Pre [<constraints name>]:*

*<Boolean OCL expression>*

The examples of a precondition in OCL is as below.

Let's consider a class called "BankAccount" with a method "withdraw" that deducts a specified amount from the account balance. The precondition for this method could be that the withdrawal amount should be positive and not exceed the current balance.

*context BankAccount :: withdraw(amount: Integer)*

*pre: amount > 0 and amount <= self.balance*

In this example, the precondition specifies that the "amount" parameter passed to the "withdraw" method should be greater than 0 and less than or equal to the current balance of the bank account. This ensures that a valid withdrawal amount is provided and prevents overdrawing from the account.

3) **POST-CONDITIONS:** Preconditions and postconditions are used to document and enforce the expected behavior of operations. They help in validating inputs and ensuring the desired outcomes or effects of operations on objects or systems.

*Syntax*

*Context <classifier> :: <operation> (<parameters>)*

*Post [<constraints name >]:*

*<Boolean OCL expression>*

The examples of a postcondition in OCL is-

Let's consider the same "BankAccount" class with a method "deposit" that adds a specified amount to the account balance. The postcondition for this method could be that the account balance should increase by the deposited amount.

*context BankAccount::deposit(amount: Integer)*

*post: self.balance = self.balance@pre + amount*

In this example, the postcondition specifies that the "balance" property of the bank account after executing the "deposit" method should be equal to the balance before the method was called plus the deposited amount. This ensures that the deposit operation updates the account balance correctly [14].

### III. PROPOSED SECURE ACTIVITY DIAGRAM: SECUML3ACTIVITY

In this proposed SecUML3Activity diagram, dynamic aspects of the system are shown with security stereotypes in color code notations, OCL constraints and defense mechanism algorithms. An illustration of a dynamic security specification is the operation of an authentication mechanism. There is not a comprehensive design-level behavioral definition of security stereotypes in any of the dynamic security standards that developers and programmers might employ during the implementation stage. In this paper, we are proposing security features for SecUML3Activity diagram which is an extension of detailed analysis of Login Use Case of Secure 3-Use Case diagram proposed by authors [4].

#### A. Proposed Security Notations and Stereotypes in Activity Diagrams

It is easier to understand an activity diagram when it is modeled using UML notations. Information can be easily communicated to non-technical staff members, such as a client by way of a picture. However, there might be certain gaps in the UML diagrams when a programmer uses them to write implementation code. For instance, it is possible that the diagram doesn't show the initial values for certain attributes or doesn't clearly define the constraints. Writing the entire code without consulting the requirement specification or other documentation becomes challenging for the programmer. OCL plays an important role to clarify the UML diagrams, and accordingly write the complete code for the same. Since activity diagram is a behavior model, the relationship between model elements is usually more complex. Software engineering research encourages systematic literature review for identifying, evaluating, and interpreting research question [32]. The use of colors has been recognized in software engineering research to make software modeling more comprehensible. The proposed activity diagram notations are represented in various colors codes along with color description as mentioned in Table II.

The proposed colored notations are helpful in visual representation and reduce the cognitive load of software developers. The white color is used to represent normal activity diagram notations; red color in dotted line represents attacks performed by external entities. The double lined blue color is used to represent the attack mitigation and providing defense mechanism. These colored notations for SecUML3Activity

diagrams are mentioned in Table III for attack and defensive activity.

TABLE II. COLOR NOTATIONS DESCRIPTION

Color	Description
White	White represent component is in normal state.
Red	Red color is used to represent/highlight insecure or threatened components. These components are more likely to get attacked successfully by outside entities.
Blue	Blue is to represent the defensive or precautionary components. These components act as defensive measures to avoid or mitigate attack.

TABLE III. PROPOSED NOTATIONS FOR SECUML3ACTIVITY DIAGRAM

Symbol	Activity Diagram Notations	Attack Notations	Defense Notations
Start			
Activity			
Connector			
Joint/Synchronization bar			
Fork			
Decision			
Send signal			
Receive signal			
End			

The stereotypes proposed by authors are used to develop secure implementation. The developer can prevent attacks like Buffer Overflow (BOF), SQL Injection (SQLI), Encryption, Session Expiration, Connection flooding for login into the system.

Stereotype: << BufferOverflow >>

Tag: {BOF}

Stereotype: <<Encryption>>

Tag: {Encryptfield}

Stereotype: <<SQLi>>

Tag: { SQLfield }

If the logged in user remains idle for more than specified time, the session must be forcibly killed to prevent session expiration attacks using

Stereotype: <<SessionExpiry>>

Tag: {Exp\_Time}

If there is a vulnerability in an application to allow more connections than the service provider supports, the stereotype must be inserted in the diagram part that represents the maximum number of allowed connections.

Stereotype: <<maxconn>>

Tag: {Maxconn}

### B. Proposed Secure Constraints in SecUML3Activity Diagram

The OCL constraint is proposed to check the length, any special characters in entered username and password in the login page with the help of constraints. The foundation for applying Five Primary Security Input Validation Attributes (FPSIVA) in the web design phase is OCL [16][21]. It defines FPSIVA which can be used to design activity diagrams in software development. The below mentioned stereotypes used in activity diagrams are designed using FPSIVA parameters.

<<Precondition >>

Context Login :: checkCredentials()

Pre: user name <=12

Pre: Pwd >=8

<<Invariant >>

Context Login :: checkCredentials()

user name =Boolean

Pwd=Boolean

<<Invariant >>

Context Login :: checkCredentials()

Is active=Boolean

It must be ensured that post condition invariants to be applied after login entry to homepage as mentioned below –

<<Postcondition>>

Context Home :: checkAllowUser()

Post: valid User=Boolean

Post: Pwd=Ecrypt(password)

The password needs to be encrypted for transferring over the communication network. Number of attempts by malicious user can be detected with the help of following constraint -

Context Login Invariant :

No. of attempt : self. User > 5

FPSIVA parameters can be used for input validation in activity diagram such as -

(i) var.type : < type > - It is used to validate the type of input data and verify if it can be accepted < type >.

user name: string

(ii) var.format : < pattern > - It is used to validate the format of input data and verify if it can be accepted < pattern >.

(iii) var.length : < number > - It is used to validate the length of input data.

user name.length : 12, Pwd.length :8

(iv) var.Charset: < pattern > - It is used to check characters with its < pattern >

user name.charset : [A-Z, a-z, 0-9].

(v) var.value : < reasonableness > - It is used to check reasonable values of input data.

No of attempts.value:5.

### C. SecUML3ActivityDesign

The proposed SecUML3Activity diagram for Login use case of College Management System (CMS) is divided into three swim lanes like Login Activity, Attack Activity, and Defense Activity. The complete flow of the system is shown by the Activity diagram. The swimlane of the activity diagram will be mapped with 2 swim lanes. The first swimlane will be simulated for attack. Each activity with a dotted line in red color notation and second swimlane will be simulated for providing defense mechanisms in blue color double line notations for the attacks. Due to space constraint, we have shown the Login activity of the case study. The proposed security color code notations, stereotypes and constraints are simulated with the login activity diagram in College Management case study as shown in Fig. 1. The login activity end element A is connected to start element of attack activity diagram. The end element of attack activity diagram B is connected to start element of defense activity diagram.

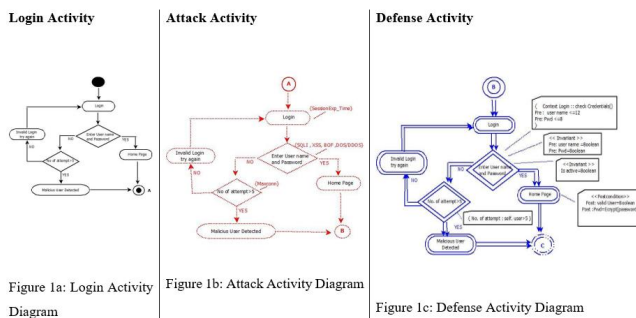

Fig. 1. Proposed SecUML3Activity diagram of Login CMS Use Case.

For clear visualization of the activity diagram, each activity as well as complete proposed SecUML3Activity diagram is shown in Appendix A (Fig. 2 to Fig. 5).

### D. Proposed relationship between SecUML3 Activity and Secure 3 Use Case Diagram

Activity diagrams are basically behavioral representations of use case diagrams with the flow of events. The login use case proposed by the author at [2] is simulated in SecUML3 Activity Diagram. The Secure 3-UseCase is already proposed with the Secure SRS model with CIA-AAA verification during authentication of user's login to the system. The security of use cases is enhanced by considering functional requirements, non-functional requirements, and quality attributes in Secure SRS model [2]. The notations, stereotypes and defense algorithms used in Secure 3-UseCase are inherited in SecUML3 Activity Diagram of College Management System (CMS) to mitigate the attacks in the real world.

Based on SecUML3Activity diagram for Login use case shown in Fig. 1, i.e.

$$Login_{CMS} \in Secure3UseCase_{CMS}$$

$$adLogin \in SecUML3AD_{CMS}$$

where Initial node is  $IN_{Login} \in IN_{CMS}$

and Activity partition is  $Faculty \in AP_{Login}$

There is consistency between Secure 3-UseCase diagram and SecUML3Activity Diagram through the relationship mentioned below.

$$\exists Login \in Secure3UseCase_{CMS}: \exists adLogin \in SecUML3AD_{CMS}$$

### E. Proposed Defense Mechanism Algorithm

The following Defense Mechanism Algorithm against Web based attacks were defined.

1) *SQL injection*: SQLI attacks take place on software applications through different methods like Tautologies, Illegal/Logically Incorrect Queries, UNION Query, Piggy-Backed Queries, Timing Inference attack.

Incident  $\in$  {Web page Field Access, URL Header Access}

#### Algorithm 1: Defense Mechanism Algorithm against SQL Injection

INPUT: SQL Injection through text fields in the web page.

OUTPUT: A secure web page that is free from SQLi.

Start

Read text entered by user in text fields

Create insert parameterized queries instead of string concatenation

Create roles.

For each role,

```
{
  Assign a User
}
```

For each user,

```
{
  Grant appropriate permissions to accomplish Role
  Based Access Control
}
```

---

```
| }  
  
| If User has permission to perform action on Database  
| | {  
| |   Fire Query  
| | }  
| Else  
| | {  
| |   Drop user inserted malicious query.  
| |   Use escape Queries for user inputs to get rid of  
| |   special characters.  
| | }  
End
```

---

2) *Cross Site Scripting (XSS)*: XSS attack occurs when dynamic content that hasn't been checked for malicious content, proper validation makes entry into a web page field.

Incident  $\in$  {Web page Field Access, URL Header Access}

---

**Algorithm 2:** Defense Mechanism Algorithm against Cross Site Scripting

---

INPUT: Input field on web page, URL header access used for taking input

OUTPUT: External script is executed

Start

Insert <body onload=alert (Testing XSS')> into input field.

Submit input

```
| If alert is shown in web browser then  
| | {  
| |   Simple XSS is performed.  
| |   Web service is vulnerable to XSS attack.  
| | }  
| Else  
| | {  
| |   Web service is not vulnerable to XSS attack.  
| | }
```

End

---

3) *Check for DoS/DDoS attacks*: DoS/DDoS attacks are classified into different types like Ping of Death, TCP SYN Attack, ICMP Smurf, UDP Flood attack. TCP SYN Attacks arising due to bugs in operating system can be prevented using security patches. Intrusion Detection Systems (IDS) are helpful to identify and stop illegal intrusion into the systems. Firewalls can be placed into the network to block traffic coming from unknown IP. Routers can be used to limit network access and dropping suspected traffic using Access Control List (ACL).

Incident  $\in$  {URL Header Access}

---

**Algorithm 3:** Defense Mechanism Algorithm against DoS/DDoS attack

---

INPUT: DoS/ DDoS attack through URL header access of web page.

OUTPUT: A secure web page that is free from DoS/ DDoS attack.

---

Start

Read (User Inputs like Source IP address, Destination IP address, Payload)

Extract IP header

```
| If Source IP  $\in$  BlackIP List, then  
| | {  
| |   Drop Packet  
| | }  
| Else if Payloadsize > Payloadthreshold then  
| | {  
| |   Drop packet and add to BlackIP List  
| | }  
| End if
```

End

---

4) *Check for access validation*: Due to absence of centralized middleware in Web page, it becomes necessary to specify the address (URI) of the page and the transport protocol (HTTP). Hence, Access validation can be done with the help of secure key management like security tokens for secure authentication.

Incident  $\in$  {Web page Field Access, URL Header Access}

---

**Algorithm 4:** Defense Mechanism Algorithm to check for access validation

---

INPUT: request through text fields, URL header access in the web page.

OUTPUT: A secure web page that is free from mis-user access attack.

Start

Issue security tokens to WSC through Security Token Service  
Bind the same security token with WSP

Validate security token for transaction

```
| If WSC Security Token  $\in$  WSP Security Token, then  
| | {  
| |   Allow payload for transaction  
| | }  
| Else  
| | {  
| |   Drop payload and cancel the transaction  
| | }
```

End

---

#### IV. RESULT AND DISCUSSION

Based on extensive literature survey, security with OCL constraints using Five Primary Security Input Validation Attributes (FPSIVA) parameters for input validation is provided. The web modeling of software applications consisting of various security-colored notations and stereotypes in secure activity diagrams is proposed to distinguish main activity diagram from attackers' activity diagram and defensive activity diagram. Also, defense mechanism algorithms are proposed to build secure activity diagrams. The consistency between UML diagram is maintained through relationship between proposed SecUML3Activity diagram and Secure 3-

Use Case diagram proposed by authors in earlier work. The various B-Tech and M-Tech software Projects are implemented using secure analysis.

Proposed SecUML3Activity diagram is derived from the Secure 3 Use Case diagram proposed by the author in their earlier work [2]. The proposed strategy is to maintain consistencies between these UML diagrams to avoid errors, defects, vulnerabilities that may arise in software development. This relationship between these two UML diagrams is well explained through mathematical modeling. The input validation of parameters is done through OCL constraints using Five Primary Security Input Validation Attributes (FPSIVA) parameters. The use of colors has been recognized by Software Engineering research to make graphical software models easier to follow, hence as per requirement of secure activity diagrams, three security color code notations and stereotypes in activity diagrams are proposed to distinguish the activities. White color is used to represent activity diagram in normal state. Red color in dotted line is used to represent attack activity components. Blue color with double line is used to represent the defensive activity components. The defense mechanism algorithms against SQL Injection (SQLI), Cross Site Scripting (XSS), DoS/ DDoS attack, access validation is also provided for making system more secure and robust.

## V. CONCLUSION AND FUTURE WORK

The main purpose of this research is to provide security in activity diagrams to prevent external and internal attacks on the web application. The defects, errors, and problems in the software systems occur due to inconsistencies between UML diagrams in analysis phase.

The security features of SecUML3Activity diagram in analysis phase of SDLC can be mapped with component diagram of software architecture, secure data structure design and secure algorithms design against top 10 attacks on software. This standardized proposed secure UML stack with defense mechanism can be used as the reference document for the coding phase and help developers to build more secure applications. The work is in progress.

# An Efficient Vision-based Approach for Optimizing Energy Consumption in Internet of Things and Smart Homes

LIU Chenguang\*

Department of Information Engineering, Hebei Chemical and Pharmaceutical College, Shijiazhuang, 050000, China

**Abstract**—One of the primary forces for digital transformation is how quickly the world is changing. Additionally, and at a dizzying pace, the world economy is being transformed by digital technology. The billions of daily online connections between individuals, organizations, devices, data, and processes that generate economic activity are known as the "digital economy." The Internet, mobile technology, and the Internet of Things (IoT) all contribute to hyper-interconnection, or the growing connectivity of people, organizations, and machines, which is the foundation of the digital economy. Simultaneously with these developments, the demand for energy is more than the supply, which leads to energy shortage. In order to keep pace with energy demand, new strategies are being developed. As a result of the emergence and expansion of smart homes, there is a growing need for digitization in applications such as energy efficient automation and safety. With the increase in the amount of electricity consumed and the introduction of new energy sources, the reduction of electricity costs for households becomes increasingly important. Basically, this article uses machine vision technology. In this paper, a YOIO method is used for facial recognition. And compared to all kinds of YOIO methods, the YOIOv5n method was the fastest and most efficient method. So, by using the YOIOv5s method on the Jetson Nano platform, it creates the possibility of authenticating the residents of the houses to identify them to turn on or off the sources of energy consumption in the houses. Therefore, the presented system is designed with the aim of optimizing energy consumption in houses and with the aim of ensuring the safety of the residents of the houses.

**Keywords**—IoT; Internet of things; digital economics; smart cities; digitization; machine vision; YOIO; YOIOv5n

## I. INTRODUCTION

Don Tapscott, an internationally recognized expert on the economic and social effects of technology, popularized the phrase "Digital Economy" in his 1994 book "The Digital Economy: Promise and Peril in the Age of Networked Intelligence." Information in all of its forms is converted to digital form in the new [digital] economy, where it is stored as bits in computers and sent over networks at the speed of light. Although the digital economy did not have a single beginning, significant turning points in its history include the invention of the internet and the introduction of personal computers in the early 1980s, the creation of the world wide web in 1989 and the public launch of that platform in the early 1990s, as well as the introduction of the first smartphones in the late 1990.

The Internet of Things (IoT) is a prevalent concept and an essential part of daily living. which are employed in a wide range of fields, such as transportation, healthcare, and industry, as well as smart homes and smart cities from a security standpoint, it appears that both intelligent devices and users must start a safe communication channel in order to recognize digital form. IoT offers a wide range of options for assisting people in carrying out their regular tasks.

The Internet of Things (IoT) today provides a powerful tool that not only connects wireless communication devices but also remote sensors for heating/cooling or any other necessary utility inside the building to more likely regulate energy usage and improve the living experience in modern homes [1]. A smart home is a house that has been incorporated into the Internet of Things (IoT) and offers its residents comfort, security, convenience, improved quality of life [2]. The IoT is the underpinning platform of a smart home network that connects various smart devices, including wearables, smart meters, and smartphones. Smart home technologies have the potential to improve and facilitate people's lives and independence.

Modern civilization is undergoing a trend known as "smart home technology," which creates intelligent living spaces for daily comfort and ease [3]. Smart homes are automated structures with control, monitoring, and detecting hardware and systems, including heating and cooling, lighting, ventilation, and security. Gateways are the name given to these contemporary systems, which include sensors and switches and communicate via a central axis. These gateways are control systems with user interfaces for smartphones, tablets, and computers. The Internet of Things controls the communication network (IoT).

The quality of human life, well-being, productivity, energy efficiency, and safety may all be impacted by the usage of smart technology in a house, building, or environment, including sensors, actuators, and artificial intelligence (AI) [4]. According to the chart below, the share of energy efficiency among smart home technology trends was 31% in 2018 and increased to 42% in 2020 and is in third place.

In the following, the second part of study refers to studies from 2020 to 2021 in the field of using the Internet of Things to optimize energy consumption in smart homes. The third part defines the methodology, the fourth part specifies results and model evaluation. The fifth part of the findings and finally the sixth part refers to the conclusion and future studies.

The main research contributions of this study are as follows,

- 1) The research paper introduces a facial recognition method based on YOLOv5n, showcasing enhanced efficiency and speed compared to other YOLO methods.
- 2) The integration of YOLOv5s onto the Jetson Nano platform enables the deployment of facial recognition systems for energy consumption optimization in residential houses with limited resources.
- 3) The presented system combines facial recognition technology with energy management, aiming to optimize energy consumption in houses while ensuring the safety of residents.

## II. RELATED WORKS

By favoring various types of equipment, people nowadays are ignoring the cost and usage of electricity. Numerous innovative methods of controlling, tracking, and monitoring a

home's energy savings have emerged as a result of rising energy prices and demand [5].

A new generation of homes called "smart homes" has been made possible by improvements in energy conversion, communication, and information technologies. These homes allow individuals to enhance the comfort, convenience, safety, and entertainment of their homes while also reducing energy waste. In many nations, Home Energy Management Systems (HEMS) are crucial for accomplishing the objectives of smart energy houses. The market for smart homes is expanding quickly as well. It is particularly getting better in areas like energy efficiency systems, lighting, entertainment, and fire detection, among others.

In Table I studies regarding the optimization of energy consumption through the Internet of Things in smart homes in 2020 to 2021 are presented.

TABLE I. RELATED WORKS

### III. METHODOLOGY

#### A. Proposed System Architecture

Due to its understanding of its own things, a smart house provides its people with individualized services. Homes should not only consume less energy but also be more livable and productive because the home environment influences people's quality of life and capacity to work. When using 2D cameras as sensors, deployment should be adjusted so that the financial gains from energy savings outweigh the associated expenses. Controlling the entire home is not practicable nor possible, it should be stressed. In addition to the activity patterns identified by data monitoring, actual 2D camera sensor data on such inputs should be used to optimize final energy management and consumption. Consequently, the gadget can adjust to new circumstances that were not present in the early models, as well as changes in the setting of the house. The three layers that make up this platform's design are sufficiently all-encompassing to address the requirements of various smart settings, including those considered in the context of smart homes. The IoT-based smart home's three-layer structure is as follows:

Layer 1: Measuring or interpreting sensor data in accordance with user preferences and saving this information in a separate cloud server through a network gateway.

Layer 2: Processing and arranging data gathered from user personal information at.

Layer 3: Data reproduction or application layer, which repeats processed data as information about specific interactions between users and equipment and applies the gathered data to enhance the functionality and performance of the device and provide users better services.

A framework with sensors that assess power use has been created in order to enhance home maintenance and make homes "smart" and efficient. In order to assess if someone is at home, the user may also use the motion sensor's processed data from the cloud service, which offer the meaning of "safe." Additionally, a voltage stabilizer will automatically operate on the installed cloud server to prevent any problems. Users may easily connect to the network using their phone service thanks to the building's Wi-Fi connection. Smart technology enables users to make their homes safer. Among the smart home devices, cameras set throughout the home enable environment monitoring from a phone or other device as needed. Residents will interact with the security system through their mobile or smart phone interfaces. The safety system reacts when it notices motion or unusual movement. As a result, it is clear that this intelligent defense is far more dependable and

trustworthy than the emergency siren. To guarantee the effective and efficient operation of all gadgets, residents will also receive the home equipment power consumption control program. Therefore, here are some of the main advantages of our smart home architecture: optimizing and reducing energy consumption, increasing the performance of the home, identify the source of electrical energy leakage, predictive maintenance improves capital use, increasing the security of the home according to the alarm system based on the presence or absence of inhabitants.

#### B. Proposed System

The regulation of energy consumption results in lower energy use throughout the house [16]. The suggested system's objective is to control or lower energy usage by machine vision. A subset of artificial intelligence is machine vision [17]. This technology uses two-dimensional cameras that are already placed in homes as vision sensors from the automobile to decrease the amount of power used. The proposed system detects whether a person is a resident or a non-resident when they enter the house. Of course, this also applies when they depart, and if a resident leaves the house, power is turned on. Electrical equipment is switched off, and if a visitor departs, the system detects him as a stranger and does not turn off the electrical equipment. This paper presents a smart home energy management system that includes 2D cameras, electric vehicles and energy storage units. The process of the system is provided in Fig. 1.

#### C. Resident Authentication

People may now be identified using a number of different authentication techniques. These techniques include visual biometric devices such as retina scans, iris recognition, fingerprint scanning, hand geometry recognition, ear authentication, signature recognition, and facial recognition as well as chemical biometric devices such as DNA (deoxyribonucleic acid) matching and vein or vascular scanners such as Finger vein ID. Behavioral identifiers such as gait and typing recognition are also included. The facial recognition approach is employed in this investigation.

1) *Face recognition process:* The system will upload photographs into the recognized member's database for the facial recognition procedure. Any new record may be added as needed to the database [18]. Add a fresh photo and the face registration name to the database. Face recognition uses the picture that is retrieved from the database and compared to the image that was collected to identify the subject in the front camera module. The door will open if a match is found in the faces. If not, a red bulb will come on. The bell will ring if it is the home's owner. If not, a message that someone is waiting

outside your house will be issued. When the image of an unfamiliar individual is found, this system provides alerts.

2) *Face recognition platform:* The facial recognition algorithm is included in Jetson Nano. In this system, data is sent via the cloud to a remote server from a smartphone. An IoT-based system can be implemented to automate the authentication process for security purposes. The electricity and power consumption in this system is low because it needs very little electricity. It needs at least five volts to work. The Nano Jetson module includes the TensorRT-powered AI development kit in JetPack. It allows the processing of complex deep learning algorithms. The specifications of the Jetson Nano used are as follows:

- GPU: 128-core NVIDIA Maxwell
- CPU: Quad-core ARM A57 @ 1.43 GHz
- Memory: 2 GB 64-bit LPDDR4 25.6 GB/s
- Storage microSD (Card not included)
- Camera 1x MIPI CSI-2 connector

3) *YOLO based face recognition:* The YOLOv5 based algorithm used for facial recognition. A single neural network was utilized by YOLO to identify and estimate positions. It predicts the positions of items based on the characteristics of the entire picture [4]. The four network model variations of YOLOv5—YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x—are based on the differences in network depth and breadth. According to the literature, the YOLOv5s network's

detection and placement speed is quicker than YOLOv4's, and its accuracy is comparable. The backbone, neck, and head are the three primary parts of the YOLOv5 network. Backbone gathers and creates image characteristics on various pictures when the image is input. Next, the Head predicts the image characteristics to provide bounding boxes and predicted categories after the Neck stitches the image features and delivers them to the prediction layer. The GIOU is the network loss function used by the YOLOv5 network, as illustrated in Equation (1).

$$GIOU = IOU - \frac{|C-(A \cup B)|}{|C|} \quad (1)$$

Where  $A, B \subseteq S \subseteq R^n$  represent two arbitrary boxes.  $C$  represents the smallest convex box,  $C \subseteq S \subseteq R^n$ , enclosing both  $A$  and  $B$  and  $IOU = |A \cap B| / |A \cup B|$ .

Combining the GIOU loss function with the non-maximum suppression method filters the best target frame when the input network predicts picture features [15].

#### D. Dataset

In this research, a dataset including 500 images was used. The images are about 50 people and collect 10 images from each. Among them, 80% of the images were used for training and 20% for evaluation. These images are labeled according to the training and evaluation of the YOLOv5 model. The YOLO pattern was used to label the images. The images are labeled in ten classes for each person.

Fig. 1. Proposed system.

#### E. Model Generation

In this study, transfer learning is used to retrain algorithms YOLOv5 series which is based on the dataset of common

objects in the field (COCO). This dataset was trained with 330 thousand images and 80 classes. This model is used as pretrained model for transfer learning. In modeling, it is used a

batch size of 16 and 100 epochs. The modeling processes are performed for different versions of YOLOv5. These versions are v5n, v5s, v5m, v5l, v5x. The model with deep layers performs better in training and converges faster, as seen by the results while training with the same number of repetitions. The v5n model in more epochs is reached in balance and the error has been minimized, but in the v5x model, there is an error in fewer epochs' energy storage units.

#### IV. RESULTS AND MODEL EVALUATION

This section presents experimental results and performance analysis for face recognition using different YOLOv5 models.

##### A. Performance Metric

Performance analysis is checked in this section. The generated model based on YOLOv5 is evaluated. In this study, Precision, Recall, F1 and mAP metrics are used for evaluation of the model.

The first three metrics are computed by TP (true positive), TN (true negative), FP (false positive) and FN (false negative). The explanations are shown in Table II.

TABLE II. THE METRICS DEFINITION FOR PERFORMANCE ANALYSIS

Metric	Explanations
TP	Refers to how many faces are successfully identified
TN	Refers to how many backgrounds are identified as backgrounds
FP	Refers to the number of backgrounds that are wrongly identified as backgrounds
FN	Refers to the number of faces that were misclassified as a backdrop

Precision (P): The precision determines the accuracy and reliability of the positive answers of the models being correct. Equation 2 presents how the P metric is calculated.

$$P = \frac{TP}{TP+FP} \quad (2)$$

Recall (R): Recall metric determines the ability and sensitivity of the models in performing the correct classification. According to equation 3, this is done by calculating the ratio of correct positive answers to the sum of correct positive answers and false negative answers. This standard is also known as the correct positive response rate and model accuracy rate.

$$R = \frac{TP}{TP+FN} \quad (3)$$

F1-score: F-score is determined according to equation 4 by calculating the equivalent weighted average of two metrics, Precision(P) and Recall(R). The detection rate of positive samples, which is the difference between the evaluation metrics, is considered by both precision and recall in the R-P curve. A more visual way to evaluate the models is the average accuracy (AP), which represents the area under the R-P curve (AUC), higher AP means better machine learning model. mAP is an average of AP values. Therefore, the higher and to the right the R-P curve is, the better the model will perform.

$$F1 - score = 2 * \frac{P*R}{P+R} \quad (4)$$

##### B. Performance Analysis

In this study, YOLO algorithm is most popular and the most efficient algorithms are selected for face recognition purpose in the proposed system. In order to do fair comparison, we experimented various versions of YOLO algorithms in the same data to demonstrate which algorithm is better than others. The result of performance analyses shows that, among the models of YOLOv5, YOLOv5n with mAP = 0.77, F1-score=0.74, R=0.70 and P=0.78 is the smallest network model, which has only 1.9 million parameters. Because the models come in various sizes, the smaller model requires less time during diagnosing. As a result, the lowest time for the YOLOv5n model is required for the huge model, which requires more time.

#### V. CONCLUSION AND FUTURE STUDIES

Large data from sensors and energy meters demand extremely effective data processing systems, where contemporary technologies like Big Data and the Internet of Things have found their place in the development of energy applications. The advancement of new data mining techniques has outpaced the capabilities of conventional energy modeling and forecast techniques. Various smart technologies have been used to save energy. Traditional building energy modeling that uses software and statistical methods does not provide the need for quick and precise prediction required by decision-making systems. As a novel approach to energy modeling and assessment for many types of buildings, IOT models have demonstrated considerable potential. The pros and drawbacks of each model are discussed in this study, which gives an overview of IOT models used for benchmarking and predicting building energy usage.

In this paper, a YOIO method is used for facial recognition. And compared to all kinds of YOIO methods, the YOIOv5n method was the fastest and most efficient method. So, by using the YOIOv5s method on the Jetson Nano platform, it creates the possibility of authenticating the residents of the houses to identify them to turn on or off the sources of energy consumption in the houses. Therefore, the presented system is designed with the aim of optimizing energy consumption in houses and with the aim of ensuring the safety of the residents of the houses. Future research can focus on optimizing energy consumption strategies by developing advanced algorithms and techniques, such as reinforcement learning, to dynamically adjust energy usage based on authenticated residents' identities and preferences. Further study should address privacy and security concerns by exploring privacy-preserving techniques and implementing robust security measures to protect sensitive resident data during the authentication process in the facial recognition-based energy optimization system. Moreover, future studies on the use of Internet of Things in smart homes to optimize energy consumption will focus more on the use of mobile phone GPS. Moreover, The Intelligent Computational Engine will be created and used with the established electric energy consumption prediction models to achieve automated, real-time, and optimum control of electric energy consumption. This will reduce ineffective energy management, wasted energy resources, and high energy prices.

# Application of Medical Brain CT/MRI Image Fusion Algorithm based on Neural Network

Dan Yang\*

School of Software and Big Data, Changzhou College of Information Technology, Changzhou, China

**Abstract**—In recent years, fused images have been developed for fast processing of medical images, which provide a more reliable basis for reducing the burden on physicians because they can contain multiple times the image information. In order to achieve fast and accurate recognition results in medical image recognition, avoid similar blocks and shadow fitting in CT/MR fusion images, and improve the entire medical system, in this study, CT/MRI image fusion of brain images is studied based on algorithms generated by Convolutional Neural Network (CNN). The study utilizes Rolling Guidance Filter (RGF) to divide medical CT/MRI images into two parts, one of which is used for model training and the other for image fusion. In the experiments, the results of all three experiments are compared with the Nonsub Sampled Contourlet Transform - Piecewise Convolutional Neural Network (NSCT - PCNN), and the CNN-RGF MI/IE/SSIM/AG values of CNN-RGF are superior compared to the conventional algorithm of NSCT-RCNN with an average improvement of 10.0% and above, and the resulting CNN-RGF observed meningitis, hydrocephalus, and cerebral infarction with an average of 24.8% higher compared to NSCT-RCNN. The outcomes show that for brain image fusion and detection, the CNN-RGF approach put forward in the study performs better.

**Keywords**—Convolutional neural network; image; integration; CT; MRI

## I. INTRODUCTION

In recent years, medical imaging has been rapidly developing as it has started to be involved in disease diagnosis and widely used in clinical treatment. As the amount of comprehensive information increases, medical images using a single modality mode gradually fail to meet the needs of physicians. The information provided by traditional medical images can be too one-sided, and there are many tissues and organs in the human body, so doctors using the naked eye to identify the images will inevitably produce eye fatigue, thus affecting the accuracy of diagnosis [1, 2]. Moreover, the development of medical devices is really backward, and the blurriness of imaging is sometimes even lower than the resolution of the human eye, so it is necessary to consider the fusion of multiple images together. Through a method to aggregate multiple medical images into one, not only can the useful information be concentrated into one, which improves the image utilization rate, but also can reduce the amount of images for doctors to see, which is convenient for doctors to locate the precise lesion and target medication to patients, and perhaps treat more difficult and complicated diseases [3]. Therefore, research on fusing multiple images together is imminent. Recently, a classical algorithm, Convolutional Neural Network (CNN), has come into the view of researchers

and become popular in image fusion. The CNN has powerful feature extraction capability, and the Rolling Guidance Filter (RGF) is able to handle the similarity blocks and anaglyph of fused images well [4]. Based on the advantages of both, this study establishes a CNN-RGF algorithm to fuse medical images at pixel level considering four plain objective quantities after CT/MRI fusion images. The aim is to achieve fast and accurate recognition results in medical image recognition, and to avoid similar blocks and shadow-fitting CT/MRI fused images. This will reduce the processing burden of doctors, improve their efficiency, and thus improve the whole medical system. The main contribution of the research is to extract and fuse different image information of the same target from different angles, levels, or types of sensors. At the same time, the low transparency information in the image is processed through image denoising, enhancement, and other image processing techniques, thereby significantly improving the accuracy, restoration, and reliability of the image, and providing clearer and more accurate expression for the generation of target images a fused image with complete content and rich image information. The innovation of the research lies in the use of a pyramid based multi-scale image decomposition method, which enables fusion at each decomposition level. Each source image is decomposed through a regional Laplacian pyramid, making the image features more distinct. Therefore, this method plays an important role in medical image fusion.

The research structure is mainly divided into four parts. The first part is a summary of relevant research on medical image fusion at home and abroad. The second part is to build a brain CT/MRI image fusion model based on CNN, and introduce the specific improvement process and research of the algorithm. The third part is to analyze the performance of the constructed model, reflecting its performance through indicators such as accuracy and error. The fourth part is a summary and analysis of the research, discussing the achievements and shortcomings of the research, and proposing suggestions for future research directions.

## II. RELATED WORKS

A very important branch of image processing technology, i.e., medical image fusion, has a very important role in doctors' rapid treatment of patients, targeted drug administration, etc. Wang et al. [5] studied multi-feature fusion in depth and proposed a medical brain image algorithm based on it. Texture information was obtained by feature extraction of CNNs, and morphological features were obtained by feature extraction of voxel information. These two types of features were concatenated and then the feature selection stage was

optimized using a heuristic search algorithm. They analyzed experimentally to select the optimal values of the parameters based on the heuristic search and extracted the optimal feature subset after determining the parameter values. Finally, the algorithm improved the accuracy and efficiency of brain image classification compared to similar algorithms. Polinati et al. proposed a new method for medical image fusion, incorporating content decomposition and sigmoid function [6]. They considered and implemented the use of empirical wavelet transform for content-based decomposition for preserving edges and corner points. They discovered that using detail layer fusion directly results in significant artefacts, so they used the sigmoid function to improve weight scaling. They tested their suggested method with previous fusion methods after fusing 24 pairs of MRI-PET and MRI-SPECT pictures, and they discovered that both the qualitative and quantitative outcomes had significantly improved. By first filtering the CT and MR image sets through a set of various scaled filter sets, different pairs of representations of CT and MR were obtained. Each pair of different representations was then used to train the corresponding CNN to obtain the final fused image, and it was compared with nine recent state-of-the-art multimodal fusion methods. Wang et al. [7] proposed a fusion method based on a multi-CNN combination of fuzzy neural networks. The experimental findings demonstrated that in objective evaluation and visual quality, the fusion approach greatly exceeded other comparative fusion methods. The method excelled in four measures, enhanced multimodal medical picture fusion quality, and helped doctors diagnose diseases more accurately. A brand-new picture fusion technique based on sparse representation was proposed by Yu et al. [8]. They studied that after merging all source images into a joint matrix and training it by an algorithm, an overcomplete coefficient would be obtained that can be used to represent this matrix. The obtained over-completeness was used as coefficients of the image features and combined with choose-max fusion rules. The fused images were reconstructed from the connected coefficients and the overcomplete dictionary and compared with the conventional algorithms. They found that the method had better fusion performance compared to three state-of-the-art algorithms.

Using the non-subsampled shear wave transform (NSST), smooth wavelet transform, and impulsive coupled neural network, Singh and Gupta suggested a multilevel multimodal fusion model [9]. A weighted Laplace pyramid was used to extract structural features from the source image and apply them to an adaptive model that can map the feature weights used for low-band component fusion using absolute maxima and absolute differences, a rule that allows fusion of high-frequency NSST components to preserve complex directional details. The first step was to use NSST to decompose the source image into optimal sparse multi-resolution components. The strategy, when compared to previous methods, dramatically improved medical picture fusion with good visual quality and improved computational metrics, according to experimental results. The non-subsampled contour wave transform (NSCT) domain image fusion approach was proposed by Yu et al. and is based on pulse-output neural networks (PCNN) and hybrid frog-leaping algorithms (SFLA) [10]. First, the source image was decomposed into low-

frequency and high-frequency subbands using NSCT, and secondly, different PCNN fusion rules were designed. Finally, the fused images were reconstructed by inverse NSCT. The fused image preserved more of the original image's information with strong edge retention, according to a visual and quantitative examination of the experimental results. Guan et al. proposed an image fusion algorithm based on multi-scale analysis coupled with approximate sparse representation to better deal with the singularity of high-dimensional features of images and to take into account the fusion of image target features and average intensity information [11]. The high-frequency and low-frequency information of the image was obtained by the scale analysis of the source image, and the specific target detail information was highlighted. The approximate sparse representation was designed to approximate the singular curve with the smallest coefficients. A decision mapping was constructed to analyze the activity and matching degree of all coefficients on the same subband and output the decision values, which were used to match and fuse the images. Then the final fused image was obtained by multi-scale inverse transform. The experimental results showed that better visual effects can be obtained with high robustness and wide application.

Multiple researchers have found that CT/MRI image fusion algorithms are very popular internationally and have achieved relatively successful data in experiments, with an overall success rate of over 80% for image fusion [12-16]. Although image fusion has made some progress, its effectiveness still has a significant room for improvement. Research has found that there is relatively little research on using CNN algorithms to form composite neural networks in image fusion. Therefore, combining CNN and RGF can leverage their respective advantages, compensate for the shortcomings of individual algorithms, and perfectly avoid their own shortcomings. The research aims to further improve the effectiveness of medical image fusion.

### III. CNN-BASED BRAIN CT/MRI IMAGE FUSION STUDY

A medical image fusion method based on pyramid and CNN is proposed. By using multi-scale decomposition of pyramids that are more conducive to human visual perception, the fusion effect is improved. At the same time, the idea of support vector machine (SVM) is used to improve the CNN network, which does not rely on empirical initialization parameters and effectively extracts image features to obtain more suitable weight maps. The pooling and sampling layers in traditional CNN networks is removed to reduce the loss of image information.

#### A. Application of Multi-Scale Geometric Transform in Image Fusion Algorithm

The research on the overall framework of medical image fusion proposes a medical image fusion algorithm that can be summarized into the following four steps. The first step is to input the source image into an improved CNN and generate a weight map. The second step is pyramid decomposition, which uses the multi-scale image decomposition method of the pyramid to fuse at each decomposition level. Each source image is decomposed through the regional Laplace pyramid. The third step is coefficient fusion. The fourth step is the

reconstruction of the Laplace pyramid. The specific framework diagram is shown in Fig. 1.

Computed Tomography (CT) is an important tool for diagnosing lesions because of its rapid scanning capability, while Magnetic Resonance Imaging (MR) has the strongest resolution of soft tissue and can observe lesions without dead space [17-19]. By combining CT/MRI together, the accuracy of unimodal medical images can be greatly improved. For two images of the same target, the levels after fusion can be divided into three kinds, as in Fig. 2.

From Fig. 2, the fusion of images can be divided into three levels: pixel, feature and decision. Among them, direct fusion from the original image is called pixel fusion; feature extraction of the original image once and then fusion is called feature fusion; feature extraction of the image that has been extracted once and then fusion is called decision fusion, implying that a decision can be made directly from the decision fused image. The contribution of decision fusion to CT/MRI of the brain is many, including but not limited to the timely detection of lesions, saving the time of doctors and providing a possibility of cure for patients. In order that no one will suffer, this study investigates the method of brain CT/MRI image fusion, which will be discussed in detail next. Independent individual neurons have simple structures, but neural network systems composed of large numbers of neurons are rich in behavior. The relationships between neurons are intricate and

complex. The expressions of neurons are shown in Equation (1) [20].

$$\begin{cases} y_l = f \left( \sum_{k=0}^{N_2-1} \omega''_{kl} x_k'' - \theta_l'' \right) \\ x_k'' = f \left( \sum_{j=0}^{N_1-1} \omega'_{kj} x_j' - \theta_k' \right) \\ x_j' = f \left( \sum_{i=0}^{N-1} \omega_{ij} x_i - \theta_j \right) \end{cases} \quad (1)$$

In the above Equation (1), the nonlinear function is denoted as  $f$ ; two neurons are defined as  $i, j$ ; then the link between them is called  $\omega_j$  and its threshold is called  $\theta$ . To reflect how much valid information is contained in the image, Mutual Information (MI) is chosen to judge the size of information data in the image. It supposes that there exist  $(X, Y)$  as random variables and their distribution is jointly located at  $p(x, y)$ , then  $p(x)p(y)$  is called the edge of the distribution, then their relationship is as denoted in Equation (2).

$$I(X, Y) = \sum_{x \in X} \sum_{y \in Y} p(x, y) \log \frac{p(x, y)}{p(x)p(y)} \quad (2)$$

Fig. 1. Overall framework of medical image fusion process.

Fig. 2. Three different levels of image fusion.

For problems involving brain images, it is not enough to discriminate the amount of data by MI alone, but also requires the complement of Information Entropy (IE). The smaller the IE, the more residual the image is, as indicated in Equation (3).

$$H(x) = E(I(x_i)) = E\left(\log\left(2, \frac{1}{P(x_i)}\right)\right) = -\sum P(x_i) \log(2, P(x_i)) (i = 1, 2, \dots, n) \quad (3)$$

CNN is the most commonly used network model in medical field. A complete CNN mainly consists of input, convolutional, pooling, fully connected and output layers. Among them, the convolutional layer is the core of CNN and is also the source of the name of CNN. It assumes that  $\omega_i$  represents the full-valued vector, the convolution operation is noted as  $\otimes$ , and the activation function is called  $\otimes$ , the operations in the convolution layer are as expressed in Equation (4).

$$H_i = f(H_{i-1} \otimes \omega_i + b_i) \quad (4)$$

To construct multi-resolution images, the concept of Local Laplacian Pyramid (LLP) is also introduced. LLP has the power to not only accurately distinguish between the edges and textures of an image, but even to fuse the image with the tower layer. Due to many updates, LLP has never had any artifact problems. Before performing LLP operation on an image, a Gaussian Pyramid (GP) decomposition is performed, as in Equation (5).

$$\begin{cases} G_i^*\left(\frac{i+m}{2}, \frac{j+n}{2}\right) = \begin{cases} G_i\left(\frac{i+m}{2}, \frac{j+n}{2}\right) & \frac{i+m}{2}, \frac{j+n}{2} \in Z \\ 0 & \text{Elses} \end{cases} \\ G_i^*(i, j) = 4 \sum_{m=-2}^2 \sum_{n=-2}^2 w(m, n) G_i\left(\frac{i+m}{2}, \frac{j+n}{2}\right) \end{cases} \quad (5)$$

In Equation (5),  $G_i^*$  is the image after GP processing, and  $i, j$  means the current GP layer number. The image after undergoing GP decomposition cannot obtain the risk in the evolutionary process, such as the empirical risk, but also the information is lost [21]. To avoid information loss and at the same time deepen the impression of information in the network, the residual learning module is built according to Equations (3) to (5) as in Fig. 3.

In Fig. 3, the input primitive image can finally obtain an optimized image of size  $6*6*256$  after first undergoing C-level evolution. Then two steps of weighting are performed, and after passing it, it can be input among LLP, which is calculated as Equation (6).

$$\begin{cases} O = \text{collapsywhane}(S_i[I'(v)]) \\ I'(v) = \begin{cases} g + \text{sign}(v-g)\sigma_r \left(\frac{|v-g|}{\sigma_r}\right)^\alpha & |v-g| \leq \sigma_r \\ g + \text{sign}(v-g)\left(\beta(|v-g| - \sigma_r) + \sigma_r\right) & \text{else} \end{cases} \end{cases} \quad (6)$$

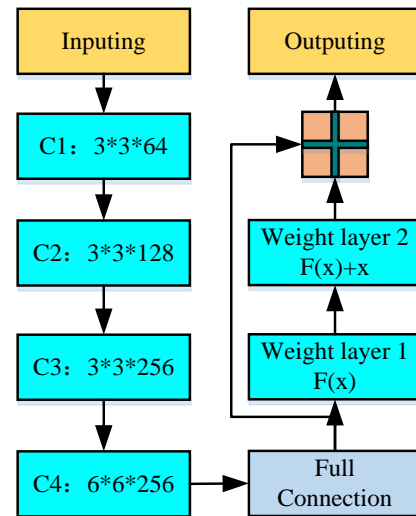

Fig. 3. Residual learning module.

In Equation (6), the image output by LLP is called  $O$ , and the image of each layer is noted as  $S_i$ . After a set of processes in LLP, the coefficients due to the decomposition are obtained, which are denoted as  $v$ , then  $I'(v)$  is also called the standard function based on the decomposition coefficients. The reconstruction operator is then denoted as *collapsywhane* and the pixel value obtained from the LLP can be called  $g$ . In addition,  $\alpha, \beta, \sigma_r$  are three variable parameters of LLP, which are intensity threshold, detail factor and ranging factor. The intensity threshold serves as a boundary to distinguish edges from details; the detail factor and the range factor control the enhancement and reduction, respectively, one controlling the details and the other controlling the range. After the GP and LP, the signal analysis is performed. The signal analysis tool is the well-known Multiscale Geometric Analysis (MGA), whose flow is shown in Fig. 4.

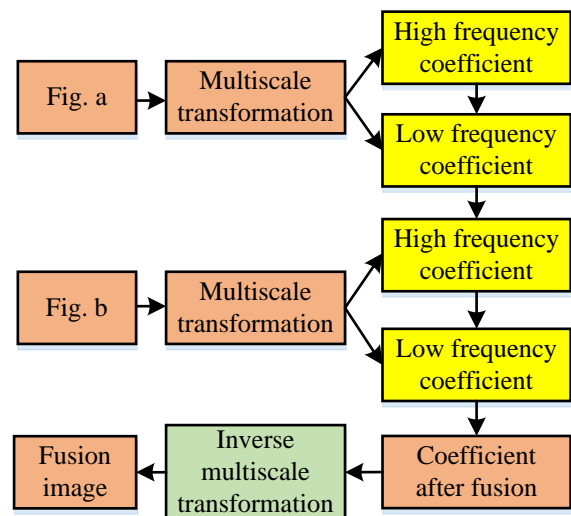

Fig. 4. Multi-scale geometric transformation image fusion.

In Fig. 4, the original image is first multi-scale transformed, which will result in a decomposed source image, and the fusion rule is applied to the decomposed image to fuse high-frequency coefficients or low-frequency coefficients, as appropriate. Then the fused coefficients are inverse multi-scale transformed, and finally the fused image is recombined to form [22]. For the fused image, the gap between the distortion and the original image is contacted, i.e., the Fidelity of Visual Information (VIF) is calculated, as in Equation (7).

$$VIF_k(A, B, F) = \frac{\sum_b FVID_{k,b}(A, B, F)}{\sum_b FVIND_{k,b}(A, B, F)} \quad (7)$$

In Equation (7), the visual information degree of distortion or not is expressed by  $FVID, FVIND$ , respectively.  $A, B, F$  denotes the degree of information of the pixel and  $b$  denotes the value of the coordinate at which it is located.

### B. MR/CT Medical Image Fusion based on the Combination of CNN and Rolling Guide Filtering

RGF has the ability to guarantee smooth details even under scale measurement. RGF works iteratively and converges particularly fast; RGF works over a wide range, and small structure removal and edge restoration are its features, which are well suited for medical image studies. If it assumes that  $I$  is the input image, then  $G$  represents the output image, the standard deviation of the Gaussian filter is noted as  $\sigma_s^2$  and the pixel index can be expressed by  $p, q$  as in Equation (8).

$$G(p) = \frac{1}{K_p} \sum_{q \in N(p)} \exp\left(-\frac{\|p-q\|^2}{2\sigma_s^2}\right) I(q) \quad (8)$$

In Equation (8), when  $K_p = \sum_{q \in N(p)} \exp\left(-\frac{\|p-q\|^2}{2\sigma_s^2}\right)$  is used, it means that it is available for normalization. When the RGF takes another approach to recover the edges, that must be the joint RGF iteration, at which time the source output of the filter is represented by  $J^t$ . When the filter iterates to  $t$  times, the

output at that time is represented by  $J^{t+1}$ , and the relationship between them is as in Equation (9).

$$J^{t+1}(p) = \frac{1}{K_p} \sum_{q \in N(p)} \exp\left(-\frac{\|p-q\|^2}{2\sigma_s^2} - \frac{\|J^t(p) - J^t(q)\|^2}{2\sigma_s^2}\right) I(q) \quad (9)$$

In Equation (9), the weight range is controlled jointly using  $I, \sigma_r^2$ . The CNN model is testing the activity level metric while using a huge number of photos to train its data and create adaptive fusion rules. CNN is able to greatly reduce the difficulty of designing fusion rules because image fusion with CNN is more efficient than manual design, as shown in Fig. 5.

From Fig. 5, a normal image block size is  $16 \times 16$ , and after a nonlinear mapping, it gets 64 feature maps of size  $16 \times 16$ , which should be processed with special care to prevent information loss. 64 images undergo another nonlinear mapping, and then compression in the image, which can get 128 refined images of  $8 \times 8$ . The refined image can also undergo a final expansion to obtain 256  $8 \times 8$  results. This is already the limit of convolutional kernel, if it is too large, it is easy to cause information loss; if it is too small, the feature extraction is not obvious enough [23-25]. For medical class images, fluctuations in other local regions can be better characterized, so a new parametric max-min filtering algorithm is introduced, calculated as in Equation (10).

$$\bar{I}(i, j) = \max_{(m,n) \in \Omega} (I(m, n)) - \min_{(m,n) \in \Omega} (I(m, n)) \quad (10)$$

In Equation (10), the original image is recorded with  $I$ , the center of  $I$  is noted as  $\Omega$  and  $(i, j)$  is any point.

$\max_{(m,n) \in \Omega} (I(m, n))$  and  $\min_{(m,n) \in \Omega} (I(m, n))$  are the max and the mini filters. Images sometimes have similar shared blocks, which can be established in Equation (11).

$$\eta_q = \|P_q - P_r\|_{E_w} \quad (11)$$

Fig. 5. CNN structure.

In Equation (11),  $\eta_q$  represents the Euclidean distance of the similar parts between the shared blocks. The given reference block is noted as  $P_q$ , and the candidate block is defined as  $P_r$ . The candidate blocks are to avoid gradient reciprocity and gradient destruction, and also to be adaptive to the weights that appear. The fusion of the input graph is set according to the known judging criteria, as in Fig. 6.

Fig. 6. Image fusion process.

From Fig. 6, if the detail image has the feature of local similarity, then the block can be cut into a large number of square blocks of equal size, called Shared Similar Block (SSB), which is defined by Equation (12).

$$L_W^S(r) = L_{W^A}(r) \cap L_{W^B}(r) \quad (12)$$

In Equation (12), the image  $A, B$  has  $k$  similar blocks to the image  $L_{W^A}, L_{W^B}$ , respectively, and the SSB to be calculated is  $L_W^S(r)$ . The SSB is somewhat different from the traditional perceptron, as reflected in the optimization of the fixed denominator, and the optimization function is as in Equation (13).

$$\min \frac{\|W\|_2^2}{2}, y_i (W^T x_i + b) \geq 1 (i = 1 - N) \quad (13)$$

In Equation (13),  $\min \frac{\|W\|_2^2}{2}$  is defined as the large distance from all points to the shared plane, and  $y_i$  implies a regression analysis that can seek the optimal solution for learning ability and distance. For human vision, the color and state of the image are very sensitive, so a small deficiency in a key location can cause a large change. For medical matters, the larger the area of the image is the more informative it is. Medical imaging characteristics can prove that the largest and smallest pixel difference reflects important information. So for the study of images, the first step is to perform a pyramid decomposition so that the fusion applies to each level, as in Fig. 7.

Fig. 7. Improved algorithm for image fusion.

In Fig. 7, the original images  $A, B$  and  $W$  are input to the algorithm based on the combination of rolling filter and CNN to obtain three initial images  $L_A, L_B$  and  $L_W$ . The obtained three images are input into the Laplace pyramid and then feature fusion operation is performed to be able to output the final image  $F$ . The risk in this is mainly in two aspects, containing empirical risk and structural risk, to be considered simultaneously. The empirical risk is to be controlled by the generalization of the CNN, and the study is to control both time and geographic location because it is most influenced by environmental factors and other factors are negligible [26-28]. Structural risk reduction is to be achieved by dimensionality reduction of the CNN, as reflected in the histogram of the probability distribution of the input. The function mapping is then performed by hidden neurons, and assuming that the filter convolves the image support values and the standard convolution kernel of step size is maximally pooled, Equation (14) can be obtained.

$$c_{i,j,o}(\psi) = f \left( \sum_{h=-0.5k}^{0.5k} \sum_{w=-0.5k}^{0.5k} \sum_{u=1}^N \theta_{h,w,u,o} \bullet \psi_{g(h,w,i,j,u)} \right) \quad (14)$$

In Equation (14), the kernel weights are represented by  $\theta$ ;  $u$  denotes the scale of the maximum pool operation;  $(i, j)$  is the coordinate;  $f(\bullet)$  represents the activation function of Relu, which is chosen to represent the elements of the previous layer of feedback for this operation.

#### IV. ANALYSIS OF MEDICAL MR/CT IMAGE FUSION MODEL BASED ON CNN

##### A. Determination of Model Parameters for Fused CNN-RGF

For this study, the dataset from The First Affiliated Hospital of Harbin Medical University was used, and images of normal brains as well as common disease brains, such as brain atrophy, were selected. The experimental environment, i.e., the parameters, is shown in Table I.

For the image processing, the image was first normalized and then compared with NSCT - PCNN for comparison, as shown in Fig. 8 [29, 30].

TABLE I. EXPERIMENTAL PARAMETERS

GPU	Internal storage	Operating system	Channel output
NVIDIA Tesla M60	256GB*2	128Ubuntu 21.02.20	64; 128; 256
Flash memory	Operator	Input	Filter parameters
CUDA Toolkit 23.0	Python	3.0	3*3; Floor2
Step length	Number residual blocks	Display card	CPU
1	32	Tensor flow 2.40	Windows X10

Fig. 8. Comparison chart of CT/MRI fusion effect.

From Fig. 8, the brain luminosity of NSCT - PCNN imaging was not as bright as CNN-RGF, and even in the processing of details, it was obvious that CNN-RGF was more carefully discriminated. Even though NSCT - PCNN was more economically cost effective, it was more important to be medically rigorous. Then the dataset had to be trained iteratively as well as with error training, as in Fig. 9.

From Fig. 9, the accuracy of CNN-RGF was lower than that of NSCT-PCNN until 200 iterations, but the error rate was higher than that of NSCT-PCNN with the increase of the iteration times. However, when the iteration times reached 200 or more, the accuracy of CNN-RGF was unmatched by NSCT-PCNN. Although the increase in the iteration times decreased the operational efficiency of the algorithm, the accuracy also increased with the iteration times. Since the recognition of brain images was important for brain diseases, the accuracy of image recognition was more important, and based on this, the CNN-RGF algorithm proposed in the study had more significant advantages. The corresponding results in Fig. 9 are shown in Table II.

TABLE II. PERFORMANCE MEAN AND STANDARD DEVIATION OF MODEL TRAINING

Algorithm	Precision			Deviation		
	Highest Value	Average Value	Standard Deviation	Minimum	Average Value	Standard Deviation
CNN-RGF	0.94	0.85	0.13	0.52	0.64	0.11
NSCT-PCNN	0.81	0.69	0.18	0.71	0.86	0.13

In Table II, the highest accuracy value of CNN-RGF was 0.94, the average value was 0.85, and the error was 0.13; The highest accuracy of NSCT-PCNN was 0.81, with an average of 0.69 and a deviation of 0.18. The minimum error value of CNN-RGF was 0.52, the average value was 0.64, and the deviation was 0.11. The highest accuracy of NSCT-PCNN was 0.71, with an average of 0.86 and a deviation of 0.13. The results indicated that the proposed CNN-RGF model had higher accuracy and stability.

B. Experimental Data Validation based on CNN-RGF Model

To make the results more generalizable and applicable to all hospitals, this study provided a high-level evaluation of the results based on several common metrics. These were MI, IE, Structural Similarity (SSIM) and Average Grads (AG). The values obtained from the above four box indicators belonged to dimensionless values and were mainly used for comparison. Three common brain diseases were studied based on the four metrics, and the generated results were compared using NSCT-PCNN with CNN-RGF, as shown in Fig. 10.

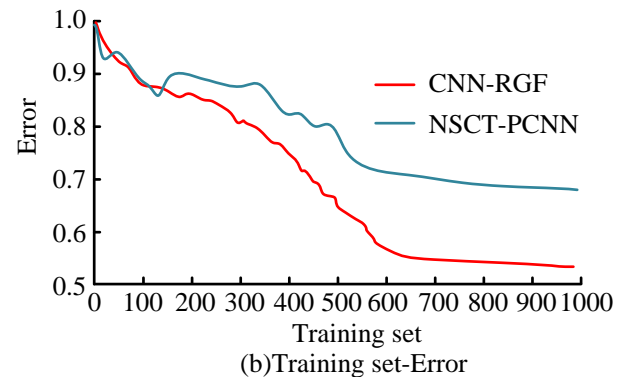

Fig. 9. Iterative training and error training of datasets.

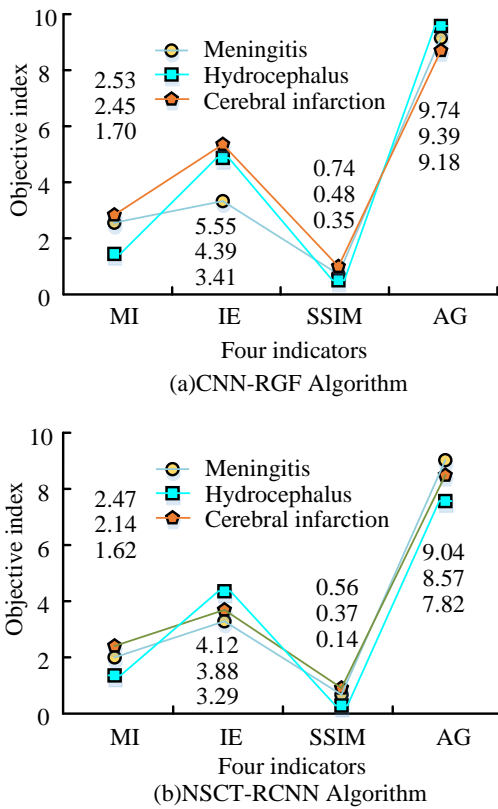

Fig. 10. Comparison of three kinds of encephalopathy and four indexes by using CNN-RGF (a) and NSCT-RCNN (b).

From Fig. 10, firstly three brain diseases, including meningitis, hydrocephalus and cerebral infarction, were characterized in CNN-RGF which was higher than NSCT-RCNN. In other words, the image quality obtained by fusion was better when CNN-RGF was used to characterize brain diseases. The CNN-RGF algorithm reached the optimum in all three groups of experiments for meningitis, hydrocephalus and cerebral infarction, and the enhancements for MI reached 25%, 2.5% and 20.5%, respectively, which were the plain objective constants with the largest enhancements. The smallest improvement was SSIM, but it also reached 16.6%, 1.6%, and 15.0%, respectively. Among them, MI could reflect the rate of change of image brightness, and SSIM could consider both brightness and contrast of the image. The MI and SSIM values were considered together, i.e., the higher their values, the clearer the image. The corresponding results in Fig. 10 are shown in Table III.

In Table III, both CNN-RGF and NSCT-PCNN had higher evaluation values for various indicators in the same disease. In the standard deviation, CNN-RGF also exhibited better stability. To make the test results more comprehensive, their CT/MRI objective indexes were also evaluated, as shown in Fig. 11.

In Fig. 11, CNN-RGF outperformed the NSCT-RCNN algorithm in all objective metrics when observing CT/MRI maps of the brain. The observation of MI in meningitis reached the optimal value, the observation of SSIM in cerebral infarction belonged to the suboptimal value, and the four

objective values based on CT/MRI were improved by 22.5% on average compared with the NSCT-RCNN algorithm, which could provide a large number of medical CT/MRI quality images. Since medical images represent personal privacy, the First Hospital of Harbin Medical University did not keep some data. The dataset for this study required some pioneering, which largely limited the performance of the constructed model. The corresponding results in Fig. 11 are shown in Table IV.

In Table IV, both CNN-RGF and NSCT-PCNN had higher evaluation values for various indicators in the same disease; In the standard deviation, CNN-RGF also exhibited better stability. Taking into account the implications, a complementary experiment was designed and implemented, i.e., based on MR/SPECTION metric observations, as shown in Fig. 12.

TABLE III. DETECTION INDEX RESULTS OF DIFFERENT ALGORITHMS IN ENCEPHALOPATHY

Index		Meningitis	Hydrocephalus	Cerebral infarction
CNN-RGF	MI	1.70±0.13	2.45±0.22	2.53±0.23
	IE	3.41±0.33	4.39±0.36	5.55±0.42
	SSIM	0.35±0.06	0.48±0.09	0.74±0.11
	AG	9.18±0.59	9.39±0.61	9.74±0.62
NSCT-PCNN	MI	1.62±0.12	2.14±0.15	2.47±0.19

NSCT-PCNN	MI	0.82±0.04	1.03±0.05	0.27±0.03
	IE	4.24±0.39	2.17±0.11	0.46±0.07
	SSIM	0.82±0.16	1.05±0.13	2.17±0.28
	AG	5.82±0.68	6.28±0.75	6.17±0.47

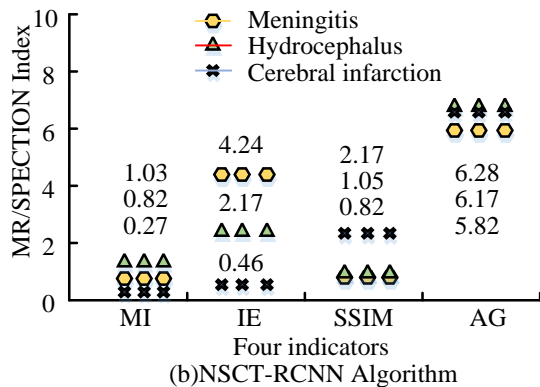

Fig. 12. Comparison of three kinds of encephalopathy and MR/SPECTION indexes by using CNN-RGF (a) and NSCT-RCNN (b).

From Fig. 12, it was indeed very necessary to test the complementation experiment, i.e., it was very different from the previous images. However, the difference was only in the shape, and the specific values of the four indexes of the MR/SPECTION images were still better for CNN-RGF than for NSCT-RCNN. Testing MR/SPECTION images, the MI/IE/SSIM/AG values of CNN-RGF were obtained as 1.77/5.77/2.17/6.45 for meningitis. The average values of MI/IE/SSIM/AG for hydrocephalus were 2.20/3.80/3.55/6.28; MI/IE/SSIM/AG for cerebral infarction were 0.54/1.04/4.07/7.20. The average values were 24.8% higher than those of NSCT-RCNN, and the CT/MRI images produced by the CNN-RGF algorithm were clearer. It is proved that CNN-RGF can retain the details of CT/MRI images well and can provide better quality CT/MRI images. The corresponding results in Fig. 12 are shown in Table V.

In Table IV, both CNN-RGF and NSCT-PCNN had higher evaluation values for various indicators in the same disease. In the standard deviation, CNN-RGF also exhibited better stability. To ensure the without loss of generality of the proposed method, NWPU VHR-10 data set was used to verify the model performance. The NWPU VHR-10 dataset was an aerial photography dataset, and aerial images were also processed using methods such as cropping and stitching. Therefore, CNN-RGF was studied for this dataset, and the performance results were reflected through accuracy and recall indicators. The specific results are shown in Table VI.

TABLE VI. THE APPLICATION EFFECT OF CNN-RGF ALGORITHM IN NWPU VHR-10 DATASET

Comparison algorithm	Precision	Recall
Neural Network	0.673	0.616
K-Nearest Neighbor	0.785	0.690
SVM	0.820	0.714
CNN-RGF	0.913	0.873

In Table VI, the accuracy of CNN-RGF in the NWPU VHR-10 dataset was 0.913, and the recall rate was 0.873. Compared to other models, the performance proposed in the study has significantly improved. Although its accuracy was slightly lower, which might be due to the complex environment of aerial images, the results demonstrated the effectiveness of the proposed method.

## V. CONCLUSION

This research used the brain image data of the First Affiliated Hospital of Harbin Medical University, and used CNN to extract its features. The extracted image used RGF to process the image's similar blocks and artifacts. Using the CNN-RGF method to fuse CT/MRI images, after the fusion was completed, it was first tested for naive objective quantities. The four simple objective indicators of CNN-RGF in meningitis, MI/IE/SSIM/AG, were 2.45/3.41/0.48/9.39; The MI/IE/SSIM/AG in Hydrocephalus was 1.70/4.39/0.35/9.74; The MI/IE/SSIM/AG in cerebral infarction was 2.53/5.55/0.74/9.18. At the same time, NSCT-RCNN algorithm was selected for comparative experiments. The measured MI/IE/SSIM/AG values of NSCT-RCNN in meningitis, Hydrocephalus, and cerebral infarction were 2.14/3.29/0.37/9.04, 1.62/4.12/0.14/7.82, 2.47/3.88/0.56/8.57, respectively. Among the three common brain diseases, the naive objective values obtained by CNN-RGF were higher than

those obtained by NSCT-RCNN, with an average improvement level of over 15%, indicating that the CT/MRI image quality obtained through CNN-RGF fusion was higher. To make the results universal, objective data testing of CT/MRI was supplemented. The CT/MRI objective data of CNN-RGF in meningitis, Hydrocephalus and cerebral infarction were 4.34/6.99/0.70/5.76, 3.51/5.05/0.61/4.80, 2.38/5.52/0.70/6.46 respectively; In NSCT-RCNN, they were 3.50/5.54/0.28/3.17, 2.07/4.27/0.05/2.46, 1.42/5.38/0.28/3.24, respectively. The values obtained from the above results were all dimensionless and were mainly used for comparing the effectiveness of algorithms. Therefore, from the extensive testing, the CT/MRI objective data values obtained from CNN-RGF were higher than those from NSCT-RCNN, with an average improvement level of over 10%. This proved that the CT/MRI obtained through CNN-RGF fusion was more suitable for major hospitals.

Because the first affiliated Hospital of Harbin Medical University lacked some data, the performance of the constructed model was limited. Due to scientific rigor, supplementary experiments were designed and implemented to observe MR/SPECTION indicators. The MR/SPECTION observations of meningitis in CNN-RGF were 1.77/5.77/2.17/6.45, respectively. The observed value of Hydrocephalus on MR/SPECTION was 2.20/3.80/3.55/6.28; The observed values of MR/SPECTION for cerebral infarction were 0.54/1.04/4.07/7.20, with an average of 24.8% higher than NSCT-RCNN. Taking the human eye resolution MI=8.00 as a reference, it could reach MI=2.40 as clear, indicating that for NSCT-RCNN fusion images, the characterization of meningitis and cerebral infarction cannot even reach the minimum standard. Compared with the traditional algorithm NSCT-RCNN, CNN-RGF was more suitable for application in hospitals. But there are not many medical images studied, because medical images have privacy and are not suitable for widespread dissemination. With the increase of volunteers, it is believed that future research can be improved.

# Motion Path Planning of Wearable Lower Limb Exoskeleton Robot Based on Feature Description

Ying Wang<sup>1\*</sup>, Songyu Sui<sup>2</sup>

Department of Physical Science and Technology, Tangshan Normal University, Tangshan, Hebei, 063000, China<sup>1</sup>  
College of Mechanical Engineering, North China University of Science and Technology, Tangshan, Hebei, 063210, China<sup>2</sup>

**Abstract**—Wearable lower extremity exoskeleton robot is a kind of training equipment designed for the disabled or powerless in the lower extremity. In order to improve the environmental adaptability of the robot and better meet the use habits of patients, it is necessary to plan and design the movement path, and a movement path planning model of wearable lower extremity exoskeleton robot based on feature description is proposed, which describes the objects with different wearing frequencies and training intensities. Taking the wearer's natural walking gait as the constraint feature quantity and the control object model, the spatial planning and design of exoskeleton structures such as hip joint, knee joint and ankle joint are adopted, and the traditional single-degree-of-freedom rotating pair is replaced by a four-bar mechanism, which improves the bionic performance of the knee joint. Combining the feature description and the spatial planning algorithm model, an error compensation method based on iterative least square method is adopted to identify geometric parameters. The feature identification model of robot moving path planning is constructed, and the adaptive strong coupling tracking identification and path planning of robot moving path are realized through feature description and spatial distance error identification results. The simulation test results show that the cooperative positioning error is reduced and the torque error is compensated in real time by using this method to plan the movement path of the wearable lower limb exoskeleton robot, which makes the robot obtain better movement planning effect and enhance the stability of the mechanism.

**Keywords**—Feature description; wearable lower limb exoskeleton robot; motion path planning; least square identification; geometric parameter

## I. INTRODUCTION

With the increasing types of robots and the expanding application fields of robots, the application of robots in rehabilitation training of patients with limb injuries has become an important direction of robot design and research. Wearable lower extremity exoskeleton robot is a training device designed for the disabled or powerless. The wearable lower extremity exoskeleton robot is worn on the lower limbs of patients, and the auxiliary parameter identification of multi-dimensional sensors is used as input, and the robot's movement planning design is realized through the robot control system and path planning system, which makes the wearable lower extremity exoskeleton convenient and comfortable to wear, safe and reliable to use, and fast and accurate to respond. Therefore, this paper studies the path planning method of wearable lower limb exoskeleton robot. Through path planning and intelligent

control system design, combined with power-assisted training design, the fitness level of robot under different wearing frequencies and training intensity is improved [1].

In the planning and design of the movement path of the wearable lower extremity exoskeleton robot, it is necessary to dynamically plan and design the movement path in combination with the user's power training needs and the wearer's injury degree. In the traditional methods, the movement path planning and design methods of the wearable lower extremity exoskeleton robot mainly include fuzzy PID control method, variable structure PID control method and inversion control method, etc. [2,3], and a distributed feature sampling model of the movement path of the wearable lower extremity exoskeleton robot is established. Combining spatial path parameter identification and inverse parameter control, the dynamic spatial fusion processing is carried out for patients with different degrees in the process of power-assisted training, and the movement path planning and design of wearable lower extremity exoskeleton robot is realized by using error compensation control algorithm and SLAM algorithm. In reference [4], a zero-force control method of 6-RUS parallel robot based on generalized coordinate form dynamics is proposed, and the influence of mechanism noise on torque data is analyzed. The global area method is used to obtain the actual output torque of the motor at a certain position in the workspace, so as to realize zero-force control and spatial path planning and design of the robot. However, the torque measurement accuracy of this method for robot moving path planning is not high. In reference [5], the configuration, motion mechanism and modeling control model of amphibious bionic robot are analyzed. According to the structural types of amphibious robots, amphibious robots are divided into leg propulsion, wheel-leg/fin composite propulsion, snake propulsion and other methods, and path planning and design are realized through parameter identification of multi-environment motion model, but this method has poor anti-interference and weak spatial recognition ability. Research [6] proposes the establishment of a mathematical model for robots, the construction of a motion situational awareness map, the establishment of an improved artificial potential field, the establishment of a repulsive potential function and priority model between robots, and the application of PID adaptive tracking algorithm. Study [7] proposes the use of adaptive RBFNN algorithm for disturbance estimation and compensation, and the use of nonlinear state error feedback control to achieve attitude tracking of rotor flying multi joint robotic arms, Has strong robustness and fast response ability.

\*Corresponding Author.

Aiming at the above problems, this paper puts forward a movement path planning model of wearable lower extremity exoskeleton robot based on feature description.

1) Different wearing frequencies and training intensities are taken as feature description objects, and the natural walking gait of the wearer is taken as constraint feature quantity and control object model, and a four-bar mechanism is adopted to replace the traditional single-degree-of-freedom rotating pair, thus improving the bionic performance of the knee joint.

2) Combining the feature description and the spatial planning algorithm model, the feature identification model of robot moving path planning is constructed by using the error compensation method based on iterative least square method, and the adaptive strong coupling tracking identification and path planning of robot moving path are realized through the results of feature description and spatial distance error identification.

3) The experimental test shows the superior performance of this method in improving the moving path planning ability of wearable lower limb exoskeleton robot.

This method can more accurately predict users' motion intentions and generate motion paths that better meet user needs by analyzing and modeling human motion features. Thus providing more precise and coordinated motion assistance, improving motion performance.

## II. STRUCTURE MODEL AND DESIGN PRINCIPLE OF WEARABLE LOWER LIMB EXOSKELETON ROBOT

Based on the principle of ergonomics, a wearable exoskeleton robot for the disabled or powerless lower limbs is designed. The hip joint, knee joint and leg bar are designed respectively [6]. Firstly, at the left and right hip joints, the parallel mechanism is used to realize the power-assisted movement of the joint center. Then, the traditional single-degree-of-freedom rotating pair is replaced by a four-bar mechanism to realize the bending action of the knee joint. Then, the leg bar is designed according to the human body configuration. Finally, the ankle joint is designed by belt drive.

Among them, the hip joint is composed of Hooke's articulated U-pair, movable P-pair, Hooke's articulated U-pair, fixed platform connecting leg bars, and movable platform tied to the waist; The knee joint is composed of a four-bar linkage formed by articulation, a linear driving electric cylinder and a fixed part of the electric cylinder.

As shown in Fig. 1, the robot wearing the lower limb exoskeleton is composed of a hip joint A, a knee joint B, an ankle joint C, a leg bar D and an inner strap E which are connected by bolts in turn. Among them, as shown in the figure, the leg bar imitates the human body structure, and there is a certain angle between the thigh and the calf on the vertical plane, which makes the structure more suitable for the human lower limbs [7].

Fig. 2 is a schematic diagram of the hip joint structure, and the hip joint is assisted by a parallel mechanism. Among them, the parallel mechanism is composed of Hooke's articulated U-

pair A1, moving P-pair A2, Hooke's articulated U-pair A3, fixed platform A4 connecting leg bars and moving platform A5 tied to waist. The parallel mechanism can achieve three degrees of freedom of hip joint ergonomically required, namely, forward and backward swing (thigh flexion/extension), lateral swing (abduction/adduction) and torsion (external rotation/internal rotation), which is consistent with the freedom of motion required by human hip joint and ensures human comfort [8].

Fig. 3 is a schematic diagram of the structure of the knee joint, which realizes the bending motion of the knee through a four-bar linkage mechanism. Specifically, it consists of a hinged four-bar mechanism B1, a linear driving electric cylinder B2 and an electric cylinder fixing piece B3. Compared with the single-degree-of-freedom rotation, the instantaneous center trajectory of the four-bar mechanism is closer to the trajectory of the human knee joint, thus achieving the goal of better coordination between the exoskeleton and the human body [9].

Fig. 4 is a schematic diagram of the ankle joint structure. As shown in the figure, the ankle joint is composed of an upper joint fixing piece C1, a rotating pair end cover C2 and a rotating pair C3. When the human body walks, it can drive the rotating pair to rotate, improving the comfort experience.

Fig. 1. Structure diagram of robot wearing lower limb exoskeleton.

Fig. 2. Schematic diagram of hip joint structure.

Fig. 3. Schematic diagram of knee joint structure.

Fig. 4. Schematic diagram of ankle joint structure.

#### Advantages of wearing lower limb exoskeleton robot:

- 1) It is suitable for adjusting the length of lower limbs of people of different ages and heights, and it is convenient for wearers of different heights to perform various operations [10].
- 2) The left and right hip joints are designed in a parallel structure symmetrical about the central axis, and the movement center of the exoskeleton and the center of the human hip joint are more fitted, which ensures that the movement center of the wearable robot falls on the center of the hip joint, thus ensuring the fit between the wearable robot and the human body, being more bionic and enhancing the comfort of users.
- 3) The knee joint adopts a four-bar mechanism to replace the traditional single-degree-of-freedom rotating pair, which improves the bionic performance of the knee joint. Combining with ergonomics, the thigh in the standing state is set to be vertical to the horizontal plane, and there is a certain angle between the calf and the thigh, so that the center of gravity of the human body falls inside the ankle joint and the sole support to enhance the stability of the mechanism.

Both the upper and lower leg connecting rod and the lumbar support structure are telescopic, as shown in Fig. 5 and Fig. 6, that is, the upper and lower leg connecting rod and the lumbar support structure are designed into two sections with adjusting threaded holes, so as to improve the body compatibility with robot wearers, adapt to the bodies of different patients and improve the comfort.

In the design process, according to the bionic design method, the hip joint, knee joint and ankle joint of exoskeleton are designed, in which the hip joint adopts parallel mechanism and the knee joint adopts four-bar mechanism closer to the knee joint instead of the traditional rotating pair. The leg bar part adopts an adjustable two-bar structure, which is convenient for different people to wear.

### III. CONSTRAINT PARAMETERS AND CONTROL OBJECTS OF ROBOT MOVING PATH PLANNING

#### A. Constrained Parameter Model

In order to realize the movement path planning of the wearable lower extremity exoskeleton robot based on feature description, inspired by the musculoskeletal system of human leg [11], firstly, the collection model of the sensitive parameters of the trajectory tracking deviation of the skeletal robot is established, and the Snelson X-shaped mechanism is improved. According to the biological simplified model and deformation feature analysis, the internal biomechanics and motion mechanism of the human leg are analyzed, and the distribution of the sensitive parameters of the timing deviation of the wearable lower extremity exoskeleton robot is obtained as follows:

$$F = \frac{\int_0^{L_z} T_C(x) dx}{L_z} + \frac{M \cos \alpha}{4\pi\mu_0 R^5} [2(2h)^2 - a^2] \quad (1)$$

Where,  $\int_0^{L_z} T_C(x) dx$  represents the number of internal biological spine or trunk joints of human legs,  $L_z$  represents the geometric shape parameters of bone and femoral condyle surfaces,  $M$  represents the dynamic characteristic components of muscle and bone in the equivalent mapping model, and  $h$  represents the flexible dynamic parameters imitating human muscle tissue. Based on the energy loss analysis, the dynamic characteristic parameters of redundant degrees of freedom of tensegrity structure are obtained as follows:

$$P = P_{cu} + P_h + P_e = \sum_{n=m}^{N-1} \left\{ \left[ e^f_{m-1}(n) \right]^2 + \left[ e^b_{m-1}(n-1) \right]^2 \right\} \quad (2)$$

In the above formula,  $P_{cu}$  is the inertia loss of the wearable lower limb exoskeleton robot around each axis of the body coordinate system,  $P_h$  is the force density distribution matrix, and  $P_b$  is the component group of the axial force  $f$  of the node  $P$  in the  $X$  and  $Z$  directions. Assuming that the unit size of the

tensegrity mechanism is  $\mu_1$ , it can be analyzed and identified according to the diagonal matrix composed of axial stiffness deformation, so as to realize the analysis of the changing posture and movement position [12].

### B. Control Object Model

Taking the wearer's natural walking gait as the constraint feature quantity and the control object model, the spatial planning and design of the hip joint, knee joint and ankle joint of the exoskeleton are adopted, and the steady-state control model of the characteristics of the Snelson X tensegrity structure itself is obtained as follows:

$$S = K(t) + \sum_{n=m}^{N-1} \left[ e^b_{m-1} (n-1) \right]^2 \quad (3)$$

Where,  $e^b_{m-1}$  is the complementary sequence of the cooperative positioning errors of the two legs, and  $K(t)$  is the measured distance between the end effectors of the two legs. Based on the identified geometric parameters, the behavior conditions of the two legs are analyzed, and when  $F^T F \leq I$  is met. Calculate the measured distance of the robot end when it is configured as  $i$  and  $k$ , and get the quantitative parameters of the trajectory feature distribution of the wearable lower limb exoskeleton robot as follows:

$$Y_\phi = \frac{\omega \dot{M}}{4\pi R^2} + \left[ e^f_{m-1}(n) e^b_{m-1}(n-1) \right] \quad (4)$$

Where,  $R$  is the characteristic value of the rotation period, based on the kinematic characteristics of nonlinear feedback control, the controlled object model is constructed based on the description and analysis of joint offset, connecting rod length and connecting rod torsion characteristics, and the geometric stiffness equation of the wearable lower limb exoskeleton mechanism is obtained by the method of modifying the geometric stiffness matrix of the mechanism:

$$u(k) = Kx(k - (\tau_{sc} + \tau_{ca})) = Kx(k - \tau_k) \quad (5)$$

According to the kinematics model of the robot from the measuring coordinate system to the end tool coordinate system, the actual arrival position of the end effector is inconsistent with the calculated position of the theoretical model. The geometric parameters are identified and analyzed, and the error compensation terms SA of the left leg and the right leg of the two-legged system are obtained by using the combined control of Coriolis force and centrifugal force  $w^{(k)} \in L_2(0, \infty)$ . When  $\|z(k)\|_2 \leq \gamma \|w(k)\|_2$  is met, according to the dynamic characteristics analysis of joint offset, connecting rod length and connecting rod torsion, the spatial planning function of kinematic model of end tool coordinate system is obtained as follows:

$$V_k = x^T(k) P x(k) + \sum_{i=k-\tau_k}^{k-1} x^T(i) K^T R K x(i) \quad (6)$$

Where  $P$ ,  $R$  are displacement vectors of geometric parameter errors of the robot. For the dynamic modeling of the wearable lower limb exoskeleton robot, the vector between the

origin points of the end tool coordinate system is introduced, and the gradient gain function is obtained according to the detection result of the transformation matrix of the basic coordinate system of the biped robot:

$$\begin{aligned} \Delta V_k &= Vx(k+1) - Vx(k) \\ &= x^T(k+1) P x(k+1) - x^T(k) P \\ &\quad - K^T R K x(k) - x^T(k - \tau_k) K^T R K x(k - \tau_k) \end{aligned} \quad (7)$$

While  $w^{(k)}=0$ , the position detection model of the ends of legs in the measurement coordinate system is constructed, and the spatial planning and design of the robot's moving path is realized according to the position distribution [13].

## IV. OPTIMIZATION OF MOBILE PATH PLANNING ALGORITHM FOR WEARABLE LOWER LIMB EXOSKELETON ROBOT

### A. Feature Description and Spatial Planning Algorithm

The hip joint, knee joint and ankle joint of exoskeleton are planned and designed in space, and the four-bar mechanism is used to replace the traditional single-degree-of-freedom rotating pair, which improves the bionic performance of the knee joint [14]. The gradient vector of cooperative positioning between the theoretical end distance and the real end distance meets the following requirements:

$$\Delta V_k = \Phi_1 \Pi_1 \Phi_1^T < 0 \quad (8)$$

Taking the centroid parameters of the wearable lower limb exoskeleton robot as the constraint object, through error compensation and feature description, the distribution function of the end position in the ontology-based coordinate system is measured as follows:

$$F(x) = \sum_{q=1}^Q e_q^T e_q = \sum_{q=1}^Q \sum_{k=1}^m e_{kq}^2 = \sum_{i=1}^N v_i^2 \quad (9)$$

Where,  $eq$  is the matching sample set of the best trajectory path of the wearable lower limb exoskeleton robot. Through the calibration of geometric error and non-geometric error, the distribution of transformation parameters of the two-leg base coordinate system is obtained as follows:

$$x^T = [w_{11}, \dots, w_m, z_{11}, \dots, z_m] \quad (10)$$

Where,  $w_{11}, \dots, w_m, z_{11}, \dots, z_m$  are the inertia weights, after geometric and non-geometric error compensation, the control function of feature description and spatial planning optimization is obtained as follows:

$$k_m = R / \rho_{m-1} = \frac{P_L}{P_E} = \left\{ \left[ e^f_{m-1}(n) \right]^2 + \left[ e^b_{m-1}(n-1) \right]^2 \right\} \quad (11)$$

Where,  $\rho_{m-1}$  is the tracking expected displacement vector that oscillates during the identification process,  $P_L$  is the change rate of the position distribution of the laser tracker, and

$P_E$  is the joint angle variable of the left leg in the right leg base coordinate system, thus the formula for the tracking step size distribution of the end position trajectory is obtained as follows:

$$C(t) = V_0^2 \cdot G_x = \sigma_{wp}^2 \left( \frac{N+P+1}{N-P-1} \right) \quad (12)$$

Wherein,  $G_x$  is the system gain of the end position and  $\sigma_{wp}^2$  is the transformation parameter of the base coordinate system. The dynamic analysis model of the movement path planning of the wearable lower limb exoskeleton robot is analyzed to realize the dynamic planning and design of the movement path of the skeletal robot [15].

### B. Adaptive Strong Coupling Tracking and Identification of Robot Moving Path

The four-bar mechanism is used to replace the traditional single-degree-of-freedom rotating pair, which improves the bionic performance of the knee joint. The proposed four bar mechanism has significant advantages in improving the bionic performance of the knee joint compared to traditional rotating pairs. It can better simulate the complex motion of the human knee joint and provide torque output that conforms to the physiological characteristics of the human body through improvements in multi degree of freedom control, torque distribution, stability, and controllability. In addition, the four bar mechanism can also save energy, improve energy utilization efficiency, extend battery life, or reduce external energy consumption. Overall, the introduction of a four bar mechanism can significantly improve the bionic performance of the knee joint, making it closer to the motion characteristics and functions of the human knee joint.

Combining the feature description and the spatial planning algorithm model, the control model of the dynamic planning of the left leg in the right leg base coordinate system is obtained by using the error compensation method based on the iterative least square method to identify geometric parameters and the optimization constraint method.

$$\dot{\sigma}_i = \begin{cases} \mu \sin \frac{\pi e}{2\mu}, & |e_i| < \mu \\ \mu, & |e_i| \geq \mu \\ -\mu, & |e_i| \leq -\mu \end{cases} \quad (\mu > 0) \quad (13)$$

Where,  $\mu$  is the sliding mode switching gain and  $e_i$  is the trajectory deviation error, trajectory tracking and spatial planning are carried out according to the correlation between the steady-state disturbance  $w^{(k)}$  of the step tracking of the wearable lower extremity exoskeleton robot and the acceleration measurement matrix  $u_i^{(k)}$ , and the trajectory distribution spatial parameters of the wearable lower extremity exoskeleton robot are obtained based on geometric error and non-geometric error calibration, and the parameter

identification model of the spatial positioning and perception of the mobile robot is described as follows:

$$H_0 = \sqrt{E}KR'(t) + R(t) - \left( \frac{P_e + P_h}{\omega_r} \right) \frac{M}{4\pi\mu_0 R^3} \sqrt{1 + 3\cos^2 \theta} \quad (14)$$

$$T(\alpha) = T + Y(r) - (P_w + P_b) / \omega_r \quad (15)$$

Wherein,  $\mu_0$  is the dynamic distribution parameter with the smallest linearization error of the system,  $M$  is the fuzzy distribution matrix in the robot base coordinate system,  $P_e$  is the error of identifying geometric parameters,  $P_h$  is the base coordinate system from the right leg to the left leg,  $R(t)$  is the coordinate matching point of each mechanism node,  $R'(t)$  is the parameter matrix of the mechanism unit node. The error compensation method based on iterative least square method is used to identify geometric parameters, and the feature identification model of robot moving path planning is constructed. The adaptive strong coupling tracking identification and path planning of robot moving path are realized through feature description and spatial distance error identification results [16].

## V. EXPERIMENTAL TEST

In this simulation experiment, we choose ROS as the simulation environment, and use SolidWorks modeling to create a lower limb Exoskeleton robot model. Obtain joint angle data as motion features through sensors and input it into a feature based path planning algorithm. In the experimental scenario, we simulated walking tasks and set different environmental conditions, with a ground slope range of [0,10] and 10 obstacles randomly distributed in the environment. The robot can complete the movement and reset of hip joint and knee joint with a single motor drive, and the input pressure reaches the maximum at 100N, and the dynamic error difference of trajectory tracking is set to 0.14mm. When the robot stands and locks, the deviation of the constraint point is 12.7%, the offset length is 1.355mm, the torsion angle of the connecting rod is 1.570rad, and the length of the connecting rod is 3.125. A four-bar mechanism is adopted to replace the traditional single-degree-of-freedom rotating pair, and the maximum/average position error of the robot is 0.2814mm/0.1431mm, and the average inverse kinematics calculation time of the robot's hip joint driven by DC motor is 0.01134ms, which is the longest for the robot. The setting parameters are shown in Table I.

According to the above parameter setting, given that the time of lower limb flexion is 0.064s, the support ability of the lower limb in the standing state is tested, and according to the statistical analysis results of mechanical characteristic parameters, the wearable lower limb exoskeleton robot is realized, and the detection results of robot movement path tracking parameters are shown in Fig. 5.

TABLE I. DH PARAMETER DISTRIBUTION

Joint node	Joint angle /rad	Offset length /mm	Connecting rod torsion angle $a_i$ /rad
1	0.921	76.456	5.626
2	1.059	79.955	6.656
3	0.598	83.033	3.666
4	1.245	76.936	8.900
5	1.225	80.504	8.371
6	1.627	80.435	9.400
7	0.627	81.337	8.469
8	1.931	79.710	7.665

By analyzing Fig. 5, it is known that this method can accurately detect the moving path of the robot, and the trajectory tracking and recognition ability is good, and the legged robot always maintains a stable locking state during the process of increasing the load. The convergence curve of the test robot's moving path tracking is shown in Fig. 6.

Fig. 5. Detection of robot moving path tracking parameters.

Fig. 6. Convergence curve of robot trajectory tracking.

By analyzing Fig. 6, we know that the method in this paper has a good convergence when planning and tracking the movement path of the wearable lower extremity exoskeleton robot, while the traditional PID control method has a large oscillation and the convergence error of EKF control method is high. The tracking error of the movement path of the wearable lower extremity exoskeleton robot is tested, as shown in Table II. By analyzing the results in Table II, we know that the method in this paper has a good adaptability and strong oscillation suppression ability, which improves the stability and robustness of the movement planning of the wearable lower extremity exoskeleton robot.

TABLE II. COMPARISON OF TRAJECTORY TRACKING ERRORS

Iterations	This method	PID	EKF	Integral control
100	0.041	0.135	0.403	0.189
200	0.018	0.084	0.132	0.151
300	0.006	0.057	0.136	0.177
400	0.000	0.023	0.110	0.074

Through the analysis of the comprehensive experimental results, the method proposed in this paper shows accuracy and stability in the path planning of the wearable lower limb Exoskeleton robot. The experimental results show that this method can accurately detect the motion path of the robot and has strong trajectory tracking and recognition capabilities. Even with increased load, the legged robot can still maintain a stable locking state. In addition, the method shows good convergence and low tracking error when planning and tracking the path of the wearable lower limb Exoskeleton robot.

Through experimental verification, we found that our method has excellent performance in path planning. It can accurately identify the user's motion intention and generate motion paths that match the user's needs. At the same time, this method can also adaptively adjust according to environmental changes and individual differences of users to provide more comfortable and efficient motion assistance. In addition, the method shows stability and accuracy in the tracking process, and can accurately track the user's trajectory, so that the Exoskeleton robot can effectively work with the user.

However, it should be noted that although the method presented in this paper has shown good performance in experiments, there are still some limitations. For example, the accuracy of feature extraction and description may be influenced by factors such as sensor accuracy, noise, and interference. In addition, further research is needed to consider individual differences and adaptability. Therefore, before applying this method to practical scenarios, it needs to be further validated and improved.

## VI. CONCLUSIONS

In order to improve the environmental adaptability of the robot and better meet the usage habits of patients, it is necessary to plan and design the movement path. A movement path planning model of the wearable lower limb exoskeleton robot based on feature description is proposed, with different wearing frequencies and training intensities as the feature description objects, and the wearer's natural walking gait as the constraint feature quantity and control object model, and the hip joint, knee joint and ankle joint of the exoskeleton are used for spatial planning and design. A four-bar mechanism is used to replace the traditional single-degree-of-freedom rotating pair, which improves the bionic performance of the knee joint. Combining the feature description and the spatial planning algorithm model, a feature identification model of robot movement path planning is constructed by using the error compensation method based on iterative least square method, and the adaptive strong coupling tracking identification and path planning of robot movement path are realized through the results of feature description and spatial distance error identification. The simulation test results show that this method can reduce the cooperative positioning error and compensate the torque error in real time, which makes the robot obtain better movement planning effect and enhance the stability of the mechanism. The trajectory tracking of the wearable lower extremity exoskeleton robot has good adaptability and strong oscillation suppression ability. There may be differences in the motion characteristics and needs of each user. The current research mainly focuses on average feature descriptions and models, and the consideration of individual differences is not sufficient. Therefore, in practical applications, further research is needed on how to incorporate individual differences and adaptability into the path planning process.

**Abstract**—Now-a-days, failure detection and prediction have become a significant research focus on enhancing the reliability and availability of IT infrastructure components. Log analysis is an emerging domain aimed at diminishing downtime caused by IT infrastructure components' failure. However, it can be challenging due to poor log quality and large data sizes. The proposed system automatically classifies logs based on log level and semantic analysis, allowing for a precise understanding of the meaning of log entries. Using the BERT pre-trained model, semantic vectors are generated for various IT infrastructures, such as Server Applications, Cloud Systems, Operating Systems, Supercomputers, and Mobile Systems. These vectors are then used to train machine learning (ML) classifiers for log categorization. The trained models are competent in classifying logs by comprehending the context of different types of logs. Additionally, semantic analysis outperforms sentiment analysis when dealing with unobserved log records. The proposed system significantly reduces engineers' day-to-day error-handling work by automating the log analysis process.

**Keywords**—System log; log analysis; BERT; classification; failure prediction; failure detection

## I. INTRODUCTION

IT infrastructures, consisting of complex and interconnected systems, are vulnerable to various failures, such as hardware failures, software glitches, network outages, security breaches, and other unforeseen events that can disrupt critical business operations. With rapid development in size and functionality, IT infrastructures have become increasingly complex and agile. Enriched accessibility to IT infrastructure is vital as the usage of computer systems has penetrated all aspects of society. Moreover, a small failure in any of the infrastructure components gives rise to catastrophic failures accompanied by downtime [1]. Research [2] shows that these failures can lead to financial losses, reputational damage, and customer dissatisfaction. Thus, developing a system that can perform accurate and timely failure detection is paramount. Such a system will be helpful for organizations to proactively detect and resolve potential problems, minimize downtime, and improve the overall reliability and efficiency of IT operations.

System logs are one of the most worthwhile records that register important events, various services, and the state of operations. By analyzing system logs, IT teams can monitor for signs of anomalies or irregularities that may indicate potential failures. Accordingly, system logs have been widely used to understand the behavior of computer systems and

monitor their health. Each computer system generates system logs on the execution of the event; thus, an ample amount of records are available. Even so, log analysis is troublesome due to the size of the data. As stated in a systematic literature review [3], many researchers have used logs in log analysis, anomaly and failure detection, troubleshooting, and prediction research.

The failure detection using log data framework comprises six steps, such as i) Log collection: Logs are obtainable in raw and unstructured formats. Different systems generate various types of logs; therefore, different types of logs ought to be collected for investigation. ii) Log parsing: In this step, unstructured logs are refined to be converted into a structured format. The primary objective of log parsing is to excerpt log templates from raw system logs. Log parsing substitutes the variable part of the log with special characters and preserves only the constant part. iii) Structured logs: Results acquired from the parsing are stored in the .csv file format; this data is used for further processing. iv) Feature extraction: Log templates and the contents produced in the course of log parsing are preferred as features for encoding. v) Vector representation: Log templates and contents are converted into vector representation in order to furnish them as input to machine learning models. vi) Anomaly / Failure Detection: Eventually, excavated vectors are served to the machine learning or deep learning models to classify logs in accordance with the allocated log level. Logs are classified into different categories, which include "fail," "Fatal," "error," etc. levels. These categories demand attention as they indicate the abnormal behavior of the system. The stated log levels are allocated to the logging statements on executing any exception in the system. Thus, the administrator gets anomalous data to emphasize and can take remedial action accordingly.

As per the literature, machine learning [4] and deep learning [5] have popular techniques effectively applied to classify logs. This classification can save time on log analysis and assist system administrators in concentrating on doubtful log entries. System logs are a combination of text, numbers, and special symbols. The data is available in natural language format and cannot be directly used to build ML (Machine Learning) and DL (Deep Learning) models. Many researchers utilized various NLP techniques for embedding purposes in the existing literature. But considering the nature of the log data and challenges in handling system logs such as voluminous data, commonly used words, the occurrence of the same word with different meanings, etc., direct vector conversion is not significant. Thus, vectors are required to

generate based on the word's context. Therefore, it is necessary to follow the process of text data conversion to numerical vectors based on semantics.

Proposed feature extraction with semantic analysis conquers the challenges related to variation in log format and imbalanced data. The proposed systems comprehend the semantic analysis of log templates by practicing the BERT pre-trained model. The system employs the BERT to procreate sentence vectors, bearing in mind the log templates and contents acquired against log parsing. At last, machine learning techniques are employed to classify log entries contingent on earmarked levels.

The Contributions in this paper are summarized as follows.

1) The proposed system for classifying logs is based on analyzing the meaning of logs with the BERT model that has already been trained.

2) Different Infrastructures such as Apache, OpenStack, Windows, BGL, and Android logs are collected and parsed using the "Drain" parser to derive log templates.

3) Sentence embedding is done on the derived log templates to determine each entry's meaning.

4) Extracted features are provided to machine learning classifiers to analyze logs pertaining to levels. The main goal of the classification is to test the efficiency of the semantic analysis done by different NLP techniques.

The proposed system will significantly diminish manual errors by enabling automated and accurate solutions to failure prediction.

The paper has eight sections, including details: Section II discusses related work. Section III has the descriptive analysis of the datasets, including log data collection and preprocessing. Section IV includes NLP-based feature extraction techniques. Section V investigates the models and technical definitions of the methodology used to perform experimentations. Sections VI and VII emphasize the experimental setup, followed by derived results. Finally, the conclusion and future directions are stated in Section VIII.

## II. RELATED WORK

Failure prediction is a crucial aspect of IT infrastructure monitoring as it enables organizations to proactively detect and mitigate potential issues before they result in costly downtime or performance degradation. The system can identify patterns or anomalies that may indicate impending failures and take preventive measures to avoid or minimize the impact of such failures. System logs, which are records of events and activities generated by various components of an IT system, can be invaluable in failure detection and prediction in IT infrastructures. System logs capture essential real-time information about IT resources' behavior, performance, and status, such as servers, networks, applications, and databases. One of the primary uses of system logs in failure detection is to provide visibility into the operational state of IT systems. By monitoring system logs, IT teams can detect such anomalies early and take preventive actions to mitigate potential failures. System logs can also be

used in failure prediction by leveraging machine learning and statistical techniques.

Wang et al. [6] propose that system downtime can be reduced by identifying the reason for failure, making anomaly and failure detection, prediction, and root cause analysis. Despite being an emerging domain, automated log analysis is complicated due to the manual evaluation of system logs by administrators, who track simple words like "kill," "exception," "dead," "fail," etc., to investigate defects [3]. In order to address the challenges of unavailability, reliability, and performance in IT infrastructure, it is vital to study machines as they are, understanding what they do instead of what is expected [7]. Various rule-based and classification-based approaches [8][9], including machine learning [10][11] and deep learning [12][13] techniques, have been proposed for automated system log analysis. Moreover, supervised [14] and unsupervised [15] learning techniques applied to massive, unstructured system logs have gained significant attention in recent years, with a substantial research corpus of similar work.

Recently, NLP-based analysis has been introduced to understand the meaning of logs for log analysis in complex IT infrastructures [16]. Word2Vec has been applied by authors [17] to perform word embedding of log contents, followed by finding log sequences using TF-IDF. Unsupervised learning has been utilized for the extracted features, resulting in a 67.25% improved F1 score compared to LogCluster [18]. Researchers [19] have calculated polarity scores to identify abnormal behaviors in HPC systems with a 96% F-score. In the recent past, many researchers have been concentrating on the use of BERT [20] re-BERT [21] pre-trained model as an embedding technique and LSTM [22][23], Bi-LSTM [24][25] attention base mechanism for classification purpose.

## III. ILLUSTRATIVE ANALYSIS OF THE DATASET

### A. Dataset Collection

System logs are intended to be the primary source of information about the system; thus, the availability of a log dataset for research is a demanding obligation. Log data records every operational detail of each component of the IT infrastructure at run-time. The mishandling of such sensitive data may cause several issues. Therefore, system logs are not easily obtainable for research and experimentation. He, Zhu, He, & Lyu, in 2020 [26], collected sample logs and made them available on "loghub" [27] for study. An extra set of logs are produced in the labs and released for research determination. In the systematic literature review [3], we discussed details about availability of more datasets that are accessible for research purpose.

### B. Dataset Preprocessing with Log Parser

Systems logs are the "print" statements scripted by engineers under software development and documented in the course of the carrying out of affiliated operations. The logs are composed of a constant log header (id, state, timestamp, level, etc.) and a dynamic part (updates on operation execution). The primary purpose of log parsing is to transform unstructured logs toward structured data by extracting the constant part from logs called log templates. The sample log parsing

technique is shown in Fig. 1. Log message or content is "Component State Change: Component \042SCSI-WWID:01000010:6005-08b4-0001-00c6-0006-3000-003d-0000\042 is in the unavailable state (HWID=1973)" from which log template is extracted as "Component State Change: Component <\*> is in the unavailable state (HWID=<\*>)."

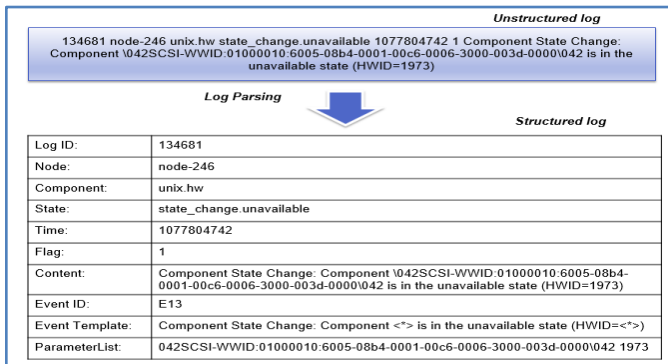

Fig. 1. Components of example HPC log.

Various researchers have discussed miscellaneous log parsers such as POP [28], Spell [29], SLCT [30], etc. Drain [31] parser has been adapted in this research work to parse log datasets. Drain elected for experimentation by examining execution time, availability, accuracy, and flexibility parameters. The drain parser employed the fixed-depth tree structure to perform and retrieve log templates. Table I presents the summary of findings on the performance of Drain on various types of logs. For the parsing, datasets are selected from multiple infrastructures, such as Apache as a server application, OpenStack as a cloud system, Windows as an operating system, BGL as a supercomputer, and Android as a mobile system. Table I contains the column number of log messages utilized for the parsing, the derived unique number of templates, and the maximum template length. Thus "Drain's" is a better parser for this research due to its parsing accuracy.

### C. Feature Extraction

System logs are a combination of text, numbers, and special symbols. Natural language data cannot be used directly to build ML (Machine Learning) and DL (Deep Learning) models. For this reason, it is imperative to follow the action of text data conversion to numerical vectors, known as vectorization or word embedding. The mined vectors can be employed to train different Machine learning and Deep learning models for classification, detection, and prediction purposes; in this way, word embedding is imitated for feature extraction.

At present, different Natural Language Processing (NLP) models are available for feature extraction in view of sentiment and semantic analysis. TF-IDF, polarity score, word2vec, and doc2vec work based on word frequency or position occurrence in the given text and analyze word-related sentiments. Whereas BERT, GPT2, and XL [16] function contingent on the semantics of words regarding the position and meaning of words accompanying them. The BERT model is pre-trained on massive datasets like Wikipedia and proposed by Google to be fine-tuned on a particular dataset. Pre-trained word embedding models are applied for vector representation of log templates and to strengthen the prediction of unobserved log entries. Moreover, BERT supports domain-specific semantic information and can address out-of-vocabulary (OOV) words in novel kinds of logs during run-time [32].

This experimentation focuses on doc2vec and BERT sentence embedding techniques to get vectors of log templates. Whereas TF-IDF is unsuitable in log datasets as the TF-IDF work on the weighting methods, and weights are assigned considering the frequency of occurrence of words. In the case of system logs, common words represent the different meanings of the log messages, and frequently occurring words are unnecessary. Thus, TF-IDF is unsuitable, even if it archives good classification accuracy. Fig. 2 renders the process of feature extraction. First, the unstructured log is processed toward a structured format; then, log templates are excavated with the Drain parser. Then the log template is preprocessed to expel special symbols and stop words; further steaming is performed. This cleaned data will be available for tokenization, followed by vectorization.

## IV. FEATURE EXTRACTION TECHNIQUES

### A. Doc2Vec

Doc2vec is a Natural Language Processing (NLP) technique for converting documents into vectors. Doc2vec's work is based on the conception of Word2vec. The direct encouragement for the development of doc2vec is to induce a vector illustration of a group of words collected together to be presented as a single unit, irrespective of the length of the document. The pivotal variance in the word and sentence representation is that words carry logical structure, but documents don't. Mikilov and Le [23] introduced an additional vector, Paragraph ID, along with the word2vec model to solve this issue. Thus, at the time of word vectors training, the document vector also gets trained, and eventually, the document is converted to numerical form. This model is the Distributed Memory version of the Paragraph Vector (PV-DM).

TABLE I. EXPERIMENTAL RESULTS OF DRAIN PARSER ON VARIOUS DATASETS

Dataset	Source Type	Size of Data	Number of log Messages	Number of Unique Template	Template Max Length	Parsing Accuracy
Apache	Server Application	4.90 MB	56,481	44	42	1
OpenStack	OpenStack infrastructure log	5.4 MB	207,820	7,221	104	0.73
Windows	Windows event log	267.465 MB	611,103	176	173	0.99
BGL	Supercomputer	708.76 MB	4,747,963	619	376	0.99
Android	Android framework log	25.7 MB	1,555,005	14,899	124	0.91

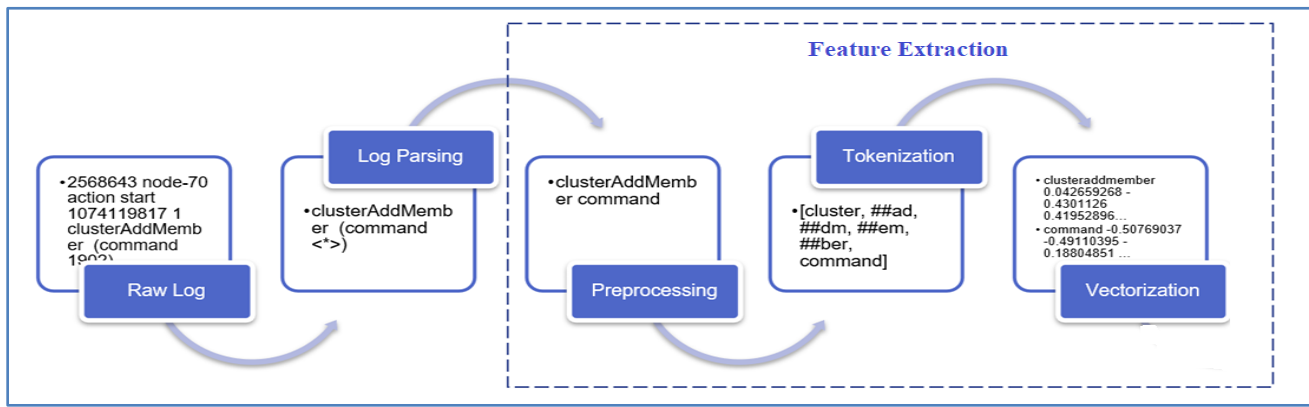

Fig. 2. Process of feature extraction.

To utilize the doc2vec model, the following steps need to be pursued. First, furnish the dataset, which is to be turned into vectors. A word vector is created for an individual word, and combining related word vectors creates a document vector for each document [33]. The softmax hidden layer is used to train the weights, and then all weights are set to find the sentence vector.

**B. Bidirectional Encoder Representations from Transformers (BERT)**

BERT models are the most acceptable preference for obtaining superior-quality language features from the offered text dataset. Furthermore, the model can be fine-tuned for specific tasks such as semantic analysis or question answering, relying on input datasets. BERT is a pre-trained language model that is directionally trained [34]. Devlin et al. demonstrated that a directionally trained language model could possess a more profound sense of language context and flow than single-direction language models [35].

The BERT pre-trained model outperforms word2vec as this approach assigns dynamic numerical vectors to each token, considering the context within which the word appears whereas in word2vec, each word has a fixed numerical vector allocated. Experimentation uses BERT to pull out features by generating word and sentence embedding vectors from log templates and contents. This research focuses on the feature extraction part of the BERT; thus, the remaining part is not considered for an explanation. Here, log templates and contents are elicited from the Drain parser and presented to the BERT model to extract the features. BERT is a pre-trained model taking input data in a specific format. BERT mainly adds an [SEP] as the split between consecutive sentences and

an [CLS] at the start of the sentence. The BERT model offers intrinsic tokenizing. The supplied input is spitted into multiple tokens considering the corpus records. Following that, the embedding layer creates an embedding vector for each token, which includes [CLS] and [SEP]. Log template data desires to be converted into torch tensors and called the BERT model to evoke embedding. The BERT PyTorch interface demands that the data be in torch tensors rather than Python lists. The bert-base-uncased model contains 13 layers (1 for input embedding and +12 for output embedding) of the transformer encoder and 768-hidden units of all transformers.

Every token has 13 independent vectors, each of length 768 but necessary to get separate vectors for every token or single vector presentation of the entire sentence. Individual vectors are calculated by adding the last four layers together. Furthermore, a 768-length vector is calculated for each sentence by taking the average of the second to the final hidden layer.

Table II presents a comparative analysis of Doc2Vec and BERT embedding techniques. This summarized view is bestowed in reference to the critical points observed during the study of Doc2Vec and BERT techniques. These techniques are compared using a type of embedding suitable for which kind of data and the pros-cons of the method. Doc2Vec works on static sentence embedding, whereas BERT considers the context of the words for embedding.

Thus, Doc2Vec is the appropriate choice in a problem where semantic relations between the words are essential. To extract contextual ties between words, BERT works very efficiently.

TABLE II. COMPARATIVE ANALYSIS OF WORD EMBEDDING TECHNIQUES / MODELS

Technique/Model	Embedding Type	Suitable for	Pros	Cons
Doc2Vec	Static Sentence Embedding	Semantic Relation Between Word	Generate a vector representation of a group of words collected to present as a single unit.	The co-occurrence matrix of sentences occupies plenty of memory for storage.
BERT	Contextualized Word Embedding	Contextual Relation Between Word	Capable of gaining context-sensitive bi-directional feature representation.	Fine-tuning and pre-training are inconsistent. Long training time due to the immense size of model files

## V. CLASSIFICATION MODEL

### A. Model Definition

Machine learning classifiers are essential tools for a wide range of applications. They have the potential to revolutionize many industries by automating tasks, improving accuracy, and providing new insights into complex systems. These classifiers work by learning patterns and relationships within a given dataset and then using that knowledge to classify new data into pre-defined categories or classes. In recent research, the authors explored using multiple classifiers to group logs based on log level. The working of machine learning classifiers can vary depending on the algorithm used. This study experimented on five different infrastructure logs using k-Nearest Neighbors, Linear Regression, Support Vector Machines, Naïve Bayes, Gradient Boosting Decision Trees, and Random Forest machine learning classifiers.

1) *K-Nearest Neighbors (KNN)*: IT is a machine learning classifier that can be used for regression and classification tasks. A non-parametric algorithm finds the K closest training examples (i.e., neighbors) to a new data point and uses their class labels to make a prediction [36].

2) *Linear regression*: Linear regression is a type of regression analysis that models the relationship between a dependent variable and one or more independent variables [37]. It is commonly used for predicting continuous values, such as sales revenue or stock prices.

3) *Support Vector Machines (SVMs)*: SVMs are supervised learning algorithms that can be used for classification or regression tasks [38]. SVMs try to find the optimal hyperplane that separates the different classes in the dataset.

4) *Naïve bayes*: Naïve Bayes is a probabilistic algorithm that can be used for classification tasks [39]. It is based on Bayes' theorem and assumes that the features in the data are independent of each other.

5) *Gradient boosting decision trees*: Gradient boosting is an ensemble learning technique that combines multiple decision trees to improve prediction accuracy. It involves training a series of decision trees in sequence, with each subsequent tree trying to correct the errors of the previous one [40].

6) *Random forests*: Random forests are also an ensemble learning technique that uses multiple decision trees to improve prediction accuracy [41]. However, unlike gradient boosting, random forests train each decision tree independently and then aggregate their predictions to make the final prediction.

### B. Evaluation Metrics

Classification of logs is based on the level earmarked for the log entry. In the different IT infrastructures, log entries hold numerous types of levels. Thus, a multi-class classification technique is favored to accomplish the classification. Generally, a multi-class classifier's performance is appraised by the Micro-F1 score and Macro-F1 Score [42]. Therefore, TP (True Positives), TN (True Negative), FP (False

Positives), and FN (False Negatives) values were collected from each category of level and further utilized to calculate micro precision, macro precision, micro recall, macro recall, and macro-F1.

For a provided log category  $i$ , outcomes are labeled as  $TP_i$ ,  $TN_i$ ,  $FP_i$ , and  $FN_i$ . Where  $TP_i$  represents the number of true positives in logs belonging to the  $i$  category.  $TN_i$  represents the true negative in logs belonging to the  $i$  category.  $FP_i$  represents false positives, and  $FN_i$  means false negatives in logs belonging to the  $i$  category.

Considering values of  $TP_i$ ,  $TN_i$ ,  $FP_i$ , and  $FN_i$ ,  $precision_i$  and  $recall_i$  are evaluated as:

$Precision_i$  can be calculated as the percentage of positively labeled predictions made out of all predictions under the  $i$  category of the level [43].

$$Precision_i = \frac{TP_i}{TP_i + FP_i} \quad (1)$$

The  $Recall_i$  can be calculated as the number of correct predicted results divided by applicable instances. Recall provides the number of accurately predicted results divided by all relevant samples [43].

$$Recall_i = \frac{TP_i}{TP_i + FN_i} \quad (2)$$

Macro-F1: Employed to compute the F1- score in the instance of multi-class settings. Macro-F1 is known as the macro-averaged F1 score and is calculated as simple arithmetic means of the F1 scores of each class [44].

$$Macro\ Average\ Precision = \frac{\sum_{k=1}^k Precision_k}{k} \quad (3)$$

$$Macro\ Average\ Recall = \frac{\sum_{k=1}^k Recall_k}{k} \quad (4)$$

$$Macro\ F1\ Score = 2 * \left( \frac{MacroAveragePrecision * MacroAverageRecall}{MacroAveragePrecision^{-1} + MacroAverageRecall^{-1}} \right) \quad (5)$$

Specificity is calculated on the negatives that are detected accurately. Specificity is also known as True Negative Rate (TNR), which denotes the classifier's ability to enter negative entries in the actual class [45]. In the case of logs, the system administrator can select a log level with correct specificity to proctor the anomalies or failures.

$$Specificity_i = \frac{TN_i}{TN_i + FP_i} \quad (6)$$

The metrics used to measure model performance are training and testing splits accuracy. Accuracy is the rate of the absolutely classified data to all the data [46].

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (7)$$

## VI. IMPLEMENTATION DETAILS

All models are implemented in Python and executed on the Symbiosis Institute of Technology (Pune, India) server. Various datasets such as Apache, OpenStack, Windows, BGL, and Android were utilized to conduct the experimentation. These datasets carry a vast number of log messages ranging

from around fifty-six thousand to 11 million (refer to Table III for dataset details). Because of the excellent server configuration made executing the BERT feature extraction technique and ML classifiers on a massive data size possible.

TABLE III. DATASET DESCRIPTION

Dataset	Description	Source Type	Period	Number of logs
Apache	Apache webserver error log	Server Application	263.9 days	56,481
OpenStack	OpenStack infrastructure log	Cloud System	NA.	207,820
Windows	Windows event log	Operating System	NA.	611,103
BGL	Blue Gene/L supercomputer log	Supercomputer	214.7 days	4,747,963
Android	Android framework log	Mobile System	NA.	1,555,005

The "Drain" parser is employed to parse the log messages into log templates. An environment was created to run the Drain parser by installing dependencies such as Python 2.7, Scipy, NumPy, sci-kit-learn, and pandas. The unstructured logs were converted into the structured format and preserved in the .csv file. The results of parsing using Drain are presented in Table I.

For feature extraction, we construct Doc2Vec and BERT sentence embedding models. Doc2Vec model was developed considering vector size 10, windows as 2, minimum count of records one, and assigned workers as 4. At the same time, the Bert-base-uncased model was employed to obtain sentence vectors of log templates and contents. Considering the time required for embedding and model training, optimizing the performance of the BERT pre-trained model was indispensable. According to [47] BERT model works effectively when max\_seq\_len is 25, pooling\_layer is set as 12, priority batch size is 16, and prefetch\_size is set as 10. The exact configuration was followed to improve the speed of the embedding process.

The classification models were trained over random training and testing data selection from the provided datasets. Records are selected using different seeds, as 70% and 80% of log entries as training data, and 30% and 20% remain as testing data. All classifiers were experimentally evaluated based on precision, recall, F1-score, specificity, and accuracy for each log level within our labeled dataset.

## VII. RESULTS

Table IV demonstrates the accuracy of classification models where BERT is utilized as an embedding technique to apprehend the meaning of log templates and contents. The K-

nearest neighbor model indicates lower accuracy among the seven implemented classifiers, whereas Random Forest offers higher classification accuracy for all datasets. As per the observation from Table IV, although the training and testing ratio changes yet there is an insignificant difference in the accuracy values.

Minimum accuracy was recorded as 81.47% for the BGL dataset using KNN, whereas 90.22% accuracy for the Apache dataset using the SVM model. The accuracy score greater than 90% is highlighted in Table IV. Higher accuracy was derived on an 80% training ratio for the Apache dataset using Linear Regression, SVM, and Random Forest and for the OpenStack dataset using Random Forest. Table IV observations show the KNN model returns lower accuracy, and the Random Forest model returns higher accuracy for almost all datasets. The difference between the minimum and maximum accuracy is 8.75%; thus, we can conclude that all implemented classification models have roughly comparable accuracy on Apache, OpenStack, Windows, BGL, and Android datasets. Based on this discussion, it is stated that semantic analysis using BERT helps classify various types of log records efficaciously. In addition, it is claimed that OpenStack and Android datasets are more suitable for the evaluation of the robustness of the classification model in the case of unseen log records. A more significant number of log templates are recorded for OpenStack and Android datasets in the parsing process (stated in Table I).

### A. Results on Apache Dataset

Fig. 3 presents a metaphorical evaluation of seven classifiers over the Apache webserver error log dataset, considering a 30% and 20% testing data ratio. Prior to the classification, features were extracted with the help of the BERT model. Random Forest achieves the highest precision (96.08%) among the seven techniques and carries an F1 score of 92.71% in both cases, considering the 30% and 20% testing data ratio. This demonstrates that Random Forest provides the best classification results on semantic analysis of log templates and contents of log records. KNN, LinearRegression Support Vector Machines, Gradient Boosting Decision Trees, and Random Forests obtain consistent precision values on the Apache dataset, although the training-to-testing data ratio varies. Gradient Boosting Decision Trees and Random Forests show high precision but a low recall rate compared to other models. It is ascertained that all implemented models achieve consistent results on the Apache dataset, which implies that the semantics of the Apache log template and contents are derived correctly; thus, models can understand and perform classification operations. Also, unique templates (44) are derived during parsing 56,481 log records (refer to Table I) with 100% accuracy. The observation revealed the importance of log parsing in the log-based failure detection process.

TABLE IV. CLASSIFICATION ACCURACY IN PERCENTAGE ON VARIOUS DATASETS CONSIDERING 30% AND 20% TESTING DATA USING BERT EMBEDDING TECHNIQUE

IT Infra-structure	Training Ratio	k-Nearest Neighbors	Linear Regression	Support Vector Machines	Naïve Bayes	Gradient Boosting Decision Trees	Random Forest
Apache	70%	86.36	88.04	88.54	87.88	88.69	89.69
	80%	86.95	<b>90.01</b>	<b>90.22</b>	89.46	89.13	89.65
OpenStack	70%	84.17	86.11	86.34	85.27	86.07	88.17
	80%	85.17	88.02	88.14	87.94	87.81	89.34
Windows	70%	82.11	84.36	84.36	83.99	84.39	84.45
	80%	83.35	86.77	86.77	85.23	85.73	85.39
BGL	70%	81.47	83.39	83.39	83.79	83.09	85.21
	80%	82.98	85.79	85.70	85.74	85.01	86.89
Android	70%	81.89	83.89	83.89	81.87	82.46	85.72
	80%	83.67	85.79	85.79	84.72	84.72	87.56

Fig. 3. Precision, recall, f1-score, and specificity in percentage on Apache datasets considering 70% and 80% of training data using BERT embedding technique.

**B. Results on OpenStack Dataset**

Fig. 4 presents a metaphorical evaluation of seven classifiers over the OpenStack infrastructure log dataset, considering a 70% and 80% training data ratio, respectively. Before the classification, features were extracted with the help of the BERT model. KNN, Linear Regression, Support Vector Machines, Naïve Bayes, Gradient Boosting Decision Trees, and Random Forests achieved more than 90% precision when experiments were conducted on 30% of testing records and 20% of testing records, respectively. The precision, recall, F1-Score, and specificity improved by increasing the training-to-testing ratio. Among the seven implemented classifiers, Random Forest has the highest precision (95.13%), recall (89.31%), and F1 Score (92.13%) over 80% of the training data. The OpenStack dataset is preferred to check the classification efficiency for unobserved log records as it records a higher number (7,221) of log templates in 207,820 total log entries (refer to Table I), 3.47% of the whole dataset. In contrast, other datasets retrieve less than 1% of log templates. More variations in the log template promote checking the capability of semantic analysis to extract rigorous meaning that imparts to accurate classification.

**C. Results on Windows Dataset**

Fig. 5 presents a metaphorical evaluation of seven classifiers over the Windows event log dataset, considering a 70% and 80% training data ratio. Before the classification, features were extracted with the help of the BERT model. K-Nearest Neighbors records minimum precision as 85.67% and maximum precision by Random Forest as 87.99%, which

means the difference in precision is significantly less for seven classification models. Although the precision, recall, and F1-Score values are less than 90%, they are consistent for all implemented classifiers. The Windows dataset results are decreasing compared to Apache and OpenStack datasets due to the size of the data and the number of unique templates. In the Windows dataset, 176 unique templates were extracted from 611,103 (refer to Table I) event records, which is only 0.02%. Here, unique templates are fewer, but the contents of the individual events fluctuate in compliance with the recorded message.

Fig. 4. Precision, recall, f1-score, and specificity in percentage on Openstack datasets considering 70% and 80% of training data using the BERT embedding technique.

Fig. 5. Precision, recall, f1-score, and specificity in percentage on Windows datasets considering 70% and 80% of training data using BERT embedding technique.

**D. Results on BGL Dataset**

Fig. 6 presents an illustrative evaluation of seven classifiers over the Blue Gene/L supercomputer log dataset, considering a 70% and 80% training data ratio. Before the classification, features were extracted with the help of the BERT model. KNN records minimum precision as 82.89% and maximum by Random Forest as 86.77%, which means the

difference in precision is significantly less for seven classification models. Although the precision, recall, and F1-Score values are less than 90%, they are consistent for all implemented classifiers. The BGL dataset results are decreasing compared to Apache and OpenStack due to the size of the data and the number of unique templates. In the Windows dataset, 619 unique templates were extracted from 4,747,963 (refer to Table I) log records, which is only 0.01%. Here unique templates are lesser, but the contents in the individual log fluctuate in compliance with the recorded message. According to observation, 1-2 % change in the precision, recall, and F1-Score values on different testing ratios, such as lower results recorded on the 30% testing ratio, whereas improved results by 1-2% recorded on 20% testing data.

Fig. 6. Precision, recall, f1-score, and specificity in percentage on BGL datasets considering 70% and 80% of training data using the BERT embedding technique.

#### E. Results on Android Dataset

Fig. 7 presents a metaphorical evaluation of seven classifiers over the Android framework log dataset, considering a 70% and 80% training data ratio. Before the classification, features were extracted with the help of the BERT model. KNN records the minimum precision as 78.34%. The difference in precision is significantly less for the seven classification models. The Android dataset results are decreasing compared to Apache and OpenStack due to the size of the data and the number of unique templates. In the Android dataset, 14,899 unique templates were extracted from 1,555,005 (refer to Table I) log records, which is only 0.09% of the whole dataset. Thus, the Android dataset is preferred to check the classification efficiency for unseen log records. More variations in the template help check the capability of semantic analysis to extract exact meaning that contributes to accurate classification. As a bottom line, it is stated that the greater the number of log records and the greater the number of unique templates, the more they help to train the model effectively.

Fig. 7. Precision, recall, f1-score, and specificity in percentage on Android datasets considering 70% and 80% of training data using the BERT embedding technique.

#### VIII. CONCLUSION AND FUTURE WORK

This paper describes an automatic and accurate classification of logs to facilitate system administrators during cause analysis of failures using system logs generated by various massive-scale IT infrastructures. The implemented models are able to understand the meaning of records and then classify them based on their level for log entries from multiple infrastructures such as Apache, OpenStack, Windows, BGL, and Android. The system admin can pay more attention to bizarre records and adopt remedial measures on the Anomalous records pointed out in the classification results,

The proposed system works efficiently on different types of log entries irrespective of changes in the format and imbalanced data. Thus, this work indicates how semantic analysis using BERT and classification using Linear Regression, Support Vector Machines, Naïve Bayes, Gradient Boosting Decision Trees, and Random Forests models furnish robust classification of new log entries. Considering the results and discussion points, K-Nearest Neighbors does not work well due to the imbalanced nature of log records. It is observed that, as compared with Doc2Vec, the semantic analysis achieved by the BERT pre-trained model is better while working with different classifiers. In addition, BERT influences the classification of any log record type with all classifiers and precisely processes the unseen or new log entries.

Experimentation using BERT as an embedding technique and machine learning models as classifiers derived precision, recall, F1 scores, and specificity in the range of 80% to 90%. In the extension to this work, we will try to improve the results to reduce false alerts with the help of applying deep learning techniques such as LSTM. Future work put forward the enforcement of LSTM models and propounding modified LSTM models to secure better results. Also, the system implemented with feature extraction and classification is semi-automated. In the future, the proposed system will be enhanced to implement a fully automated classification system to reduce human intervention.

**Abstract**—Jamming attacks represent a significant problem in 5G mobile networks, requiring an effective detection mechanism to ensure network security. This study focused on finding effective methods for detecting these attacks using machine learning techniques. The effectiveness of Ensemble Learning and the XGBOOST-Ensemble Learning combination was evaluated by comparing their performance to other existing approaches. To carry out this study, the WSN-DS database, widely used in attack detection, was used. The results obtained show that the hybrid method, XGBOOST-Ensemble Learning, outperforms other approaches, including those described in the literature, with an accuracy ranging from 99.46% to 99.72%. This underlines the effectiveness of this method for accurately detecting jamming attacks in 5G networks. By using advanced machine learning techniques, the present study helps strengthen the security of 5G mobile networks by providing a reliable mechanism to detect and prevent jamming attacks. These encouraging results also open avenues for future research to further improve the accuracy and effectiveness of attack detection in radiocommunication in general and specifically in 5G networks, thereby ensuring better protection for next-generation wireless communications.

**Keywords**—Jamming attacks; 5G mobile networks; ensemble learning; XGBOOST-ensemble learning; attack detection

## I. INTRODUCTION

Radiocommunication is defined, according to the International Telecommunication Union (ITU), as telecommunication carried out using radioelectric waves, that is to say, an electromagnetic wave that propagates in space without an artificial guide and whose frequency is by convention less than 3000 GHz [1]. The fields of application of this form of communication are numerous, including Wi-Fi, mobile, satellite, IoT networks, wireless sensors, high-altitude platforms, smart cities, smart grids, connected vehicles, etc. All these applications use propagation of the useful signal emitted in all directions, often in environments with multiple and sometimes complex obstacles, thus undergoing all kinds of disturbances, including intrusions by jamming for denial of service (DoS) and distributed denial of service (DDoS) [2]. Jamming attacks consist of intentionally transmitting a signal [3] that covers the frequencies used by the communication system to degrade the quality of the signal received by a communication device. Jamming signals can be relatively weak intentional electromagnetic interference (IEMI) [4] that degrades the performance of radio communication networks

without damaging them. With the proliferation of connected objects (IoT) and the convergence of networks, the number of devices used in everyday life and connected to the Internet by radio communication has increased considerably in recent years. According to statistics, this number has increased from 1 million in 1992 to more than 50 billion in 2020[5] globally. With this reality, telecommunications networks, particularly 5G mobile networks, have undergone significant transformations to adapt to this exponential growth of connected devices. Significant contributions include the evolution of the radio access network (RAN), the part of 5G that connects end-user devices. Architectures such as C-RAN, O-RAN, vRAN, etc., have been proposed to address these challenges. These new network architectures have improved the flexibility, capacity, and efficiency of 5G mobile networks. However, with this evolution, new security challenges have also emerged. Among these challenges, jamming attacks represent a significant problem that compromises network security. Despite the advantages offered by new network architectures, the security of C-RAN networks has been questioned due to their vulnerability [6] to malicious jamming attacks, especially regarding the use of radio resources. Even the most advanced C-RANs can be subject to all sorts of attacks on radio networks.

Different types of jamming attacks can be used against C-RAN, including random, reactive, deceptive, and constant jamming [7]. These attacks seriously threaten the proper functioning of C-RAN networks and can compromise the quality of services offered to end users.

In order to counter these jamming attacks, it is essential to put in place effective detection mechanisms. This study focuses on using machine learning techniques to detect these attacks in C-RAN networks. The effectiveness of Ensemble Learning and the XGBOOST-Ensemble Learning combination is specifically assessed, comparing their performance to other existing approaches.

By identifying and evaluating the different jamming attacks possible in C-RAN networks, our study aims to strengthen the security of these networks by proposing advanced detection mechanisms. These results will allow a better understanding of the characteristics of these attacks and the development of appropriate countermeasures to protect C-RAN networks from the harmful consequences of jamming attacks.

The issue of jamming attack detection in 5G mobile networks using machine learning (ML) techniques is addressed in this study. The approach developed here, uses a specific database (WSN-DS) to evaluate and compare the performance of different machine Learning algorithms. The goal is to determine the most efficient algorithm for detecting jamming attacks based on this data set. The present study has made the following contributions:

- The use of machine learning techniques, in particular ensemble learning and the XGBOOST-ensemble learning combination, to detect jamming attacks. This innovative approach leverages the capabilities of these advanced techniques to improve detection accuracy.

- Performance evaluation of ensemble learning and XGBOOST-ensemble learning in comparison with other existing approaches. This comparative evaluation highlights the superior effectiveness of the hybrid XGBOOST-Ensemble Learning method, which outperforms the other approaches studied and those described in the literature.

This paper is organized as follows. After the introduction, which sets out the problem addressed in this paper in Section I, Section II presents a literature review of previous work on intrusion detection attacks and methods (ML-IDS) in radio communications, particularly in 5G. The ML-IDS methodology adopted in this work (EL-IDS) is formulated and presented in Section III. The results obtained are presented in Section IV and discussed in Section V. Finally, Section VI focuses on the research objective and draws conclusions from this study.

## II. RELATED WORK

The new generation of wireless communication networks, the fifth generation (5G), guarantees a high transmission rate and low latency and maintains good connectivity between heterogeneous mobile devices. 5G cellular networks provide the key infrastructure to deliver emerging services. Security anomaly detection is increasingly important in protecting systems from malicious attacks. Several authors have conducted interference studies in the 5G network. F Wu et al. studied a mixed digital interference (MNI) recognition approach based on convolutional neural networks (CNN) [8]. The results of this work showed that the accuracy could reach 97% or more for different signal-to-noise ratios and fading channels. M. Usama et al. proposed a technique stimulated by recent advances in deep learning to exploit the rich information hidden in large volumes of data and tackle resource allocation problems [9]. Mughaid et al. built a simulator for NOMA and applied a drop attack to extract a dataset from the simulation model. The accuracy of detecting drop attacks using data extracted after applying ML algorithms is 95.7% for LR. Furthermore, their methodology for detecting wireless cyberattacks in 5G networks is based on applying ML and DL techniques such as Decision Trees, KNN, Multi-class Decision Jungle, Multi-class Decision Forest, and Multi-class Neural Networks. The proposed work is implemented and tested using a complete set of reference data on Wi-Fi networks [10]. The experiments yielded 99% accuracy for the KNN algorithm and 93% for DF and the neural network. L. Xiao et al. investigated MEC systems' attack patterns, focusing on mobile offloading

and caching procedures. In this article, they propose security solutions that apply Reinforcement Learning (RL) techniques to provide secure offload to edge nodes against jamming attacks; also, lightweight authentication and secure collaborative caching schemes have been designed to protect data confidentiality[11]. The results of these reinforcement learning-based methods for mobile edge caching are relevant. Y. Wang et al. presented an anonymous jamming detection model for 5G and beyond based on critical signal parameters collected from the radio access network and core network protocol stacks on a test bench. 5G trial. The results of their approach give supervised instantaneous detection models an area under the curve (AUC) between 0.964 and 1 compared to time-based long-term memory models (LSTM), which reach an AUC between 0.923 and 1 [12]. Jamming and intrusion detection remain 5G's most important research areas of maintaining the trustworthiness of use cases and preventing user experience degradation by avoiding a severe infrastructure failure or a denial of service in critical applications within the company. Similarly, Marouane Hachimi et al. proposed machine learning-based intrusion detection in the 5G C-RAN network to enhance security [5]. Their approach was to classify the types of jamming attacks within a 5G network. Their experiment gave an attack classification accuracy of 94.51% with a false negative rate of 7.84%.

The work presented above indicates that the studies carried out by these authors have focused on interference recognition in Wi-Fi networks using Machine Learning and Deep Learning models.

Furthermore, these studies highlight the use of Machine Learning and Deep Learning algorithms for interference classification, but have not delved into comparative studies that evaluate the performance of different interference classification models in Wi-Fi networks. The present study uses Machine Learning techniques, in particular Ensemble Learning (Random Forest, KNN, Naïve Bayes, Logistic Regression) and the XGBOOST-Ensemble Learning combination (XGBOOST-Random Forest, XGBOOST-KNN XGBOOST-Naïve Bayes, XGBOOST-Logistic Regression) to detect interference attacks in the 5G network. It compares the performance of different interference identification techniques, to highlight their impact on the accuracy of interference classification. The use of these different approaches provides a better understanding of Ensemble-Learning classification methods and the XGBOOST-Ensemble Learning combination, highlighting the strengths and weaknesses of each technique in detecting interference in the 5G network.

## III. MATERIAL AND METHOD

### A. Material

The database used for our study is the WSN-DS: a data set for intrusion detection systems in wireless sensor networks. It contains 374,661 simple connection vectors, each including 23 characteristics, and is labeled as normal or attack. The specific attack types are scattered into different attack categories, namely constant jamming, random jamming, deceptive jamming, and reactive jamming, in addition to the normal case (without attack).

The experiments used Python programming on a DELL desktop computer with an Intel(R) Core i7-10700 CPU clocked at 2.90 GHz, 32 GB of RAM, and a card NVIDIA Quadro P400 graphics.

### B. Deployment Architecture

Fig. 1 presents the architecture. It divides base stations into Radio Remote Heads (RRH) and the Baseband Unit (BBU). RRH is the unit that provides the interface to the fiber and performs the digital processing, digital-to-analog conversion.

The traditional C-RAN architecture is based on Mobile Cloud Computing (MCC) principles with centralized BBUs in remote data centers. Resources provided to mobile users are typically located at the end of a long chain of nodes and across a mobile backhaul that can be congested at any time. However, more and more applications today operate almost in real time with requirements for very short transmission times. Thus, the performance of C-RAN systems is highly dependent on the physical proximity between mobile users and cloud servers.

The objective of this architecture is to concede the calculation and the storage to the H-RRHs near the mobile user to increase the processing capacity of the mobile terminals and allow the unloading of the greedy tasks in resources. All the added resources from the Cloud-RRH.

In addition, using cloud containers instead of virtual machines (VMs) at the RRH cloud level saves performance and processing time. A container is a collection of self-contained components ready to be deployed, and it can include libraries to be able to run the applications. Unlike VMs, multiple containers can share the same host operating system with its libraries and binaries. The containers are much lighter, translating into faster launch and easier migration from one machine to another.

Despite these proposals for attractive solutions introduced in this new C-RAN architecture, the radio interface remains a significant challenge in the face of jamming attacks using radio resources. For experimental results, a specialized dataset for Wireless Sensor Networks (WSN) was analyzed to classify jamming attacks; WSN-DS can have normal or malicious network traffic.

Fig. 1. Deployment architecture of EL-IDS in the CRAN – CRRH environment).

### C. Learning Algorithms

The choice of the appropriate Learning algorithm [13] is crucial for the performance of a prediction model. In the present study, we opted for the use of Learning ensembles composed of the following algorithms: Random Forest, KNN, Naïve Bayes, Logistic Regression and XGBOOST. Each classification algorithm has its advantages and disadvantages, and we decided to combine them with XGBOOST for feature extraction to improve the performance of our classification model. When the data is insufficient, the learning set can use bootstrapping to train various classifiers using the different data samples, and also if the data is too large to train a single classifier then it is possible to partition the data into subsets for training purposes.

1) *KNN (K Nearest Neighbor)*: The nearest neighbor (KNN) method [14] is a popular classification method in data mining and statistics due to its simplicity of implementation and significant performance in classification. However, traditional KNN methods cannot assign a fixed k value (even if set by experts) to all tested samples. Previous solutions assign different k values to different test samples by cross-validation, but they are usually very time-consuming [15]. The KNN method has been widely used in data mining and machine learning applications due to its simplicity of implementation and remarkable performance.

2) *Naive bayes*: Naïve Bayes is one of the most popular data mining algorithms. Its effectiveness relies on the attribute independence assumption, although this may be violated in many real-world datasets. Many efforts have been made to mitigate this assumption, among which feature selection is a critical approach [16].

The naive Bayes classifier has surprised machine learning researchers by performing well on various learning problems. The researchers sought to overcome the main weakness of naive Bayes attribute independence and improve the algorithm's performance [17]. The naive Bayes classifier simplifies learning by assuming that features are class-independent. Although independence is generally a bad assumption, naive Bayes often compete with more sophisticated classifiers in practice.

3) *Logistic regression*: Logistic regression is used to obtain the odds ratio in the presence of more than one explanatory variable. The procedure is similar to multiple linear regression, except that the response variable is binomial. The result is the impact of each variable on the odds ratio of the observed event. The main advantage is avoiding confounding effects by analyzing the association of all variables [18]. It is an algorithm based on a statistical model allowing the study of the relations between a set of qualitative variables,  $X_i$ , and a qualitative variable  $Y$ . It uses a generalized linear model on a logistic function as a link function. The probability of predicting an event with the logistic regression model is established or not from the optimization of the regression coefficients, and its result continuously varies between 0 and 1.

4) *Random forest*: Random forest is a supervised learning algorithm used for classification and regression. It combines multiple decision trees to produce more accurate predictions. Random forest is useful for datasets with categorical or continuous variables and can handle missing data. The RF algorithm randomly divides the data set into training data (in-bag) for training and validation data (out-of-bag) for testing. The level of learning and 2/3 of the data set is devoted to training data and 1/3 to validation data. Subsequently, many decision trees are randomly created using "bootstrap samples" from the dataset. The branching of each tree is determined by randomly selected predictors at node points [19].

5) *XGBOOST*: XGBOOST is an improved model of the Gradient Boost algorithm. This machine Learning algorithm solves common business problems while relying on a minimum amount of resources [20]. Extreme gradient boosting is a method that is used to reduce the number of errors in predictive data analysis. XGBOOST is an assembly of decision trees (weak learners) that predict residuals and correct errors of previous decision trees. The particularity of this algorithm lies in the decision tree used. It is a recently introduced machine learning algorithm, which has proven to be very powerful in modeling complex processes in other research areas.

#### D. Methods

The methodology used in this study is based on several well-defined steps, thus providing a solid and rigorous approach to achieving our objectives. The most advanced intrusion detection techniques are studied to enable the security system monitoring the network to analyze traffic in order to discover actions that disrupt network confidentiality, integrity and availability.

Here is a detailed description of these steps:

- Step 1 : Data preprocessing

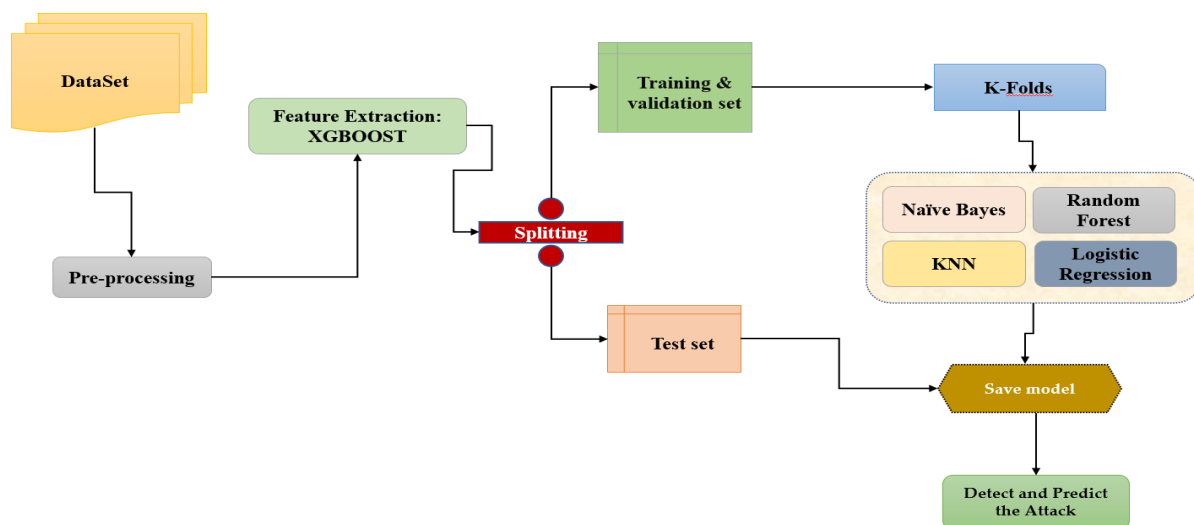

Fig. 2. Illustration of our methodology.

In this first stage, data were pre-processed to prepare them for subsequent analysis. Two distinct groups of data are created: the independent variables and the dependent variable. The "Type of attack" column is designated as the dependent variable in our dataset. The transformation of this categorical variable into a numerical value to facilitate analysis is carried out.

- Step 2 : Feature extraction

In this step, the XGBOOST algorithm is used to extract the characteristics of the independent variables. This advanced method enables us to highlight patterns and significant information in the data. Next, our data are divided into three parts: training, validation and testing. This division enables us to measure the effectiveness of the model on separate data sets and ensure its generalizability.

- Step 3 : Training with cross-validation

In this crucial step, the model was trained using cross-validation with algorithms. This approach makes it possible to test different algorithms and select the best performing one for classifying instruction types, the specific task. The training and validation sets are used to adjust the model parameters and evaluate its performance.

- Step 4 : Testing and evaluation

The test phase is essential for evaluating the quality of our model and detecting attacks. The test dataset used is independent of the training and validation datasets, to assess the model's actual performance. The results obtained are carefully examined and compared with known attacks to measure the model's effectiveness in detecting attacks.

Following this well-structured methodology, an in-depth study is carried out on attack detection, pre-processing the data, extracting relevant features, training the model by cross-validation and rigorously evaluating its performance.

Fig. 2 below summarizes the methodology adopted:

### E. Evaluation Metrics

To evaluate the results of this study, several measures were used. Efficiency (MCC). The differential equations are: accuracy, precision, recall, F1 score and Matthew's correlation coefficient. The differential equations are as follows:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (1)$$

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F1\ score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (4)$$

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \quad (5)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (6)$$

The Receiver Operating Characteristic (ROC) curve is a graph that shows the performance of a binary classification model. It describes the rate of true positives (sensitivity) as a function of the rate of false positives at different classification thresholds. An ideal ROC curve is approximately in the upper left corner of the graph, denoting high sensitivity and specificity.

The confusion matrix is a table that summarizes the results of the predictions of a classification model. It evaluates the model's predictions with the actual values from the dataset and classifies them into four categories: true positives, true negatives, false positives, and false negatives. The confusion matrix is used to compare a model's precision, recall, specificity, and overall accuracy.

### IV. RESULTS

The results are structured into two main parts: ensemble learning and XGBOOST Ensemble Learning.

The results of the machine learning models and XGBOOST-Ensemble learning have been presented separately. The machine learning models of the XGBOOST-Ensemble Learning combination outperform the machine learning models of ensemble learning, with a maximum accuracy of 99.72%.

### V. DISCUSSION

#### A. Case of Ensemble Learning

The Table I presents the metrics results:

The Random Forest model presents exceptional performances on all the criteria evaluated. It achieves high precision, a high F1 score, and high recall, all at 99.68%. The very low MSE of 0.007 indicates that the model predictions are close to the actual values. Moreover, the MCC of 98.18% indicates a robust correlation between the predictions and the actual observations. The execution time is reasonable at 356.15 ms.

The KNN model also performs well, although slightly lower than the Random Forest. Measurements of precision, F1 score, and recall are around 98%. The MSE of 0.063 indicates a slight average error of the predictions compared to the actual values. The execution time is longer at 1730.48 ms, which can be a drawback if efficiency is an important criterion.

The Naïve Bayes model has lower performance than the two previous models. Although precision and F1 score are reasonable at 88.10%, recall is relatively low at 84.83%. The high MSE of 0.358 indicates a more significant error of predictions against actual values compared to previous models. The MCC of 48.35% suggests a moderate correlation between predictions and actual observations. However, the execution time is very fast at only 2.62 ms.

The logistic regression model performs lower than other models. Precision and F1 scores sit at 86.24%, while recall is slightly higher at 88.21%. The high MSE of 0.511 indicates a significant prediction error compared to the actual values. The low MCC of 14.76% suggests a weak correlation between predictions and actual observations. Execution time is moderately fast at 185.65 ms.

The Random Forest model is the best among the four evaluated models regarding overall performance, with outstanding results on all measures. The KNN also shows good performance, although lower. Naïve Bayes models and logistic regression show relatively weaker performance, with more significant errors and less strong correlation between predictions and actual observations. Fig. 3 presents the histogram representing the performance of the models.

The Fig. 4 represents the ROC curve and the confusion matrix of the best model, namely the Random Forest.

TABLE I. CASE OF ENSEMBLE LEARNING METRICS RESULTS

Models	Accuracy (%)	Time(ms)	Precision (%)	F1 score (%)	MSE	Recall (%)	MCC (%)
Random Forest	99.68	356.15	99.68	99.68	0.007	99.68	98.18
KNN	98.23	1730.48	98.21	98.21	0.063	98.23	89.72
Naïve Bayes	84.83	2.62	88.10	88.10	0.358	84.83	48.35
Logistic Regression	88.21	185.65	86.24	86.24	0.511	88.21	14.76

Fig. 3. Model performance histogram of case of ensemble learning.

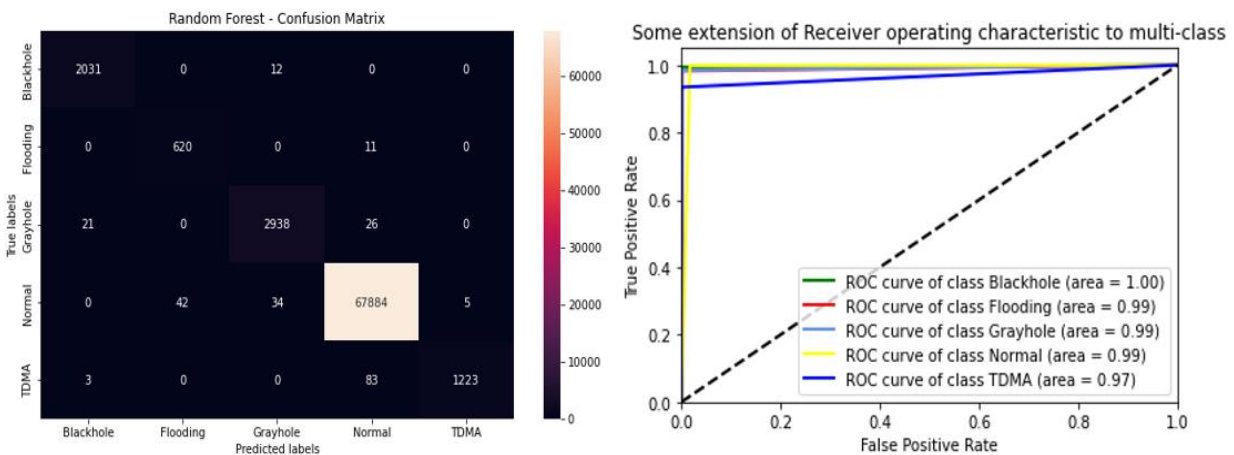

Fig. 4. ROC curve and confusion matrix of Random Forest.

**B. Case of XGBOOST- Ensemble Learning**

All of the models presented in Table II have high levels of accuracy, with scores ranging between 99.46% and 99.72%. This performance demonstrates their ability to classify the vast majority of samples accurately.

The execution time varies depending on the classification methods used. The XGBOOST-Naïve Bayes model is the fastest, with an execution time of only 1.369 milliseconds, while the XGBOOST-Random Forest model is the slowest, requiring 606.06 milliseconds. The other two models fall between these extremes regarding execution time. It is essential to consider these differences based on your specific application needs.

All models have an accuracy ranging from 99.46% to 99.72%, demonstrating their ability to classify most positive samples accurately. These models are, therefore, effective in avoiding false positives.

The F1 score, which combines precision and recall, presents high values for all models, ranging between 99.46% and 99.72%. This indicates a good balance between accuracy and the ability to recall positive samples.

The low MSE (Mean Squared Error) values obtained here indicate a low error in the predictions made. However, it should be noted that their interpretation may be limited in the context of classification.

Recall measures the ability of models to detect true positives among all truly positive samples. All models exhibit high recall values ranging from 99.46% to 99.72%, demonstrating their ability to identify positive samples.

The Matthews Correlation Coefficient (MCC) is a measure that considers the four categories of classification results. All models obtain high values of MCC, ranging from 96.98% to 98.41%, indicating a strong correlation between predictions and actual observations.

In conclusion, the models' performances based on XGBOOST and the other algorithms are globally compelling. The histogram represents the performance of these models visually.

Fig. 5 presents the histogram representing the performance of the models.

The ROC curve and the confusion matrix of the best model, namely the XGBOOST-Logistics Regression, are represented by the Fig. 6.

TABLE II. CASE OF XGBOOST-ENSEMBLE LEARNING METRICS RESULTS

Models	Accuracy (%)	Time(ms)	Precision (%)	F1 score (%)	MSE	Recall (%)	MCC (%)
XGBOOST-Random Forest	99.69	606.06	99.69	99.69	0.0066	99.69	98.25
XGBOOST-KNN	99.69	25.708	99.69	99.69	0.0064	99.69	98.26
XGBOOST-Naïve Bayes	99.46	1.369	99.47	99.47	0.0092	99.46	96.98
<b>XGBOOST-Logistic Regression</b>	<b>99.72</b>	<b>83.806</b>	<b>99.72</b>	<b>99.72</b>	<b>0.006</b>	<b>99.72</b>	<b>98.41</b>

Fig. 5. Model performance histogram of case of XGBOOST- ensemble learning.

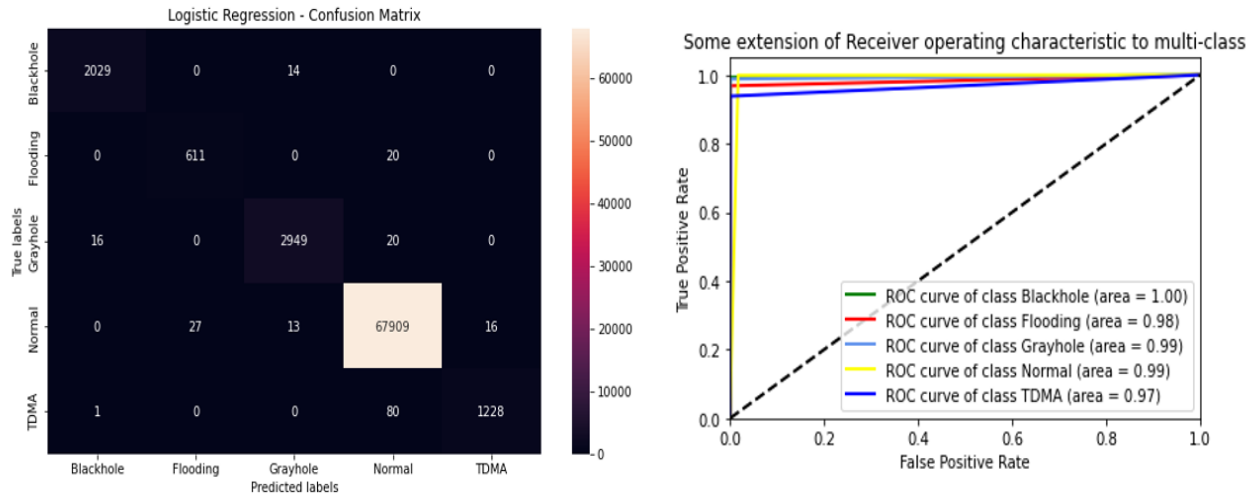

Fig. 6. ROC curve and confusion matrix of XGBOOST- ensemble learning.

C. Comparison with Existing Methods

The results of our experiments exceeded those of the state of the art. Table III shows the results. These results are also represented by the histogram, as shown in Fig. 7.

Fig. 7 shows the histogram comparing the results with those of the state of the art. A comparison was made between the proposed system and the methods used by other researchers in the field of intrusion detection in wireless sensor networks. The results showed that our system outperforms other authors' methods in the two approaches we performed.

TABLE III. COMPARISON WITH EXISTING RESULTS

Method	Accuracy (%)
Marouane Hachimi et al[16]	94,51%
Singh, N et al [17]	98,29%
Shaimaa Ahmed et al[18]	97,9%
<b>Our method of scenario1</b>	<b>99,68%</b>
<b>Our method of scenario2</b>	<b>99,72%</b>

Fig. 7. Histogram of best scores of experiments.

In the first case, using the ensemble learning approach with the Random Forest algorithm, our system achieved an accuracy rate of 99.68%. This means that our method detected intrusions with high accuracy, surpassing the results obtained by other researchers. In the second case, using the XGBOOST-Logistic Regression approach as part of the Learning Ensemble, our system achieved an even higher accuracy rate of 99.72%. This remarkable performance highlights the effectiveness of our method of detecting intrusions in wireless sensor networks accurately.

These results demonstrate the superiority of our system compared to existing methods in terms of intrusion detection accuracy. The approach developed in this paper, based on advanced machine learning techniques, offers remarkable performance, strengthening the security of wireless sensor networks and guaranteeing more effective protection against intrusions.

Importantly, these results also demonstrate the importance of continued research in this area, as they pave the way for future improvements and new approaches for even more accurate detection of intrusions in wireless sensor networks.

## VI. CONCLUSION

In conclusion, the present study has demonstrated that the use of machine learning techniques, in particular ensemble learning and the XGBOOST-Ensemble Learning combination, is promising for the detection of attacks in 5G networks. The results show that the hybrid method, XGBOOST-Ensemble Learning, outperforms all other approaches, including those described in the literature, with an accuracy between 99.46% and 99.72%. These results confirm the effectiveness of ensemble learning in detecting attacks in 5G networks. This study represents a significant advance in the detection of attacks in 5G networks using machine learning techniques. The promising results pave the way for further research and continuous improvements in 5G network security, helping to ensure the reliability and protection of next-generation wireless communications. Future works will explore other attack detection methods based on statistical analysis approaches, such as operational approach models. This will enable us to improve detection accuracy and develop more robust defense systems against attacks in 5G networks. Another avenue would be to integrate real-time detection techniques to enable a rapid

and proactive response to potential attacks, thereby strengthening the security of 5G networks.

**Abstract**—In graph analytics, the identification of influential nodes in real-world networks plays a crucial role in understanding network dynamics and enabling various applications. However, traditional centrality metrics often fall short in capturing the interplay between local and global network information. To address this limitation, the Global Structure Model (GSM) and its improved version (IGSM) have been proposed. Nonetheless, these models still lack an adequate representation of path length. This research aims to enhance existing approaches by developing a hybrid model called H-GSM. The H-GSM algorithm integrates the GSM framework with local and global centrality measurements, specifically Degree Centrality (DC) and K-Shell Centrality (KS). By incorporating these additional measures, the H-GSM model strives to improve the accuracy of identifying influential nodes in complex networks. To evaluate the effectiveness of the H-GSM model, real-world datasets are employed, and comparative analyses are conducted against existing techniques. The results demonstrate that the H-GSM model outperforms these techniques, showcasing its enhanced performance in identifying influential nodes. As future research directions, it is proposed to explore different combinations of index styles and centrality measures within the H-GSM framework.

**Keywords**—Centrality indices; combination; hybrid; global structure model; influential nodes

## I. INTRODUCTION

In the captivating world of graph analytics, identifying significant nodes is critical, providing invaluable insights into the structure and behavior of many real-world networks. Networks with considerable sways, such as social networks, biological networks, and information networks, are characterized by nodes that operate as hubs or influencers, shaping the behavior of the entire network. Understanding and locating these significant nodes improves our understanding of network dynamics and offers possibilities for applications such as targeted marketing, recommendation systems, and vulnerability analyses [1], [2].

Centrality measurements are the preferred metric in network analysis for evaluating the relevance and influence of individual nodes or edges. DC [3], betweenness centrality (BC)[4], closeness centrality (CC)[5], and PageRank (PR) [6] are metrics that have been created to identify nodes that play essential roles depending on a variety of parameters. These traditional metrics primarily focus on local or global network information [7], [8], frequently failing to capture the delicate

interplay between the two. Local influence measurements, such as DC and CC, focus on a node's close connections and proximity to other nodes, elucidating its impact on information or resource flow within a narrow network section[9]–[11]. Global impact metrics, on the other hand, such as BC and PR, take into account the more extensive network structure and the importance of nodes to which a specific node is connected. These metrics excel at identifying nodes that serve as bridges between distinct network groups or enhance network connectivity across the board. These global measures are limited since they are computationally expensive and do not function well in the absence of a complete network structure [9], [12]–[14]. Evaluating local and global influence is critical to have a complete sense of node relevance. Nodes strongly influenced at both scales will likely hold critical positions within the network's complicated structure. They could impact immediate network behavior while altering its overall structure and dynamics.

Ullah's[15] Global Structure Model (GSM) provides a framework for ranking nodes in a network based on their local and global significance. This model uses the K-shell value to assess individual influence while considering neighboring node K-shell values and including path length to determine the global effect. It is worth noting, however, that the GSM falls short of adequately capturing the impact of path length, allowing the opportunity for further improvement. To remedy this issue, an improvement of GSM (IGSM) [16] has been made, which uses DC as its primary parameter rather than KS. Despite these advancements, precisely assessing the value of individual nodes within complex networks remains a substantial problem, emphasizing the need for ongoing study and developing novel ways to acquire more profound insights into network topologies.

This study continues our prior efforts in [17] and [18]. We successfully identified indices based on their similarity, demonstrating the improved performance obtained by combining indices from different network topologies, particularly when incorporating local and global centrality metrics. Next, we enhanced our findings by integrating the GSM with local and global centrality measurements by proposing a new hybrid model (H-GSM). Based on these findings, the current study intends to improve the algorithm using DC and KS framework.

The primary contribution of this study lies in the creation and evaluation of the H-GSM framework. The H-GSM framework combines the GSM with the comprehensive analysis provided by DC and KS, resulting in an improved ability to identify influential nodes. Notably, this integration enables the capturing of the intricate relationship between local and global network information, which is often overlooked by conventional centrality metrics. The findings of this study offer valuable insights for further exploration of different combinations of index styles and centrality measures, thereby advancing the understanding and application of network analysis methodologies.

## II. PRELIMINARIES

GSM and IGSM consider the node's self-influence and global influence, except that GSM believes in KS-decomposition, while IGSM is the improvement that applied DC. The formula is expressed as follows:

$$GSM(i) = SI(i) \times GI(i) = e^{-\frac{KS(i)}{n}} \times \sum_{i \neq j} \frac{KS(j)}{d_{ij}} \quad (1)$$

$$IGSM(i) = improved\_SI(i) \times improved\_GI(i) = e^{-\frac{DC(i)}{n}} \times \sum_{i \neq j} \frac{DC(j)}{d_{ij}^{ceil(\log_2(aver\_degree))}} \quad (2)$$

where  $KS(i)$  refers to the K-shell decomposition value of node  $i$ ,  $DC(i)$  refers to the degree value of a node, and  $d_{ij}$  refers to the path length between node  $i$  and node  $j$ .

These methods have grown in popularity because they are straightforward and enable researchers to quickly collect node values and use them in massive networks, broadening the scope of their potential applications. However, determining each node's significance within a network accurately presents a significant barrier for both the K-shell decomposition and the DC techniques. There need to be more levels in the K-shell decomposition method, which causes many nodes to be assigned to the same level [12], [19]. While DC only considers edge information, it ignores other essential elements like the structure of the entire network [20]. As a result, it might be challenging to accurately distinguish each node's relevance in large-scale networks where many nodes may have identical DC values. DC needs to recognize the significance of position data within the network. Due to their distinct placements or responsibilities in tying together various network regions, nodes with the same DC value may have differing degrees of influence. Alternative approaches that consider additional network properties and the impact of location information are needed to get over these constraints and develop a more thorough knowledge of node influence.

In this study, a hybrid approach of global structural model is proposed. It is suggested that the overall structure of the network is influenced by each node's capacity to impact itself. Because of this, the self-influence participant is essential to global influence. The following is how our suggested method is expressed:

$$H - GSM(i) = hSI(i) \times hGI(i) = e^{-\frac{DC(i)+KS(i)}{n}} \times \sum_{i \neq j} \frac{e^{-\frac{DC(i)+KS(i)}{n}}}{d_{ij}^{ceil(\log_2(aver\_hSI))}} \quad (3)$$

Fig. 1 is a sample network of 7 nodes and 10 edges, showing each node's classification from the KS-Decomposition. Using node 3 as an example, the overall steps for calculating H-GSM is shown.

Fig. 1. Sample network.

Step 1: Determine KS and DC values.

$$DC(3) = 5 \quad KS(3) = 3$$

Step 2: Calculate hybrid self-influence (hSI).

$$\begin{aligned} hSI(3) &= e^{-\left[\frac{DC(3)+KS(3)}{n}\right]} \\ &= e^{-\left[\frac{5+3}{7}\right]} \\ &= 3.1357 \end{aligned}$$

Step 3: Calculate hybrid global influence (iGI).

$$\begin{aligned} hGI(3) &= \sum_{i \neq j} \frac{hSI(j)}{d_{ij}^{ceil(\log_2(aver\_hSI))}} \\ &= \frac{2.7183}{1^{ceil(\log_2(2.1944))}} + \frac{2.3564}{1^{ceil(\log_2(2.1944))}} + \frac{2.7182}{1^{ceil(\log_2(2.1944))}} \\ &\quad + \frac{1.3307}{2^{ceil(\log_2(2.1944))}} + \frac{1.7708}{1^{ceil(\log_2(2.1944))}} + \frac{1.3307}{1^{ceil(\log_2(2.1944))}} \\ &= 10.9777 \end{aligned}$$

Step 4: Calculate node influence of H-GSM.

$$\begin{aligned} H-GSM(3) &= hSI(3) \times hGI(3) \\ &= 3.1357 \times 10.9777 \\ &= 34.4228 \end{aligned}$$

Table I presents the rankings of centrality indices of different methods. Notably, the H-GSM metric consistently assigns rankings to nodes, distinguishing it from other centrality indices. The methodology is expanded through experimentation to conduct a comprehensive analysis of a more complex network.

TABLE II. RANKING OF NODES OF THE SAMPLE NETWORK

Rank	DC	BC	CC	PR	GSM	IGSM	H-GSM
1	3	3	3	3	3	3	3
2	1, 2	1	1, 2	0	1, 2	2	2
3	0	2	0	2	0	1	0
4	5	0, 4, 5, 6	5	1	5	0	1
5	4, 6		6	5	6	5	5
6			4	4	4	6	6
7				6		4	4

### III. METHODOLOGY

#### A. Datasets

This investigation utilized nine distinct real-world datasets, each featuring varying network sizes and unweighted attributes, to conduct further analyses. Table II presents information regarding the intricacies and classification of the network. The networks are available for download from KONECT (<http://konect.cc/networks/>) and NETWORK (<http://networkrepository.com/>). The variables  $n$ ,  $m$ ,  $k$ , and  $K_{max}$  are utilized to describe the characteristics of a network. Specifically,  $n$  represents the number of nodes,  $m$  represents the number of edges,  $k$  represents the average degree of the network, and  $K_{max}$  represents the highest degree present in the network.

TABLE III. DETAILS ON EXPERIMENTED NETWORK

Network	Type	$n$	$m$	$\langle k \rangle$	$K_{max}$
Karate	Social	34	78	4.588	17
Netscience1	Co-authorship	379	914	4.82	34
Router	Networking	2113	6632	6.128	38

#### B. Experimental Environment

The experiment setup is performed on a system with configuration on Windows 11 platform 64-bit system; the machine hardware configuration is an Intel® Core i7-8550U CPU @ 2.4 Hz processor, 24 GB of RAM; and Python-Visual Studio Code 1.56.2 is used for programming.

Regarding the proposed model analysis, the model is subjected to testing and validation procedures to ensure its capacity to represent each node's relative significance accurately. The proposed model is assessed through the implementation of the following procedures:

#### C. SIR Model

The Susceptible-Infected-Recovered (SIR) model is well-known for investigating each node's spreading dynamics. We will employ this section to quantify the performance of H-GSM and other benchmark centralities. All seed nodes are vulnerable for the first time. The seed node is likely to infect its nearest and next-nearest neighbor nodes (in the susceptible state) at each time step, and each node (the infected node) has a chance of recovering. This procedure was continued until no further infected nodes were discovered. Finally, all nodes gathered are used to simulate the actual node impact.  $S(t)$ ,  $I(t)$ , and  $R(t)$  represent the number of nodes in the susceptible, infected, and recovered states, respectively. Each loop represents a time step,  $t$ , and  $F(t)$  returns the total number of infected and recovered nodes at time  $t$ , which can be used to assess the influence of the original infected node. The infected

nodes will recover at step  $t$  with a probability of  $\rho$ . When no infected nodes remain, the propagation process is complete. Identical operations are performed for each node in each network using 100 distinct SIR model iterations.

#### D. Comprehensive Cumulative Distribution Function

The comprehensive cumulative distribution function (CCDF) is a commonly utilized tool in network analysis to compare and analyze centrality measures. The CCDF facilitates examining the distribution of centrality values across network nodes. By comparing the CCDFs of various centrality measures, scholars can evaluate how these measures capture distinct facets of node significance and how they order nodes based on centrality. This comparative analysis offers valuable insights into the network's attributes and actions. The value of the CCDF at a given rank,  $r$  in a ranking list is obtained by summing the probabilities of all the ranks greater than  $r$ . The mathematical expression for the CCDF can be represented as:

$$CCDF(r) = 1 - \frac{\sum_{i=1}^r n_i}{n} \quad (5)$$

where  $n$  is the total number of network nodes and  $\sum_{i=1}^r n_i$  refers to the number of numerical rankings less than or equal to  $r$  in the ranking list.

Through the graphical representation of the CCDF, it is possible to visually inspect the extreme values of the distribution, which correspond to nodes exhibiting elevated levels of centrality. This data can aid in identifying the most critical nodes within the network. A more pronounced slope of the centrality line in a CCDF plot indicates a higher degree of concentration of nodes with high centrality. In contrast, a less steep line suggests a more equitable distribution of centrality values among the nodes within the network.

#### E. Kendall's $\tau$ Correlation Coefficients

Kendall's  $\tau$ -correlation coefficient is used to evaluate the consistency between two rankings or order of things, making it a valuable tool for comparing centrality indexes. Each centrality indices rank nodes based on their importance or centrality in a network. We may measure how well the ranks provided by different indices agree by comparing them using Kendall. Using Kendall, we may assess the degree of agreement or concordance between the levels of nodes obtained by various centrality measures. Suppose two centrality indices give similar rankings (i.e., nodes ranked highly by one index are also ranked highly by the other). The Kendall coefficient will be high, suggesting a strong positive association. If the ranks differ significantly, the Kendall tau coefficient will be low, indicating a weak connection or disagreement between the indices. We may use Kendall to statistically analyze the consistency or divergence of multiple centrality measures and acquire insights into how well they capture similar or dissimilar characteristics of node importance in a network. The formula is as follows:

$$\tau(X, Y) = \frac{2(C - D)}{n(n - 1)} \quad (6)$$

where C and D are the numbers of concordant pairs and discordant pairs, respectively.

#### IV. RESULTS AND DISCUSSIONS

Fig. 2 shows how the distribution of nodes on those three networks over time, changed for various centrality indices for the top-10 node rank. A distinct line represents each centrality index. The analysis of centrality indices reveals that H-GSM exhibits consistently higher F(t) values than other metrics. This implies they exhibit a higher degree of efficacy in disseminating the pathogen. They show unique modes of distribution. The H-GSM protocol demonstrates a comparatively gradual rise in its initial phase, a diminished apex, and a protracted duration of sustained levels. GSM-based approaches exhibit higher F(t) values than conventional centrality metrics like DC, BC, CC, and PR. According to the Karate dataset, the disease is less likely to spread effectively. Incorporating iterative and incremental elements within H-GSM enhances its capacity to propagate the pandemic. This illustrates the importance of integrating multiple components and iterative procedures in models of epidemic propagation.

The utilization of standard deviation (SD) values furnishes insights into the degree of variability exhibited by the performance of individual centrality measures. Successive display of the standard deviation values for DC, BC, CC, PR, GSM, IGSM, and H-GSM is observed. Smaller standard deviation values suggest more significant levels of consistency and stability in behavior, while larger standard deviation values indicate increased levels of unpredictability. Upon examination of the graph, it is evident that H-GSM networks exhibiting a greater quantity of nodes demonstrate a decreased standard deviation compared to networks with fewer nodes.

The CCDF plot in Fig. 3 compares various centrality indices when network nodes are eliminated. The findings indicate that the metrics above exhibit varied characteristics and levels of susceptibility toward removing nodes. By examining the diminishing patterns of the curves, one can gain insight into the unique features of each method. A linear curve devoid of inflection points implies that each node is categorized with a distinct value. At the same time, a more pronounced descent indicates a more significant number of nodes being allocated to the same rank. The swift reductions observed in DC and BC highlight their noteworthy susceptibility and impact on the broader network connectivity and dissemination of information. The data suggest that CC experiences a gradual decrease, implying a comparatively less significant influence on the overall structure of the network. The decline in PR is relatively slower, indicating a less severe impact on the network's connectivity. The slower declination of GSM, IGSM, and H-GSM results in moderate sensitivities when nodes are removed. The comparative analysis of the three approaches across the three networks reveals that H-GSM effectively discerns the impact of individual nodes.

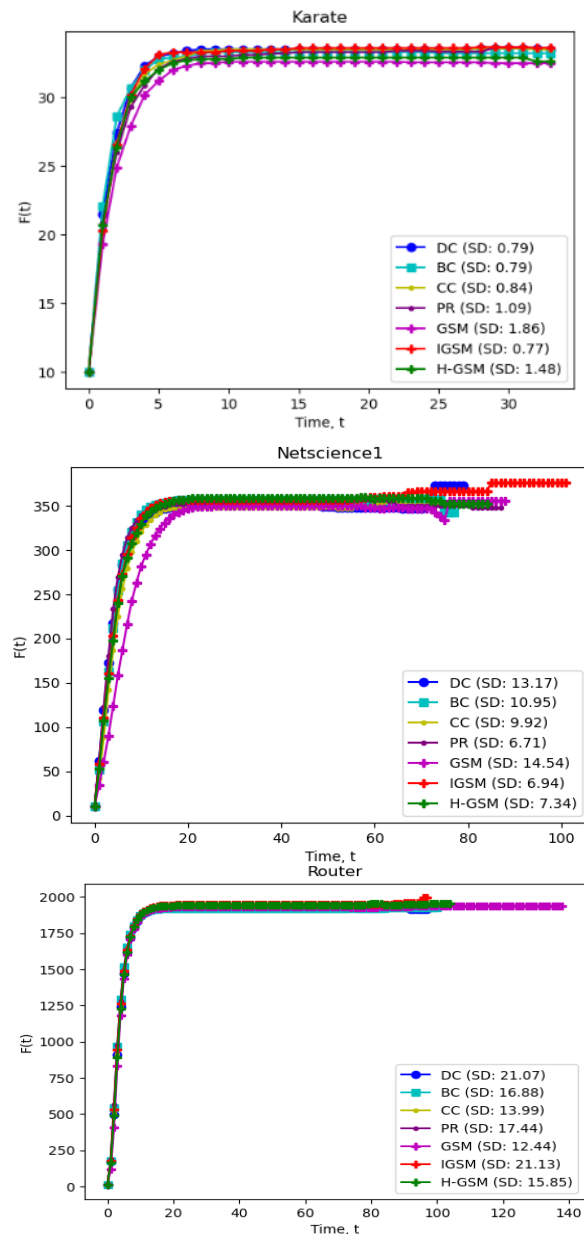

Fig. 2. Propagation influence of top-10 ranking effect.

Fig. 3. CCDF diagram of ranking results of each method.

Kendall's model with SIR was employed to assess the impact of nodes in various networks and verify the H-GSM's suitability and efficacy. Fig. 4 displays Kendall's values of the H-GSM algorithm and others under consideration. As evidenced by the data, H-GSM outperforms other methods regarding Kendall values. This indicates that H-GSM exhibits superior performance across diverse networks featuring varying node sizes.

Fig. 4. Kendall coefficients between different propagation probabilities with the SIR model.

To conduct a more comprehensive examination of the propagation phenomenon of H-GSM, we analyzed the dissemination influence of nodes ranked in the SIR model. Value of  $\beta=0.1$  was chosen, while  $\alpha$  was varied between 0.01 and 0.1. This decision was made due to the potential for propagation across the entire network when larger alpha values are utilized. Tables III, IV, and V display the nodes ranked in the top ten for the Karate, Netscience1, and Router networks. It was observed that a significant proportion of the nodes that ranked within the top 10 of H-GSM were also present in other algorithms. Thus, the validity of the proposed H-GSM has been confirmed.

This study aimed to compare the efficacy of the proposed H-GSM with that of GSM in terms of node spreading. Consequently, in H-GSM and GSM, solely different nodes are considered seed nodes to analyze the propagation effect. A mean value of 100 rotations is calculated. In the illustrated instance presented in Fig. 5, it was observed that the impact of node 26, which is present in H-GSM, surpasses that of node 7 in GSM. The results indicate that our proposed H-GSM model exhibits a superior infection effect than the original GSM model. The findings are consistent across other networks, as depicted in Fig. 6 and 7.

TABLE IV. TOP-10 RANKING NODES OF THE KARATE NETWORK

Rank	DC	BC	CC	PR	GSM	IGSM	H-GSM

## V. CONCLUSIONS

In conclusion, this study addresses the challenge of identifying influential nodes in complex networks. Despite the existing methodologies, node identification remains a significant concern for researchers. To overcome this challenge, a new algorithm called H-GSM is proposed, which integrates degree and k-shell centrality measures. By incorporating both local and global centrality metrics, the H-GSM model improves upon the existing GSM model, effectively capturing the network's intricate influences. To evaluate the effectiveness of the H-GSM model, experiments are conducted on three different complex networks with varying sizes. The model's performance is assessed by examining its spreading ability using the SIR model and comparing various centrality metrics using Kendall's tau correlation coefficient. The experimental results demonstrate that the H-GSM algorithm outperforms established benchmarks in accurately identifying influential nodes. In future research, further enhancements of the algorithm's performance outcomes are planned by exploring different combinations of index styles and centrality measures. These investigations will contribute to advancing the understanding and application of network analysis techniques. Overall, the H-GSM algorithm presented in this study offers a promising approach for unraveling influential nodes in complex networks and holds potential for future advancements in the field.

**Abstract**—In image classification, multi-granularity refers to the ability to classify images with different levels of detail or resolution. This is a challenging task because the distinction between subcategories is often minimal, needing a high level of visual detail and precise representation of the features specific to each class. In dental informatics, and more specifically tooth classification poses many challenges due to overlapping teeth, varying sizes, shapes, and illumination levels. To address these issues, this paper considers various data granularity levels since a deeper level of details can be acquired with increased granularity. Three tooth granularity levels are considered in this study named Two Classes Granularity Level (2CGL), Four Classes Granularity Level (4CGL), and Seven Classes Granularity Level (7CGL) to analyze the performance of teeth detection and classification at multi-granularity levels in Granular Intra-Oral Image (GIOI) dataset. Subsequently, a Faster Region-Convolutional Neural Network (FR-CNN) based on three ResNet models is proposed for teeth detection and classification at multi-granularity levels from the GIOI dataset. The FR-CNN-ResNet models exploit the effect of the tooth classification granularity technique to empower the models with accurate features that lead to improved model performance. The results indicate a remarkable detection effect in investigating the granularity effect on the FR-CNN-ResNet model's performance. The FR-CNN-ResNet-50 model achieved 0.94 mAP for 2CGL, 0.74 mAP for 4CGL, and 0.69 mAP for 7CGL, respectively. The findings demonstrated that multi-granularity enables flexible and nuanced analysis of visual data, which can be useful in a wide range of applications.

**Keywords**—Dental informatics; intra-oral image; deep learning; faster region-convolutional neural network; classification; granularity level; tooth detection

## I. INTRODUCTION

As living standards improve and dental health awareness increases, a growing number of individuals are pursuing dental treatments (such as orthodontics, dental implants, and restoration) as a means to maintain a healthy lifestyle [1]. According to the WHO Global Oral Health Status Report (2022), almost 3.5 billion people worldwide are affected by oral illnesses [2]. In underdeveloped nations, the lack of oral hygiene knowledge, limited access to dental care facilities, and high cost of treatment contribute to untreated dental issues,

resulting in severe consequences for individuals in these regions [3].

Extensive research has been conducted to explore Deep learning-based object detection methods for dental disease diagnosis in various dental models including radiographic images, CBCT images, and intra-oral images [4] [5].

Radiographs and periodontal images are widely used as objective diagnostic tools for tooth disease diagnosing. This includes bitewing, periapical, and panoramic images. Despite their widespread use these images are known to have limitations. For example, they are likely to contain tooth ghost images, low resolution and contrast, overlaps, angulation, magnification, and other artifactual information which are sources of unwanted features and noise [6]. Alternatively, CBCT is employed for their high-quality three-dimensional volumetric information which addresses the issue of distortion and superimposition of bony and dental structures [7]. However, automatic segmentation using CBCT poses certain difficulties, such as noisy images, unclear edges, presence of a human skull [8].

Recently, intra-oral dental images are used for tooth disease diagnosis. They provide valuable insights into a patient's oral health status and help in formulating treatment plans [9]. This approach (i) does not necessitate specialized equipment for data acquisition, (ii) offer rich features despite small image size, and (iii) consequently requires low computational cost for image processing and object detection tasks. However, the identification and detection of individual teeth in these images present some challenges such as partial occlusion, overlapping, and varying illumination [10] [11]. Another issue is unavailability of comprehensive intra-oral image datasets.

Deep learning (DL) has emerged as a powerful approach for overcoming the challenges in the dentistry domain, capable of autonomously extracting high-level and discriminative characteristics from a given dataset [12]. Convolutional neural networks (CNNs) have achieved significant appeal among DL approaches due to their well-established multilayer structure. CNN-based techniques for dental image processing have demonstrated outstanding performance in a variety of clinical tasks, most notably tooth detection and classification/

numbering across many dental imaging modalities, including cone-beam computed tomography (CBCT) [13] and radiography images [14]. However, the classification of tooth types in intra-oral dental images is a challenging task due to the complex and diverse structures found in these images [15]. These images have rich geometrical structure which makes it difficult to learn the discriminative features among the tooth classes. Despite some common morphological characteristics for distinguishing tooth type between individuals, there exist great variances in surface appearance with the same type of tooth [11]. Additionally, teeth classification in intra-oral images is demanding due to the inhomogeneous texture or color distribution of teeth. For example, even if the images represented the same incisor type, there are often strong differences in the directionality, granularity, or color tone of teeth. These variations make it challenging to classify the teeth accurately. Hence analysis of dental images using deep learning models has caught the attention of many researchers [16].

To overcome the aforementioned challenges, we hypothesize that the discriminative local detailed information of intra-oral images is naturally hidden in various granularity patches of the images. Multi-granularity in image classification is useful for applications such as object recognition, where objects may be present at different scales or levels of complexity. By classifying objects at multiple levels of granularity, it is possible to accurately identify objects of different sizes or shapes, which can be useful for tasks such as autonomous navigation or robotic manipulation. Thus, the underlying research work examines the effect of granularity in tooth detection and classification using intra-oral images. The multiple levels of granularity are used to specify the structural levels of the tooth. The granularity level changes based on the three tooth groups considered in this study. The Granular Intra-Oral Image (GIOI) dataset consists of three granular levels named Two Classes Granularity Level (2CGL) of the upper and lower jaw, Four Classes of Granularity Level (4CGL) of incisor, canine, premolar, and molar, and Seven Classes Granularity Level (7CGL) is used for tooth classification.

The following are the main contributions of this study:

- Modeling of faster region-convolutional neural network (FRCNN) based on three types of ResNet models for multi-granularity levels teeth classification from intra-oral images.
- Analysis of teeth detection and classification at multi-granularity levels via FRCNN.

The rest of the paper is divided into the following sections. Section II summarizes the previous research on tooth detection and classification, and granularity level classification. Section III offers the proposed methodology. The experimental findings are presented and discussed in Section IV. Section V analyses the effect of granularity levels on the tooth classification task. Section VI provides the conclusion of the research work and suggests opportunities for further study.

## II. RELATED WORK

The core of this research work is to analyze teeth detection and classification at multi-granularity levels via FRCNN from Granular Intra-Oral Image (GIOI) dataset. Therefore, to get a better understanding of the existing research work, this section presents a review of related work on the topic of (i) tooth classification using deep learning models including Faster R-CNN, AlexNet, and VGG; and (ii) the effect of multi-granularity on classification accuracy.

### A. Tooth Classification using Deep Learning Models

In the context of deep learning, this study used Convolutional Neural Network (CNN). A CNN is a type of Artificial Neural Network (ANN) that is commonly used in Deep learning for image, text, object recognition, and classification. CNNs have been widely used in computer vision tasks such as object detection, face recognition, and image segmentation [17]. They have also been applied in other domains, such as natural language processing and dentistry.

In an automated diagnostic procedure, classifying teeth is a crucial task. Researchers have examined the classification task using a small sample of tooth periapical pictures; one such study was carried out by Zhang et al. [18] employed a cascade network structure for the automated identification of 32 teeth positions. Their approach utilized multiple CNNs as the fundamental modules and achieved an F1-Score, precision, and recall of 80.4, 80.3, and 80.6, respectively. Oktay [19] introduced a CNN-based method for tooth detection in dental panoramic X-ray images. The approach accurately determines the potential positions of three tooth types (incisors, premolars, and molars), achieving a remarkable accuracy level of over 0.92. Similarly to this, Miki et al. [13] used 52 CBCT images to categorize teeth into seven types based on their location. AlexNet was employed as the CNN structure in this study, and it achieved a classification accuracy of 88.8%. In research on automated detection and labeling of 2D teeth, Zhang et al. [18] and Chen et al. [20] used CNN to identify teeth in periapical radiographs, and experimental findings indicated that their precision rates were 95% and 90% respectively. These findings ensured the importance of deep learning models such as AlexNet [13] [19] and VGG [18] in achieving accurate and efficient detection for automated dental charting and proper surgical and treatment planning.

Another model based on GoogleNet, a fully convolutional network (FCN) was proposed to detect teeth by Muramatsu et al. [21]. The classification of teeth by type (i.e., incisors, canines, premolars, and molar) and tooth condition was performed using a ResNet-50-based pre-trained network. Görürgöz et al. [22] applied transfer learning with a pre-trained GoogLeNet Inception v3 CNN and developed an algorithm consisting of jaw classification, region detection, and final classification models. The proposed algorithm achieved an F1 score, precision, and sensitivity of 0.8720, 0.7812, and 0.9867, respectively. These findings demonstrate the potential of CNN algorithms for efficient and precise tooth detection and numbering in dental imaging, which could lead to more reliable diagnoses and treatments.

These studies show that CNN models are trained on a large dataset of dental images, where each image is labeled with the coordinates or bounding boxes representing the location of each tooth. CNN learns to recognize patterns and features that differentiate teeth from the background and other structures in the image [23]. It's important to note that different studies proposed specific modifications or variations of CNN architectures to optimize tooth detection and classification performance such as AlexNet, Faster R-CNN, GoogLeNet, RCNN, and ResNet.

Tooth detection and classification using Faster R-CNN (Faster Region-based Convolutional Neural Network) [24] is an area of research that focuses on automating the process of identifying and categorizing teeth in dental images. The effectiveness of Faster R-CNN in tooth numbering and identifying dental cavities on oral radiographs was studied by Tuzoff et al. [25]. They used the Faster R-CNN architecture for teeth detection using 1,352 adult panoramic radiographs. A two-stage system was proposed, in which faster R-CNN is used to detect the teeth followed by a VGG-16 network to identify and number. Nonetheless, the study encountered misclassification errors resulting from similarities between adjacent teeth. Chen et al. [20] suggested employing Faster R-CNN for tooth detection and recognition in dental periapical films. The test dataset demonstrated precision and recall values of over 90%. However, the study faced challenges due to complications such as missing teeth and root canal treatments in the images from regular clinical work. Mahdi et al. [26] presented an automatic teeth recognition model that leverages the Faster R-CNN technique based on the residual network. This model represents a significant step forward in dental image analysis, achieving impressive results with high mean Average Precision (mAP) scores of 0.974 and 0.981 for ResNet-50 and ResNet-101, respectively. In a similar vein, Bilgir et al. [27] developed a Faster R-CNN model that automated tooth numbering over a dataset of 2,482 panoramic radiographs with a precision of 0.96. Estai et al. [28] proposed a three-step method for automatically detecting and counting teeth in digital orthopantomography (OPG) pictures. They used U-Net, Faster R-CNN, and VGG-16 CNN models. The results showed that it had a high recall and precision score of 0.99 for tooth detection and 0.98 for tooth numbering, indicating its potential importance in general dentistry and forensic medicine applications.

It is concluded that Faster R-CNN is sensitive to objects with missing features i.e., broken tooth [20], overlapping [29], occlusion [25], blur, and noise [30]. These issues distort the fine details of the tooth [26] [31]. This leads to low classification accuracy [32] and limits the model's generalization ability on other imaging modalities or dental issues [13]. Despite these issues, there are various advantages to using Faster R-CNN for tooth identification and classification tasks. It enables exact tooth localization in dental pictures while effectively handling size and aspect ratio variations [33]. Research has shown that Faster R-CNN accurately identifies the position of teeth with a high IOU value [20]. The model exhibits significant potential in dental image processing tasks, assisting in dental diagnosis, treatment

planning, and various other applications within the dental field [34].

### B. Effect of Multi-Granularity on Classification Tasks

The ability to analyze or portray data at numerous levels of detail or abstraction is referred to as multi-granularity. Multi-granularity is important for a range of applications since it provides for more nuanced and flexible data processing. It has been the focus of recent studies in fields such as scene classification [35], land change detection [36], and brain image analysis [37]. This section reviews relevant research on the role of granularity in various classification problems.

Several researchers have recently investigated the use of multi-granularity in medical image classification, employing a range of approaches and techniques. Within these investigations, Wu et al. [38] focused their research on lung nodule classification. Their study evaluated a novel approach using a publicly available lung nodule dataset, and the results demonstrated that employing the multi-granularity approach resulted in enhanced classification accuracy. In addition, Wang et al. [39] provided a unique method for producing generalized visual representations for medical images using multi-granularity cross-modal alignment. To assess the effectiveness of their approach, they used a variety of medical imaging datasets, including chest X-rays and mammograms. The results showed that the proposed model outperformed existing methods in a variety of classification and retrieval tasks, highlighting the effectiveness of multi-granularity cross-modal alignment in acquiring comprehensive visual representations for medical images. Wang et al. [36] suggested a multi-granularity framework for extracting latent ontologies from remote sensing datasets, which they tested in six different scenarios. The results showed that combining three granularity levels produced the best results, with the second level of granularity providing the highest accuracy. On the other hand, the third level of granularity exhibited comparatively lower accuracy. Furthermore, the study highlighted that fine-scale cropping increased classification accuracy whereas excessive cropping degraded performance. Additionally, Zuo et al. [40] presented an innovative method for fine-grained crop disease classification that combines multi-granularity feature aggregation with self-attention and spatial reasoning to improve accuracy. The evaluation outcomes showcase the effectiveness of incorporating multi-granularity feature aggregation, self-attention, and spatial reasoning in the field of fine-grained crop disease classification.

In the past few years, significant progress has been made in deep learning-based image classification and object re-identification. For instance, Ouyang et al. [41] introduced a hybrid methodology that merges a CNN with a modified capsule network for remote sensing image classification. Their model incorporated spatial-spectral attention and multi-granularity features, allowing it to effectively capture precise spatial and spectral information. Likewise, Tu et al. [42] introduced the Multi-granularity Mutual Learning Network (MMNet) for object re-identification. The MMNet integrates multiple modules to effectively learn distinctive features across varying visual granularities. By capturing diverse discriminative local features from multiple granularities, the MMNet demonstrated superior performance compared to

previous approaches. Wu et al. [43] presented a CNN-based image classification approach that takes advantage of multi-granularity features. The fundamental goal of this research is to incorporate the concept of hierarchical structure categorization and to investigate the incorporation of granularity computing theory in deep learning. The experimental findings revealed the enhanced model's usefulness, with higher image classification accuracy and superior generalization capabilities. Chen et al. [44] investigated the impact of label granularity on CNN classification performance. Experiments on several datasets revealed that training with fine-grained labels improved the accuracy of classifying coarse-grained classes, in contrast to training with coarse-grained labels. According to their research, while training a CNN for natural images, using fine-grained labels outperforms using coarse-grained labels from the same dataset. The utilization of fine-grained labels enables the network to learn more intricate and specific features. Zhu et al. [45] introduced a novel methodology for few-shot learning that incorporates multi-granularity techniques. The proposed approach was tested on many few-shot learning datasets, including CIFAR-FS and mini-ImageNet. The outcomes substantiated the efficacy of multi-granularity episodic contrastive learning in the context of few-shot learning.

The presented review identifies that granularity level classification leads to improvement in computational efficiency, adaptation capability (even if shallow models and the small dataset is used), and extracting fine-grained feature [43]. Additionally, the multi-granularity technique is less prone to overfitting when compared to deep networks and offers better generalization and increased classification accuracy [46] [44] [43]. However, despite these benefits, granular-level classification studies in the domain of tooth classification are seldom seen and its relevance in this domain needs to be explored.

### III. PROPOSED METHODOLOGY

This section introduces the methodology used to achieve the main aim of this study which is to analyze the effect of teeth detection and classification at multi-granularity levels using FRCNN. The overview of the proposed method to detect teeth at multi-granularity levels using FRCNN is presented in Fig. 1. The detection pipelines as shown in Fig. 1 perform four essential steps: data collection, data pre-processing, modeling detection, and finally providing results and discussion.

The following subsections will provide the details of data collection and pre-processing criteria including inclusion and exclusion criteria, ground truth marking scheme and consequent labeling procedure, and identification and implementation of label-preserving data augmentation methods. Additionally, the proposed CNN model and model evaluation will be introduced:

#### A. Dataset Preparation

A significant challenge in the advancement and practical adoption of DL models lies in acquiring adequately large, curated, and representative training data, along with expert annotations. In this section, the fundamental steps for preparing a dental imaging dataset for addressing the issue of

tooth classification in Intra-Oral imaging using deep learning models are described.

1) *Data acquisition:* With the absence of a publicly available dataset, this study proposes the GIOI dataset that offers three teeth classification granularity levels as shown in Fig. 2, i.e., Two Classes of Granularity Level (2CGL) of maxilla and mandible; Four Classes of Granularity Level (4CGL) of incisor, canine, premolar, and molar; and Seven Classes Granularity Level (7CGL) of teeth numbering. In the proposed GIOI dataset development phase, the Advanced Medical and Dental Institute at University Sains Malaysia (USM) and University Technology PETRONAS (UTP) have collaborated to develop the GIOI dataset. These images represent subjects from different age groups and genders. The images are also captured at different distances and illumination levels to present rich feature diversity.

2) *Data Pre-Processing:* The first stage in pre-processing was to filter the dataset by setting the inclusion and exclusion criteria. The images were visually analyzed, and the images containing gum or cavity diseases are extracted. Additionally, images having missing teeth or wisdom teeth are also excluded. Table I and Table II display the inclusion and exclusion criteria that were used for the data pre-processing.

Fig. 1. Overview of the proposed tooth detection model.

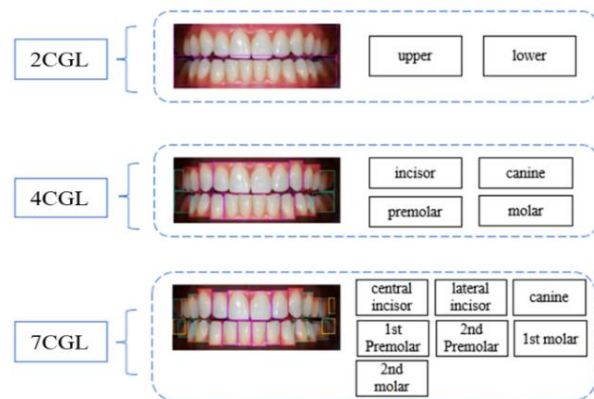

Fig. 2. Teeth classification granularity levels in the GIOI.

TABLE I. INCLUSION CRITERIA

Inclusion Criteria
Adults between 18-50 ages were included.
Both male and female.
Stained teeth.
Different orientations (left, right, upper, lower).
The gap between teeth.

TABLE II. EXCLUSION CRITERIA

Exclusion Criteria
Crowded tooth.
Wisdom tooth.
Missing and broken tooth.
Tongue.
The tooth has braces.
Teeth have gum or cavity diseases.

The GIOI dataset contained 550 images and seven-tooth classes (Central Incisor, Lateral Incisor, Canine, 1st Premolar, 2nd Premolar, 1st molar, 2nd molar). The current study used the ISO standard tooth numbering system to identify each tooth with a unique label [7]. The VGG Image Annotator (VIA) [47] web application has been used for annotating and labeling the training set samples. VIA is an open-source software that allows human annotators to define and describe regions in an image.

3) *Data augmentation*: the data set contained unequal samples, that is, the number of different types of samples was different. To enhance the dataset, data augmentation was used as an option [48]. Data augmentation effectively expands the dataset size and quality. The effectiveness of data augmentation for dental image augmentation was assessed by including image mixing, geometric transformation, transforms, and kernel filters [49]. As a result, 2,260 augmented images were acquired for training. Table III contains the specifics of this assessment.

TABLE III. DATA AUGMENTATION METHODS FOR DENTAL IMAGES

Type of Augmentation	Post Augmentation Observation	Label Preservation	Selection Status
Vertical flip	Tooth visual attributes do not remain intact.	No	Rejected
Horizontal flip	Tooth visual attributes remain intact.	Yes	Selected
ChannelShuffle	Resulting in an image that is not a true representative of a real-world scenario.	No	Rejected
Brightness and contrast	Introduces a wide range of illuminations.	Yes	Selected
Noise injection	Improves the model's generalization ability	Yes	Selected
Cropping	This may result in the loss of distinguishable tooth features	No	Rejected
Motion blur	Simulates the possible sudden motion of the optical sensor/subject in a real-world scenario.	Yes	Selected
RandomGridShuffle	Tooth visual attributes do not remain intact.	No	Rejected
Histogram equalization	Improves the image's contrast level.	Yes	Selected
image compression	This keeps the resolution of an image	Yes	Selected

**B. Model Architecture**

In this paper, the Faster R-CNN architecture is supported by three types of ResNet [50] network: ResNet-50, ResNet-101, and ResNet-152 as backbone models. Fig. 3 shows the FR-CNN-ResNet model. The first phase of the model includes

the backbone models that generate the feature map. The second phase is the region proposal network (RPN), for identifying areas of an input image that most likely contain a region of interest. The last phase includes the detection network. The RPN generates region proposals (bounding boxes) for potential objects in an image, while the detection network classifies the proposals and refines their bounding boxes. The RPN is a fully convolutional network that is trained to predict objectness scores and bounding box offsets at each position in an image. It uses a sliding window approach to generate region proposals, which are then passed to the detection network. When the RPN generates a set of candidate regions, each region is represented by a fixed-size feature map, which can be of different sizes depending on the size of the input image and the region proposal. However, the detection network that processes these regions requires a fixed-size input to apply convolutional layers.

ROI (Region of Interest) pooling addresses this discrepancy by dividing the fixed-size feature map for each region proposal into a fixed number of equally sized sub-windows and then applying a max pooling operation to each sub-window to produce a fixed-size output. The output of the ROI pooling operation is a feature map of fixed size that can be fed into the detection network. The detection network in Faster R-CNN is based on the Fast R-CNN [51] architecture, which consists of two main components: a convolutional feature extractor and a set of fully connected layers for object classification and bounding box regression. It takes the region proposals generated by the region proposal network (RPN) as input and produces the final object detection results.

Fig. 3. FR-CNN-ResNet model.

The main activities of the FR-CNN-ResNet algorithm are presented in the following nine steps:

Step 1: The system fed the images to the backbone ResNet50, ResNet101, or ResNet101 models.

Step 2: The backbone models extract the features from the images.

Step 3: The RPN takes the feature maps as input and generates a set of object proposals, which are regions in the image that are likely to contain objects.

Step 4: The proposed regions generated by the RPN in Step 3 are passed through ROI pooling, which divides the fixed-size feature map for each region proposal into a fixed number of equally sized sub-windows.

Step 5: The detection network takes the fixed-size feature maps generated in Step 4 by the ROI pooling layer as input and produces the final object detection results.

Step 6: The final output is obtained by applying non-maximum suppression to remove duplicate predictions and keep only the most confident detections.

### C. Model Evaluation and Performance Measures

Average Precision (AP) [50] is a popular evaluation metric for object detection tasks that measures the accuracy of the predicted object bounding boxes. AP is calculated based on a precision-recall curve that summarizes the trade-off between precision and recalls for different object detection thresholds. The average precision value is computed for recall values ranging from 0 to 1.

Precision [51] is a performance metric used in object detection to measure the proportion of correct positive detections out of all the positive detections made by the network. Precision measures how accurate the algorithm is in detecting objects. The given equation was used to calculate precision:

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (1)$$

Recall [50] is a performance metric used in object detection to measure the proportion of actual positive detections out of all the positive instances present in the dataset. In other words, recall measures how well the algorithm can detect all the objects present in the image. The following equation used for recall calculation:

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (2)$$

The F1 score is a performance metric used in object detection that combines precision and recalls into a single score. The F1 score provides a balanced view of the network's accuracy by considering both the number of correct detections and the number of missed detections. It is defined by the following equation:

$$F1\ score = \frac{2 \times (precision \times recall)}{(precision + recall)} \quad (3)$$

## IV. RESULTS AND DISCUSSION

The presented study evaluates the effect of granularity on tooth detection and classification using FR-CNN-ResNet models. The GIOI dataset, consisting of three teeth classification granularity levels, is considered in testing the proposed FR-CNN-ResNet model. The total number of epochs was set as 100 for all different backbone ResNet models. The

batch size for all Faster R-CNN backbone models was set as 2. In addition, two learning rate values were used, i.e., 0.001 and 0.0001. This section presents the experimental results for all three classification granularity levels separately.

### A. Case 1: Two Classes Granularity Level (2CGL)

1) The two classes' granularity level (2CGL) consists of two tooth classes i.e.: upper and lower. A total of 2,260 images containing 2078 upper and 1956 lower were used to train the models in seven different experiments. A total of 107 images are used to test the models. It has been identified that the lower learning rate during training of Faster RCNN variants resulted in lower mean average precision during the testing of all such models. This indicates the unsuitability of a smaller learning rate for 2CGL tooth classification. For all F-RCNN variants, the optimal accuracy was achieved using a constant learning rate of 0.001.

As depicted in Fig. 4, the highest average precision of 0.95 and 0.93 for the upper and lower tooth, respectively, is achieved by the FR-CNN-ResNet-50. With FR-CNN-ResNet-101, the average precision for upper and lower teeth is observed to be the lowest among all types of FR-CNN models. With a deeper backbone, i.e., ResNet-152, no significant improvement is observed by the FR-CNN-ResNet-152 model in the average precision of target classes. This performance indicates that at 2CGL, the FR-CNN-ResNet-50 model is the best choice. Similarly, the highest mAP of 0.94 was achieved by FR-CNN-ResNet-50. The lowest mAP of 0.742 is yielded by the FR-CNN-ResNet-101 model trained on a lower learning rate. This confirms that a lower learning rate and deeper backbones are not optimal for optimal classification at the 2CGL level.

The model exhibited FR-CNN-ResNet-50 achieves a competitive and high mAP of 0.94. As presented in Table IV, the model also exhibited perfect or near-to-perfect recalls for upper and lower teeth classification results. Additionally, the best F1 scores for upper and lower teeth classification are equal to 0.96 and 0.94 for the FR-CNN-ResNet-50 model. This performance indicates that this model for 2CGL is ideal as it is trained quickly and generates very competitive results compared to other models.

Fig. 4. 2CGL average precision comparison of the models.

TABLE IV. 2CGL AVERAGE PRECISION, RECALL, AND F1 SCORES FOR EACH MODEL

2CGL Classes	AP			Recall			F1-Score		
	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152
Upper	<b>0.95</b>	0.89	0.90	0.97	0.92	0.93	<b>0.96</b>	0.90	0.92
Lower	<b>0.93</b>	0.81	0.81	0.96	0.85	0.86	<b>0.94</b>	0.83	0.83

Overall, the average precision of upper teeth remains higher as compared to lower teeth. This can be attributed to labeling precision as naturally lower teeth are occluded by upper teeth. For this reason, the bounded boxes for upper teeth are more precise as compared to lower teeth as it contains some part of upper teeth. FR-CNN-ResNet is generally good at detecting large objects because it uses region proposals to identify potential object locations and then applies a classifier to each region proposal to determine the presence and location of an object. The RPN in FR-CNN-ResNet generates region proposals by sliding a small network over the convolutional feature map output by the backbone network. The size of the sliding window is fixed, and the stride can be adjusted to control the region proposal density. Because of this mechanism, FR-CNN-ResNet can effectively detect large objects but may struggle with detecting small objects due to the limitations of the region proposal mechanism.

B. Case 2: Four Classes Granularity Level (4CGL)

1) This section presents the results of the granular level two (4CGL) classification, which consists of four classes, i.e., Incisor, Canine, Premolar, and Molar. A total of 2,260 images containing 4091 incisors, 8138 canines, 7940 premolars, and 6564 molars were used to train the models in seven different experiments and 107 images were used for testing. Within FR-CNN-ResNet models, the learning rate again played an important role. With a lower learning rate, i.e., 0.0001, mAP remained low, as compared to the mAP of the model trained with a higher learning rate of 0.001.

As presented in Fig. 5, the highest average precision (AP) of 0.849 is produced by the FR-CNN-ResNet-50 model for the incisor tooth class, followed by the Canine, Premolar, and Molar tooth class which achieved an AP of 0.82, 0.73 and 0.58 respectively. The following factors contribute to higher average precision for incisor class, (i) no occlusion, (ii) large size, and (iii) high illumination. As discussed in Table V, the FR-CNN-ResNet-50 model also has the highest recall and F1 values for all classes. This result also concludes that FR-CNN-ResNet-50 is less sensitive to occlusion, object size, and low illumination.

As shown in Table V, the highest mAP of 0.74 was observed by FR-CNN-ResNet-50. The other models are significantly behind where FR-CNN-ResNet-101 and FR-CNN-ResNet-152 achieved mAP of 0.71 and 0.63, respectively. This result indicates that for 4CGL, FR-CNN-ResNet-50 is the best model among the three for teeth classification and detection.

Fig. 5. 4CGL average precision comparison of the models.

TABLE V. 4CGL AVERAGE PRECISION, RECALL, AND F1 SCORES FOR EACH MODEL

4CGL Classes	AP			Recall			F1		
	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152
Incisor	<b>0.85</b>	0.8	0.7	<b>0.88</b>	0.8	0.8	<b>0.87</b>	0.8	0.7
Canine	<b>0.82</b>	0.7	0.7	<b>0.86</b>	0.8	0.7	<b>0.84</b>	0.8	0.7
Premolar	<b>0.74</b>	0.7	0.6	<b>0.78</b>	0.7	0.6	<b>0.75</b>	0.7	0.6
Molar	<b>0.58</b>	0.5	0.4	<b>0.66</b>	0.5	0.5	<b>0.63</b>	0.5	0.4

These results conclude that by using a pre-trained ResNet-50 as the backbone network, the Faster R-CNN model can leverage the high-level features learned by ResNet-50 to accurately classify medical images. Moreover, the ResNet-50 architecture has a deep network structure that allows it to learn complex features in medical images, including subtle differences between images that may be indicative of different conditions or diseases. This makes it particularly effective in medical image classification tasks where subtle differences can be critical in diagnosing a disease. However, the choice of backbone architecture depends on the specific task and dataset, and other backbones such as ResNet-101 or ResNet-152 may perform better in some scenarios.

C. Case 3: Seven Classes Granularity Level (7CGL)

This section presents the results of the Seven Classes Granularity Level (7CGL) classification, which consists of seven classes, i.e., Central Incisor, Lateral Incisor, Canine, 1st Premolar, 2nd Premolar, 1st molar, and 2nd molar. This level of granularity creates three major issues, (i) objects with low illumination conditions, (ii) large variation in object size, and (iii) class imbalance. A total of 2,260 images were used to train the models in seven different experiments, and 107 images were used for testing. Within FR-CNN models, the learning rate again played an important role. With a lower learning rate, i.e., 0.0001, mAP remained low, compared to the mAP of the model trained on a higher learning rate of 0.001.

Fig. 6. 7CGL average precision comparison of the models.

A comparative performance analysis is presented in Fig. 6 which highlights that the performance of all models decreases as the target tooth is further away from the central position. However, in all performance measures, FR-CNN-ResNet-50 remains the best-performing model.

As presented in Table VI, the average precision for all models gradually decreased as tooth location moved from front to behind. Overall, FR-CNN-ResNet-101 yielded the lowest average precision score, while FR-CNN-ResNet-50 again emerged as the top-performing model. FR-CNN-ResNet-50 recall values also remained high for the central incisor and lateral incisor. The model produced a perfect recall value. Considering the F1 scores of all three models, it is again evident that at the 7CGL level, FR-CNN-ResNet-50 has the

TABLE VI. 7CGL AVERAGE PRECISION, RECALL, AND F1 SCORES FOR EACH MODEL

7CGL Classes	AP			Recall			F1-Score		
	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152	FR-CNN-ResNet-50	FR-CNN-ResNet-101	FR-CNN-ResNet-152
Central Incisor	<b>0.84</b>	0.77	0.82	<b>0.87</b>	0.83	0.85	<b>0.85</b>	0.80	0.84
Lateral Incisor	0.81	0.73	0.76	0.86	0.81	0.82	0.84	0.77	0.79
Canine	0.80	0.72	0.76	0.85	0.79	0.81	0.82	0.75	0.78
1 <sup>st</sup> Premolar	0.72	0.59	0.65	0.79	0.69	0.73	0.75	0.63	0.69
2 <sup>nd</sup> Premolar	0.64	0.39	0.51	0.73	0.54	0.62	0.68	0.45	0.56
1 <sup>st</sup> Molar	0.57	0.36	0.45	0.69	0.47	0.57	0.63	0.41	0.50
2 <sup>nd</sup> Molar	<b>0.49</b>	0.30	0.38	0.61	0.42	0.50	0.54	0.35	0.43

#### V. ANALYSIS OF THE EFFECT OF GRANULARITY LEVELS ON TOOTH CLASSIFICATION TASK

In this study, three different models of FR-CNN ResNet were implemented for three granularity level cases named 2CGL, 4CGL, and 7CGL to demonstrate the influence of using different granularities in tooth classification. For all FR-CNN variants, the optimal performance is achieved using a constant learning rate of 0.001. Within the FR-CNN-ResNet models, the learning rate played an important role in which, with a lower learning rate, i.e., 0.0001, mAP remained low, as compared to the mAP of models trained on a higher learning rate of 0.001. This result confirms that a lower learning rate and deeper backbones are not optimal for classification at 2CGL, 4CGL, and 7CGL cases.

For an individual granularity level, the first granularity level achieves the best classification accuracy while the third is

the least accurate. The best improvement can be observed in the 2CGL with the FR-CNN-ResNet-50 model, where the mAP result is 0.94 better than FR-CNN-ResNet-101, which achieved the lowest mAP of 0.85. And FR-CNN-ResNet-50 model remained significantly higher than other models in 4CGL, which achieved an mAP of 0.74. For 7CGL, the performance of all models decreases as the target tooth is further away from the central position. Overall, FR-CNN-ResNet-101 yielded the lowest average precision score, while FR-CNN-ResNet-50 again emerged as the top-performing model by achieving an mAP of 0.69.

highest F1 scores for all seven classes. However, the model's performance significantly decreased for smaller and occluded teeth such as 2nd Premolar, 1st Molar, and 2nd Molar.

Overall mAP of FR-CNN-ResNet-50 remained highest at 0.69, followed by FR-CNN ResNet-101 and FR-CNN ResNet-50 with mAP of 0.55 and 0.62, respectively. One possible reason for the low mAP of FRCNN can be attributed to its limitation with detecting small objects, especially if large objects surround them, as the region proposal network may overlook.

FR-CNN-ResNet, like many object detection models, can struggle to detect small objects as the size of the RPN anchors, which are the pre-defined boxes used to search for objects in an image, may be too large relative to the size of the small objects being searched for. This means that the RPN may fail to generate proposals that accurately localize small objects. In the case of occluded objects, the RPN may still generate proposals that partially or completely overlap with the occluded object, allowing the CNN to classify and localize the object within the proposal. However, the accuracy of object detection for occluded objects may still be affected by the extent of occlusion and the quality of the proposals generated by the RPN. In the case of objects with low illumination, the features extracted from the image may be less informative due to reduced contrast and detail in the image. This can make it more difficult for the model to distinguish the object from the background or other objects in the scene.

These results indicate that with the largest granularity level as shown in 2CGL and 4CGL, the tooth structure and the tooth features are clear. Therefore, FR-CNN-ResNet has the strong ability to exploit features such as shape and texture features. The following factors contribute to higher average precision

for 2CGL and 4CGL, (i) no occlusion, (ii) large size, and (iii) high illumination. As the level of drowsiness becomes more detailed in 7CGL, it becomes increasingly difficult to achieve a high level of precision in detecting and classifying teeth due to the intricate structure of teeth [52] [53]. Furthermore, it is difficult for FR-CNN-ResNet to identify objects from low-resolution images as the features extracted from the image may be less informative due to reduced contrast and detail in the image [53]. This can make it more difficult for the model to distinguish the object from the background or other objects in the scene [21]. FR-CNN-ResNet can learn and recognize features of objects even when they are partially occluded, due to the use of shared convolutional layers that extract features from different parts of the image [54] [55]. However, the accuracy of object detection for occluded objects may still be affected by the extent of occlusion and the quality of the proposals generated by the RPN [54].

## VI. CONCLUSION

The automatic detection and classification of teeth in intra-oral dental images are crucial for medical treatment and forensic identification. However, due to the complexity of the problem and limitations in the size of available data, this task remains challenging. To overcome such challenges, this paper investigates the intriguing problem that how granularity impacts the performance of CNN-based object detection and classification models. A Faster Region-Convolutional Neural Network based on ResNet models is proposed for teeth detection and classification at multi-granularity levels from the GIOI dataset. Three different ResNet backbones, i.e., ResNet-50, Res-Net101, and ResNet-152 were evaluated. The evaluation results showed that the proposed FR-CNN-ResNet model is appropriate for teeth classification at three granular levels named, 2CGL, 4CGL, and 7CGL. Additionally, it was revealed that the FR-CNN-ResNet-50 performed better than the FR-CNN-ResNet-101 and FR-CNN-ResNet-152 at each of the three granular levels, where the FR-CNN-ResNet-50 achieved mAP of 0.94, 0.74 and 0.69 at 2CGL, 4CGL, and 7CGL respectively. Overall, it is concluded that multi-granular approaches in intra-oral dental image analysis have the potential to capture significant details and improve the accuracy of automated detection and classification tasks, which can aid in medical treatment and forensic identification.

As a practical implementation, the integration of Faster R-CNN with additional networks will extend its capabilities beyond tooth detection and numbering. It will enable predictions regarding the presence of various dental conditions, including orthodontic issues, tooth fillings, and the overall assessment of dental health to facilitate the patient and dentist.

This study has two known limitations which will be addressed in future work. Firstly, for deep learning methods, large-curated datasets will be used to further improve the performance parameters. Secondly, only a few cases of the 3rd molar tooth class were identified during the dataset generation procedure, thus resulting in removing the 3rd molar class. Further in the future, a yolo-based model will be proposed to preserve topological information and the precise spatial location of pixels for each tooth.

## ACKNOWLEDGMENT

The authors would like to express their sincere gratitude and appreciation to Universiti Teknologi PETRONAS for their generous provision of resources and materials, which were instrumental in the successful completion of this research work.

# A Hybrid Approach for Underwater Image Enhancement using CNN and GAN

Aparna Menon, R Aarthi

Department of Computer Science and Engineering, Amrita School of Computing,  
Coimbatore, Amrita Vishwa Vidyapeetham, India

**Abstract**—Underwater image-capturing technology has advanced over the years, and varieties of artificial intelligence-based applications have been developed on digital and synthetic images. The low-quality and low-resolution underwater images are challenging factors for use in existing image processing in computer vision applications. Degraded or low-quality photos are common issues in the underwater imaging process due to natural factors like low illumination and scattering. The recent techniques use deep learning architectures like CNN, GAN, or other models for image enhancement. Although adversarial-based architectures provide good perceptual quality, they performed worse in quantitative tests compared with convolutional-based networks. A hybrid technique is proposed in this paper that blends both designs to gain advantages of the CNN and GAN architectures. The generator component produces or makes images, which contributes to the creation of a sizable training set. The EUVP dataset is used for experimentation for model training and testing. The PSNR score was observed to measure the visual quality of the resultant images produced by models. The proposed system was able to provide an improved image with a higher PSNR score and SSIM score with state-of-the-art methods.

**Keywords**—Convolutional neural network (CNN); generative adversarial networks (GAN); enhancing underwater visual perception (EUVP); underwater images; image enhancement; computer vision; artificial intelligence

## I. INTRODUCTION

Underwater imaging involves capturing images of objects and creatures that can only be seen underwater using specialized tools and procedures. For research projects, studies of various aquatic animals, and other undersea items, the ocean floor is always a fascinating subject. Fish and marine mammals are popular subjects for photographers, but they also look for coral reefs, underwater cave networks, underwater landscapes, crustaceans, seaweeds, and so on. When researchers need to look at objects on the seabed over time, underwater photography is highly helpful. Numerous aquatic animals can be found below the surface of the water and are harmed by the disposal of plastics and other garbage. Ocean exploration [1] and mapping will help to close knowledge gaps in areas such as tectonics, maritime hazards, etc. Enhancing scientific understanding of the deep sea will aid in managing and utilizing ocean resources sustainably.

When light travels through water, it degrades the image in ways that are not seen in typical airborne photos. Normal images are frequently of high quality; therefore image enhancement is rarely necessary. However, the quality is quite

poor for underwater photos because of the way light scatters in the water, which makes image processing challenging. The quality of images recently received more attention due to it being a crucial component of image processing. Image enhancement [2] is the process of enhancing the image quality while preserving all the information thereby producing results that are better suited for display or to prepare images for additional analysis in a variety of computer vision applications, such as object detection, image classification, scene understanding, and many other things. Underexposure, overexposure, low contrast, backlit images, improper colour balance, and out-of-focus subjects are some of the challenges [3] faced by underwater images. Other challenges in underwater imaging can be categorized as the need for adequate resolution and appropriate illumination conditions in order to provide high-quality images. The clarity of underwater images is crucial for many scientific and engineering uses in the ocean, including marine biology research and ocean rescue as well. Light of different wavelengths is absorbed in an underwater environment [4] at different rates, producing distinct colour casts. Light scattering [4] also reduces contrast and softens visual details. A lot of features hidden under the water can be shown by boosting an image's resolution, which can then be used by underwater researchers to enhance marine technology without endangering aquatic life. Therefore, techniques for underwater picture rectification are needed for both computer applications and scientific research. Both optical and acoustic technologies are employed to gather underwater data.

Contrarily, image processing offers a practical means of obtaining high-quality low-cost photos and videos. In the last ten years, the improvement and restoration of images from deep learning continued to attract attention. For a range of technical and scientific tasks, clear underwater photographs and recordings can offer vital information about the undersea habitat. However, the impacts of quality depletion, particularly the effects of bouncing back at vast distances, usually severely harm raw underwater photos and films [5]. The main causes of emerging problems are water's selective absorption and dispersion of light, in addition to the usage of synthetic illumination in deep water. The poor contrast and brightness, colour variations, hazy features, and uneven bright spot of the damaged underwater photos limit their practical applicability.

More focus has been placed on underwater image enhancement techniques as a crucial processing step. Due to the challenges in taking underwater images, their high cost, and the low quality problems brought on by low illumination

and light scattering under the water, a robust image improvement model would be extremely helpful in underwater research. These enhanced images can be applied to further tasks like segmentation, object detection, and others. Image Enhancement methods span the spectrum from the conventional, such as histogram equalization [6] and physical model-based methods [7], to the data-driven, such as convolutional neural networks [8] and generative adversarial networks [9].

Over the past few decades, deep learning techniques [10,11] have developed quickly and are now often utilized in a wide range of computer vision and image processing tasks. A way to utilize generative networks is image enhancement or super-resolution. Likewise CNNs outperforms traditional image enhancement because they search for patterns in the data that is provided. Convolutional layers are used to stack them and create intangible concepts. Comparing the state-of-the-art techniques, it is evident that adversarial networks place a greater emphasis on enhancing the visual quality of the photos. Convolutional networks, however, provide accurate quantitative results.

This study examines the shortcomings of current image enhancement techniques and suggests a hybrid solution for improving underwater images. The most recent image enhancement methods are examined in order to raise the photos' perceptual and quantitative quality. In order to obtain the favorable aspects of both models, two state-of-the-art methods are combined. To improve the poor-quality images, the proposed model is developed utilizing deep convolutional neural networks [12] and generative adversarial networks [13]. The underlying problem consists of increasing perceptual quality [14] and better performance in quantitative tests as well.

The concept of underwater imaging, its importance, challenges, and the premise of this paper are briefly discussed in Section I. The significant background information from related works is briefly introduced in Section II. The main portion of this study is introduced in Section III. The algorithm suggested in this paper was tested and describes the results of those tests and conducts an unbiased analysis of the algorithm's performance in Section IV. A summary and analysis of this paper's findings are provided in Section V.

## II. RELATED WORKS

Multiple techniques exist for improving and saving underwater photographs. Various techniques make use of physical models, while others don't. The Jaffe-McGlamery model [15] provides a precise physical representation for underwater imaging. Between the underwater photographs and the recovered images in a physical model, the model forges a link. By calculating the light's penetration and determining the ambient light of the surrounding underwater environment, one can produce reconstructed underwater images. Heng-Hua Chang [16] suggested a resilient single underwater image restoration system for enhancing graphic quality. Sheezan [17] described a restoration method for underwater pictures that prioritizes aesthetic quality. A red-channel method was suggested by Galdran [18] to correct underneath images.

Preprocessing underwater monocular vision with an improved DCP technique was presented by Tang et al. [19].

The traditional model-free technique focuses on changing the pixels of underwater photos, offering a more direct way to improve underwater photography than physical model-based improvement and rebuilding. Examples of techniques include white balance, gamma correction, histogram equalization, wavelet modification, and the Retinex algorithm. In order to produce thorough, high-quality photographs, experts typically utilize multiple techniques because underwater photography can degrade in a variety of ways. Examples include the blending of histogram equalization and wavelet transformation, the blending of wavelet transformation, white balance, and histogram equalization, and the blending of histogram equalization, white balance, and gamma correction.

New techniques for image processing have emerged as a result of the development of artificial intelligence (AI) over the preceding ten years. Neural networks (NN) and support vector machines (SVM) are good examples. Deep learning is used to improve photographs, notably image dehazing [20], as discussed by Jisnu, K & Meena, Gaurav. A network of deep neural networks was implemented by Li et al. [21] to de-scatter the underwater image. The use of a deep convolutional neural network (CNN) has been recommended by Perez et al. [22] to dehaze underwater shots. Deep CNN was implemented by Wang et al. [23] to color-correct and eliminate haze from underwater photographs. Cao et al. [24] exhibited clear latent deep CNN underwater reconstruction images.

Ground truth for underwater images can be challenging, so the typical deep learning framework can only be used to train models using ground truth from unique underwater images. The use of GAN by Fabbri et al. [25] improved the aesthetic appeal of aquatic scenes. Using an unsupervised GAN, Li et al. [26] described real-time underwater photo colour correction. A generative adversarial model with cycle consistency was employed by Li et al. The output of underwater photography will be fed into a neural network to build CNN models. The use of GAN to enhance the visual appeal of underwater photos was introduced by the author [25].

In order to increase underwater image quality from the perspectives of colour balance and dehazing, CNN is employed in the study. Despite the fact that it has been shown that GAN is mostly successful in reducing colour variance in underwater photographs. The clarity of underwater photographs can be increased by using a complete eliminating hazing model, which reduces the cumulative mistakes that arise from measuring background illumination and light transmission individually when a standard recovery model is applied. The employment of CNN in the single device eliminating hazing model, GAN colour adjusting, the improvement of ground truth, and the use of the blending technique for improving contrast are a few of the highlights.

The recommended picture improvement technique is tested on a large number of underwater photos from EUVP dataset [27], and some of the results are presented.

### III. PROPOSED METHOD

When compared to GAN-based models, CNN models are more concerned with improving numerical parameters while GAN-based models are more interested in the perceived quality of the improved images. Although the deep learning-based method for underwater image enhancement has made good progress, there is still much potential for development, particularly in the method's qualitative and quantitative capabilities. In order to address those issues, the paper suggests a hybrid strategy; thereby, performed an experiment combining GAN and CNN as a hybrid technique to get an enhanced image with better quantitative value and perceptual quality. We attempted the hybrid approach in two different ways. Initially, CNN and GAN were two parallel systems combined with concatenation. But because the two models must be trained independently, there was a large time commitment. The two models were afterward tested in a pipeline. The basic flow diagram of the system is discussed in the below section and briefly explains how the system works from the normal CNN and GAN to a hybrid architecture in which the input images are passed through both to get an enhanced image. This project will make use of the EUVP dataset [27], which will provide a detailed look.

#### A. Architecture of the Proposed System

Fig. 1 shows the hybrid system requires both CNN and GAN connected in a pipeline. The input image is passed through the pipeline architecture, thereby obtaining an enhanced image. The restored images are created with the help of the animation class of matplotlib. In the GAN architecture,

both the generator and the discriminator work together. The generator tries to produce better images after each epoch of the training and the discriminator acts like a binary classifier to detect real or fake images. In the CNN architecture, the input images pass through the layers and obtain the features of the input image. And these outputs of both GAN and CNN combined to get the resultant enhanced image. The loss function is attempted to be minimized by the generator and maximized by the discriminator as in a min-max game.

#### B. Dataset

1) *EUVP dataset*: The EUVP (Enhancing Underwater Visual Perception) dataset[27] offers multiple sets of paired and unpaired image examples of low and acceptable visual clarity in order to facilitate the supervised training of underwater picture enhancement algorithms. Table I shows the paired image details from the dataset[27] and Fig. 2 gives few examples of the paired images. In Table II, the details of the unpaired images are depicted and Fig. 3 shows some sample images from the unpaired set of the dataset[27].

TABLE I. PAIRED IMAGE DETAILS DATASET FROM EUVP DATASET[27]

Dataset Name	Training Pairs	Validation	Total Images
Underwater Dark	5550	570	11670
Underwater ImageNet	3700	1270	8670
Underwater Scenes	2185	130	4500

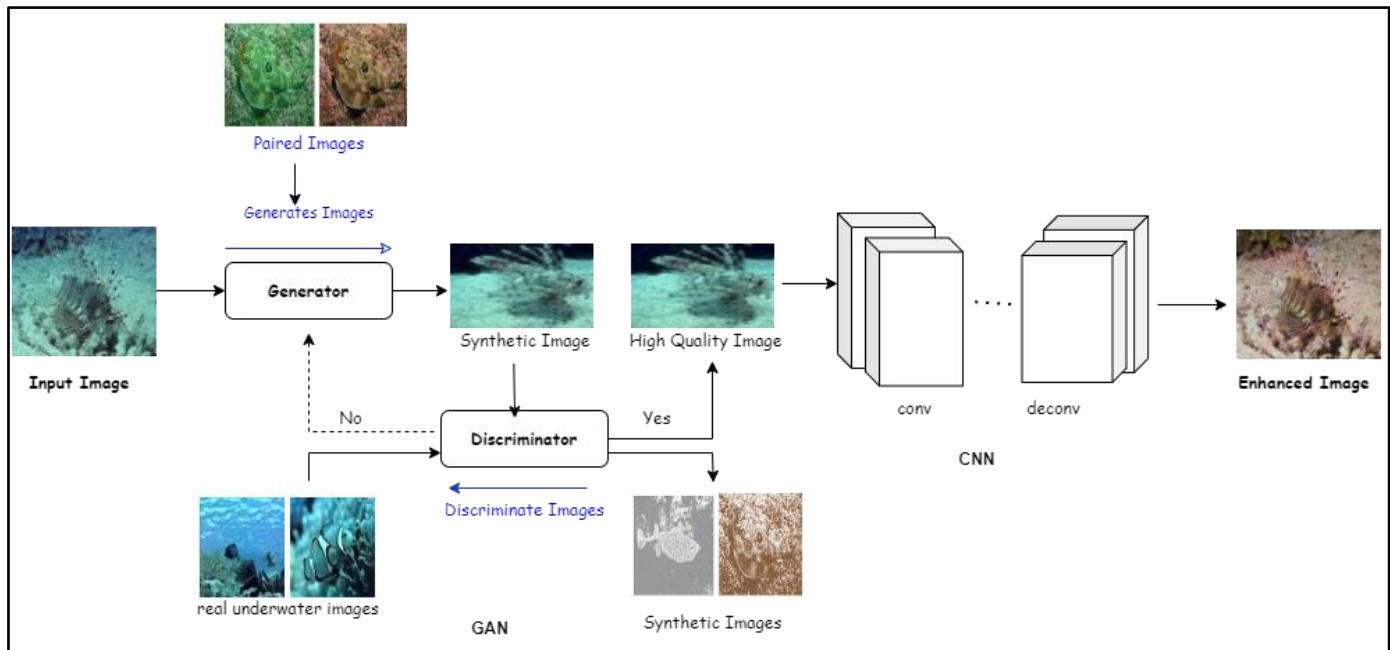

Fig. 1. Implementation flow using the suggested system, from raw input image to improved image

Fig. 2. Samples of the paired images from the EUVP dataset[27].

TABLE II. UNPAIRED IMAGE DETAILS DATASET FROM EUVP DATASET [27]

Poor Quality	Good Quality	Validation	Total Images
3195	3140	330	6665

Fig. 3. Samples of the unpaired images from the EUVP dataset [27].

### C. Platform and Specifications

The studies were carried out using a Google Colab Pro cloud-based subscription. 24GB CPU RAM and 16GB VRAM of the Tesla V100 GPU were used. We also ran some local tests on NVIDIA RTX 3060 GPUs with 6GB VRAM and 16GB CPU RAM. The complete application was written in the Python 3.7 programming language using the Pytorch module. To validate the project and see how it is advancing the state-of-the-art models used numerous experiments that were carried out.

## IV. RESULTS AND INFERENCE

Section IV explains many experiments carried out while the application was being developed and how measurements are utilized which are compared using results from other models. In this chapter, various screenshots of the findings are shown. Finally, all comparisons are shown in tabular style with the results of the baseline model.

### A. Metrics For Evaluation

1) *Peak signal-to-noise ratio (PSNR)*: The peak signal-to-noise ratio (PSNR) is used to interpret the image[28]. The signal-to-noise ratio is a term used in engineering to convey the association between a signal's maximum power and the power of corrupting noise that reduces the accuracy of its representation. Due to the fact that many signals have a broad dynamic range, PSNR is frequently expressed as a logarithmic value employing the decibel scale. PSNR is widely used to gauge the quality of reconstruction for lossy-compressed images and movies.

$$PSNR = 20\log_{10}(MAX/(MSE)^{1/2}) \quad (1)$$

where MAX is the highest pixel value that the image can contain and MSE is Mean Squared Error.

2) *Structural Similarity Index (SSIM)*: The Structural Similarity Index (SSIM)[28], a perceptual metric, quantifies the extent to which imagery is lost due to problems with data transmission or other processing steps like data encoding. The Structural SIMilarity (SSIM) index is a tool for calculating how similar two images are. On the assumption that the other image is thought to be of ideal quality, the SSIM index can be used to assess the quality of one of the images being compared.

$$SSIM(x,y) = ((2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)) / ((\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)) \quad (2)$$

where,  $\mu_x$  is the pixel sample mean of  $x$ ,  $\mu_y$  is the pixel sample mean of  $y$ ,  $\sigma_x^2$  is the variance of  $x$ ,  $\sigma_y^2$  is the variance of  $y$ ,  $\sigma_{xy}$  is the covariance of  $x$  and  $y$ ,  $c_1 = (k_1L)^2$ ,  $c_2 = (k_2L)^2$  are two variables to stabilize the division with weak denominator and  $L$  is the dynamic range of the pixel values,  $k_1 = 0.1$  and  $k_2 = 0.3$  by default.

3) *Loss function*: The first description of the typical GAN loss function [29], often known as the min-max loss, was made in a 2014 article titled "Generative Adversarial Networks" by Ian Goodfellow et al. The resulting value is enhanced by the discriminator, while it is diminished by the generator. This explanation of the defeat seemed to work well when viewed as a min-max game. In reality, it saturates the generator, which means that if it falls behind the discriminator during training, it commonly stops.

$$E_x[\log(D(x))] + E_z[\log(1-D(G(z)))] \quad (3)$$

Discriminator loss and Generator loss are two additional categories that can be tailored to the Standard GAN loss function.

Generator Loss:

$$\nabla\theta_g(1/m)\sum_{i=1}^m \log(1-D(G(z^{(i)}))) \quad (4)$$

Discriminator Loss:

$$\nabla\theta_d(1/m)\sum_{i=1}^m [\log D(x^{(i)}) + \log(1-D(G(z^{(i)})))] \quad (5)$$

In this function:

$D(x)$  is the discriminator's estimate of the probability that real data instance  $x$  is real,  $E_x$  is the expected value over all real data instances,  $G(z)$  is the generator's output when given noise  $z$ ,  $D(G(z))$  is the discriminator's estimate of the probability that a fake instance is real,  $E_z$  is the expected value over all random inputs to the generator (in effect, the expected value over all generated fake instances  $G(z)$ ).

### B. Experiments and Results

The Underwater\_dark set from the EUVP dataset, which contains 5550 pairs of photos for training as two sets, is used to train the suggested model. One group includes low-resolution (or grey) photographs, while the other has upgraded (or coloured) images. For every pair, both sets share the same filenames. Another 570 images were used for validation. As a

total, we have used 11,670 images from the dataset [27] for the experimentation and implementation. The degraded photos that were utilized for training are shown in Fig. 4. And Fig. 5 explains the generator and discriminator loss obtained while training. It is evident from Table III that the suggested hybrid technique performs better than the current models. The results demonstrate that, in comparison to our hybrid approach, the current models do not provide good quantitative results. The suggested approach produced better quantitative results with increased visual quality, as seen in Fig. 6 and Fig. 7. The outcomes of our hybrid technique are displayed in Fig. 6 by comparison with the input test image and the ground truth. The findings of the suggested approach are also compared to those of the current methods in Fig. 7 where our hybrid method makes a distinct quality difference.

Fig. 4. Different training images from the EUVP dataset.

Fig. 5. The graph for generator and discriminator loss during training.

TABLE III. PSNR AND SSIM SCORES OF FIVE DIFFERENT IMAGES

Input Image	CNN		GAN		Hybrid Method	
	PSNR	SSIM	PSNR	SSIM	PSNR	SSIM
(a)	<b>14.46</b>	0.4575	16.89	0.3635	18.96	0.4365

## V. CONCLUSION AND FUTURE SCOPE

Due to the visual characteristics of light in water, an image acquired underwater degrades. However, traditional forms are insufficient for accurate reconstruction due to the deterioration of the observed image. We suggested a hybrid method for enhancing underwater descriptions in this research. The hybrid technique is with CNN and GAN, which produces better results. According to experimental data, the suggested technique outperforms the standard procedures when combined in visual and quantitative evaluation. The proposed model can improve the detailed information of the image by enhancing it, according to comparisons made between it and enhancement algorithms recently proposed. Although this method is best suited for enhancing images with fluctuating lighting levels, it has significant limitations when it comes to effectively restoring the details of extended exposure areas. However, augmentation restricts the local dark region when the lighting is too unbalanced, calling for further research. Another issue with the current system is we need to train a lot of data. This could take up a lot of time and space and be very complex in training. We performed various experiments and recorded the results for the proposed architecture.

As a future enhancement, the upgraded images can be taken as the input and can perform image segmentation and object detection as well to create an awareness about the pollution under the water and thereby help the aquatic lives to get a better life.

# End-to-End Real-time Architecture for Fraud Detection in Online Digital Transactions

ABBASSI Hanae, BERKAOUI Abdellah, ELMENDILI Saida, GAHI Youssef

Engineering Sciences Laboratory-National School of Applied Sciences, Ibn Tofail University, Kenitra, Morocco

**Abstract**—The banking sector is witnessing a fierce concurrence characterized by changing business models, new entrants such as FinTechs, and new customer behaviors. Financial institutions try to adapt to this trend and invent new ways and channels to reach and interact with their customers. While banks are opening their services to avoid missing this shift, they become naturally exposed to fraud attempts through their digital banking platforms. Therefore, fraud prevention and detection are considered must-have capabilities. Detecting fraud at an optimal time requires developing and deploying scalable learning systems capable of ingesting and analyzing vast volumes of streaming records. Current improvements in data analytics algorithms and the advent of open-source technologies for big data processing and storage bring up novel avenues for fraud identification. In this article, we provide a real-time architecture for detecting transactional fraud via behavioral analysis that incorporates big data analysis techniques such as Spark, Kafka, and h2o with an unsupervised machine learning (ML) algorithm named Isolation Forest. The results of experiments on a significant dataset of digital transactions indicate that this architecture is robust, effective, and reliable across a large set of transactions yielding 99% of accuracy, and a precision of 87%.

**Keywords**—Online fraud; big data analytics; fraud detection; behavior analysis; isolation forest

## I. INTRODUCTION

Digital transaction fraud happens when an entity gains illegal entry to a banking account and utilizes it to make online transactions. Fraud detection techniques seek to exploit two fundamental limits that fraudsters experience while committing online transaction theft. First, most fraud techniques are susceptible to restricted time limits since consumers and banks block account access immediately with fraud discovery. Therefore, fraudsters are needed to hit the credit limit on the account in a brief amount of time, and as a result, their act is revealed in the shape of suspicious transactions over these shorter periods. In addition, the second type of restraint is created by the variety of digital transactions exposed by financial institutions and the variety of customer behaviors and awareness regarding fraud threats throughout these channels. Fortunately, monitoring measures applied from the financial institutions' side added to device security measures used from the customer's side may impede, in many cases, fraud attempts. Such impediments push fraudsters to target a small niche of customers that don't frequently interact through digital channels or aren't aware of security measures [1] that should be applied. As a result of this condition, fraudulent transactions are made at a few specific accounts that vary from the area set of customers to which the requirements above are applied.

Conventional methods for detecting system fraud are rule-based [2] [3]. Although rule-based solutions help prevent many fraudulent transactions, they remain static and don't adapt to fraud trends changes even when humans adjust continuously. As a result, machine learning-based algorithms have emerged as a non-deterministic approach employed for digital payment fraud detection in recent years. This area of study, however, has received little attention in the literature. Many of the solutions that have been examined propose a technique based on intelligent field knowledge features or make a fundamental assumption about transaction chronology [4]. To conduct a digital payment transaction, a fraudster should first login into the banking system. The payment and login are two separate processes that must be performed within this sequence. Anyway, this simple procedure follows a typical series of events. Although the bulk of fraud efforts are more complicated, the utmost existing systems focus on records from the most contemporary transactions, depending on hand-engineered characteristics that will presumably identify broad connections.

The target of this study is real-time fraud detection in digital banking. In this context, a fraud detection scheme aims to determine the risk within each item as in kind of fraud likelihood in real-time. The bank may then opt to authorize the transaction, refuse it, or demand a specific type of authentication on the consumer after completing it. To tackle this issue, we present a real-time architecture for detecting transactional fraud through behavioral analysis, which combines big data analysis tools (Kafka, Spark, and h2o) with the Isolation Forest algorithm to see suspicious transactions and provide excellent detection performance. The experimental findings are provided to confirm the efficacy of our strategy.

Concisely, the following are the foremost contributions of the present research:

- 1) Establishing an advanced fraud detection architecture for digital transactions by combining an unsupervised learner with big data analytics kits for real-time detection and training time reduction, enabling it to identify fraud in a typical online transaction context,
- 2) Using efficient feature engineering methods on the raw data. This involves producing aggregate features based on transaction frequency and isolating complex characteristics including the transaction's date to month, day, location, and so on. Because of the variety of features, our model can detect patterns that individuals or primitive machine learning algorithms cannot,

- 3) Applying the isolation forest model for identifying suspicious transactions,
- 4) Extensive evaluations have been carried out to assess the efficacy of the suggested architecture.

Our suggested architecture outperforms crucial benchmarks on online transaction fraud data encompassing over a hundred million transactions in a thorough experimental examination. More precisely, we show how our method can be used to meet strict operating time limitations while still maximizing prediction performance requirements relevant.

The remnant of this article is structured as following: in the second part, we present a review of the online transactions' fraud detection literature. Section III presents the research summary. Section IV offers the Isolation Forest learner. Section V describes our suggested architecture for online fraud transaction detection. And Section VI outlines the end-to-end data pipeline and the dataset used and explains the findings. Further Section VII discusses our results providing comparison with state-of-the-art studies. Finally, Section VIII concludes the work with suggestions for further research.

## II. FRAUD DETECTION TECHNIQUES FOR ONLINE TRANSACTIONS

World banking services and industries have been subjected to massive e-frauds, which have resulted in the overturning of whole organizations, enormous investment losses, and considerable litigation expenditures. As a result, companies and scientific studies have shown a keen interest in detecting online fraud. This section examines various significant study topics relevant to our work.

### A. Outline of Extant Banking Fraud Recognition Methods and their Drawbacks

For many years, the general strategy in the cybersecurity business has been to prevent hypothetically fraudulent transactions by enforcing a set of strict criteria. A fraudulent identification rule-based system is designed to detect only elevated abusive transactions [4] [5]. This strategy efficiently reduces scam attempts and provides clients with a wisdom of security by uncovering well-known fraud trends. Nonetheless, rule-based detecting fraud technologies have shown in the arena that they are unable to go on with the gradually complex strategies used by cheats to jeopardize important properties: Cybercriminals may readily counteract a set of predetermined levels [6], [7] and fixed criteria are useless for identifying developing risks and adapting to previously undisclosed fraudulent transactions.

The miss of information to examine is another significant drawback of rule-based detecting systems more inventive the fraudulent strategy, the less the info you will get in examined trades [8]. This dearth of information might indicate that valuable data are not being gathered and saved, that data is available although lacking crucial points [7], or that data cannot relate to particular other info.

Many methods have been created and tried over time to increase the efficacy of rule-based detection strategies. However, recent trends indicate that deploying analytics

regularly on a flexible data architecture and reliable machine learning algorithms might yield promising outcomes.

### B. On Machine Learning-based e-Banking Fraud Detection

Recently, machine learning Fraud Detection has risen to prominence [9] [10] [11] [12]. Because of its more accurate findings, the anti-fraud domain is shifting from rule-based fraud identification to ML fraud detection. We present here some online fraud detection studies.

By using supervised machine learning methods, [13] have wanted to construct a transactional fraud detection algorithm capable of efficiently classifying an online transaction as illegitimate or legitimate. A credit-card fraud classifier was created utilizing three supervised machine-learning (ML) algorithms. SVM, LR (logistic regression), and neural networks are among these methods. All the classifiers attain about the same classification accuracy. The results show that the support vector machine beats the others.

Along with this, two algorithms, namely XGBoost, and Fully Connected Neural Network (FCNN), whose AUC merits may reach 0.912 and 0.969 correspondingly, have been developed by [14]. In the meantime, they have developed an interactive method for identifying online transaction fraud relying on the XGBoost model to evaluate submitted transaction data autonomously and provide customers with fraud detection findings. On the other side, to increase detection performance and quicken the convergence of identification, [15] has suggested an online transactional fraud detection approach using unbalanced data relying on the semantic integration of two unsupervised learners such as an artificial bee colony model and k-means. In the suggested method, ABC functions as a secondary classification level to handle the k-means classifier's inability to investigate the real bunches since it is susceptible to the beginning circumstance. The experiment results showed up to 100% True positive and less than 2% False Positive. In the same context [16] have offered a tailored alert model for detecting fraud in online transactions by mining a set of instances in each customer's regular transaction log. The suggested methodology segmented every consumer's log into transactions extracted a collection of chronological sequence arrangements and used it to identify if a novel transaction is malicious. The entering transaction is separated within many windows, and an alert is raised if the typical behaviors are not discovered in the subsequent windows. According to the experimental outcomes, the suggested approach beats the rule-based paradigm and the Markov chain method.

Moreover, FinDeepBehaviorCluster has been proposed by [17]. They have used temporal attention-based Bi-LSTM to determine sequential embed and handled click data in real-time as an event sequence to exploit the behavior sequence data. Handmade features reflecting domain expertise are produced to improve the system's interpretability. By integrating the two sorts of traits, a hybrid behavior interpretation has been created. Then, to group transactions with similar behavior, a pHDBSCAN (i.e., GPU-powered HDBSCAN) is used. The results show that FinDeepBehaviorCluster successfully detects lacking suspicious transactions having excellent business value. By merging machine learning with big data analytics

tools, [18] have presented a robust method for detecting fraud in online-based transactions. To notice whether electronic transfer behaviors are aberrant, the big data of internet-based e-transactions, which includes (credit card details data and trading), is first refined in the transaction pre-processing stage module, and then transferred to a rule-based specialist system module, which would be achieved with Spark streaming and divvied up platform Kafka. The regular records from the expert system module are then applied in the machine learning fraud prevention module to execute behavioral analysis via DT (Decision Tree), CNN, and SVM algorithms. The findings exhibit that the proposed strategy produces satisfactory results. Also, to identify Internet financial fraud, [8] have proposed a sophisticated and scattered Big Data approach. They have used Hadoop and Spark GraphX to identify and express every vertex's topologic feature in a dense lowly-dimensional vector using the graph embedding technique Node2Vec. The suggested approach seeks to anticipate the dataset's spurious entries. The findings indicate that the proposed strategy enhances the precision and accuracy of Online fraudulent transaction detection systems. In that same vein [19] have created a real-time scam detection for credit cards system utilizing big data technologies such as Microsoft Azure. The

given outcomes are pretty accurate by applying a variety of ML learners, such as Extreme Random Trees and Stochastic Gradient Descent.

Recently, the isolation forest learner has been applied in online banking transactions fraud detection, given its reputation as one of the most powerful algorithms. In fact, [20] have examined two unsupervised learners for CCFD i.e. credit card fraud detection (isolation forest (IForest) and local outlier factor (LOF)). When comparing precision and recalls for the two models, the findings show that Isolation Forest beats the local outlier factor. Additionally, the fraud detection percentage is about 0.27, whereas the LOF (local outlier factor) discovery rate is barely 0.02. The accuracy of the Isolation Forest is 0.99774 higher than that of the local outlier factor. Similarly, the IForest and LOF techniques were employed by [21] to detect fraudulent credit card transactions. The experiments provide good results.

All the studies discussed here are fascinating and revolve around fraud detection in large data circumstances. They offer trustworthy and promising prediction algorithms for preventing fraud. We present the comparison of all these models in the Table I.

TABLE I. PREVIOUS FINDINGS FOR OTHER STUDIES

Paper	Used dataset	Techniques used	Performance	Limits
[13]	Credit card dataset	SVM, LR, and neural networks	The support vector machine beats the others	The precision of the ANN is around twelve percent less than that of both of the models
[14]	Online transactions	XGBoost, and Fully Connected Neural Network (FCNN)	XGBoost reaches 0.912 and FCNN 0.969	The system can't identify malicious transactions in real-time as they occur
[15]	Online transactions	artificial bee colony model and k-means	Results showed up to 100% True positive and less than 2% False Positive	Quadratic Discriminant Analysis give the fewer accuracy
[16]	Online transactions	Tailored alert model for detecting fraud in online transactions	The suggested approach beats the rule-based paradigm and the Markov chain method.	The suggested methodology detects fraud by using regular patterns; however, it will only identify scams when individuals display considerably different trading habits than typical.
[17]	real-world e-commerce transaction data	temporal attention-based Bi-LSTM, pHDBSCAN	Results show that the proposed method successfully detects lacking suspicious transactions having excellent business value.	Unable to identify low frequency of fraudulent transaction
[18]	internet-based e-transactions (credit card details data and trading)	Spark streaming and Kafka. DT, support vector machine, and CNN	The findings show that the proposed strategy produces satisfactory results.	The outcomes need to be improved
[8]	Credit card dataset	Spark GraphX, Hadoop, and graph embedding technique Node2Vec	The findings indicate that the proposed strategy enhances the precision and accuracy of Online fraudulent transaction detection systems.	The suggested model will be enhanced to successfully learn the newly generated features, resulting in better identification of fraud.
[19]	Credit card dataset	Microsoft Azure, Extreme Random Trees, and Stochastic Gradient Descent.	Good accuracy	Does not handle the class imbalance problem
[20]	Credit card dataset	IForest and LOF	The findings show that Isolation Forest beats the local outlier factor within 0.99774 of accuracy. The fraud detection percentage is about 0.27, whereas the LOF discovery rate is scarcely 0.02.	The LOF learner yield low performance
[21]	Credit card dataset	IForest and LOF	The experiments provide good results.	LOF give the worst results

The upcoming section will highlight the comparative study of this literature reviewed methods for online fraud detection and present the motivations of our paper.

### III. SUMMARY AND MOTIVATIONS

Based on our literature review analysis in the previous section, we noticed that researchers have proposed several machine Learning approaches particularly supervised ones involving SVM, LR, DT, and NB algorithms, for detecting online transaction fraud. The majority of the approaches examined have shown to be beneficial in the process; nonetheless, due to changes in the fraudster's behavioral patterns, real-time fraud detection is always difficult, and algorithms fail to give better accuracy.

As the outcomes reveal, systems for detecting fraud that utilize SVM and LR offer good accuracy yet suffer from considerable overhead when handling huge datasets. Additionally, because the fraudulent act is shifting, these learners are just assisting in learning current trends in fraud. From another viewpoint, ANN, decision tree, and NB provide moderate accuracy and mid-scope at the expense of high prices.

Another limitation of these related studies is that most of them establish a profile of regular cases and then detect anything that does not fall within the usual profile as an abnormality; leading to misclassification, a high false positive rate, and also, they are not adept at handling real-time detection. In contrast with that, IForest segregates observations by picking a property and then erratically determining a splitting point between the selected property's maximum and minimum values [22]. The amount of splits required to isolate a trial equals the path length from the root node to the ending node [23]; by giving high fraud detection accuracy over large datasets, with the least false positive rates.

This study suggests a new end-to-end real-time architecture for online transaction fraud detection based on isolation forest learners. Combining the advantages of big data analytics tools and the unsupervised isolation forest with the aim to overcome the existing approaches' limitations and dealing with real-time detection and prevention of digital transactions while minimizing false positive rate, and false alarms, regulating latency in addition to speed, and dependability.

### IV. ISOLATION FOREST

Isolation Forest is defined as an unsupervised ML learner. It employs a similar technique as the (RF) Random Forest algorithm and is based on the notion of decision trees. Rather than using the typical properties of data points, the isolation forest algorithm's basic idea and approach are to detect abnormalities — for example, fraudulent transactions [24] [25].

Isolation forest outperforms other techniques in anomaly detection algorithms due to several advantages. First, it requires tiny samples from considerable datasets to generate an anomaly detection algorithm, making it rapid and robust. Secondly, no examples of abnormalities in the training sample are required. Furthermore, the tree depth serves as the foundation for its distance threshold for detecting anomalies independent of the sample dimensionality scale. It may

function as both a supervised and unsupervised learner, and its goal is for irregularities to be less frequent than everyday observations and to differ from their values.

To build the IForest (Isolation Forest), determine the amount of (Itrees) isolation trees within the forest. Next, for every isolation tree, the following procedures are taken [26] [27]:

- Select  $n$  instances at random from the training dataset.
- Pick an attribute at random to divide on.
- At random, select a separated value from a uniformly distributed covering the minimum to the most significant rate of the feature set in Step 2.

Assuming a dataset has  $n$  instances,  $h(x)$  is the route length as  $x$ . The average path length  $c(n)$  is afterward used to normalize the value of the path length  $h(x)$ . As Itrees have the same shape as the BStree (Binary Search Tree), the following equation is used to obtain the value of  $c(n)$ , where  $H(i)$  is the harmonical number that may be obtained via [28] [29] :

$$c(n) = 2H(n - 1) - \frac{2(n-1)}{n} \quad (1)$$

The abnormality score within each data point  $x$  in a database with  $n$  occurrences is obtained by using the following:

$$s(x, n) = 2^{-\frac{E(h(x))}{c(n)}} \quad (2)$$

with  $(E(h(x)))$  is the mean of  $h(x)$  across a set of Itrees).

The nearer a data point's anomaly score is near 1, the more likely that data point is an outlier. On the other hand, the records point is more probable to be regular if the abnormality count is near zero.

### V. END-TO-END FRAUD DETECTION SOLUTION ARCHITECTURE

This section proposes a real-time scalable architecture for preventing and detecting fraud in online transactions using big data analytics algorithms to improve the capacity to manage highly complex online transaction fraud instances. In this part, we will present a fraud detection pipeline as a sequence of steps applied to every transaction to mitigate the risk of fraud occurrence. This pipeline will consequently drive the suggested architecture and the technology stack used for its implementation.

#### A. Fraud Detection Pipeline

Let's say the banking account provider receives an authorization request for a transaction. Initially, the Online Detecting Fraud system captures the transaction data and its context in real-time. To prevent fraud, deterministic rules are positioned as barriers that should be imperatively checked before effectively executing the transaction. Given that these rules are implemented as part of the transaction, criteria such as low latency should be a real concern. Therefore, enforcing these rules must be performed in milliseconds. Otherwise, the customers will notice a significant delay while interacting with the bank application. Once these barriers are overcome, the customer transaction is executed. Next, we move forward with

fraud detection using more sophisticated and non-deterministic data analytics techniques.

At this stage, the goal is to detect suspicious transactions based on customers' past interactions with the bank's application. To see these transactions, customer data would be processed in real-time and fed to a pre-trained isolation forest model. This model makes predictions and produces suspicious transactions with an associated score. Transactions with a score over a predefined threshold would be displayed in a fraud monitoring application for human supervisors who will investigate customer behavior to confirm or reject those cases. The transaction monitoring agents might perform some curative actions and notify account holders of the occurrence of these high fraud-risk transactions by "mobile app alerts, e-mail or SMS." The fraudulent instances observed by the transaction monitoring and customer care departments are gathered, and the associated transactions in the database are tagged as suspicious. To sum up, any customer transaction will go through the pipeline below in Fig. 1:

Fig. 1. Customer transaction pipeline.

Each of the presented steps has different prerequisites to balance user experience and prevention from potential fraudsters. Consequently, implementation choices and used technologies were driven by these requirements. The Table II presents each step, along with its prerequisites and implementation choices:

TABLE II. FRAUD DETECTION STEPS WITH THERE PREREQUISITES

Layer	Description & prerequisites	Implementation choices
Events streaming	Refers to events streaming from digital banking applications. This component must publish events as soon as they occur.	Kafka-connect. Kafka producer API
Data capture	Refers to events captured in a resilient way as well as making them available to different consumers.	Apache Kafka
Fraud prevention	Refers to real-time fraud prevention while transactions are in motion. This step must respond with a significantly reduced latency, given that the end-user would be blocked until this prevention is performed.	Apache Kafka Streams
Fraud detection	Refers to detection of fraud in a non-deterministic way, affecting a score to each transaction and persisting information about suspicious transactions.	Apache Spark Spark Streaming H2O PostgreSQL
Monitoring	Refers to making potential fraud alerts available to human supervisors that could analyze and eventually contact end-users and perform curative actions accordingly.	React NodeJS
Alerting	Refers to raising alerts once a suspicious alert is confirmed to be fraudulent. These alerts could be consumed afterward by third-party consumers for actions such as account blocking and SMS notifications...	Kafka-connect. Kafka producer API

### B. End-to-End Solution Architecture

The Fig. 2 below presents an overview of the suggested architecture after gluing together the building blocks exposed previously:

Fig. 2. End to end real time fraud detection architecture.

The prevention layer will be built with Kafka and KSQL. Kafka, the most ubiquitous and extensible stream processing platform, has been optimized for real-time use [30] [31]. KSQL, on the other hand, is a continuous query language. While it may be used for interactive data exploration, its primary aim is to construct stream processing apps. Our architectural scheme is as follows; Large data transactions originate from various sources, including websites, neobanks, social media, etc. These transactions are obtained in real-time using Apache Kafka and KSQL in the form of a stream. For instance –, if we have the same account number as that of the previous transaction at a different location in fewer than ten-minute period later, the system will deem it suspicious and reject it instantly without sending a verification email or SMS to the account's owner.

Real-time fraud detection consists of several layers, including a real-time transaction ingestion layer, a processing layer for handling massive amounts of information in storage for increased reliability and fault-tolerant, and fraud notifications via visual representation. First, the vast data of online transactions is ingested. Then, the processing layer retrieves the transactions in real time, which can handle the transaction data quickly and efficiently. This layer notably depicts two commonly used techniques. Spark streaming and Sparkling water for deploying the predictive model and its integration with the Spark distributed processing engine.

On the other hand, an isolation forest is used to predict the degree of fraud and identify it as accurately as possible in the shortest period. To verify whether a transaction is illegal, isolation forest learns the model from the account holder's behavioral patterns. We examine the location and time gap among different transactions, the frequency of transactions, and other criteria while regulating the account holder's history of transactions. The transactional data will then be saved and utilized for monitoring in a frontend application, which exposes visualizations and curative actions connected with backend APIs.

### C. Solution Infrastructure Deployment

At the core of this architecture implementation, we relied on a distributed cluster on which model training and spark streaming data processing and inference jobs were deployed. In addition, other components, namely Kafka and fraud monitoring applications, were deployed separately on other servers. The Table III shows the servers used for each element:

TABLE III. USED SERVERS

Component	Servers / Characteristics
Spark streaming / H2O	Driver : CPU: 1 core RAM: 4 Go Storage: 50 Go
	Worker 1 : CPU: 2 cores RAM: 8 Go Storage: 50 Go
	Worker 2 : CPU : 2 cores RAM : 8 Go Storage : 50 Go
Kafka	Worker 3 : CPU : 2 cores RAM : 8 Go Storage : 50 Go
	Broker 1 : CPU : 2 cores RAM : 8 Go Storage : 50 Go
	Broker 2 : CPU : 2 cores RAM : 8 Go Storage : 50 Go
Monitoring application	Broker 3 : CPU : 2 cores RAM : 8 Go Storage : 50 Go
	Application server / Database: CPU : 2 cores RAM : 8 Go Storage : 50 Go

In the next section, we will focus on the used dataset as well as the model implementation (ie spark streaming job and its integration with H2O isolation forest implementation). For these two components we will expose the approach along with key results and metrics.

## VI. SIMULATION AND RESULTS

This section depicts the database and the evaluation criteria that were utilized in our study. The outcomes of the suggested method's experiments are then provided.

### A. Dataset

The database used in our work contains online transactions generated with an approach that simulated real customer behavior. The generated dataset contains more than 100 million rows following the structure below:

- User\_id: identifier of the user connected to the portal.
- Account: account number of the customer connected to the portal.
- Event\_type: type of event captured by the audit trail.

- Event\_payload: payload containing event attributes.
- Event\_description: descriptive text of the event
- Device\_id: mac address of the device used for the action.
- Ip\_address: IP address
- Timestamp.

The event attribute reflects various actions that customers could typically perform in a digital banking platform:

- LOGIN\_ATTEMPT
- LOGIN\_SUCCESSFULL
- LOGIN\_FAILED
- LOGOUT
- VIEW\_ACCOUNT\_BALANCE
- VIEW\_ACCOUNT\_HISTORY
- VIEW\_ACCOUNT\_OPERATION
- MONEY\_TRANSFERT
- ADD\_BENEFICIARY
- REMOVE\_BENEFICIARY
- PROVISION\_CARD
- BILL\_PAYMENT
- VIEW\_CONTRACT
- VIEW\_CARD

To reflect real customer behavior, data was generated concerning the sequence of events that could occur from a user interacting with the bank application. For example, the interaction sequence should start with LOGIN\_ATTEMPT event followed by LOGIN\_SUCCESSFUL or LOGIN\_FAILED. Once the customer is logged in, they can view the account balance, add beneficiary to make money transfer to them, pay bills, or any other event reflecting the exposed services by the bank. To integrate suspicious events, the data generation script randomly picks some users for which money transfers are performed at an unusual rate or failed login attempts are performed from unknown devices. Those fraudulent transactions are then labeled and saved separately as a baseline for later model evaluation. The generated data served for model training and was published afterward to a Kafka topic using scripts relying on Kafka producer API.

### B. Model Training and Inference

Before model training, generated events were processed as part of the feature engineering step to extract relevant features for our context. Below are key features used to train the model:

- User\_id
- Account
- Login\_attempts\_count

- Last\_login\_timestamp
- Last\_transaction\_amount
- Beneficiary\_account
- Transactions\_sum
- Transaction\_to\_max
- Device\_id
- Device\_id\_last\_timestamp
- Device\_id\_bill\_payment

Once the features were extracted, the model was trained on the provisioned cluster using h2O integrated with an Apache Spark job. The integration was done using the Sparkling water package, which was installed and used afterward to create an h2OContext employed to train our model in a distributed way. In our model training, we sought to optimize isolation forest hyperparameters such as the number of trees and tree depth that would allow us to detect all the fraudulent transactions while minimizing false positives. During our training, we reached an optimal performance with values of 200 as the number of trees and 18 as tree depth. The performance of our model with these parameters is exposed through classification metrics in the section below.

### C. Experimental Criteria

During this work, we used our dataset partitioned into five sets to train the isolation forest. While the training set is made up of 80% of the data.

The experiment outcomes are assessed using accuracy, the F1-S, precision, and recall, as specified in Table IV. The Accuracy metric represents the overall performance of fraud detection. Precision is another word for a predictive value that is positive. A true positive rate is identical to the recall. The harmonious mean of (recall - accuracy) is the "F1-score". The (True Positive i.e. TP) alludes to the amount of accurately anticipated suspicious transactions within all right suspect transactions, false positive (i.e. FP) alludes to the total of regular transactions that are wrongly identified as suspicious, (TN i.e. true negative) relates to several precisely indicated normal actions for all right regular operations, and false negative i.e. FN refers to the amount of suspicious transactions that are erroneously marked as regular ones.

TABLE IV. EVALUATIONS METRICS

Performance metrics	Formulas
Precision:	$\frac{TP}{TP + FP}$ (3)
Recall:	$\frac{TP}{(TP + FN)}$ (4)
Accuracy:	$\frac{((TP + TN))}{(TP + TN + FP + FN)}$ (5)
F1 score:	$2 \times \frac{(\text{precision} \times \text{recall})}{(\text{precision} + \text{recall})}$ (6)

The ROC curve is accompanied by a graphical display that compares the TP to the FP at several criteria. We additionally employ the AUC i.e., area under the ROC curve alongside the abovementioned measurements as a comprehensive performance measure. Since it does not depend on a criterion

value, the AUC is considered a superior performance metric to accuracy. The nearer the AUC number is to one, the finer a model's overall efficiency.

#### D. Experimental Results

Utilizing our private dataset, we experimented with the isolation forest using Python and a sparkling water engine. The output model was packaged and integrated with Spark Streaming through Sparkling Water to perform fraud detection in real-time as per previously exposed architecture. Table V and Table VI summarize the obtained results after completing the training iteration.

TABLE V. TRAINING ITERATIONS

	Events	transactions	Labeled Fraud attempts
Iteration 1	20000000	187234	151
Iteration 2	20000000	234567	213
Iteration 3	20000000	198654	195
Iteration 4	20000000	272647	286
Iteration 5	20000000	324546	323

The Table VI presents the mean of critical metrics after training the model against the above mentioned dataset.

TABLE VI. MODEL METRICS

Metrics	Accuracy	Precision	Recall	F1-score
	0,99	0,87	0,97	0,91

#### VII. DISCUSSION

We discussed the procedures needed to set up an online transaction fraud detection architecture in real-time utilizing Spark, Kafka, and h2O in this article. After that, the experimentation kit was utilized to build an isolation forest-based machine-learning model. The system was able to expedite its analysis by combining real-time and batch-time analysis, yielding promising results. We also looked at the efficacy of the isolation forest model. Our model's performance has been evaluated using four distinct metrics such as accuracy, recall, f1-score, and precision.

On top of that, we compare the outcomes of the presented study's work to the current fraud detection techniques. As an example [32] have employed the SVM, apriori algorithm, and SVMIG (i.e SVM with Information Gain) to handle transactional fraud detection. The outcomes give an accuracy of 0.94. Authors of [33] have applied six ML learners involving LR, XGBoost, DT, SVM, ET (Extra Tree), and the RF on the European cardholder database. These learners were integrated with AdaBoost to boost their performance of fraud classification. The experiments yield more than 98% of accuracy.

Along with that, [34] have suggested a hybrid model named AED-LGB (AE with probabilistic LGBM) to detect fraudulent transactions using real word transactional dataset. Experimental evaluation shown around 0.98 of accuracy. Also, [35] have utilized the Naïve Bayes Based classifier for transaction fraud detection on a credit card dataset. They have compared the proposed model with the state-of-the-art ML methods. The finding reveals that the NB beat the others with an accuracy of 0.97.

In line with the findings in the present article and the findings in current state-of-the-art systems for detecting fraud this study provides a high digital transaction fraud detection accuracy (0.99) using relevant big data analysis tools to speed up model analysis and training and also to detect suspects' transactions as soon as they arise. In contrast to the research published in [32], [33], [34], and [35].

#### VIII. CONCLUSION AND FUTURE WORK

Fraud screening is critical in digital transactions, and the most significant difficulty is the financial burden of fraud if it is investigated, detected, or prevented. As though transactions happen in real-time, there is a need for a method that takes no time and remains as effective as the scope and structure of the bank that handles it. In this study, we presented an end-to-end real-time architecture using behavioral analysis for digital transactions fraud detection centered on combining the isolation forest algorithm and current big data analytics technologies. This technique aims to regulate latency, speed, and reliability by employing batch processing to give complete and precise interpretations of batch sets alongside immediate stream analysis to provide observations of live data. In our scenario, the batch layer handles data preparation and model training providing effective outcomes on a real dataset. The F1-score and recall of our model is about 91% and 97% correspondingly.

We want to do more study in two areas in the further works. The first looks at the computing requirements of a real-time suspicion detection technology. The second goal is to investigate the use of increasingly sophisticated ML techniques and the combination of DL (deep learning) algorithms and relevant big data tools in fraud detection.

**Abstract**—The objective of this work is to use a novel soft computing approach to predict the anti-inflammatory effect of bio copper nanoparticles. Using a modified technique, various doses of the *Musa sapientum* extract and copper nanoparticles were examined for their anti-inflammatory capabilities. Protein denaturation was evaluated, and an inhibition percentage was computed. The outcomes demonstrated that the quantity of copper nanoparticles raised the inhibition percentage, indicating a greater anti-inflammatory efficacy. In order to forecast the anti-inflammatory action based on the input variables of contact duration, operating temperature, and beginning concentration, an artificial neural network (ANN) was created. Using experimental data, the ANN model was developed, tested, and its performance assessed. The outcomes showed that the ANN model has a high degree of accuracy in predicting the anti-inflammatory action. In the context of summary, copper nanoparticles produced by *Musa sapientum* show considerable anti-inflammatory action. The ANN model and the suggested soft computing technique, which included the creation of copper nanoparticles, made an accurate prediction of the anti-inflammatory capabilities. This study aids in creating new methods for estimating the efficacy of bioactive nanoparticles in diverse therapeutic uses, such as the treatment of inflammation.

**Keywords**—Copper; nanoparticles; green synthesis; prediction; artificial neural network

## I. INTRODUCTION

Humans regularly come into contact with natural goods through the foods they eat and the herbal supplements they take. It is challenging to easily determine bioactive natural compounds in complex combinations like plant extracts, which contributes to the slow rate of their discovery [1]. The body's natural protection against damage, infection, or stimulation is fundamentally the inflammation responses, which support tissue homeostasis in hostile settings [2]. Acute and chronic inflammation, are the two main categories used to

classify inflammation. An Acute inflammation is a type of innate immune response, but chronic inflammation lasts a extended time and leads to numerous debilitating chronic illnesses, including cancer, autoimmune conditions, cardiovascular disease, also neurological diseases. Thus according to statistics, chronic inflammatory illnesses cause three out of every five deaths worldwide [3]. The production and release of chemical mediators by the cells in the sick, damaged, or injured tissue serve as the catalyst for the inflammatory response. White blood cells also called leukocytes are used at the site of inflammation as just a consequence of additional signals produced by inflamed tissues. Any infectious or toxic agent is destroyed by leukocytes, which also remove cellular waste from injured tissue. This inflammatory response typically promotes the healing process. An unchecked inflammatory reaction, however, could be harmful [4].

One aspect of the body's immunological reaction is inflammation. An inflammatory response is responsible for infections, healing wounds, and any tissue injury. Inflammation is the outcome of numerous defensive system feedbacks in reaction to physical harm or illness. Acute inflammation develops quickly and becomes serious in a short period of while. Its symptoms linger for just a few times although, in some cases, they might persist for several weeks. Acute inflammation is frequently accompanied by swelling, redness, discomfort, immobility, and heat. Acute bronchitis, abrasions or cuts on the skin, sore throat from the flu or even cold, afflicted ingrown toenails, acute appendicitis, dermatitis, tonsillitis, sinusitis, high-intensity workout, infectious meningitis, and physical trauma are a few circumstances and diseases that can result in acute inflammation. Chronic inflammation seems to be a continuous state of tissue injury, active inflammation, and repair that lasts for a long time (months and or years). The harshness and consequences of chronic inflammation characteristically depend on the cause of

damage and then how well the body is able to repair and manage the damage. Common signs of chronic inflammation include body aches, fevers, rashes, weight increase or loss, weariness, joint discomfort, and mouth sores. Certain diseases, including diabetes, cancer, cardiovascular conditions, (COPD), rheumatoid arthritis, hepatitis, allergies, Tuberculosis, periodontitis, asthma, and also chronic peptic ulcer, might progress as a result of chronic inflammation [5]. Inflammation was therefore initially described by a collection of clinical symptoms rather than by a particular mechanism. Human disorders that exhibit the five traditional inflammatory symptoms of redness, pain, swelling, heat, and consequent decrease of organ function are caused by inflammation established in Fig. 1 [6].

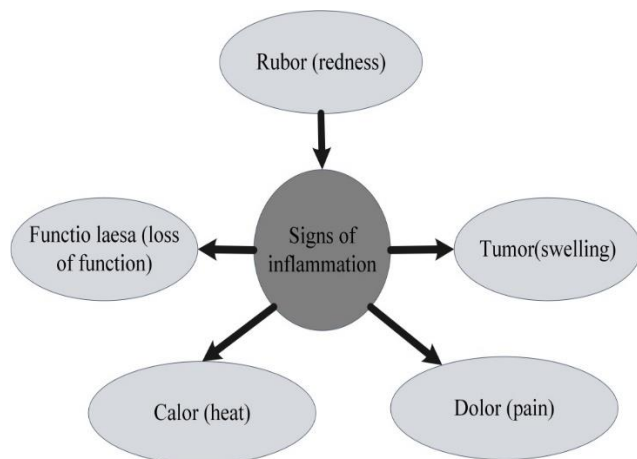

Fig. 1. Signs of inflammation.

Employing nanotechnology in the area of drug administration is a cutting-edge method to deliver medications on the Nano scale to particular organs in a regulated manner to enhance their therapeutic efficacy and minimize negative effects [7]. Among the most active fields of research right now in the fields of materials science, biomedicine, and healthcare is nanotechnology [8]. Metallic nanoparticles seem to be versatile and have stayed utilized in a wide range of industries, therapeutic, as well as medical application, such as wastewater treatment, drug delivery, cancer treatment, and DNA investigation, as well as for antibacterial agents, biosensors, and solar energy generation. It has been claimed that an economical and environmentally responsible alternative to both physical and chemical processes is the green production of metallic nanoparticles. Due to potential uses in business and medicine, copper nanoparticles (CuNPs) have caught the interest of researchers recently. The most efficient method has been determined to involve the biosynthesis of metal oxide nanomaterial's using various plant extracts, including such leaves, stems, cores, and flowers. Numerous phytochemicals found in plant extracts function as stabilizers and retarders of metal oxide nanoparticles. Additionally, the creation of nanoparticles utilizing phytochemical substances is safe for the environment, cheap, straightforward, and may be done at ambient temperature [9]. Additionally, it will aid in reducing the effects of environmental harm brought on by artificial techniques and materials [10].

Nano emulsion, nanoparticles, liposomes, niosomes, and other Nano carriers all have been designed to hold various medications and are meant to deliver them to particular tissues [11]. One of the Nano carriers that facilitate targeting, the delivery, and the controlled release of medications is thought to be niosomes. Niosomes also play an important role in the delivery of naturally occurring medicinal compounds, improving both their physical stability and effectiveness. They are mostly self-assembled bilayer vesicles made of non-ionic surfactants and cholesterol. It has the advantage of encasing and delivering medications that are both hydrophilic as well as hydrophobic. It might be administered via a number of delivery methods, such as parenteral, topical, and oral [12]. Metallic nanoparticles are multifunctional and are utilized in a widespread range of applications in science and medicine, involving cancer treatment, drug distribution, wastewater remediation, and DNA analysis. Metallic nanoparticles have newly generated a lot of attention due to their distinctive physical as well as chemical characteristics. Alternatives to chemical and physical processes that are both affordable and environmentally benign include the synthesis and depiction of metallic nanoparticles. Copper Nanoparticles (CuNPs) have received a lot of interest recently from researchers due to their numerous uses in medicine, industries, and other sectors [13].

Due to the existence of numerous bioactive chemicals in plants, numerous plant parts or entire plants have been employed for the green production of Cu NPs. Plant extracts were being used successfully for this purpose [4]. Cu Nanoparticles have successfully synthesized utilizing extracts from a variability of plant species, including *Musa sapientum* stem extract. Bananas (Genus *Musa*) have indeed been cultivated for a very long period [5]. Pharmacological research demonstrates the nutritional as well as traditional medicinal benefits of all banana parts. Numerous animal model studies, vitro experiments, and clinical studies also support the utilization of various banana portions in the treatment of a variety of illnesses, including cancer, ulcers, diabetes, hypertension, and diarrhoea [14].

The methods utilized to create them and characterize them are constantly being refined. As nanoparticles to be used in a variety of industries, controlling over their shape and size is crucial. Furthermore, because of their large surface energy, these nanomaterials are very unbalanced and aggregate to form raw material. As a result, several stabilizing agents such as surfactants, block copolymers, dendrimers, and microgels are used to stabilize metallic nanoparticles. The hybridization microgels, which include metallic nanoparticles, combine the characteristics of nanomaterials with polymeric microgels. Metallic nanoparticle-loaded hybrid microgels offer application promise in optics, biomedicine, photonics, electronics, and catalysis. Dynamic light scattering (DLS), Scanning electron microscopy, Transmission electron microscopy (TEM), atomic force microscopy, X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), and ultraviolet visible spectroscopy (UV/Vis) are used to identify hybridized microgels. Since every approach is intended to collect a particular type of data that can't be gained using the other, it is difficult to evaluate one approach to

another because each has its own merits and drawbacks. Among some of the techniques described above, UV/Vis spectroscopy is just one approach that may be utilized to examine the dynamics of bulge as well as deswelling of polymeric microgels as well as hybrid microgels with tiny size of particles. Assessment of hybridized microgels loaded with Plasmonic nanoparticles and research into their usage often includes the use of UV/VIS spectroscopy. According to reports, it is a useful instrument for analyzing and adjusting the optical characteristics of Plasmonic nanoparticles put into polymeric microgels. UV/Vis spectroscopic is another method that may be used to study the catalytic performance of nanomaterials [15].

A quick analytic method for determining light's absorption or transmission is UV-visible spectroscopic. The majority of spectrometers have a functional range of wavelength among 200nm and 1100nm, despite the fact that the visual portion extends up to 800 nm and the UV frequency varies from 100nm to 380nm. Due to the vacuous nature of UV-vis lighting in the spectral area from 100 nm to 200 nm, which is regarded as infrared light exceeding 800 nm, it is of little practical value. The capacity of a substance to gather and emit photons determines its colour, and the human visual system is capable of distinguishing between up to 10 million distinct colours. Transmission is the process by which light travels via medium, reflecting off both transparency and impenetrable surfaces, and is bent by crystalline [16].

The more popular method for tackling this kind of issue is the artificial neural network, essentially mimics the human brain when addressing a problem. As a result, scientists are endeavouring to create an adaptive framework, such as an artificial neural network, to forecast the temperature depended on the results of many elements. Artificial intelligence (AI) is used in artificial neural networks (ANNs). An arithmetic model called an ANN is enthused by the structure and or functionality of neural networks in biology. A neural network utilizes a connectionist style of calculation to interpret the data and consists of a connected group of artificial neurons. Generally speaking, an Artificial Neural Network is a outstanding performance that changes its structure in requital to information passing and through the network even during the learning experience, whether that information is either internal or external. Modern tools for modelling non-linear numerical data comprise neural networks. They are characteristically applied to recognize patterns in data and otherwise model complex associations between inputs and outcomes. ANN has been effectively utilized in a wide range of applications. An artificial neural network (ANN) is a computational system that takes its cues from the biological neural networks that perform actions in the human brain. Neural networks have the ability to "learn" and correlate huge datasets gleaned from simulations or experimentation. The developed neural network is used as an evaluation method to make accurate predictions about the outcomes. They can produce excellent prediction accuracy ratings thanks to effective approaches for both validation and training [17]. The proposed work focuses on the comparison between the experimental and numerical data indicates a close agreement, with the numerical values closely matching the experimental

values. This suggests that the soft computing methodology, specifically the Artificial Neural Networks (ANNs) used in this study, effectively predicts the anti-inflammatory activity of CuNPs. The alignment between the experimental and numerical results validates the reliability and accuracy of the soft computing approach in predicting bioactive properties, contributing to its relevance in drug discovery.

The primary contributions using required establishing the study are as follows:

- The extract is made from *Musa Sapientum* powder.
- Using the extract, it was previously created, Cu nanoparticles are created.
- Cu nanoparticles were characterised using UV-visible spectroscopy in step three.
- Anti-inflammatory is discovered through calculation of inhibition.
- The effectiveness of the suggested methodology is proven by validating its function and evaluating it against alternative approaches.

This report's remaining sections are organized as follows: Section II presents the relevant works and provides a comprehensive analysis of them. Information on the problem statement is included in Section III. In Section IV, the proposed soft computing Artificial Neural Network topologies are thoroughly examined. The results of the experiment are given, examined, and thoroughly analysed in Section V, along with comparisons to current best practises. Discussion is given in Section VI. The conclusion of the paper is found in Section VII.

## II. RELATED WORKS

Metabolomics evaluation of the chosen sponge would be followed by molecular docking research to discover and expect the subordinate metabolites that capacity contributes to its capacity of constraining cancer. This investigation will look at the anti-inflammatory as well as anti-cancer possibility of the Red Sea sponges having own mass and silver nanostructure. Silver nanoparticles made from the Red Sea sponge *Phyllospongia lamellosa* are extracted using chloroform (CE) and ethyl acetate (EE). UV-visible spectrophotometric, Transmission electron microscopy, and Fourier-transform infrared spectroscopy (FTIR) studies were used to evaluate the produced silver nanoparticles. Cells from the MCF-7, MDB-231, and MCF-10A tumour types were used to test the compounds' anti-cancer properties. COX-1 and COX-2 anti-inflammatory activity was evaluated. Molecular docking as well as metabolomics examines constructed on liquid chromatography-mass spectrometry (LC-MS) also were employed. To determine whether such a formulation is applicable as an anti-cancer therapeutic agent in the study, further separation and decontamination of the active ingredients from the sample crude extract of the sponge are required, and in vivo tests are needed in the study [18].

The research used a dependable and ecologically friendly method to create silver nanoparticles from leaf extract of *Brachychiton populneus* (BP-AgNPs) in an aqueous solution.

FTIR, energy dispersive X-ray analysis, scanning electron microscopy, and UV-Vis spectroscopy were utilized to analyse the silver nanoparticles generated from the *Brachychiton populneus* (EDX). Ag Nanoparticles' antioxidant, ant diabetic, anti-inflammatory, and cytotoxic properties were also revealed. By using a UV-Visible spectrum, the creation of BP-Ag Nanoparticles was confirmed at 453 nm. According to the FTIR study, functional groups including such as nitro, alkane, phenol, alkene, alcohol, fluoro, and flavones that are contained in plant extract are responsible for the stability, synthesis, and capping of Ag Nanoparticles. Nanoparticles with a cubical shape were evenly dispersed, according to the SEM examination. Ag Nanoparticles had an average diameter of 12 nm, as determined from SEM images using ImageJ software. Silver at 3 keV and also additional trace elements including oxygen and also chlorine were confirmed by the EDX spectrum. In compared to conventional pharmaceuticals, the biologically synthesized silver nanoparticles showed demonstrated ant diabetic (alpha amylase assay), antioxidant (DPPH assay), cytotoxic (MTT assay) and anti-inflammatory (albumin denaturation assay), properties against U87 and HEK293 cell lines. BP-AgNPs have shown inhibition in these assays in a concentration reliant on way and had minor IC50 values than standards. These findings all point to the potential biological benefits of silver nanoparticles. The key characteristics of silver nanoparticles biologically synthesized suggest potential uses for them in the biomedical field. Additionally, the production of silver nanoparticles by plant-mediated processes uses less energy, is advantageous to living things, generates little waste, and is environmentally friendly [19].

In order to encapsulate diosmin as well as address its physicochemical problems, nanostructured lipid carriers (NLCs) suitable for ocular deliver optimized were optimised using the response surface methodology (RSM). A straightforward and scalable process was used to create NLCs: melt emulsification, accompanied by ultra-sonication. Four different independent variables comprised the research designs (liquid lipid concentration, surfactant concentration, solid lipid concentration, and kind of solid lipid). By using a variance analysis of variance, the factors' impact on the NLC size and PDI (responses) was evaluated (ANOVA). The desirability function was used to choose the optimal formulation (0.993). Diosmin was incorporated into NLCs at two distinct concentrations (80 as well as 160 M). A physical and chemical and technical investigation of drug-loaded nanocarriers (D-NLCs) revealed mean particle sizes of 83.5 nm as well as 82.21 nm for formulations made with diosmin at concentrations of 80.0 mM otherwise 160 mM, respectively, and a net negative surface charge of 18.5 nm and 18.0 nm, respectively, for the two batches. The constructions were examined for viscosity, pH (6.5), and osmolarity adjustments to make them more ocular environment friendly. Stability experiments were subsequently conducted to evaluate D-NLC behaviour beneath various storing circumstances for up to 60 days, revealing that NLC samples are well-stabilized at room temperature. NLCs are cytocompatible with retinal epithelium, according to in-vitro research on ARPE-19 cells. D-NLCs were also tested in-vitro for their impact on a framework of retinal inflammation, confirming their cytoprotective

properties at different doses. It was discovered that RSM is a trustworthy model for enhancing NLCs for diosmin encapsulation. Additional research is being conducted to evaluate and verify the anti-inflammatory efficacy of D-NLCs in order to achieve this goal. Furthermore, the antioxidant activity of loaded NLCs is not assessed because the improved manufacture of reactive oxygen species (ROS) represents a different feature of ocular degenerative disorders [20].

The Se Nanoparticles were examined for physicochemical characteristics and also anti-inflammatory activity in vivo in the research. *Kluyveromyces lactis* GG799 (*K. lactis* GG799) was used to synthesize SeNPs in a sustainable and environmentally, effective, and inexpensive manner. Sodium selenite was successfully converted by *K. lactis* GG799 producing bright red Se Nanoparticles with particle diameters between 80 as well as 150 nm, and the nanoparticles were collected inside the cells. Following isolation, component findings indicate that the SeNPs were primarily capped by protein and polysaccharides. By reducing oxidative stress as well as intestinal inflammation, dietetic supplementation containing 0.6 mg kg<sup>-1</sup> Selenium (in the procedure of biogenic SeNPs) significantly reduced dextran sulphate sodium (Would seem ulcerative colitis. These results indicated that Se Nanoparticles produced by *K. lactis* GG799 might represent a auspicious and secure Selenium supplement again for the management of IBD. However, to improve preventive and therapeutic properties and lessen the negative consequences, high bioactivity nanoparticles and low toxicity, are still required [21].

The extracts as of several edible portions of *Parkia Timoriana* exhibited considerable 2, 2 diphenyl 1 picrylhydrazyl (DPPH), 2,2' azino bis (3 ethylbenzothiazoline 6 sulfonic acid (ABTS), as well as Phosphomolybdate rummaging action in line with high antioxidant aptitudes. *P. timoriana* extract significantly decreased the growth of *Escherichia coli*, *Bacillus subtilis*, *Bacillus pumilus*, as well as *Pseudomonas aeruginosa*. The functional groups, as well as bioactive chemicals found in the various edible sections of the plant were identified by analysis of the extracts utilizing gas chromatography mass-mass spectrometry (GC-MS) and then Fourier transform infrared spectroscopy. Phenols, alkenes, carboxylic acids, glycogen, aliphatic amines, alkyl halides, primary amines, secondary amines, ether, esters, lipids, aromatics, halogen, nitro compounds, triglycerides, with anti-cancer, antimicrobial, as well as anti-inflammatory characteristics, among other substances, showed characteristic peaks. Additionally, 49 bioactive chemicals that are recognized to have a range of pharmacological actions were found by the GC-MS study. The found bioactive compounds were then subjected to and in silico molecular docking investigations, which suggested potential anti-inflammatory as well as anticancer activities. This is, as far as we are aware, the first publication on the bioactive components of *P. timoriana* extracts that have significant pharmacological, antibacterial, and antioxidant belongings. The research may result in the growth of new herbal treatments for a variety of disorders using *P. timoriana*, as well as maybe new drugs. Formulations are not examined, despite the fact that their

bioactivity as well as clinical studies are essential for the creation of novel medications [22].

Many substances, including phenolic compounds, flavones, flavanones, triterpenoid acids, chalcones, sugars, and fatty acids, amongst many others, have really been extracted from the *Eysenhardtia platycarpa* plant. In the study, computational screening for anti-inflammatory action was conducted using Molinspiration® as well as PASS Online on natural flavanone 1 (retrieved from *Eysenhardtia platycarpa*) as the main chemical as well as flavanones 1a–1d by way of its structural counterparts. Utilizing two investigational designs, a rat ear edoema caused by arachidonic acid and even a mouse ear lobe edoema caused by 12-O-tetradecanoylphorbol acetate, the hydroalcoholic solutions of flavanones 1, 1a-1d (FS1, FS1a-FS1d) also were assayed to evaluate their *in vivo* anti-inflammatory cutaneous impact. TNF-, IL-1, and IL-6 pro-inflammatory cytokines too were analyzed histologically in rat ear tissue that had been irritated by AA. The outcomes demonstrated that edoema inhibition was brought about by the solutions of flavanone hydro alcoholic in both tested mice. According to this study, the evaluated flavanones would be useful in the treatment of inflammatory skin disorders in the coming [23].

Antiviral and anti-inflammatory drugs may therefore be essential in the treatment of COVID-19 patients. *Pimenta dioica* leaves contains ethyl acetate extract, four bioactive substances were extracted and recognized using spectroscopic data: gallic acid 3, ferulic acid 1, rutin 2, as well as chlorogenic acid 4. Additionally, as a possible mechanism of action, molecular docking but also dynamics calculations for the separated and revealed compounds (1-4) in contradiction of SARS-CoV-2 major protease (Mpro) were carried out. Additionally, the half-maximal cytotoxicity (CC50) and SARSCoV-2 inhibitory doses of each substance were evaluated (IC50). The consequences of cure with *P. dioica* aqueous extract, gallic acid 3, ferulic acid 1, rutin 2, and chlorogenic acid 4 were observed by measurement of TNF-, IL-1, G-CSF, IL-2, IL-10, and gene function of miRNA 21-3P as well as miRNA-155 stages to evaluate the anti-inflammatory impacts crucial for COVID-19 affected ones. Likewise, lung toxic effects were stimulated in rats by mercuric chloride. Promising anti-SARS-CoV-2 properties were demonstrated by gallic acid 3, rutin 2, and chlorogenic acid 4, with IC50 ideals of 31 g/mL, 108 g/mL, and then 360 g/mL, correspondingly. Additionally, ferulic acid 1 as well as rutin 2 conducts was found to have stronger anti-inflammatory impacts. The outcomes could be encouraging for further preclinical and also clinical research, particularly on rutin 2 individually or in conjunction with the other separates for the treatment of COVID-19. These substances have not been studied separately or in conjunction with other organic or synthetic items as natural products [24].

The primary protein found in quinoa seeds, chenopodin, is described in this research for the first time in terms of its possible immunomodulatory properties. The study was capable of distinguishing two distinct types of chenopodin, denoted as LcC (Lower charge Chenopodin, and 30% of entire chenopodin) and HcC (Higher charge Chenopodin, and 70% of entire chenopodin), following analyze the molecular

characteristics of the pure protein. By assessing NF-B activity and IL-8 appearance investigations in undistinguishable Caco-2 cells, the biological functions of LcC and HcC were examined. IL-1 was used to induce inflammatory. According to the findings, LcC and HcC may have anti-inflammatory properties in an intestine typical system, and their actions may vary based on their physical structure. Additionally, *in silico* analysis and structurally estimations were used to look into the molecular action mechanisms and the structural or functional connections of the protein responsible for the identified bioactive components. This approach is ineffective because it does not usually preserve the relationship between transcript and protein levels. In fact, even a little change in transcriptional rates might have a significant impact on how much protein is produced [25].

To create extraction with a high concentration of polyphenols, two tomato pomace (TP) feedstocks were investigated. Biomass security is compromised by TPs rapid disintegration, therefore occurs naturally microflora was examined for preservation, and after 60 days of the treatment, own lactic bacterium predominated. Chemical characteristics of the extraction of TPs and TPs fermentation (TPF) and tests for anti-inflammatory and antioxidant activity were performed. A most bioactive polyphenol component, aglycone-polyphenols (A-PP), was used to categories phenolic and flavonoids acids. The quantity of A-PP was reduced by fermenting; however, the composition remained mostly same. Regardless of the decrease in A-PP, the existence of fermented metabolites with aromatic substitutes boosted antioxidant capacity. All TP and TPF possess anti-inflammatory qualities, which are solely reliant on the A-PP concentration. The Partial Least Square (PLS) method revealed greatest active compounds as kaempferol, naringenin chalcone, cinnamic acid as well as gallic acid along with description of the effective dosage, and fermenting kept the anti-inflammatory action. This attribute will recommend the use of the extraction for additional use as supplemental components or additional components in the nutraceutical, cosmetic, and bioactive compounds sectors, along with the good security aspect of the fermenting biomass. This method is ineffective since, in certain circumstances, high-dose antioxidant supplementation may be associated with health concern [26].

### III. PROBLEM STATEMENT

The complexity of extracts, isolation of phytoconstituents with the highest levels of purity, and the poorest yield of active phytoconstituents from plants are all barriers to the detection and growth of drugs from natural sources. Despite the difficulties in developing drugs from phytoconstituents, plants make attractive targets for the search for fresh anti-inflammatory leads. The main difficulties in developing new drugs are finding novel compounds with appropriate activity and pharmacokinetic characteristics. More chiral centres, steric complexity, more oxygen atoms, molecular stiffness, and more hydrogen bond donors as well as acceptors are only a few of the distinctive characteristics of the phytoconstituents. The investigation focuses on *Musa sapientum*'s anti-inflammatory properties in copper nanoparticles with Artificial Neural Network. Numerous studies have found that using *Musa sapientum*, particularly the

peels because of their potent anti-inflammatory and antibacterial properties, produces the best outcomes but here a soft computing approach like Artificial Neural Network is utilizing for predicting anti-inflammatory activity [27].

#### IV. MATERIALS AND APPROACHES

##### A. Extract Preparation

The powder of *Musa sapientum* was weighed and measured to be 1g. Following the measurement of the powdered sample, 100ml of distilled water was added to the sample and the mixture then was then boiled for about 5 to 10 minutes at a temperature of 60–80 degrees Celsius. After cooling down, filtration was performed. Filter paper, a funnel, and a measuring cylinder were used to filter the mixture's contents. The resultant filtrate was viscous.

##### B. Synthesis of *Musa Sapientum* Mediated Cu Nanoparticles

CuSO<sub>4</sub> in the amount of 0.01 mg was approximately weighed, and dissolved in 8 ml of distilled water, and then combined with the filtered extract. To produce green synthesis, the extract is retained in the shaker and allowed to sit in the stirrer for a period of one hour. An ultraviolet (UV) spectrometer was used to periodically check on the conversion of CuSO<sub>4</sub> to Cu Nanoparticles.

##### C. UV-Visible Spectra Examination

UV-Visible spectroscopy was utilised to track the Cu Nanoparticles' signature. For the characterization of colloidal particles, this is a useful force. Metal particles display substantial surface plasmon resonance (SPR) absorption in the visible range and are extremely sensitive to surface change, making them excellent candidates for research with UV-Visible spectroscopy. Surface Plasmon Resonance property confirmed the existence of Cu Nanoparticles.

##### D. Anti-Inflammatory Activity

The following procedure, which was modified somewhat from Muzushima and Kabayashi's original suggestion, was utilized to test the anti-inflammatory possessions of *musa sapientum*. In order to adjust the pH level of the mixture to 6.3, a small amount of 1N hydrochloric acid was used in combination with 0.45 mL of bovine serum albumin (1% aqueous solution) and also 0.05 mL of *musa sapientum* extract of differed fixation (10µL, 20µL, 30µL, 40µL, and 50µL). These samples underwent a 20-minute period of room temperature incubation followed by a 30-minute period of heating at 55 °C of temperature in a water bath. After cooling the prepared samples and the absorbance at 660 nm was calculated spectrophotometrically. The benchmark was Diclofenac sodium. As a control, Dimethyl Sulfoxide (DMSO) is used. The following Eq. (1) was used to calculate the percentage of protein denaturation.

$$\text{Inhibition \%} = \frac{\text{Absorbance of control} - \text{Absorbance of sample}}{\text{Absorbance of control}} \times 100 \quad (1)$$

##### E. Soft Computing Approach

Soft computing approaches, such as Artificial Neural Networks (ANNs), offer distinct advantages and relevance compared to existing methods in various fields, including drug

discovery and prediction of bioactive properties. Unlike traditional computational techniques that rely on explicit mathematical models and assumptions. One key advantage of soft computing approaches is their ability to learn from data and adapt to changing conditions. ANNs, for example, can be trained using large datasets to capture intricate patterns and correlations, enabling them to make accurate predictions and classifications. This adaptability makes soft computing approaches well-suited for handling diverse and dynamic datasets, especially when dealing with complex molecular structures and interactions in drug discovery. Soft computing approaches can effectively handle incomplete or noisy data, which is common in biological and chemical systems. By employing robust algorithms and learning mechanisms, ANNs can tolerate missing or uncertain data points, providing reliable predictions even in the presence of such imperfections. This flexibility allows researchers to work with real-world datasets that may be incomplete or contain measurement errors, enhancing the applicability and reliability of the predictions. The relevance of soft computing approaches lies in their ability to handle complexity, adaptability to dynamic datasets, robustness to noise and incomplete data, and capability to model nonlinear relationships. These characteristics make them powerful tools in the prediction and analysis of bioactive properties, facilitating the discovery of potential drug candidates and enhancing our understanding of complex biological systems.

##### F. Artificial Neural Network

A variety of applications have successfully used ANN is established in Fig. 2. A computing system called an artificial neural network (ANN) is stimulated by the biological neural networks in the human brain that carry out specific tasks. Huge datasets gathered from simulations or experiments can be "learned" by neural networks, which can also correlate these datasets. Using the created neural network as an evaluation tool, precise outcome predictions are made. Thanks to their efficient validation and training methods, they may generate great prediction accuracy ratings.

Fig. 2. Proposed artificial neural network.

1) *Data pre-processing*: The experimental results were modelled using a feed-forward back propagation training approach in an effort to forecast the effectiveness of Cu Nanoparticles on anti-inflammatory utilizing Artificial Neural Network. One S variable at a time formed the foundation of the experimentation in this study. This was accomplished by varying just one input factor while holding the other two variables constant. Experimental cases were created in the work using the outcomes of experiments. The testing and training sets of the dataset were split randomly. The remaining data were used for testing, and the rest for training. Eq. (2) was used to normalize the training and testing datasets in order to reduce error.

$$A_i = \frac{y_i - y_{\min}}{y_{\max} - y_{\min}} \times (s_{\max} - s_{\min}) + s_{\min} \quad (2)$$

The variable  $y_i$  stands in for the input or output in (2).  $y_{\min}$  and  $y_{\max}$  are the extreme values of  $y_i$ , while  $A_i$  is the normalised value of  $y_i$ . The range limits to which our  $y_i$  is scaled are  $s_{\min}$  and  $s_{\max}$ . The input and also output data in this study were normalised among 0 and 1. After modelling, results were restored to their original value. A three-layer Artificial Neural Network was used to simulate the experimental dataset.

2) *Creation of an artificial neural network model*: The usage of ANN [28] as a modelling tool is very common to approximate complicated systems that cannot be modelled using traditional modelling techniques. They are typically employed in classification, pattern recognition, as well as function approximation. To choose the artificial neural

network (ANN) and training procedure for a specific task, no precise formula has been discovered. Trial and error is used to determine the framework and method to apply while tackling a certain problem. However, this choice could begin with a modest network construction before moving on to a complicated one up until a satisfactory solution is found with a permissible smallest fault. There are numerous network designs used in ANN modelling. The fundamental design that uses a back propagation training technique to train input data is the feed-forward neural network. The framework may vary depending on the counting of layers in the architecture, the number of neurons in every layer, and then the allocation functions at the layer of input as well as output.

A three-layer ANN was used in the study, with the input layer (autonomous variable) including 3 neurons that is contact time, operating temperature, as well as initial concentration, a hidden layer containing 17 neurons, as well as an output layer (dependent variable) comprising 1 neuron. The output and hidden layers of the neural network were activated using both linear as well as non-linear activation functions according to the network structure. There were created experimental data instances. The training sub-dataset of 70% and then testing sub-dataset (30%) of the dataset were randomly separated. The efficiency of the constructed ANN models was evaluated. The powdered *Musa Sapientum* is used to create the extract. Cu nanoparticles are produced using the extract that we previously made. In step three, Cu materials were studied utilizing UV-visible spectroscopy. Calculating inhibition leads to the identification of anti-inflammatory. By confirming the function of the proposed methodology is demonstrated in Fig. 3.

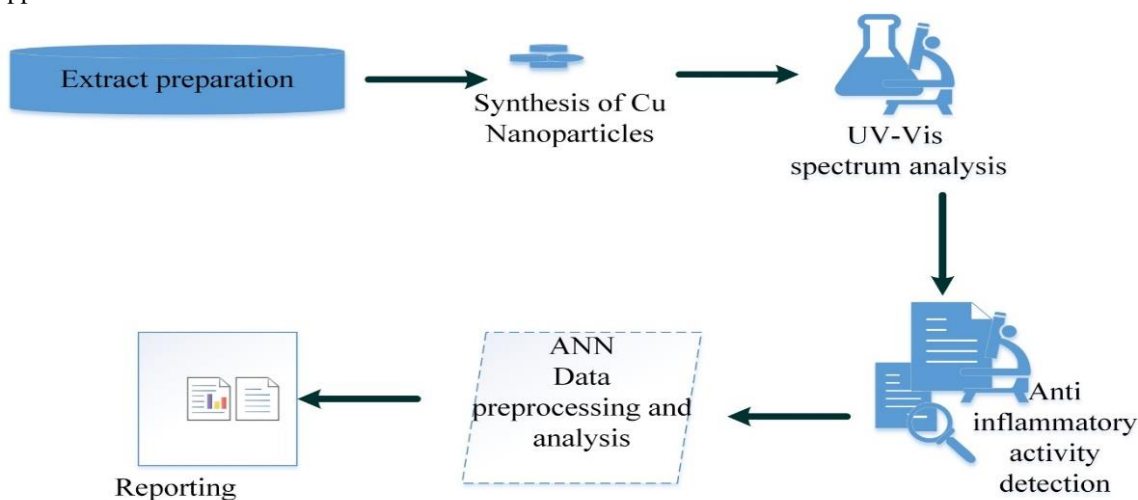

Fig. 3. Proposed ANN model for predicting anti-inflammatory activity.

## V. RESULTS

The purpose of the research was to determine whether *Musa Sapientum* and the copper nanoparticles that it was mediated by had anti-inflammatory properties. It made use of descriptive statistics. It has been determined that the inhibition percentage was reported to be 43.4% in 10  $\mu\text{L}$  concentration, 47.6% in 20  $\mu\text{L}$  concentration, 83.5% in 30  $\mu\text{L}$ , 85.5% in 40

$\mu\text{L}$ , and 85.9% in 50  $\mu\text{L}$  concentration. These results in a good anti-inflammatory activity were found from 10  $\mu\text{L}$  concentration to 50  $\mu\text{L}$  concentration in Table I and Fig. 4.

The standard value of the concentration at 10  $\mu\text{L}$  is 50.8%, 20  $\mu\text{L}$  is 57.8%, 30  $\mu\text{L}$  is 67.6%, 40  $\mu\text{L}$  is 77.9%, and 50  $\mu\text{L}$  is 89.6%; these values likewise gradually rise with concentration. The standard value of the concentrations is

compared with the Cu Nano particles inhibition % is tabularized in Table II and explained in Fig. 5.

TABLE I. INHIBITION PERCENTAGE FOR ANTI-INFLAMMATORY ACTIVITY

Concentration (μL)	Inhibition (%)
10	43.4
20	47.6
30	83.5
40	85.5
50	85.9

Fig. 4. Inhibition percentage for anti-inflammatory activity.

TABLE II. COMPARISON BETWEEN STANDARD AND CU NANOPARTICLE

Concentration (μL)	Inhibition (%)	
	standard	Cu Nanoparticles
10	50.9	43.4
20	57.9	47.6
30	67.7	83.5
40	78.0	85.5
50	89.7	85.9

Fig. 5. Comparison between standard and Cu Nanoparticle.

TABLE III. EXPERIMENTAL AND NUMERICAL DATA ANALYSIS WITH EXISTING EXPERIMENTS

Concentration (μL)	Incineration	
	Experimental Data (CuNPs)	Numerical Data
10	43.5	44.6
20	47.5	47.1
30	83.6	85.5
40	85.4	87.9
50	85.8	88.4

Table III presents the experimental and numerical data analysis for different concentrations of Cu nanoparticles (CuNPs). The table shows the inhibition percentage of CuNPs obtained through experimental incineration and numerical calculations. The comparison between the experimental and numerical data indicates a close agreement, with the numerical values closely matching the experimental values. This suggests that the soft computing methodology, specifically the Artificial Neural Networks (ANNs) used in this study, effectively predicts the anti-inflammatory activity of CuNPs. The alignment between the experimental and numerical results validates the reliability and accuracy of the soft computing approach in predicting bioactive properties, contributing to its relevance in drug discovery [29].

#### A. Detection of the Ideal Number of Hidden Neurons

The neural network technology's key parameter is the number of hidden neurons. Essentially, this is helpful in figuring out the ideal brain architecture. Using a trial-and-error methodology, 1 to 20 neurons were utilised in hidden layer to optimize the network structure. The effectiveness of every chosen number of neurons is detailed.

#### B. Performance Evaluation

The structure model's accuracy is a measure of how accurately it operates. Typically, it is determined by the ratio of successfully predicted measurements to all observable data. Accuracy is stated in Eq. (3).

$$Accuracy(\%) = \frac{T_{positive} + T_{negative}}{(T_{positive} + F_{positive} + F_{negative} + T_{negative})} \times 100 \quad (3)$$

Nevertheless, the inhibition process approaches equilibrium for inhibition% of 50 μL with 85.9%. 50 μL was deemed to be the ideal concentration has 96.34% accuracy for process in the Table with a high priority for inhibition %. The correlation between the experiment's results and the projected ANN accuracy results is shown in Fig. 6 and Table IV.

TABLE IV. ACCURACY OF PROPOSED ANN

Concentration (μL)	Inhibition (%)	Accuracy (%)
10	43.4	64.76
20	47.6	65.88
30	83.5	77.61
40	85.5	77.58
50	85.9	96.34

Fig. 6. Accuracy of proposed ANN.

## VI. DISCUSSION

Banana peel is a significant by-product of numerous small-scale and large-scale hospitality industries and functions as a sophisticated biological matter. Chemically, it is composed of simple cellulose, sugars, lignin, and hemicelluloses. It can serve as a suitable substrate for microbial operations to achieve products with value added because of its availability and worth. Numerous initiatives have been attempted to create protein-enriched animal feed, citric acid, industrial enzymes, and other commercially viable goods. It has been demonstrated that plantain bananas have anti-inflammatory and ulcer-healing properties. The medication made from plantain sources that helps ulcers heal may also have an impact on how wounds mend. For instance, plantain blossoms have been used to heal ulcers and diarrhoea, and extracts from the plant have antihyperglycemic properties. The peel has antibacterial, antifungal, and anti-denaturation effects. Banana leaf methanolic extract was claimed to have anti-inflammatory

and antibacterial properties in earlier research. The hemagglutininations as well as hydrogen peroxide-induced hemolysis of human red blood cells were inhibited by the banana extract. The anti-inflammatory properties of *Musa sapientum* and their connection to copper-mediated nanoparticles are shown in a bar graph. It is clear that copper-mediated nanoparticles have good anti-inflammatory effect because the virtually maximum percentage of inhibition (86%) was seen and 83.5% of that inhibition was detected in copper nanoparticles. Yet, with an inhibition percentage of 50 μL with 85.9%, the inhibition process gets closer to equilibrium. 50 μL was determined to have a 96.34% accuracy rate for the process and a vital element for inhibition percentage.

## VII. CONCLUSION

Cu Nanoparticles synthesised by *Musa sapientum* has significant biological processes, and the recognized biological technique is chosen over alternative ways because it is less harmful to the environment and calls for fewer downstream processing steps. Plant-based bio-resources are used in this cutting-edge, environmentally friendly approach as stabilizing and reducing agents. UV-Visual study indicates that Cu-NPs had formed. According to this study's findings, *Musa sapientum* has stronger anti-inflammatory effects when copper nanoparticles are included. This information can be used for further research into using them as reduced bio toxic substitutes for currently available chemically synthesized biomaterials. Numerous designed nanoparticles have been prepared and evaluated and finished the clinical studies in light of this. The healthy cells throughout the body are left behind as this infiltrate the unhealthy cells. As kind of a result of the aforementioned findings, it is clear that environmentally friendly copper nanoparticles could operate as a great biological activity agent and could also be efficiently and economically applied for numerous medicinal purposes. Future research issues have arisen as a result of how nanoparticle aggregation impacts biological activity by inhibiting their entrance inside bacterial cells in addition to how variations in manufacture, processing, and storage can cause oxidation and result in undesired forms. Based on specified inputs, the artificial neural network archetypal was provided to forecast the inhibition% of anti-inflammatory action. The model was evaluated, and the overall result for 50 μL was 96.34%. As a result, the ability of the artificial neural network to forecast inhibition percentage was examined with accuracy level of 96.34% for 50 μL. The proposed model also evaluated the Experimental and numerical data analysis for different concentrations of Cu. While the study's usage of Artificial Neural Networks (ANNs), a type of soft computing, has some intriguing benefits, the drawbacks that must be noted is the calibre and representativeness of the training dataset have a significant impact on ANN performance. Insufficient or skewed data might provide poor models and wrong forecasts. Therefore, efforts should be taken to guarantee that there are plenty and varied datasets available for the ANN model's training.

# Automatic Essay Scoring for Arabic Short Answer Questions using Text Mining Techniques

Maram Meccawy, Afnan Ali Bayazed, Bashayer Al-Abdullah, Hind Algamdi  
Information Systems Department, Faculty of Computing and Information Technology,  
King Abdulaziz University, Jeddah, Saudi Arabia

**Abstract**—Automated Essay Scoring (AES) systems involve using a specially designed computing program to mark students' essays. It is a form of online assessment supported by natural language processing (NLP). These systems seek to exploit advanced technologies to reduce the time and effort spent on the exam scoring process. These systems have been applied in several languages, including Arabic. Nevertheless, the applicable NLP techniques in Arabic AES are still limited, and further investigation is needed to make NLP suitable for Arabic to achieve human-like scoring accuracy. Therefore, this comparative empirical experimental study tested two word-embedding deep learning approaches, namely BERT and Word2vec, along with a knowledge-based similarity approach; Arabic WordNet. The study used the Cosine similarity measure to provide optimal student answer scores. Several experiments were conducted for each of the proposed approaches on two available Arabic short answer question datasets to explore the effect of the stemming level. The quantitative results of this study indicated that advanced models of contextual embedding can improve the efficiency of Arabic AES as the meaning of words can differ in the different contexts. Therefore, serve as a catalyst for future research based on contextual embedding models, as the BERT approach achieved the best Pearson Correlation (.84) and RMSE (1.003). However, this research area needs further investigation to increase the accuracy of Arabic AES to become a practical online scoring system.

**Keywords**—Arabic language; Automated Essay Scoring (AES); Automated Scoring (AS); Educational Technologies; NLP

## I. INTRODUCTION

Online learning has become an integral part of the educational system in the wake of the COVID-19 pandemic, during which most countries had to close their educational institutions as a precautionary measure to preserve the safety of the public from the spread of infection. Shifting to online education was an alternative solution to cope with the restrictions imposed by the lockdown of educational institutions; however, it imposes many social and educational challenges [1], particularly when it comes to online assessment. A study which looked into assessment during the COVID-19 lockdown has suggested the need for a multilevel approach to the problems of cheating and plagiarism [2]. Even prior to the pandemic, assessment was a well-known challenge in education encountered by both traditional and online education [3]. It continues to be a dominant issue in the online learning arena even in the post-pandemic world.

Assessment in education describes the “processes of evaluating the effectiveness of sequences of instructional

activities when the sequence was completed” [4], and it has been divided into formative and summative assessments [5]. Formative assessment is part of the instructional process in the classroom; it provides the feedback needed to adjust the teaching and learning activities to suit the learners while they are engaged. On the other hand, summative assessment is given periodically in order to assess the learners' level of knowledge or achievement at a certain point in time. The AES in the context of this work is considered as a form of summative assessment.

Despite the diversity of methods for assessing students' progress, the examination method has been used predominately to measure students' performance and knowledge. Namely, examinations are held at the end of the course in addition to course assignments [6]. The academic examination is a considerable undertaking in the education process due to the significant number of students who take the exams. A massive overhead of time and effort is involved, with teachers having to score exams instead of focusing on other important aspects of the educational process [7].

At this point, automated scoring (AS) systems appear to be one of the best solutions to overcome these challenges. AS systems offer a collection of different grading approaches based on measuring the similarity between the answer posed and the expected answer [8]. AS systems introduce an effective alternative scoring mechanism for several types of questions such as true/false (T/F) questions, multiple choice questions (MCQs), and fill-in the blank questions. Nevertheless, the grading of essay questions and short answer questions is a complex task in AS systems, as such systems need deep knowledge and understanding of the nature of texts in a language process [9]. Hence, automated essay scoring (AES) [10] has emerged as a way to grade student essays.

There are different approaches used in the context of AES to measure the similarity between model answers (MAs) and student answers (SAs). One approach is string-based similarity [11], which involves scaling the string's sequence and the composition of the letter; in comparison, corpus-based similarity [12] measures similarity depending on the information obtained from large corpora. Moreover, the knowledge-based similarity approach [13], which is one of the most popular approaches for measuring text similarity, utilizes information derived from the semantic network Arabic WordNet.

According to research presented in [14], many research efforts have focused on developing and studying automated

scoring for short and essay questions written in English. In comparison, a limited number of studies in this area have been conducted to address automated Arabic short answer questions. The Arabic language, spoken by approximately 400 million people [15], is a complex language, with many synonyms for one word, differences in the meaning of a word according to its different formation, and richness of morphology. Accordingly, there is a lack of a practical system in Arabic to conduct automated scoring of short or essay questions due to the accuracy of the proposed frameworks being insufficient. Some studies have proposed a framework that translates the Arabic answer into English to measure the similarity between the model answer and student answer [16]. In contrast, other studies have proposed solutions that are centred around processing the Arabic language. For example, the work presented in [17] showed that using synonyms and finding the root of words can close the difference between a model answer and student answer. Another study has suggested that using deep learning can enhance the accuracy of Arabic AES [14].

The focus of this study was automated short text answer scoring presented in Arabic using a text mining technique with deep learning algorithms for natural language processing (NLP). The study aimed to investigate the effects of stemming level on measuring similarity between student answer (SAs) and model answer (MAs) It contributes the following to the following to this research area:

- Provide a comparative empirical study by comparing different word-embedding approaches to examine the word's surrounding context.
- Investigate mechanisms that depend on raising the percentage of similarity between the SA and MA by increasing the number of correct words in the SA.
- Evaluate the proposed models in the literature using two different available Arabic corporuses.

The rest of this paper is organized as follows. Section II presents the related work, while Section III explains the methodology used in this study. Section IV presents and discusses the study results. Finally, the conclusion in Section V and recommendations for future work are given in Section VI.

## II. RELATED WORKS

This section presents works related to the processing of Arabic short answer scoring and the present state-of-the-art approaches for short answer scoring for the English and Arabic languages.

Previous students have introduced models for Arabic AES that use string-based techniques of text similarity; for example, research in [18] presents a system for online exams in Arabic that is based on the Stemming and Levenshtein algorithms. The system reduces the words that have the same stem to a common phrasing. The results of this study showed that the proposed system is effective as a classification tool for Arabic essay questions.

Several other studies dealing with AS in Arabic have employed corpus-based algorithms such as Latent Semantic Analysis (LSA), which is an NLP technique that evaluates the similarity between two documents. This method relies on generating vectors-presentation for semantic terms, words, or even the concepts [19]. Research in [20] presented a system for scoring Arabic short answers by embedding LSA with the main three important syntactic features: lemmatization, the mistake of words, and the number of common words. They employed bag-of-words (BOW) to present feature vectors that mapped into the Cosine algorithms to measure the similarity between student answers (SAs) and model answers (MAs). To evaluate their approach, an Arabic short answer corpus was generated, and the best result was 96.72%. Similarly, research in [21] applied a similar approach, though their approach was centred on a semantic perspective as it combined LSA with linguistic features. After performing the normalization process, the authors generated feature vectors using Term Frequency-Inverse Document Frequency (TF-IDF) as the input to the Cosine algorithm. To improve the accuracy of LSA, the study leveraged part-of-speech (POS) with Term Frequency (TF) to take into account the syntactic of words. Moreover, the work in [22] utilized LSA with pre-processing of answers, for example, by removing stop-words, applying the replacing synonyms technique, and applying a stemming process. Meanwhile, the study in [23] proposed a new automated essay scoring approach focused primarily on measuring the similarity based on the root extraction and the synonyms of the keywords in addition to using the Cosine similarity. Moreover, they used the ROUGE metric to evaluate the obtained results, which gave a high accuracy rate of 84.5%, which indicated that the model's scoring could approximate human scoring.

Furthermore, another related work rendered an automated grading model for Arabic essays with the aim of gaining and achieving better efficiency [17]. In this case, features were extracted from the SA and MA by utilizing the F\_score tools, and Arabic WordNet was used as a helpful method for semantic similarity, which is considered as a knowledge-based algorithm. The proposed model recorded better accuracy when Arabic WordNet was used than without it.

Moreover, other research efforts presented frameworks using hybrid approaches of a string-based corpus and knowledge-based corpus. Research presented by [24] compared different algorithms to inspect the optimal solution of Arabic automatic grading. They employed two string-based text similarities methods: the Damerau-Levenshtein algorithm and the N-gram algorithm. Further, the LSA and DISCO were used as corpus-based text similarity algorithms. The authors applied four testing methods, namely Stop, Raw, Stop-Stem, and Stem, to investigate the accuracy of string-based algorithms. However, they only used the stop method to test corpus-based algorithms, since the semantic similarity between the stop words does not need to be measured. In addition, they calculated the correlation constant between the manual grading and the automatic system grading. Thus, the results showed that the N-gram with stop method resulted in 0.820 as the best correlation. Generally, the character-based N-gram algorithm achieved better results than the other type.

On the other hand, for the corpus-based algorithms, the DISCO algorithm achieved a higher correlation than the LSA algorithm, since it is built on words that have a common distribution.

Similarly, research work in [8] introduced a comparative study by investigating 14 string-based algorithms and two corpus-based algorithms. These algorithms were evaluated across two main models. The first was the holistic model, which compares the full form of an SA to an MA without splitting the SA and ignoring the MA's partition scheme. The second was the partitioning model, which divides the answer of the student into a group of sentences based on the sentence boundary detection templates and then maps each sentence to the most similar element on the MA. The  $r$  correlation and the RMSE were used to measure the correlation, while the MaxSim and the AvgSim were used to calculate the similarity. Accordingly, the experiment showed that corpus-based algorithms produce lower error rate values, and the N-gram (Bi-gram, Tri-gram) approach recorded the best  $r$  correlation of 0.826, with the partitioning model achieving results better than the holistic model in all cases.

Additionally, the same authors have also addressed this issue by translating Arabic text into English language [16]. They developed a framework that evaluates the similarity between SAs and MAs by fundamentally translating Arabic answers into the English language. The reason behind this choice was the limitation of available Arabic text processing resources and tools. Their proposed system was composed of five main stages as they applied different measuring techniques of text similarity in a separate and hybrid way; thus, the obtained scoring was scaled using the K-mean cluster.

On the other hand, work in [25] used supervised machine learning and classification algorithms to produce a new Arabic essay grading database that is compatible with machine learning. The study depended on leveraging machine learning algorithms to evaluate the database. Thus, the study used the several classifiers to build the training model of the database such as NB, Meta-classifier, and decision tree (J48). The results obtained from the third experiment using Meta-classifier showed a higher accuracy rate of 83%. Likewise, [26] provided a system in the context of web-based learning focusing on the Vector Space Model (VSM) and Latent Semantic Indexing (LSI). The system firstly extracted significant information from the essays by applying the VSM for information retrieval techniques. Then it applied the VSM and LSI to determine the degree of similarity between the student essay and the model essay after each essay has been converted to vector space. Finally, it used the Cosine similarity to measure the score of SA. The results showed that the proposed system provided scoring accuracy close to the traditional scoring by the professor.

Several state-of-the-art deep learning approaches have been used to process text similarity and conduct automatic scoring (AS). These approaches mainly rely on automated multi-layered feature-distributed representation and learning. Embedding models have emerged based on deep learning methods: word-embedding and paragraph-embedding have

become cutting-edge models in the NLP field [27]. Several contributions have employed embedding models to address AS in the English language [28-30]. Moreover, the study in [31] provided two main approaches for grading short answer questions. In the first approach, the study used four different methods based on word-embedding models: Word2vec, GloVe, and Fasttext3 by summation pre-trained word vectors. In the second approach, it used trained three deep learning models to extract the paragraph vector. Finally, Cosine similarity was used to measure the similarity between the vector of the MAs and the vector of the SAs. The best value the study produced for RMSE was 0.797.

In addition, in its comparative empirical work, research provided in [32] developed a model for AS by configuration of three presentation feature vectors: a manually extracted feature, word2vec, and a contextual embedding feature using the BERTmodel. The best-recorded accuracy was by the configuration of three feature vectors of  $75.2 \pm 1.0$  Quantized Classification. Table I summarises the approaches to handling automated short answer scoring as introduced in this section.

TABLE I. SUMMARY OF APPLIED APPROACHES IN RELATED WORK

Approach	Published Work	Area
String-based	[25].	Arabic automated online exam scoring
Corpus-based	[17], [20], [21], [23]	Arabic automated short answer scoring
Hybrid approaches (String-based, Corpus based)	[8], [24].	Arabic automated short answer scoring
Hybrid approaches (string based, corpus based, knowledge based – WordNet)	[16]	Translate Arabic short answers into English for automated scoring
Word embedding & paraphrase embedding with cosine	[31]	English automated short answer scoring
Word embedding (Word2vec), contextual embedding (Bert)	[27], [32],[33].	English automated short answer scoring

To conclude, more research on how to leverage deep learning approaches, or use contextual embedding, for Arabic automatic short answer scoring is needed. Thus, this comparative empirical study attempted to implement three different approaches for the following feature presentation vectors: 1) word-embedding using Word2vec, 2) contextual-embedding using Bert, and 3) WordNet as the knowledge-based algorithm, with the Cosine algorithm to measure text similarity between student answers (SAs) and model answers (MAs). Furthermore, it also investigated the effect of stemming levels on the performance of the proposed approaches.

### III. METHODOLOGY

This section outlines the proposed process for evaluating two different models for measuring text similarity for Arabic short answer questions: (1) knowledge-based similarity and (2) word and contextual embedding similarity. The two models were implemented by some suggested libraries of NLP

and the Python programming language. The research methodology is illustrated in Fig. 1.

Fig. 1. Methodology.

In the first stage, data were collected, which include both SAs and MAs. In the second stage, data were converted to comma-separated value (CSV) format. In the third stage, the pre-processing took place, which consisted of four phases in the following order: data cleaning, data normalization, stop-word removal, and finally steam and lemmatization. In the fourth stage, the three different approaches (WordNet, Word2vec, and Bert) were tested to find the highest accuracy in AS. In the fifth stage, the similarity between the SAs and MAs was measured utilising the Cosine similarity. Finally, the scores were calculated.

#### A. Data Collection

In this study, data collection was based on two Arabic datasets provided by Ouahrani and Bennour [14] and Rababah and Al-Taani [23].

The dataset in AR-ASAG [14] consists of three different exams with the MAs and SAs of three different classes collected from a cybercrime course exam. Each exam consists of 16 short answer questions, and each question on each exam has a different number of student answers. The dataset thus contains 2,133 SAs with a total of 48 questions.

The Arabic dataset produced in [23] consists of 11 questions from the official Jordanian History course exam. Each question includes the MA created by the teacher and the answers of 50 students, with an average of 50 words per answer. The questions in both datasets include one or more of the question types shown in Table II.

TABLE II. DATASET QUESTION TYPES

Arabic Question Type	Translation
عرف	Define
اشرح	Explain
علل	Justify
ما النتائج المترتبة على	What are the consequences
ما الفرق	What is the difference

#### B. Convert to CSV Format

A comma-separated value (CSV) file is a set text file that uses a comma to separate values. Each line of the file is a data record that consists of one or more fields separated by commas. After the datasets were obtained, the data were converted to the CSV format.

#### C. Pre-process

1) *Cleaning data*: cleaning the data is an essential process in text mining that removes the noise from the data and prepares the data for processing. Therefore, all the punctuation marks were removed, including full stops, commas, and parentheses, in order to make the data more understandable in the comparison with the correct answer in the MA. The difference in data before and after cleaning is shown in Table III.

TABLE III. DATA CLEANING

Student Answer before Data Cleaning	Student Answer after Data Cleaning	Translation
هي كل سلوك غير أخلاقي يتم باستخدام الوسائل الالكترونية (الهاتف، الكمبيوتر...), يتمثل في حصول مرتكب الجريمة على ما يريد لتحقيق أهدافه الشخصية بينما يتحمل الضحية وهو المستخدم العقوبة، تتمثل في سرقة المعلومات	هي كل سلوك غير أخلاقي يتم باستخدام الوسائل الالكترونية الهاتف الكمبيوتر يتمثل في حصول مرتكب الجريمة على ما يريد لتحقيق أهدافه الشخصية بينما يتحمل الضحية وهو المستخدم العقوبة تتمثل في سرقة المعلومات	It is every immoral behaviour that takes place using electronic means (telephone, computer...), represented by the perpetrator obtaining what he wants to achieve his personal goals, while the victim, who is the user, bears the penalty, represented by stolen information.
هي سلوك غير قانوني عبر أجهزة إلكترونية، لأهداف مادية أو معنوية غالبا لإتلاف أو سرقة المعلومات وهي مثلا: النصب والاحتيال، التعدي الإلكتروني، التجسس وانتهاك الخصوصية	هي سلوك غير قانوني عبر أجهزة إلكترونية لأهداف مادية أو معنوية غالبا لإتلاف أو سرقة المعلومات وهي مثلا: النصب والاحتيال التعدي الإلكتروني والتجسس وانتهاك الخصوصية	It is illegal behaviour through electronic devices, often for material or moral purposes, to destroy or steal information, for example: fraud, electronic infringement, espionage and violation of privacy.
هي سلوك غير قانوني يتم باستخدام الأجهزة الإلكترونية، يتم تحميل المجرم منه على فوائد مادية ومعنوية، يتحمل الضحية خسارة مقابل ذلك الهدف من الجريمة إتلاف أو سرقة المعلومات	هي سلوك غير قانوني يتم باستخدام الأجهزة الإلكترونية يتم تحميل المجرم منه على فوائد مادية ومعنوية يتحمل الضحية خسارة مقابل ذلك الهدف من الجريمة إتلاف أو سرقة المعلومات	It is an illegal behaviour that takes place using electronic devices, for which the criminal is charged with material and moral benefits, and the victim bears a loss due to the goal of the crime, destroying or stealing information.

2) *Normalization*: At this stage, data were processed using advanced techniques by developing the normalization functions for some specific letters, as in Arabic, some letters are written in various forms. Thus, the Tashaphyne Library [34] was used for normalizing the following letters: Alef (أ،إ،آ)، Hamza (ء،ى،ؤ)، Ya'a (ي،ى)، and Ha'a (ه،ة). Furthermore, other methods were used for removing diacritics format (known in as Tashkeel) as shown in Table IV.

TABLE IV. NORMALIZATION

Letters form	Normalized into	Function name
أ،إ،آ	ا	Alef normalization
ي،ى	ي	Ya,a Normalization
ه،ة	ه	Ha'a Normalization
ء،ى،ؤ	ء	Hamza Normalization

output layers to support ultra-modern approaches that process different enormous jobs [33].

This work employed a pre-trained BERT model from the AraBert models' list. The bert-base-arabertv2 was predicted to extract layers where the external output layer was selected to draw out all remaining embedding layers. Thus, the proposed model utilized only the external node of the last embedding layer as it perfectly defined the sentences in a few dimensions. These embeddings will be closer to each other if they are more similar.

#### E. Text Similarity Measures

To measure the similarity between the character space vectors of an SA and an MA, the Cosine method was employed. Cosine works mathematically by calculating the Cosine of the angle between two vectors dropped down in a multi-dimensional space. The resulting similarity value falls in the range from -1 to 1. The -1 indicates strong non-similarity, while 1 refers to perfect similarity [39] and [27]. Thus, in this study, to align a predicted score with a human score, the data were normalized to 0-5.

### IV. RESULTS (SCORE) AND DISCUSSION

This section discusses the results of the comparative experiments that tested the three proposed approaches aimed at addressing Arabic automated short answer scoring. These experiments were conducted using data from two datasets: AR-ASAG and another dataset in [23]. Each dataset and approach were tested using the two mentioned stemming tools to examine the influence of the stemming level, light stem and base stem, on scoring precision for Arabic, which includes massive inflections. The proposed approaches were evaluated by comparing human scoring with the automated model scoring using the two most frequently mentioned measurement methods in related works for this area. All the experiments reported using both the Pearson correlation coefficient and Root Mean Squared Error (RMSE). The Pearson correlation coefficient is a precise measurement used to assess the linear relationship across two variables, represented in the range of -1, 1 to indicate the weakness or strength of the relationship, where the higher value is preferable. RMSE is the ideal method for measuring the variance between a predicted score and a true score. This method gives a non-negative value where, generally, a low RMSE is best. Table VII and Table VIII display the sample of grades to compare human scoring with model scoring.

#### A. Proposed Approaches on AR-ASAG

Table IX reports the results acquired from all three approaches that were applied to the dataset AR-ASAG. The first approach, WordNet with Cosine, achieved a relatively better Pearson correlation with the light stem (.75) while recording an RMSE with a lower value with the base stem. In Word2vec with Cosine, the light stem again produced an approximately higher Pearson correlation (0.7758) and lower RMSE (1.3577) than the base stem. Similar results can be observed in BERT with Cosine, with a light stem producing a Pearson correlation of 0.7616 and an RMSE value of 1.0439.

Overall, the Word2vec with Cosine resulted in the best Pearson correlation at .77 compared with the other approaches, while BERT with Cosine achieved the lowest RMSE with light stem on AR-ASAG.

#### B. Proposed Approaches on Dataset (Rababah & Al-Taani, 2017)

The same experiments were performed on the dataset [23] as that shown in Table X. WordNet, Word2vec, and BERT resulted in the lower RMSE with the base stem as 1.06, 1.12, and 1.003, respectively. The higher Pearson Correlation with base stem was achieved by Word2vec of .83 and BERT of 0.84. For this dataset, the BERT + Cosine approach recorded the best Pearson Correlation and RMSE.

TABLE VII. SAMPLE OF HUMAN & MODEL SCORING ON AR-ASAG

Approaches	Human Scoring	Model Scoring
WordNet+Cosine	3.5	3
	4	3
	5	2.5
	3.75	3
Word2vec+Cosine	4	3.79
	2	2.5
	4.5	4.33
	5	4.67
BERT+Cosine	2.5	2.5
	5	3
	2.25	3
	3	3

TABLE VIII. SAMPLE OF HUMAN & MODEL SCORING ON (RABABAH & AL-TAANI, 2017) DATASET

Approaches	Human Scoring	Model Scoring
WordNet+Cosine	2	3
	2	2.5
	2	1.5
	2	2
Word2vec+Cosine	1	1.5
	1	1
	1	2
	4.43	4.5
BERT+Cosine	1	1
	1	1.5
	2.5	3
	2	3

TABLE IX. THE RESULT OF PROPOSED APPROACHES ON AR-ASAG

Approaches	Stem	Pearson Correlation	RMSE
WordNet+Cosine	Base	0.7469	1.4977
	Light	0.7553	1.4646
Word2vec+Cosine	Base	0.7693	1.3879
	Light	<b>0.7758</b>	1.3577
BERT+Cosine	Base	0.7536	1.4516
	Light	0.7616	<b>1.0439</b>

TABLE X. THE RESULT OF PROPOSED APPROACHES ON DATASET OF (RABABAH & AL-TAANI)

Approaches	Stem	Pearson Correlation	RMSE
WordNet+Cosine	Base	0.806195	1.1220652
	Light	0.820854	1.153378
Word2vec+Cosine	Base	0.837094	1.0655779
	Light	0.828779	1.1118528
BERT+Cosine	Base	<b>0.841902</b>	<b>1.00308459</b>
	Light	0.837253	1.0439487

The following observations are introduced based on the results of the above experiments. First, the light root and base root are approximately equivalent as they achieved close results to each other, as another study [14] also reported. The best among them cannot be determined here, as this work recorded that the optimal performed stemming level can differ with different datasets and various feature representation approaches. The light stemming was better when performed on the AR-ASAG dataset, while the other dataset had a higher Pearson correlation and lower REMS with the base stem.

Moreover, processing the contextual embedding between words has improved the accuracy of Arabic AES compared with other similarity measurements. The BERT with Cosine achieved the best RMSE across the two used datasets as the lowest RMSE was 1.00308. In addition, the best Pearson Correlation among all performed experiments was 0.841902 for the BERT algorithm.

### V. CONCLUSION

This comparative empirical study evaluated the efficiency of different word embedding approaches in the context of Arabic automatic essay scoring (AES). Two available datasets were acquired, and several pre-processing methods were employed for these datasets. For the feature presentation, three different approaches were proposed to examine their efficiency as feature extract models in this domain. Therefore, the WordNet, Word2vec, and BERT approaches have been applied individually to extract the features of the student answer (SA) and model answer (MA), and the Cosine similarity was used to identify the closest-scoring model to human scoring by measuring the similarity between the SAs and MAs.

Four experiments were conducted for each proposed approach to study the effect of stemming techniques on the performance of these approaches. After that, Pearson correlations and RMSEs were calculated to compare the scores produced by the experiments with human scores. The results indicated that advanced models of contextual embedding can improve the efficiency of Arabic AES as the meaning of words can differ in the different contexts. Nevertheless, it is worth mentioning that these experiments were conducted on only two available Arabic short answers datasets, and hence the results are tied to them. The same experiments should be repeated on more datasets to get more generic results. Therefore, this area needs more investigation to improve the accuracy of Arabic AES in order for it to be realised as a practical online scoring system.

### VI. FUTURE WORK

Future work could endeavour to present a benchmark dataset for the Arabic language. Furthermore, proposing a hybrid approach, such as combining WordNet with word-embedding and contextual-embedding, could enhance the accuracy of the approach.

**Abstract**—A face recognition system's initial three processes are face detection, feature extraction, and facial expression recognition. The initial step of face detection involves colour model skin colour detection, lighting adjustment to achieve uniformity on the face, and morphological techniques to maintain the necessary face region. To extract facial characteristics such the eyes, nose, and mouth, the output of the first step is employed. Third-step methodology using automated face emotion recognition. This study's goal is to apply the Adaptive Neuro Fuzzy Inference System (ANFIS) algorithm to increase the precision of the current face recognition systems. For the purpose of removing noise and unwanted information from the data sets, independent data sets and a pre-processing technique are built in this study based on color, texture, and shape, to determine the features of the face. The output of the three-feature extraction process is given to the ANFIS model as input. By using our training picture data sets, it has already been trained. This model receives a test image as input, then evaluates the three aspects of the input image, and then recognizes the test image based on correlation. The determination of whether input has been authenticated or not is made using fuzzy logic. The proposed ANFIS method is compared to the existing methods such as Minimum Distance Classifier (MDC), Support Vector Machine (SVM), Case Based Reasoning (CBR) with the following quality measure like error rate, accuracy, precision, recall. Finally, the performance is analyzed by combining all feature extractions with existing classification methods such as MDC, KNN (K-Nearest Neighbour), SVM, ANFIS and CBR. Based on the performance of classification techniques, it is observed that the face detection failures are reduced, such that overall accuracy for CBR is 92% and it is 97% in ANFIS.

**Keywords**—ANFIS; Image processing; face recognition; feature extraction; fuzzy logic

## I. INTRODUCTION

Computer vision includes face recognition. Face recognition [1] is a biometric approach for identifying a person based on an image of their face. Biological characteristics are used to identify a person. Human eyes can quickly recognize

people by simply glancing at them, but they have a limited focus span. As a result, a computerized approach for facial recognition is developed. Face recognition [2] is the process of automatically detecting and authenticating a person from a photograph or video. Despite the fact that face recognition has been extensively explored [3], there are still obstacles to overcome a number of issues, including:

- Misalignment.
- Pose Variation.
- Illumination Variation.
- Expression Variation.

The efficacy and precision of face recognition must be improved; hence several approaches must be tested. A method for identifying a person based on their input image is called face recognition. Face recognition can be used on mobile devices due to its adaptability. Face recognition on mobile devices has a variety of disadvantages, such as processing power restrictions, storage space restrictions [4], network bandwidth restrictions, privacy problems, and security issues [5]. On mobile devices, face recognition can be used to identify users, identify social networking sites, and separate individuals. It is well-liked in the marketing and security industries [6]. There are many conventional security apps, including applications for username (identity) and password (credentials) [7]. Passwords can be cracked or detected, making traditional mobile apps easy targets for theft. Contrarily, face recognition apps are more effective than conventional ones because they are more versatile and safer, and they do away with the necessity for the user to remember passwords [8]. The finest biometrics for these devices are face recognition programs because they include cameras. The novelty of the proposed work is we consider the color, shape and texture feature of the image. In existing methods, they are considered any on parameter either color or shape or texture. Machine learning implementation we are using the ANFIS model. This paper's

goal is to introduce a facial recognition system for mobile devices.

This paper is structured as follows: Literature review is presented in Section II. The proposed model is explained in Section III. Results are shown and discussed in Section IV. Finally, the conclusion of the presented work is discussed in Section V.

## II. LITERATURE SURVEY

We will go through a handful of the many different types of recognition techniques that exist. Based on the input image, the authors of [9] suggested a face identification system for mobile phones. They did this by developing a number of ROI preprocessing steps, the Viola-Jones approach, and Principal Component Analysis (PCA). The system's goals are to speed up and simplify image searches. A unique application for facial recognition on mobile devices was introduced by the developers of [10] that leverages the Bridge Approach (BA) to speed up processing and makes it possible to use the system from any location with an internet connection. Face detection and feature extraction are done with the OpenCV library; face recognition is done with the WEKA library. The face and eye detection, as well as a set of Region of Interest (ROI) preprocessing, were proposed as part of the design and implementation of a face recognition system for the mobile phone platform by the authors of [11]. The PCA has an accuracy rate of 93.8 percent, and Linear Discriminant Analysis (LDA), which has an accuracy rate of 96 percent, are the recognition techniques used. The use of facial recognition on mobile devices was done by the authors of [12]. The PCA method was used by them for recognition. After using the technique, the accuracy for a given threshold was about 92 percent, and it took 0.35 seconds for a small sample of test photos to identify the person. The authors of [13] developed a facial recognition system in MATLAB and tested it on Direct Region of Interest Device (DROID) mobile devices. It examined various face detection techniques (such as color segmentation and template matching) and provided two

methods for recognition (Eigen & Fisher face). With a computation time of 1.58 seconds on DROID, it has an Eigen face recognition rate of 84.3 percent and a fisher face recognition rate of 94 percent [14].

## III. PROPOSED METHOD

In this research work, face recognition is done using image processing, pre-processing, feature extraction, and ANFIS. Input images were collected using digital camera pre-processing technique was used remove the noise. Feature extraction was used to extract the essential feature from the pre-processed output image. The ANFIS was used to recognize the face. Receiver Operating Characteristic (ROC) curve was used to evaluate the proposed system performance.

### A. Input Image

Every matrix element in a recorded image is typically referred to as a pixel [15]. Two categories can be used to describe input images taken with a digital camera:

- 1) Testing image
- 2) Training image

Training images and Testing images were obtained using a digital camera for Fig. 1. In this research, we used 16 different data sets. 1600 photos total were used as input, with 1120 images used for the training data set and 480 images used for the testing data (Given in Table I). We are utilizing a jpeg image with dimensions of 256 x 234 pixels.

### B. Pre-processing

In this research work, normalization method and soft coring filter were used (shown in Fig. 2). In Fig. 3, Pre-processing is a method used to remove the noise from the input image. Normalization method was used to convert the RGB image into gray scale image using (1) [16].

$$I(x, y, z) = \frac{Gx + Gy + Gz}{3} \quad (1)$$

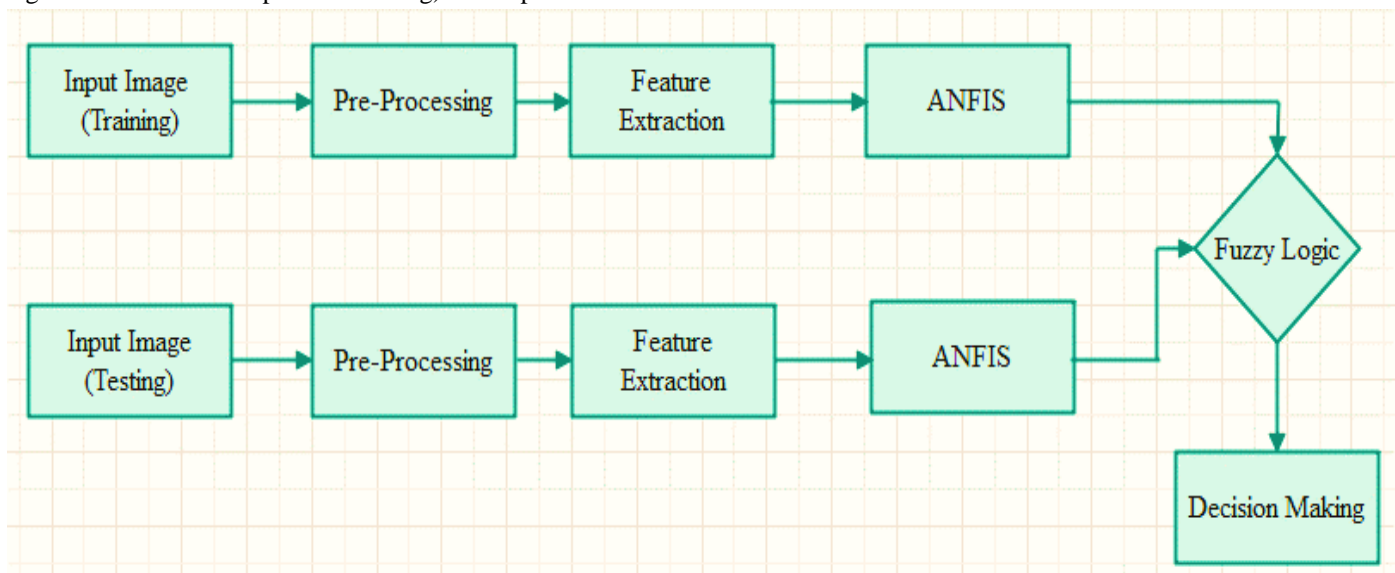

Fig. 1. Block diagram for proposed system

TABLE I. SAMPLE DATABASE

Fig. 2. Pre-processed output image.

The output of the soft coring function was applied after the normalized output picture had been passed through the high pass filter  $\alpha(\cdot)$  using equation (4).

$$P(x, y) = Ih(x, y) + \alpha(I(x, y)), \quad (2)$$

where,

$P(x, y)$  – Preprocessed output image

$Ih(x, y)$  – Highpass filter output image

$$Ih(x, y) = I(x, y) - Z(e^{jwx}, e^{jwy}) \quad (3)$$

$Z(e^{jwx}, e^{jwy})$ - High pass filter co-efficient

$\alpha(I(x, y))$ - Soft coring function

$$\alpha(I(x, y)) = m \cdot I(x, y) \left(1 - e^{-\frac{|I(x, y)|}{\tau}}\right) \quad (4)$$

$m, \tau$  – Random variables ranges between 0 to 1.

Fig. 3. Soft coring filter.

A nonlinear technique called soft coring filtering is used to remove extraneous data from normalized images [17]. Based on a kernel function that may be executed in the frequency domain, a Gaussian high pass filter is utilized to graphically display the data. With the aid of the sliding windowing technique, the Gaussian high pass filter quickly produces a Fourier transform in two dimensions of convolutions [18].

Gaussian high pass filter was used to remove the noise from the input image using equation (3). To extract the input image's line and edge information, the soft coring kernel function was employed. Two dimensional images were filtered using the soft coring approach, which significantly reduced data loss as compared to the median filtering method. Two step pre-processing method contributes to the quality of the image to be enhanced, reduction of processing time, compensation of illumination, reduction of the shaded background, maintenance of the image contrast and brightness [19]. Median filtering cannot apply for the boundary or edges of the input image to overcome this issue we used soft coring filter.

### C. Feature Extraction

1) *Texture feature extraction:* After the preprocessing the images are used for feature extraction. Geometry-based techniques use geometric information as a features measure, such as feature relative locations and sizes of the face components. Kanade [20] devised a method that used a vertical edge map to locate the eyes, mouth, and nose. These procedures necessitate a threshold and may have a negative impact on the final result [21]. Co-occurrences matrix-based technique was used to extract the texture feature using. The following features of co-occurrence matrix can be measured.

- Inertia (contrast).
- Energy.
- Entropy.
- Contrast.

Fig. 4. Texture Feature extraction output image.

The output of the texture feature method is shown in Fig. 4. The element difference moment of order 2 is called as contrast [22]. It has relatively minimum values when maximum values appear in the main diagonal of co-occurrence matrix

$$Contrast = \sum_{g1} \sum_{g2} (g1 - g2)^2 C_{g1 g2} \quad (5)$$

where,  $g1$  = grey level value of pixel location at  $(x,y)$ ;

$g2$ =grey level value of pixel location at  $(x,Dx,y,Dy)$ ;

$Dx,Dy$ =displacement vector of  $x$  and  $y$ ;

$C$ =co-occurrence matrix

The energy value is calculated by using the following (6). If all values in the co-occurrence matrix are equal, then energy value is maximum.

$$ENERGY = \sum_{g1} \sum_{g2} C_{g1 g2}^2 \quad (6)$$

Entropy is used to calculate the information of the grey level image. To calculate the entropy value the (7) is used:

$$ENTROPY = - \sum_{g1} \sum_{g2} C_{g1 g2} \log_2 C_{g1 g2} \quad (7)$$

2) *Shape features extraction*: To match the found face components, this method uses a previously established standard face pattern template [23]. This makes use of the proper energy function. The facial image with the best match to a template will use the least amount of energy. Y. Zhong et al. [24] adopt this method, which requires prior knowledge of a priori template modelling. It also necessitates additional computing costs, which have a significant impact on its performance [25]. For faster searching speeds and more template matching optimization, genetic algorithms can be utilized. In this research work, we used canny edge detection method for shape feature extraction (output shown in Fig. 5). This method was used to detect wide range of object edges in an image.

3) *Color feature extraction*: In this research work we used threshold-based segmentation as color feature extraction method. Skin color is used to isolate the face in this method [26]. Any non-skin color part of the face is considered a potential for localization of the eyes and/or mouth. Due to the diversity of ethnic backgrounds, this approach performs poorly on facial image datasets. Color feature is extracted by using (8).

$$E(x, y) = \begin{cases} 0 & \text{if } P(x, y) < T1 \\ 1 & \text{if } T1 \leq P(x, y) \leq T2 \\ 0 & \text{if } P(x, y) > T2 \end{cases} \quad (8)$$

where  $T1$  –Lower threshold value,  $T2$ - Upper threshold value.

Fig. 5. Shape feature extraction output image.

4) *ANFIS (Adaptive Neuro Fuzzy Interface System)*: The outputs of feature extraction methods for colour, texture, and form were fed into the ANFIS. The ANFIS machine learning method, which combines fuzzy logic and neural network methods, is supervised [27]. We are using feed-forward neural networks as a neural network methodology and the Takagi-Sugeno fuzzy logic method as a fuzzy logic method. The architecture of the ANFIS is shown in Fig. 6, which has many layers. Layer 1: In this research work, we used Gaussian membership function. Layer 2: In this layer every node is adaptive, it is labelled as  $\pi$ . The output of this layer is the multiplying result of the first layer as shown in ANFIS architecture, Fig. 6. In this research, the target value is calculated using O R logic. Layer 3: In this layer every node is adaptive, it is labelled as  $N$ . The output of this layer is the ratio of firing strength of each node to the sum of all the nodes firing strength. Layer 4: In this layer every node is adaptive. Layer 5: In this layer there is a single node, it is non adaptive and represented as  $\sum$ . Layer 6: Output Layer. Six rules make up the Takagi-Sugeno fuzzy model. With ANFIS, the problems with facial detection are overcome. A hybrid learning strategy was used to identify the face utilising the back propagation gradient approach and the least squares method. The nodes in the ANFIS network met the specifications for each tier. IF/THEN rules might build a network realisation in ANFIS. Each layer of the ANFIS network's neurons carried out the same duty [28]. To implement this algorithm, we were used MATLAB software. Fig. 7 and 8 display the ANFIS confusion matrix and colour feature extraction result.

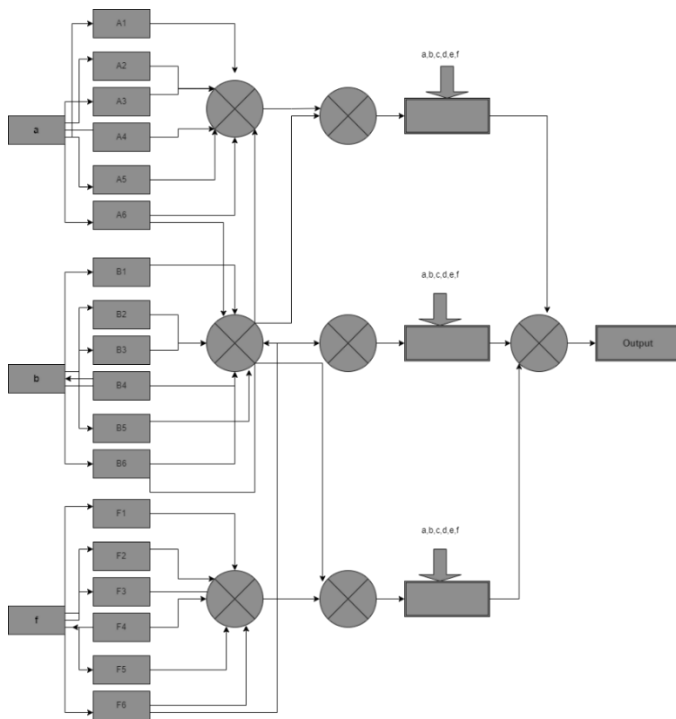

Fig. 6. ANFIS architecture.

Fig. 8. ANFIS output.

5) *Face recognition*: The last procedure in our suggested approach employs the Pearson Correlation Coefficient. Pearson correlation assesses the degree to which two variables are linearly related [29]. We use the Pearson correlation to determine the covariance between a person's features and authorized users' features in the database in order to gain access to the mobile device.

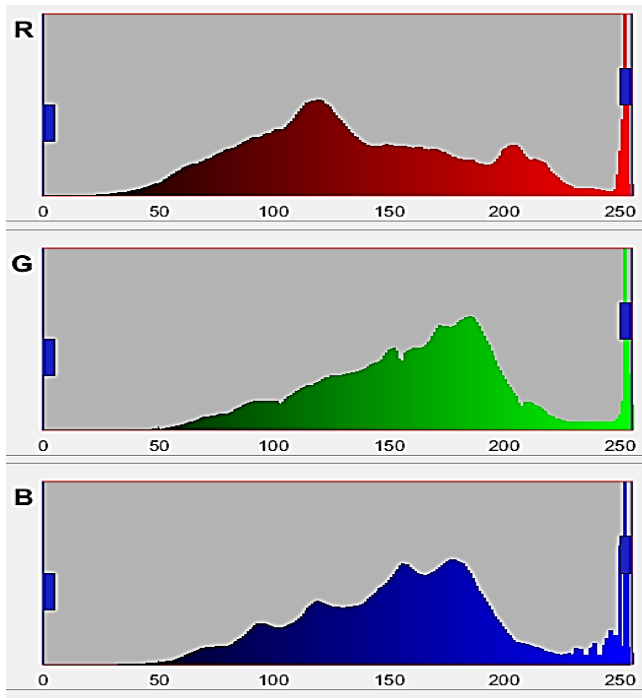

Fig. 7. Color feature extraction output.

If the covariance ratio is equal to or higher than a specific threshold, the system will accept the person as an authorized user; otherwise, the system will deny the access request. The built-in Pearson correlation function in MATLAB is used in this project. We have n "data pairings," where n is the number. The symbol n stands for the bivariate sample n2. The two images A and B have a greater correlation coefficient, which suggests that they are closely related. Based on the covariance rate, we determined whether or not the person is known. If the covariance ratio is equal to or higher than a specific threshold, the system will accept the person as an authorized user; otherwise, the system will deny the access request [30]. It contrasts the 30 measurements of the person requesting access to the system with the measurements of those who have been granted access in the (SQLite) database.

#### IV. RESULTS

The ROC curve is a graph used to depict the relationship between sensitivity and specificity and to represent the output of a classification system for various threshold values. True Positive Rate (TPR), probability detection, and recall are additional names for sensitivity [31]. Specificity is also known as the False Positive Rate (FPR), the likelihood of a false alert, and fallout. A diagnosis paradigm for classifying instances into groups is the ROC curve. The continuous output is the diagnosis output (real value). The classifier having different boundaries between different classes can be classified by threshold value [32]. The binary classification system is having two classes, one normal cell class which is labelled as positive (P) and other one is abnormal cell class, and it is labelled as negative (N).

The binary classifier has four possible outcomes are

- True Positive (TP).

- False Positive (FP).
- True Negative (TN).
- False Negative (FN).

TABLE II. TRUE POSITIVE AND NEGATIVE VALUES

		Training Image	
		P	N
Testing Image	P	TP	FN
	N	FP	TN

Plotting the cumulative distribution functions of specificity on the x-axis and sensitivity on the y-axis results in the ROC curve. Using (9) and (10) as a basis for actual positive and negative values, determine the sensitivity and specificity values. The following criteria are used to calculate the true positive and negative values, as shown in Table II.

$$Sensitivity = \frac{TP}{(TP+FN)} \quad (9)$$

$$Specificity = \frac{TN}{TN+FP} \quad (10)$$

where, TP- True Positive, TN- True Negative, FN- False Negative, and FP- False Positive.

The examination of ROC curves is a more effective method for choosing an optimization model, class distribution, disease diagnosis, and decision-making. The ROC curve is employed in a variety of fields, including biometrics, machine learning, hazard prediction, radiography, model performance evaluation, and medicine. Based on the diagonal splits in the ROC area, ROC curve analysis is used to identify person [33]. The disease-affected image is represented by the ROC curve above the diagonal, and the disease-free picture is represented by the ROC curve below the diagonal. The threshold value largely determines the ROC curve output, thus choosing the right threshold value will help the analysis of the ROC curve perform better. Fig. 9 displays the ROC curve. Plotting the cumulative distribution functions of specificity on the x-axis and sensitivity on the y-axis results in the ROC curve [34]. The system is performing well and efficiently if the curve in the plot is above the 45-degree slope line. In this research work, we used soft coring filtering method to remove the noise from the input image. The performance of the soft coring filter was compared with median filter based on the quality measure like Mean Square Error (MSE), Peak to Signal Noise Ratio (PSNR), Structural SIMilarity (SSIM), Peak Root mean square Difference (PRD) and Signal Noise Ratio (SNR) [35].

The MSE value was calculated using the following formula.

$$MSE = \frac{1}{MN} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} [f(x,y) - f^\wedge(x,y)]^2 \quad (11)$$

where f(x,y) – input image; x- row value; y-column value.

The PSNR value was calculated using the following formula.

$$PSNR = 10 \log_{10} \left( \frac{MAXi^2}{MSE} \right) \quad (12)$$

where MAXi – Pixel value maximum; MSE-Mean Square Error.

The SSIM value was calculated using the following formula.

$$SSIM(x,y) = \frac{(2\mu_x\mu_y+C1)(2\sigma_{xy}+C2)}{(\mu_x^2+\mu_y^2+C1)(\sigma_x^2+\sigma_y^2+C2)} \quad (13)$$

where  $\mu$  - mean;  $\sigma$ - variance.

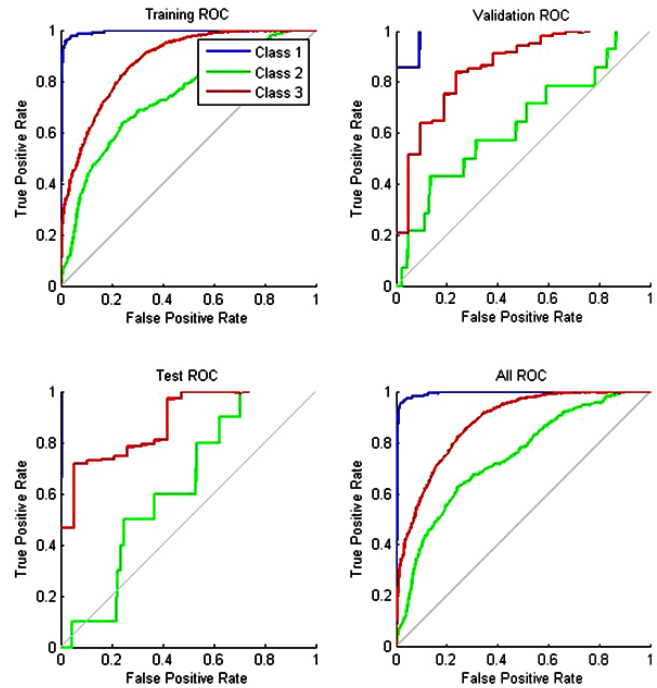

Fig. 9. ROC Output.

The PRD value was calculated using the following formula.

$$PRD = \sqrt{\frac{MSE}{\sum f^2}} \times 100 \quad (14)$$

where MSE-Mean Square Error; f-image.

To calculate the SNR value using the following formula

$$SNR = \frac{\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} (f^\wedge(x,y))^2}{\sum_{x=0}^{M-1} \sum_{y=0}^{N-1} [f(x,y) - f^\wedge(x,y)]^2} \quad (15)$$

where f(x,y) – input image; x- row value; y-column value.

Tables III and IV show the performance of filtering technique in terms of MSE, PSNR, SSIM, PRD and SNR. In soft coring filter MSE, SNR and PRD values were low when compared with median filter technique whereas PSNR and SSIM values were high compared with median filter technique [36]. This graph can be used to determine how well filtering methods based on the MSE, PSNR, SSIM, PRD, and SNR perform (shown in Fig. 10 and 11). The MSE, SNR, and PRD values of the median filter were high when compared to the Soft coring filter technique. The median filter's PSNR and SSIM values were poor when compared to the Soft coring filter method. It suggests that when compared to median filters, soft coring filters perform better.

Fig. 11. Performance analyses of Feature extraction techniques.

Table V illustrates the sensitivity, specificity, F1 score, and accuracy of the feature extraction approach. In Fig. 12, color, shape, and texture were quantified using feature extraction techniques with and without filters for these four metrics. With the filter, the sensitivity values were 81.25, 80.26, and 84.36. Other feature extraction methods have lower sensitivity than the texture feature extraction approach. With the filter, the specificity values were 86.23, 85.32, and 82.34. Other feature extraction methods have lower specificity than the colour feature extraction approach [37-38]. The F1 score after applying the filter was 84.35, 83.56, and 81.26. In comparison to other feature extraction techniques, colour feature extraction produced a higher F1 score. There were three different filter accuracy values: 85.26, 84.35, and 83.28. Compared to other feature extraction techniques, the colour feature extraction method offered greater accuracy.

Fig. 12. (a),(b),(c),(d) Performance analysis of classification.

TABLE V. FEATURE EXTRACTION ANALYSIS

Technique	Without Filter %				With Filter %			
	SEN	SPEC	FI	Acc	SEN	SPEC	FI	Acc
Color	71.21	74.36	76.28	78.54	81.25	86.23	84.35	85.26
Shape	70.32	72.36	74.35	75.63	80.26	85.32	83.56	84.35
Texture	75.36	72.36	73.62	77.25	84.36	82.34	81.26	83.28

From Tables VI to IX, it was concluded that classification strategies that integrated feature extraction approaches with values of attributes like sensitivity, specificity, F1 score, and accuracy generated better results. To recognize faces, three approaches were used: assessing the performance of colour, shape, and texture feature extractions separately, then combining (colour and shape), (shape and texture), and (texture and colour), and lastly merging all feature extraction methods (colour, shape, and texture). The fusion of colour, shape, and texture feature extraction methodology produced more accuracy than earlier feature extraction techniques, as seen in Fig. 12 [39]. Accuracy values for the MDC, KNN, SVM, CBR, and ANFIS techniques are 81, 85, 88, 93, and 97, respectively.

The overall performance of several classification algorithms used for facial recognition classification in terms of execution time is shown in Table X and Fig. 13. ANFIS performed faster than the other categorization algorithms in a comparison. Each data set took 36, 34, 35, 32, 34, 33, 34, 31, 32, 34, 35, and 36 seconds to execute in seconds. The total effectiveness of several classification algorithms utilized for face recognition categorization is shown in Table XI and Fig. 14. According to a comparison of classification methods, ANFIS had higher accuracy than all other methods, with 97.67

percent, 97.45 percent, 97.56 percent, 97.54 percent, 97.61 percent, 97.43 percent, 97.36 percent, 97.63 percent, 97.72 percent, 97.68 percent, 97.28 percent, 97.34 percent, 97.52 percent, 97.62 percent, and 97.48 percent. The average number of iteration performance measures employed is shown in Table XII and Fig. 15. According to a comparison of categorization techniques, ANFIS had the lowest average number of iterations of all methods, with 39, 38, 37, 37, 39, 38, 38, 37, 37, 36, 38, 37, 36, 37, 38 and 36 of data sets.

Fig. 15. Performance analysis based on average number of iterations

The overall performance of precision for various classification techniques utilised for the classification of data sets is shown in Table XIII and Fig. 16. According to a comparison of classification methods, ANFIS has higher precision than all other approaches, with precision values for every data set of 97.23%, 97.11%, 97.15%, 97.21%, 97.21%,

97.18%, 97.16%, 97.27%, 97.26%, 97.11%, 97.21%, 97.23%, 97.24%, 97.27%, and 97.28%. The overall recall performance of various classification techniques utilised for classifying data sets is shown in Table XIV and Fig. 17 respectively. Upon comparative analysis of classification methods, ANFIS had higher recall above all other methods that was 96.67%, 96.58%, 96.29%, 96.42%, 96.78%, 96.63%, 96.74%, 96.76%, 96.28%, 96.39%, 96.74%, 96.26%, 96.58%, 96.59%, 96.96% and 96.76% for each data sets.

## V. CONCLUSION

Face Detection is required as a preprocessing procedure in a workflow for a variety of applications such as active presence analysis, recognition, and reidentification. In the past, numerous research in the area of face detection were conducted, and multiple robust methods were suggested and tested on diverse datasets. These approaches are also used in a variety of applications. Despite the fact that this domain appears to be rather old and that considerable work has obviously gone into it, there is still opportunity for development. Previous research has focused on challenges such as face positions, emotions, picture scales, and occlusions, with promising results. Work on advanced topics such as low-resolution pictures, suggested anchoring, scale-invariance of models, and model size reduction has been investigated in recent years, with many solutions given. In this article, we will cover the most recent papers in this field, the difficulties they address, and the technologies they employ. The Adaptive Neuro Fuzzy Inference System (ANFIS) method was designed to overcome this problem. In classification techniques like MDC, KNN, SVM, CBR, ANFIS; The performance of ANFIS resulted in better recognition of face. The proposed research method was compared with the existing methods such as MDC, KNN and SVM which proved to provide better accuracy than the latter. CBR accuracy value were 92% and it is 97% in ANFIS. The performance of proposed system was analysed using the following quality measure like execution time, accuracy, F1 score, precision, recall, iteration and error rate ANFIS resulted in better performance compared to other existing system. The limitation of the proposed system is we were used MATLAB software, it needs more memory space to run this project. In future we will try to implement this project in opensource software's like Open CV.

**Abstract**—Usually, identifying dynamic parameters for robots involves utilizing the Inverse Dynamic Model (IDM) which is linear in relation to the parameters being identified, alongside Linear Least Squares (LLS) methods. To implement this approach, precise measurements of both torque and position must be obtained at a high frequency. Additionally, velocities and accelerations must be estimated by implementing a band-pass filtering technique on the position data. Given the presence of noise in the observation matrix and the closed-loop nature of the identification process, we have modified the Instrumental Variable (IV) method to address the issue of noisy observations. A novel identification technique, named (Direct and Inverse Dynamic Identification Model) DIDIM, which requires only torque measurements as input variables, has recently been successfully applied to a 6-degree-of-freedom industrial robot. DIDIM employs a closed-loop output error approach that utilizes closed-loop simulations of the robot. The experimental results reveal that the IV and DIDIM methods exhibit numerical equivalence. In this paper, we conduct a comparison of these two methods using a double step least squares (2SLS) analysis. We experimentally validate this study using a 2-degree-of-freedom planar robot.

**Keywords**—Identification; double least squares; instrumental variable; DIDIM method; robotics dynamics

## I. INTRODUCTION

The identification process for robots usually relies on the use of the inverse dynamic model and linear least squares methods. To create an overdetermined system, the IDM is sampled during the robot's motion with exciting trajectories. This technique has proven successful in identifying many robots and prototypes [1], [2], [3]. However, it requires precise measurements of joint positions and torques at a high sampling frequency (above 100Hz). Moreover, the identification is done in closed-loop due to the unstable nature of the double integrator, resulting in a noisy observation matrix. Consequently, in theory, the LLS estimator can present a bias [4].

To tackle this problem, we have adjusted the instrumental variable (IV) technique [5], taking inspiration from Hugues Garnier's team's research [6], [7], [8]. Recently, a new identification method was introduced and validated on a 2-degree-of-freedom robot [9]. This approach only requires joint torques as input parameters. The robot is simulated in closed loop, assuming the same control structure and exciting trajectories. The best-fit parameters minimize the squared difference between the simulated and measured torques. Experimental findings indicate that the results from the IV

method match numerically with those from the DIDIM method, indicating a strong connection between the two approaches.

The objective of this paper is to compare the methods using the double least squares technique and to experience the method of DIDIM with IV if it is perfect to our robot or not. The paper is organized as follows: Section II covers the modeling and identification of robots, Section III presents the identified prototype, Section IV explains the IV and DIDIM methods, Section V discusses the double least squares method, and finally, Section VI analyzes the results of the experiments.

## II. MODELING AND IDENTIFICATION OF ROBOTS

### A. Modelisation

The expression for the inverse dynamic model of a robot with  $n$  degrees of freedom is given as [10]:

$$\tau_{idm} = M(\theta)\ddot{\theta} + N(\theta, \dot{\theta}) \quad (1)$$

Where  $\theta$  represents the  $(n \times 1)$  vector of joint positions,  $\dot{\theta}$  and  $\ddot{\theta}$  are its temporal derivatives,  $\tau_{idm}$  denotes the  $(n \times 1)$  vector of joint torques,  $M(\theta)$  stands for the  $(n \times n)$  symmetric inertia matrix, and  $N(\theta, \dot{\theta})$  represents the  $(n \times 1)$  vector that combines centrifugal, Coriolis, gravitational, and friction forces. By employing the modified Denavit and Hartenberg geometric description (DHM), we can derive a linear inverse dynamic model in terms of standard dynamic parameters [10]:

$$\tau_{idm} = IDM_{STD}(\theta, \dot{\theta}, \ddot{\theta})\chi_{STD} \quad (2)$$

$IDM_{STD}(\theta, \dot{\theta}, \ddot{\theta})$  represents the standard linear regressor of size  $(n \times c)$ , where  $\chi_{STD}$  is the  $c \times 1$  column vector of standard dynamic parameters. These parameters include the inertia tensor coefficients  $XX_j, XY_j, XZ_j, YY_j, YZ_j, ZZ_j$  of body  $^j J_j$ , its mass denoted  $m_j$ , the first moment vector around the origin of body  $j$  denoted  $^j M_j, = [MX_j MY_j MZ_j]$ , the Coulomb and viscous friction parameters denoted respectively as  $Fs_j$  and  $Fv_j$ , and the actuator inertia  $Ia_j$ .

One crucial stage in the identification process is to identify the basic parameters. This is because some standard parameters combine in the inverse dynamic model's expression, and only their combination or grouping can be identified. The search for basic parameters involves determining the rank of  $IDM_{STD}$  and identifying linear combinations among its columns. Two

primary methods can be used to calculate the minimum inertial parameters: a literal method that involves energy calculations [10] and a numerical method based on QR decomposition [11].

The general relation for the minimal system is as follows:

$$\tau_{idm} = IDM(\theta, \dot{\theta}, \ddot{\theta})\chi \quad (3)$$

**IDM** ( $\theta, \dot{\theta}, \ddot{\theta}$ ) is the minimal linear regressor of dimension  $n \times b$ , where  $\chi$  is the column vector of base parameters of dimension  $(b \times 1)$ . However, due to noise and model errors, the actual torque  $\tau$  deviates from  $\tau_{idm}$  and can be expressed as:

$$\tau = \tau_{idm} + e = IDM(\theta, \dot{\theta}, \ddot{\theta})\chi + e \quad (4)$$

### B. Identification

The inverse dynamic model is sampled while the robot is being actuated to obtain an overdetermined system, which can be expressed as [12]:

$$Y(\tau) = W(\theta, \dot{\theta}, \ddot{\theta})\chi + \rho \quad (5)$$

$$\text{Or: } Y(\tau) = \left[ \begin{matrix} (Y^1(\tau))^T \\ \dots \\ (Y^n(\tau))^T \end{matrix} \right]^T, \mathbf{Y}^j(\tau) = \left[ \tau^j(1) \dots \tau^j(n_e) \right]^T$$

$$W(\theta, \dot{\theta}, \ddot{\theta}) = \begin{bmatrix} \mathbf{W}^1 \\ \dots \\ \mathbf{W}^n \end{bmatrix}, \mathbf{W}^j = \begin{bmatrix} \text{IDM}^j(\theta_1, \dot{\theta}_2, \ddot{\theta}_3) \\ \dots \\ \text{IDM}^j(\theta_{n_e}, \dot{\theta}_{n_e}, \ddot{\theta}_{n_e}) \end{bmatrix}$$

$Y(\tau)$  is the measurement vector with a dimension of  $(r \times 1)$ , and  $W$  is the observation matrix with a dimension of  $(r \times b)$ , where  $r = n_e \times n$ , and  $n_e$  is the number of recovered samples.

The estimation theory provides a broad range of methods. Classical methods can be employed to solve overdetermined systems, as long as the elements of  $W$  are handled appropriately to obtain good results.

$$\hat{\chi} = \min_{\hat{\chi}} \|\rho\|^2 \quad (6)$$

Since we are considering both base parameters and exciting trajectories,  $W$  has a maximum rank, leading to an explicit and unique solution for  $\hat{\chi}$ .

$$\hat{\chi} = \left( (W^T W)^{-1} W^T \right) Y = W^+ Y \quad (7)$$

In practice, the identified values are estimated with their standard deviation by assuming that  $W$  is deterministic and that  $\rho$  is a centered random vector with independent components, standard deviation  $\sigma_\rho$ , and covariance matrix  $C_\rho$  given by:

$$C_\rho = E(\rho\rho^T) = \sigma_\rho^2 I_r \quad (8)$$

where,  $I_r$  is the  $r$ -dimensional identity matrix. Assuming that the error vector is centered and has independent components with equal variances, the standard deviation  $\sigma_\rho$  can be calculated using the following unbiased estimator:

$$\sigma_\rho^2 = \|Y - W\hat{\chi}\|^2 / (r - b) \quad (9)$$

The expression for the covariance matrix of the estimation error is:

$$C_{\hat{\chi}} = \sigma_\rho^2 (W^T W)^{-1} \quad (10)$$

We deduce the standard deviation:

$$\sigma_{\hat{\chi}_j} = \sqrt{C_{\hat{\chi}}(\mathbf{j}, \mathbf{j})} \quad (11)$$

The relative standard deviation is estimated by:

$$\sigma_{\hat{\chi}_{j\%}} = 100 \sigma_{\hat{\chi}_j} / |\hat{\chi}_j| \quad (12)$$

While [13] has used this interpretation, it should be approached with caution in our case as the assumption of a deterministic  $W$  is not satisfied. The proposed model is not perfect, and the measurements are noisy, requiring preprocessing.

Although this criterion can be used to evaluate the quality of identification, the fact that  $W$  is not deterministic, and the experimental data is noisy poses a challenge. To overcome this, [13] suggests filtering both  $Y$  and the columns of  $W$ .

### C. Conclusion

The LLS approach is particularly advantageous because it avoids the need to integrate a differential system and eliminates issues with initial conditions. However, calculating velocities and accelerations via bandpass filtering of position is required. Lastly, the direct dynamic model (DDM) provided below must be validated through post-simulation.

$$M(\theta)\ddot{\theta} = \tau - N(\theta, \dot{\theta}) \quad (13)$$

Given that  $M(q)$  is a positive definite square matrix, the accelerations can be expressed as:

$$\ddot{\theta} = M^{-1}(\theta)(\tau - N(\theta, \dot{\theta})) \quad (14)$$

## III. METHOD IV AND DIDIM

### A. Method IV

The statistical assumptions necessary for the LLS estimator to work efficiently are not met in practical applications. Equation (5) involves constructing the observation matrix  $W$  using joint positions  $\theta$ , as well as numerically computed derivatives  $\dot{\theta}$  and  $\ddot{\theta}$ , making  $W$  noisy. Additionally, the identification process is performed in a closed loop, further violating the assumptions. As a result, the LLS estimator may be inconsistent.

The IV method addresses this issue [5]. By constructing an instrumental matrix  $V$ , the IV method proposes a consistent estimator that satisfies:

$$V^T Y = V^T W_{\hat{\chi}} + V^T \rho_{iv} = V^T W \hat{\chi}_{iv} \quad (15)$$

The solution in the sense of the instrumental variable is:

$$\hat{\chi}_{iv} = (V^T W)^{-1} V^T Y \quad (16)$$

Later on,  $V$  is computed as a function of  $\hat{\chi}^k$  (since only the IV method is discussed in this subsection, we use  $\hat{\chi}^k$  instead of  $\hat{\chi}_{iv}^k$  as there is no ambiguity). This defines an iterative procedure as follows:

$$\hat{\chi}^{k+1} = (V_k^T W)^{-1} V_k^T Y \quad (17)$$

where,

$$V_k = V(\hat{\chi}^k) \quad (18)$$

Given that  $V_k^T W$  matrix is invertible, the following assumptions are made:

$$\lim_{m \rightarrow \infty} (V_k^T W / m) \quad (19)$$

$$\lim_{m \rightarrow \infty} (V_k^T \rho_{iv} / m) = E(V_k^T \rho_{iv}) \quad (20)$$

Each value of  $\hat{\chi}^k$  converges to  $\chi$  with  $m$ , where  $m$  denotes the number of repetitions of  $W$  and  $\rho_{iv}$ .

One of the primary challenges is to determine an instrumental matrix  $V$ . One possible solution involves constructing an observation matrix using simulated data rather than measured data. These simulated data, known as instruments, are the outputs of an auxiliary system that approximates the noise-free model of the system to be identified [6][8]. In robotics, this auxiliary model is the robot's DDM, given by equation (13) [14]. The IV method adapted for identifying a robot's dynamics can be outlined by the following algorithm, as illustrated in Fig. 1:

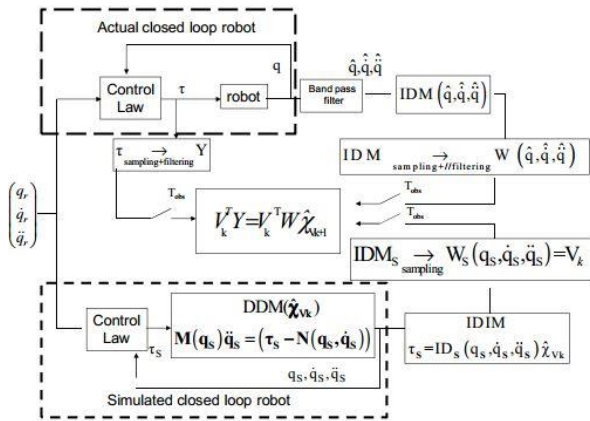

Fig. 1. Instrumental variable procedure.

\*During each iteration,  $\theta_s$ ,  $\dot{\theta}_s$ , and  $\ddot{\theta}_s$  are calculated by simulating and integrating the robot's DDM with the parameters identified in the previous iteration. The same control structure and exciting trajectories used for the real robot are applied.  $W_s$  is obtained by sampling  $IDM(\theta_s, \dot{\theta}_s, \ddot{\theta}_s)$ , and the instrumental matrix is selected as follows:

$$V(\hat{\chi}^k) = W_s(\theta_s(\hat{\chi}^k), \dot{\theta}_s(\hat{\chi}^k), \ddot{\theta}_s(\hat{\chi}^k)) \quad (21)$$

\* $Y(\tau)$  and  $W(\theta, \dot{\theta}, \ddot{\theta})$  they are constructed as in (5).

\*  $\hat{\chi}^{k+1}$  is given by (17). The algorithm stops when the relative errors become negligible:

$$\left( \frac{\|\rho_{iv}^{k+1}\| - \|\rho_{iv}^k\|}{\|\rho_{iv}^k\|} \right) \leq tol_1 \quad (22)$$

$$\max_{1, \dots, b} \left| \frac{\hat{\chi}^{k+1} - \hat{\chi}^k}{\hat{\chi}^k} \right| \leq tol_2 \quad (23)$$

Where  $tol_1$  is an ideally small value set by the user. Typically, there is a trade-off between accuracy and convergence speed.

It has been demonstrated in [15][16] that applying a filter  $F(s)$  to the columns of  $V$  is not mandatory. However, to reduce the sizes of  $Y$ ,  $W$ , and  $V$ , we use a sub-sampling filter and isolate the frequency range of interest. Typically, the cutoff frequency of this filter is set to 10 times the closed-loop system's bandwidth value to achieve a balance between precision and convergence speed.

### B. DIDIM Method

DIDIM is a closed-loop output error (CLOE) identification method that does not require position measurement [9]. The output  $y = \tau$  is the actual torque  $\tau$ . The simulated output  $y_s = \tau_{ddm}$  is the simulated torque of the DDM given by (13).

The signal  $\theta_{ddm}(t, \chi)$  is the result of integrating the DDM. The optimal solution  $\hat{\chi}$  minimizes the quadratic criterion  $J(\chi) = \|Y_s - Y\|^2$ . The vectors  $Y(\tau)$  and  $Y_s = Y(\tau_{ddm})$  are obtained by sampling the vectors  $\tau$  and  $\tau_{ddm}$  respectively.

The solution to this nonlinear problem is obtained through the application of Gauss-Newton regression. This approach relies on a Taylor series expansion of  $y_s$  around the current estimate of parameters at time  $k$ , represented by  $\hat{\chi}^k$  (given that this subsection only pertains to the DIDIM method, we use the notation  $\hat{\chi}^k$  instead of  $\hat{\chi}_{didim}^k$  for clarity):

$$y_s(\chi^{k+1}) = y_s(\chi^k) + \left( \frac{\partial(y_s(\chi))}{\partial \chi} \right)_{\chi^k} (\chi^{k+1} - \chi^k) + o \quad (24)$$

Where  $\left( \frac{\partial(y_s(\chi))}{\partial \chi} \right)_{\chi^k}$  is the Jacobian matrix of dimension  $(n \times b)$ . The MDD input torque  $\tau_{ddm}$  can be calculated analytically with the MDI expression (3) such that:

$$y_s(\chi) = \tau_{ddm}(\chi) = \tau_{idm}(\chi) = IDM(\theta_{ddm}(\chi), \dot{\theta}_{ddm}(\chi), \ddot{\theta}_{ddm}(\chi)) \chi \quad (25)$$

In this case, the Jacobian matrix is given by:

$$\begin{aligned} \left( \frac{\partial(y_s)}{\partial \chi} \right)_{\chi^k} &= \left( \frac{\partial(\tau_{ddm})}{\partial \chi} \right)_{\chi^k} = \left( \frac{\partial(\tau_{idm})}{\partial \chi} \right)_{\chi^k} \\ &= \frac{\partial}{\partial \chi} \left( IDM(\theta_{ddm}(\hat{\chi}^k), \dot{\theta}_{ddm}(\hat{\chi}^k), \ddot{\theta}_{ddm}(\hat{\chi}^k)) \hat{\chi}^k \right) \end{aligned} \quad (26)$$

As we use the same control for both the simulation and the real robot, the simulated states (positions, velocities, and accelerations) are minimally dependent on  $\chi$ . At each  $\hat{\chi}^k$  value, the Jacobian matrix (26) can be approximated as:

$$\left(\frac{\partial(y_s)}{\partial\chi}\right)_{\hat{\chi}^k} = IDM(\theta_{ddm}(\hat{\chi}^k), \dot{\theta}_{ddm}(\hat{\chi}^k), \ddot{\theta}_{ddm}(\hat{\chi}^k)) \quad (27)$$

Taking into account (27), the Taylor expansion becomes:

$$y = \tau = IDM(\theta_{ddm}(\hat{\chi}^k), \dot{\theta}_{ddm}(\hat{\chi}^k), \ddot{\theta}_{ddm}(\hat{\chi}^k))\chi^{k+1} + (o + e) \quad (28)$$

The MDI (3) estimates the states  $(\theta, \dot{\theta}, \ddot{\theta})$  using  $(\theta_{ddm}, \dot{\theta}_{ddm}, \ddot{\theta}_{ddm})$  obtained by simulating and integrating (13). At each iteration  $k$ , we sample (28) to obtain an over-determined linear system given by:

$$Y = W_{ddm}(\theta_{ddm}(\hat{\chi}^k), \dot{\theta}_{ddm}(\hat{\chi}^k), \ddot{\theta}_{ddm}(\hat{\chi}^k))\chi^{k+1} + \rho_{didim} \quad (29)$$

The MCLs are then applied to obtain the estimate at  $k+1$  denoted  $\hat{\chi}^{k+1}$ .

$$\hat{\chi}^{k+1} = (W_{ddm}^T W_{ddm})^{-1} W_{ddm}^T Y \quad (30)$$

This algorithm is iterated until:

$$\left(\|\rho_{didim}^{k+1}\| - \|\rho_{didim}^k\|\right) / \|\rho_{didim}^k\| \leq tol_1 \quad (31)$$

$$\max_{1 \dots b} \left| \left( \hat{\chi}^{k+1} - \hat{\chi}^k \right) / \hat{\chi}^k \right| \leq tol_2 \quad (32)$$

Where  $tol_1$  is an ideally small value set by the user. Generally, a compromise is made between accuracy and speed of convergence.

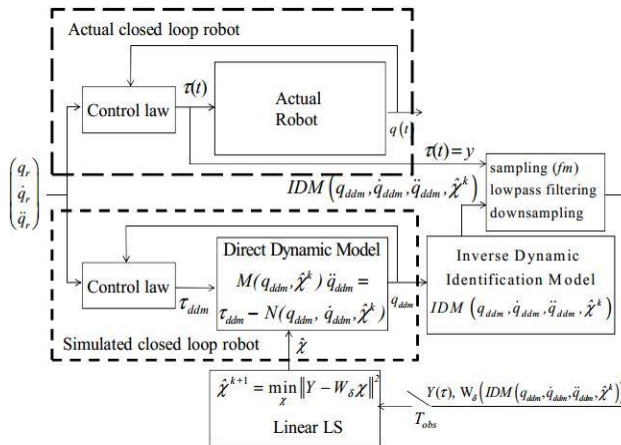

Fig. 2. Procedure of the DIDIM method.

The DIDIM method is named after its use of both direct and inverse dynamic models. As shown in Fig. 2, this approach combines these models to achieve dynamic identification.

### C. MDD Simulation and Integration

According to [8], the instrumental matrix must be close to the  $W_{nf}$  matrix defined by:

$$W_{nf} = W(\theta_{nf}, \dot{\theta}_{nf}, \ddot{\theta}_{nf}) \quad (33)$$

where,  $\theta_{nf}, \dot{\theta}_{nf}, \ddot{\theta}_{nf}$  are the noiseless values of  $\theta, \dot{\theta}, \ddot{\theta}$ .

Assuming model errors are negligible, it is necessary to have a well-tuned control loop that keeps  $\theta_{nf}, \dot{\theta}_{nf}$  and  $\ddot{\theta}_{nf}$  close to the reference states  $\theta_r, \dot{\theta}_r$  and  $\ddot{\theta}_r$ . According to (33), the simulated states  $\theta_s, \dot{\theta}_s$  and  $\ddot{\theta}_s$  must remain close to  $\theta_r, \dot{\theta}_r$  and  $\ddot{\theta}_r$  at every iteration of the algorithm. To achieve this, we use the same control structure for simulation as we do for the robot and adjust the control gains at each iteration to maintain the closed-loop bandwidth. This ensures that the bandwidth remains constant, regardless of the estimate  $\hat{\chi}^k$ . Therefore, we obtain:

$$(\theta_{nf}, \dot{\theta}_{nf}, \ddot{\theta}_{nf}) = (\theta_s, \dot{\theta}_s, \ddot{\theta}_s) = (\theta_r, \dot{\theta}_r, \ddot{\theta}_r) \forall \hat{\chi}_{iv}^k \quad (34)$$

Adapting the control gains at each iteration in the simulator allows us to ensure the approximation (27). Thus, (34) becomes:

$$(\theta_{nf}, \dot{\theta}_{nf}, \ddot{\theta}_{nf}) = (\theta_{ddm}, \dot{\theta}_{ddm}, \ddot{\theta}_{ddm}) = (\theta_r, \dot{\theta}_r, \ddot{\theta}_r) \forall \hat{\chi}_{didim}^k \quad (35)$$

This relation allows us to write that we have:

$$(\theta_{ddm}, \dot{\theta}_{ddm}, \ddot{\theta}_{ddm}) = (\theta_s, \dot{\theta}_s, \ddot{\theta}_s) \forall \hat{\chi}_{iv}^k \text{ and } \forall \hat{\chi}_{didim}^k \quad (36)$$

We arrive at the following results: the matrix  $W_{ddm}$  is precisely our instrumental matrix  $V$ , and (30) can be expressed in this way as well:

$$\hat{\chi}_{didim}^k = (V_k^T V_k)^{-1} V_k^T Y \quad (37)$$

The article does not provide an explanation of gain modulation at each iteration as it is beyond the scope of the paper. A brief overview can be found in [15],[16].

### D. Initialization of Algorithms

There are multiple methods to initialize the algorithm, such as using the CAD values or the identified LS values. However, since we ensure (34) and (35) in simulation, the easiest approach is to set  $\hat{Z}_{j0}$  and the other parameters to 0, which is called regular initialization [9]. This method results in an invertible initial mass matrix.

## IV. PROTOTYPE TO IDENTIFY AND RESULTS

We employ the IV and DIDIM methods on a two-degree-of-freedom planar robot depicted in Fig. 3, utilizing the modified Denavit-Hartenberg notation for geometric representation. The robot operates without a reducer (direct drive) and is actuated using DC motors. The inverse dynamic model is dependent on 8 minimal parameters  $\chi = [ZZ_{1R} \text{fv}_1 \text{fs}_1 \text{ZZ}_2 \text{MX}_2 \text{MY}_2 \text{fv}_2 \text{fs}_2]^T$ . Position control of the robot is achieved through a PD controller, with a closed-loop bandwidth of 2Hz, and an acquisition frequency of 200Hz. The torque is obtained from the current reference  $v_{ir}$ , with the current loop having a broad bandwidth (1KHz):

$$\tau_j = g t_j v_{irj} \quad (38)$$

$g t_j$  being the  $j$ -axis actuation gain.

Fig. 3. Prototype 2 DDL plan to identify.

Experimental application of the IV and DIDIM methods is carried out on the 2-degree-of-freedom planar prototype. In the IV method, the current command image and the position of each motor are measured, while only the current command image of each motor is measured in the DIDIM method.

In both methods, the columns of  $V$  are filtered using an under-sampling filter with a cutoff frequency of 20Hz, as the closed-loop bandwidth is 2Hz. All information regarding the rigid model is preserved, and the MATLAB decimate command is utilized for filter implementation.

Both methods use identical exciting trajectories and control structures as those used on the actual robot for simulation. The control gains are adjusted for every iteration.

In the case of the IV method, a fourth-order bidirectional Butterworth filter is used to filter the position, with a cutoff frequency of 20Hz. The velocity and acceleration are obtained through a centered difference calculation, ensuring that there is no phase distortion. Lastly, each column of  $W$  is filtered using the same under sampling filter as that used for filtering the columns of  $V$ .

Both methods are initialized with regular initialization. The simulation and MDD integration are carried out on the same MATLAB-SIMULINK platform for both methods. The platform is run on a laptop equipped with an INTEL Pentium 4 single-core processor operating on WINDOWS XP. Each iteration, which includes MDD integration and optimal solution calculation, takes approximately thirty seconds.

The experimental results are reported in Table I for the IV method and in Table II for the DIDIM method. Table III shows the convergence of the parameters, with both algorithms converging in just three iterations.

The key finding is that the IV method provides the same numerical estimation as the DIDIM method. The only difference is in the values of the parameters  $F_{v1}$  and  $F_{v2}$ , which have minimal impact on the robot's dynamics. As these parameters have a high relative standard deviation, their removal from the model results in little variation in the identified values of the other parameters and the residual norm.

From these experimental results, we can conclude that numerically  $\hat{\chi}_{IV} = \hat{\chi}_{DIDIM}$ . This can be explained by the following intuitive reasoning: the instruments are constructed from a simulation and integration of the MDD. Therefore, if the instruments are representative of the model to be identified,

then we can assume that  $W = V + w$  where  $w$  is a noise matrix of dimension  $(r \times b)$ . Furthermore, if each column of  $w$  denoted by  $w_k$  is orthogonal to the space spanned by the columns of  $V$ , then we have  $V^T w = \text{zeros}(b, b)$ . With these conditions, we do indeed obtain  $\hat{\chi}_{IV} = \hat{\chi}_{DIDIM}$ .

The next section will present the method of least squares, which we will use to prove this statement.

## V. DOUBLE LEAST SQUARES METHOD

### A. General Idea

As stated in [4], Theil introduced the method of two-stage least squares in 1953, and independently, Basman also introduced it in 1957 for simultaneous equation modeling. The Two-Stage Least Squares (2SLS) approach involves estimation in two stages:

- During the first stage, we carry out a regression of each column of  $W$ , denoted by  $W_{:,k}$ , on  $V$ , to separate the part of  $W_{:,k}$  that is correlated with  $\rho$  from the part that is correlated with the model. This leads to an estimation of  $W_{:,k}$ , denoted by  $\hat{W}_{:,k}$ . By concatenating the estimated columns  $\hat{W}_{:,k}$ , we obtain an estimate of the matrix  $W$ , denoted by  $\hat{W}$ .

- To perform the second stage, we regress  $Y$  on  $\hat{W}$ . Thus, we obtain the following general solution:

$$\hat{\chi}_{2SLS} = (\hat{W}^T \hat{W})^{-1} \hat{W}^T Y \quad (39)$$

This is the 2SLS solution.

### B. Implementation

Typically, when using 2SLS, the first regression stage for each column of  $W$  is defined as follows:

$$W_{:,k} = V \Pi_k + w_k \quad (40)$$

Where  $\Pi_k$  is a coefficient vector of dimension  $(b \times 1)$  and where  $w_k$  is a noise vector of dimension  $(r \times 1)$ . We obtain the estimate of each column  $W_{:,k}$  as:

$$\hat{W}_{:,k} = V \hat{\Pi}_k \quad (41)$$

After performing this regression for each column of  $W$  and concatenating the estimated columns, we obtain a matrix equation in the form:

$$\hat{W} = V \hat{\Pi} \quad (42)$$

Where  $\hat{\Pi} = [\hat{\Pi}_1 \dots \hat{\Pi}_k \dots \hat{\Pi}_b]$  is a matrix of constant coefficients of dimension  $(b \times b)$ . This relationship also involves:

$$W = \hat{W} + w = V \hat{\Pi} + w \quad (43)$$

The second step is the regression of  $Y$  on  $\hat{W}$ . We have:

$$\hat{W} = V \hat{\Pi} = V(V^T V)^{-1} V^T W \quad (44)$$

By incorporating this relation into (39) and assuming that relation (19) holds, we obtain:

$$\hat{\chi}_{2SLS} = (V^T W)^{-1} V^T Y \quad (45)$$

$$\hat{\chi}_{2SLS} = \hat{\chi}_{IV} \quad (46)$$

Therefore, the 2SLS solution is equivalent to the instrumental variable solution.

### C. Using 2SLS to Compare IV and DIDIM

Using the 2SLS algorithm to identify the dynamic parameters of robots is feasible, given our knowledge on constructing the instrumental matrix  $V$ . However, our objective is to establish a link between the IV method and the DIDIM method.

By utilizing 2SLS, we can examine the projection of each column  $W_{:,k}$  of  $W$  (and thus,  $W$  as a whole) onto the space formed by the columns of  $V$ . Equation (44) denotes the orthogonal projection of each column  $W_{:,k}$  onto the space generated by the columns of  $V$ . To conduct the first regression of each column  $W_{:,k}$  on  $V$ , we express it as follows:

$$W_{:,k} = (\text{ones}(r,1) V) \Pi_k + w_k \quad (47)$$

Where

$$V = [V_{:,1} \dots V_{:,b}] \quad (48)$$

$$\Pi_k = [\pi_{0,k} \pi_{1,k} \dots \pi_{b,k}]^T$$

An offset term denoted as  $\pi_{0,k}$  is deliberately introduced to estimate the average value of the residual  $w_k$ . The estimated value of this term, denoted as  $\hat{\pi}_{0,k}$ , is expected to be zero in theory.

Once we have obtained the estimates, we can interpret the results as follows:

$$\hat{\pi}_{j,k} = 1 \quad \text{pour } j=k \quad (49)$$

$$\hat{\pi}_{j,k} = 0 \quad \text{pour } j \neq k \quad (50)$$

In terms of physicality, this indicates that the instruments are reliable (i.e., adequately reflecting the model to be identified) and that we have effectively separated the portion of  $W_{:,k}$  that correlates with  $\rho$  and the portion that corresponds to the model. Through concatenation, we achieve:

$$\hat{W} = [\text{ones}(r,1) V] \hat{\Pi} \quad (51)$$

With:

$$\hat{\Pi} = \begin{bmatrix} \text{zeros}(1,b) \\ I_{b,b} \end{bmatrix} \quad (52)$$

$I_{b,b}$  represents the identity matrix with dimensions  $(b \times b)$ . Now, let's delve into the details of this relationship:

$$\hat{W} = \text{zeros}(r,b) + V I_{b,b} = V \quad (53)$$

So, with (39) we get:

$$\hat{\chi}_{2SLS} = (V^T V)^{-1} V^T Y = \hat{\chi}_{\text{didim}} \quad (54)$$

Or, according to (46):

$$\hat{\chi}_{2SLS} = \hat{\chi}_{iv} = \hat{\chi}_{\text{didim}} \quad (55)$$

Another way to arrive at this result is by expressing that we have, using equations (43) and (53):

$$W = V + w \quad (56)$$

Alternatively, using geometric construction, we can establish that every residual  $w_k$  is perpendicular to the subspace formed by the columns of  $V$  (normal equation). Consequently, this leads to the following implication:

$$V^T w = \text{zeros}(b,b) \quad (57)$$

So by incorporating (56), (57) into (16), we get:

$$\hat{\chi}_{iv} = (V^T V)^{-1} V^T Y \quad (58)$$

And we find well (55).

D. Conclusion

Through the utilization of 2SLS, we have established that the solution yielded by the IV method is equivalent to the solution obtained through DIDIM, given that relations (49) and (50) are upheld. These two relationships hold great significance as they imply the following physical interpretations:

- The instruments demonstrate high quality, effectively capturing the essence of the physical model under consideration. This has allowed us to successfully separate the component of W that correlates with the model from the component that correlates with  $\rho$ .
- Moreover, the model error remains significantly minimal in comparison to other sources of noise.

During the experimental phase, we conduct the dual regression at every iteration of the IV method. Furthermore, we specify the necessary conditions to ensure the continuous validation of both relationships (49) and (50).

VI. EXPERIMENTAL RESULTS AND ANALYSIS

The experimental trials are carried out using identical conditions as outlined in Section IV. The dual regression is executed for every iteration and each column of W. The resulting estimated vectors  $\hat{\Pi}_k$  are stored in an array for subsequent analysis of the estimations.

The determined coefficient values for each  $\hat{\Pi}_k$  at every iteration are consolidated in Table IV. To improve clarity, the results for each column are presented individually, Tables IV to XI.

$\pi_{7,8}$	0.002	0.001	-0.002	0.001
$\pi_{8,8}$	1.0	1.0	1.0	1.0

The estimated values obtained through 2SLS are identical to those presented in Table I and Table II. Based on these experimental findings, we can conclude that it is possible to

write  $\hat{\Pi} = \begin{bmatrix} \text{zeros}(1,b) \\ I_{b,b} \end{bmatrix}$  for each iteration. This suggests that relations (49) and (50) are practically fulfilled. Consequently, we have effectively confirmed through experimentation that we have  $\hat{\chi}_{iv} = \hat{\chi}_{didim}$ .

The slight discrepancies we observe could be attributed to minor modeling errors.

The crucial aspect of this analysis revolves around relations (36), (49), and (50). Essentially, these relations indicate that we can treat the states simulated by the IV method and the DIDIM method as interchangeable, and that column  $W_{:,k}$  projects orthogonally onto its counterpart  $V_{:,k}$ . Importantly,  $W_{:,k}$  is not derived from a linear combination of multiple columns of  $V$ , which could potentially be the case in an absolute sense. As a result, we effectively differentiate the component of  $W_{:,k}$  that is correlated with the model from the component correlated with  $\rho$ . The strong adherence of relations (49) and (50) primarily arises from the careful adjustment of control gains during each iteration in the simulation, aiming to ensure that  $(\theta_s, \dot{\theta}_s, \ddot{\theta}_s) = (\theta_{ddm}, \dot{\theta}_{ddm}, \ddot{\theta}_{ddm}) = (\theta_{nf}, \dot{\theta}_{nf}, \ddot{\theta}_{nf})$  closely approximates  $(\theta_r, \dot{\theta}_r, \ddot{\theta}_r)$ , while keeping modeling errors at a minimum. Experiments were conducted with significant modeling errors. For example, we intentionally omitted the term  $LMX_2$  from the model. As a result, both methods converge to an inaccurate solution. Consequently, relations (49) and (50) are no longer fulfilled. This serves as evidence that our projections are flawed because

$Y$  is being regressed on a subspace that no longer accurately represents the model.

### A. The Parameters Used

To overcome these issues, an alternative identification approach is proposed. This method relies on a closed-loop simulation, where the direct dynamic model is used with the same control law and reference trajectories as those applied to the real robot. The parameters obtained through this identification method are determined by minimizing the 2-norm of the error between the measured torque and the simulated torque. This results in a nonlinear least squares problem. The analytical expression of the sensitivity functions is greatly simplified by using the inverse model to express the simulated torque, which greatly facilitates the calculation of the solution.

In the robot identification procedure, the inverse dynamic model (IDM) and the linear least squares (LLS) method are commonly used. To create an overdetermined system, the IDM is sampled during the robot's motion using stimulating trajectories. This approach has proven to be effective in identifying numerous robots and prototypes [17], [20], [3].

However, it requires accurate measurements of joint positions and torques at a high sampling frequency (greater than 100 Hz). Furthermore, the identification is performed in a closed loop due to the inherent instability of the double integrator, resulting in a noisy observation matrix. Consequently, in theory, the linear least squares estimator may exhibit bias [19].

To address this issue, we have adapted the instrumental variables (IV) technique, building upon the research work conducted by Hugues Garnier's team [6], [9], [8]. Recently, a new identification method has been proposed and validated on a two-degree-of-freedom robot [18]. This approach only requires the joint torques as input parameters. The robot is simulated in a closed loop, assuming the same control structure and stimulating trajectories.

The optimal parameters are determined by minimizing the squared difference between the simulated and measured torques. Experimental results demonstrate a significant correlation between the outcomes obtained using the instrumental variables (IV) method and those of the DIDIM method, indicating a strong agreement between these two approaches.

## VII. CONCLUSION

This paper presents a comparative analysis of the IV and DIDIM methods using 2SLS. The theoretical framework is substantiated by experimental findings. The results of this study demonstrate that under specific conditions, we achieve a numerical equality of  $\hat{\chi}_{iv} = \hat{\chi}_{didim}$ .

From our standpoint, this outcome holds significance as it indicates that the IV method, as employed in robot identification and widely used in various applications, tends to converge towards the model-based approach. This observation provides a possible explanation for the IV method's resilience to assumptions made about noise. However, it would be overly

simplistic, and possibly incorrect, to equate the IV method with the model-based method. The outcome relies on the construction of our instruments and how they are implemented.

In the end, 2SLS could serve as a diagnostic tool, enabling us to examine the projection of each regressor column onto the space formed by the instrumental matrix columns. The MDI and DIDIM methods will be implemented on cable-driven parallel structure interfaces, such as the VIRTUOSE robots developed by HAPTION; also, will explore other methods for robot enhancement.

**Abstract**—Oftentimes, many people or even medical workers misdiagnose skin cancer, which may lead to malpractice and thus, resulting in delayed recovery or life-threatening complications. In this research, a Graph Convolutional Network (GCN) method is proposed as a classification model and Delaunay triangulation as its feature extraction method to classify various types of skin cancers. Delaunay triangulation serves the purpose of boundary extraction, and this implementation allows the model to focus only on the cancerous lesion and ignore the skin around it. This way, the types of skin cancer can be predicted more accurately. Furthermore, GCN offers many advantages in medical image analysis over traditional CNN models. GCN can model interactions between different regions and structures in an image and perform messaging between nodes, whereas CNN is not explicitly designed to do such thing. Other than that, GCN can also leverage transfer learning and few-shot learning techniques to address the challenges of limited annotated medical image datasets. However, the result shows that the proposed model tends to overfit and is unable to generate correct predictions for new skin cancer images. There are several reasons that could lead the model to overfit, such as imbalance data, incorrect feature extraction, insufficient features for data prediction, or the data containing noise.

**Keywords**—Skin cancer; Delaunay triangulation; graph convolutional network; GCN; multilabel image classification; convolutional neural network; CNN

## I. INTRODUCTION

Skin cancer is the most prevalent form of cancer for people with white or light-colored skin all over the world. Exposure to ultraviolet radiation (UVR) is a primary etiologic agent in the emergence of skin cancer, which may result in DNA damage and genetic abnormalities, subsequently leading to skin cancer [1]. In general, skin cancers are classified as melanoma or non-melanoma. Skin cancer, which includes both melanoma and non-melanoma, are the particularly prevalent form of cancer malignancies in the white population. However, the one responsible for the majority of deaths caused by cancer is melanoma skin cancer [2].

Melanoma screening is not suggested as a population screening tool for wide range of reasons. This is because the effectiveness of early detection or screening programs has not yet been tested in randomized trials [3]. Although the majority of at-risk patients attend medical appointments or even a doctor's appointment that offers the option of skin testing in melanoma detection, only a few medical practitioners have specialized knowledge or training in melanoma detection. In

the study published by Annals of Oncology, researches compared the performance of 58 international dermatologists and found CNN's skin cancer diagnoses to be more accurate than diagnoses made by a panel of dermatologists. [4].

Considering that not many non-dermatologist healthcare workers and dermatologists could correctly identify melanomas, it could harm patients with skin cancer. Not knowing that one has skin cancer, patients would carry on with their lives and consider it as a normal mole, little that they know that it is a skin cancer. Ignoring the first signs of skin cancer would let the cancer grow malignant, and eventually will harm the patients. Even when healthcare workers successfully diagnose a patient with skin cancer, there are still possibilities of human error such as misdiagnosing skin cancer type (melanoma or non-melanoma, malignant or benign) which could further harm the patients through medical malpractice, namely giving the inappropriate treatment which would result in delayed recovery, and negative medical outcomes (additional pains or even other non-life threatening and life-threatening complications).

Misdiagnosis and malpractice only harm patients in a way that is very dangerous for that person and even would cost a person's life. Considering that these issues happened in real life and could even happen to ourselves, this study strives to help medical workers and patients overcome these issues. With the help of current technology, it will aid medical personnel in identifying both malignant and benign melanoma skin cancers, as well as skin cancers that are not melanoma related. Time and effort are required to gain experiences. Medical professionals have spent years researching and treating patients in a manner that only they can. Several researches have proven that modern technology outperforms medical professionals in terms of knowledge. In some cases, if not all, a doctor's opinion is needed rather than relying solely on technology. Additionally, technology can be used as a tool to substantiate medical opinion with expert advice [5].

Several research projects on the automated classification of melanoma imagery utilizing computer vision and machine learning algorithms have been carried out. Despite the fact that these researches show promising outcomes, the application of computer vision and traditional machine learning has a significant impact on classification performance through features identified in skin lesion segmentation results and classification methods [5]. This study proposes the fusion of Delaunay triangulation and graph convolutional network (GCN) as a method to classify images of skin cancer types.

The use of deep learning hoped to reduce human intervention and improve accuracy.

Both methods used were hoped to give better results in classifying skin cancer. Delaunay triangulation is used to segment cancer from the skin or to extract masks from lesion regions without requiring a training phase so that the neural network can better classify the type of skin cancer. Whilst convolutional neural network (CNN) has emerged as the most advanced network for pattern identification in medical image analysis, it is not without limitations [6], graph convolutional network (GCN) can handle irregular and non-grid data. Many real-world applications, such as social analytics, identifying fraudulent activity, traffic forecasts, computer vision, and others, generate graphs naturally. Data can be shown as graphs that encode structural details to represent relationships between items and provide more interesting insights underlying the data [7].

The data used in this study are skin cancer images obtained from the Kaggle website. The images are then resized and go through further data preprocessing steps. Skin cancer mask points were then generated using the Delaunay triangulation method. The obtained points were stored in an array and used in the modeling step using the GCN model. Delaunay triangulation serves the purpose of boundary extraction, and this implementation allows the model to focus only on the cancerous lesion and ignore the skin around it. Furthermore, GCN offers many advantages in medical image analysis over using traditional CNN models. GCN can model interactions between different regions and structures in an image and perform messaging between nodes. Other than that, GCN also can leverage transfer learning and few shot learning techniques to address the challenges of limited annotated medical image datasets.

By using cancer lesion points obtained using Delaunay triangulation and GCN as its model, classification tasks may be performed more accurately, even when dealing with images with significant noise that can lead to overfitting. When using CNN as the model, the images were processed as it is without any further data preprocessing steps. CNN itself is considered as the most advanced network for pattern identification in medical image analysis. However, when faced with images of skin cancer taken from quite a distance, the model would not perform well. Rather than focusing on the cancer lesion alone, the model would also focus on the skin surrounding it. The model would attempt too hard in seeking the most suitable fit to the data which will lead to overfit, as not everyone has the same skin color.

## II. RELATED WORK

There are many studies relevant to the proposed topic of this research. One example is a study by Shi Yin and friends who performed the diagnosis of kidney disease using ultrasound imaging [8]. In this study, the researchers used a methodology that builds on recent advances in Deep MIL, employing a convolutional neural network (CNN) to extract instance-level data from 2D kidney ultrasound images and a graph convolutional network (GCN) examine the characteristics of and further optimize the instance level. It works by looking at possible correlations between instances of

the same bag. ReLU activation function was used in this study. GCNs, knowledge-based MIL collection, and instance-level monitoring based on instances with reliable labels can improve MIL classification performance. The dataset used in this study was based on a dataset of US clinical renal scans from renal patients collected at the Children's Hospital of Philadelphia (CHOP). This study shows that their proposed method obtained an accuracy of 84.89%.

Other research on skin cancer detection is proposed by Abilash Panja, Christy Jackson J, and Abdul Quadir [9]. The researchers presented a deep convolutional neural network (CNN) to classify melanoma images into either benign or malignant groups. The model is constructed with convolution layer, activation layer, batch normalization layer, and pooling layer, with each of the convolutional layers has an activation function that uses ReLU, while the output layer has an activation function that is sigmoid, and the use of binary cross entropy for model fitting. Deep neural network's stability and performance are improved by using a normalization layer. The dataset used in this work originates from the ISIC archive repository dataset, which includes 2637 input photos for training from two benign and harmful classes, as well as 800 test images. The research compared the epoch and loss function performance differences with 100 random images, and has achieved 83.38% accuracy with 10 epochs, 87.52% with 25 epoch, 91.21% with 50 epoch, and 95.61% with 100 epoch. A dropout value of 0.5% was used as a constant in all experiments, giving the best performance at 100 epochs with 95% accuracy.

Research by Muhammad Arif and friends also predicts skin cancer using two different datasets: the datasets associated with the Interactive Atlas of Dermoscopy (EDRA) and the newly suggested International Skin Imaging Collaboration (ISIC), 2017. There are 2000 photos accessible for training, with only about 400 of those identified as melanoma. It also includes 150 images that can be utilized as the test set and 600 images to function as the set used for validation. This research uses ADF techniques in image processing to reduce noise, K-means clustering, and modified K-means clustering. In this research, modified K-means clustering shows better results than other methods with accuracy up to 0.9992%. This study discovered the fact that the neural network hybrid CNN (CNN+IHHO) classifier outperforms other approaches that includes ResNet, VGG, and DenseNet, with a performance rating of 97.3%. [10].

In most researches, the Convolutional Neural Network is the most common method to use when classifying images and can give more than 80% accuracy. However, this research proposes a fusion of Delaunay Triangulation method and Graph Convolutional Network (GCN) to predict skin cancer. Delaunay Triangulation is used to extract the cancer lesion areas and separate it from the healthy skin area. The extracted feature is used to train the GCN model, in hopes that the model can provide higher accuracy than previous studies by using only the cancer lesion area.

### III. METHODOLOGY

#### A. Dataset Description

The data was collected by International Skin Imaging Collaboration (ISIC) through Kaggle platform [11], consisting of 2357 skin cancer images of over 2000 patients from various sources such as Hospital Clínic de Barcelona, Medical University of Vienna, Memorial Sloan Kettering Cancer Center, Melanoma Institute Australia, The University of Queensland, and the University of Athens Medical School in 2020 [12]. There are two folders in the dataset, Training and Testing. Training folder is composed of nine folders with the total of 2239 images, representing nine types of skin cancer disease: Actinic Keratosis, Basal Cell Carcinoma, Dermatofibroma, Melanoma, Nevus, Pigmented Benign Keratosis, Seborrheic Keratosis, Squamous Cell Carcinoma, and Vascular Lesion. Testing folder also consists of nine folders with a total of 118 images. However, this research only uses the first five folders and classifies those five types of skin cancer disease due to insufficient resources of RAM and memory.

#### B. Proposed Methodology

The proposed methodology consists of (1) Exploratory Data Analysis, (2) Data Preprocessing, and (3) Modeling and Evaluation. The flow of the process is shown in Fig. 1.

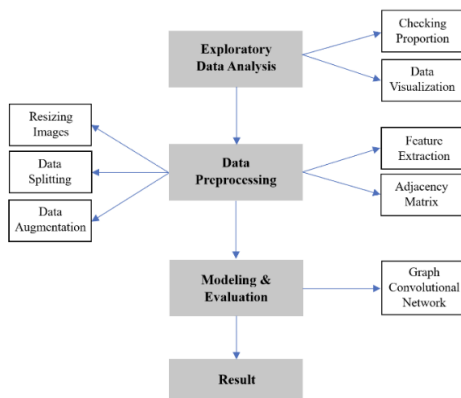

Fig. 1. Proposed methodology.

1) *Exploratory data analysis*: Research begins with importing and loading the data into the software, and then randomly visualizing nine images to get an overall depiction of the dataset. The software used for this research is Google Colab, with Python as the programming language. The process of visualizing the dataset and retrieving insights from it was done using the functions and libraries that are available in Python such as Matplotlib and Tensorflow Keras. After the data visualization process, the proportion of each skin cancer class is checked to decide whether the data needs to be balanced through data augmentation process or left as is.

2) *Data preprocessing*: The process consists of resizing all images into 180x180 pixels dimension, data splitting, data augmentation for training set, feature extraction process, and adjacency matrix creation. In the data splitting process, data is divided into three sets, namely the training set, validation set,

and testing set. Training set will be used for modeling process and validation set will be used for model evaluation. After splitting, the data augmentation process is carried out to add the number of images in each class to balance the training set. Then, a feature extraction process is carried out using Delaunay Triangulation method to generate the graph representation of each cancer image along with the average pixel values inside the graph, which can help differentiate between healthy skin and cancer skin region. Lastly, adjacency matrices are created based on the Delaunay points to describe the connectivity between nodes in each graph.

3) *Modeling and evaluation*: A Graph Convolutional Network model was created and trained using the pixels and adjacency matrix of all images in the training set as inputs. After that, the model is evaluated using the validation set. During evaluation process, the model is being analyzed whether it was overfitting or underfitting. The model result was compared with the previous result and was then modified a few times to improve its performance.

4) *Result*: After finding a model with the best performance, the model was then implemented to the testing set to predict the outcomes.

#### C. Delaunay Triangulation

Delaunay triangulation is a method of dividing a region into sub regions in triangular shapes [13]. This method generates a graph representation of the cancer shape in each image, which can be used as an input in Graph Convolutional Network. The graph will make it easier to distinguish the cancer skin from the normal skin as well as measuring the size of the cancer region.

The Delaunay triangulation implemented in this research is based on Quickhull Algorithm to compute the 2D convex hull of a set of points that are generated from the contour of each image, with the process as follows:

- Each image is converted into Grayscale color to find its contour.
- A set of points (100 points) are extracted from the contour of each image.
- Convex hulls are computed from those points using Quickhull Algorithm below [14]:
  - a) Find maximum and minimum points along the x dimension of that set of points.
  - b) Add the minimum and maximum points to the convex hull.
  - c) Connect the maximum and minimum points into a line.
  - d) Divide the remaining points into two subsets based on whether they are above or below the line.
  - e) Find points that are the farthest from the line and add them to the convex hull.
  - f) Construct a triangle using the line and the farthest point.
  - g) Remove all points in the subset that lies inside the triangle.

h) Step d to g are carried out recursively until no points remain in any subset.

i) The remaining set of points in the convex hull represents Delaunay triangulation.

- The average pixel values of each Delaunay triangle are extracted.
- Lastly, adjacency matrices are created based on the Delaunay points. Adjacency matrices have rows and columns labeled by graph vertices, with the number 0 or 1 in position  $(x_i, x_j)$  based on whether  $x_i$  and  $x_j$  are adjacent (1) or not (2), respectively [15].

#### D. Graph Convolutional Network

In this research, Graph Convolutional Network is used as a model to predict the types of skin cancer. Graph Convolutional Network (GCN) is a type of multilayer neural network that directly operates on graph-structured data, where it produces a vector representation of each node based on the features of its surrounding node [16]. GCN is used as it is suitable for inputs generated by Delaunay Triangulation, which is in the form of graphs (vertices, edge, and adjacency information for the triangles).

In the research, the GCN model propagates values forward through five layers using the Forward Propagation equation. The equation can be seen below (1):

$$H^{[i+1]} = \alpha(W^{[i]} H^{[i]} \bar{A}) \quad (1)$$

where  $H^{[i+1]}$  is the feature representation of layer  $i+1$ ,  $\alpha$  is the activation function applied for the inputs in each layer,  $W^{[i]}$  is the weight values for layer  $i$ ,  $H^{[i]}$  is the feature representation of layer  $i$ , and  $\bar{A}$  is the normalized adjacency matrix [17].

### IV. RESULT AND DISCUSSION

The Training dataset consists of 2239 skin cancer images distributed in nine folders. However, by using only five classes due to insufficient resources, there are only 1380 images left to use. The overall depiction of skin cancer provided by the dataset can be seen in Fig. 2.

Fig. 2. Data depiction.

In the above figure, six images of skin cancer belonging to five classes are visualized using TensorFlow Keras library in Python to process the images, and Matplotlib library to visualize the processed images. The five classes of skin cancer in the dataset are Actinic Keratosis, Basal Cell Carcinoma, Dermatofibroma, Melanoma, and Nevus.

1) *Actinic keratosis*: Also known as Solar Keratosis, Actinic Keratosis is a precancerous skin condition caused by a long-term exposure of Ultraviolet radiation from the sun. This condition is mostly found at places that are commonly exposed to sun, such as the backs of the hands or the face, often affecting forehead, temple, balding scalp, upper or vermilion of lower lip, cheeks, ears, and nose [18].

2) *Basal cell carcinoma*: Basal Cell Carcinoma is a skin cancer forming in the basal cell of a skin, which is located in the lower part of epidermis (outside layer of a skin). This type of cancer has a form of shiny bump or scaly flat patch on the skin and can gradually grow over time. This condition is caused by DNA mutation, inherited gene defects, or excessive exposure of ultraviolet (UV) rays. It is most commonly found among elderly male, as well as people with fair skin, blue eyes, and blond or red hair [19].

3) *Dermatofibroma*: Also known as Cutaneous Fibrous Histiocytoma, Dermatofibroma is a benign fibrous nodule that appears commonly on the skin of lower legs, upper backs, and arms. This condition is mostly found among females more than males and occurs in adults of any ethnicity. Some causes of dermatofibromas are a reaction to trauma, such as insect bite or small cuts in the area where the nodule later formed [20].

4) *Melanoma*: Melanoma is a type of skin cancer that is produced by malignant transformations of melanocytes, which are the cells that produce pigment on the skin [21]. It is caused mainly by overexposure of Ultraviolet radiation or artificial sources like solarium, can spread to many parts of the body, and can be incurable. This cancer is mostly found in people with pale skin, moles in skin, many sunburns, or old age [22].

5) *Nevus*: Also called a mole, Nevus (plural: Nevi) is a patch of skin formed due to an overgrowth of cells in the epidermis (outermost layer) part of skin. Nevus is harmless and common; it can be seen at birth or develop in early childhood. Any individual, of all ages and ethnicities can develop a nevus on their skin, and as they get older, nevi can become darker and thicker or even grow into wart-like form [23].

The proportion and number of images in each class from the dataset can be seen in Table I.

TABLE I. DATA PROPORTION

Class	Number of Images	Proportion
Melanoma	438	32%
Basal Cell Carcinoma	376	27%
Nevus	357	26%
Actinic Keratosis	114	8%
Dermatofibroma	95	7%

Result shows that the proportion of data in each class is imbalanced. Therefore, a data augmentation process is necessary to balance the data and ensure a good performance for the model. An imbalanced data can cause bias towards the model and cause lower accuracy to minority classes. Data augmentation will increase the size of those minority classes to obtain the same size as the largest class [24]. Several transformation techniques such as vertical and horizontal flipping, shifting, zooming, as well as rotating images are used when duplicating the data to increase its variety. The transformation process is carried out using `ImageDataGenerator()` function from Tensorflow Keras library.

After the Exploratory Data Analysis process, Data Preprocessing is carried out starting with resizing the height and width of all images into 180 pixels. Resizing images is important as images captured by cameras can vary in size, but a neural network only receives 1 input size. Thus, establishing a base size for all images is crucial so the images can be fed into the algorithms [25].

In Data Splitting process, the resized images in the Training folder are divided into Training set and Validation set, with the proportion of 80% and 20% respectively. An empirical analysis has proven that the best results are obtained by allocating 20-30% of the original dataset for validation set and the remaining 70-80% proportion for training set, as it can provide adequate data for training a model as well as avoid overfitting [26].

After splitting the dataset, Feature Extraction process is carried out using Delaunay triangulation method to generate a graph representation of each image and extract its pixels, as explained in the methodology. Delaunay triangulation method is carried out using `Delaunay()` function from Scipy library in Python, and its result can be seen in Fig. 3.

In the figure, the original image is shown on the left side, whereas images on the right side are the result after Delaunay triangles are generated. The Delaunay method is able to generate triangles properly in the cancer area of four classes. However, triangles in Nevus class are generated in the background instead of the area of interest. This is the weakness found when using Delaunay Triangulation method for skin cancer data.

In this research, adjacency matrices are created using NumPy library in Python, with the adjacency information based on the graph formed by Delaunay triangles. The distance of all points on the graph are calculated using Euclidean Distance formula, and two points are considered connected or adjacent if the distance is greater than 2.5 pixels. The Euclidean Distance method uses Pythagorean theorem [27], with the equation as seen below (2):

$$d_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (2)$$

where  $d_{ij}$  is the distance between position  $i$  and  $j$ ,  $(x_i, y_i)$  is the coordinate of a point in position  $i$ , and  $(x_j, y_j)$  is the coordinate of a point in position  $j$ .

Fig. 3. Delaunay points.

After generating the graph representation of each image, a GCN model is built to receive two inputs, which are the adjacency matrix and pixels matrix of each image. The model is constructed using 5 Graph Convolutional layers, a batch normalization after each Graph Convolutional layer, 1 flatten layer, and 1 output layer. Each graph convolutional layer has 32, 64, 128, 256, and 512 filters respectively, and all layers use ReLU activation function as well as L2 regularization method.

Batch normalization layers are added as they can normalize the output of the layer. Input that has been normalized can increase stability of the optimization process, which helps improve model's performance [28]. L2 regularization is added in each Graph Convolutional layer as it can do regularization to help overcome overfitting problem. L2 regularization can learn complex patterns well, so it is suitable for data in the form of images, which have complex patterns [29].

A ReLU activation function is used in all Graph Convolutional layers as it is the most often used function in the neural network model and can overcome the vanishing gradient problem, which occurs when the gradients of activation function become very small during backpropagation process and causes very small updates in the weights of earlier layers,

so the model learns slowly or not learning at all. This problem may occur when using sigmoid and hyperbolic tan (tanh) activation functions [30]. The graph of ReLU function can be seen in Fig. 4 [31], and the formula of ReLU is defined below (3):

$$f(x) = \max(0, x) \quad (3)$$

Fig. 4. ReLU activation function.

The model is compiled using ‘Adam’ optimizer and ‘categorical\_crossentropy’ as its loss function. Categorical cross entropy is specifically used for multi-class classification problems by taking class 1, 2, or n shaped labels, whereas the Adam optimizer is used because for classification problems, it often performs better at generalizing than other optimizers [32]. Thus, it is better at preventing overfitting for most cases.

After compilation, the model is trained with 50 epochs and a batch size of 64, so the model can train for up to 50 iterations and utilize 64 training examples in one iteration. Once the model is trained, evaluation process is carried on. The accuracy and loss during the last epoch can be seen in Table II.

TABLE II. ACCURACY AND LOSS OF LAST EPOCH

	<i>Accuracy</i>	<i>Loss</i>
<i>Training Set</i>	0.66	1.22
<i>Validation Set</i>	0.32	3.10

The accuracies and losses of training and validation set during the model training using all epochs from 1 to 50 can be seen in Fig. 5 and 6. During the training process, the accuracy of the model significantly improved, and the loss values were stable throughout each epoch. However, the accuracy of the validation process increased or decreased significantly during the modeling process. The loss value of the validation process decreased significantly from epoch 0 to approximately epoch 1 and experienced a fairly large increase and decrease from approximately epoch 1 to epoch 7.

The above Accuracy and Loss Graph is based on the range of epochs and visualized using Matplotlib library in Python. In the graph, it can be seen that the accuracy for training set kept increasing until it reached more than 60%, showing that the model works quite well in predicting the training set. However,

the accuracy difference between training and validation set gradually increases, as the accuracy of validation set makes no significant improvement during each epoch. Thus, this shows that the GCN model tends to overfit, even though the loss value during training process of each epoch kept decreasing.

Fig. 5. Training & validation accuracy.

Fig. 6. Training and validation loss.

After evaluating the model’s performance, the model is used to predict the testing set. Some prediction results can be seen in Table III.

The last accuracy result for the validation process is around 32%, which causes unreliable prediction results for the testing set. From the table, it can be seen that the image with the name ISIC\_0024411 is predicted to be in Dermatofibroma. In reality, the image belongs to Basal Cell Carcinoma class. Moreover, the image with the name ISIC\_0024403 and ISIC\_0024431 is predicted to be Nevus when in reality, the image belongs to Basal Cell Carcinoma as well.

TABLE III. ACCURACY AND LOSS OF LAST EPOCH

N o.	ActinicKeratitis	Basal Cell Carcinoma	Dermatofibroma	Melanoma	Nevus	Image name	Highest Probability
1	0.27	0.05	0.41	0.10	0.17	ISIC_0024411	Dermatofibroma
2	0.21	0.58	0.18	0.00	0.03	ISIC_0024472	Basal Cell Carcinoma
3	0.00	0.02	0.01	0.00	0.97	ISIC_0024403	Nevus
4	0.32	0.26	0.03	0.10	0.29	ISIC_0024454	Actinic Keratosis
5	0.02	0.00	0.37	0.01	0.60	ISIC_0024431	Nevus

TABLE IV. CNN vs GCN

	CNN	GCN
Training Accuracy	96.55%	66%
Validation Accuracy	60.14%	32%
Training Loss	0.07	1.22
Validation Loss	1.93	3.10

When compared with the proposed model, convolutional neural network (CNN) performed better. A comparison of accuracy using the CNN model is shown in Fig. 7 and Table IV. The accuracy of the training process was 96.55% and the accuracy of the validation process was 60.14%. As shown in Fig. 8, the loss in the training process steadily decreased from epoch to epoch and did not change significantly from epoch 40 to epoch 50. However, the loss in the validation process was the other way around. From epoch 0 to approximately epoch 5, the loss of the validation process decreased significantly, and from there until the last epoch the loss increased significantly. A comparison of accuracy and loss in Table IV shows the better performance of CNN compared to the proposed model. The accuracy of the CNN model both in the training and validation process outperformed the proposed model by 30%. The gap between the training and validation processes' loss values is similar for both CNN and GCN models. However, the loss value of the proposed model is higher.

Even though it produced better accuracies and losses than the proposed model, the CNN model overfitted. Overfitting is a scenario that occurs when the predictive model fails to generalize the observed data properly in order to fit both training and testing data well. An overfitting condition takes place when the model attempts too hard in seeking the most suitable fit to the data it was trained on and adapts for noise in the data by retaining multiple training data characteristics rather than discovering a general prediction rule [33]. For CNN model, the accuracies and losses of the training process kept improving through each epoch or iteration, while the accuracy and loss of the validation process stopped improving after going through a certain amount of iteration.

### V. CONCLUSION

The accuracy and loss values of CNN model are higher than the GCN model. Images used in this study were taken at close range, where cancer lesions are clearly visible, and the cancer-to-skin area ratio is nearly balanced. However, the model using CNN is overfitted. The model did not seek to fit the data well by focusing only on cancerous areas, but also on normal skin areas.

When compared with CNN, the accuracy of the proposed model is terrible, with only 66% for the training process, and 32% for the validation process. On the other hand, the accuracy of training process generated from the CNN model is 96.55% and 60.14% for validation process. Furthermore, the last loss value from the training process is lower than the validation process. As the model performs better in the training process

Fig. 7. Training and validation accuracy of the CNN model.

Fig. 8. Training and validation loss of the CNN model.

and poorly in the validation process, it can be concluded that the model is overfit. Consequently, when the test process was carried out, the prediction results were inaccurate.

There are several reasons that could lead the model to overfit, such as imbalance data, or even the data contain noise. Looking at the data proportion table from Table I, it could be clearly seen that the data distribution within the classes were imbalanced as the class Actinic keratosis was only represented by 8% of the total data, and class Dermatofibroma was only represented by 7% of the total data while the other classes were represented by 20% to 30% of the total data. Other than that, when conducting feature extraction using Delaunay triangulation method, it seems that for some images or data, the method could not map the point properly, ultimately giving inappropriate inputs for the model; hence, the terrible accuracy and loss value, and inaccurate predictions or diagnoses.

The last thing to be considered is insufficient features for reliable predictions. The data obtained from the Kaggle website itself has an imbalance data distribution within the classes, with "Pigmented Benign Keratosis" and "Melanoma" as the classes that has the highest number of data. As a result, the model could not learn properly from the classes that has too little data. The differences of the types of skin cancer are challenging to tell even for the human's eye. In this case, the same thing happen for the algorithm. When given to little data to learn from, the algorithm could not classify the type of skin cancer properly. This study paves the way for further in-depth future work to modify the algorithm so that it can perform better and guarantee that the algorithm performs acceptably and predict accurate diagnoses.

**Abstract**—In a world where smartphones dominate the market and provide opportunities to a vast population, this work introduces an innovative application that enables users to order irrigated vegetable crops from urban farmers. The application utilizes simple fertigation system technology, which can be easily implemented in small areas such as homes. Currently, consumers and sellers rely on traditional methods like paper or other means to place orders for vertical farming. However, research shows that these methods are unreliable and only offer temporary relevance. Additionally, the traditional agriculture supply chain diminishes the appeal of urban farming as its benefits do not outweigh the disadvantages. The primary objective of this application is to promote the concept of urban farming by creating an online marketplace that bypasses traditional methods. This allows consumers to directly order from the farmers themselves, serving as an alternative to the agricultural supply chain. Furthermore, a monitoring system has been integrated into the application as an additional tool, enabling farmers to remotely monitor and control their farms. This feature is particularly beneficial for urban farmers with farms in multiple locations who may lack the time to physically visit each one.

**Keywords**—Vertical farming; mobile application; online market; farm monitoring; urban farmer; agriculture supply chain

## I. INTRODUCTION

Mobile applications have had a significant impact on today's world, exerting a large influence on the way communities think and on their goals and standards. In the economy, mobile applications have opened up numerous new opportunities for individuals to successfully earn money online. A catalyst for this success has been the emergence of M-commerce mobile applications. M-commerce mobile applications provide a platform where sellers can offer their products, allowing customers to browse and make purchases. Despite the growing popularity of M-commerce mobile applications, the agriculture sector has yet to fully embrace this tool to enhance farmers' profitability.
