June 2023

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

**Kohei Arai**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Doroła Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: A Fuzzy Reward and Punishment Scheme for Vehicular Ad Hoc Networks

*Authors: Rezvi Shahariar, Chris Phillips*

**PAGE 1 – 17**

Paper 2: Investigating the User Experience and Evaluating Usability Issues in AI-Enabled Learning Mobile Apps: An Analysis of User Reviews

*Authors: Bassam Alsanousi, Abdulmohsen S. Albeshar, Hyunsook Do, Stephanie Ludi*

**PAGE 18 – 29**

Paper 3: A Hybrid Method Based on Gravitational Search and Genetic Algorithms for Task Scheduling in Cloud Computing

*Authors: Xiuyan ZHANG*

**PAGE 30 – 36**

Paper 4: Shape Control of a Dual-Segment Soft Robot using Depth Vision

*Authors: Hu Junfeng, Zhang Jun*

**PAGE 37 – 44**

Paper 5: Fast Pasture Classification Method using Ground-based Camera and the Modified Green Red Vegetation Index (MGRVI)

*Authors: Boris Evstatiev, Tsvetelina Mladenova, Nikolay Valov, Tsenka Zhelyazkova, Mariya Gerdzhikova, Mima Todorova, Neli Grozeva, Atanas Sevov, Georgi Stanchev*

**PAGE 45 – 51**

Paper 6: Instructional Digital Model to Promote Virtual Teaching and Learning for Autism Care Centres

*Authors: Norziana Yahya, Nazean Jomhari, Mohd Azahani Md Taib, Nahdatul Akma Ahmad*

**PAGE 52 – 64**

Paper 7: Investigating OpenAI's ChatGPT Potentials in Generating Chatbot's Dialogue for English as a Foreign Language Learning

*Authors: Julio Christian Young, Makoto Shishido*

**PAGE 65 – 72**

Paper 8: ConvNeXt-based Mango Leaf Disease Detection: Differentiating Pathogens and Pests for Improved Accuracy

*Authors: Asha Rani K P, Gowrishankar S*

**PAGE 73 – 82**

Paper 9: A Fine-grained Access Control Model with Enhanced Flexibility and On-chain Policy Execution for IoT Systems

*Authors: Hoang-Anh Pham, Ngoc Nhuan Do, Nguyen Huynh-Tuong*

**PAGE 83 – 93**

Paper 10: DelClustE: Protecting Users from Credit-Card Fraud Transaction via the Deep-Learning Cluster Ensemble

*Authors: Fidelis Obukohwo Aghware, Rume Elizabeth Yoro, Patrick Ogholoruwami Ejeh, Christopher Chukwufunaya Odiakaose, Frances Uche Emordi, Arnold Adimabua Ojugo*

**PAGE 94 – 100**

Paper 11: Proof of Spacetime as a Defensive Technique Against Model Extraction Attacks

*Authors: Tatsuki Fukuda*

**PAGE 101 – 106**

**Paper 12: Deep Learning-based Intrusion Detection: A Novel Approach for Identifying Brute-Force Attacks on FTP and SSH Protocol**

*Authors: Noura Alotibi, Majid Alshammari*

**PAGE 107 – 111**

**Paper 13: Method for Characterization of Customer Churn Based on LightBGM and Experimental Approach for Mitigation of Churn**

*Authors: Kohei Arai, Ikuya Fujikawa, Yusuke Nakagawa, Ryoya Momozaki, Sayuri Ogawa*

**PAGE 112 – 118**

**Paper 14: Artificial Intelligence-based Detection of Fava Bean Rust Disease in Agricultural Settings: An Innovative Approach**

*Authors: Hicham Slimani, Jamal El Mhamdi, Abdelilah Jilbab*

**PAGE 119 – 128**

**Paper 15: Bidirectional Long-Short-Term Memory with Attention Mechanism for Emotion Analysis in Textual Content**

*Authors: Batyrkhan Omarov, Zhandos Zhumanov*

**PAGE 129 – 136**

**Paper 16: Artificial Intelligence Enabled Mobile Chatbot Psychologist using AIML and Cognitive Behavioral Therapy**

*Authors: Batyrkhan Omarov, Zhandos Zhumanov, Aidana Gumar, Leilya Kuntunova*

**PAGE 137 – 146**

**Paper 17: A Multi-branch Feature Fusion Model Based on Convolutional Neural Network for Hyperspectral Remote Sensing Image Classification**

*Authors: Jinli Zhang, Ziqiang Chen, Yuanfa Ji, Xiyan Sun, Yang Bai*

**PAGE 147 – 156**

**Paper 18: Socio Technical Framework to Improve Work Behavior During Smart City Implementation**

*Authors: Eko Haryadi, Abdul Karim, Lizawati Salahuddin*

**PAGE 157 – 166**

**Paper 19: Detecting Malware with Classification Machine Learning Techniques**

*Authors: Mohd Azahari Mohd Yusof, Zubaile Abdullah, Firkhan Ali Hamid Ali, Khairul Amin Mohamad Sukri, Hanizan Shaker Hussain*

**PAGE 167 – 172**

**Paper 20: Evaluation of the Accidents Risk Caused by Truck Drivers using a Fuzzy Bayesian Approach**

*Authors: Imane Benallou, Abdellah Azmani, Monir Azmani*

**PAGE 173 – 182**

**Paper 21: Software Cost Estimation using Stacked Ensemble Classifier and Feature Selection**

*Authors: Mustafa Hammad*

**PAGE 183 – 189**

**Paper 22: An Algorithm Based on Self-balancing Binary Search Tree to Generate Balanced, Intra-homogeneous and Inter-homogeneous Learning Groups**

*Authors: Ali Ben Ammar, Amir Abdalla Minalla*

**PAGE 190 – 197**

**Paper 23: Multi-Features Audio Extraction for Speech Emotion Recognition Based on Deep Learning**

*Authors: Jutono Gondohanindijo, Muljono, Edi Noersasongko, Pujiono, De Rosal Moses Setiadi*

**PAGE 198 – 206**

**Paper 24: Hierarchical Convolutional Neural Networks using CCP-3 Block Architecture for Apparel Image Classification**

*Authors: Natthamon Chamnong, Jeeraporn Werapun, Anantaporn Hanskunatai*

**PAGE 207 – 219**

**Paper 25: Towards Point Cloud Classification Network Based on Multilayer Feature Fusion and Projected Images**

*Authors: Tengfeng Song, YiZhi He, Muhammad Tahir, Jianbo Li, Zhao Li, Imran Saeed*

**PAGE 220 – 230**

**Paper 26: Early Detection of Autism Spectrum Disorder (ASD) using Traditional Machine Learning Models**

*Authors: Prasenjit Mukherjee, Sourav Sadhukhan, Manish Godse, Baisakhi Chakraborty*

**PAGE 231 – 245**

**Paper 27: Speaker Recognition Improvement for Degraded Human Voice using Modified-MFCC with GMM**

*Authors: Amit Moondra, Poonam Chahal*

**PAGE 246 – 252**

**Paper 28: Application of Conv-1D and Bi-LSTM to Classify and Detect Epilepsy in EEG Data**

*Authors: Chetana R, A Shubha Rao, Mahantesh K*

**PAGE 253 – 261**

**Paper 29: A New Fuzzy Lexicon Expansion and Sentiment Aware Recommendation System in e-Commerce**

*Authors: Manikandan. B, Rama. P, Chakaravarthi. S*

**PAGE 262 – 269**

**Paper 30: Information Technology Technical Support Success Factors in Higher Education: Principal Component Analysis**

*Authors: Geeta Pursan, Timothy. T. Adeliyi, Seena Joseph*

**PAGE 270 – 282**

**Paper 31: Effect of Distance and Direction on Distress Keyword Recognition using Ensembled Bagged Trees with a Ceiling-Mounted Omnidirectional Microphone**

*Authors: Nadhirah Johari, Mazlina Mamat, Yew Hoe Tung, Aroland Kiring*

**PAGE 283 – 290**

**Paper 32: A Feature-based Transfer Learning to Improve the Image Classification with Support Vector Machine**

*Authors: Nina Sevani, Kurniawati Azizah, Wisnu Jatmiko*

**PAGE 291 – 301**

**Paper 33: Distributed Training of Deep Autoencoder for Network Intrusion Detection**

*Authors: Haripriya C, Prabhudev Jagadeesh M. P*

**PAGE 302 – 308**

**Paper 34: An Arabic Intelligent Diagnosis Assistant for Psychologists using Deep Learning**

*Authors: Asmaa Alayed, Manar Alrabie, Sarah Aldumaiji, Ghaida Allhyani, Sahar Siyam, Reem Qaid*

**PAGE 309 – 317**

**Paper 35: The Evaluation of a Persuasive Learning Tool using Think-Aloud Protocol**

*Authors: Muhammad 'Aqil Abd Rahman, Mohamad Hidir Mhd Salim, Nazlena Mohamad Ali*

**PAGE 318 – 325**

**Paper 36: Real-Time Intrusion Detection of Insider Threats in Industrial Control System Workstations Through File Integrity Monitoring**

*Authors: Bakil Al-Muntaser, Mohamad Afendee Mohamed, Ammar Yaseen Tuama*

**PAGE 326 – 333**

**Paper 37: Clustering Based on Gray Wolf Optimization Algorithm for Internet of Things over Wireless Nodes**

*Authors: Chunfen HU, Haifei ZHOU, Shiyun LV*

**PAGE 334 – 341**

**Paper 38: Intelligent Moroccan License Plate Recognition System Based on YOLOv5 Build with Customized Dataset**

*Authors: El Mehdi Ben Laoula, Marouane Midaoui, Mohamed Youssfi, Omar Bouattane*

**PAGE 342 – 351**

**Paper 39: Deep Learning for Personal Activity Recognition Under More Complex and Different Placement Positions of Smart Phone**

*Authors: Bhagya Rekha Sangiseti, Suresh Pabboju*

**PAGE 352 – 360**

**Paper 40: A Review on Security Techniques in Image Steganography**

*Authors: Sami Ghoul, Rossilawati Sulaiman, Zarina Shukur*

**PAGE 361 – 385**

**Paper 41: Automated Type Identification and Size Measurement for Low-Voltage Metering Box Based on RGB-Depth Image**

*Authors: Pengyuan Liu, Xurong Jin, Shaokui Yan, Tingting Hu, Yuanfeng Zhou, Ling He, Xiaomei Yang*

**PAGE 386 – 396**

**Paper 42: Data-driven Decision Making in Higher Education Institutions: State-of-play**

*Authors: Silvia Gaffandzhieva, Sadiq Hussain, Slavoljub Hilčenko, Rositsa Doneva, Kirina Boykova*

**PAGE 397 – 405**

**Paper 43: Semi-Dense U-Net: A Novel U-Net Architecture for Face Detection**

*Authors: Ganesh Pai, Sharmila Kumari M*

**PAGE 406 – 414**

**Paper 44: End to End Text to Speech Synthesis for Malay Language using Tacotron and Tacotron 2**

*Authors: Azrul Fahmi Abdul Aziz, Sabrina Tiun, Noraini Ruslan*

**PAGE 415 – 421**

**Paper 45: A New Model for Blood Cancer Classification Based on Deep Learning Techniques**

*Authors: Hagar Mohamed, Fahad Kamal Elsheref, Shrouk Reda Kamal*

**PAGE 422 – 429**

**Paper 46: Deep Feature Fusion Network for Lane Line Segmentation in Urban Traffic Scenes**

*Authors: Hoanh Nguyen*

**PAGE 430 – 435**

**Paper 47: Enhancing Skin Diseases Classification Through Dual Ensemble Learning and Pre-trained CNNs**

*Authors: Oussama El Gannour, Soufiane Hamida, Yasser Lamalem, Bouchaib Cherradi, Shawki Saleh, Abdelhadi Raihani*

**PAGE 436 – 445**

**Paper 48: Auto-Regressive Integrated Moving Average Threshold Influence Techniques for Stock Data Analysis**

*Authors: Bhupinder Singh, Santosh Kumar Henge, Sanjeev Kumar Mandal, Manoj Kumar Yadav, Poonam Tomar Yadav, Aditya Upadhyay, Srinivasan Iyer, Rajkumar A Gupta*

**PAGE 446 – 455**

**Paper 49: Evaluations on Competitiveness of Service Sector in Yangtze River Economic Belt of China Based on Dual-core Diamond Model**

*Authors: Ming Zhao, Qingjun Zeng, Dan Wang, Jiafu Su*

**PAGE 456 – 467**

**Paper 50: Enhancing COVID-19 Diagnosis Through a Hybrid CNN and Gray Wolf Optimizer Framework**

*Authors: Yechun JIN, Guanxiong ZHANG, Jie LI*

**PAGE 468 – 478**

**Paper 51: Automated Epileptic Seizure Detection using Improved Crystal Structure Algorithm with Stacked Autoencoder**

*Authors: Srikanth Cherukuvada, R. Kayalvizhi*

**PAGE 479 – 486**

**Paper 52: Evaluation of the Effects of 2D Animation on Business Law: Elements of a Valid Contract**

*Authors: Sarni Suhaila Rahim, Nur Zulaiha Fadlan Faizal, Shahril Parumo, Hazira Saleh*

**PAGE 487 – 496**

**Paper 53: A Novel Approach to Multi-Layer-Perceptron Training using Quadratic Interpolation Flower Pollination Neural Network on Non-Binary Datasets**

*Authors: Yulianto Triwahyuadi Polly, Sri Hartati, Suprpto, Bambang Sumiarto*

**PAGE 497 – 504**

**Paper 54: Hamming Distance Approach to Reduce Role Mining Scalability**

*Authors: Nazirah Abd Hamid, Siti Rahayu Selamat, Rabiah Ahmad, Mumtazimah Mohamad*

**PAGE 505 – 510**

**Paper 55: Towards Path Planning Algorithm Combining with A-Star Algorithm and Dynamic Window Approach Algorithm**

*Authors: Kaiyu Li, Xiugang Gong, Muhammad Tahir, Tao Wang, Rajesh Kumar*

**PAGE 511 – 519**

**Paper 56: Advances in Machine Learning and Explainable Artificial Intelligence for Depression Prediction**

*Authors: Haewon Byeon*

**PAGE 520 – 526**

**Paper 57: State-of-the-Art Analysis of Multiple Object Detection Techniques using Deep Learning**

*Authors: Kanhaiya Sharma, Sandeep Singh Rawat, Deepak Parashar, Shivam Sharma, Shubhangi Roy, Shibani Sahoo*

**PAGE 527 – 534**

**Paper 58: Enhancing IoT Security with Deep Stack Encoder using Various Optimizers for Botnet Attack Prediction**

*Authors: Archana Kalidindi, Mahesh Babu Arrama*

**PAGE 535 – 544**

**Paper 59: Behavior Intention of Chronic Illness Patients in Malaysia to Use IoT-based Healthcare Services**

*Authors: Huda Hussein Mohamad Jawad, Zainuddin Bin Hassan, Bilal Bahaa Zaidan*

**PAGE 545 – 563**

**Paper 60: Dynamic Difficulty Adjustment of Serious-Game Based on Synthetic Fog using Activity Theory Model**

*Authors: Fresy Nugroho, Puspa Miladin Nuraida Safitri Abdul Basid, Firma Sahrul Bahtiar, I. G. P. Asto Budijahjanto*

**PAGE 564 – 573**

**Paper 61: Detection of Breast Cancer using Convolutional Neural Networks with Learning Transfer Mechanisms**

*Authors: Victor Guevara-Ponce, Ofelia Roque-Paredes, Carlos Zerga-Morales, Andrea Flores-Huerta, Mario Aymerich-Lau, Orlando Iparraguirre-Villanueva*

**PAGE 574 – 580**

**Paper 62: Zero-Watermarking for Medical Images Based on Regions of Interest Detection using K-Means Clustering and Discrete Fourier Transform**

*Authors: Rodrigo Eduardo Arevalo-Ancona, Manuel Cedillo-Hernandez*

**PAGE 581 – 588**

**Paper 63: Kalman Filter-based Signal Processing for Robot Target Tracking**

*Authors: Baofu Gong*

**PAGE 589 – 597**

**Paper 64: Vehicle Path Planning Based on Gradient Statistical Mutation Quantum Genetic Algorithm**

*Authors: Hui Li, Huiping Qin, Zi'ao Han, Kai Lu*

**PAGE 598 – 607**

**Paper 65: Apache Spark in Healthcare: Advancing Data-Driven Innovations and Better Patient Care**

*Authors: Lalit Shrotriya, Kanhaiya Sharma, Deepak Parashar, Kushagra Mishra, Sandeep Singh Rawat, Harsh Pagare*

**PAGE 608 – 616**

**Paper 66: Weight Optimization Based on Firefly Algorithm for Analogy-based Effort Estimation**

*Authors: Ayman Jalal AlMutlaq, Dayang N. A. Jawawi, Adila Firdaus Binti Arbain*

**PAGE 617 – 628**

**Paper 67: Hierarchical and Efficient Identity-based Encryption Against Side Channel Attacks**

*Authors: Qihong Yu, Jian Shen, Jiguo Li, Sai Ji*

**PAGE 629 – 640**

**Paper 68: Image Specular Highlight Removal using Generative Adversarial Network and Enhanced Grey Wolf Optimization Technique**

*Authors: Maddikera Krishna Reddy, J. C. Sekhar, Vuda Sreenivasa Rao, Mohammed Saleh Al Ansari, Yousef A. Baker El-Ebiary, Jarubula Ramu, R. Manikandan*

**PAGE 641 – 652**

**Paper 69: Developing a Security Policy for the Use of CCTV in the Northern Border University**

*Authors: Ahmad Alshammari*

**PAGE 653 – 660**

**Paper 70: Enhanced Gravitational Search Algorithm Based on Improved Convergence Strategy**

*Authors: Norlina Mohd Sabri, Ummu Fatimah Mohd Bahrin, Mazidah Puteh*

**PAGE 661 – 670**

**Paper 71: Proposed Secure Activity Diagram for Software Development**

*Authors: Madhuri N. Gedam, Bandu B. Meshram*

**PAGE 671 – 680**

**Paper 72: An Efficient Vision-based Approach for Optimizing Energy Consumption in Internet of Things and Smart Homes**

*Authors: LIU Chenguang*

**PAGE 681 – 686**

**Paper 73: Application of Medical Brain CT/MRI Image Fusion Algorithm based on Neural Network**

*Authors: Dan Yang*

**PAGE 687 – 697**

**Paper 74: Motion Path Planning of Wearable Lower Limb Exoskeleton Robot Based on Feature Description**

*Authors: Ying Wang, Songyu Sui*

**PAGE 698 – 704**

**Paper 75: Robust Analysis of IT Infrastructure's Log Data with BERT Language Model**

*Authors: Deepali Arun Bhanage, Ambika Vishal Pawar*

**PAGE 705 – 714**

**Paper 76: Application of the Learning Set for the Detection of Jamming Attacks in 5G Mobile Networks**

*Authors: Brou Médard KOUASSI, Vincent MONSAN, Abou Bakary BALLO, Kacoutchy Jean AYIKPA, Diarra MAMADOU, Kablan Jérôme ADOU*

**PAGE 715 – 723**

**Paper 77: Hybrid Global Structure Model for Unraveling Influential Nodes in Complex Networks**

*Authors: Mohd Fariduddin Mukhtar, Zuraida Abal Abas, Amir Hamzah Abdul Rasib, Siti Haryanti Hairol Anuar, Nurul Hafizah Mohd Zaki, Ahmad Fadzli Nizam Abdul Rahman, Zaheera Zainal Abidin, Abdul Samad Shibghatullah*

**PAGE 724 – 730**

**Paper 78: Multi-Granularity Tooth Analysis via Faster Region-Convolutional Neural Networks for Effective Tooth Detection and Classification**

*Authors: Samah AbuSalim, Nordin Zakaria, Salama A Mostafa, Yew Kwang Hooi, Norehan Mokhtar, Said Jadid Abdulkadir*

**PAGE 731 – 741**

**Paper 79: A Hybrid Approach for Underwater Image Enhancement using CNN and GAN**

*Authors: Aparna Menon, R Aarthi*

**PAGE 742 – 748**

**Paper 80: End-to-End Real-time Architecture for Fraud Detection in Online Digital Transactions**

*Authors: ABBASSI Hanae, BERKAOUI Abdellah, ELMENDILI Saida, GAHI Youssef*

**PAGE 749 – 757**

**Paper 81: Prediction of Anti-inflammatory Activity of Bio Copper Nanoparticle using an Innovative Soft Computing Methodology**

*Authors: Dyuti Banerjee, G. Kiran Kumar, Farrukh Sobia, Subuhi Kashif Ansari, Anuradha. S, R. Manikandan*

**PAGE 758 – 767**

**Paper 82: Automatic Essay Scoring for Arabic Short Answer Questions using Text Mining Techniques**

*Authors: Maram Meccawy, Afnan Ali Bayazed, Bashayer Al-Abdullah, Hind Algamdi*

**PAGE 768 – 775**

**Paper 83: Combination of Adaptive Neuro Fuzzy Inference System and Machine Learning Algorithm for Recognition of Human Facial Expressions**

*Authors: B. Dhanalaxmi, B. Madhuravani, Yeligei Raju, C. Balaswamy, A. Athiraja, G. Charles Babu, T. Samraj Lawrence*

**PAGE 776 – 787**

**Paper 84: Comparative Analysis of DIDIM and IV Approaches using Double Least Squares Method**

*Authors: Fadwa SAADA, David DELOUCHE, Karim CHABIR, Mohamed Naceur ABDELKRIM*

**PAGE 788 – 796**

**Paper 85: Skin Cancer Classification using Delaunay Triangulation and Graph Convolutional Network**

*Authors: Caroline Angelina Sunarya, Jocelyn Verna Siswanto, Grace Shirley Cam, Felix Indra Kurniadi*

**PAGE 797 – 805**

**Paper 86: Fertigation Technology Meets Online Market: A Multipurpose Mobile App for Urban Farming**

*Authors: Jamil Abedalrahim Jamil Alsayaydeh, Mohd Faizal bin Yusof, Asyraf Salmi, Adam Wong Yoon Khang, Safarudin Gazali Herawan*

**PAGE 806 – 813**

**Paper 87: Offensive Language Identification in Low Resource Languages using Bidirectional Long-Short-Term Memory Network**

*Authors: Aigerim Toktarova, Aktore Abushakhma, Elvira Adylbekova, Ainur Manapova, Bolganay Kaldarova, Yerzhan Atayev, Bakhyt Kassenova, Ainash Aidarkhanova*

**PAGE 814 – 821**

**Paper 88: Query-Focused Multi-document Summarization Survey**

*Authors: Entesar Alanzi, Safa Alballaa*

**PAGE 822 – 833**

**Paper 89: Ensuring Information Security of Web Resources Based on Blockchain Technologies**

*Authors: Barakova Aliya, Ussatova Olga, Begimbayeva Yenlik, Ibrahim Sogukpinar*

**PAGE 834 – 843**

**Paper 90: A Hybrid Multiple Indefinite Kernel Learning Framework for Disease Classification from Gene Expression Data**

*Authors: Swetha S, Srinivasan G N, Dayananda P*

**PAGE 844 – 855**

**Paper 91: A 3D Processing Technique to Detect Lung Tumor**

*Authors: Nabila ELLOUMI, Slim Ben CHAABANE, Hassan SEDDIK, TOUNSI Nadra*

**PAGE 856 – 866**

**Paper 92: Prediction of Breast Cancer using Traditional and Ensemble Technique: A Machine Learning Approach**

*Authors: Tamanna Islam, Amatul Bushra Akhi, Farzana Akter, Md. Najmul Hasan, Munira Akter Lata*

**PAGE 867 – 875**

**Paper 93: Research on Settlement Prediction of Building Foundation in Smart City Based on BP Network**

*Authors: Luyao Wei*

**PAGE 876 – 884**

**Paper 94: A Classified Warning Method for Heavy Overload in Distribution Networks Considering the Characteristics of Unbalanced Datasets**

*Authors: Guohui Ren*

**PAGE 885 – 892**

**Paper 95: A Novel Method for Myocardial Image Classification using Data Augmentation**

*Authors: Qing kun Zhu*

**PAGE 893 – 901**

**Paper 96: Design and Application of Online Courses under the Threshold of Smart Innovation Education**

*Authors: Qin Wang, Anya Xiong, Huirong Zhu*

**PAGE 902 – 911**

**Paper 97: Object Detection-based Automatic Waste Segregation using Robotic Arm**

*Authors: Azza Elsayed Ibrahim, Rasha Shoitan, Mona M. Moussa, Heba A. Elnemr, Young Im Cho, Mohamed S. Abdallah*

**PAGE 912 – 926**

**Paper 98: Diversity-based Test Case Prioritization Technique to Improve Faults Detection Rate**

*Authors: Jamal Abdullahi Nuh, Tieng Wei Koh, Salmi Baharom, Mohd Hafeez Osman, Lawal Babangida, Sukumar Letchmunan, Si Na Kew*

**PAGE 927 – 934**

**Paper 99: Exploring the Impact of Hybrid Recommender Systems on Personalized Mental Health Recommendations**

*Authors: Idayati Mazlan, Noraswaliza Abdullah, Norashikin Ahmad*

**PAGE 935 – 944**

**Paper 100: Classification of Garlic Land Based on Growth Phase using Convolutional Neural Network**

*Authors: Durrotul Mukhibah, Imas Sukaesih Sitanggang, Annisa*

**PAGE 945 – 951**

**Paper 101: Evaluating Game Application Interfaces for Older Adults with Mild Cognitive Impairment**

*Authors: Nita Rosa Damayanti, Nazlena Mohamad Ali*

**PAGE 952 – 956**

**Paper 102: Intelligent Recommendation of Open Educational Resources: Building a Recommendation Model Based on Deep Neural Networks**

*Authors: Zongkui Wang*

**PAGE 957 – 964**

**Paper 103: Role of Artificial Intelligence and Business Decision Making**

*Authors: Anupama Prasanth, Densy John Vadakkan, Priyanka Surendran, Bindhya Thomas*

**PAGE 965 – 969**

**Paper 104: Unusual Human Behavior Detection System in Real-Time Video Systems**

*Authors: Yanbin Bu, Ting Chen, Hongxiu Duan, Mei Liu, Yandan Xue*

**PAGE 970 – 979**

**Paper 105: A Comprehensive Study of DCNN Algorithms-based Transfer Learning for Human Eye Cataract Detection**

*Authors: Omar Jilani Jidan, Susmoy Paul, Anirban Roy, Sharun Akter Khushbu, Mirajul Islam, S.M. Saiful Islam Badhon*

**PAGE 980 – 989**

**Paper 106: System Dynamics Approach in Supporting The Achievement of The Sustainable Development on MSMEs: A Collection of Case Studies**

*Authors: Julia Kurniasih, Zuraida Abal Abas, Sifi Azirah Asmai, Agung Budhi Wibowo*

**PAGE 990 – 998**

**Paper 107: A Precise Survey on Multi-agent in Medical Domains**

*Authors: Arwa Alshehri, Fatimah Alshahrani, Habib Shah*

**PAGE 999 – 1009**

**Paper 108: Technology Adoption and Usage Behaviors in Field Incident Management System Utilization**

*Authors: Cory Antonio Buyan, Noelyn M. De Jesus, Eltimar T. Castro Jr*

**PAGE 1010 – 1018**

**Paper 109: Damage Security Intelligent Identification of Wharf Concrete Structures under Deep Learning and Digital Image Technology**

*Authors: Jinbo Zhu, Yuesong Li, Pengrui Zhu*

**PAGE 1019 – 1026**

**Paper 110: Application of Top-N Rule-based Optimal Recommendation System for Language Education Content based on Parallel Computing**

*Authors: Nan Hu*

**PAGE 1027 – 1037**

**Paper 111: A Novel ML Approach for Computing Missing Sift, Provean, and Mutassessor Scores in Tp53 Mutation Pathogenicity Prediction**

*Authors: Rashmi Siddalingappa, Sekar Kanagaraj*

**PAGE 1038 – 1047**

**Paper 112: An Empirical Deep Learning Approach for Arabic News Classification**

*Authors: Roobaea Alroobaea*

**PAGE 1048 – 1055**

**Paper 113: Application Methods of Image Design Based on Virtual Reality and Interaction**

*Authors: Shasha Mao*

**PAGE 1056 – 1064**

**Paper 114: Video Surveillance Vehicle Detection Method Incorporating Attention Mechanism and YOLOv5**

*Authors: Yi Pan, Zhu Zhao, Yan Hu, Qing Wang*

**PAGE 1065 – 1073**

**Paper 115: Stroke Risk Prediction: Comparing Different Sampling Algorithms**

*Authors: Qiuyang Yin, Xiaoyan Ye, Binhua Huang, Lei Qin, Xiaoying Ye, Jian Wang*

# A Fuzzy Reward and Punishment Scheme for Vehicular Ad Hoc Networks

Rezvi Shahariar, Chris Phillips

School of Electronic Engineering and Computer Science, Queen Mary, University of London, London, England

**Abstract**—Trust management is an important security approach for the successful implementation of Vehicular Ad Hoc Networks (VANETs). Trust models evaluate messages to assign reward or punishment. This can be used to influence a driver's future behaviour. In the author's previous work, a sender-side based trust management framework is developed which avoids the receiver evaluation of messages. However, this does not guarantee that a trusted driver will not lie. These "untrue attacks" are resolved by the RSUs using collaboration to rule on a dispute, providing a fixed amount of reward and punishment. The lack of sophistication is addressed in this paper with a novel fuzzy RSU controller considering the severity of incident, driver past behaviour, and RSU confidence to determine the reward or punishment for the conflicted drivers. Although any driver can lie in any situation, it is expected that trustworthy drivers are more likely to remain so, and vice versa. This behaviour is captured in a Markov chain model for sender and reporter drivers where their lying characteristics depend on trust score and trust state. Each trust state defines the driver's likelihood of lying using different probability distribution. An extensive simulation is performed to evaluate the performance of the fuzzy assessment and examine the Markov chain driver behaviour model with changing the initial trust score of all or some drivers in Veins simulator. The fuzzy and the fixed RSU assessment schemes are compared, and the result shows that the fuzzy scheme can encourage drivers to improve their behaviour.

**Keywords**—VANET; Trust management; fuzzy logic; Markov chain; reward and punishment; driver behaviour model

## I. INTRODUCTION

Vehicular Ad Hoc Networks (VANETs) can play a major role in the successful implementation of the Intelligent Transport System (ITS). However, the implementation of VANETs and ITS face many security threats concerning traffic events. There are many security approaches in state-of-the-art literature which aim to address these threats, though the completeness of these approaches is limited in thwarting both internal and external attacks. Attacks from authorized users can be curbed by a trust model [1-4]. However, each trust model has some limitations. Research to-date presents many models to evaluate the trust of vehicles and their messages. Trust approaches differ by their evaluation mechanism, and the infrastructures considered in the approaches. Some schemes evaluate only the trust of vehicles, whereas others evaluate the trustworthiness of messages. There are also some hybrid approaches which evaluate both the vehicles and messages. In this way, approaches isolate malicious vehicles from benign ones. Typically, the trustworthiness of relayed messages is evaluated using some measures and

computational processes [5]. Once the malicious vehicles are identified, then it possible to limit or ignore their actions. To this end, some schemes also blacklist vehicles and/or drivers [6, 7]. Additionally, approaches incentivize trustworthy announcements (positive behaviour) to motivate vehicles to act honestly in the future [3, 6, 8]. Conversely, approaches punish mischievous behaviours to limit their future actions to avoid launching of future attacks [6, 9]. By arranging punishments to lower their trust score, drivers may feel guilty and be more careful about their future actions. In this way, the VANET can thwart attacks from authorized users by adopting a trust model which penalizes malicious activities and rewards benevolent behaviour. Even so, in some approaches [2, 3, 5, 10, 11], both reliable and unreliable vehicles can announce messages. The approach in [6] does not need any trust metric dissemination unlike these schemes [2, 4, 12] which require substantial trust data dissemination to verify an original announcement.

Trust evaluation can be performed at either the sender [6] and/or receiver side [2, 4, 10, 11, 13]. If receiver vehicles evaluate the trust of sender vehicles and/or messages, then the approach incurs additional delay and results in a higher communication overhead. Whereas, if a device in the sender vehicle can evaluate the trust, then there is typically no need to evaluate the trust of sender messages. Receivers do not need to rely on further communication with other sources (RSU, neighbour vehicles) for opinions or recommendation data.

A trust management framework is proposed in [6] which adopts sender-side trust evaluation inside a Tamper Proof Device (TPD) which is equipped onto every regular vehicle. This TPD is responsible for altering the trust of all drivers of a regular vehicle. In this approach, drivers receive rewards from announcements after the expiration of reward withhold timer. The accuracy of the message, responsiveness of the driver, and the distance travelled from the event location are used to calculate the reward or penalize a driver. The TPD updates the trust of a driver using a standard set of rules. The TPD does not know the truthfulness of a message unless it receives a report/complaint from a reporter vehicle about the announcement. The framework thus includes a collaboration procedure to determine the validity of a disputed event by an RSU. The dispute concerns "an event" announced by a sender whereas a reporter says, "an opposite event". The RSU then collects feedback from the vehicles (trusted clarifiers) which are visiting the presumed event location thereafter. With this data, the RSU decides, and sends rewards and punishment to the respective drivers when the decision is ready. In comparison to TPD reward and punishment, the RSU reward

and punishment mechanism is simple, and it only assigns a fixed reward or punishment to the disputed drivers irrespective of the severity of incident, driver past behaviour, and RSU confidence in the sender or reporter (environmental dynamics). Thus, in this paper an advanced RSU reward and punishment generator is developed to assign a justified level of reward or punishment to the drivers concerned. It is found in the state-of-the-art that many researchers use Mamdani fuzzy logic to deal with the imprecision and uncertainty. In the Mamdani fuzzy logic, each rule output is a fuzzy set, and the rules can be designed intuitively with some expert knowledge.

In [6], an RSU assigns only fixed rewards and punishment based on the decision and does not consider the environmental dynamics. It is found that there is some uncertainty and incompleteness involved in the dispute resolution process.. Thus, our attention is drawn to developing an advanced model to reward or punish drivers using a fuzzy logic based RSU assessment method. This model considers various factors and then allocates justified levels of reward or punishment accordingly. Also, in [6] the driver behaviour is modelled with a straightforward probabilistic distribution. Drivers with higher trust scores send less untrue messages. However, the probability distribution is fixed and not influenced by the changing trust score of the driver. This is why a Markov-chain based driver behaviour model is introduced. The states of the Markov model are associated with a specific range of trust scores. From each state, a driver's lying probability is defined which controls their likelihood of making trustworthy or malicious announcements. From a higher trust state, drivers announce less untrue messages whereas from the lower trust state they are more likely to announce untrue messages. The following contributions are made in this paper:

- The RSU reward and punishment mechanism is amended using Mamdani fuzzy logic-based assessment. This method considers the severity of incident, confidence score in the sender or reporter and driver past behaviour.
- A Markov-chain based driver behaviour model is used to govern the behaviour of drivers from different trust states. The state transition model along with the conditions to move between states is given. Also, from each state, the trustworthy / malicious announcement probability is defined.
- A series of experiments have been conducted to validate and compare the performance of the fuzzy versus fixed reward and punishment schemes.
- The Markov chain behaviour model is examined by defining the probabilistic distribution of sender, reporter drivers from different trust states and changing the initial trust distribution of drivers.

The paper is organized as follows: Section II reviews trust models based on fuzzy logic and Markov chain-based models and similar state-of-the-art. Section III briefly introduces author's earlier trust framework and presents the proposed fuzzy logic based RSU reward and punishment assessment method as well as Markov Chain driver behaviour model. Section IV describes the simulation environment and

parameters for the experiments. Section V gives analysis and validation of results. Section VI compares fuzzy versus fixed RSU rewards and punishments and analyses the driver behaviour model with changing trust scores. Section VII presents the discussions. Finally, this work is concluded in the Section VIII where possible future research directions are indicated.

## II. LITERATURE REVIEW

This work primarily implements a fuzzy logic-based reward and punishment mechanism at RSUs. Additionally, a Markov model-based driver behaviour is developed to control the behaviour of drivers. These are improvements to the trust framework presented in [6]. First, some of the existing state-of-the-art trust models are briefly reviewed including fuzzy logic and Markov-model approaches. Trust approaches vary from different perspectives. For example, they can be differentiated based on whether they are application-oriented (architecture-less) [14] or architecture-based [3, 4]. Some approaches are centralized like [15] whilst others employ a decentralized architecture like [16]. Also, they can differ based on their data collection mechanism. For example, some schemes use only direct recommendations as [17]; others use both direct and indirect recommendations like [12, 34] for trust evaluation. Trust evaluation mechanisms are divided into three main classes which are Entity-Oriented Trust Models (EOTMs), Data-Oriented Trust Models (DOTMs), and Hybrid Trust Model (HTMs). These trust evaluation mechanisms are briefly reviewed next.

### A. Entity-Oriented Trust Models (EOTMs)

Entity-oriented trust models are epitomized by [10], where the researchers securely manage allocated credit using a Tamper Proof Module (TPM) on every vehicle. A vehicle first gets the transmission cost and the signed message from its TPM. Receiver vehicles consider the sender's reputation to decide whether to trust a message and the trust is revised using feedback from all receivers. This approach considers the presence of false attacks and benevolent vehicles. However, the process for setting a revised trust score can lead to excessive communication. In [18], the researchers consider familiarity, packet delivery ratio, timeliness, and interaction frequency to manipulate a weight-based aggregated final trust. They analyse the time-aware trust of vehicles from histories of interactions. However, they do not consider any attacker model for validation. In [4], a trust model uses a false message detection scheme to generate feedback on received messages which computes the trust of vehicles. Vehicles utilize primary and secondary scores from the RSUs for further communication until the next periodic update. The scheme is evaluated in the presence of false messages for both urban and highway environments. Nevertheless, it suffers from excessive trust metric dissemination.

In [15], a Reputation-based Global Trust Management (RGTE) scheme employing a Reputation Management Center (RMC) is presented. The RMC keeps track of the updated reputation of all vehicles. Every vehicle sends its recommendation about its neighbours to the RMC and then it uses central limit theory to exclude unreasonable recommendations. It updates reputation of vehicles for which

it receives recommendations. Whenever a receiver receives a message, it directly consults the RMC about the reputation of the sender. However, in this model, the server is contacted frequently for reputation requests and replies.

A fuzzy logic-based direct trust and Q-learning-based indirect trust is considered in [12]. This approach analyses precision and recall metrics with varying the number of malicious vehicles. However, the overhead is high as it involves repeated sensing of messages from neighbours. The authors in [19] apply fuzzy logic to calculate trust using experience, plausibility, and location accuracy. Furthermore, location accuracy is determined using fog nodes. It can detect bogus attacks and message alteration attacks. However, vehicles consulting with fog nodes for location accuracy raise the communication overhead. The authors in [20] also use fuzzy logic and calculate the relaying trust and coordinating trust. Then the final trust is computed from these two and a path is identified using a set of rules and experiences. However, this model only considers trust-based routing to deliver a message along the most trusted path.

The study [21] selects an optimal path for packet forwarding using fuzzy logic-based transmission method. In this method, driving direction, vehicle speed, link time, hop count are used for relay node selection. Additionally, it considers the future state of vehicles. In [22], a fuzzy logic-based trust model is proposed that uses the RSU assessment, emulation attack attempts, and collaboration degree to assess the trust of vehicles. It incentivises good behaviour and punishes malicious vehicles. However, their analysis only concentrates on network performance measurement considering the malicious behaviour of making the connection slow, modifying messages, and stating false opinions.

In [23], a fuzzy logic-based trust model is proposed to address uncertainty and inaccurate trust estimation in a VANET. In this method, edge servers compute the trust of vehicles using fuzzy logic from packet drop, alteration, and false message injection factors. The analysis considers message alteration attacks and bad-mouthing attacks. In [24], a fuzzy logic-based system is used for vehicle authentication. This system only considers distance and trust factors to classify vehicles as partially or fully trusted or malicious. However, this approach is not analysed in the presence of a known adversary.

In [25], a fuzzy-logic-based trust model is presented where plausibility, experience, and vehicle type are used to decide on the validity of events. The fuzzy decision-making module of receiver vehicles utilizes these factors to compute the trust of the sender to determine whether to accept or reject or to forward a message. The analysis considers simple, opinion tampering, and on-off attacks. Every receiver vehicle applies fuzzy logic independently to forward an announcement to a further vehicle. The researchers in [26] propose a Hidden Markov Model (HMM) based trust evaluation method which computes trust of vehicles at the RSUs. This model improves the accuracy in detecting malicious vehicles compared to a baseline scheme.

### B. Data-Oriented Trust Models (DOTMs)

In [27], the researchers present machine learning based trust models (i.e. KNN, decision tree, naïve Bayes, and random forest). An RSU runs a location spoofing attack detection framework which uses stored data and received Basic Safety Messages (BSMs). The model is trained with both legitimate and malicious data. The analysis examines the accuracy, precision, and recall for all machine learning approaches. However, the analysis is limited to the BSM data. Research [28] differentiates malicious vehicles from benevolent ones using an ensemble learning algorithm and a decision tree-based model. The analysis includes measuring the accuracy, precision, and recall. However, it only identifies fake positional data.

In [29] author proposes a fuzzy system considering network density, relaying distance, and trust inconsistency to predict the relaying trust of vehicles. Then the coordinated trust is computed using velocity, connection degree and loss parameters. After that, the final trust is computed using a fuzzy system considering the relaying and coordinated trust that is used to find a trusted path. However, the model only selects the trusted relayer to confirm the trusted path for delivering messages. In [30], the authors propose a data oriented HMM-based reputation model. This model evaluates the reliability and the legitimacy of the announced messages. The reputation of vehicles is updated based on the correctness of safety and non-safety messages. The study [31] presents a vehicle behavioural monitoring and trust computational model to classify fake and legitimate messages. This model uses a neuro-fuzzy method to evaluate the behaviour of vehicles. It features accurate malicious message detection from speed and emission data. Using this data, the model can isolate misbehaving vehicles and discard messages from them.

### C. Hybrid Trust Models (HTMs)

In [32], the researchers present a Markov Chain-based hybrid trust model for VANETs. In this scheme, a state transition model, and the state transition probabilities are presented considering a cooperation factor and the accurate evaluation of messages. The monitoring process considers trustworthy message broadcasting besides cooperativeness, and they examined camouflaged behaviour. The researchers in [33] consider the likelihood and impact of taking a decision when both the event and the opposite event coexist. This approach is compared with a multi-faceted trust model. The results suggest that this approach always selects a low-risk action relative to a typical trust-based approach. However, the model is designed for a clustered environment.

In [34], the researchers develop a Bayesian inference-based direct and recommendation-based trust model. The direct trust considers penalties and time-decaying information. Also, the confidence of direct trust is checked beforehand to avoid unnecessary recommendation trust calculations. The analysis considers packet drop and interception as malicious behaviours. Alternatively, in [35], a self-organizing hybrid trust model is proposed for both urban and rural scenarios. This approach keeps a history of interactions and then validates the received messages by assigning a credit. This model accepts the message with the highest trust for a

particular event. It can detect fake event locations, source locations, and event times as well as revoke messages from malicious vehicles. However, this model is not evaluated against a baseline. Study [36] embeds the trust certificate of a vehicle with the message that a receiver uses as a weight to evaluate the trust of the data. A vehicle that visits the event location either confirms or denies the event. The vehicle sends all stored feedback to an RSU to forward it to the Certificate Authority (CA) to update a vehicle's trust certificate. Later, vehicles receive updated trust certificates from the CA via an RSU. Thus, the approach suffers from communication overhead to frequently update trust certificates.

In [37], trust is computed from past experiences, neighbouring vehicle information, trust of the vehicle, and the packet delivery ratio. This approach has a trust manager, route manager, and decision manager. The trust manager finds the path trust and calculates the required time to forward a message to the destination. The decision manager informs a nearby RSU if the vehicle does not want to participate in packet forwarding. This model selects a path with the highest trust and lowest delay. The approach considers the packet delivery ratio, delay, and the number of routes. However, they only implement the trusted routing. In [38], a vehicle learns cognitively from the environment and develops contexts around an event to infer the trust. It defines a context which associates a set of interrelated concepts (for example vehicle, evaluation, event). This framework considers experience, opinion, and role for the trust evaluation. For outlier detection, time, speed, and distance thresholds are used. Besides finding the trust level for every report, this approach also finds the confidence of the report. The framework is simulated in both rural and urban scenarios and compared against existing frameworks. However, malicious vehicles can bypass the outlier-based detection process and can send false messages within the acceptable threshold they set for this model. In [39], an RSU is solely responsible for the trust computation of vehicles, and it collects recommendations and feedback from vehicles. Besides this, the RSU creates, manages, and merges clusters for the VANET. The scheme is robust against thwarting Sybil and wormhole attacks. The RSU also identifies malicious vehicles and prevents them joining another cluster. Though they maintain trustworthy clusters, this requires considerable dissemination and cluster management at the RSUs which demands significant computational effort.

### III. PROPOSED RSU ASSESSMENT METHOD AND DRIVER BEHAVIOUR MODEL

The proposed RSU assessment method is used only to assign RSU reward and punishment to drivers who are involved in disputes relating to untrue attack dissemination in the network. This is an extension to the trust framework described in [6]. The Markov model is used for behavioural analysis of drivers with this trust framework.

#### A. Sender – Side Trust Framework

In [6], a trust management framework is presented where a Tamper Proof Device (TPD) is fitted to each regular vehicle providing trust-based access control to the VANET. This framework considers regular vehicles, along with police,

ambulance, and fire service vehicles. The main components of the framework are the vehicles, RSUs, and the Trust Authority (TA). RSUs send incident data to the TA for storage. Vehicles take different roles based on their activities in the network. When a vehicle announces a message, then it is a sender vehicle. When a vehicle receives a message, it is called a receiver vehicle. When a vehicle notices an announcement is invalid, it can become an untrue attack reporter. However, this report can be malicious as well for which the framework arranges some punishment upon an RSU ruling. An RSU collaborates with the vehicles which are visiting the event location near the time to decide on the validity of the event. The vehicles which send feedback when collaboration is running are called clarifiers.

The following equations define the trust thresholds to achieve access control. Equation (1) confirms the trust score of a driver stays in the range of 0.05 to 0.9 irrespective of trust adjustments. Equation (2) relates to access-blocking of a driver/vehicle. Equation (3) regulates the message relaying ability and Equation (4) determines ability of regular vehicles to make announcements.

$$T_i = \begin{cases} 0.05, & T_i < 0.05 \\ 0.9, & T_i > 0.9 \\ T_i, & 0.05 < T_i \leq 0.9 \end{cases} \quad (1)$$

$$T_i = \{Blacklist. \quad T \leq 0.05\} \quad (2)$$

$$Message \ Relaying \ Ability = \begin{cases} False, & 0.05 \leq T < 0.25 \\ True, & T \geq 0.25 \end{cases} \quad (3)$$

$$Message \ Generation \ Ability = \begin{cases} Limited, & 0.05 \leq T < 0.5 \\ All, & T \geq 0.5 \end{cases} \quad (4)$$

Within this framework, regular vehicles are classified as *access-blocked* ( $T = 0.05$ ), *not trusted* ( $0.05 < T \leq 0.25$ ), *lowly trusted* ( $0.25 < T < 0.5$ ), *trusted* ( $0.5 \leq T < 0.8$ ), and *highly trusted* ( $0.8 < T \leq 0.9$ ). The trust of official vehicles is  $T = 1.0$  which is higher than the maximum trust of a regular vehicle ( $T=0.9$ ). A set of rules are employed for governing the actions of regular vehicles [6].

1) *Trust based access control for message announcements*: It is assumed each driver can announce an event if it is seen in the dashboard. It is dynamically updated based on the driver's trust score. Messages are organized into classes and each class is associated with a range of trust scores for access control. Vehicles must achieve a particular trust score to announce messages of a certain class. The framework rewards trustworthy announcements from the TPD after expiry of a withhold timer and optionally penalizes a driver if a driver delays beyond an acceptable limit. The TPD updates trust in relation to announcements, reporting, clarifying, relaying, and beaconing besides adjusting trust with RSU rewards and punishments.

2) *Functional diagram of the framework*: Assume, a trusted sender sends an announcement based on what he/she observes on a road which receivers receive and relay. The event is reported (opposite event) by a reporter after he/she thinks that the event has not occurred at the said location. An RSU upon reception of the report starts collaboration to decide

on the truthfulness of the event. Then it informs the TA of its decision and sends fixed rewards (0.1) / punishments (0.1) to the respective drivers based on the decision. The TPD of the respective drivers combines the RSU assessment with the driver's current trust. Additionally, the TA decides on whether blacklisting of a driver is necessary. This decision is conveyed via an RSU and the driver's TPD implements it. The functionality is shown in Fig. 1.

3) *RSU untrue message detection*: When a reporter reports an untrue attack, an RSU resolves the issue using a sum of weighted feedback calculation. This feedback data are collected from clarifier vehicles. However, when an official vehicle sends feedback, an RSU directly uses this to decide on the dispute. The TA also maintains a driver profile database consisting of the recent records from disputed decisions. A decision results in either a reward or punishment for a driver which are saved into this list. The untrue message detection mechanism is shown in Fig. 2.

In [6], the untrue detection process executes at RSUs to allocate the fixed reward and punishment without considering the severity of incident, driver past behaviour, and RSU confidence in the sender or reporter. Thus, the reward and punishment scheme lacks a sophisticated model to assess the appropriate magnitude of the reward or punishment. These parameters are important to consider as they are related to the event and the driver. They also vary from one event to another, from one driver to another, and the collected feedback. A fuzzy logic-based reward and punishment scheme is a good fit as these parameters are uncertain and inexact, although the reward or punishment should be based on the severity level of the incident. Also, fuzzy logic can approximately imitate the human-level decision making. The fuzzy logic based RSU controller can account for various factors and assign a justified level of reward or punishment for a given driver.

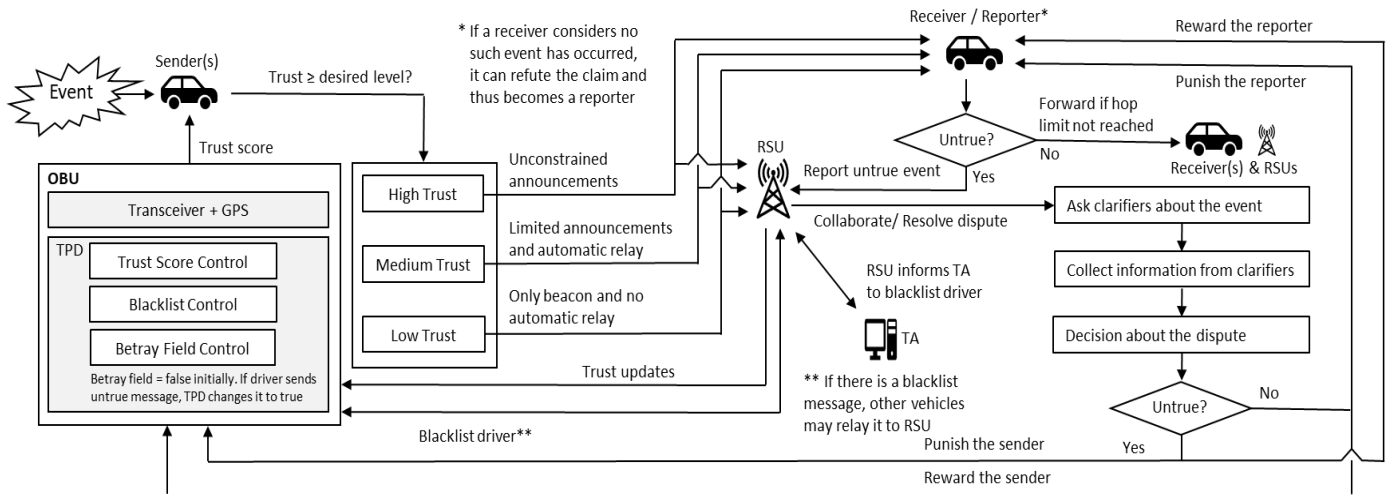

Fig. 1. Functional diagram of the trust framework [6].

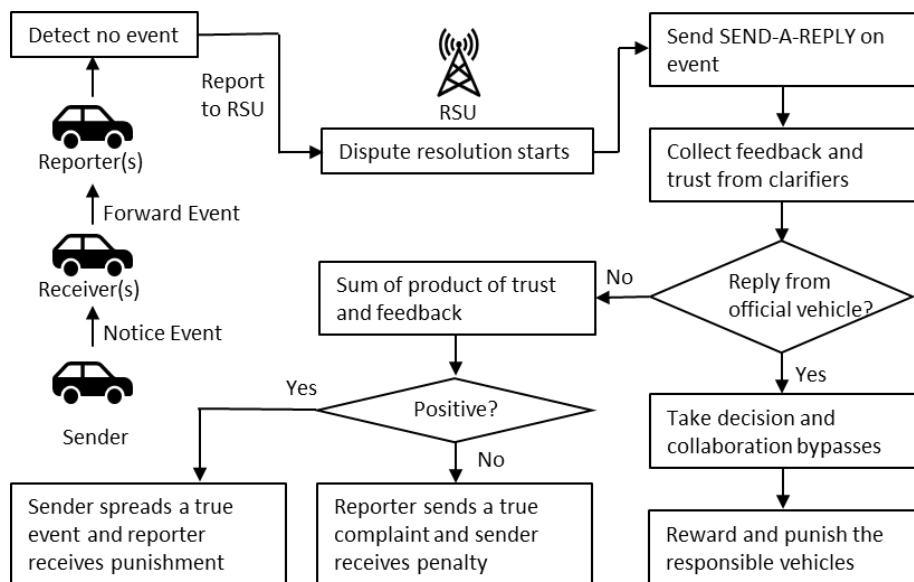

Fig. 2. RSU steps for untrue message detection.

**B. Overview of the Proposed Fuzzy RSU Reward or Punishment Assessment Scheme**

Fig. 3 depicts the proposed fuzzy RSU controller for determining reward or punishment. It starts from the left-hand side where it collects three inputs which are driver past behaviour, confidence in the sender or reporter and severity of the incident. This involves some form of pre-processing of input data to feed into the fuzzy controller. Then these inputs are handed over to the fuzzifier to produce input fuzzy sets. These sets are delivered to the fuzzy inference module which evaluates the fuzzy rules on the input fuzzy sets to produce the output fuzzy sets. These sets are then transferred to the defuzzifier module to generate the crisp number as output variables which is sent to the respective drivers as the level of reward or punishment for their action. A disputed decision at an RSU invokes the execution of this function to calculate the extent of reward or punishment for a conflicted announcement.

Fig. 3. A block diagram of the proposed fuzzy logic based RSU controller.

1) *Fuzzification*: Fuzzification finds the degree of membership for each input to the fuzzy sets (one or more linguistic variables) using a membership function. To find the degree of belonging, first the shape of the membership functions for every input are defined. Then the degree of belonging to the fuzzy sets are determined for each input. Membership functions are defined intuitively with the help of linguistic variables as shown in Table I.

TABLE I. INPUT FUZZY SETS

Input Parameters	Fuzzy sets
Driver Past Behaviour (DPB)	Good (G), Neutral (N), and Bad (B)
Severity of the Incident (SI)	Not Severe (NS), Less Severe (LS), and High Severe (HS)
RSU Confidence (RCS)	Low (L), Medium (M), and High (H)
Reward/Punishment	Very Low (VL), Low (L), Medium (M), High (H), and Very High (VH)

a) *Driver Past Behaviour (DPB)*: The RSU uses a membership function to convert each input to the degree of belonging to the fuzzy sets. RSUs always send data concerning the rewarded and punished drivers to the TA. An RSU asks for DPB data from the TA. Let, NoP and NoR be the recorded number of rewards and punishments for the concerned drivers from their previous disputed events. When the TA sends NoP and NoR data to a dispute resolver RSU, then it estimates the ratio of NoP/(NoR+ NoP) for the relevant drivers. The RSU feeds this data directly into the fuzzifier to get a degree of belonging of the DPB to each from the set:

{“Good”, “Medium”, “Bad”}. The DPB ranges from 0 to 1 and each DPB value is separated by 0.1. For example, if a driver record contains 4 punishments out of the 10 most recent records, then the DPB is 0.4. The fuzzification returns the fuzzy value as {Good: 0.24, Medium: 0.76, Bad:0}. Fig. 4 shows the membership function for driver past behaviour.

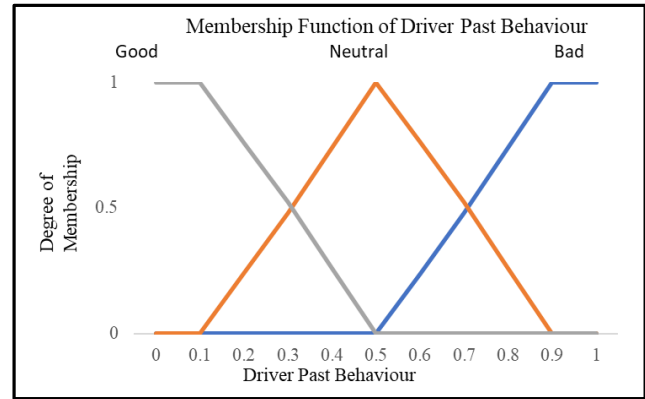

Fig. 4. Membership function for driver past behaviour.

b) *Severity of Incident (SI)*: The list of potential events is shown in Table II for this fuzzy controller. This is just an example list of possible events. In this Table, the event's name, and its severity (assumed impact on human lives) are shown.

TABLE II. POSSIBLE EVENT LIST

Incident Name	SEVERITY LEVEL (LOWEST TO HIGHEST)
Road Clear	0
Debris or Road Spillage (Oil or Muds or Sands)	1
Illegal Waste Dumping	2
Poor Conditioned Road	3
Minor Road Defect (Faded Sign) or Malfunctioning Traffic Element	4
Stranded or Abandoned Vehicle or Obstacle or No Obstacle	5
Major Road Defect (Pothole, Illegal Sign)	6
Diversion or Road Maintenance	7
Severe Weather (Snowy Road or Poor Visibility Due to Fog etc) or Environmental Incident	8
Flood or Fallen Tree on Road	9
Congestion	10
Traffic jam	11
Accident	12

Every RSU stores a copy of this table. When there is a dispute, the RSU looks up the severity level from the table to feed into the fuzzifier. Three fuzzy sets {“Not Severe”, “Less Severe”, and “High Severe”} are used for this input. When the SI is inputted, the fuzzification returns the fuzzy value as {Not Severe: 0.18, Less Severe: 0.82, High Severe: 0}. Fig. 5 shows the membership function for the severity of incident.

Fig. 5. Membership function for severity of incident.

c) *RSU Confidence in the Sender or Reporter*: An RSU obtains a confidence score from the received feedback using the ratio of feedback that supports the sender’s event to the sum of feedback which supports and contradicts the announcement. This is the RSU’s confidence in the sender. Similarly, the RSU confidence in the reporter is defined as the ratio of feedback that supports the reporter’s report to the sum of the feedback which both supports and contradicts the reporter’s report. Three fuzzy sets are defined for the RSU confidence which are {“Low”, “Medium”, and “High”}. The RSU confidence in the sender or reporter may or may not differ based on the feedback. The fuzzification returns the fuzzy value as {Low: 0, Medium: 0.33, High:0.67} for RSU confidence. Fig. 6 shows the membership function for RSU confidence in the sender or reporter.

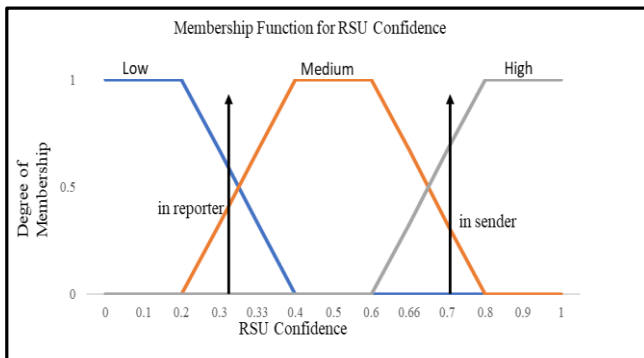

Fig. 6. Membership function for RSU confidence.

2) *Fuzzy rules for reward and punishment*: There is a separate set of rules for reward and punishment. Table III shows the set of rules used for rewarding whereas Table IV is used for punishing drivers. The reason for maintaining two sets of rules is that for one situation the reward may be smaller, but the punishment should be higher. Let output membership be OM. As each input has three fuzzy sets, thus the total number of rules is  $3*3*3=27$  which are given next. The first rule from Table III says as “if the (Driver Past Behaviour (DPB) is Good) AND (Severity of Incident (SI) is Not Severe (NS)) AND (RSU Confidence (RC) is Low), then the Reward is Low”. This explanation goes to other rules as well.

TABLE III. FUZZY RULES USED FOR REWARD

Rules	DPB	SI	RC	R
1	Good	Not Severe	Low	Low
2	Good	Not Severe	Medium	Medium
3	Good	Not Severe	High	High
4	Good	Low Severe	Low	Medium
5	Good	Low Severe	Medium	High
6	Good	Low Severe	High	Very High
7	Good	High Severe	Low	High
8	Good	High Severe	Medium	Very High
9	Good	High Severe	High	Very High
10	Neutral	Not Severe	Low	Low
11	Neutral	Not Severe	Medium	Low
12	Neutral	Not Severe	High	Medium
13	Neutral	Low Severe	Low	Low
14	Neutral	Low Severe	Medium	Medium
15	Neutral	Low Severe	High	High
16	Neutral	High Severe	Low	Medium
17	Neutral	High Severe	Medium	High
18	Neutral	High Severe	High	Very High
19	Bad	Not Severe	Low	Very Low
20	Bad	Not Severe	Medium	Very Low
21	Bad	Not Severe	High	Low
22	Bad	Low Severe	Low	Very Low
23	Bad	Low Severe	Medium	Low
24	Bad	Low Severe	High	Medium
25	Bad	High Severe	Low	Low
26	Bad	High Severe	Medium	Medium
27	Bad	High Severe	High	High

TABLE IV. FUZZY RULES USED FOR PUNISHMENT

Rules	DPB	SI	RC	P
1	Good	Not Severe	Low	Very Low
2	Good	Not Severe	Medium	Very Low
3	Good	Not Severe	High	Low
4	Good	Low Severe	Low	Low
5	Good	Low Severe	Medium	Low
6	Good	Low Severe	High	Medium
7	Good	High Severe	Low	Medium
8	Good	High Severe	Medium	High
9	Good	High Severe	High	High
10	Neutral	Not Severe	Low	Low
11	Neutral	Not Severe	Medium	Low
12	Neutral	Not Severe	High	Low
13	Neutral	Low Severe	Low	Low
14	Neutral	Low Severe	Medium	Medium
15	Neutral	Low Severe	High	Medium
16	Neutral	High Severe	Low	Medium
17	Neutral	High Severe	Medium	High
18	Neutral	High Severe	High	Very High
19	Bad	Not Severe	Low	Very Low
20	Bad	Not Severe	Medium	Low
21	Bad	Not Severe	High	Low
22	Bad	Low Severe	Low	Low
23	Bad	Low Severe	Medium	Medium
24	Bad	Low Severe	High	High
25	Bad	High Severe	Low	Very High
26	Bad	High Severe	Medium	Very High
27	Bad	High Severe	High	Very High

3) *Fuzzy inference:* Human decision making can be approximated by using fuzzy inference. Fuzzy Inference produces fuzzy output sets from the input fuzzy sets. During the fuzzy inference, each rule executes sequentially to obtain the desired output fuzzy set. A rule executes when its antecedent is satisfied. The antecedent of each rule is formed using Fuzzy AND, Fuzzy OR and Fuzzy NOT. The Fuzzy AND and Fuzzy OR are used as fuzzy logical operators. Fuzzy AND returns the minimum of all membership values from the antecedent part whereas a Fuzzy OR returns the maximum to clip or bound the height of output membership function. This means the output of the antecedent define the corresponding degree of membership value of the consequent part of each rule. Fig. 7 shows the output membership function of the reward/punishment where the reward is 0.08 and the punishment is 0.03.

Fig. 7. Output membership functions for reward and punishment.

4) *Aggregation:* In this step, all outputs from the fuzzy inference are combined to get one aggregated fuzzy output set which is fed into the defuzzifier module to get the fuzzy reward and punishment. During aggregation, all similar output fuzzy sets are merged into one and their resultant fuzzy set has the maximum consequent from all similar output fuzzy sets. For example, if three rules produce **Low** output fuzzy set with the degree of membership are 0.05, 0.064, and 0.021, then the aggregation combines these into one **Low** output fuzzy set with the degree of membership equals 0.064.

5) *Defuzzification:* A defuzzification method takes the aggregated output fuzzy membership function and produces one crisp number which is the desired output from this system. Centre of Gravity (COG) is the most widely accepted defuzzification method to find the final defuzzified value. It is the final step of the fuzzy system. The most widely defuzzification method of Mamdani inference is the centroid technique. It delivers a point where a vertical line divides the aggregated output fuzzy set into two equal masses. This method finds a point which represents the COG of a fuzzy set, A, on the interval [a, b]. Here,  $\mu$  denotes the degree of membership. A reasonable estimation can be obtained by sampling a set of points. This is expressed as in Equation (5).

$$COG = \frac{\int_a^b \mu_A(x) x dx}{\int_a^b \mu_A(x) dx} \quad (5)$$

6) An Example Fuzzy Inference for reward

a) *Fuzzy Inference:* In Fig. 8, the truncated execution of two rules for calculating fuzzy reward is shown as they are selected during the fuzzy inference. The execution of other rules is deleted deliberately to save space. The antecedent part of the rules is evaluated first to generate an output from each rule with the height defined by the min or Fuzzy AND operation of the antecedents. The DPB is 0.8, SI is 4, and the RSU confidence is 0.33 for example fuzzy inference. Similarly, fuzzy punishment is determined using the rules from Table IV.

b) *Redundant rule reduction for reward:* When multiple rules produce the same output fuzzy set with different values, they can be combined into one by taking the maximum of all consequent values for the same output fuzzy set; As the rules 10, 11, 13, and 23 have Low output fuzzy set, so taking the maximum gives us Rule 23 with 0.65 as the membership degree for the Low output fuzzy set. As there is only one Medium fuzzy set, it is included directly. Also, Rules 19, 20, and 22 have the Very Low output fuzzy set, thus the maximum consequent value from these three rules is Rule 20 to include in the selected group for aggregation. This situation is depicted in Fig. 9.

R-22

R-23

Fig. 8. Fuzzy rule inference for reward assessment.

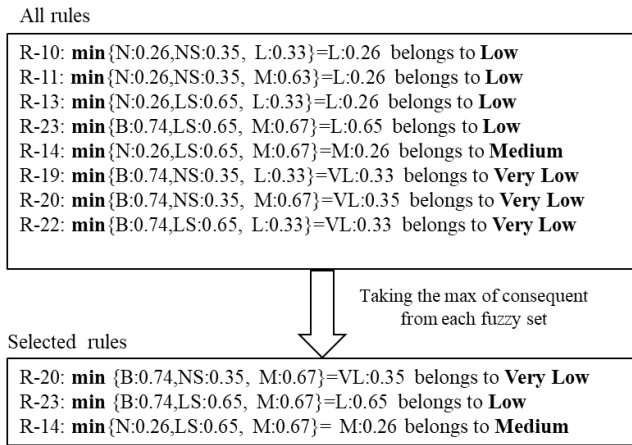

Fig. 9. Redundant rules reduction for reward.

c) *Aggregation of the consequents for reward:* The aggregation is applied to the selected rules which merges them to get the combined output membership function. In this step, only the output fuzzy sets with the highest degree of membership are used where all the output fuzzy sets with a lower value are inclusively covered. This is a combined fuzzy set as depicted in Fig. 10.

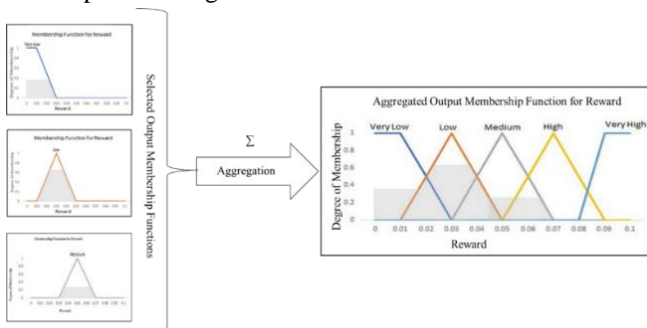

Fig. 10. Aggregated output membership for reward assessment.

d) *Defuzzification for reward:* Fig. 11 shows the assessed reward from the centroid defuzzification method. First, the area is sliced equally as shown in Fig. 11. Then the reward of 0.030014 is obtained as shown with a green arrow on the x-axis.

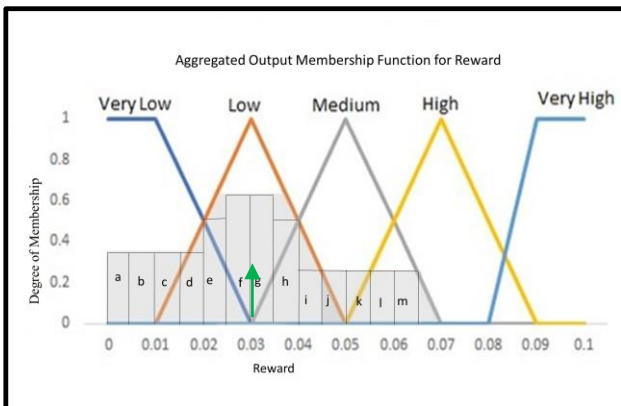

Fig. 11. Defuzzified reward for the example case.

Alternatively, from the “good” state, a driver can improve trust to move into the “very good” state to become a highly trusted vehicle. Once a driver is in the “very good” trust state, it is harder to lose trust as he/she only announces untrue messages with 0.1 probability. As such, the model captures the philosophy that good drivers tend to remain so, and vice versa unless they are encouraged to modify their behaviour. For consecutive untrue message announcements, a driver’s trust score is reduced. In this case, he/she may be moved to the “good” or “normal” state. It is even possible to move into the “bad” or “very bad” state when he turns severely malicious. In this way, a mal-intent driver loses his/her trust and may be access-blocked in the network from where he/she cannot participate in any communication. When a vehicle is access-blocked, an external procedure is assumed to enable him/her to be reset to the “normal” trust state, if permitted.

A clarifier is a vehicle which sends feedback in response to an RSU query. This feedback is consistent with the driver behaviour model. This allows the behaviour of clarifiers to be programmed similarly to the probabilities defined for different trust states of the sender and/or reporter drivers. As the trust model does not evaluate a clarifier’s feedback, their behaviour analysis is not considered as important as the sender or reporter information.

### C. Markov Chain Driver Behaviour Model

Driver announcements are only randomly reported by some reporters with the attack generation probability is set to 0.4 in the analysis of the current model [6]. In the series of experiments, a driver’s behaviour is not modelled to see at what situation they are sending more trustworthy or malicious messages. The disputes only arise from the reporter’s untrue attack messages which are generated randomly when the probability function returns true. This is why a model is developed which can control the message announcement behaviour from the driver. To this end, Markov-chain state transition model is created which can provide driver behaviour modelling and control message announcements. The proposed driver behaviour model is defined with some fixed states and from each states announcement probability for both trustworthiness and maliciousness are defined. There are some fixed conditions to switch between the states of this model.

The trust states of the proposed Markov chain model are defined with drivers lying probabilities to examine their honesty or lying behaviour. These states are defined based on the different trust thresholds set for the framework. Trust states are ordered according to the increasing trust values. Thus, a driver who wants to reach a higher trust state must achieve a higher trust value by announcing only trustworthy messages. A driver switches to another state when its trust score falls outside the range of trust scores for the current state. It is believed that a driver with a higher trust state possess the higher probability to announce more trustworthy messages than those with a lower trust state. With this model, acceptable behaviour means announcing trustworthy messages whereas the unacceptable behaviour means announcing untrue messages. When a trustworthy message is announced, a driver improves the trust score from it. If another driver sends a report about it and the sender driver wins the dispute, then RSU reward is added with the current trust. As a result, the

sender driver possibly makes a transition to another state which is associated with higher trust scores than the current one. In contrast, a driver loses trust score from the announcement of an untrue message when another reporter sends an untrue attack about it and the message is proved malicious by an RSU. Whether an announcement would be trustworthy or untrue, it is directly related to the driver behaviour. Hence, these activities are modelled with the proposed Markov chain-based state transition diagram by setting the probabilistic distribution to control untrue and trustworthy message announcements from each state. From each state, a driver earns rewards from the announcement, clarifying, reporting, forwarding and gets either reward or punishment from an RSU if there is a dispute relating to his/her announcement.

The proposed Markov model has six different trust states out of which one is the access-blocked state. A driver reaches this state when he/she is blacklisted, and his/her trust becomes 0.05. Other states are associated with different ranges of trust values. The six trust states are: “very good”, “good”, “normal”, “bad”, “very bad” and “access-blocked”. The probabilities of sending trustworthy and untrue messages from these states are set as shown in Table V which can be configured with different values to simulate the variation in driver behaviour. Table VI lists the probability of sending untrue attacks in the different trust states which defines the behaviour of the reporter drivers. These values are selected such that drivers with higher trust states send less untrue messages and reports than in the lower trust states. In a real-world scenario, a driver can react differently at different times which can be modelled with a Markov chain-based driver behaviour model using a different probabilistic distribution.

TABLE V. DRIVER’S ANNOUNCEMENT LYING PROBABILITY

Trust States	Probability of Announcing Trustworthy Message	Probability of Announcing Malicious Message
“very good”	0.8	0.2
”good”	0.6	0.4
”normal”	0.4	0.6
“bad”	0.2	0.8
“very bad”	0.1	0.9
“access blocked”	0	0

TABLE VI. REPORTER’S UNTRUE ATTACK REPORTING PROBABILITY

Trust States	Probability of Reporting an Untrue Attack	Probability of Not Reporting an Untrue Attack
“very good”	0.1	0.9
”good”	0.3	0.7
”normal”	0.5	0.5
“bad”	0.7	0.3
“very bad”	0.9	0.1
“access-blocked”	0	0

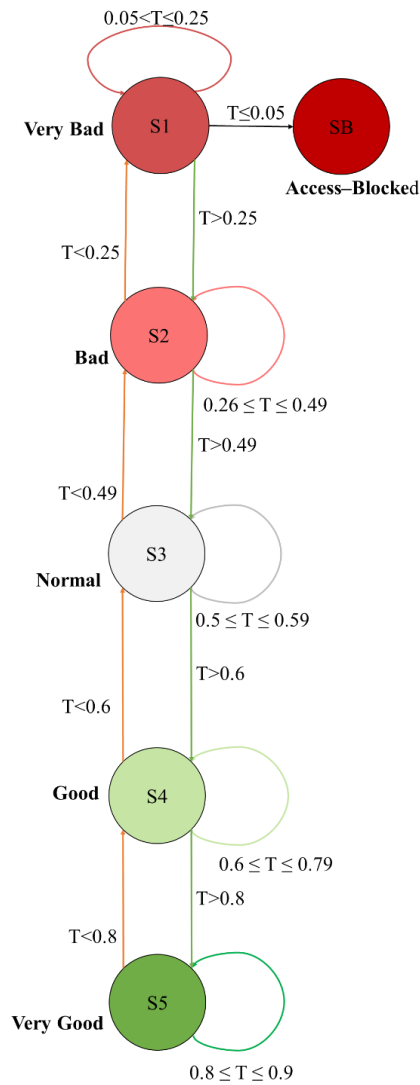

Fig. 12. Markov-chain behavioural model (state transition diagram).

With these trust states, a Markovian state transition-based driver behaviour model is presented, which is consistent with the trust framework described in Subsection III.A. A diagram of this model is shown in Fig. 12. It has fixed trust states, and each state is associated with a range of trust scores. A driver remains in a given state when his/her trust belongs to the range of trust values related to that state. With this model, a driver starts his/her journey from the “normal” state with a trust value equal to 0.5. From this state, a driver sends some announcements and relays events from others.

This model covers the announcement lying behaviour of drivers. Thus, from a “normal” state, a driver can build trust to reach the “good” state if he/she continues announcing trustworthy messages in the network. Also, he/she can lose trust by announcing untrue messages to reach the “bad” state from the “normal” state. He/she can even move to the “very bad” trust state if most of the announcements are untrue. In the worst case, the driver may be access-blocked if his/her trust score reaches 0.05.

#### IV. IMPLEMENTATION

First, Mamdani type fuzzy inference is implemented in MATLAB 2022 for RSU reward and punishment assessment. This provides a built-in fuzzy logic designer app where three inputs are created, their input membership functions, and corresponding fuzzy sets. After that, two different set of rules are entered into the rule editor of, and all the rules are given equal weight. As this is a two-output fuzzy system, two output membership functions and corresponding fuzzy sets are created. The fuzzy OR operator is used for punishment and the fuzzy AND is applied to the reward assessment. There are three fuzzy sets for each input and five fuzzy sets for each output. During the fuzzy inference for each dispute, all twenty seven rules are evaluated individually to produce the fuzzy output sets for each output. The aggregation applies on these output fuzzy sets and then the centroid method is applied on the combined fuzzy sets to return the desired fuzzy reward and punishment. These output values from MATLAB are directly processed and inserted into two different lists in the OMNeT++ to be used with the proposed model. There are eleven possible values of DBP. Hence, for each DBP value, all possible values of SI and RSU confidence are considered. In this way, different combinations of input values are used with the fuzzy system. For each DPB, a list of values is produced, and a different data structure in OMNeT++ is created to enable faster searching for different combinations of input values.

When a dispute decision is ready, an RSU asks for the DPB data from the TA. As the TA maintains a list of past records for all drivers, it can serve the query readily. After that, the RSU calculates the DPB for the relevant drivers. The RSU also calculates a confidence score of the disputing drivers from the collected feedback. Additionally, the RSU determines the severity level of event. The RSU then looks up the corresponding fuzzy reward and fuzzy punishment from the list. These values are directly used in the reward and punishment messages which the RSU announces and forwards to nearby RSUs to announce, too. In this way, each respective driver/vehicle receives the fuzzy RSU reward and punishment.

The following set of experiments use the Markov chain-based driver behaviour model which is implemented inside the TPD of every regular vehicle. This model governs the driver's announcement behaviour by setting the probability of sending trustworthy and untrue messages based on the behaviour state.

#### V. ANALYSIS AND VALIDATION OF THE MARKOV CHAIN-DRIVER BEHAVIOUR MODEL

##### A. Simulation Setup

A set of experiments has been carried out to evaluate the behaviour of sender or reporter drivers by changing their lying probability to observe the proportion of trustworthy and untrue messages generated from different trust states over the simulation period. The trust framework, the fuzzy reward and punishment mechanism, and the Markov state transition model are implemented in Veins [40] which comprises OMNeT++ [41] and SUMO [42]. It is an open-source framework which enables online communication between OMNeT++ and SUMO when the simulation is running. The participating

vehicles run for 5000 simulation seconds (s) on a fixed circular route in the Erlangen city map shown in Fig. 13. 100 vehicles are added at the start of the simulation and their numbers are kept constant throughout the experiment. Vehicles undergo a warm-up period where they move without announcing any event. When the warm-up period has elapsed, a fixed sender driver announces messages periodically at 1000s periodic intervals for each event type starting from the 500s. The simulation includes multiple types of event announcement from the same driver of V[0] for behavioural analysis. The events are scheduled as an accident message at 500s, a debris message at 700s, a road defect message at 900s, a traffic element problem message at 1100s and a tree on the road message at 1300s. Reporters deterministically send untrue attack reports based on the probabilistic distribution defined in Table VI.

As it is required to model the behavioural change of these reporters as well, their trusts are shown in Fig. 15 to 20 beside the sender driver. In this way, a series of experiments are conducted with different initial trust distributions and then the trust evolution is observed to examine the distinctive driver behaviour. A fixed reward and punishment mechanism is used from the disputes to update the trust of drivers so the result can differentiate their behaviour, whether they lie or not and in what circumstances they lie. Other rewards and punishments within the trust framework are not enabled for this analysis of driver behaviour.

In this series of experiments, drivers can send untrue attacks even when their trust score is less than 0.5 which was not allowed with the trust model presented in [6]. If a driver can send a message from a particular trust state, then he/she is allowed to send an untrue attack version of the originated message. The RSUs employ a 120-second collaboration timer to determine the validity of a dispute from the clarifier feedback. Thus, the verification time delays the reception of rewards and punishments from an RSU. Also, RSU reward is disseminated in one message and RSU punishment is sent in another message to the driver which also adds an additional delay besides their availability to an RSU and wireless collisions. Thus, the collaboration timer and a vehicle's availability, delays the reception of reward or punishment at the vehicles concerned. Table VII lists the parameters for the experiments.

There are two sets of experiments conducted for examining driver behaviour model. In the first set of experiments, clarifiers send opinion based on the witness and a probability distribution. If a driver with a "very high" trust state generates an event, then the clarifiers send positive opinions with 0.8 probability and negative opinions with 0.2 probability. For the "good" trust state, clarifiers send positive opinions to 60% of cases and negative opinions to 40% of cases. A message from a "normal" trust state originating from a driver gets 40% positive and 60% negative opinions. From the "bad" state, clarifiers deny announcements 80% of the time and support only 20% of the time. From the "very bad" state, clarifiers deny announcements 90% of the time and support only 20% of the time. This distribution can be changed as needed to model the variation in a sender or reporter driver's behaviour. In the second set of experiments,

clarifiers send feedback based on the probability distribution of their trust states as shown in Table VIII and the reporters send report based on the Table VI.

TABLE VII. SIMULATION PARAMETERS

Parameters	Values
Fuzzy reward and punishment	Varied
Fixed reward and punishment	0.1
Data Collection Nature	1. When all features enabled 2. When only RSU judgement applied
Simulation Period	5000s
Warm-up Period	500s
Announcement Interval	1000s
Initial Trust	Uniform distribution (0.5-0.6)
Number of Vehicles	100
Multiple types of Events Generated	Yes
Number of RSUs	12
Number of TA	1
Attacker Model	Untrue and Inconsistent Behaviour
Untrue Attack Generation	Based on the message class
Announcement Reward	Maximum of 0.8 (0.1 to 0.8 based on delay and distance)
Clarifier Reward	Maximum of 0.8
Relaying Reward	0.002
Collaboration Timer	120s

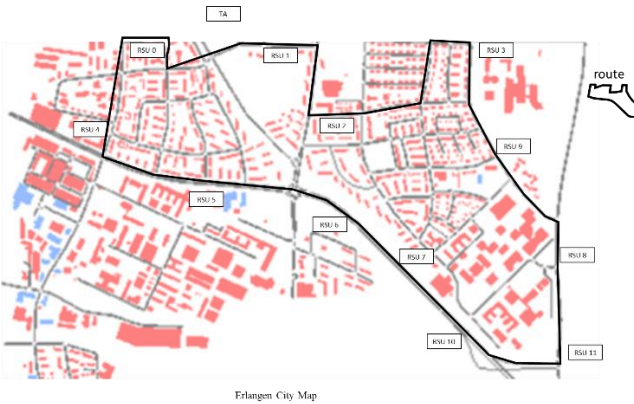

Fig. 13. Erlangen city map from [40].

**B. Behavioural Analysis of the Sender and Reporter Drivers**

1) *Uniform Trust Distribution (0.4 to 0.5):* In this experiment, all vehicles are inserted, and drivers are assigned their initial trust using a uniform distribution in the range of 0.4 to 0.5. Fig. 14 records the lying behaviour data from this experiment. The x-axis shows the simulation seconds, and the y-axis shows how trust score changes from the rewards and punishments. Though 100 drivers are present, the trust records of most drivers are not included in this chart for simplicity as their trust remains constant.

a) *Results:* There is an accident message scheduled from V0 which is not announced as the trust of the driver is insufficient. This is why a change in the trust data only commences from 700s when V[0] announces a debris message. As the trust of V[0] is low, driver has a higher chance to lie to others which is modelled using a probabilistic distribution. As the driver of V[0] lies, the drivers of V[2] and V[3] improve their trust by sending untrue attacks and they win against the driver of V[0]. This is visible from the chart. The other two drivers do not participate in the reporting process and hence their trust remains constant over the simulation period. Also, V[5] wins one dispute over V[0] which is indicated by a trust increment at about 3600s. It is seen that the announcement of trustworthy messages varies based on a driver’s trust state.

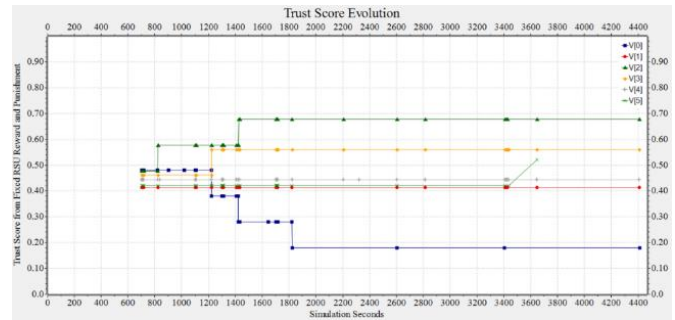

Fig. 14. Behavioural analysis of the drivers with trust (0.4-0.5).

2) *Fixed trust score of 0.9:* In this experiment, all drivers start from a very high trust state with a trust score of 0.9. Fig. 15 records the lying behaviour data from this experiment. The driver of V[0] is set to send 90% trustworthy and 10% of malicious announcements from this state.

a) *Results:* It is seen very few announcements are reported from V[1] and V[5] as they are also assigned “very good” trust states though their malicious probability is 0.2. This results in the constant trust score of the driver of V[0] while some reporters send untrue attacks maliciously which are disproved at RSUs. Hence, some reporters receive RSU punishments at different times during the latter part of the simulation. The drivers of V[1] and V[2] send only untrue attacks for which their trust is reduced. Thus, as configured, with a higher trust state there are fewer untrusted messages announced. Additionally, reporter drivers send fewer untrue attacks when their trust scores and corresponding trust states are higher.

Fig. 15. Behavioural analysis of the drivers with trust=0.9.

C. Behavioural Analysis of Sender with Fixed Trust (0.6) of Reporter and Clarifier

1) *Simulation setup:* The set of parameters are same as they are listed in Table VII. 100 vehicles are added and then they elapse a warm-up period. One sender driver of V[0] sends message periodically and five reporters from V[0],...,V[5] send reports based on the probability distribution defined in Table VI. Table VIII lists the feedback generation probability of clarifier vehicles. In the next two experiments, clarifiers send feedback based on the probability distribution of their trust states. Also, the reporters send report based on the probability distribution of their trust states. After that their behaviour are captured in Fig. 16 and Fig. 17.

TABLE VIII. CLARIFIER’S FEEDBACK PROBABILITY

Trust States	Probability of Sending Positive Feedback	Probability of Sending Negative Feedback
“very good”	0.8	0.2
”good”	0.6	0.4
”normal”	0.4	0.6
“bad”	0.2	0.8
“very bad”	0.1	0.9
“access blocked”	0	0

2) *With sender driver’s trust of 0.3:* Fig. 16 shows the trust score evolution of six vehicles. In this experiment, the trust of sender driver is set to 0.3, the trust of the reporter and the clarifier is set to 0.6. Clarifiers send opinion when an RSU asks based on their probability distribution of trust states. As, the trust score of the reporter and clarifier belong to the “Good” trust state. With these settings, reporter vehicles send untrue attacks with only 30% of cases and clarifiers send positive opinion in 60% of cases when they observe event on road. They also send negative feedback with 0.4 probability if they do not see the event on the said location. In this way, their communication is achieved.

a) *Results:* Until first 1400s, there is no dispute, and no trust change observes. After that, there are many reports announced for which the driver of V[0] only wins. As the reporters sends report maliciously. The reporter driver of V[5] loses all disputes which reduces trust to 0.2 at 2400s. The driver of V[3] does not report any announcements from V[0] until 2800s as seen from the chart. After this time, V[3] sends many reports which are proved false to RSU, so the trust is reduced to 0.2 at 4030s. Other reporters excluding V[4] occasionally sends untrue attacks and they also lose the disputes to V[0]. In this way, V[0] builds trust as always it announces trustworthy messages and some reporters being malicious lose trust. In Fig. 16, the sender driver slowly improves trust from only the RSU rewards, and the malicious reporters receive only RSU punishments as their reports are proved false by RSUs. As the sender is trustworthy throughout the simulation, all reporters receive RSU punishments which reduces their trust score, and their trust state moves from “normal” to “bad” and then “very bad” as a consequence.

Fig. 16. Behaviour analysis of driver when trust score is 0.3.

3) *With sender driver’s trust of 0.7:* In this experiment, sender driver starts with 0.7 trust score and from “normal” trust state whereas the clarifier’s and reporter’s trust state are same to the previous experiment. They both start with the “Good” trust state.

a) *Results:* In this experiment, the driver of V[0] only builds trust as always send trustworthy announcements. Reporter drivers V[2], V[5], and V[3] send reports maliciously for which they lose all disputes. These are noticed by the trust decrements in Fig. 17. Reporter V[4] does not send any report and V[1] sends only one untrue report for which it receives the RSU punishment. When a reporter sends a malicious report and receives RSU punishment, then subsequently it sends more report maliciously as their trust states moves toward “bad” state. As the sender driver reaches “Good” trust state early in Fig. 17, it only announces trustworthy messages and when reporters send false reports, they receive RSU punishments. As they move from “Normal” to “Bad” states the reporters send more false reports and hence they receive more RSU punishments.

Fig. 17. Behaviour analysis of driver when trust score is 0.7.

VI. PERFORMANCE COMPARISON OF THE PROPOSED FUZZY JUDGEMENT VS. FIXED RSU JUDGEMENT

A. Performance Comparison Using Only RSU Reward and Punishment

1) *Simulation setup:* The fuzzy reward or punishment method is applied when dispute decisions are ready at RSUs. Hence, the comparison is made between the fuzzy vs fixed reward and punishment schemes. To this end, a series of experiments is conducted to evaluate their performance. When the warm-up period has elapsed, a fixed sender driver of V[0] announces messages periodically at 1000s periodic intervals for each event type starting from the 500s. In this set of

experiments, multiple types of event announcement are considered from the same driver V[0] for this comparison which is announced similarly in the behaviour analysis. When they are announced, a fixed set of reporter drivers of vehicles V[1], V[2], V[3], V[4], and V[5] deterministically sends untrue attack reports after their reception. The trust data is recorded separately for both the fuzzy and fixed systems. The trust framework has other TPD rewards and punishments which are omitted for differentiating these assessment results since fuzzy logic is only used to improve the RSU reward and punishment mechanism. Updates to trust from the fuzzy and fixed reward and punishment schemes are shown on graphs to compare them. After this, two trust density distributions are presented for each scheme. One shows the initial trust data, and the other provides the trust data when the simulation ends.

2) *Scenario 1 – Trust Updates from the Fuzzy RSU:* Fig. 18 shows the trust score evolution for six vehicles only. Trust is updated only from RSU judgements. The x-axis represents simulation seconds, and the y-axis shows the updated trust from the fuzzy RSU unit. During this experiment, the driver of V[0] sends scheduled events periodically. The initial trusts are assigned from a uniform distribution with the range of 0.5 to 0.6. The driver of V[0] starts with a “normal” trust state which governs his/her behaviour in message announcements. This state is configured to send more malicious messages than the trustworthy messages in the state transition model.

a) *Results:* It is seen that V[0] builds trust from the fuzzy rewards as it announces only trustworthy messages while the reporters get fuzzy punishments which reduces their trust as the simulation progresses. First, V[0] moves to “Good” state and then to “Very Good” states. V[0] reaches the maximum trust at about 1800s with “Very Good” state. Alternatively, reporters in this experiment send untrue reports and move from the “normal” to the “bad” trust state. For example, the driver of V[2] always sends false reports and receives RSU punishments. His/her trust score plunges to the lowest value of 0.34 at 2900s due to being malicious. It is noticeable that the first reward of V[0] is highest as the driver has no punishment records in the DBP whereas the latter judgements are not seen as high as the first one. Since, some latter rewards are from the disputes relating to the less severe announcements. Alternatively, the fuzzy RSU punishments are not very harsh initially which is seen in the reporter vehicles V[1] and V[5]’s punishments. They increase slightly in the later punishments where the severity of incident, punishment records in the DPB, and RSU confidence influence the outcome. In later disputes, event severity levels are different which vary the punishment. Hence, the rewards / punishments vary throughout the experiment whereas in the fixed reward scheme trust increments / decrements are fixed irrespective of mitigating factors. So, with the fuzzy scheme, a driver has more chances to improve trust scores from subsequent announcements and trustworthy reporting. This way their network participation lifespan is extended. Fig. 19 depicts the trust scores of all vehicles which participated in this experiment. It is noticeable from this figure that the trust

scores of most vehicles are unchanged throughout the simulation as they do not report or announce any messages and there is no forwarding or clarifying reward for others.

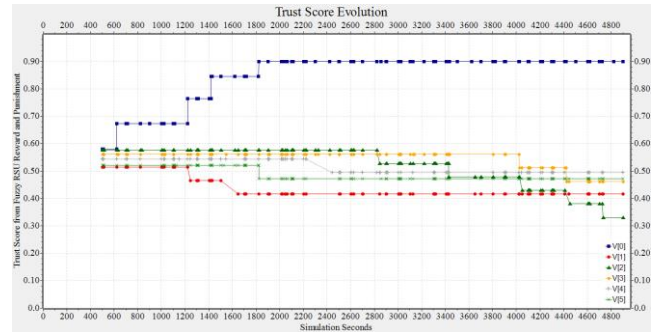

Fig. 18. Trust score evolution of six vehicles from the fuzzy reward and punishment.

Fig. 19. Trust score evolution of all vehicles with the fuzzy reward and punishment.

Fig. 20 shows the trust score density distribution of vehicles collected at the beginning and at the end of the simulation. The initial trust score of all vehicles is between 0.5 and 0.6. The right-side chart shows that V[0] reaches 0.9 which is marked by a dot. Most vehicles do not see any trust score alterations apart from three vehicles which are the reporters in this experiment. This is because general vehicles do not engage in any disputes from which they can earn or lose trust. Additionally, they are not given any reward from the forwarding or other activities. The long gap in the right chart means no vehicle other than V[0] achieves this score due to the experimental design and this result is as expected. Also, the driver behaviour model governs their honest and dishonest announcements. It is seen with the fuzzy system, the magnitude of reward and punishment are more nuanced than the fixed system so vehicles have more time to correct their future behaviour and resume normal operation. The blacklisting of a vehicle or reaching the highest trust is also delayed when using the fuzzy system. Even so, in the fuzzy system when only RSU rewards and punishments are given, the sender vehicle still reaches 0.9 trust. The reporter vehicle reaches a low trust score though it has some trust left to carry out further communication and it could choose to correct its behaviour and achieve good trust score in due course. Overall, with the fuzzy system the trust scores are more stable than the fixed system in the sense that when trust is gained or lost it does not change dramatically. Additionally, the fuzzy system considers environmental dynamics for fuzzy judgements, e.g.,

event severity, driver past behaviour and confidence score which is appropriate when reviewing disputes.

Fig. 20. Distribution of trust scores at the start and the end.

3) Scenario 2 – Trust Updates from the Fixed RSU: The next experiment measures the trust score of vehicles only from the fixed RSU reward and punishment mechanism. In Fig. 21, simulation time is on the x-axis and the y-axis shows the trust score. This is conducted with the set of parameters defined in Table V, but the RSU reward and punishment is fixed (0.1) for every driver.

a) Results: V[0] sends a malicious message initially and receives an RSU punishment that reduces its trust below 0.5. From this stage, it is configured to send more malicious messages 80% of time. Thus, its trust subsequently decreases from RSU punishments. When its trust score belongs to the “very bad” state, it sends all malicious messages. In this way, its trust is reduced to 0.05 which meets the condition to block its access. Alternatively, the reports from V[1] wins all disputes and hence its characteristic shows an upward trend. Also, V[4] and V[5] win two other disputes over V[0] and hence receive RSU rewards. It should be noted that there are no events after the 4400 seconds. It is seen that trust adjustments are faster in the fixed RSU judgement system as it assigns a higher amount (0.1) irrespective of event type and driver behaviour compared to the fuzzy system which provides a value in the range 0.01 to 0.1 based on the evaluation result. When only RSU rewards and punishments are given, in the fixed system vehicle V[0] is access-blocked. This is due to the RSU decisions about the announcement being untrue along with the magnitude of the penalty. Fig. 22 shows the trust scores of all vehicles in this experiment. In this figure most of the vehicles do not change their trust score as they do not participate in any reporting or announcement. Besides, they are not given any reward for clarifying and forwarding.

Fig. 21. Trust score evolution from fixed reward and punishment.

Fig. 22. Trust score evolution with fixed reward and punishment.

Fig. 23 shows the initial trust and the final trust distribution in two density curves. The first density chart shows the trust scores of all vehicles generated from a uniform distribution. However, the right-hand chart plots the trust scores of all vehicles when the simulation ends. As expected, in the second chart, the trust of most vehicles is unchanged as they do not engage in any disputes from which their trust can change. The right-hand chart confirms some vehicles with positive behaviour build their trust from truthfully reporting activities whereas the sender V0 is access-blocked, leaving its trust at 0.05. With this fixed RSU judgement, vehicles have less opportunity to modify their behaviour and vehicle access-blocking is more likely as shown in the right chart in Fig. 21.

Fig. 23. Distribution of trust scores at the beginning and the end.

## VII. DISCUSSION

The trust model with the fuzzy reward or punishment assessment scheme controls the broadcasting of messages at the sender side based on the trust score of drivers / vehicles so a receiver driver / vehicle can believe in a message instantly and does not need to take any further action. By regulating the ability to broadcast, malicious vehicles, once identified, are unable to continue to broadcast messages. Though, blacklisting is present in most existing approaches it requires the trust score to reach zero. Therefore, a malicious vehicle can create many hazardous problems before being blacklisted. Furthermore, driver decision times (response times) are reduced as trust does not need to be verified on a per message basis. This also reduces the communication overhead. It uses the RSU for ruling on a dispute when needed using clarifier feedback, rather than approaches which gather direct and/or indirect trust or opinions from surrounding neighbours, which may include false recommendations from malicious vehicles. However, the application of fuzzy reward or punishment assessment is only limited to the dispute resolution process at the RSU. Additionally, it requires presence of clarifier vehicles to send feedback to assist in the resolution of disputes.

### VIII. CONCLUSION AND FUTURE WORK

In this paper, a Mamdani fuzzy logic based RSU reward and punishment assessment scheme is presented. This application considers event severity, driver past behaviour and RSU confidence (calculated from the feedback of the clarifier vehicles) to determine an appropriate level of reward or punishment for the drivers involved. The reward and punishment mechanism uses a different set of rules to assess the output. The fuzzy RSU reward or punishment assessment scheme is an extension of the fixed RSU judgement mechanism in the previous sender-side trust framework [6]. The RSU ruling is only needed when there is a dispute (when both an event and opposite event exist) in the network. The fuzzy RSU controller is invoked only when it receives untrue attack reports, which is expected to be occasional. A Markov-chain based driver behaviour model is also included to control the announcement behaviour of driver when conducting the series of experiments.

The fuzzy approach is compared against a fixed reward and punishment scheme. Trust evolution timelines are provided in each case along with trust density distribution curves when only the RSU mechanism is active. The results suggest the fuzzy system achieves a more stable trust environment. This assessment also employs a Markov-chain based driver behaviour model whereby good drivers are assumed to behave in a positive manner more generally, and vice versa. This allows the nuanced fuzzy controller decisions to encourage drivers to behave better, and to provide fairer allocation of rewards and punishments based on several factors. However, in the future other inputs to the fuzzy controller could be considered.

**Abstract**—Integrating artificial intelligence (AI) has become crucial in modern mobile application development. However, the current integration of AI in mobile learning applications presents several challenges regarding mobile app usability. This study aims to identify critical usability issues of AI-enabled mobile learning apps by analyzing user reviews. We conducted a qualitative and content analysis of user reviews for two groups of AI apps from the education category - language learning apps and educational support apps. Our findings reveal that while users generally report positive experiences, several AI-related usability issues impact user satisfaction, effectiveness, and efficiency. These challenges include AI-related functionality issues, performance, bias, explanation, and ineffective Features. To enhance user experience and learning outcomes, developers must improve AI technology and adapt learning methodologies to meet users' diverse demands and preferences while addressing these issues. By overcoming these challenges, AI-powered mobile learning apps can continue to evolve and provide users with engaging and personalized learning experiences.

## I. INTRODUCTION

There is a growing demand for mobile apps incorporating artificial intelligence (AI) as more people use them to enhance their daily lives. The size of the AI apps market is expected to expand rapidly in the coming years [1]. By incorporating AI into mobile apps, programmers can introduce cognitive and logical characteristics that lead to a diverse selection of smartphone applications. [2]. Implementing AI technology is prevalent across various facets of human existence, particularly within the field of education [3].

Mobile learning applications incorporating AI provide a sophisticated educational atmosphere, progressive pedagogical techniques, and easily accessible platforms for learners [4]. Recent studies have noted the positive impact of AI-based in English education [5]. The increasing trend of mobile assisting language learning apps has resulted in the utilization of AI-powered speaking applications equipped with speech evaluation mechanisms to facilitate English as a foreign language (EFL) speaking exercises [6]. Besides, the current wave of artificial intelligence is already impacting the management and domination of math education apps [7].

However, AI systems must demonstrate effectiveness and efficiency while ensuring user satisfaction. This is crucial

because usability strongly influences the success and quality of software [8]. Therefore, to evaluate the usability issues in AI-enabled learning mobile apps, this research will utilize usability key factors such as user satisfaction, efficiency, and effectiveness, commonly considered when assessing mobile apps [9] [10].

The rapid expansion of mobile devices has resulted in an upsurge in mobile applications accompanied by user reviews [11]. In mobile app marketplaces like the Apple Store and Google Play, users can rate apps and post reviews about adding a feature, reporting an issue, and their experiences using them. These reviews can be rich sources of information for developing future software versions [12]. In other words, developers can improve software quality and identify missing features by analyzing user reviews [11]. The previous study has shown that these reviews possess information related to user usability [13]. Thus, analyzing app reviews is a helpful way to identify any usability problems that users might face and to reveal any looked-for improvements [14]. Groen et al. [15] discovered that these app reviews have the ability to discover quality features directly affecting users.

Despite the wide adoption of AI-enabled learning mobile apps, there is still a need to better understand the specific usability issues associated with these apps. The purpose of this study is to address this gap. Additionally, while several studies [11] [14] [16] [17] [18] analyzed user reviews to detect usability issues to enhance software quality, there is insufficient research regarding the specific examination of AI-enabled learning apps. This is an area that our study aims to investigate and address.

In response to the identified gaps, this research makes notable contributions to the field of AI-enabled mobile learning apps. Through a comprehensive analysis of user reviews focusing on user experience and usability issues, our study offers a robust understanding that can assist app developers and designers in improving the design and development of AI-enabled mobile learning apps. Understanding user perspectives can address usability issues, improve user satisfaction, increase effectiveness, and enhance efficiency in mobile learning experiences. The research findings also contribute to the broader understanding of AI in education, highlighting the challenges and opportunities associated with AI integration in mobile learning apps, thus facilitating their wider acceptance and use among learners and educators.

This study aims to perform a thorough usability evaluation

of AI-enabled mobile learning apps, following ISO 9241 standards [9] [10], measuring effectiveness, efficiency, and satisfaction. The primary objective is to identify potential usability issues affecting user satisfaction, effectiveness, and efficiency. Additionally, to identify the primary challenges and deficiencies that AI-enabled learning applications encounter in delivering satisfactory performance. This study provides valuable information for application developers and designers to improve app usability by analyzing user reviews of various AI-enabled mobile applications in the education category. The findings help identify the apps with significant problems and weaknesses, showing where improvements should be focused. Based on these goals, this research aims to answer the following research questions:

**RQ1:** How is the user experience with AI-enabled mobile learning apps?

**RQ2:** To what extent do usability issues impact user satisfaction, effectiveness, and efficiency in AI-enabled mobile learning apps?

**RQ3:** What are the most prevalent usability issues related to AI in AI-enabled mobile learning apps?

The responses to the research questions mentioned above will offer crucial insights into the most prevalent usability issues related to AI-enabled mobile applications for language learning and educational support. These insights can be leveraged to identify areas that require improvement and formulate effective strategies to enhance the usability of these apps. Ultimately, this research aims to improve the usability of AI-enabled mobile learning apps, thereby enhancing user satisfaction, effectiveness, and efficiency.

The paper is organized as follows: Section II presents usability evaluation in mobile applications, and leverages user reviews for detecting usability issues in diverse mobile applications. Then, Section III explains and justifies the research methodology utilized in this study. Section IV presents the results, while Section V engages in the discussion of the results. Section VI focuses on addressing potential threats to validity. Finally, Section VII concludes the paper and discusses future work.

## II. RELATED WORK

This section highlights the most usability evaluation in mobile apps and the utilization of user reviews to detect usability problems in mobile apps.

### A. Usability Evaluation in Mobile Application

Many studies have conducted usability evaluations of mobile apps [15] [19] [20]. For instance, a systematic review by [19] showed a literature review on a comprehensive examination of the usability of mobile apps. They found that the definition of ISO 9241-11 has been mostly used in HCI, followed by ISO 25010 definition. Furthermore, they discovered that efficiency, satisfaction, and effectiveness were the most frequent attributes. Another systematic study by Sunardi et al. [20] introduced a literature review of the most usability evaluations. They observed that satisfaction, efficiency, and effectiveness are the most well-known usability evaluations. Another systematic review by [21] discussed mobile app

usability in different mobile app categories. They identified frequent usability for mobile applications and required design features for a particular mobile application category. Another study by [22] proposed a model that aims to employ opinion mining to evaluate the subjective usability of the software automatically. This model is centered on three crucial quality factors of usability: effectiveness, efficiency, and satisfaction. Moreover, Alhejji et al. [23] completed a comprehensive analysis, assessment, and comparison of the usability of mobile banking apps, considering both iOS and Android platforms in Saudi Arabia. The researchers evaluated usability based on effectiveness, efficiency, and satisfaction, as defined by ISO 9241.

### B. Leveraging user Reviews for Detecting Usability Issues in Diverse Mobile Applications

Previous studies used user reviews to extract valuable information [11] [14] [16] [17]. Felwah and Rita [14] analyzed 1236 reviews from 106 mental health apps to detect usability issues. They categorized usability issues into six groups, finding that the results could offer app developers valuable design advice to enhance the usability of mental health apps. The further study analyzed [16] user reviews in stroke caregiving applications to identify usability problems. They found some usability issues such as errors, efficiency, and effectiveness because of the misunderstanding of the user needs of app developers. The authors categorized the user reviews as negative or neutral using the usability evaluation criteria of Nielsen and Bevan, as well as considering the extent of the user experience. In addition, another work by [17] reviewed mobile applications created for the COVID-19 pandemic. The writers gathered feedback from users in the form of ratings and reviews as well as information on the objectives and features of the app. The review's results emphasized the need for new application development and further improvement, revealing design features like ease to use, cultural sensitivity, usefulness, privacy, responsiveness, security, flexibility, support, performance, and reliability. Another work by Pawel and Anna [11] investigated the potential of user reviews to extract usability and user experience problems in WhatsApp. They identified seven usability factors that were connected to the issues that were reported. Using different dictionary sources, they used a sentiment analysis by grouping all the negative and positive words from the user reviews. Another research study by [24] proposed employing machine learning (ML) techniques to ascertain users' perspectives. Furthermore, they utilized and compared the effectiveness of five different ML classifier algorithms. Lastly, [18] explored user reviews and discovered novel usability issues associated with disaster applications by adapting a pre-existing usability framework. The existing research on usability in mobile app user reviews has been extensive. However, the usability of AI-enabled mobile applications for language learning and educational support has received limited attention in previous research. Therefore, this study aims to analyze user reviews and uncover potential usability issues associated with AI mobile applications in this specific domain.

## III. METHODOLOGY

Our motivation is to empirically evaluate usability issues in AI-enabled mobile applications designed for language learning

TABLE I. APP'S STATISTICS

App Group	App Name	Number of Reviews
Language Learning	ELSA: Learn And Speak English	45,576
	Duolingo: language lessons	276,819
	Cake - Learn English & Korean	80,309
Educational Support	Socratic by Google	5,789
	Microsoft Math Solver	3,651
	Symbolab: Math Problem Solver	1,248
	Photomath	22,1559

and educational support. To accomplish this, we have devised an approach comprising six steps, which we will refer to as A, B, C, D, E, and F, as shown in Fig. 1. This section provides a detailed description of each step.

#### A. Identifying AI Mobile Apps Designed for Self-Education

Our objective is to assess the usability issues in mobile applications designed for language learning and educational support using AI. To achieve this, we have identified a specific subset selection criteria to filter out the relevant apps. These selection criteria are outlined below.

- **Initial Selected Apps:** We selected the top 100 worldwide downloaded mobile applications in the education category. We sourced this information from the ranking lists on data.ai<sup>1</sup>. This selection aimed to include the widely used apps in our study.
- **AI-Enabled Mobile Apps:** Then, we manually investigated the description of each initialed selected top 100 apps in the education category to ensure whether an app uses AI features, as shown in Fig. 2.
- **Number of App Reviews:** We excluded apps with reviews less than 1000.

This study identified mobile applications in the education category that explicitly incorporated AI technology. we aimed to investigate the usability issues associated with apps that used AI for educational purposes. After reviewing the top 100 apps in the education category based on the selection criteria, we found that only thirteen apps met our selection criteria. Since most of our study heavily relies on user reviews, we want to ensure these apps have sufficient user reviews. Therefore, we discarded apps with reviews of less than 1000. Additionally, we excluded apps unrelated to language learning and educational support to ensure our analysis focused on relevant apps. As a result, this allowed us to filter out seven AI-enabled mobile applications, namely: *ELSA: Learn And Speak English*, *Duolingo: language lessons*, *Cake - Learn English & Korean*, *Socratic by Google*, *Microsoft Math Solver*, *Symbolab: Math Problem Solver* and *Photomath*. Although these apps belong to the same category, they serve different purposes. Consequently, we classified them into two groups - language learning and educational support, as shown in the Table I.

<sup>1</sup><https://www.data.ai/>

#### B. Data Collection and Cleaning

After identifying seven AI mobile applications for learning languages and educational support, we collected all available app reviews for these apps from Google Play Store. To do so, we utilized *Google-Play-Scraper*<sup>2</sup> using Python to crawl user reviews for each app. We collected **634,951** user reviews for all seven apps between March 2022 and March 2023. However, we found that the initial data contained irrelevant and noisy information, such as short sentences, emojis, and non-English reviews, which could be problematic when answering our research questions. Therefore, we used Natural Language Processing (NLP) libraries to make our results more reliable by removing all irrelevant and noisy data. We utilized the following cleaning criteria to filter out irrelevant reviews:

- 1) Blank content.
- 2) Emojis-only content.
- 3) Emojis and numbers from the content.
- 4) Duplication content.
- 5) Non-English.
- 6) Less than two words.

As a result, we exclude 189,491 irrelevant app reviews with the remaining **445,460** relevant reviews.

#### C. Sentiment Analysis

We conducted sentiment analysis to filter out reviews to positive, negative, and neutral as it offers advantages in identifying usability [25]. To determine the sentiment of each review sentence, we utilized a domain-specific sentiment analysis tool, SentiStrength-SE [26], specifically designed for analyzing text in software engineering, including analyzing user reviews [27]. The SentiStrength-SE algorithm evaluates each word individually and assigns a score to indicate its sentiment. The tool allocated numerical values to positive and negative words, ranging from +1 to +5 for positive and -1 to -5 for negative [28]. The polarity of sentiment, as determined by its value, can be categorized as negative when the value is less than 0, positive when the value is greater than 0, or neutral when the value is equal to 0. This classification allows for assessing the severity of the sentiment based on its proximity to 0. This approach, as described in [29], provides a framework for understanding the sentiment expressed in user reviews. To compute the overall sentiment score for each sentence, we determined the highest positive and negative scores and combined them [28]. By utilizing the SentiStrength-SE tool on **445,460** reviews, it filtered them based on three categories (Neutral = 163,142, Positive = 247,640, and **Negative = 34,678**). This process is beneficial for collecting candidate reviews for our evaluation in the next step and reduces the number of reviews that will be matched with usability factors: satisfaction, effectiveness, and efficiency [22].

#### D. Usability Keywords Filtering

The purpose of using usability keyword filtering in this step is to identify potential usability issues quantitatively by analyzing user reviews. However, the reviews we obtained contained mixed feedback, including positive, neutral, and negative opinions. We only analyzed the negative reviews since

<sup>2</sup><https://pypi.org/project/google-play-scraper/>

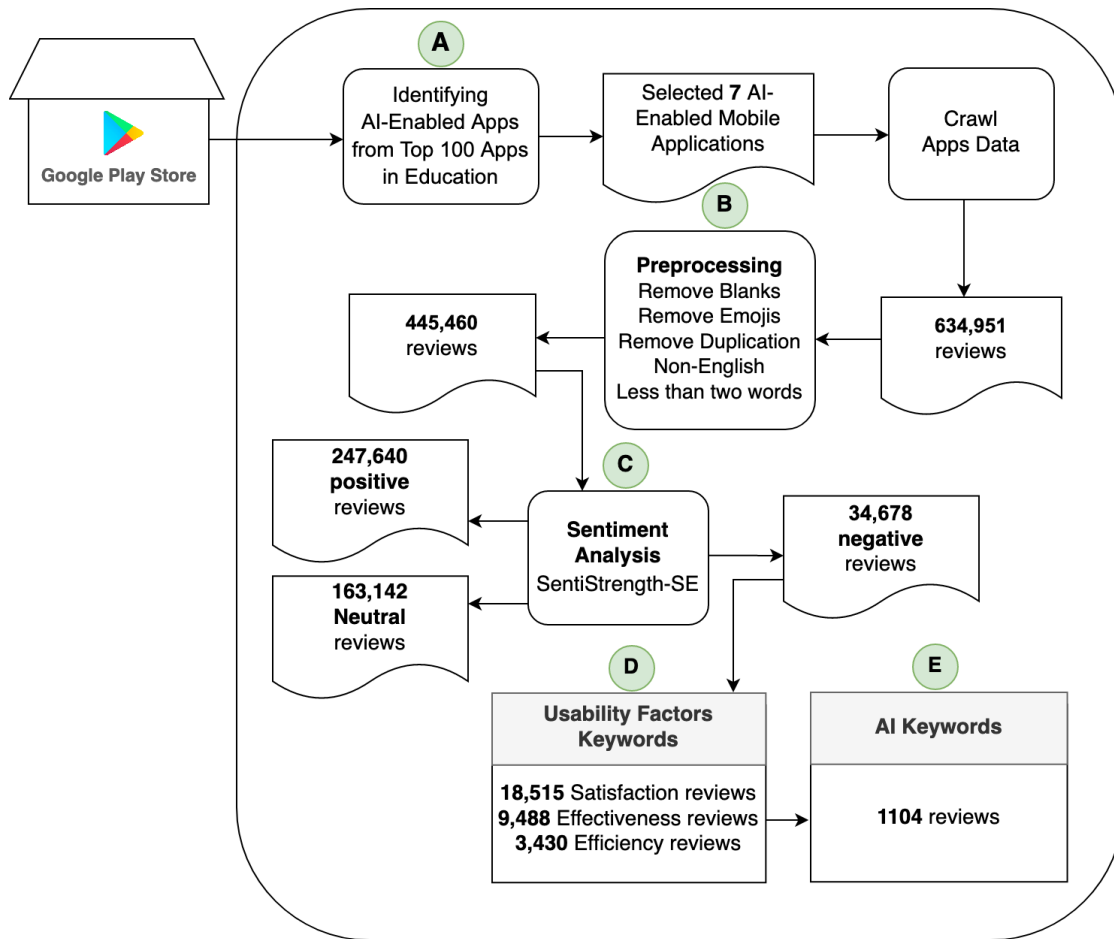

Fig. 1. Overview approach.

Our English learning app is powered by Artificial Intelligence (AI) that can quickly assess your fluency level and help you learn English, no matter what your native language is. ELSA has 7,100+ AI language learning activities and tools to help you speak in an...

Fig. 2. App's description.

we focused on examining the usability issues in AI-enabled mobile learning. As defined by ISO 9241-11, Usability refers to how effective and efficient a product is and the degree of user satisfaction after using it [30]. To better understand the usability issues associated with these apps, we constructed three negative polarity lexicons based on satisfaction, effectiveness, and efficiency keywords. These keywords were identified by conducting a thorough examination of relevant studies [23] [11], as shown in Fig. 3. We labeled the app reviews using a Python script that employs the NLTK library, which considers lemmatization and stemming. For example, the word “crashed” can be lemmatized to “crash,” and “disappointing” can be stemmed to “disappoint”. Using these techniques, we could identify and classify specific usability issues more effectively, leading to more accurate results. Next, we calculated the count and frequency of negative reviews of each usability factor [9]. This resulted in 18,515 reviews related to satisfaction, 9,488 reviews on effectiveness, and 3,430 on efficiency. We then

determined the overall usability score for each app review by adding the negative satisfaction, effectiveness, and efficiency scores together [10] [30]. We evaluated the usability issues of AI-enabled mobile apps for language learning and educational support by comparing the usability scores. Then, we identified which apps had the most usability issues and which had minor ones.

#### E. AI Keywords Filtering

After identifying usability issues from the previous step, we combined the results of 28,948 relevant negative usability reviews to filter out reviews based on AI terms [31], as shown in Fig. 4, to find only AI-related reviews. To achieve this, we developed another Python script that employs the NLTK library, which considers lemmatization and stemming, as before. This allows for more effective identification and classification of specific AI-related usability issues, ensuring more accurate results. For example, “speech recognition” can be lemmatized

to “speech recognize”, and the word “voice recognition” can be stemmed to “voic recognit” The filtered result was 1104 AI-related reviews out of 28,948. We then randomly selected AI-related reviews based on their rating [25], resulting in 221 reviews. Then, quantitative data analysis was used to examine the most prevalent usability issues related to AI in AI-enabled mobile apps for language learning and educational support. The qualitative content analysis approach enabled identifying and examining how these usability issues are reflected in user experiences. We performed a thematic analysis of the data using Excel software. Based on the steps outlined in Fig. 5, we conducted a manual analysis of the sample AI-related reviews [32]:

1. Randomly select 221 AI reviews based on the rating criteria.
2. Conduct a comprehensive reading of all 221 selected reviews to gain a deep understanding of the data.
3. Identify and note any patterns or ideas that emerge from the reviews.
4. Generate initial codes from the patterns and ideas identified in the reviews.
5. Review the codes to identify overarching themes and sub-themes that capture the essence of the data.
6. Refine the results by reviewing and comparing the themes to the original data to ensure they accurately reflect the content and context of the reviews.
7. Define and label each theme and sub-theme to make it clear and understandable.
8. Provide quotes from the reviews to illustrate each theme and sub-themes.

We coded the sample reviews manually after reading them multiple times to familiarize themselves with the information. We assigned codes to significant phrases and sentences relevant to AI-related issues [32]. Additionally, as the research progressed, we modified the codes to represent the substance and context of the information accurately. Then, we analyzed the codes to identify recurring themes and sub-themes [33]. We appropriately labeled the data to reflect the content and context of the information. To uphold the accuracy and reliability of the analysis, we conducted various tests and inspections, including reviewing the coding strategy and checking inter-coder reliability with a second researcher. We addressed any inconsistencies or misunderstandings through discussion and agreement. We systematically conducted the manual analysis process, ensuring the findings’ validity and reliability. The analysis followed the guidelines provided by [34].

#### IV. RESULTS

Our evaluation examined the impact of usability issues on using AI-enabled mobile learning apps and their impact on user satisfaction, effectiveness, and efficiency. The usability issues are crucial to explore, as they can influence user behavior and affect the overall performance of educational apps. By analyzing user reviews of various AI-enabled mobile apps for learning languages and educational support, this study aims to illuminate the possible challenges or concerns that users encounter while using these apps and assess how these issues affect the user experience.

**RQ1:** How is the user experience with AI-enabled mobile learning apps?

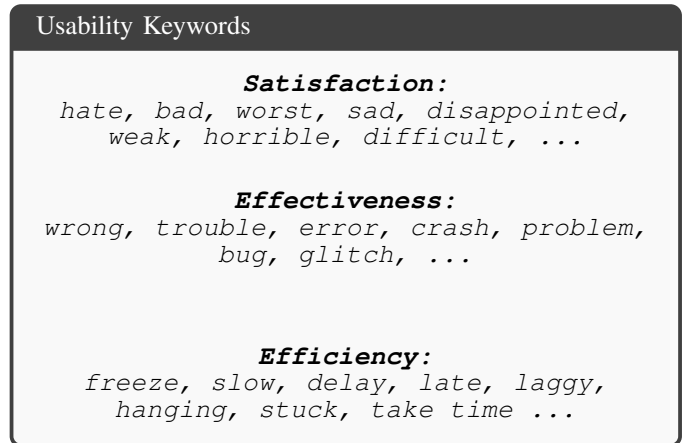

Fig. 3. Negative usability keywords.

Fig. 4. Keywords related to AI.

**RQ1 Rational:** This question aims to determine the overall sentiment of user reviews towards AI-enabled mobile learning apps. The sentiment analysis will provide insight into how users experience and perceive these types of apps, helping identify potential improvement areas. Understanding the sentiment of user reviews can assist developers and designers in creating better AI-enabled mobile learning apps that align with users’ needs and expectations.

**RQ1 Results:** As described in the methodology section, we conducted sentiment analysis to identify the sentiment expressed in user reviews. The sentiment analysis results for AI-enabled learning apps shown in Fig. 6 revealed that in the learning language app group Duolingo: language lessons had the highest number of reviews, totaling 213,307. However, the app received the highest negative reviews, with 21,441 users expressing dissatisfaction with its features. In addition, the app had 67,043 neutral reviews. ELSA Learn English, Get Fluent received 25,410 reviews, with 16,506 positive and only 797 negatives, resulting in a high percentage of positive reviews. The app also had 8,107 neutral reviews. Similarly, Cake - Learn English & Korean received 48,435 reviews, with 32,461 positive and 1,048 negative reviews, resulting in the highest positive review count in this category. The app also had 14,926 neutral reviews. The app also had 14,926 neutral reviews. Among the educational support app group, Socratic by Google received 3,744 reviews, with 1,940 being the highest positive, 217 negatives, and 1,587 natural reviews. Microsoft Math Solver and Symbolab: Math Problem Solver had fewer reviews, with 2,593 and 893 reviews, respectively. Symbolab: Math Problem Solver had the highest negative reviews, with 140 users expressing dissatisfaction with its features and 413 neutral reviews, followed by Microsoft Math Solver, with 240 negative reviews and 1147 natural reviews. Photomath

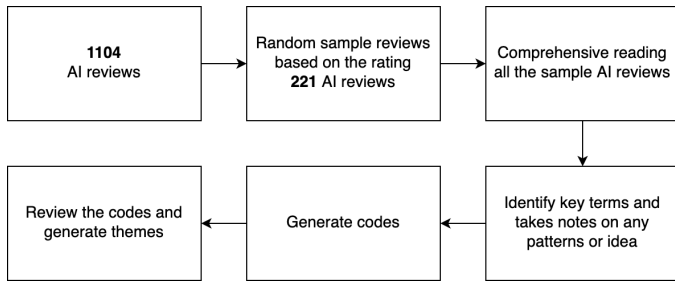

Fig. 5. A brief overview of our manual qualitative content analysis approach.

**RQ1 Summary.** This summary highlights that Duolingo had the highest number of negative reviews among language learning apps, while Cake - Learn English Korean had high percentages of positive reviews. Socratic by Google had the highest positive reviews among educational support apps, while Symbolab: Math Problem Solver had the highest negative reviews. Overall, the apps had more positive than negative reviews, with many neutral reviews.

(a) Language learning apps.

(b) Educational support apps.

Fig. 6. The user experience with the seven AI-enabled mobile learning apps.

received the highest number of reviews, with 70,364 positive, 10,795 negatives, and 69,919 neutral reviews, resulting in the second-highest positive reviews count alongside Microsoft Math Solver in this category. Overall, the AI-enabled mobile learning apps had more positive than negative reviews, with 247,640 positive reviews, 34,678 negative reviews, and 163,142 neutral reviews out of 445,460 total reviews.

**RQ2:** To what extent are the usability issues of using AI-enabled mobile learning apps impact user satisfaction, effectiveness, and efficiency?

**RQ2 Rational:** With the increasing prevalence of AI in mobile learning apps, it's essential to assess the impact of usability issues on user satisfaction, effectiveness, and efficiency. Investigating these factors can help identify potential problems and provide insights for developers and designers to improve these apps.

**RQ2 Results:** To address this question, we conducted a study that filtered out reviews based on usability factors described in the methodology section. After filtration, the word clouds of the app reviews show the most occurrences of negative usability keywords in Fig. 7. Our results in Table II indicate that usability issues impact user satisfaction, effectiveness, and efficiency in AI-enabled mobile learning apps. In the language learning apps category, ELSA Learn English and Get Fluent exhibited the highest dissatisfaction score at 61%, suggesting user discontent with the app. Duolingo: language lessons and Cake - Learn English & Korean showed quite similar dissatisfaction scores at 56% and 57%, respectively, indicating a close level of user satisfaction between the two apps. Notably, Cake - Learn English & Korean excelled with the lowest dissatisfaction scores in effectiveness and efficiency at 12% and 5%, respectively, suggesting that users find this app both effective and efficient for language learning. Both Duolingo: language lessons and ELSA Learn English and Get Fluent showed dissatisfaction scores in effectiveness at 33% and 23%, respectively. However, their efficiency dissatisfaction scores were 11% and 8%, respectively, suggesting these apps do not significantly impede users' learning efficiency. Moving to the educational support apps category, Symbolab: Math Problem Solver had the highest dissatisfaction score at 79%, indicating substantial user discontent. Microsoft Math Solver displayed a dissatisfaction score of 59% with a relatively high effectiveness dissatisfaction score of 24%. This suggests a moderate impact on user satisfaction, with a relatively lower efficiency dissatisfaction score of 6% compared to its higher effectiveness dissatisfaction score. Despite having the second highest dissatisfaction score at 63%, Socratic by Google presented low dissatisfaction scores for effectiveness and efficiency at 12% and 5%, respectively, suggesting a smaller impact on these areas. Photomath stands out with a relatively low overall dissatisfaction score of 48%, indicating better user satisfaction than other apps in this category. However, there is room for improvement as its effectiveness and efficiency dissatisfaction scores sit at 19% and 9%, respectively. Regarding the total usability score shown in Fig. 8, among the language learning apps, Duolingo: language lessons achieved the highest total usability score of 99%, indicating that users

encountered the most usability issues with this app, particularly regarding negative satisfaction and negative effectiveness. ELSA Learn English and Get Fluent obtained a total usability score of 93%, signifying significant usability issues related to satisfaction and effectiveness. On the other hand, Cake - Learn English & Korean obtained the lowest total usability score of 74%, suggesting that users encountered fewer usability issues with this app. In the educational support apps category, Symbolab: Math Problem Solver garnered the highest total usability score at 101%, indicating higher usability issues with this app compared to other apps in this category. Photomath received the lowest usability score of 75%, indicating moderate usability issues. Understanding the impact of usability issues in AI-enabled mobile learning apps can guide developers and designers in proactively identifying and resolving these problems. This process can enhance overall user satisfaction, effectiveness, and efficiency. The knowledge gained from addressing these issues will inform future improvements in the design and functionality of these apps, ultimately leading to more effective and gratifying learning experiences.

**RQ2 Summary.** The result showed notable usability issues with AI-enabled mobile learning apps. Among the language learning apps, Duolingo: language lessons had the highest usability issues score of 99%, while Symbolab: Math Problem Solver obtained the highest score of 101% among the educational support apps. Developers and designers can use this information to improve the overall usability of these apps.

**RQ3:** What are the most prevalent usability issues in AI-enabled mobile learning apps?

**RQ3 Rational:** This question aims to pinpoint the most frequently encountered AI-related usability problems in mobile applications designed for language learning and educational support, as reported by users in their reviews. By gaining insight into these prevalent issues, developers and researchers can concentrate on enhancing the usability aspects tied to AI technology. This knowledge will aid in refining the overall user experience and satisfaction with these apps, ultimately providing significant benefits to learners and educators.

**RQ3 Results:** To answer this question, we conducted a thematic analysis as described in the methodology section. We applied the thematic analysis to the two apps group learning languages apps and educational support apps. The result of the analysis is shown in Table III and outlined below:

#### Learning Languages Apps Group:

**AI-related functionality issues:** This theme refers to problems users face with the artificial intelligence components in the app. These issues can directly affect the user experience and hinder their learning process. There are two sub-themes under this main theme:

**a. Voice recognition:** This highlights issues where the app fails to recognize or understand the user's voice accurately, leading to frustration and a poor learning experience. A user complained that *"the app became unstable, and AI doesn't care about recognizing anything. You can sing a song instead of the correct answer, and AI will accept it. Most of the time,*

*it freezes in the middle of the lesson, and the mic button gets stuck, among other issues. Don't buy their plan until they fix their app."* The issues related to voice recognition underline the importance of extensive testing and improvement of AI technology to ensure accuracy and effectiveness in aiding users' language acquisition journey.

**b. AI understanding of user input:** This deals with situations where the app's AI fails to understand or process the user's input accurately, resulting in irrelevant or incorrect content being presented to the user, limiting the learning experience's effectiveness. One user reported, *"It was a good tool to start learning a new language from scratch. But I find that the AI component doesn't work very well. It gives easy exercises for the same word right after I've already done a more challenging one. Also, I have to practice a lot of unnecessary stuff like names and cities. A lot of practices are highly redundant, so I think I waste a lot of time practicing easy and unnecessary stuff. Furthermore, I have no choice in what to practice. All in all, it's not the most efficient."* It is crucial to integrate AI technology into language learning apps for a fulfilling educational journey.

**AI Performance:** This theme refers to issues related to the app's performance and capabilities of the AI component. These issues can affect the overall effectiveness of the app in helping users learn a language. There are three sub-themes under this main theme:

**a. Learning methodology:** This includes issues where the AI's approach to teaching a language is deemed ineffective or flawed. Users might find the exercises repetitive, redundant, or not challenging enough, which may hinder their learning progress. One user states, *"The app is basically good but its AI is too bossy. Nobody needs to be mocked for missing lessons. People get busy sometimes, and constant reminders ain't cool. They just piss people off even more."* To guarantee a satisfactory user experience, developers must design AI language learning applications with stimulating activities and lucid explanations.

**b. AI-generated content:** This refers to issues with AI-generated content, such as inconsistencies, errors, or low-quality material. These problems can lead to confusion or a less engaging learning experience. One user points out, *"It's totally useless. It randomly recognizes or rejects what you're saying; there's no logic behind it. I've been using it for a while but have seen no improvement. It doesn't show you how to produce some sounds, just provides some useless text. It accepts incorrect input and randomly rejects correct input, creating an illusion of functionality. Additionally, it records all your voice data and stores it on their servers indefinitely. Even when you request deletion, the data remains."* Developers must ensure that the AI-generated content they produce is of high quality and accuracy, providing users with a positive learning experience. By focusing on improving AI-generated content, the app can better meet users' needs and enhance their language learning journey.

**Instant Feedback Issues:** This theme addresses problems that arise when the language learning app's AI does not offer sufficient, comprehensible guidance on the material being taught, resulting in user confusion and frustration. This main theme consists of a single sub-theme:

Fig. 7. The word clouds of app reviews display the most frequent occurrences of negative usability keywords.

Fig. 8. The overall usability issues in the seven AI-Enabled mobile learning apps.

**a. Diverse challenges with AI-generated feedback:** This sub-theme pertains to situations where the app's generated content is unclear, confusing, or not provided, leading to an unsatisfactory learning experience. Without feedback, users might find it difficult to identify their errors and understand how to improve, which could impede their progress. For example, a user mentioned, "I am learning Ukrainian from a professional teacher along with using the app Many times I am taught something that contradicts what Duolingo says Very confusing. The two voices that read out the questions also mispronounce the words I know this because I have Google translate as well as actual Ukrainians telling me that its wrong My main issue is that it does not explain why the answer is what it is If I knew the rule maybe Id get the right answer Im just frustrated and needed to vent." It shows inaccurate or inconsistent feedback on users' pronunciation, leading to frustration and impeding their language learning progress. Addressing these concerns is crucial in enhancing the user experience and facilitating effective language learning.

**Educational Support Apps Group:**

**AI-related Functionality Issues:** This theme's main focus is on the difficulties users encounter when using the artificial intelligence elements included in the application. These challenges could reduce user satisfaction and prevent them from advancing academically. Resolving these issues could improve the efficiency and effectiveness of AI-based learning applications. The primary theme is divided into two subthemes:

**a. Inaccurate problem recognition:** Users report that the app fails to recognize problems, showing a different problem or failing to recognize specific symbols accurately. One user states, "Horrible All it can do is solve basic questions and I ended up getting in a row idk how ppl like this app but it acts like ai I take a picture of the question and then it shows a totally different problem I expect you to fix this monstrosity."

**b. Poor image recognition:** Users report issues with the app's image recognition capabilities, making it difficult to capture and solve problems accurately. A user shares, "This app is complete literal trash It cant even recognize an extremely simple variable equation system properly much less solve it Leave the image recognition to the big boys like"

TABLE II. THE ANALYSIS OF OCCURRENCE AND FREQUENCY OF NEGATIVE REVIEWS FOR EACH USABILITY FACTOR

App Name	App Group	Negative Reviews	Satisfaction (%)	Effectiveness (%)	Efficiency (%)	Total Usability (%)
Duolingo: language lessons		21441	56	33	11	99
ELSA Learn English, Get Fluent	Language Learning	797	61	23	8	93
Cake - Learn English & Korean		1048	57	12	5	74
Socratic by Google		217	63	12	5	80
Microsoft Math Solver	Educational Support	240	59	24	6	89
Symbolab: Math Problem Solver		140	79	15	8	101
Photomath		10795	48	19	9	75

Google and Microsoft, You're an embarrassment to society and to yourselves."

**c. Inability to solve complex problems:** Users mention that the app is limited in solving complex mathematical problems or specific algorithms. As one user mentions, "As long as this app does not solve the Gau Algorithm, it is worthless for me. Can't read matrix integrals or equations with more than one variable. Total trash."

**AI Performance:** This theme draws attention to concerns with the performance and capabilities of the app's AI component, such as flaws or inconsistencies that could reduce the app's overall usefulness in aiding users in learning or problem-solving. Improved user satisfaction and learning outcomes can result from higher AI performance. This overarching theme has two sub-themes:

**a. Inconsistent handwriting recognition:** Users find that the app struggles to recognize handwritten problems, leading to incorrect solutions accurately. One user shares, "Has a bit of trouble with handwriting recognition and larger, more complex problems, but those problems are to be expected from any algorithm."

**b. Limited language support:** Users report that the app cannot recognize or solve problems written in certain languages, limiting its usefulness for non-English speakers. A user complains, "Time-wasting app for Nepalese. Because it doesn't recognize the math problems properly which is written in Nepali language, so don't waste your valuable time, guys, in this app."

**Ineffective Features:** This theme highlights aspects of the app that are inadequate or ineffective in helping users achieve their educational goals. Developers can enhance their app's functionality by addressing these concerns and meeting user demands.

**a. Limited problem-solving capabilities:** Users find the app's ability to solve certain problems insufficient or lacking. One user complains, "This app is complete literal trash. It can't even recognize an extremely simple variable equation system properly, much less solve it."

**Instant Feedback Issues:**

This refers to situations where the AI-generated feedback is either delayed, unclear, or not provided, affecting the user experience and learning process. Addressing these issues is crucial for enhancing the user experience and promoting effective learning through the app. Improving the clarity and simplicity of AI-generated content can enhance the general user experience and the effectiveness of educational support apps.

**RQ3 Summary.** We identified several usability issues in AI-enabled mobile language learning and educational support apps. These issues include functionality problems related to AI, performance issues, ineffective features, and lack of instant feedback. Addressing these issues is essential to improve the effectiveness of the apps and enhance the overall user experience.

**a. Varied concerns with AI-generated feedback:** This underline specific example where the explanations or information provided by the AI is unclear, confusing, difficult to understand, or not presented at all. One user complained, "I am not happy with the new version the old version used to show each explanation in cost but now The AI Tutorial which was free in old version And now I have to buy in Photo math plus that saying is correct that old is gold old version is the worst now I wanted to solve one equation and wanted the AI Tutorial but now it says pay monthly or Anually education should be free I want the old version back." Addressing these concerns is crucial to improve the user experience and facilitating learning through these apps. Focusing on the clarity and simplicity of AI-generated feedback can help relieve these concerns, eventually enhancing user experience and the effectiveness of educational support apps.

Overall, during the analysis, we identified the most prevalent usability issues related to AI in AI-enabled mobile learning applications. These issues include voice and image recognition, AI understanding of user input, poor AI performance, instant feedback issues, ineffective features, and lack of clarity in AI-generated content. It is crucial to address these issues to enhance the usability of these apps, improve user experiences, and ultimately support the success of both learners and educators.

V. RESULTS DISCUSSION

Our evaluation of user reviews indicates that AI-enabled mobile learning apps generally provide a positive user experience, but several usability issues can affect user satisfaction, effectiveness, and efficiency. Below are some key takeaways from our analysis:

**Takeaway 1: Positive user experiences.** Most user reviews for the apps we analyzed were positive, with users praising them for their fun, easy-to-use interface, and short, engaging lessons. For example, one user of the Cake - Learn English Korean user wrote, "Love this app! It's been helping me a lot with learning Korean. It's fun, easy, and the lessons are short,

TABLE III. THEMATIC ANALYSIS RESULTS: AI-RELATED ISSUES IN AI-ENABLED MOBILE LEARNING APPS

App Group	Theme	Sub theme
Language Learning	AI-related functionality issues	a. Voice recognition b. AI understanding of user input
	AI Performance	a. Learning methodology b. AI-generated content
	Instant Feedback Issues	a. Varied concerns with AI-generated feedback
Educational Support Apps	AI-related functionality issues	a. Inaccurate problem recognition b. Poor image recognition c. Inability to solve complex problems
	AI Performance	a. Inconsistent handwriting recognition b. Limited language support
	Ineffective Features	a. Limited problem-solving capabilities
	Instant Feedback Issues	a. Varied concerns with AI-generated feedback

which is perfect for my busy schedule.” Another user of the Photomath app noted, “Really excellent mind-blowing capture information calculation step-by-step procedure brilliant app. Everyone must need this app.” These positive reviews suggest that AI-enabled mobile learning apps can be an effective and enjoyable way for users to learn new languages or receive educational support.

**Takeaway 2: AI-related usability issues.** Our analysis revealed several AI-related usability issues that can negatively impact user satisfaction, effectiveness, and efficiency. Some of the issues are voice recognition from learning apps and image recognition from educational support apps. For example, one user of the Duolingo app noted, “The voice recognition sometimes makes mistakes, which can be frustrating.” Addressing these issues will be critical for improving the future usability of AI-enabled mobile learning apps. Another example from one of the users of the Photomath app noted, “This app is complete literal trash It cant even recognize an extremely simple variable equation system properly much less solve it Leave the image recognition to the big boys like Google and Microsoft Youre an embarrassment to society and to yourselves.” Addressing these issues will be critical for improving the future usability of AI-enabled mobile learning apps.

**Takeaway 3: Diverse challenges in AI performance and accuracy.** Our analysis revealed that users reported various AI performance and accuracy issues in AI-enabled mobile learning apps. These challenges spanned from language understanding and voice recognition to problem-solving capabilities, image recognition, and inconsistent handwriting recognition. For instance, a user of the Photomath app observed, “Inaccurate problem recognition, poor image recognition, and inability to solve complex problems.” Moreover, there were issues with limited language support and speech recognition. These problems can adversely affect the learning experience and the effectiveness of the applications. It underscores the critical need for continuous development and improvement in AI technology to address these performance issues, thereby enhancing the user experience.

**Takeaway 4: Provide AI explanation.** With the advancement of AI, previous studies have developed tools and libraries that aim to explain the behavior and output of AI models [35]. This feature is essential, particularly from the user’s perspective. Our analysis shows that unexplained AI predictions contribute to users’ frustration and make it difficult for them to understand such predictions. For example, one user of the Socratic by Google app noted, “I wish there was a way to see how the AI is coming up with its solutions. Sometimes it’s not clear why it’s giving me the answer it is.” This user’s comment illustrates how users can become frustrated when the AI model does not explain its behavior when recognizing or rejecting user input. By providing AI explanation frameworks, developers can provide the AI output to the users and explain how and why the AI decided to make that output, which can increase user satisfaction.

**Takeaway 5: Reduce Bias in AI.** Even though the root cause of bias comes from the data itself [36], since data engineering is an essential step in machine learning, it also affects the model functionality and the degree of biased output. Addressing these biases is essential for improving AI-enabled mobile learning apps. For example, one user of the Duolingo app noted, “The app’s AI tends to favor certain accents and pronunciations over others, making it difficult for learners with different accents to get accurate feedback.” Another user of the ELSA app noted, “Please add british accent AI I want it so bad.” These examples highlight how biases in AI can negatively impact users’ experiences and learning outcomes. By addressing these biases, developers can create more inclusive and effective AI-enabled mobile learning apps.

**Takeaway 6: Addressing ineffective AI features.** Our analysis also identified several AI features that were deemed ineffective or flawed, such as limited problem-solving capabilities, limited language support, and repetitive or redundant exercises. For example, a user voiced dissatisfaction “The app’s problem-solving AI is quite limited and often fails to provide accurate solutions. It struggles with complex math equations and frequently gives incorrect answers ...” To mitigate these challenges and improve the user experience, it is necessary to

enhance the application's AI technology or refine the learning methodology.

Despite the generally positive assessments of AI-enabled mobile learning apps, our investigation has revealed critical findings that highlight areas for development. To improve user satisfaction, effectiveness, and efficiency, developers must address usability challenges related to AI performance, accuracy, bias, and explanation. By solving these issues, developers can create more effective and inclusive mobile learning apps that utilize AI to provide engaging and personalized learning experiences. Moreover, enhancing AI technology and adapting learning paradigms to meet users' diverse demands and preferences is essential. These measures will ensure that AI-powered mobile learning apps continue to evolve and offer students engaging learning opportunities.

## VI. THREATS TO VALIDITY

Evaluating the usability of AI-enabled mobile apps for language learning and educational support involves data gathering, filtering, and manual classification, which can be susceptible to various threats that may impact the results.

**Internal Validity** Regarding internal threats to our evaluation, one concern is the accuracy of the thematic analysis and the coding process, particularly in matching AI reviews with appropriate themes. This process is susceptible to human error and incorrect matches. To address this issue, we employed a rigorous thematic analysis approach in which two authors independently coded the reviews and established a code of agreement. The agreement was measured using a scale of 1 for strongly agree, 0 for neutral, and -1 for disagree. We only included reviews in our analysis that both authors strongly agreed on to minimize the potential for error and ensure the reliability of our findings.

**External Validity** Regarding external validity, our findings may need to be more generalizable. The data collection process only included mobile apps from the Android platform. Therefore, the results of this study may not apply to other mobile platforms, such as the Apple App Store.

## VII. CONCLUSION AND FUTURE WORK

In conclusion, AI-enabled mobile learning apps have shown great potential to provide users with effective learning experiences. However, addressing usability issues related to AI-related functionality, performance, bias, explanation, and ineffective features is crucial to enhancing user satisfaction, effectiveness, and efficiency. Developers must prioritize enhancing specific AI technologies and adapting learning methodologies to cater to users' diverse needs and preferences. By implementing these improvements, AI-powered mobile learning apps can become more inclusive and effective, leading to engaging and personalized learning experiences for users and fostering a promising future for AI-enabled mobile learning applications.

# A Hybrid Method Based on Gravitational Search and Genetic Algorithms for Task Scheduling in Cloud Computing

Xiuyan ZHANG <sup>1\*</sup>

Hengshui College of Vocational Technology, Hengshui, 053000, China

**Abstract**—Cloud computing has emerged as a novel technology that offers convenient and cost-effective access to a scalable pool of computing resources over the internet. Task scheduling plays a crucial role in optimizing the functionality of cloud services. However, inefficient scheduling practices can result in resource wastage or a decline in service quality due to under- or overloaded resources. To address this challenge, this research paper introduces a hybrid approach that combines gravitational search and genetic algorithms to tackle the task scheduling problem in cloud computing environments. The proposed method leverages the strengths of both gravitational search and genetic algorithms to achieve enhanced scheduling performance. By integrating the unique search capabilities of the gravitational search algorithm with the optimization and adaptation capabilities of the genetic algorithm, a more effective and efficient solution is achieved. The experimental results validate the superiority of the proposed method over existing approaches in terms of total cost optimization. The experimental evaluation demonstrates that the hybrid method outperforms previous scheduling methods in achieving optimal resource allocation and minimizing costs. The improved performance is attributed to the combined strengths of the gravitational search and genetic algorithms in effectively exploring and exploiting the solution space. These findings underscore the potential of the proposed hybrid method as a valuable tool for addressing the task scheduling problem in cloud computing, ultimately leading to improved resource utilization and enhanced service quality.

**Keywords**—Cloud computing; task scheduling; genetic algorithm; gravitational search algorithm

## I. INTRODUCTION

With the advent of cloud computing, most companies are moving their on-premises infrastructure to the cloud to efficiently provide network, storage, and computing services to their customers [1]. Different service models are available in this model, allowing users to access resources on demand [2]. The convergence of Internet of Things (IoT) [3, 4], artificial intelligence [5-7], differential equations [8], machine learning [9-12], smart grids [13], and Blockchain [14] has a profound impact on cloud computing, enabling enhanced connectivity, security, energy efficiency, data analytics, optimization, and intelligent decision-making capabilities, thereby revolutionizing the way resources are managed, services are delivered, and business operations are conducted in the digital era. The cloud paradigm requires a scheduling mechanism to provide on-demand access to cloud

resources and provision of the resources needed by users [15]. Typically, in cloud environments, a scheduler is employed to identify suitable solutions for assigning constrained resources among incoming applications or tasks in order to achieve scheduling objectives, such as energy consumption, response time, and reliability [16]. As most scheduling problems are either NP-hard or NP-complete, implementing optimal or suboptimal solutions over a minimum timeframe requires a considerable amount of time [17]. Therefore, there are currently no polynomial time-scheduling algorithms available for optimizing the scheduling of restricted resources in the present computing environments. Taillard [18] provided a simple example of the dilemma we are faced with, indicating that approximately 0.02 percent of the candidate solutions take 1 to 1.01 times the total time required to obtain the most optimal solution. It is clear from this example that identifying the optimal solution to a complex problem is extremely difficult.

With an increase in the number of cloud clients, scheduling becomes quite challenging. The first scheduling algorithms were designed for grid computing, and due to their efficiency, most of them were customized for use in distributed computing [19]. Cloud computing offers users the opportunity to make use of numerous virtual resources, making it impossible to assign tasks manually to each user [20]. Commercialization and virtualization have led to cloud computing being able to handle task scheduling complexity at the virtual machine level [21]. Hence, cloud computing relies on scheduling to allocate resources efficiently and effectively to each task. Currently, a wide variety of scheduling mechanisms are available, including dynamic, static, workflow, and cloud service scheduling [22]. The cloud maintains both internal and external resource demands, with specifications for response time, resource costs, storage, and bandwidth varying by task [23].

Previous studies on cloud computing task scheduling have identified several significant gaps. Firstly, these studies often failed to adequately consider the unique characteristics of cloud computing, such as dynamic resource allocation and multi-tenancy, resulting in an inability to capture the inherent complexity and scalability requirements of cloud environments. Secondly, the lack of standardized benchmarks and evaluation metrics hindered the consistent comparison and assessment of different scheduling approaches, emphasizing the need for a standardized

evaluation framework. Thirdly, the adaptability of scheduling algorithms to dynamic environments, including changing workloads and resource availability, was insufficiently addressed, leading to suboptimal resource utilization. Additionally, the diverse requirements of cloud tasks, such as varying resource demands and quality-of-service constraints, were often overlooked, resulting in inefficient allocation strategies and performance degradation. Lastly, the challenges associated with scaling scheduling algorithms to handle large-scale cloud environments were not adequately addressed, resulting in computational inefficiencies and scalability limitations. Addressing these gaps is crucial for developing effective and efficient task scheduling mechanisms in cloud computing.

While promising approaches have been developed to efficient cloud task scheduling, the problem remains NP-complete, implying its inherent complexity. This paper introduces a hybrid method that combines gravitational search and genetic algorithms to schedule multiple tasks within a cloud environment. By combining the strengths and capabilities of gravitational search and genetic algorithms, the paper seeks to overcome the limitations of previous approaches and provide a more effective solution. This hybridization allows for a more comprehensive exploration of the solution space and enhances the ability to find optimal task scheduling solutions. To assess the performance of the proposed algorithm, the paper conducts an experimental setup. The research provides a comparative analysis that showcases the advancements and improvements achieved by comparing the proposed algorithm with previous algorithms. Using several distributions to test the proposed algorithm adds value by providing insights into its performance trends and evaluating its effectiveness across different scenarios. The rest of the paper is structured as follows. Recent works on cloud task scheduling are reviewed in Section II. Section III describes the proposed algorithm. The simulation results are reported in Section IV. Section V concludes the paper.

## II. RELATED WORKS

Lin, et al. [24] proposed an algorithm for scheduling divisible tasks in cloud computing environments that takes into account bandwidth constraints. A novel non-linear programming solution is presented to the multi-task scheduling problem. In this model, the solution yields an efficient allocation strategy that estimates the appropriate number of tasks to be assigned to each virtual resource node. An optimized allocation scheme is used to develop a heuristic algorithm for scheduling loads, known as the bandwidth-aware task scheduling algorithm (BATS). The proposed algorithm outperforms fair-based task scheduling, bandwidth-only task scheduling, and computation-only task scheduling algorithms. Chen and Guo [25] developed a real-time task scheduling approach based on the PSO algorithm. Optimization objectives encompass the imbalance degree, deadline rate, makespan, and cost. Using a utility function, tasks are assigned to machines with high performance in order to maximize the profit of cloud service providers.

Zhao, et al. [26] propose a method for scheduling tasks that considers energy and deadlines for data-intensive

applications. As a first step, tasks are modeled as binary trees using a data correlation clustering approach. It takes into account the correlations generated from initial datasets as well as those generated from intermediate datasets. Thus, the global data transmission volume is substantially reduced, which contributes to a reduction in the rate of SLA violations. Second, using the determination of task requirement degree, a Tree-to-Tree task scheduling method is presented that enhances cloud system energy efficiency by minimizing the number of active machines, reducing data transmission time, and maximizing the utilization of its computing resources.

As a solution to cloud task scheduling problems, Li and Wang [27] proposed a multi-objective optimization algorithm based on the Analytic Network Process (ANP) framework. This algorithm was developed to overcome the weaknesses in mathematical analysis, limitations of optimization capabilities of conventional multi-objective optimization algorithms, and difficulty selecting Pareto optimal solutions in cloud task scheduling. First, they presented a theoretical analysis of cloud task scheduling based on matrix concepts. The improved NSGA-II multi-objective evolutionary algorithm has been applied to cloud task scheduling to search for the Pareto set among multi-objects by utilizing Gene Expression Programming (GEP). Lastly, the ANP model is coupled with the improved NSGA-II in order to address the problem of selecting Pareto solutions. The proposed algorithm can optimize multiple goals simultaneously and can effectively avoid additional iterations caused by changes in user preferences.

Using a bio-inspired intelligent model, Basu, et al. [28] discovered the optimal way to schedule IoT applications in cloud environments with heterogeneous multiprocessors. Evolutionary foraging traits and natural selection of genes have demonstrated that only the fittest species survive in nature. In this case, a fitness schedule is defined as one that complies with task order in a multiprocessor environment. Combining the genetic and ACO algorithms, only the most effective combinations of tasks are selected for each stage. The proposed scheduling algorithm is not preemptive and is based on the assumption that each task can be assigned to a single processor. It has been evaluated with different sizes of task graphs and various numbers of processors and has been demonstrated to be as effective as the traditional GA and ACO algorithms in a heterogeneous multiprocessor environment.

## III. PROPOSED METHOD

Cloud computing is a computing pattern to meet the computing and storing needs of the final users. The cloud-based data centers need to improve their performance constantly because of increasing service requests. Task scheduling is an essential part of cloud computing for optimizing resource utilization, reducing energy consumption, minimizing response times, and maximizing energy efficiency. The users send their requests to a manager. The manager receives the requests and transmits them to all the VMs. Hence, this force is used as a tool for information exchange. Gravity law has a critical role in

finding the most optimal path among the objects (VMs). We use GA's fitting function to select the best and most optimized VMs. Then, using GSA, a percentage of the population's chromosomes (some of VMs) are optimized and are known as the active children. In a repetition loop, some chromosomes are selected, and the GSA is called. We reduce the energy and cost for the active VMs.

#### A. Gravitational Search Algorithm

In Gravitational Search Algorithm (GSA), optimized finding using gravitational laws and moving in an artificial system is performed in discrete time. The system environment is the problem definition area. Hence, this power can be used as a tool for information exchange. The masses are determined using the objective function. The GSA is formed in two stages: a) proving a discrete-time artificial system in the problem environment, the objects' primary placement, providing the rules, and setting the parameters, b) time passing, objects' movement, and updating the parameters until the stop time [29].

The gravitational laws' role is critical to find the most efficient path among the objects. According to Newton's gravity laws, each object attracts other objects using gravitational power, and there is gravity between every two objects. The objects in the search area are defined by different features in the world, like accelerations (active or inactive), algebraic force, force vector, and distance between them. There are two laws that are regenerated in each object based on the power among the particles that perform based on acceleration.

- Newton's gravity law: each particle is attracted to another particle, and the gravitational interaction between two particles generates their mass and is proportional to the distance square between the particles inversely. The gravity force between two objects with masses of  $M_1$  and  $M_2$  and distance  $R$  is proportional to the multiplication of two objects' mass distance and inverse of the square of the distance between them. Newton obtained Eq. (1) for the gravitational force between two objects ( $F$ ) by calculating the  $G$  constant, named the gravity constant [30].

$$F = G \frac{M_1 M_2}{R^2} \quad (1)$$

- Newton's motion law: Force has a direct relationship to mass and internal acceleration. The next particle's velocity depends on the primary particle's velocity and the velocity change. A particle's acceleration (a) depends on the force and the mass of the particle [31].

The motion laws of Newton are the basic physics laws. Based on first Newton's law, each object maintains its stability or uniform movement on a direct line unless it is forced to change under one or some forces. Applying force to an object makes it accelerate based on its force and mass, according to the second Newton's law. More force leads to higher acceleration, and higher mass leads to less acceleration. Newton calculates the relation among acceleration, force, and mass using Eq. (2), where

acceleration, force, and mass are presented by  $a$ ,  $F$ , and  $M$ , respectively.

$$a = \frac{F}{M} \quad (2)$$

Acceleration is velocity changes in time unit, and velocity is passing a specified distance in a determined time duration. Therefore, particles that are heavier and closer to each other apply more gravitational force than lighter and farther particles. Another note is that in physics, there are three types of mass for an object. Active, passive, and inertia gravitational mass are equal for an object. Higher active gravitational mass for an object leads to higher gravitational force around it. The inactive gravitational mass shows the power of interaction in the gravitational field. Inertia mass is an object's resistance measure when changing its location and movement. Less Inertia, the mass of an object, makes more velocity changes. The amount of these three masses in physics is equal to each other.

#### B. Genetic Algorithm

Genetic Algorithm (GA) is a search technique in computer science to find the optimal solution. A solution for the considered problem is indicated using a list of parameters, namely chromosomes or genomes. The GAs uses the natural selection principle of Darwin to find the optimal formula for the patterns' prediction or comparison. In a nutshell, genetic analysis (GA) is a pattern-based programming approach that employs genetic evaluation to solve issues. The input is the issue, the solutions are programmed using the pattern, and the fitness function assesses each candidate solution that is essentially chosen randomly. The chromosomes are generally shown as a simple string of data, and other types of data structures also can be used. During each generation, each characteristic is evaluated, and the fitting value is measured using the fitting function. The stronger elements or the chromosomes with the fitting value near the optimal population have more chance to live during other periods and regeneration, and the weaker ones are destroyed. In other words, the algorithm saves the inputs near the optimal answer and ignores others. Then the algorithm enters a loop including four steps: selection, reproduction, mutation, and evaluation.

#### C. Hybrid Algorithm for Task Scheduling

A combination of GA and GSA is used in this section to solve the task scheduling problem in cloud computing. Both algorithms have advantages and disadvantages. For example, in GA, information about the selected person for hanging is destroyed, while GSA has a specific memory. In other words, in GA, the solutions are updated using the general operators, while GSA does not have such operators. In practical applications, the particles may lose variety during the algorithm execution because of parameter setting and executing the algorithm. Hence, they lose their ability to search in the search space. We conclude GSA works well in the primary stages of finding the solution. But it is trapped in the following stages. Thus, defining new operators for GSA is required to increase its efficiency in solving different non-linear criterion functions.

The new algorithm, GA-GSA, is proposed by combining the GA and GSA features. In this algorithm, GSA performance to find the optimal solution improves by adding genetic operators like selection, crossover, and mutation. First, the algorithm's solution is adjusted by the GSA. Then each solution is updated using genetic operators like selection, crossover, and mutation. The selection applies to find the best candidate based on the algorithm's fitting function. Then the solution is updated by applying the crossover and mutation. Elitism, a functional characteristic of GA, is a tool to select the best people for their children's reproduction and replacement. Exploration and exploitation abilities from the GSA algorithm improve by applying genetic operators. In this method, the advantages of GSA and GA by applying genetic operators to the GSA algorithm are embedded. First, the GSA algorithm is utilized to find the problem solution. Then the best solution is corrected during each period using the genetic operators for a balance between exploration and exploitation processes.

GSA and GA are two popular metaheuristic optimization techniques known for their successful application to a wide range of optimization problems. These algorithms are particularly suitable for addressing the cloud task scheduling problem due to the following reasons:

- Global optimization: Both GSA and GA are designed to search for global optima, enabling them to find optimal or near-optimal solutions for cloud task scheduling, which involves considering multiple tasks and resources.
- Population-based approach: GSA and GA work with a population of candidate solutions, allowing them to explore a diverse set of solutions simultaneously. This is beneficial for cloud task scheduling as it involves considering multiple scheduling possibilities and trade-offs.
- Non-deterministic search: GSA and GA employ a non-deterministic search strategy, making them flexible and suitable for the complex and dynamic nature of cloud task scheduling. They can handle uncertain arrival times and resource availability without relying on gradient information or assumptions about the problem's structure.
- Exploration and exploitation: GSA and GA strike a balance between exploration and exploitation, enabling them to explore different scheduling options while exploiting known good solutions. This balance is crucial for improving efficiency in cloud task scheduling.
- Scalability: GSA and GA can handle large-scale systems with numerous tasks and resources, which is essential for cloud task scheduling. They achieve scalability by parallelizing the evaluation and search processes, enabling efficient exploration and optimization in large-scale cloud environments.

- Adaptability: GSA and GA can be easily customized to incorporate problem-specific constraints and objectives. In cloud task scheduling, where various constraints such as task dependencies and resource availability exist, GSA and GA can adapt to handle these constraints and optimize specific objectives, making them flexible for different cloud environments.

1) *Gravitational search algorithm:* A particle force in the cloud is based on a gravitational constant, and  $G(t)$  is in a special time constant.  $G(t)$  specifies the particle potential and enhances the movement efficiency. The constant gravity help to exponentially increase the search space and efficiency improvement of the use of the resources. The gravitational constant  $G$  starts with a primary value and reduces over time.

2) *Calculating GA fitness function:* This method searches the problem space to find the best, not optimal answer. GA can be introduced as a general search method that imitates the natural biological evolution laws. This search usually uses to generate useful solutions for solving optimization problems. We use the GA concept to generate a difference among the Human Resources (HR) capabilities. HRs are important components of societies and organizations. Each organization's success depends on its HR. The organizations meet their goals using knowledge, experience, power, and human skills. Since HRs are distributed geographically, generating infrastructure is required to share knowledge, skills, and human experiences. In this method, each chromosome is considered a VM.

If  $S = \{VM1, VM2, \dots, VMn\}$  is the considered set of chromosomes, the chromosomes can be selected with the highest chance using the rank selection. In the rank-based selection plan, the chromosomes are saved in the population for the first time according to their fitting values based on Eq. (3), where  $p_i$  is the probability of selecting the  $i$ th chromosome,  $n$  is the population size,  $R(n)$  is the best chromosome, and  $R(1)$  is the worst chromosome in the population.

$$p_i = \frac{R(i)}{\sum_{i=1}^n R(i)} \quad i = 1, 2, \dots, n \quad (3)$$

3) *Calculating resources costs:* Assume  $R_j$  that is considered constant is the unit cost of the  $j$ th resource, and the max cost is the maximum cost of a user on the  $j$ th resource. Hence the cost of executing the  $i$ th task is estimated using Eq. (4). The max cost in this equation is the most expensive task. The total cost of a solution (chromosome) is calculated using Eq. (5), showing the cost of a chromosome in the population.

$$F_{cost}(I) = \frac{T(i, j) \times R_j}{Max\ cost^{1-a}} \quad (4)$$

$$F_{cost}(B) = \sum F_{cost}(j) \quad 1 \geq j \geq M \quad (5)$$

4) *Calculating energy consumption:* The energy model, including the system-level energy-saving techniques Dynamic Voltage Scale (DVS), acts based on a simple principle. It reduces the power supply voltage and the clock frequency of the CPU to reduce energy consumption. The energy model used in the Complementary Metal Oxide Semiconductor (CMOS) is used in this paper. The processor power is a dynamic estimate using Eq. 6, where A is the number of switches in each clock cycle,  $C_{ef}$  is the efficient load capacity, and V and f are the power supply voltage and the operational frequency, respectively. Based on the equation, the stored power supply voltage is a principal and important criterion. Hence, its reduction affects energy consumption.

$$P_{dynamic} = AC_{ef}V^2f \quad (6)$$

5) *Updating the masses based on the evaluation function:* The best position of the particles is returned to the tasks for scheduling. Then the tasks are assigned to the VMs based on their locations to execute on the data centers. Then, all the cloud GSA scheduling continues until all tasks on the VMs are executed to obtain the minimum time and cost of all the calculations. Best () saves the fitting value, which is the minimum value among the particles. Worst () saves the maximum fitting value among the particles in the search space. The new locations are considered the location of the new masses in the search space. The new masses' weights are normalized using the following equations. The best () and worst () values are calculated for the particles to minimize total cost and mass as follows.

$$m_i(t) = \frac{fit_j(t) - worst(t)}{best(t) - worst(t)} \quad (7)$$

$$M_i(t) = \frac{m_i(t)}{\sum_{j=1}^N m_j(t)} \quad (8)$$

In the above equations,  $fit_j$  shows the fitting of the  $i^{th}$  factor's mass at time t, worst () and best () show the amount of the merit of the worst and best factors of the population in time that is calculated using the following equations in the minimum finding problems.

$$best(t) = \frac{\min}{j \in (1, \dots, N)} fit_j(t) \quad (9)$$

$$worst(t) = \frac{\max}{j \in (1, \dots, N)} fit_j(t) \quad (10)$$

#### IV. EXPERIMENTS' RESULTS

CloudSim toolkit provides a convenient platform to model a virtualized cloud environment, which includes the components necessary to build virtual machines, brokers,

hosts, and data centers. It is a flexible and adaptable instrument suitable for facilitating the exploration, simulation, and seamless modeling of emerging cloud computing infrastructures. Consequently, we decided to use it as our experiments' simulation toolbox. A comparison of the proposed scheduling algorithm with state-of-the-art algorithms, such as the hybrid PSO-ACO, ACO, and improved PSO algorithms, has been made to evaluate its performance.

Table I provides the experimental parameters for our experiments. To assess these scheduling techniques, we ran our trials with 20, 300, and 500 jobs over 20 virtual computer resources. In these experiments, each CPU can handle 500, 1000, and 1500 MIPS. The task length ranges between 400 and 600 MI. Fig. 1 to 3 illustrate the experimental results. By varying the number of iterations, the capabilities of the four algorithms were evaluated. A comparison is made between the costs associated with different data sizes.

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Number of tasks	100-500
Population size	100
Max iteration	200
Number of VMs	30
Memory size	512
MIPS	500-1500
Number of hosts	10

Fig. 1 presents a comparison of costs for four different algorithms with varying iterations. Among the metaheuristic algorithms, our algorithm demonstrates the lowest cost, followed by ACO, while IPSO yields the highest cost. Interestingly, the number of iterations does not significantly affect the performance of the PSO-based algorithm. In contrast, IPSO exhibits the highest costs, likely due to the presence of a jitter in the curve as the number of iterations increases. Conversely, both the ACO-PSO and our algorithm showcase smooth transitions between iterations, indicating their stability and efficiency.

Fig. 1. Comparison for 100 tasks.

Fig. 2. Comparison for 300 tasks.

Fig. 3. Comparison for 500 tasks.

Moving on to Fig. 2, it illustrates the results obtained from different algorithms regarding total costs for a scenario involving 300 tasks. Our algorithm proves to be the most cost-effective, yielding the lowest amount of cost, while ACO represents the highest cost. It is worth mentioning that the PSO-ACO algorithm combines the local search and mutation procedures of both ACO and PSO simultaneously. In comparison to the other algorithms, our algorithm showcases a remarkable reduction in energy consumption. Specifically, it achieves a 6% reduction compared to IPSO, a 5% reduction compared to PSO-ACO, and an 8% reduction compared to ACO, all for a scenario involving 500 tasks and 200 iterations.

These findings demonstrate the superior energy efficiency of our algorithm. Furthermore, the observations from Fig. 3 reveal that as the task load increases, the optimization percentage of our algorithm improves significantly. This suggests that our algorithm adapts well to scenarios with higher task demands and exhibits a notable capability to optimize resource allocation efficiently. In summary, the comparisons and results presented highlight the strengths and advantages of our algorithm in terms of cost optimization, stability, energy consumption reduction, and adaptability to higher task loads.

## V. CONCLUSION

This research paper has made several theoretical contributions to cloud computing scheduling. Firstly, it introduced a novel hybrid algorithm that combines genetic and gravitational search algorithms to address the task scheduling challenge in cloud environments. This hybrid approach leverages the strengths of both algorithms, providing a more efficient and effective scheduling mechanism. By integrating genetic operators and gravitational search principles, our method offers improved optimization capabilities and better adaptability to dynamic workload patterns and resource availability. The key results of this research demonstrate that our hybrid algorithm surpasses previous approaches in terms of energy consumption. By achieving better optimization and adaptability, the proposed algorithm provides an advanced solution for cloud task scheduling. These findings have practical implications for cloud service providers and users, enabling more efficient resource utilization, improved energy efficiency, and enhanced quality of service. However, it is important to acknowledge the limitations of this study. The experimental evaluation was conducted on a specific set of benchmarks and scenarios, which may not fully capture the diversity and complexity of real-world cloud environments. Therefore, further validation and testing on a broader range of datasets and workloads would be valuable for comprehensively assessing the algorithm's performance. There are several hints for future research in this area. Firstly, investigating the scalability of the proposed hybrid algorithm to handle large-scale cloud environments would be worthwhile. Exploring the algorithm's performance under different QoS constraints and diverse task profiles could also lead to further improvements. Furthermore, considering the impact of task dependencies and dynamic resource allocation on scheduling effectiveness would contribute to a more comprehensive understanding of cloud task scheduling.

# Shape Control of a Dual-Segment Soft Robot using Depth Vision

Hu Junfeng<sup>1\*</sup>, Zhang Jun<sup>2</sup>  
Jiangxi University of Science and Technology  
School of Mechanical and Electrical Engineering  
Ganzhou, China

**Abstract**—Pneumatic soft robots outperform rigid robots in complex environments due to the high flexibility of their redundant configurations, and their shape control is considered a prerequisite for applications in unstructured environments. In this paper, we propose a depth vision-based shape control method for a two-segment soft robot, which uses a binocular camera to achieve 3D shape control of the soft robot. A closed-loop control algorithm based on depth vision is designed for shape compensation when subject to its own non-linear responsiveness and coupling by solving for the shape feature parameters used to describe the robot and analytically modeling the motion of curved feature points. Experimental results show that the position and angle errors are less than 2 mm and 1° respectively, the curvature error is less than 0.0001mm-1, and the algorithm has convergence performance for L-type and S-type shape reference 3D shapes. This work provides a general method for being able to adjust the shape of a soft robot without on-board sensors.

**Keywords**—Pneumatic soft robot; shape control; depth vision; shape feature

## I. INTRODUCTION

In recent years, soft robots have attracted more and more attention due to their advantages in dexterous operation and safe interaction in complex unstructured environments, and have been widely used in exploration and rescue, medical surgery, seabed grasping and other fields [1]. The unique infinite degree of freedom soft mechanism gives the soft robot good environmental adaptability, but also brings challenges to the precise control of its overall shape [2], especially when it navigates in unstructured environments.

To fully utilize the flexibility of soft robots and apply them in restricted environments, such as complex trajectory tracking [3], it is necessary to simultaneously control their configurations to meet the desired complex shape requirements. Parameterized curve models have been widely used in soft robots, such as the PH curve [4] or spline curve [5]. In parameterized curves, Wiese et al. considered the third-order Hermite spline curve [6] for precise shape kinematics calculations of soft robots, while Gonthina et al. proposed a complex modeling method based on Euler parameterized curves [7], which has the advantages of high accuracy and computational efficiency but has not been used for control purposes. Existing methods calculate control points through curve arc length parameters [8] and optimize the positional errors numerically, but they are not suitable for solving feature

point mapping problems and involve complex numerical calculations.

Currently, model-based methods can achieve shape control but require 3D position and virtual joint parameters as feedback information [9]. In practical applications, due to the soft structure of soft robots, it is difficult to embed rigid sensors and high-cost limitations, making it sometimes impossible to directly measure 3D positions and shape parameters. In this case, vision-based shape control can provide a universal, economical, and feasible solution [10],[11],[12].

Vision-based feedback systems, due to their independence and small size, can provide visual information feedback for soft robots using cameras, and visual servo has been extensively studied [13],[14],[15]. Wang et al. [16] first achieved hand-eye visual servo control of cable-driven soft robots based on kinematic modeling, and Greer et al. [17] solved the visual servo problem of soft robots by estimating the Jacobian matrix from image feedback. Considering that the endpoint position of a soft robot can be detected and calculated using a visual method, a feasible shape can be determined in 3D space, and then a visual shape control method can be designed to track the desired reference shape [18]. Although parameterized curves have been proven to be feasible in 3D shape design tasks for continuum robots [19], it is still difficult to match the spatial position of currently measured feature points with the target position on the reference shape, making it difficult to control the feature points and therefore not suitable for designing the desired reference shape.

To address this issue, a constant-curvature-based three-dimensional shape feature design method is proposed. Curvature-based shape description methods have been widely used in modeling soft robots [20], and this paper uses a constant-curvature-based method to describe the three-dimensional shape of the robot. Then, the shape feature is determined using the solved curvature-based method to determine the desired three-dimensional shape curve. A visual shape control algorithm based on the constant-curvature feature is proposed. To perform simple and efficient visual shape control, markers are attached to the soft robot to capture its three-dimensional shape. Their spatial positions are then compared with the desired target positions to generate error feedback. Therefore, the feature matching problem is solved by constructing the shape feature. A visual control algorithm

based on inverse kinematics is designed to drive the soft robot to track the desired shape feature.

The main contributions of this paper are twofold. Firstly, in the case of reconstructing the three-dimensional coordinates of feature endpoints, the expected reference space shape feature is solved, and the shape curvature feature is introduced to solve the challenge of point feature correspondence, reconstructing the center curve of the soft robot. Second, using the solved shape feature, a three-dimensional visual shape algorithm is designed. In the remainder, the organization of this paper is as follows, Section II and Section III respectively explain the design of the soft robot's spatial shape feature and visual shape control algorithm, and Section IV performs experimental verification. The conclusion of this study is presented in Section V.

## II. SHAPE FEATURE DESIGN

The prototype soft body robot is shown in Fig. 1(a). The two-segment soft robot is made of silicone, both with a cross-sectional diameter of 30 mm and an overall length of 410 mm. The soft robot consists of two segments, each controlled individually by three air hoses, shown in Fig. 1(b). The robot can be made to perform specified movements by adjusting the air pressure variables, Overall view of the actuation system is shown in Fig. 1(c).

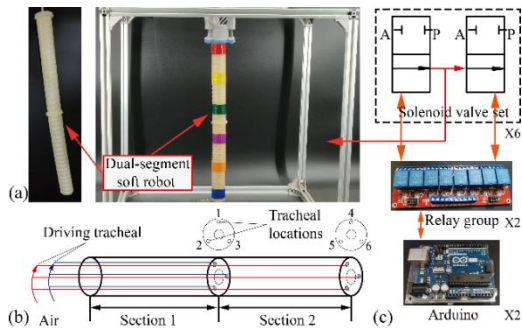

Fig. 1. Prototype of an air-driven soft-bodied robot. (a) Dual-segment soft robot. (b) Sketch of soft robot. (c) Overall view of the actuation system.

In practical applications of soft robots in unstructured environments, it may sometimes be impossible to obtain global pose and shape information for executing control tasks. In light of this, previous research has demonstrated the feasibility of vision systems in measuring pose and sensing shape, inspiring the development and application of effective visual control algorithms in such scenarios. To address the shape design and vision-based shape control problems of soft robots, a solution is proposed using a method based on constant curvature for shape feature design, which utilizes the given three-dimensional endpoint conditions that are capable of estimating the shape curve. Curvature has been widely used in academia to study the shape of soft continuum robots [21]. The objective of the curvature feature design task is to determine feasible reference shape features under the constraint of given endpoints. The method used is to establish a constant curvature motion model based on the given feature endpoints to solve the three-dimensional shape feature parameters of the curve and thus determine the shape curve of the soft robot.

Based on the geometric characteristics of soft robots, a series of continuous circular arcs are used to approximate smooth curves in this study. Therefore, the reference shape of the soft robot is considered to be approximated by a finite group of continuous constant curvature in free space [22],[23]. As shown in Fig. 2, the expression of the robot shape feature is written as the following function:

$$\begin{cases} K = [K_1, K_2, \dots, K_i, \dots, K_n] \\ L = [L_1, L_2, \dots, L_i, \dots, L_n] \\ \varphi = [\varphi_1, \varphi_2, \dots, \varphi_i, \dots, \varphi_n] \\ \theta = K \cdot L \end{cases} \quad (1)$$

where  $K$ ,  $L$ ,  $\varphi$  and  $\theta$  represent the vectors of curvature, arc length, deflection angle, and bending angle of the soft robot, respectively. The endpoint position can be represented using the chain rule of homogeneous transformation matrices, which has been extensively proven in the field of soft robotics [24]. Therefore, the curvature, arc length, bending angle, and deflection angle of each segment can be solved by using the endpoint position, and the function relationship between the endpoint coordinates and  $K$ ,  $\varphi$  and  $\theta$  can be directly obtained.

$$\begin{cases} x_e - x_s = \frac{1}{K} (1 - \cos \theta) \cdot \cos \varphi \\ y_e - y_s = \frac{1}{K} (1 - \cos \theta) \cdot \sin \varphi \\ z_e - z_s = \frac{1}{K} \cdot \sin \theta \end{cases} \quad (2)$$

where  $(x_e, y_e, z_e)$  and  $(x_s, y_s, z_s)$  denote the 3D spatial shape curve endpoints and start points.

This section therefore solves for the curvature features and generates a soft robot reference shape curve by giving constraints on the spatial endpoints.

Fig. 2. Constant curvature geometry model.

## III. SHAPE CONTROL

This section discusses the design of a shape control algorithm based on deep vision, which can drive a soft robot to track the 3D reference shape solved in the first section. Typically, the main challenge faced by visual shape control

tasks is that point feature-based visual shape control algorithms are unable to address feature correspondence issues [25].

Shape control based on deep vision requires matching the currently measured shape parameters with the given expected shape parameters, which generates shape parameter errors. When considering the expected reference shape given in space and the nonlinear response characteristics of the soft robot itself [26], the relationship between shape features and robot motion becomes complex, making it difficult to establish feature correspondence between the reference point features and the detected three-dimensional points of the robot shape. This hinders the design of visual shape controllers. To address this problem, a visual shape control algorithm based on constant curvature is proposed, which uses curvature, endpoints, and inflection points as reference shape features, overcoming the obstacle of finding point feature correspondences.

### A. Shape Mapping Models

This section establishes a mapping model for shape features, laying the foundation for the design of visual shape control algorithms. A prototype of a two-segment soft robot driven by a six-pneumatic circuit is selected as the experimental platform. Three points are marked on the cross-section of each segment as features to adjust their motion in the spatial coordinate system. In the shape control scheme based on deep vision, the coordinates of these features should be compared with their expected reference coordinates to generate shape errors, which are then used to calculate the drive for closed-loop control. However, due to the difficulty in matching the reference position of the feature points with the currently measured position during the motion of the soft robot, visual shape control based on point features becomes challenging. This paper simplifies the solution of feature point correspondence by constructing shape curvature features. It is known that three feature points can uniquely determine the curvature, bending angle, and deflection angle of a circular arc, and these three feature points can be directly measured, as shown in Fig. 3, where and are the starting and ending points of the soft robot, respectively. Therefore, in general for the shape control task, we analyze the construction of the  $i^{\text{th}}$  shape feature.

Curvature, bending angle, and deflection angle are introduced as spatial curve shape features, while the inflection points and endpoints of the curve also determine the unique pose of the soft robot. Therefore, the expected reference shape feature parameters contain the reference curvature, bending angle, deflection angle, inflection point position, and endpoint position. These three-dimensional shape feature parameters can be solved based on the shape feature design task in the previous section. The reference spatial shape feature vector  $s_d$  is defined as follows:

$$\begin{cases} s_d = [f_d, p_d]^T \\ f_d = [f_{d,1}, \dots, f_{d,i}, \dots, f_{d,n}]^T \\ p_d = [p_{md,1}, \dots, p_{md,i}, \dots, p_{md,n-1}, \dots, p_s, p_e] \end{cases} \quad (3)$$

where  $f_d$  contains the combination of  $n$  curvatures, bending angles, and deflection angles calculated according to the constant curvature design algorithm, and  $p_d$  contains  $n-1$  inflection points  $p_{md}$  and two visual detection starting points  $p_s$  and ending points  $p_e$ . Therefore,  $2n+1$  features are used in the visual shape control task. The currently measured spatial shape feature vector is given by the following equation.

$$\begin{cases} s = [f, g]^T \\ f = [f_1, \dots, f_i, \dots, f_n]^T \\ p = [p_{m,1}, \dots, p_{m,i}, \dots, p_{m,n-1}, \dots, p_s, p_e] \end{cases} \quad (4)$$

The shape feature parameter error is defined as  $E = s_d - s$ , based on the given shape feature mapping, a visual-based three-dimensional shape control algorithm is developed, which uses the calibrated binocular camera to feedback the robot's 3D motion information, so that its actual shape finally converges to the reference shape. The schematic diagram of the control task is shown in Fig. 3, where represents the three marked points on the  $i^{\text{th}}$  segment, corresponds to the starting point, and corresponds to the ending point, used to construct the  $i^{\text{th}}$  segment's shape feature.

### B. Control Scheme

The control objective is to drive the soft robot to track the desired reference shape generated in the first part. This paper selects curvature, bend angle, deflection angle, inflection point, endpoint, and start point as the shape features to solve the correspondence problem between measured point features and their reference values. The number of selected shape features is  $m=2n+1$ , which drives the soft robot to converge to the desired shape. In the control task, the desired shape features are time-invariant.

Fig. 3. Schematic diagram of a vision-based 3D shape control task.

Based on the method of describing soft robot shape features using constant curvature, a vision-based inverse kinematics shape control scheme has been developed as shown in Fig. 4. It should be noted that the endpoint of the soft robot is a key point used for shape control, and the measured endpoint position can be used for shape information feedback.  $s_n(K, \varphi, L)_n$  represents the current shape feature parameters,  $s_{dn}(K, \varphi, L)_{dn}$  represents the expected shape feature parameters, and  $A_{dn}$  represents the theoretical actuation output calculated by the controller based on the given expected shape parameter error  $(\Delta K, \Delta \varphi, \Delta L)$ .

Fig. 4. Shape control scheme with feedback mechanism.

For soft robot, there is an unknown variable  $J$  which can be used to establish the mapping between shape parameters and actuation of soft robot

$$s_{dn} - s_n \approx J(A_{dn} - A_n) \quad (5)$$

Given the expected shape parameter  $s_{dn}$ , the corresponding expected induced pneumatic can be calculated as

$$A_{dn} \approx J^{-1}(s_{dn} - s_n) + A_n \quad (6)$$

where,  $J$  values of different shapes are different. After iteration,  $J$  is updated as  $J_n$ , which represents the unique value of iteration for the  $n^{th}$  time, thus, it can be obtained  $A_{dn}$

$$A_{dn} = J_n^{-1}(s_{dn} - s_n) + A_n \quad (7)$$

The challenge of this solution is how to accurately find  $J_n$  of different shapes. To solve this problem, a nonlinear mapping function is designed to make

$$A_{dn} = f_n(s_{dn}, s_n, A_n) \quad (8)$$

According to the known shape characteristic information, the method based on the inverse kinematics model and the empirical fitting formula is implemented to find the required actuating input, by updating the iterative feedback shape information to close to the desired shape

$$A_{dn} \leftarrow f_n(s_{dn}, s_n, A_n) \quad (9)$$

Under the non-extendable cavity hypothesis, as shown in Fig. 2, the relationship between a specific actuating length  $L_{n,i}$  and the segment shape parameter  $s_n(K, \varphi, L)_n$  can be defined geometrically

$$L_{n,i} = K_n L_n d \cos[\varphi_n + (i-1)\psi] \quad (10)$$

Where  $i \in \{1, 2, 3\}$  denotes the number of the chamber  $A, B, C$ ,  $\psi = \frac{2\pi}{3}$  denotes the trichotomy Angle of the circle, and the cross-section radius of the chamber is  $d$ . Let's rewrite the above equation

$$L_{n+1} - L_n = \underbrace{\begin{bmatrix} L_n dc_{\varphi_n} & -L_n K_n ds_{\varphi_n} & K_n dc_{\varphi_n} \\ L_n dc_{\varphi_n+\psi} & -L_n K_n ds_{\varphi_n+\psi} & K_n dc_{\varphi_n+\psi} \\ L_n dc_{\varphi_n+2\psi} & -L_n K_n ds_{\varphi_n+2\psi} & K_n dc_{\varphi_n+2\psi} \end{bmatrix}}_{J^{-1}} \underbrace{\begin{bmatrix} \Delta K_n \\ \Delta \varphi_n \\ \Delta L_n \end{bmatrix}}_{\Delta s_n} \quad (11)$$

According to the fitting of several experiments, it can be seen that the induced pressure has an approximate linear relationship with the chamber elongation, that is  $A_n \propto L_n$ , the  $f_n(\cdot)$  design is completed

$$A_{dn} = \alpha J_n^{-1}(s_{dn} - s_n) + A_n \quad (12)$$

Where  $\alpha = 0.2$  is the proportionality coefficient.

#### IV. CONTROL EXPERIMENTS

This section aims to verify the effectiveness of the proposed design of the soft robot shape features and the vision-based shape control algorithm. The experimental setup is shown in Fig. 6(a). A prototype of a two-segment soft robot driven by six pneumatic actuators is selected as the experimental platform for algorithm verification. Three different colored markers are labeled on each segment to construct the required shape features. A calibrated binocular camera is used to detect the motion and shape of the soft robot, and provide visual feedback to the controller by perceiving the spatial position of the marker feature points. The image processing framework process is shown in Fig 5, and the 3D reconstruction of the two-segment soft robot is based on the detected feature point positions. First, the RGB image of the soft robot is binarized, and the feature points are identified using color reduction and median filtering algorithms. The corresponding labels are assigned to the shape feature endpoints, and the shape reconstruction is completed by combining stereo depth information.

Fig. 5. Stereo vision tracking and 3D reconstruction of a soft robot.

The shape control objective is to drive the dual-segment soft robot to converge to a specified expected shape, using the known endpoint and inflection points as shape features and controlling the robot with the control algorithm. In the verification process, the soft robot base and binocular camera are fixed, ensuring that the starting point of the detected curve is consistent. Given the endpoint positions of the dual-segment soft robot in spatial coordinates, the feature curvature  $K$ , bending angle  $\theta$ , and deflection angle  $\varphi$  can be solved using Eq. (2), and the solved 3D shape features are used as the reference input for the shape controller, which can uniquely control the output robot reference shape. As shown in Fig. 6(b), L-shaped and S-shaped expected reference shapes can be tracked by detecting the three-dimensional positions of the feature endpoints through depth vision, allowing for the reconstruction of the soft robot's arbitrary omnidirectional motion configurations. Table I provides the calculated results of curvature  $K$ , bending angle  $\theta$ , and deflection angle  $\varphi$  for the L-type and S-type shape features. The proposed shape control

algorithm is then used to verify the performance of the soft robot tracking the L- type and S- type shapes.

Fig. 6. Experiments on shape control of soft robots.

L-type shape control: As shown in Fig. 7, the performance of L-type shape control was verified. Fig. 7(a) shows the captured images during the L-type shape control task. In these images, the curve labeled with orange represents the initial

shape, the red curve represents the expected shape, and the blue curve represents the actual final shape, demonstrating the ability of the soft robot to achieve the expected 2D shape motion using the proposed control algorithm. To verify the accuracy and convergence ability of the proposed controller, the error curves of endpoint position, turning point position, bending angle, and curvature with respect to the iteration number are also displayed in Fig. 7(b) to (d). The error in shape feature parameters with respect to the expected shape is  $\Delta K_1=5.121e-5mm^{-1}$ ,  $\Delta\theta_1=0.12$ ,  $\Delta K_2=2.822e-5mm^{-1}$ , and  $\Delta\theta_2=0.64^\circ$ . The shape feature error of the soft robot converged after the second iteration of feedback using visual feedback of the shape feature information. It is noteworthy that the iteration number refers to the finite number of times used to achieve the expected shape using visual feedback of the shape feature information.

S-type shape control: The S-type shape means that the two segments deform in opposite directions. Fig. 8 shows the experimental results of the visual shape control performance of the S-type shape. Fig. 8(a) shows images captured from the camera and the captured three-dimensional shape curve during the control process. Compared to L-type shape control, the shape error is relatively significant, possibly due to the motion interference caused by the two segments with opposite deformations, where while the proximal part approaches the expected shape, the shape error of the distal part may increase. Fig. 8(b) to (e) show the errors of the endpoint positions, inflection point positions, bending angles, deflection angles, and curvatures of the two segments with iteration number. The final shape parameters of the soft robot also tend to be stable, with the errors of shape feature compared to the expected shape being  $\Delta K_1=0.0004mm^{-1}$ ,  $\Delta\varphi_1=0.69^\circ$ ,  $\Delta\theta_1=0.65^\circ$ , and  $\Delta K_2=0.0004mm^{-1}$ ,  $\Delta\varphi_2=0.996^\circ$ ,  $\Delta\theta_2=0.39^\circ$ . That is, the error of the soft robot shape curve also converges after the second iteration feedback.

## V. CONCLUSION AND DISCUSSION

In this paper, a shape design algorithm and visual shape control scheme for a dual-segment soft robot in three-dimensional space were proposed. By using marker features, the problem of reference shape design and control was solved solely through visual feedback. In the shape tracking experiment, the spatial shape deviation of the dual-segment soft robot was obtained using depth vision, and the visual perception of the endpoint and inflection point was used as closed-loop feedback for shape compensation. With this method, the overall configuration of the robot was adjusted by controlling its shape features without adding any other onboard sensors. It has good effect in shape servo control of L-type and S-type shapes. The motion information of the robot is directly captured by visual sensing to generate the three-dimensional shape of the soft robot. In order to control the soft robot into the desired shape, the feedback and control of its shape feature parameters are transformed. The results showed that the position and angle errors of the shape feature were both less than 2mm and 1°, respectively, and the curvature error was less than 0.0001 mm<sup>-1</sup>. This method exhibited good precision tracking and convergence performance for the required L-type and S-type shapes. The problem of reference shape design and servo for continuously deformed soft robot with only visual feedback is solved. This work demonstrates that soft robots have unlimited applications in future explorations in rescue and minimally invasive surgery fields, enabling safer human-machine interactions. In the future work, especially for the shape dynamic control task of soft robots, an efficient 3D curve tracking method and a model for real-time calculation of shape feature parameters are needed to conduct dynamic response analysis of the shape control system, so as to propose a better shape control strategy to cope with the challenges brought by coupled motion. It will also further promote the research of accurate shape modeling and algorithm design, and the extension of dynamic control of soft robot shape will also be used in more complex interactive environments and fast response control tasks.

**Abstract**—The assessment of aboveground biomass is important for achieving rational usage of pasture resources and for maximizing the quantity and quality of milk and meat production. This study presents a method for fast approximation of pastures' biomass. Unlike most similar studies, which rely on unmanned aerial vehicle and satellite obtained data, this study focuses on photos made by stationary or mobile ground-based visual spectrum camera. The developed methodology uses raster analysis, based on the MGRVI index, in order to classify the pasture into two categories: "grazed" and "ungrazed". Thereafter, the developed methodology accounts for the perspective in order to obtain the actual area of each class in square meters and in percent. The methodology was applied on an experimental pasture, located near the city of Troyan (Bulgaria). Two images were selected, with the first one representing a mostly ungrazed pasture and the second one – a mostly grazed one. Thereafter the images were analyzed using QGIS 3.0 as well as a specially developed software tool. An important advantage of the proposed methodology is that it does not require expensive equipment and technological knowledge, as it relies on commonly available tools, such as the camera of mobile phones.

## I. INTRODUCTION

Extensive animal husbandry in mountainous areas is highly dependent on grass and its condition in meadows and pastures. The pastures are used during the summer for raising cattle gradually by parts, while the fodder is set aside to feed the animals in the winter. However, the production of grass is not unlimited and depends on various factors - topography, the impossibility of using mechanization to a large extent, the short vegetative cycle in high places (longer retention of snow, temperature differences and precipitation, drought). The intensive use of pastures and the incorrect management and selection of the appropriate capacity of the area in relation to the animals kept on it can cause degradation of the used pastures and lead to subsequent damage of them and to the environment. Therefore, the assessment of aboveground biomass is important in order to achieve the goal of rational use of pasture resources and to maximize the quantity and quality of milk and meat production.

Natural grass associations are not only accepted as a huge natural resource that enables environmentally friendly and low-cost rearing of ruminants, but they also have significant ecological functions: they protect the soil from water and wind erosion and groundwater from pollution [1-3], reduce the effect of greenhouse gasses, absorbing part of CO<sub>2</sub> in the process of photosynthesis, preserve biodiversity [4,5].

The meadows and pastures in Bulgaria occupy 27.8% of the usable area of the country, but a large number of them are not used in a systematic and regulated manner, as a result of which the grasslands degrade, and this also leads to a decrease in the productivity and quality of the obtained biomass [3]. Identifying and applying adequate measures requires a good knowledge of their condition [6,7]. This necessitates conducting research on the density of grass vegetation, evenness of grazing, participation of valuable cereal and legume species and the ratio between them, presence of shrubs, pests and pollution [8,9].

Grass communities are used by grazing and mowing (individually or in combination), which when carried out correctly limit the spread and development of shrubs and trees, suppress the dominance of rough and poisonous species, weeds and ruderals. Traditional grazing management factors are number, type and category of grazing animals, spatial and temporal distribution of forage demand, timing and length of grazing periods [10]. Overgrazing of grassland leads to the loss of valuable perennial species and subsequent soil erosion [11-14]. The lack of grazing also has a negative impact on the grassland, leading to the spread of weeds, overgrowth and the reduction of the grazing area [15].

Very often, the decrease in pasture productivity is also a result of the uneven distribution of grazing. According to [16], in arid and semi-arid regions, timely corrections of animal numbers and practices that are applied to alleviate unwanted selective grazing of animals improve grazing uniformity and are more effective in maintaining and improving pasture productivity than fencing and rotational grazing systems. Improving grazing uniformity can help both to increase productivity and to preserve biodiversity and habitats in grasslands [17]. By accurately determining the degree of grazing, it is possible to improve the management of the

pasture territory, to provide data for predictive and simulation models for its effective use [18].

Conventional methods for evaluating the indicators determining the extent and uniformity of grazing and the productivity of the rangeland area are subjective, time-consuming and only applicable to small-scale rangeland monitoring. These methods are particularly difficult in large, remote areas. Conventional methods involve laborious crawling over large areas, cutting and drying a large number of samples of a certain area (e.g., 0.25 m<sup>2</sup>), where the dried biomass values are recalculated to a larger area.

In order to maintain natural pastures in a state of high productivity, to increase the efficiency of their use, it is necessary to prospectively introduce innovative methods and technologies for remote and rapid analysis to estimate the density of the grass cover, the degree of grazing, the botanical composition, the productivity and quality of the vegetation from the point of view of precision agriculture and the intelligent management of natural grass associations.

Different automated approaches are used to assess the condition of pastures, in addition to the standard on-site sampling methods of the pasture itself. One of these approaches is to use sensors, to measure soil indicators and parameters, to send data about them to a software application and, based on the processing and analysis of this data, to make predictions about the state of the biomass on the surface [19-22]. It is obvious that this method is not particularly good and reliable. The information obtained through it about the condition of the plants on the surface is not direct, and on the basis of various indicators of the soil, attempts are made to make predictions about the plants.

Recently, the methods using various sensors and cameras on board unmanned aerial vehicles (UAV) are relevant and intensively developed. Their development provides new alternatives for collecting data from meadows, as they are much more mobile and offer different possibilities than those of agricultural machinery and agricultural aviation, and even satellite images. There is already quite a bit of research into the applicability of such technologies [23,24] and definitely this approach gives promising results in biomass estimation compared to manual field measurements. Key advantages of such approach include access to hard-to-reach areas, slow flight speed and, respectively, the possibility of good quality photography, development of technologies in this area and cameras allow detailed images; there is no risk for the people who use the technique or for the pilots for example. The disadvantages of this approach are that this type of equipment is still relatively expensive, and working with it is also not so simple and requires certain knowledge and experience, which is why not every farmer will decide on such a step to purchase such devices.

The use of cameras with multispectral sensors allows to compile/determine vegetation indices, based on RGB and infrared images and use these indices to estimate grassland surface biomass [25,26]. Remote sensing is an effective tool to address the challenges of grassland vegetation sampling to establish land cover characteristics and accurately account for grassland biomass given its high spatio-temporal variability

and large spatial scales [27-29]. Understanding this variability and how it differs regionally can help improve rangeland management by informing how to adjust stocking levels in atypical years and avoid overgrazing or insufficient forage availability in drought years [30].

According to [31], the monitoring of the condition of the grass cover of pastures is of crucial importance for their good management, as the combination of data from conventional field surveys with remote sensing (with a moderate resolution) will help to increase the accuracy of the quantitative assessment of trends in the changes of grass cover and productivity of the pasture area. And digital image analysis (aerial photographic analyses) can be a fast and precise technique for estimating the proportion of different plant groups in the grassland [32,33].

Different studies have investigated the application of remote sensing for assessment of pastures' biomass. For example, in [34] the authors compared two grazing practices for evaluation of the vegetation characteristics of a pasture: high-resolution satellite and UAV imagery. Different vegetation indices were used, such as NDVI, EVI2, LAI, WDRVI, etc., all of which require the use of near-infrared spectrum. The results showed that both approaches provide a useful tool for the farmers to optimize the management of the pasture. Similarly, in [35] UAV obtained RGB and multispectral imaging was used for assessing the pasture biomass using NDVI, NDRE, GNDVI and GRVI vegetation indices. To the best of our knowledge, no previous studies have suggested the application of ground-based cameras for assessment of the pasture condition.

All these methods for biomass estimation have their advantages and several common drawbacks - it is not easy for a farmer or even a herdsman to make this estimate himself. Furthermore, most of them rely on vegetation indices that need the infrared spectrum, which adds a significant limitation and increases the price of the sensor. This research is aimed at developing a methodology based on image processing that allows easy assessment of the condition of pastures using ordinary photographic images (even from a phone). If the images taken by livestock keepers are properly stored (for example, image databases are organized [36]), they can subsequently be used for more in-depth analysis and matching to trace how the grazing process has progressed [37]. Based on the analysis of the images, along with historical data on temperature, humidity and soil condition, it is also possible to predict what the pasture's condition may be expected to be for some period of time in the future.

The goal of this study is to develop a model which allows fast assessment of the biomass condition of pastures and meadows, which is based on a ground-based visual spectrum camera. The method should be applicable with a wide range of devices, including mobile phones, and allow easy approximation of the grazed areas.

## II. MATERIALS AND METHODS

As already stated, this study aims to develop a methodology that allows assessing the grazed area of pastures, which can be divided into three steps, as shown in Fig. 1.

Fig. 1. Summary of the proposed model.

### Step 1. Take a photo

For the first step any visual spectrum (RGB) camera can be used, which is either ground-based or UAV-based. However, it is important to know the dimensions in meters of the observed quadrilateral. In the current study it is assumed that the quadrilateral is an isosceles trapezoid, i.e., the camera is horizontally leveled with the ground.

### Step 2. Perform classification

Several RGB indices are explored in [38]. All of them are affected by the illumination quality of the images being used and care should be taken when using it to process images where there are areas affected by shadowing. Therefore, in our study we use a relatively flat pasture with a sufficiently large area and without trees shading it.

In this step a classification is performed in order to distinguish the grazed and ungrazed parts of the pasture. It is based on the MGRVI, proposed in [39]. It is considered to give the best results when separating vegetation from soil and is defined as follows:

$$MGRVI = \frac{G^2 - R^2}{G^2 + R^2} \quad (1)$$

where  $R$  and  $G$  are the red and green components, respectively, of a RGB colored pixel. MGRVI takes values from -1 (when  $R = 255$  and  $G = 0$ ) to +1 (when  $R = 0$  and  $G = 255$ ).

Next, all pixels of the image are classified in one of the two categories:

- 1) If  $MGRVI \leq 0$  then it is assumed to represent a grazed area;
- 2) If  $MGRVI > 0$  then it is assumed to represent an ungrazed area.

### Step 3. Evaluate the actual size of the grazed and ungrazed areas

In order to implement this step, the following approximations are made:

- 1) It is assumed that the pasture is perfectly flat and the camera is horizontally leveled;
- 2) It is assumed that all pixels on the same row represent the same width and height of the pasture.

It is known that under the above conditions the rectangular image, captured by the camera, corresponds to an isosceles

trapezoidal ground surface (Fig. 2). Let its two bases be  $m$  (the short one, which is near the camera) and  $n$  (the long one, which is away from the camera), its two legs are with equal size  $d$ , and all of them are measured in meters. If the image is represented with  $x$  horizontal and  $y$  vertical pixels, it is necessary to obtain the corresponding ground surface to each pixel.

If the image has  $y$  vertical pixels (from 1 to  $y$ ), then there are  $y+1$  horizontal lines (from 0 to  $y$ ) separating them (Fig. 2). Considering the shortest line (Line  $y$ ) has length  $m$  and the longest one (Line 0) has length  $n$ , then the length of the  $k^{\text{th}}$  line  $x_{l(k)}$  can be obtained with:

$$x_{l(k)} = \frac{n-m}{2} \left(1 - \frac{2k}{y}\right) + \frac{n+m}{2} \quad (2)$$

where  $k$  takes values from 0 to  $y$ .

If the image has  $x$  pixels (from 1 to  $x$ ), then the width of all pixels on the  $k^{\text{th}}$  row can be approximated as an average of their two bases (Fig. 3):

$$x_{px(k)} = \frac{x_{l(k-1)} + x_{l(k)}}{2x} \quad (3)$$

where  $k$  takes values from 1 to  $x$ .

Next, in order to approximate the corresponding height of each row of pixels, the height  $h$  of the trapezoid should be obtained:

$$h = \sqrt{d^2 - \left(\frac{n-m}{2}\right)^2} \quad (4)$$

In order to account for the influence of the perspective on the pixel height, a coefficient is defined for each pixel row, which is obtained according to:

$$p(k) = \frac{x_{l(k-1)} + x_{l(k)}}{2} \quad (5)$$

Then the corresponding pixel height of the  $k^{\text{th}}$  row can be approximated with:

$$y_{px(k)} = h \cdot \frac{p(k)}{\sum_{z=1}^y p(z)} \quad (6)$$

Finally, the corresponding area of each pixel on the  $k^{\text{th}}$  row can be obtained with:

$$A_{(k)} = x_{px(k)} \cdot y_{px(k)} = \frac{x_{l(k-1)} + x_{l(k)}}{x} \cdot h \cdot \frac{p(k)}{\sum_{k=1}^y p(k)}, m \quad (7)$$

Fig. 2. Correspondence between the pixels and the observed pasture area.

Fig. 3. Obtaining the pixel width as an average of its bases.

Using the above equations the cumulative area of each class can be obtained from Step 2 of the proposed methodology.

### III. RESULTS AND DISCUSSION

In order to test the developed methodology, an experimental study was performed on the 23<sup>rd</sup> of November 2022. The investigated pasture is located on the territory of the Research Institute of Mountain Stockbreeding and Agriculture Troyan (coords: 42.91135333102527, 24.703057318209225), as shown in Fig. 4.

Fig. 4. Location of the experimental pasture on the territory of the Research Institute of Mountain Stock-breeding and Agriculture, Troyan, Bulgaria

The analysis of the pasture at the moment of the experimental investigation showed that cereal and leguminous grasses predominate it. Furthermore, parts of the pasture are grazed and others are ungrazed. Closeup image samples from the pasture are presented in Fig. 5.

Fig. 5. Examples presenting the condition of the pasture: (a) An ungrazed part of the pasture with cereal and leguminous grasses; (b) A partly grazed part of the pasture with cereal grasses.

A number of photos of the pasture were made, using a Mobotix Mx-M16TB-R079 camera. It includes an optical sensor with resolution 3072x2048 px and an infrared sensor with resolution 336x252 px, though in this study only the visual spectrum data has been used. Two photos were selected for additional analysis, which are presented in Fig. 6:

- Image 1 (left) contains a part of the pasture, where the condition is mostly ungrazed. It can also be seen that there is an area in the upper part of the image, which represents an artificial object;
- Image 2 (right) contains a part of the pasture, which is mostly grazed. Furthermore, it contains a person standing on the field, which allows investigating the influence of artificial objects on the developed methodology.

Fig. 6. The selected RGB images that are being analyzed: (a) A mostly ungrazed area of the pasture; b) A mostly grazed area of the pasture with an artificial object (a person) on it.

The QGIS 3.0 software has been used to implement the image analysis and classification part of the methodology. Initially the MGRVI vegetation index is used to create raster contours for each input image, as shown in Fig. 7. From it can be unambiguously confirmed that the contours are dividing the grazed from the ungrazed areas of the pasture very precisely. This confirms that the chosen vegetation index is appropriate for the situation.

Fig. 7. Close-up of the created raster contours from a pasture image.

Next, according to the developed methodology, the pixels of the images are classified into grazed and ungrazed. This is

implemented by converting the contours to polygons and classifying them in two classes based on their fid property. The results from the classification for the two testing images are presented in Fig. 8.

Next, the developed methodology for analysis of the classified images has been implemented in a specialized software tool, using the Microsoft Visual Studio 2019 environment. It has been used to evaluate the grazed and ungrazed areas of the pasture, the results from which are summarized in Table I. According to the performed analysis, Image 1 represents a pasture, where 21% (57 m<sup>2</sup>) of the area is either grazed or represents artificial objects, and 79% (218 m<sup>2</sup>) of the area is ungrazed. These results indicate that this part of the pasture is in good condition and the animals could still be kept there.

Image 2 represents part of a pasture, where 71% (194 m<sup>2</sup>) of the area is grazed (or artificial), and 29% (81 m<sup>2</sup>) is ungrazed, i.e., the farmer should consider moving the animals to another part of the pasture.

Fig. 8. Classification results from the analysis of: (a) Image 1; (b) Image 2.

TABLE I. RESULTS FROM THE CLASSIFICATION OF THE TWO PASTURE IMAGES

Image	Grazed area		Ungrazed area	
	m <sup>2</sup>	%	m <sup>2</sup>	%
Image 1	57	21	218	79
Image 2	194	71	81	29

The analysis of the obtained results allows us to make several observations. The performed classification using the MGRVI index allows correct identification of grazed and ungrazed areas of the pasture under the current conditions of

the investigated pasture. Nevertheless, it should be noted that the study was done in a period without significant rainfall and with lower temperatures. Therefore, it could be speculated that the MGRVI index might be inappropriate in periods of intense growth, such as mid spring to early summer, when there is no significant color difference between grazed and ungrazed areas. This shows that more studies might be required if a complete solution is to be created.

As was already mentioned Image 2 partly contains the contours of a human being, which means that the actual condition of the pasture behind him is unknown. And even though in this study this area was classified as grazed, this should not be considered as a rule. The analysis was performed only with data from the visual spectrum, and therefore the results of the classification depend entirely on the color of the clothes the person is dressed in. Similar conclusion can be made for Image 1, where the top pixel lines represent an artificial object. It was also classified as a grazed area because of the color of the object, yet in the general case the classification could be different.

Considering the aforementioned, the general recommendation that could be made when taking such photos is to try not to include any artificial objects within the photographed area. Another option might be to add an additional spectrum (such as infrared), which allows easy identification of some artificial objects. For example, living creatures would naturally return higher temperature than the surroundings. Similar results are expected from artificial objects, which were exposed to continuous solar radiation. Naturally, the inclusion of additional spectrum would require the modification of the vegetation index used.

The proposed method has several limitations, which should be considered when using it. It provides an assessment of the state of the pasture by showing its total and actual productivity, yet it cannot assess and give an idea of the suitability for consumption grass within the pasture, because the animals have their preferences and do not graze all types of grass. According to the accepted approximations, the pasture should be flat, if accurate classification of it should be conducted, which is another limitation of the proposed model. If the observed area is not ideally flat, this will create some errors in the calculations. The impact of the aforementioned limitation might be reduced if the evaluation of the area is performed using a UAV, yet this would require the farmer to make a relatively significant investment for acquiring the appropriate tools. Furthermore, the ability to pilot a UAV requires a certain qualification, which most of the farmers do not have.

That is the reason the proposed method was not intended to provide highly accurate results, but to perform fast and easy approximation of the grazed area, which is an important factor for the rotation of animals on pastures. An important advantage of this study is that it does not require the use of expensive equipment and specific technologies, because it relies on commonly available tools, such as the cameras of mobile phones. This way the developed model could be used by pretty much all farmers if appropriate tools are provided, and the only requirement towards the users is to have general knowledge on working with mobile devices.

#### IV. CONCLUSIONS

This study presents the development of a method for fast assessment of the grazed pasture areas with the use of ground-based cameras. The classification is based on the MGRVI index, which is known to allow easy differentiation between areas with grazed and ungrazed vegetation. The created classification map is then resized in order to account for the effect of the perspective, which allows fast and relatively accurate assessment of the actual grazed and potentially ungrazed areas in m<sup>2</sup> and in percentages.

The main advantage of the proposed model is that it does not require expensive equipment, such as UAVs, but rather relies on commonly available technologies such as the cameras of mobile phones. This way if an appropriate tool, which implements the proposed methodology is developed, it could offer decision-making support for all farmers in the process of rotating their animals on pastures, without any specific technological or knowledge requirements. The development of such user-friendly mobile application is an important follow-up task, which would allow applying the developed methodology in practice.

#### ACKNOWLEDGMENT

This research was funded by the Ministry of Education and Science of Bulgaria under the National Research Program "Intelligent Animal Husbandry", grant number Д01-62/18.03.2021.

**Abstract**—The COVID-19 pandemic has led to temporary school closures affecting over 90% of students worldwide. This has exacerbated educational inequality, particularly for students with learning disabilities such as autism spectrum disorder (ASD), whose routines, services, and support they rely on have been disrupted. To address this issue, it is important to investigate virtual teaching and learning (VTL) strategies that can provide a more effective learning experience for these unique learners. The main objectives of this research are twofold: to investigate the challenges faced by teachers and students with ASD in Malaysia when adapting to online education, and to explore how the learning process occurs during the pandemic. Additionally, the study aimed to identify suitable VTL technology for autism care centres. Four autism care centres were visited for on-site observation activities, and interviews were conducted with the care centre principals. Two sets of online questionnaires were distributed to 10 autism care centres, where 6 principals and 16 teachers provided feedback. The data collected through on-site observations, interviews, and online questionnaires, were then analysed to construct an instructional digital model (IDM) for VTL. The model is very significant as a guide for the development of VTL platform for autism care centres. Finally, a VTL platform development framework was created, which provides a structure for system developers to conduct further research on the development of VTL platform based on the IDM. The framework aims to facilitate the successful implementation of the VTL.

**Keywords**—Instructional digital model; virtual teaching and learning; autism; online learning; pandemic

## I. INTRODUCTION

In response to the COVID-19 pandemic, the government of Malaysia implemented the Movement Control Order (MCO) which resulted in the closure of all kindergartens, public and private schools, including day schools and full boarding schools [1]. This disruption in the traditional classroom setting meant that many students, including those with special needs, were unable to continue their studies [2]. In response, online learning was implemented at home, but this has caused concern about the quality and inclusiveness of education, and the risk of many students being left behind has increased. In this new environment, schools, teachers, students, and parents have had to adapt to a new norm and method of teaching and learning [3].

Due to the pandemic, students with learning disabilities have faced significant challenges as their communication with

teachers has been hindered, and their access to educational resources has been restricted [4]. Among them, students with autism spectrum disorder (ASD) require specialised support to ensure that they can learn the same material as their peers in a manner that suits their skills and abilities [5]. Thus, a novel education approach is necessary to address the distinct requirements of these students in this new situation.

The lack of educators specialised in teaching students with special needs, particularly those with autism, presents significant difficulties in providing effective education [6]. However, there is now a glimmer of hope for enhancing teaching and learning methods for students with ASD through the progress of digital technology. Assistive and instructional technology allows students on the autism spectrum to participate more fully in their education, whether it is in their home, school, or community, thereby providing equal opportunities for students with special needs and those without [7].

To support virtual teaching and learning (VTL) for students with ASD, a special platform should be considered to allow these students to gain the same knowledge as other students, and thus reduce the learning gap between them. The challenges of teaching and learning involving students with ASD should be studied to determine the Information and Communication Technology (ICT) needs for teachers at care centres. An instructional digital model (IDM) needs to be established to guide the development and effective implementation of VTL.

Thus, this study aimed to answer the following research questions:

- 1) What are the challenges encountered by teachers and students with ASD when adopting online education, and how does the learning process unfold during the pandemic?
- 2) What type of ICT environment is required to facilitate the inclusion of students with ASD in virtual learning, particularly during a pandemic?
- 3) How can an IDM for VTL be developed for students with ASD based on the gathered information on their needs and limitations?

In order to answer the research questions, on-site visits were made to four selected autism care centres to obtain visual insight and understand what types of ICT equipment and tools are available and utilized at those centres. During these visits,

in addition to observing the premises, principals were also interviewed. Online questionnaires were created and distributed to the teachers and principals. The questionnaire aimed to obtain information about the ICT facilities available at the centres, as well as to gather feedback from teachers and principals on their profiles, perceived ICT skills, experiences, problems and challenges during pandemic, and their opinions on the potential integration of VTL. The study data were analysed and used to construct an IDM specifically for autism care centres.

This research paper aims to investigate the challenges and potential benefits of utilizing VTL for autism care centres. The following sections begin with a review of related works in the field. The methodology section describes the approach taken to conduct the research, including data collection and analysis methods. The analysis and discussion section presents the findings and examines their implications. Based on the results, recommendations are provided for the construction and implementation of the proposed IDM for autism care centres. The paper concludes with a summary of the findings, future directions for research, and the potential impact of IDM on the field of virtual teaching and learning for students with autism.

## II. RELATED WORKS

### A. Efforts by International Organisations

The United Nations (UN) recognises that digital technologies can be a powerful tool for individuals with ASD to access educational and vocational opportunities. Digital learning technologies have been recognised as a cost-effective way of providing specialised training and support for individuals with ASD, and they can also help to create a more inclusive society by reducing barriers to learning and employment. In 2020, the UN launched a global initiative called the "Roadmap for Digital Cooperation," which aims to ensure that everyone has access to the benefits of digital technology, including individuals with disabilities such as autism. The roadmap highlights the importance of promoting digital literacy and skills, as well as the need for accessible and inclusive digital technologies [8]. Another significant initiative is the UN's Sustainable Development Goals (SDGs), which aim to achieve universal access to quality education, including for individuals with disabilities, by 2030. SDG 4.5 specifically calls for the elimination of gender disparities in education and the promotion of inclusive and equitable education for all, including individuals with disabilities such as autism [9]. In addition to these overarching initiatives, the UN has also developed specific programs and resources to support digital learning for individuals with ASD. For example, the UNICEF Office of Research-Innocenti, in partnership with the World Autism Organisation and the International Society for Autism Research, developed a toolkit in 2020 to support the implementation of digital technologies for children with ASD. The toolkit provides guidance on how to adapt existing digital learning resources to meet the needs of children with ASD, and it includes case studies and best practices from around the world [10].

The World Health Organisation (WHO) has been actively promoting digital health through its Global Observatory for eHealth (GOe) initiative. The WHO has also published several

reports and guidelines on digital health for children with disabilities, including autism. The report highlights the importance of using digital technologies to promote health equity of children with disabilities and provides recommendations for governments and education providers [11].

The World Autism Organisation (WAO) is a non-profit organisation that focuses on improving the quality of life for individuals with ASD worldwide. WAO has launched the Autism Connection, an online community for individuals with ASD and their families. The platform provides a safe and supportive space for individuals with ASD to connect with others and share their experiences. The platform also offers resources and information on autism, including virtual events and webinars. Additionally, WAO has launched a campaign to raise awareness of the importance of virtual learning and the need to ensure that individuals with ASD have access to quality education, regardless of their location or circumstances. Through these efforts, WAO is supporting the education and development of individuals with ASD and their families, as well as the wider community [12].

### B. Online Education for Individuals with ASD in Malaysia

According to the World Health Organisation (WHO), approximately 1% of children worldwide have autism [13]. In Malaysia, research indicates that the prevalence of autism has increased, with an estimated ratio of 1 in 68 individuals without autism, and around 9,000 children are born with autism each year. The Ministry of Health (MOH) reports that the number of diagnoses for autism spectrum disorder has steadily risen over the last decade, with 589 children aged 18 and under diagnosed with ASD in 2021, a 5% increase from the previous year [14].

According to the Education Act 1996, students under the responsibility of the Ministry of Education (MOE) who have special needs are those with visual, hearing, and learning impairments. Learning disabilities refer to cognitive issues that are considered treatable and allow students to receive formal education. The Malaysian Education Development Plan (MEDP) 2013-2025 has outlined clear objectives to be met over a 13-year period concerning quality, equity, access to education, as well as educational management efficiency and effectiveness. Eleven strategic shifts have been formulated to transform the education system, with the first shift being to provide equal access to internationally recognised quality education. Students with special needs, such as those with autism, are included in this objective [15]. The Shared Prosperity Vision 2030 (SPV 2030) highlights people with special needs as a target group. The overarching principle of the new national policy is to promote the development of all communities in Malaysia [16].

Several organisations and bodies in Malaysia are responsible for providing support and assistance to individuals with ASD. One such organisation is the National Autism Society of Malaysia (NASOM), which aims to provide services and support to individuals with ASD and their families [17].

In recent years, the Malaysian government has made efforts to provide online education for individuals with ASD. One

such initiative is the MOE TV Pendidikan program, which provides online classes for students with special needs, including those with autism. The program includes subjects such as mathematics, science, and language, and is available for primary and secondary school students [18][19].

Another government initiative is the MyAutism Portal, which is an online platform that provides resources and information on autism for parents, caregivers, and educators. The portal includes various modules, such as early intervention, communication, and social skills. Additionally, the Malaysian Communications and Multimedia Commission (MCMC) has launched the JomBelajar@Home program, which provides online education for students with disabilities, including autism [20][21]. The program includes a range of subjects, including academic and vocational skills, and is accessible to students with disabilities nationwide. With the current COVID-19 pandemic situation, online education has become increasingly important for individuals with ASD who require special education.

### C. Other Related Studies

The COVID-19 pandemic has presented numerous challenges for children with ASD and their families. It has increased the burden on caregivers of children with ASD, who may not have access to the necessary resources to manage their child's condition. This highlights the need for more resources and support for caregivers, who play a critical role in the care of children with ASD [22].

A study conducted by [23] surveyed parents of children with ASD in the United States and found that they faced several challenges related to the provision of education and support for their children. These challenges included lack of resources and difficulties in maintaining routines. To address these challenges, Stenhoff et al. [24] provided guidance for educators and caregivers on how to support children with ASD during the pandemic. They stressed the importance of maintaining routines and structure, providing clear communication, and using visual supports to help children understand and cope with the changes brought about by the pandemic. The researchers explored the challenges faced by parents of children with ASD in Taiwan during the pandemic and the strategies they used to overcome them. They found that parents faced difficulties in adapting to online learning and employed a variety of strategies to overcome these challenges.

Several studies have investigated the impact of the COVID-19 pandemic on the support and therapy available for children with ASD. Johnsson et al. [25] conducted a study in India and found that teletherapy could be an effective solution for children with ASD who may not have access to traditional therapies due to the pandemic. This highlights the potential of teletherapy to overcome the lack of access to traditional therapies and provide remote access to therapy. Similarly, Furar et al. [26] investigated the impact of the pandemic on social support for families of children with ASD in Greece and found that the lack of social support has significantly affected these families, who already have limited access to experts and resources. This emphasises the need for more support for families of children with ASD, particularly during times of crisis. Furthermore, Syriopoulou-Delli et al. [27] reviewed

technology-assisted services for individuals with ASD and found that while such services have the potential to provide additional resources and support, there is a need for more resources and expertise to ensure their effectiveness and accessibility.

## III. METHODOLOGY

### A. Overview

Research plays a vital role in gathering information and data to support the development of evidence-based practices. In the context of autism care centres, research is crucial for understanding the needs of children with ASD and developing effective care strategies. Hyett et al. [28] emphasized the importance of employing various research methods in autism care centres to gain a better understanding of the needs of children with ASD and to develop effective care strategies.

The purpose of this research was to investigate the challenges encountered by teachers and students with ASD when transitioning to VTL during the COVID-19 pandemic, and to explore how the learning process unfolds in this new context. Additionally, the use of ICT in the practices and services of several autism care centres in Malaysia was also part of the study. To achieve the research goals, several activities were undertaken, including literature review, on-site observations, interviews with principals, and an online questionnaire for both teachers and principals of the autism care centres. The literature review provided a theoretical framework for the study, while on-site observations allowed for a deeper understanding of the challenges faced by teachers and students with ASD during the pandemic. Interviews with principals provided insights into the strategies used by the centres to support VTL, and the online questionnaire helped gather information from the participating teachers about their experiences and challenges regarding VTL for students with ASD.

In summary, the research emphasises the significance of using diverse research techniques to comprehend the VTL requirements of children with ASD and to produce effective care and teaching strategies in the form of digital content. The outcomes of the study are expected to facilitate the construction of an Instructional Digital Model that can support the creation of a VTL platform specifically designed for autism care centres.

### B. On-site Observation

Observation is a commonly used research method that involves direct observation and recording of behaviours and activities in a specific setting. In an autism care centre, observation can be used to study the interactions between teachers and students with ASD, the physical environment, and the effectiveness of different care strategies [29].

To conduct on-site observation in autism care centres, the researchers visited four different autism care centres from different organizations to prevent any bias. A guideline in the form of an on-site observation form was used to observe ICT facilities available at the centres. The form consisted of five sections that were specific to particular aspects of the facilities, including ICT infrastructure, security, storage, teaching and

learning, and administration. Each section required direct observation to record comments and judgments on the ICT aspects [30].

To ensure that no aspect was left unobserved, the researchers checked all required aspects on the form before concluding the observation. Through on-site observation, the researchers gained insight into the operations of the autism care centres and identified potential areas for improvement. Notes were taken, and practices or services that involved ICT were recorded.

### C. Interviews

Interviews are widely used in research to explore a range of topics related to autism, including telehealth services [31], social communication challenges [32], and classroom-based interventions [33]. Interviews are a valuable research method for exploring the experiences and perspectives of those involved in autism care, as they provide detailed and nuanced insights into the topic [34].

In this study, interviews were conducted with the principals or managers of the four autism care centres during on-site observation activities. Informed consent was obtained from each participant prior to the interview, which was based on semi-structured questions covering various aspects of the premise facilities, teachers' profiles, skills, experiences, ICT tools used in teaching, and challenges faced during the pandemic. The semi-structured questions were designed to elicit detailed information from the participants about their experiences with ICT tools in teaching and their challenges during the pandemic. The interviews were conducted in person and lasted between 30 to 60 minutes, and the audio recordings were transcribed and analysed to identify themes and patterns in the data.

In conclusion, interviews are a valuable research method for exploring the experiences and perspectives of those involved in autism care. In this study, interviews with the principals or managers of the autism care centres provided valuable insights into the use of ICT tools in teaching and the challenges faced during the pandemic. The data collected from the interviews were used to support the findings of the research and to develop recommendations for improving the use of VTL in autism care centres.

### D. Online Questionnaire

Online questionnaire is a research method that involves administering a set of questions to individuals through an online platform [35]. In an autism care centre, this method can be used to gather information from a large sample of individuals who related with students ASD, such as families, and caretakers. For instance, researchers can administer surveys to caretakers and families to understand their experiences with the care provided in the centre.

Similarly, surveys can be administered to staff members to gather information on their training needs, challenges, and suggestions for improving care. Through online surveys, researchers can collect data from a wide range of participants, providing a more comprehensive understanding of the needs of individuals with ASD [36].

This study utilized an online questionnaire as a data collection method due to time constraints and the pandemic situation that limited in-person meetings. The study used a convenience sampling technique to disseminate the questionnaire to potential respondents. The selection of autism care centres was based on their accessibility and proximity to the researcher, rather than a probability-based sampling method. The data collection platform used was Google Form, and link of questionnaire was distributed via email and the WhatsApp application to several autism care centres in Malaysia. Respondents could complete the online questionnaire on their laptop, desktop, tablet, or mobile phone, and it took approximately five minutes to finish.

The study developed two sets of online questionnaires: one for principals and another for teachers or caretakers of students with ASD who received care at the participating centres. The questionnaires were based on structured questions that covered various aspects of the participants' profiles, ICT skills, ICT experiences, ICT tools used in teaching, and challenges they faced during the pandemic [37]. The questionnaires were designed to be user-friendly and easily accessible through online platforms. The teachers and principals were provided with a link to the respective questionnaire through email and were given clear instructions on how to complete the questionnaire. The responses from the questionnaires were collected and analysed to identify themes and patterns in the data.

## IV. ANALYSIS AND DISCUSSION

### A. Overview of Research Findings

The flow of the research process to investigate the impact of the COVID-19 pandemic on teaching and learning in the selected autism care centres in Malaysia consists of several stages. A summary of the research findings based on the research process is as illustrated in Fig. 1.

The initial stage in the research process flow is data collection, whereby the investigators employed three primary methods, namely on-site observations, interviews, and online questionnaires, to collect information. The second stage is data analysis and findings, where the researchers utilised NVIVO, a qualitative data analysis software, to organise and structure the data obtained. The information collected through on-site observations, interviews, and online questionnaires underwent analysis, and the outcomes were integrated to identify recurrent themes and patterns. During this phase, three themes emerged: 1) Challenges encountered during the pandemic; 2) ICT requirements; and 3) Instructional model.

The third stage comprises interpreting the data analysis results to gain a more profound comprehension of the difficulties, technology prerequisites, and instructional approaches employed by autism care centres during the pandemic. The interpretation process involves scrutinizing the data and recommendations based on the findings within the context of existing literature and theories associated with the influence of challenges on education and the utilization of technology to promote VTL. The outcome of this phase is the identification of VTL platform elements, recommended technologies, and digital platform features.

Fig. 1. Research process flow and findings.

In the research process, the ultimate step involves constructing a model where the researchers utilised the findings from earlier stages to create an IDM for VTL in autism care centres. The objective of the IDM is to tackle the issues caused by the COVID-19 pandemic and enhance the educational experience for children with ASD in the virtual environment. The core of IDM consists of strategies, methods, and skills tailored to meet the specific requirements of students with ASD in the VTL context. At this stage, the researchers also formulated the proposed framework for the VTL development.

**B. Preliminary Analysis**

Based on the online questionnaire that received responses from 16 teachers, the result revealed that 87.5% of the responding teachers were female, and 76% were under 36 years of age. Most of them had between 1-5 years of experience in teaching-learning related to autism, and only 31.3% had ever attended a course or had a special education certificate.

In terms of ICT skills, the result found that 62.5% of the responding teachers did not have any certification in ICT skills, and 93.8% had knowledge in Microsoft Office. WhatsApp was the most commonly used social media for communication with parents or guardians. The study revealed that there is a relatively large gap between teachers' knowledge and virtual learning skills, with the majority of the respondents having moderate or very little knowledge about VTL. Videos from YouTube were the most often software used for teaching,

followed by downloaded apps from the internet, Ms PowerPoint, and others.

**C. Data Analysis**

Table I shows the categories of information collected and structured using NVIVO application. The first source, on-site observations, captured information on ICT infrastructure, including internet and WiFi availability, ICT security measures such as CCTV cameras and door access, and ICT tools for teaching and learning such as PCs, laptops, tablets, LCD TVs, digital boards, projectors, social media, educational software, and related websites. The observations also covered ICT tools for administration, including MS Office, email, and accounting systems, as well as ICT storage tools such as file explorer, USB pen, and external HD.

The second source, interview transcriptions, captured information on the premise facilities, including classrooms, kitchens, and offices, as well as the students' demographic, staff resources, teaching content and modules, financial resources, and management and administration. The interviews also captured information on the problems and challenges encountered during the pandemic.

The third source, online questionnaires, captured information on the profiles of the teachers and caregivers, their skills and experiences, ICT tools used for teaching, problems and challenges encountered during the pandemic, and their views on VTL for students with ASD.

TABLE I. DATA SOURCES AND NODES

Sources	Nodes
On-site Observation	ICT Infrastructure (Internet, WiFi)
	ICT Security (CCTV Camera, Door Access)
	ICT for Teaching Learning (PC, Laptop, Handphone, Tablet, LCD TV, Digital board, Projector, Social media, Edu software, related websites)
	ICT for Administration (Ms Office, Email, Accounting System)
	ICT Storage (File Explorer, USB Pen, External HD)
Interview Transcription (principals)	Premise facilities (classroom, kitchen, office, etc)
	Students/children demographic
	Staff resources
	Teaching content and modules
	Financial resources
	Management and administration
Online Questionnaire (teachers, principals)	Problems and challenges during pandemic
	Profiles
	Skills
	Experiences
	ICT tools used for teaching
	Views

Overall, the table shows that the study collected a wide range of information related to the impact of the pandemic on teaching and learning in autism care centres. The information is structured in a way that enables easy comparison and analysis, making it easier to draw conclusions and make recommendations based on the findings.

Three themes emerged from the data analysis were: teachers' challenges during the pandemic, ICT requirements for online teaching and learning, and an instructional model for students with ASD. The following sections provide analysis of each theme and its implications for teaching and learning in the context of the pandemic.

*D. Theme 1: Challenges during the Pandemic*

The first theme that emerged from the data analysis was the challenges that teachers faced during the pandemic. This theme is directly related to the first research question as stated in the initial section. Useful information acquired through interview sessions with participants, observations and online questionnaire were taken into account as evidence and inputs for data analysis.

Table II shows the challenges faced by teachers of the care centres in teaching children with ASD during the pandemic. As the pandemic has affected many aspects of daily life, it has also brought challenges to teaching and learning for children with ASD.

TABLE II. CHALLENGES IN TEACHING CHILDREN WITH ASD (TEACHERS' FEEDBACK)

Challenges	Description of findings
Cooperation from parents	Parents play a critical role in supporting their children's education, especially during the pandemic when much of the learning takes place at home. Ensuring cooperation from parents is important to maintain the continuity of education.
Funds for activities	Activities outside the classroom are essential for children with ASD, and the pandemic has limited the opportunities for these activities. Funding can be a challenge for carrying out these activities in a safe and effective manner.
Communication and behavioural problems	Children with ASD often struggle with communication and behaviour, and these challenges have been amplified during the pandemic due to the disruption of routines and increased stress levels.
Managing emotions and behaviours	Children with ASD may have difficulty managing their emotions and behaviours, and this can be exacerbated by the pandemic.
Repetition of teaching methods	Children with ASD often require repetition of teaching methods to achieve satisfactory learning outcomes, and this can be a challenge for educators during the pandemic when resources may be limited.
Cultivating discipline	Daily routines are essential for children with ASD, and cultivating discipline in performing these routines can be challenging during the pandemic when routines may be disrupted.
Children tantrums	Children with ASD may have tantrums, and these can be exacerbated by the pandemic due to increased stress levels.
Sexual development of autistic adolescents	Adolescents with ASD may have difficulty understanding sexual development and behaviours, and this can be a challenge for educators during the pandemic when access to resources may be limited.
Self-management and use of toilet	Children with ASD may require support in self-management and using the toilet, and this can be a challenge for educators during the pandemic when resources may be limited.

The teachers feedback provided a range of problems, including the lack of adequate training on online teaching, limited access to ICT infrastructure and resources, and difficulties in maintaining student engagement and motivation.

Table III outlines the significant difficulties and obstacles encountered by autism care centres amid the pandemic, as identified through a comprehensive analysis and feedback from principals.

TABLE III. CHALLENGES OF AUTISM CARE CENTRES DURING THE PANDEMIC (OVERALL ANALYSIS)

Challenges	Description of findings
Limited access to therapy and services	Many autism care centres had to temporarily close or reduce their services due to the pandemic. This has resulted in limited access to therapy and services for individuals with ASD, which can have a significant impact on their progress and development.
Staffing shortages	Some autism care centres have experienced staffing shortages due to illness, quarantine, or personal reasons. This has made it challenging to provide education, adequate care and support for individuals with ASD.
Financial difficulties	The pandemic has resulted in financial difficulties for the autism care centres, as they have had to incur additional expenses related to Personal Protective Equipment (PPE), cleaning, and sanitisation. This has led to reduced services and increased financial burden on the centres.
Changes in routine	Individuals with ASD thrive on routine and predictability. However, the pandemic has disrupted routines and introduced uncertainty, which can cause distress and anxiety for individuals with ASD.
Social isolation	Individuals with ASD may already struggle with social skills and communication, and the pandemic has made social isolation more prevalent. This can lead to increased feelings of loneliness, anxiety, and depression.
Technology challenges	All autism care centres have to adapt to virtual care and therapy, which can be challenging for individuals with ASD who may struggle with technology or have difficulty engaging in virtual sessions.

In conclusion, autism care centres in Malaysia have faced significant challenges during the COVID-19 pandemic. These challenges have affected the delivery of care and support as well as teaching and learning for individuals with ASD, resulting in increased stress and difficulties for both individuals with ASD and their caregivers.

*E. Theme 2: ICT requirements for online teaching and learning*

The second theme that emerged from the data analysis was the ICT requirements for online teaching and learning. The results of this data analysis have helped a lot to answer the second research question and shed light on the specific ICT needs in the context of autism care.

To gather comprehensive information regarding the ICT facilities available in autism care centers, an online questionnaire was administered due to the limitations posed by conducting on-site observations. This questionnaire was thoughtfully designed to elicit feedback on the utilization of

ICT tools and the overall capabilities of the care centers in integrating technology into their educational practices. The questionnaire received responses from 16 participants, including teachers and principals, representing six different autism care centers.

The gathered feedback, as described in Table IV, provided significant insights into the current state of ICT implementation within the participating autism care centers.

TABLE IV. ICT FACILITIES IN AUTISM CARE CENTRES

Type of Information	Description of findings
Age of autism care centre	Four centres had been operating for less than five years, one for less than ten years, and one for more than ten years.
Number of teachers	Most centres had more than five teachers. Four centres had between 10 and 20 children, while the other two had between 30 to 50. None of the centres could accommodate more than fifty children.
ICT skills	All centres had at least two teachers with ICT skills or who had attended ICT courses.
ICT infrastructure	All centres had Internet, Wi-Fi, PCs, and laptops. They also had their own websites, but most lacked multimedia and teaching-learning applications.
Software systems	None of the centres had specific software systems for administration, teachers, and learning schedules.
Network community	Three centres had a network community, while the other three did not.
Virtual teaching	Five centres frequently conducted virtual teaching-learning during the pandemic, while one did it rarely.
Communication media	WhatsApp was the most common communication medium between administrators of care centres and parents. Facebook and telephone were also frequently used.
Information communicated to parents	Invitations were the most common form of information communicated to parents, followed by news and notifications.
ICT needs	PCs and laptops were the ICT needs that all care centres stated they most wanted to help the teaching/learning process. Most centres also needed teaching-learning software, digital screen boards, and multimedia tools.
ICT knowledge and skills	Two centres stated they needed skills in using software that can help management. Two centres stated they did not need any ICT skills. The other two centres each stated they needed basic ICT technology skills and skills in using software that can aid teaching.
Digital storage	All centres used File Explorer, USB Pen Drives, Google Drive, Facebook, and YouTube for digital storage.

The teachers responded that they required a range of digital tools and resources to support online teaching, including learning management systems, video conferencing platforms, and digital content. They also responded to the need for reliable internet connectivity, devices such as laptops or tablets, and appropriate software.

The findings suggest that the autism care centres need to invest in the necessary ICT infrastructure and resources to support online teaching and learning. This includes providing teachers and students with the necessary hardware and

software and ensuring that they have reliable access to the internet. The autism care centres should also invest in developing or adopting learning management systems and video conferencing platforms that are user-friendly and accessible.

#### F. Theme 3: Instructional Model

The third theme that emerged from the data analysis was the instructional model being practiced by the autism care centres during the pandemic. Based on compilation of data collection through the on-site observation, interviews, and online questionnaires, not many autism care centres have transitioned to VTL to continue providing educational and therapeutic services to children with autism. Based on the findings, the weaknesses of VTL practice in those autism care centres are described in Table V.

TABLE V. FINDINGS OF INSTRUCTIONAL PRACTICE IN THE AUTISM CARE CENTRES

Findings	Description of findings
Lack of access to necessary digital tools	The feedback obtained from teachers indicated a need for a range of digital tools and resources to support online teaching, including learning management systems, video conferencing platforms, and digital content. Some autism care centres have no necessary funds or infrastructure to provide these tools to their teachers and students.
Poor internet connectivity	Reliable internet connectivity is essential for online teaching and learning, but some autism care centres may be located in areas with poor internet infrastructure, making it difficult for teachers and students to access online resources and participate in virtual classes.
Limited availability of devices	Teachers and students require laptops or tablets to access digital resources and participate in virtual classes, but not all autism care centres have enough devices to meet the needs of all their students.
Lack of training	Some teachers may not have the necessary skills and training to effectively deliver online instruction and may require additional training and support to adapt to the new virtual teaching environment.
Difficulty in engaging students	Some students with ASD may struggle with the lack of face-to-face interaction and find it challenging to engage with online instruction, which could hinder their learning progress. Teachers may need to adapt their teaching strategies to keep students engaged and motivated.

The findings suggest that the autism care centres should explore virtual platforms as a viable alternative to traditional classroom-based learning. This includes developing and implementing strategies that promote student engagement and motivation, such as gamification and collaborative learning activities. The autism care centres should also ensure that students have the necessary skills and resources to support online learning, such as digital literacy skills and access to appropriate ICT resources.

### V. RESULTS AND RECOMMENDATION

#### A. Proposed VTL Platform Elements

The proposed elements of a VTL platform for children with ASD should be meticulously designed to address the

distinctive needs of these learners, as illustrated in Fig. 2. By integrating these elements into a VTL platform, it is envisaged that children with ASD will benefit from a customized and effective learning experience tailored to their specific requirements.

Fig. 2. VTL Platform elements for Autism Care Centres

Table VI describes the proposed elements of a VTL platform for autism care centres.

Overall, the design and implementation of a comprehensive VTL platform specifically tailored for children with ASD have the potential to revolutionize their learning experience, ensuring that they receive the individualized support and resources they need to thrive academically and socially.

TABLE VI. PROPOSED ELEMENTS OF A VTL PLATFORM FOR AUTISM CARE CENTRES

Elements	Description
Accessibility	VTL platform and tools should be accessible to children with different abilities and disabilities. Accessibility features such as text-to-speech, closed captioning, and audio descriptions should be available.
Customisation	VTL platform should allow for customisation based on the individual needs of each child with ASD. This may include adapting the pace and difficulty of instruction, providing visual aids, and accommodating sensory preferences.
Multimodal instruction	VTL platform should provide instruction using multiple modes, such as visual, auditory, and kinesthetic, to meet the diverse learning needs of children with ASD.
Engagement	VTL platform should be designed to actively engage children with ASD in the learning process. Interactive and multimedia materials such as videos, games, and simulations can be used to enhance engagement and maintain attention.
Collaboration	VTL platform should provide opportunities for collaboration and communication between teachers, parents, and children with ASD. Online forums, chat rooms, and video conferencing can be used to facilitate collaboration and social interaction.
Feedback and progress tracking	VTL platform should include features that allow for feedback and progress tracking. Teachers and parents should be able to monitor the child's progress and provide feedback to support learning and development.
Positive reinforcement	VTL platform should include positive reinforcement strategies to motivate and encourage children with ASD. This may include rewards and praise for completing tasks and achieving goals.

### B. Proposed Technology and Digital Platform Features

During the COVID-19 pandemic, there are several technologies that can be used in various ways to support individuals with ASD. Immersive learning has been identified as a promising approach to address the learning challenges faced by students with ASD [38]. Immersive learning utilises virtual and augmented reality (VR and AR) technologies to create engaging and interactive learning environments that can be customised to meet the individual needs of students with ASD [39].

The immersive learning environment can be customised to meet the unique sensory processing needs of students with ASD, which provides a comfortable and engaging learning experience. Moreover, immersive learning environments can improve communication and social skills by allowing students to interact with virtual characters and environments [38]. Immersive learning has also been shown to be an effective tool for teaching a range of skills, including academic content, vocational skills, and life skills [40][41][42]. This versatility makes immersive learning a valuable tool for educators who work with students with ASD. Studies have shown that immersive learning can be effective in improving the social, communication, and vocational skills of students with ASD [43]. Therefore, immersive learning should be considered an important tool for educators who are working with students with ASD.

In summary, there are several technologies that can be used in various ways to support individuals with ASD. Some suggestions are described in Table VII.

TABLE VII. RECOMMENDED TECHNOLOGIES FOR AUTISM CARE CENTRES

Components	Description
Teletherapy	Many therapists and educators have turned to teletherapy, which uses videoconferencing technology to provide therapy and instruction remotely. This allows individuals with ASD to continue receiving therapy and support during the pandemic, even if they are unable to leave their homes or attend in-person appointments.
Virtual classrooms	Virtual classrooms have been used to provide instruction and support for individuals with ASD during the pandemic, allowing them to continue their education and social interaction from home.
Social media and communication apps	Social media and communication apps have been used to provide social interaction for individuals with ASD, who may have difficulty with face-to-face interactions.
Augmented Reality and Virtual Reality	These technologies have been used to provide immersive, interactive experiences for individuals with ASD, which can be especially beneficial for those who have difficulty with traditional learning methods.
Assistive technology	Assistive technology, such as speech-to-text and text-to-speech software, can be used to support individuals with ASD in their communication and learning.
Mobile apps	There are mobile apps designed for individuals with ASD which provide educational and behavioural support, as well as for communication and social skills development.
Adaptive devices	Adaptive devices, such as switches and joysticks, have been used to provide access to technology for individuals with ASD who may have difficulty using standard input devices.

Overall, technology plays an important role in supporting individuals with ASD during the COVID-19 pandemic, by providing flexible, customised learning opportunities, and social interaction, as well as providing access to therapeutic and educational resources.

As for the features of digital platform, they are listed and described in Table VIII.

TABLE VIII. FEATURES OF DIGITAL PLATFORM

Features	Description
Flexibility	Digital platform allows individuals with ASD to learn at their own pace and on their own schedule, which can be especially beneficial for those who have difficulty with traditional classroom settings.
Customisation	Digital platform can be customised to meet the specific needs of individuals with ASD, such as providing visual aids, audio support, and other accommodations.
Social interaction	Digital platform can provide opportunities for social interaction for individuals with ASD, who may have difficulty with face-to-face interactions. Virtual classrooms, social media and other online platforms can provide a safe and comfortable environment for socialisation.
Access to resources	Digital platform can provide access to a wide range of resources and materials that can be used to support the learning of individuals with ASD, such as videos, interactive activities, and simulations.
Remote learning	Digital platform can be done remotely, which can be beneficial for individuals with ASD who may have difficulty traveling to a physical location, or who may benefit from the reduced social interaction that remote learning provides.
Access to specialised teachers	Digital platform can provide access to specialised teachers, such as those trained in autism education, who can provide individualised instruction and support.
Access to global resources	With digital platform, individuals with ASD can access resources and educational materials from around the world, which can be beneficial for those who live in areas with limited resources.

In summary, the use of digital platforms can offer a multitude of benefits for individuals with ASD. It can provide a flexible and customizable learning experience that can be tailored to the specific needs and preferences of the learner, a safe and comfortable learning environment, social skills development, and access to a wider range of learning opportunities. This is particularly important for individuals with ASD, who may have different learning styles and sensory preferences. As such, digital platforms should be considered as an important tool for educators and caregivers who are working with individuals with ASD.

### C. Proposed Instructional Digital Model

Students with ASD have been notably impacted by the COVID-19 pandemic, which has caused considerable disruptions to traditional classroom-based learning. To address this challenge and promote VTL in autism care centres, an IDM has been proposed based on the challenges and needs, which are part of findings of this research study. The IDM for VTL aims to enhance the learning experience for children with ASD, making it more effective and engaging.

As depicted in Fig. 3, the proposed IDM for VTL comprises of three core components: VTL Strategies, VTL Methods, and VTL Skills.

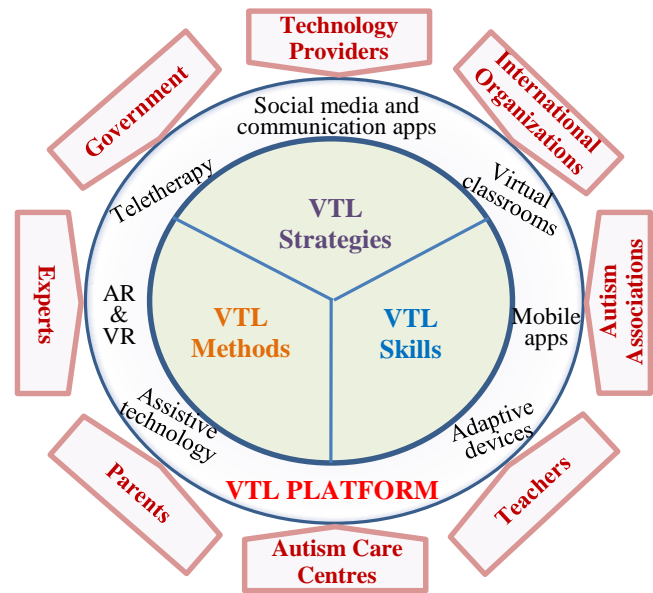

Fig. 3. Instructional Digital Model (IDM) for VTL

**VTL Strategies:** The first component of the IDM is VTL Strategies. These strategies refer to the various ways in which teaching is organised and delivered to students with ASD. They involve a range of approaches designed to enhance learning, such as the use of visual aids, repetition, and positive reinforcement. VTL Strategies also include ways to address specific needs of students with ASD, such as social skills training, sensory integration, and behaviour management.

**VTL Methods:** The second component of the IDM is VTL Methods. This component refers to the specific techniques and tools used to deliver instruction in a virtual learning environment. VTL Methods include the use of multimedia, interactive tools, and virtual reality. They also include adaptations of traditional teaching methods to suit the online environment, such as the use of digital whiteboards, chat rooms, and video conferencing.

**VTL Skills:** The third component of the IDM is VTL Skills. These refer to the specific abilities that teachers and students with ASD need to acquire to be successful in a VTL environment. VTL Skills may include the ability to navigate digital platforms, use of assistive technologies, and self-regulation techniques. Additionally, students with ASD may need support in developing social skills and self-advocacy skills to interact with their teachers and peers in the online classroom.

In summary, the IDM for VTL proposes to enhance the learning experience for teachers and children with ASD by incorporating strategies, methods, and skills designed to meet the specific needs of this population. By leveraging the strengths of technology, the IDM aims to create a more effective and engaging learning experience for students with ASD, even in the face of disruptions caused by the COVID-19 pandemic.

D. Proposed VTL Platform Development Framework

Developing and implementing a VTL platform for autism care centres requires a framework to ensure its effectiveness and success. The framework provides a structured approach to developing and implementing the VTL, ensuring that all aspects of the learning experience are accounted for and that they align with the specific needs of students with ASD.

The framework for developing the VTL platform for autism care centres is depicted in Fig. 4.

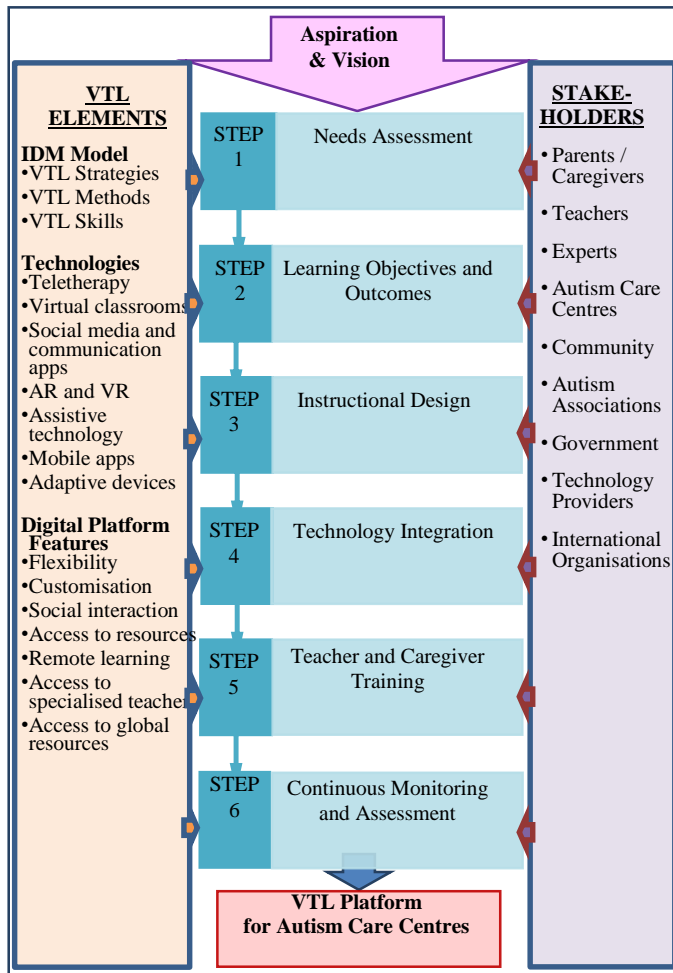

Fig. 4. VTL Platform Development Framework for Autism Care Centre

The framework also enables a standardised approach to be adopted, ensuring that the VTL is consistent across different care centres and teaching environments. Additionally, it provides a mechanism for evaluating the effectiveness of the VTL, identifying areas for improvement and ensuring that the IDM continues to evolve to meet the changing needs of students with ASD.

Details of the VTL platform development framework are described in Table IX.

In summary, the VTL platform for autism care centres is anticipated to provide a more effective and engaging learning experience for children with ASD in autism care centres in Malaysia. By following the steps outlined in this proposal,

autism care centres can develop a customised VTL platform that addresses the specific learning needs and challenges of children with ASD, while integrating appropriate technology tools and methods for VTL. The framework also includes training and ongoing support for teachers and caregivers, as well as a process for continuous monitoring and assessment of the effectiveness of VTL. Overall, the framework is essential for the successful development and implementation of the VTL platform for autism care centres, providing a roadmap for its creation and ensuring that it is effective and responsive to the needs of students with ASD.

TABLE IX. PROPOSED VTL PLATFORM DEVELOPMENT FRAMEWORK FOR PROMOTING VTL

Activity	Description
Step 1: Needs assessment	The first step in developing a VTL platform is to conduct a needs assessment to identify the specific learning needs and challenges of children with ASD in the centre. The needs assessment should also take into account the resources and technology available at the centre. This information can be collected through surveys, interviews, and observation.
Step 2: Learning objectives and outcomes	Based on the needs assessment, clear learning objectives and outcomes should be developed to guide the development of instructional materials and strategies. These learning objectives should be specific, measurable, achievable, relevant, and time-bound (SMART).
Step 3: Instructional design	The next step in developing a VTL platform is to design the instructional materials and strategies that will be used for VTL. The instructional design should be tailored to the specific learning needs of children with ASD and take into account their learning preferences, strengths, and challenges. Instructional materials and strategies should be engaging, interactive, and relevant to the learning objectives and outcomes.
Step 4: Technology integration	The development should include the integration of appropriate technology tools and platforms for VTL. This may include platforms such as Zoom, Google Classroom, or Microsoft Teams, as well as assistive technology tools such as text-to-speech or speech-to-text software. The technology integration should be aligned with the instructional design and the specific learning needs of children with ASD.
Step 5: Teacher and caregiver training	To ensure the successful implementation of VTL, it is important to provide training to teachers and caregivers on how to use the instructional materials, strategies, and technology tools effectively. This training should include best practices for VTL for children with ASD, as well as strategies for addressing technical issues and providing ongoing support to children and their families.
Step 6: Continuous monitoring and assessment	The operation of VTL should include a process for continuous monitoring and assessment of the effectiveness of VTL. This may include regular check-ins with children and their families, as well as ongoing assessment of learning outcomes and progress towards the learning objectives. This information should be used to adjust the instructional materials, strategies, and technology tools as needed to ensure the best possible learning experience for children with ASD.

### E. Comparison of IDM and other similar platforms

To assess the potential performance of the platform based on the proposed IDM, two popular platforms that provide learning needs for students with ASD were selected, and a comparison was made using the IDM criteria as described in Table X.

This comparison table provides an overview of the different features offered by the proposed IDM, Autism Speaks Learn@Home, and Therapy Tribe, helping to identify their strengths and weaknesses in relation to VTL platform elements, VTL platform technology, and digital platform features.

Under the category of VTL Platform Elements, the table compares the accessibility, customisation, multimodal instruction, engagement, collaboration, feedback and progress tracking, and positive reinforcement. The proposed IDM scores high in accessibility, customisation, engagement, collaboration, and offers positive reinforcement. Autism Speaks Learn@Home and Therapy Tribe also have high accessibility but score lower in customisation and collaboration.

TABLE X. COMPARISON OF IDM AND OTHER PLATFORMS

Feature	ProposedIDM	Autism Speaks Learn@Home	Therapy Tribe
<b>VTL Platform Elements</b>			
Accessibility	High	High	High
Customisation	High	Moderate	Moderate
Multimodal Instruction	Yes	Yes	Yes
Engagement	High	High	High
Collaboration	High	Low	High
Feedback and Progress Tracking	Yes	Yes	Yes
Positive Reinforcement	Yes	Yes	Yes
<b>VTL Platform Technology</b>			
Teletherapy	Yes	No	Yes
Virtual Classrooms	Yes	Yes	Yes
Social Media and Communication Apps	Yes	No	No
Augmented Reality and Virtual Reality	High	None	Low
Assistive Technology	Yes	No	Yes
Mobile Apps	Yes	Yes	Yes
Adaptive Devices	Yes	No	Yes
<b>Digital Platform Features</b>			
Flexibility	High	Low	Low
Customisation	Yes	No	No
Social Interaction	Yes	No	Yes
Access to Resources	High	High	High
Remote Learning	High	Low	Moderate
Access to Specialized Teachers	Yes	No	Yes
Access to Global Resources	Yes	No	No

Moving on to VTL Platform Technology, the table compares teletherapy, virtual classrooms, social media and communication apps, augmented reality and virtual reality, assistive technology, mobile apps, and adaptive devices. The proposed IDM supports teletherapy, virtual classrooms, social media and communication apps, and has a high presence of augmented reality and virtual reality. Autism Speaks Learn@Home lacks teletherapy and social media apps, while Therapy Tribe lacks virtual classrooms and has a low presence of augmented reality and virtual reality.

In terms of Digital Platform Features, the table compares flexibility, customisation, social interaction, access to resources, remote learning, access to specialized teachers, and access to global resources. IDM excels in flexibility, customisation, social interaction, access to resources, remote learning, and access to specialized teachers. Autism Speaks Learn@Home has lower flexibility and lacks customisation, while Therapy Tribe also lacks customisation and access to global resources.

In summary, it can be concluded that the proposed IDM offers a comprehensive virtual learning platform for autistic students. In comparison, Autism Speaks Learn@Home and Therapy Tribe exhibit strengths in certain areas but may have limitations in terms of customisation, collaboration, and access to specific technologies. While all three platforms aim to support autistic students in their virtual learning journey, the proposed IDM distinguishes itself with its inclusive features and advanced technologies designed to address the specific needs of autistic learners.

## VI. CONCLUSION AND FUTURE WORKS

### A. Conclusion

This report has presented the findings of a case study on the impact of the COVID-19 pandemic on teaching and learning of autism care centres in Malaysia. The research methods used in this study provided valuable insights into the practices and services of several autism care centres. On-site observation, interviews, and online questionnaire were all effective methods for gathering data. The findings of the study identified three main themes, including teachers' challenges during the pandemic, ICT requirements for online teaching and learning, and instructional model.

The findings suggest that autism care centres need to invest in training teachers on online teaching and the use of ICT resources provide the necessary ICT infrastructure and resources to support online teaching and learning, and explore digital models as a viable alternative to traditional classroom-based learning. These findings have important implications for teaching and learning in the context of the pandemic and beyond.

A special fund for autism care centres needs to be proposed and established to upgrade their ICT facilities, especially in digital content development. Regarding future research, further studies on innovative tools using advanced technology such as virtual reality (VR) and augmented reality (AR) have to be carried out to include them as part of the VTL platform. More interviews and detailed discussions with the autism experts and technologists on new methods of digital teaching and learning

for autism need to be conducted to generate comprehensive ICT requirements for the development of VTL platform.

In conclusion, the IDM proposed for promoting VTL in autism care centres in Malaysia provides a promising solution for addressing the unique learning needs of children with ASD. By following the steps outlined in the proposed framework, autism care centres can develop a customised VTL platform that addresses the specific learning needs and challenges of children with ASD, while integrating appropriate technology tools and methods for VTL. The VTL platform can provide a more effective and engaging learning experience for children with ASD and may improve their social, communication, and vocational skills. With the VTL platform's potential benefits, it could be considered an essential tool for educators who are working with children with ASD in autism care centres in Malaysia.

### B. Future Works

To ensure the effective implementation of the VTL platform in autism care centres, several key steps can be taken as potential suggestions for future works. These steps involve conducting a pilot study with a small sample of students with ASD, their teachers, and caregivers to evaluate the usability, acceptability, and efficacy of the VTL based on the proposed IDM. If successful, the VTL could be expanded to other locations, including different countries, to observe its performance in diverse cultural and linguistic contexts.

Additionally, incorporating emerging technologies such as artificial intelligence into the IDM can enhance the learning experience for students with ASD. Long-term outcomes of the VTL should also be assessed, including academic and social achievements, to determine its effectiveness over an extended period. Collaboration with stakeholders such as policymakers, education leaders, and technology providers can ensure the sustainability and widespread adoption of the VTL, while also integrating new technologies into the platform.

Furthermore, developing training programs for teachers and caregivers is crucial to equip them with the necessary skills to implement the VTL effectively and address any challenges that may arise. Evaluating the cost-effectiveness of the VTL platform and incorporating teachers and parents' feedback throughout the development process are important aspects to consider for the ongoing improvement and relevance of the VTL in meeting the needs of students with ASD.

In summary, future research of IDM to promote VTL for autism care centres holds significant promise for further advancements and improvements. By providing a comprehensive and individualized learning experience, IDM has the potential to enhance academic achievements, social skills development, and overall well-being for autistic students. The use of advanced technologies like AI and AR/VR, combined with the customization features of IDM, can create engaging and inclusive learning environments. Moreover, IDM's collaborative and interactive features foster peer interactions, socialization, and the development of essential life skills. Ultimately, IDM has the potential to revolutionize the field of VTL for autism by offering an effective and accessible platform for tailored instruction, promoting inclusive

education, and empowering autistic students to reach their full potential.

# Investigating OpenAI's ChatGPT Potentials in Generating Chatbot's Dialogue for English as a Foreign Language Learning

Julio Christian Young, Makoto Shishido

Department of Information, Communication, and Media Design Engineering, Tokyo Denki University, Tokyo, Japan

**Abstract**—Lack of opportunities is a significant hurdle for English as a Foreign Language (EFL) for students during their learning journey. Previous studies have explored the use of chatbots as learning partners to address this issue. However, the success of chatbot implementation depends on the quality of the reference dialogue content, yet research focusing on this subject is still limited. Typically, human experts are involved in creating suitable dialogue materials for students to ensure the quality of such content. Research attempting to utilize artificial intelligence (AI) technologies for generating dialogue practice materials is relatively limited, given the constraints of existing AI systems that may produce incoherent output. This research investigates the potential of leveraging OpenAI's ChatGPT, an AI system known for producing coherent output, to generate reference dialogues for an EFL chatbot system. The study aims to assess the effectiveness of ChatGPT in generating high-quality dialogue materials suitable for EFL students. By employing multiple readability metrics, we analyze the suitability of ChatGPT-generated dialogue materials and determine the target audience that can benefit the most. Our findings indicate that ChatGPT's dialogues are well-suited for students at the Common European Framework of Reference for Languages (CEFR) level A2 (elementary level). These dialogues are easily comprehensible, enabling students at this level to grasp most of the vocabulary used. Furthermore, a substantial portion of the dialogues intended for CEFR B1 (intermediate level) provides ample stimulation for learning new words. The integration of AI-powered chatbots in EFL education shows promise in overcoming limitations and providing valuable learning resources to students.

**Keywords**—ChatGPT; chatbots as learning partners; EFL chatbot system; dialogue creation

## I. INTRODUCTION

English has become the most widely spoken language globally, with approximately 1.5 billion people speaking it as a first, second, or foreign language [1]. As a result, English proficiency is increasingly becoming essential for success in various fields such as academics, business, and international relations. Undoubtedly, English language learning can significantly benefit foreign language students. From an academic standpoint, English is essential in various fields, including science, technology, engineering, and mathematics, where English is the primary language of instruction and research. Moreover, by mastering English, students can increase their chances of success in their later global careers, as it is commonly used in international business.

Despite the benefits, learning a new language can be challenging, and for foreign language students, learning English can be particularly difficult due to several factors [2]–[4]. One significant challenge foreign language students face in learning English is the lack of opportunity to practice speaking the language [4]–[7]. Many previous studies have shown that speaking a language is essential for effective communication and language acquisition [2], [8], [9]. Thus, the lack of speaking practice can lead to a significant barrier in language acquisition, as speaking is essential to build fluency and confidence in using the language. When left alone, this situation can lead to demotivation and further decrease opportunities to practice.

To deal with this situation, using chatbots in language learning has gained increasing research attention in recent years [10]–[15]. Several studies have found that chatbots can be an effective tool for helping EFL students learn the language. One of the main benefits of practicing with a chatbot is that students can gain conversation experience in a safe, low-pressure environment [11]. Furthermore, through the recent advancement of speech recognition and synthetic speech technologies, chatbots can be implemented to simulate real-life conversations [10], [15]. Other than that, a previous study also showed that students often feel less judged when they receive feedback or corrections from the chatbot [10], [11]. Furthermore, chatbots can enable students to practice anywhere and at any time outside the classroom, thus increasing their language exposure [10], [11], [15], [16]. Such flexibility can help them to overcome the challenge of limited opportunities to practice, particularly for students who may not have access to native speakers.

A successful chatbot system for language learning *typically* involves several key components, including a speech recognition (SR) module, audio content, and reference dialogue content. In previous studies, we have covered subjects related to a speech recognition module and audio content for a chatbot system for helping EFL students to learn English [10], [11]. One study evaluated the use of Vosk, an internet-free speech recognition module, and found that limiting the vocabularies recognized by the SR module during runtime improved the system's ability to recognize student speech input, resulting in a more pleasant learning experience [11]. In another study, WaveNet, a deep learning-based speech synthesizer, was evaluated for generating audio content in an EFL chatbot system [10]. While students could distinguish that the content produced by WaveNet sounded less natural

than actual human speech, they produced fewer errors when transcribing the WaveNet-generated audio, indicating that it was easier to understand.

While numerous previous studies have extensively explored speech recognition and technology for developing audio content, the chatbot's dialogue content is often still sourced from existing materials produced by humans. With the advancements in artificial intelligence and deep learning technology, it is now possible for machines to generate readable and contextually appropriate content. Using machine-generated content could reduce reliance on human-produced content in the development process, thus reducing the cost and time needed significantly. Therefore, this research aims to evaluate the potential of using artificial intelligence (AI)-generated content for reference dialogue in an EFL chatbot system.

The evaluation of the potential of machine-generated content for an EFL chatbot system will focus on a chatbot implementation by OpenAI, ChatGPT [19]. ChatGPT is a novel chatbot implementation with impressive abilities to return coherent and contextually appropriate responses based on user requests. By leveraging the vast amounts of text data, ChatGPT can generate text in various styles and tones, making it a promising option for generating content suitable for numerous purposes [19]. For EFL content generation, OpenAI has excellent potential to generate English content that could be useful for EFL students.

Therefore, this study aims to evaluate the appropriateness of ChatGPT-produced materials for dialogue practice in language learning. As ChatGPT is a relatively new technology that hasn't been extensively explored in this context, investigating its capabilities becomes necessary. We will utilize ChatGPT to produce a series of dialogue practice materials and employ multiple readability metrics to thoroughly analyze their suitability. By gaining insights into the characteristics of ChatGPT-generated dialogue, we can identify the most appropriate audience to maximize learning benefits. Determining the target audience that can derive the most from these materials will allow us to optimize their use and enhance the effectiveness of language learning experiences.

## II. LITERATURE REVIEW

### A. Voice-enabled Chatbot for EFL Learning

There are two types of chatbots: text-based and voice-enabled chatbots classified based on their modality. Voice-enabled chatbots have been proposed as a helpful tool for learning and practicing a second language (L2) speaking skills. A study in [12] discovered that L2 learners appreciated the chatbot's capacity to expose them to various conversational expressions and vocabulary and enable repetitive practice. On top of that, L2 learners prefer chatbots over human partners due to their fear of making mistakes and appearing incompetent during interactions with human partners [13].

A recent study by Han [14] showed how Alexa, a general voice-enabled chatbot, could help students by engaging them in conversations to practice their speaking skills. The

experimentation indicated that chatbot-assisted learning improved students' pronunciation and language fluency. Moreover, post-questionnaire responses showed that the integration of such chatbot positively impacted students' interest in learning and enhanced their motivation to learn. Similarly, using readily-available chatbots such as Google Assistants [15], [16], and Alexa [17], [18] also led to positive improvements in students' language proficiency. Researchers noted that students felt less embarrassed and anxious when practicing with a chatbot [15], [16]. Furthermore, chatbots promote self-directed foreign language learning outside school settings where native speakers are hard to find [17], [18].

Although general chatbots may seem appealing, several studies have suggested that such system adaptation may be less effective for L2 learners as it may not cater to their specific needs [21], [22]. Therefore, several criteria should be considered when designing a chatbot for language learning, such as language learning potential, learners' suitability, and authenticity [21]. The language learning potential criterion can be further broken down into components like interactional modification and task focus. Secondly, the learners' suitability criterion should consider various factors, such as language proficiency, age, learning style, and individual characteristics. Lastly, the authenticity criterion indicates that the materials presented within the chatbot should imitate real-life tasks that learners are likely to encounter.

A previous study [21] that implemented a task-oriented chatbot for helping students in their learning journey yielded promising results. The chatbot could maintain lengthy English conversations and engage in L2 problem-solving tasks with participants. Researchers noted that this type of speaking experience is hard to provide in regular EFL classes due to class size and time constraints within the curriculum. Similarly, an evaluation of a specifically designed EFL chatbot in [23] demonstrated the significant potential of its adaptation. The study found that the chatbot matched students' learning styles and enabled them to learn ubiquitously, thus making them enjoy their learning experience. Regardless, the study's pre-test and post-test settings revealed no significant improvement in students' Oral Proficiency Interview – Computer (OPIc) scores after the system adoption. The mixed findings in chatbot research indicate a need for further investigation.

### B. Readability Metrics for English Materials

Readability metrics are tools used to measure how easily readers can understand a written text. They are commonly used to evaluate the appropriateness of text materials by determining the complexity of the language used within the presenting material based on specific criteria. Flesch Reading Ease [24], Dale-Chall [25], and McAlpine EFLAW [26] are several commonly used readability metrics for English text materials. These metrics consider factors such as syllable counts, mini words counts, or a dictionary of difficult words to calculate a score that reflects the text's difficulty level.

Previous studies showed that these metrics could help assess the appropriateness of text materials for EFL learning [27], [28]. By utilizing these readability metrics, we can evaluate the language complexity of the chatbot's responses

and ensure they are appropriate for the target audience. For instance, if the chatbot generates too complex responses for low-level EFL learners, it may stunt their ability to comprehend and learn using the material. However, high-level EFL learners may find the material less challenging and unstimulating if the responses are simple enough. By assessing the readability of chatbot-generated material, researchers and developers can ensure that the language complexity is appropriate for the targeted EFL learner group, thus enhancing the learning experience.

For example, a study in [28] showed how Flesch-Kincaid readability metrics could be used to analyze the difficulty level of English textbooks for Chilean EFL high school students. The study illustrated how readability metrics could be used to recommend adjustments to English teaching materials according to students' level of comprehension. Another study by Gao et al. in [27] also showed the potentiality of several readability metrics as features to predict chatbots' popularity. The study found that very popular and unpopular chatbots have significant readability scores, thus indicating that readability metrics can be a valuable indicator to reflect users' interest in chatbot adoption.

This research will use three different readability metrics to assess the appropriateness of chatbot-generated material for EFL learning. This combination was chosen because each metric employs a different strategy to calculate the readability score. For instance, Flesch Reading Ease considers the syllable count when calculating the material's readability. Differently, Dale-Chall utilizes difficult words not commonly used in everyday language for calculating the difficulty. On the other hand, McAlpine EFLAW computes the readability score by using mini-words in a given text

1) *Flesch reading ease*: is a tool used to assess the readability of a given text in English. It works based on a formula proposed by Rudolf Flesch in [24]. The Flesch Reading Ease score is between 0 and 100, indicating how easy or difficult it is to understand a text. A higher score indicates that the text is easier to read, while a lower score indicates that the text is more challenging to read. The definition of the Flesch Reading Ease score is given in Formula 1,

$$206.835 - 1.015 \times \left(\frac{W}{S}\right) - 84.6 \times \left(\frac{s}{W}\right) \quad (1)$$

where  $s$ ,  $W$ , and  $S$  represent the number of syllables, words, and sentences in the given text, respectively. Then, the interpretation of the score is shown in Table I.

2) *Dale-Chall readability formula*: this is another readability formula first developed by Edgar Dale and Jeanne Chall in the 1940s adjusted further in 1995 [25]. The formula calculates a text's readability by considering its number of difficult words. The formula defines a difficult word as any word that is not in a list of common words familiar to most fourth-grade students. The formula generates a score that ranges from 0 to 10. A score of 0 indicates that the text is effortless to read, while a score of 10 indicates that the text is

challenging to read. The formula for calculating the raw score of the Dale-Chall readability score is given by Formula 2.

TABLE I. FLESCH READING EASE SCORE INTERPRETATION

Score	US School Level	Description
90.00-100.00	5 <sup>th</sup> grade	Very easy to read. Easily understood by average 11 years old students.
80.00-90.00	6 <sup>th</sup> grade	Easy to read. Conversational English for consumers.
70.00-80.00	7 <sup>th</sup> grade	Fairly easy to read.
60.00-70.00	8 <sup>th</sup> and 9 <sup>th</sup> grade	Plain English. Easily understood by 13 to 15 years old students.
50.00-60.00	10 <sup>th</sup> – 12 <sup>th</sup> grade	Fairly difficult to read.
30.00-50.00	College	Difficult to read.
10.00-30.00	College Graduate	Very difficult to read. Best understood by university graduates
0.00-10.00	Professional	Extremely difficult to read. Best understood by university graduates.

$$0.1579 \times \left(\frac{DW}{W} \times 100\right) - 0.0496 \times \left(\frac{W}{S}\right) \quad (2)$$

where  $W$ ,  $DW$ , and  $S$  represent the number of words, difficult words in the given text, respectively. The interpretation of the Dale-Chall readability score is given in Table II.

TABLE II. DALE-CHALL SCORE INTERPRETATION

Score (x)	Description
$x < 5.0$	Easily understood by an average 4 <sup>th</sup> grade student or lower.
$5.0 \leq x < 6.0$	Easily understood by an average 5 <sup>th</sup> or 6 <sup>th</sup> grade student.
$6.0 \leq x < 7.0$	Easily understood by an average 7 <sup>th</sup> or 8 <sup>th</sup> grade student.
$7.0 \leq x < 8.0$	Easily understood by an average 9 <sup>th</sup> or 10 <sup>th</sup> grade student.
$8.0 \leq x < 9.0$	Easily understood by an average 11 <sup>th</sup> or 12 <sup>th</sup> grade student.
$9.0 \leq x$	Easily understood by an average college student

The Dale-Chall readability formula was revised in 1995 to improve its accuracy and reliability. The revision included a new list of 3,000 familiar words compiled based on surveys of fourth-grade students. This new list replaced 769 words on the previous one, which had become outdated over time [25]. This research will use the new version of the Dale-Chall readability formula.

3) *McAlpine EFLAW readability formula*: is specifically developed to measure the readability of English language materials for non-native speakers of English. It regards mini words as a linguistic feature that can make English texts difficult for non-native speakers to read. Mini words are common words of one, two, or three letters. In the previous study [25], the researcher argued that a cluster of mini words in wordy cliches, colloquial expressions, and phrasal verbs confuse international readers. The McAlpine EFLAW readability score calculation is given by Formula 3.

$$EFLAW \text{ Score} = \frac{W+M}{S} \quad (3)$$

where W, M, and S represent the number of words, mini-words, and sentences in the given text. The interpretation from the McAlpine EFLAW score can be seen in Table III.

TABLE III. MCALPINE EFLAW SCORE INTERPRETATION

Score (x)	Description
$x \leq 20.49$	very easy to understand
$20.49 < x \leq 25.49$	quite easy to understand
$25.49 < x \leq 29.49$	a little difficult
$29.49 < x$	very confusing

### C. Generative Pre-training Transformers, InstructGPT, and ChatGPT

Generative Pre-trained Transformers (GPT) have emerged as a significant advancement in natural language processing (NLP) and have gained immense popularity in recent years [30], [35]. GPT, developed by OpenAI, is a deep learning model based on the Transformer architecture. It is designed to generate coherent and contextually relevant text given a prompt. The model employs a self-attention mechanism, allowing it to capture dependencies between words efficiently [30]. GPT achieved state-of-the-art performance on a wide range of language tasks due to its ability to learn from large amounts of text data. The original GPT model was trained on a dataset containing 40GB of text data from the internet [30]. As of today, OpenAI's ChatGPT is based on the GPT-3.5 model. While there is no publicly available information about the exact amount of data used for training GPT-3.5 specifically, it is worth noting that GPT-3, on which GPT-3.5 is built, was trained on a substantial corpus of text data. GPT-3's training dataset comprised approximately 570GB of text sourced from various types of content, including books, websites, and articles [31]. This extensive and diverse dataset facilitated GPT-3's ability to grasp language patterns and acquire a broad understanding of knowledge and context.

Like any other transformers-based large language model (LLM), GPT training divides into pre-training and fine-tuning stages [31]. A language model is trained on a large corpus of publicly available text data during pre-training. The model learns to predict the next word in a sentence, acquiring a broad understanding of grammar, context, and world knowledge. After pre-training, the model is fine-tuned on specific downstream tasks using supervised learning. The fine-tuning process involves training the model on a narrower dataset with labeled examples. This step allows the model to specialize in a specific task such as language translation, sentiment analysis, or question answering. There is no publicly detailed information available about how ChatGPT was trained. However, the documentation of ChatGPT mentioned that it was using a pre-trained by using a larger LLM than GPT-3 on a more significant amount of data. Then, the model was fine-tuned further to generate detailed responses based on given instructions or demonstrations (InstructGPT), using Reinforcement Learning from Human Feedback (RLHF) [32], [33].

RLHF is a technique used to improve the performance of language models through iterative fine-tuning using human-generated feedback [33]. RLHF involves collecting comparison data where different model responses are ranked

by quality. These rankings are used to create a reward model, which guides the model's training using reinforcement learning algorithms such as Proximal Policy Optimization (PPO) [34]. RLHF has been used to refine GPT models, enhancing their output quality and reducing biases—the series of human-in-the-loop iterations allowing the model to generate more coherent responses.

## III. RESEARCH METHODOLOGY

### A. Tools and Materials

As previously mentioned, this research evaluated the appropriateness of artificial intelligence (AI)-generated dialogue for EFL students using several readability criteria. The generated dialogues are intended as reference dialogue in the mobile application to help students practice their speaking skills. Students can choose a topic using the app and practice their English skills, as shown in Fig. 1.

Fig. 1. Voice-enabled chatbot mobile application.

The app provided a range of topics that students could use to practice their listening, reading, and speaking simultaneously. After selecting a topic, the app will load the reference dialogue on the selected topic. The app will always start the conversation using TTS technology by converting the first line into the reference dialogue. Then, to reply to the conversation, the student can choose one of three text options in the reference dialogue. Based on their choice, the app will engage them in a read-a-loud activity and evaluate their pronunciation using SR technology. By comparing the student's text choice and the SR transcription result, the app will re-render some text parts in red if they are not present in the transcription; otherwise, they will be in green. The conversation between a student and the bot will continue if there is still a line of dialogue in the reference dialogue. Fig. 2 depicts the interaction between the student and the app.

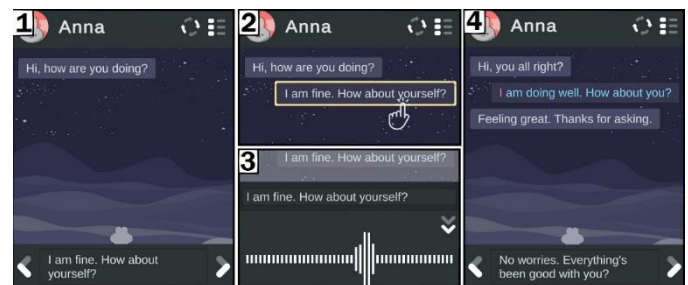

Fig. 2. Students' interactions with the application.

A successful learning outcome in a dialogue practice can only be achieved when students are willing to keep practicing the dialogue repeatedly. Students can learn more about what they are trying to understand with each repetition. Moreover, when stimuli are learned by repetition, they are remembered better and retained for a longer time. Dialogue variability is an essential factor affecting students' motivation to keep practicing. If the reference dialogues need to be more varied, students may feel bored having to practice using them repeatedly. The dialogue's difficulty level is another crucial factor affecting the learning process's success. Dialogues that are too difficult will undoubtedly lower the confidence level of the students and decrease their motivation to learn. Teachers generally spend much time and effort creating teaching materials that fulfill those two criteria.

Therefore, this research evaluates the possibility of using AI-generated materials as a reference dialogue within the app. The reference dialogues were generated by using OpenAI's ChatGPT. The dialogues were produced by inputting the following prompt to the bot: "Please help me to make a dialogue to help EFL students to practice their English. The dialogue is between A and B. A is an undergraduate student at ABC University. B is an exchange student from Italy. The topic is {{topic name}}", where {{topic name}} was selected from Table IV.

TABLE IV. LIST OF TOPICS GENERATED BY CHATGPT

Topic (1 <sup>st</sup> – 5 <sup>th</sup> )	Topic (6 <sup>th</sup> – 10 <sup>th</sup> )	Topic (11 <sup>th</sup> – 15 <sup>th</sup> )
Greet new exchange student	Fermented foods	Learn programming
Lunch Invitation	Sumo wrestling	Summer's vacation
Play arcade on weekends	Coin Laundry	Traveling to Kyoto
Foods and hobbies	Favorite snacks	Buying new clothes
Learn to use chopsticks	Sightseeing in Tokyo	Last week in Tokyo

In the prompt above, the lines "The dialogue is between A and B. A is an undergraduate student at Tokyo Denki University. B is an exchange student from Italy" are intended to give context to the AI so it could create a livelier dialogue related to students. Furthermore, a series of topics in Table IV means to test whether the ChatGPT can produce various topics for students to practice. On top of that, we asked ChatGPT to give two or three alternative lines of dialogue for each line in the produced dialogue. Later, in the experimentation, using a single dialogue from ChatGPT, 30 unique combinations will be generated. Therefore, 450 unique sample combinations of dialogues will be analyzed.

### B. Metrics and Measurements

Based on each ChatGPT-generated dialogue, an analysis process was first carried out using three readability metrics: Flesch Reading Ease, McAlpine EFLAW, and Dale-Chall readability metrics. The Flesch Reading Ease metric is intended to measure the difficulty level of a dialogue by considering the ratio of polysyllables in all words in the dialogue. The more polysyllables there are, the more complex the dialogue is assumed to be according to this metric. On the other hand, the McAlpine EFLAW metric is used to consider mini-words in dialogue. The more mini-words used, the metric assumes more complex it is. Lastly, the Dale-Chall metric

considers a list of difficult words compiled from previous studies.

The usage of these three metrics aims to cover the flaws of each metric with the other two metrics. Since the Flesch Reading Ease metric only considers the number of polysyllables in its calculation process, sentences with multiple mini-words will be considered easy to understand. Therefore, the McAlpine EFLAW readability score calculation process is carried out to complement the weakness of the metric. Then, the Dale-Chall metric is also used to determine the difficulty level of the text based on words that have few polysyllables but are challenging to understand, such as "abide," "deem," and "quail".

Based on the scores generated by each metric, a process of interpreting the difficulty level of the dialogue is carried out. The interpretation will be made by first visualizing the distribution of the difficulty level of the generated dialogue. From the visualization results, an analysis is carried out to determine the complexity of the ChatGPT-generated dialogues.

## IV. RESULTS

Based on 450 dialogue samples that aim to simulate conversations between the bot and the students in the application, the Flesch Reading Ease score for each sample was first calculated. Then, through the resulting scores, a visualization was carried out to show the scores' central tendency and distribution from all samples. Fig. 3 shows the distribution of scores from all samples.

Fig. 3. Flesch reading ease scores' distribution from all samples.

Fig. 3 shows that the sample dialogues have a score distribution ranging from 60 to 100, with most samples having scores in the range of 80-90. Hence, it can be concluded that most of the simulated dialogues are easily comprehensible to sixth-grade elementary school students. Additionally, since there is a small yet significant portion of samples with scores between 60 and 80, they can also serve as sufficient stimuli for junior high school students. However, the generated materials may not be suitable for senior high school students or students in higher education, as they could easily comprehend such materials, thus not providing an appropriate level of challenge for their learning. This interpretation can be further extended for EFL students by referring to the previous study [29]. Since most samples have scores between 80 and 90, students with a Common European Framework of Reference for Languages (CEFR) level of A2 (elementary level) will benefit the most

when using the materials. While the materials could still be suitable for students with CEFR levels A1 (beginner) and B1 (intermediate), students with levels B2 (upper intermediate) to C2 (advanced) may find the materials less challenging and too simple.

Next, the Dale-Chall readability scores were calculated for all sample dialogues. Fig. 4 illustrates the distribution of the resulting scores across all samples.

Fig. 4. Dale-Chall readability formula values' distribution for entire samples.

Similarly to the previous interpretation, based on the distribution of resulting scores shown in Fig. 4, it can be argued that the generated materials are most suitable for sixth-grade elementary school students or students in the early years of junior high school (CEFR A2 and B1). Moreover, the absence of samples with Dale-Chall scores above 8.0 confirms that the generated materials are unsuitable for students with CEFR levels B2 to C2. Finally, the McAlpine EFLAW score was calculated for each simulated conversation. The visualization of the score distribution can be observed in Fig. 5. Referring to the resulting scores in Fig. 5, as none of them have a score below 20, it can be interpreted that the resulting materials do not extensively utilize mini-words that could confuse EFL students when consuming them.

Fig. 5. McAlpine EFLAW scores' distribution for all samples.

## V. DISCUSSIONS

Based on the experimentation results, several conclusions can be drawn regarding the suitability of ChatGPT-generated materials as EFL chatbot reference dialogues. Firstly, the minimal McAlpine EFLAW score observed in all simulated conversations suggests that the dialogues generated by ChatGPT do not contain excessive use of mini-words. This indicates that wordy clichés, colloquial expressions, and

phrasal verbs, which could potentially confuse international readers, were avoided in the resulting dialogue [19]. The consistently low McAlpine EFLAW scores across all simulated dialogues indicate that EFL students can easily comprehend and understand the content. These findings provide confidence in the appropriateness of ChatGPT-generated materials as reference dialogues for EFL chatbot systems.

Additionally, the resulting Flesch Ease Reading scores indicate that most ChatGPT-generated materials are most suitable for students with CEFR levels A2 [20]. By referring further to the definition of CEFR level A2, the generated materials will be most appropriate to be used by students who exhibit the following characteristics.

- **Vocabulary:** Understand most everyday words and phrases related to personal information and basic needs; and many words and phrases related to hobbies, travel, and work.
- **Grammar:** Understand simple grammatical structures (e.g., present and past tenses) and basic question forms.
- **Reading:** Able to read short and simple texts, such as simple stories, with the help of a dictionary.
- **Writing:** Write basic sentences and short texts about personal experiences or daily routines.
- **Listening:** Understand simple and direct information in everyday conversations or short speeches on familiar topics.
- **Speaking:** Engage in basic conversations, and ask and answer questions about personal details, preferences, requests, or suggestions.

This interpretation was further supported by the resulting Dale-Chall scores obtained from the simulated dialogues. Although the Dale-Chall score calculation considers different criteria than the Flesch Reading Ease formula, a similar interpretation was reached.

## VI. CONCLUSION

In this research, we investigate the potential of ChatGPT to generate reference dialogues to help EFL students improve their English proficiency. The reference dialogues might be helpful for an EFL chatbot in mobile applications considering more limited computing resources available on mobile devices. The underlying justification stems from the fact that simulating a deterministic conversation flow involves significantly fewer computational resources than running a complex Question and Answer Generation model. However, as users may feel bored practicing using the same lines of dialogue repeatedly, each line might need alternative replies to make the conversation more varied. Therefore, based on a dialogue generated by ChatGPT, alternative replies are created by asking the model to rephrase each line within the dialogue.

Moreover, we conducted an analysis using multiple readability metrics to determine the optimal target audience for the ChatGPT-generated materials. Only a few mini-words in the generated materials suggest they are free from wordy

clichés, colloquial expressions, and phrasal verbs that could confuse EFL students. Furthermore, the resulting Flesch Ease Reading scores further affirm that the produced dialogues are most suitable for supporting students with CEFR A2. Likewise, the resulting Dale-Chall scores also support the same conclusion. The produced dialogues are well-suited for students with CEFR A2 proficiency, as they can comprehend most of the words used. Furthermore, a substantial portion of the dialogues intended for CEFR B1 can provide the CEFR A2 students with great stimulus to learn new words.

## VII. FUTURE WORK

In future work, it would be valuable to investigate the potential of ChatGPT in generating reference dialogues for different target audiences, particularly those with CEFR B2 proficiency or above. This would involve exploring the adaptability of ChatGPT's dialogue generation capabilities to cater to the specific language needs and complexities of higher-level English learners. By expanding the scope of the study to include higher proficiency levels, we can assess the effectiveness of ChatGPT-generated materials in supporting the language learning journey of a wider range of EFL students.

Additionally, it would be beneficial to explore and experiment with different prompting techniques to further enhance the variety and quality of the dialogue generated by ChatGPT. By utilizing innovative techniques, such as direct task specification, task demonstration or mimetic proxy, we can potentially influence the generated dialogues to align more closely with the desired characteristics and objectives for different target audiences.

# ConvNeXt-based Mango Leaf Disease Detection: Differentiating Pathogens and Pests for Improved Accuracy

Asha Rani K P, Gowrishankar S

Department of Computer Science & Engineering, Dr. Ambedkar Institute of Technology, Bengaluru -560056, Karnataka, India  
An Autonomous Institution Affiliated to Visvesvaraya Technological University (VTU), Belagavi-590018, India

**Abstract**—Mango farming is a key economic activity in several locations across the world. Mango trees are prone to various diseases caused by viruses and pests, which can substantially impair crops and have an effect on farmers' revenue. To stop the spread of these illnesses and to lessen the crop damage they cause, early diagnosis of these diseases is essential. Growing interest has been shown in employing deep learning models to create automated disease detection systems for crops because of recent developments in machine learning. This research article includes a study on the application of ConvNeXt models for the diagnosis of pathogen and pest caused illnesses in mango plants. The study intends to investigate the variety in how these illnesses emerge on mango leaves and assess the efficiency of ConvNeXt models in identifying and categorizing them. Images of healthy mango leaves as well as the leaves with a variety of illnesses brought on by pathogens and pests are included in the dataset used in the study. In the study, deep learning models were applied to classify mango pests and pathogens. The models achieved high accuracy on both datasets, with better performance on the pathogen dataset. Larger models consistently outperformed smaller ones, indicating their ability to learn complex features. The ConvNeXtXLarge model showed the highest accuracy: 98.79% for mango pests, 100% for mango pathogens, and 99.17% for the combined dataset. This work holds significance for mango disease detection, aiding in efficient management and potential economic benefits for farmers. However, the models' performance can be influenced by dataset quality, preprocessing techniques, and hyperparameter selection.

**Keywords**—Mango disease; pest; pathogens; machine learning; deep learning; convnext models

## I. INTRODUCTION

Mangoes, scientifically known as *Mangifera indica* L. (Family: Anacardiaceae), are tropical and subtropical fruits that are native to Indo-Burma. India boasts the largest variety of mangoes, with more than a thousand identified types [1]. India is a major mango-producing nation.

With 2.5 million hectares producing 18.0 million tonnes of mangoes per year, India takes the top spot and produces almost 50% of the world's mangoes. A significant barrier to mango cultivars producing their maximum production potential is insect infestations. Mangoes are reported to be infested by 400 distinct kinds of insect pests worldwide [2]. The pest complex and the structures of the pest community have undergone substantial change because of commercial mango agriculture, which is defined by the area expansion, altered cropping

patterns, varietal replacements and increasing chemical interventions. Moreover, climate change has unintentionally encouraged invading species or caused the creation of new pests. Formerly regarded as a minor or secondary pests, thrips, mealybugs, mites, leaf webbers, scales, stem borer, etc., have recently developed into a major concern. Mangoes are reported to be infested by 400 distinct kinds of insect pests worldwide [3].

The fruit mango is full of nutrients and has a distinct flavour, aroma and taste. With flavonoids like beta-carotene, alpha-carotene and beta-cryptoxanthin, it is a fantastic source of vitamin A. According to research findings, eating natural fruits that are high in carotenes can help prevent lung and mouth cancer. Mango fruit also contains a wealth of vitamins, minerals, fibre, prebiotic dietary substances and antioxidant components, all of which are good for human health. Consuming mango fruit guards against colon, breast leukaemia and prostate cancer, according to the recent studies [4].

One of the earliest illnesses associated with mango was powdery mildew, which is extensively present around the globe. One of the most dangerous diseases in the world is mango malformation sickness. The export market, which demands great fruit quality, is particularly concerned about mango bacterial canker, also known as bacterial black spot. Stem-end rot and mango dieback are two of the most significant diseases influencing mango yield and post-harvest losses internationally [5]. Mango wilt is a harmful disease that destroys plants.

Mango crops are commonly affected by various pests, including white scale and red wax scale, which consume the mango's leaves and fruit, causing damage and reduced quality. Other common pests include the mango leaf beetle, which can cause defoliation and the mango seed weevil, which infests the mango fruit and causes premature fruit drops [6]. Fruit flies, mealybugs, felt scales, long tailed mealybugs, shoot borers and stone weevils are also commonly found in mango crops and can cause various types of damage to the leaves and fruit. Mango shoot caterpillars, gall midges and stone bugs are also known to infest mango crops and cause stunted growth, reduced yield and fruit drop [7].

Image processing may identify plant diseases. The fruit, leaves and stems are frequently affected by disease signs. The ability to automatically detect plant disease from raw photos using Artificial Intelligence.

An efficient image-learning system for isolating plant diseases is the deep learning approach that uses neural networks. While neural networks learn how to obtain attributes to train, it can automatically extract properties from photos [8]. These methods rely on Deep Learning (DL) and conventional Machine Learning (ML) techniques.

Having a solid dataset to work with is essential for effective machine learning. The models are built or trained using the hidden patterns that these algorithms extract from the dataset and future occurrences are predicted using these learned patterns [9]. As a result, there is a strong relationship between a machine learning system's performance and the dataset's quality. Size, intra-class integrity, interclass dissimilarity and label quality, such as noise in the labels, are a few factors that may determine a dataset's quality [10].

## II. LITERATURE SURVEY

Shripad Veling et al. [11] utilized the MATLAB function "Imadjust" to enhance contrast in photographs of diseased mangoes. The improved contrast aided in the extraction of essential characteristics such as Energy, Correlation, Entropy, Cluster prominence, Homogeneity, Cluster shadow, Variance, and Dissimilarity. Their system achieved an accuracy of 90% with 92 tested samples, employing Support Vector Machines (SVM) as a classifier. The segmentation process took three seconds, while classification only required 0.1 seconds.

Faye, D et al. [12] evaluated the effectiveness of DL algorithms for predicting mango illnesses, highlighting shortcomings in their solutions. The identified issues included problems with leaf segmentation, a lack of real-time diagnosis, and insufficient training data. These challenges are crucial for researchers working on automatic detection of mango illnesses.

In their work, Kusriani et al. [13] augmented the pre-trained VGG-16 deep learning model with a fully connected network consisting of two additional layers. They took into account practical operational challenges faced by Indonesian farmers in gathering and analyzing visual data. By incorporating contrast and affine transforms, the supplemented data process achieved an overall accuracy of 76%. However, when classification was performed without augmentation on a combination of all three datasets, the accuracy dropped to 67%.

Md. Rasel Mia et al. [14] collected a training dataset comprising various photos of mango leaves with different illnesses. They developed a machine learning method using an SVM classifier that could automatically recognize symptoms of mango leaf diseases by uploading and matching fresh photos with the learned data. Their approach achieved an average detection and classification score of 80% for four different illness types.

The approach proposed by Ritika et al. [15], which utilizes a python-based webpage, offers considerable benefits to farmers in terms of pest control and pesticide application. Although SVM had low accuracy of approximately 43%, investigating the RGB values improved the results. By implementing XGBoost and CatBoost, a higher accuracy was achieved compared to SVM. Furthermore, their custom-built CNN system provided a respectable accuracy of 72.05%.

Sarder Iftekhar Ahmed et al. [16] obtained photographs from four mango orchards in Bangladesh, resulting in a collection of 4000 images representing seven illnesses found on approximately 1800 different leaves. To minimize sample bias, diverse locales in Bangladesh were selected. The images were meticulously labeled by human specialists, noise was removed, and the images were scaled to standard forms for machine learning analysis.

Arun Malik et al. [17] employed the transfer learning models VGG-16 and MobileNet for mango classification. They combined these models using the stacking ensemble learning approach to create a hybrid model. The authors constructed a dataset of 329 sunflower images obtained from Google Images, which were divided into five categories. The proposed hybrid model was compared to several contemporary deep learning models based on accuracy using the same dataset.

Inchara R et al. [18] have two objectives: first, to review the latest advancements in mango fruit evaluation prior to market delivery, and second, to explore untapped areas in post-harvest mango fruit handling. Their technology simplifies illness identification by automating the process and alerting users to any afflicted ailments. Aspects such as color, size, and shape influence the grade of the fruits and the satisfaction of the buyers.

Soleha Kousar et al. [19] present a unique technique that combines the Kuwahara filter for edge enhancement with histogram equalization to enhance image clarity and contrast. The Local Binary Pattern (LBP) feature extraction approach is used to recover significant features, enabling training of the Multi-layer Convolutionary Neural Network (MCNN) classifier. This method achieves an impressive 99% accuracy.

A standard, open-access collection of 4000 images of mango leaves with around 1800 distinct leaves is created by Sarder Iftekhar Ahmed et al., [20]. A categorical cross-entropy is used as the loss function in the CNN and ResNet50 models to handle the multi-class classification issue. The squared hinge loss is used in the CNN-SVM model.

## III. METHODOLOGY

### A. Dataset Description

1) *Mango pathogen dataset*: This dataset consists of 4000 JPEG images of mango leaves with a resolution of 240x320 pixels. Around 1800 images are unique, while the rest were generated by zooming and rotating the original images. The dataset includes a category for healthy leaves and seven categories of mango leaf diseases, including Anthracnose, Bacterial Canker, Cutting Weevil, Die Back, Gall Midge, Powdery Mildew, and Sooty Mould [21]. Every one of the eight categories has 500 photos, ensuring a fairly even distribution of examples. Using machine learning and computer vision techniques, this dataset may be used to distinguish between healthy and sick leaves (two-class prediction) and to detect various illnesses (multi-class prediction). Researchers and practitioners can use this dataset for crop disease detection and diagnosis, as well as for the development and evaluation of machine learning models for

automated identification and classification of mango diseases. Details of the classes of Mango Pathogen dataset is shown in Table I.

TABLE I. MANGO PATHOGEN DATASET DETAILS

<i>Mango Pathogen Dataset</i>		
Class Name	Image Details	
Anthracnose	500	
Bacterial Canker	500	
Cutting Weevil	500	
Die Back	500	
Gall Midge	500	
Healthy	500	
Powdery Mildew	500	
Sooty Mould	500	

2) *Mango pest dataset*: This dataset focuses on detecting pests that harm mango farming, which have a large economic impact on the country. It features photographs taken in mango farms where 15 types of pests, which result in structural and aesthetic defects in mango leaves, are present. The dataset comprises of 510 unique photos, encompassing the 15 pest categories plus the original mango leaf look, creating 16 classes [22]. The dataset was enhanced to increase its size and replicate the extensive data collecting method used by farmers. A total of 62,047 picture samples from the data augmentation procedure were employed to train the network. Annotations for both the original and enhanced picture samples are included in the dataset, which was divided into training, validation and testing sets. Using variable quantities

of pictures for training, validation and testing. Pictures in JPEG format are provided in every version of the dataset. Details of Mango Pest Dataset are shown in Table II.

Fig. 1. Proposed methodology.

### B. Procedure Used

The training process for a Transfer Learning model used for the mango leaf disease dataset involves feeding the model with labelled images and adjusting the weights to minimize the loss function. The accuracy of the model is evaluated using a separate set of labelled images during the testing process, while the validation process fine-tunes the model to prevent overfitting by testing it on a set of labelled images not used in training. A diagram illustrating the procedure is shown in the Fig. 1. The study involved two datasets, namely the pathogen and pest dataset of mango leaves. ConvNeXt models were trained separately for both datasets and also combined and trained.

### C. Transfer Learning Models Used ConvNeXt Models

ConvNeXt was developed as an extension of the transformer architecture, which was originally designed for natural language processing tasks [23]. The transformer architecture consists of a series of encoder and decoder layers, which learn to encode and decode sequential data.

ConvNeXt extends the transformer architecture to image recognition tasks by incorporating convolutional layers into the encoder and decoder layers. This allows ConvNeXt to learn spatially localized features of an image, while also leveraging the attention mechanism of the transformer.

In contrast to traditional convolutional neural networks, which typically comprise of a series of convolutional layers followed by fully connected layers, ConvNeXt uses a parallel convolutional structure that allows for increased model capacity and improved performance on image recognition tasks [24].

In Table III and Table IV parameters [25] used are

1) *Number of Layers*: The number of layers refers to the depth of a neural network, where each layer performs a set of computations on the input data before passing it to the next layer.

2) *Number of Parameters*: The number of parameters refers to the total number of learnable parameters in a neural network, which includes weights and biases.

3) *Architecture*: The architecture refers to the design and organization of a neural network, including the number of layers, the size of each layer and the connections between them.

4) *Batch normalization*: Batch normalization is a technique used to normalize the input data to each layer of a neural network, improving the overall stability and convergence of the model.

5) *Dropout*: Dropout is a regularization technique used to prevent overfitting in neural networks by randomly dropping out some of the neurons during training.

6) *Top-1 Accuracy*: Top-1 accuracy is a metric used to evaluate the performance of a neural network on a classification task, measuring the percentage of predictions that match the correct label.

7) *Top-5 Accuracy*: Top-5 accuracy is similar to top-1 accuracy, but measures the percentage of predictions that include the correct label within the top 5 predictions.

8) *Computational Complexity*: Computational complexity refers to the amount of time and resources required to perform computations in a neural network.

9) *FLOPs*: FLOPs (FLoating-point Operations Per second) is a measure of the number of floating-point arithmetic operations a neural network can perform per second[26].

10) *Activation Function*: The activation function is a mathematical function used to introduce non-linearity into the output of a neural network layer [27].

11) *Regularization*: Regularization refers to techniques used to prevent overfitting in neural networks, such as dropout and weight decay [28].

12) *Residual connections*: Residual connections are connections between layers that bypass intermediate layers,

allowing the input to flow directly to the output and improving the flow of gradients during training [29].

13) *Image augmentation*: Image augmentation is a technique used to increase the amount of training data by randomly transforming images, such as rotating, scaling or flipping.

ConvNeXts have several advantages over traditional transformers for image recognition tasks [30]. They are

1) *Spatial information*: Transformers were originally designed for sequence tasks such as natural language processing where spatial information is not as important as the order of the tokens. However, for image recognition tasks, the spatial information of the pixels is crucial. ConvNeXts include convolutional layers that can capture spatial information, enabling the model to learn local features in the image.

2) *Parameter efficiency*: Transformers have a high number of parameters due to the large attention matrices, which can limit their scalability. ConvNeXts use a parallel convolutional structure which allows for increased model capacity without a large increase in parameters, making them more efficient in terms of memory and computation.

3) *Robustness to object scale*: ConvNeXts are better able to handle object scales than transformers. In transformer-based models, the receptive field of the model is fixed and cannot change. In contrast, ConvNeXts use convolutional layers which have a varying receptive field size, enabling them to capture features at different scales.

4) *Improved accuracy*: ConvNeXts have achieved state-of-the-art performance on several benchmark image recognition datasets, including ImageNet and CIFAR-10. They have shown improved accuracy compared to traditional convolutional neural networks and transformer-based models.

Overall, the incorporation of convolutional layers in ConvNeXts provides a more efficient and effective approach to leveraging the power of transformers for image recognition tasks [31].

TABLE V. MANGO PEST DATASET IMPLEMENTATION RESULTS FOR CONVNEXT MODELS

Mango Pest Dataset			
Model	Training Accuracy	Validation Accuracy	Testing Accuracy
ConvNeXtTiny	100 %	100 %	90.90 %
ConvNeXtSmall	100 %	100 %	92.65 %

TABLE VII. COMBINATION OF BOTH MANGO PEST AND MANGO PATHOGEN DATASET IMPLEMENTATION RESULTS FOR CONVNEXT MODELS

Combination of Both Mango Pest and Mango Pathogen Dataset			
Model	Training Accuracy	Validation Accuracy	Testing Accuracy
ConvNeXtTiny	100 %	97.237%	97.23%
ConvNeXtSmall	99.53%	97.237 %	96.97 %
ConvNeXtBase	99.60 %	98.816 %	98.02 %
ConvNeXtLarge	100 %	98.947 %	98.01%
ConvNeXtXLarge	100 %	100 %	99.16%

#### IV. IMPLEMENTATION RESULT

The Table V provides the training accuracy, validation accuracy and testing accuracy for five different models (ConvNeXtTiny, ConvNeXtSmall, ConvNeXtBase, ConvNeXtLarge and ConvNeXtXLarge) trained on a Mango Pest Dataset.

The accuracy of the model over the training set throughout the training process is referred to as training accuracy. The accuracy of the model on a different validation set is referred to as validation accuracy, and this accuracy is used to assess the performance of the model during training and adjust its hyperparameters. The accuracy of the model under test is its performance on a brand-new test set that it has never seen or used before.

All five models had 100% accuracy on the training set, demonstrating that they had flawless memorization of the training data. Achieving 100% training accuracy, however, is not necessarily a desirable thing because it may signify overfitting, in which the model matches the training data too well and may not generalise well to new data.

The validation accuracies of the models vary, with the larger models generally achieving higher accuracy than the

smaller ones. However, the difference in validation accuracy between the models is relatively small, which suggests that the models are not overfitting to the training data.

Overall, the ConvNeXtXLarge model achieved the highest testing accuracy of 98.786747%, indicating that it is the best performing model on this Mango Pest Dataset.

The Table VI provides the training accuracy, validation accuracy, and testing accuracy for five different models (ConvNeXtTiny, ConvNeXtSmall, ConvNeXtBase, ConvNeXtLarge, and ConvNeXtXLarge) trained on a Mango Pathogen dataset.

The testing accuracies of the models are high, with all five models achieving above 99% accuracy. The ConvNeXtXLarge model achieved the highest testing accuracy of 100%, showing that it is the best performing model on this Mango Pathogen dataset. However, the difference in testing accuracy between the models is relatively small, which suggests that they are all performing well on this task. Overall, the results suggest that all five models are effective at identifying pathogenic infections in mangoes, with larger models performing slightly better than smaller ones.

Comparing the Table III and Table IV, it is seen that the performance of the ConvNeXt models on the Mango Pathogen dataset is better than on the Mango Pest dataset. All models achieved 100% training accuracy on both datasets, indicating that they could fit the training data perfectly. However, the testing accuracy of the models on the Mango Pathogen dataset is higher than on the Mango Pest dataset, suggesting that the models are better able to generalize to unseen data in the pathogen classification task.

The architecture of the ConvNeXt models may have contributed to their performance on these datasets. In both tables, the models have increasing accuracy as the model size increases, with the largest model, ConvNeXtXLarge, achieving the highest accuracy on both datasets. This suggests that increasing the model size and complexity can improve the model's ability to learn and classify patterns in the data.

The ConvNeXt models combine convolution layer, pooling layers, & fully linked layers in terms of their technical features. These models use the concept of grouped convolutions to capture both local and global dependencies in an image. The key idea behind ConvNeXt models is to create a network architecture that balances computational efficiency and modeling capacity. By using grouped convolutions, the number of parameters and computations required in each convolutional layer is reduced compared to fully connected convolutions. This enables deeper models with a large receptive field without significantly increasing the computational cost. The number of filters, the size of the filters, the number of groups, as well as the number of layers are some of the hyperparameters for the models. The algorithms' performance on the datasets may have also been influenced by the selection of hyperparameters. The selection of these hyperparameters can significantly affect the performance of ConvNeXt models based on different datasets.

In Table V to VI, the implementation results of ConvNeXT models for mango pest and mango pathogen datasets are

presented separately. In contrast, Table VII shows the implementation results of ConvNeXT models for a combination of both mango pest and mango pathogen datasets.

The results of Table V shows that all models performed well on the mango pest dataset, with the ConvNeXtXLarge model achieving the highest testing accuracy of 98.79%. The results of Table VI demonstrate that all models also performed well on the mango pathogen dataset, with the ConvNeXtXLarge model achieving perfect testing accuracy of 100%.

In Table VII, which shows the results for a combination of both mango pest and mango pathogen datasets, the testing accuracy of all models decreased compared to their performance in Table V and VI. This decrease in accuracy is likely due to the increased complexity of the combined dataset. However, the ConvNeXtXLarge model still achieved the highest testing accuracy of 99.17%, indicating its effectiveness in handling the combined dataset.

Overall, the results of Table VII suggests that using a combination of both mango pest and mango pathogen datasets can provide more comprehensive information about the health of mango leaves. While the accuracy of the models decreased slightly when using the combined dataset, the ConvNeXT models were still effective in detecting both pests and pathogens on mango leaves.

Table VIII shows Accuracy V/s Epoch and Loss V/s Epoch Graph for various ConvNeXt Models.

The effectiveness of the ConvNeXtTiny model upon the Mango Pathogen dataset is as shown in the confusion matrix in Fig. 2. The columns of the confusion matrix represent the anticipated labels, while the rows represent the genuine labels. Each cell of the matrix represents the count of cases where the predicted class (column) aligns with the actual class (row).

TABLE VIII. ACCURACY V/S EPOCH AND LOSS V/S EPOCH GRAPH FOR VARIOUS CONVNEXT MODELS

The accuracy steadily increases with each epoch until the fourth epoch, where it reaches its highest value of 0.9979. After that, the accuracy remains consistently high at 1.0 from the fifth epoch onwards. This indicates that the model quickly learns from the training data and achieves near-perfect accuracy in classifying the images.

The loss starts at 0.3075 in the first epoch and decreases significantly in the subsequent epochs. It reaches its lowest value of 1.2019e-05 in the eighth epoch. The decreasing loss indicates that the model is effectively minimizing errors and improving its predictive capabilities.

The accuracy steadily increases with each epoch until the seventh epoch, where it reaches its highest value of 0.9986. However, in the last epoch, the accuracy drops slightly to 0.9987. Overall, the model achieves high accuracy throughout the training process, indicating its ability to correctly classify images.

The loss starts at 0.3656 in the first epoch and decreases significantly in the subsequent epochs. It reaches its lowest value of 0.0017 in the seventh epoch. However, in the last epoch, the loss increases slightly to 0.0049. The decreasing loss indicates that the model is effectively minimizing errors and improving its predictive capabilities.

The accuracy steadily increases with each epoch, reaching a high value of 1.0 (100%) for the training dataset. On the validation dataset, the accuracy also shows a steady improvement, reaching a peak value of 0.99875 (99.875%) before the model stopped training due to early stopping.

The loss decreases significantly in the initial epochs, indicating that the model is learning and improving its predictions. After reaching a minimum value of 6.7500e-07, the loss plateaus and remains constant until the end of training.

Fig. 2. ConvNeXtTiny confusion matrix for mango pathogen dataset.

Looking at the matrix, we can see that the model performed very well, with perfect accuracy in most of the classes (classes 0 to 5 and class 7). The only class where the model made mistakes is class 6 (Powdery Mildew), where it misclassified 1 instance as class 7 (Sooty Mould). The confusion matrix indicates that the ConvNeXtTiny model achieved high accuracy on the Mango Pathogen dataset, with only a single misclassification out of 800 instances.

### V. CONCLUSION

It can be concluded that all the models have performed well on both the mango pest and pathogen datasets. However, the accuracy of the models on the mango pathogen dataset is higher compared to the mango pest dataset. This is because the pathogen dataset contains images that are more distinct and easier to classify compared to the pest dataset.

In terms of the model architecture, it is seen that larger models, i.e., ConvNeXtBase, ConvNeXtLarge, and

ConvNeXtXLarge, have consistently higher accuracy than the smaller models, i.e., ConvNeXtTiny and ConvNeXtSmall. This suggests that the larger models have more capacity to learn complex features and patterns in the images, which results in better accuracy.

ConvNeXtXLarge Model giving its highest accuracy of 98.786747% for Mango Pest Dataset, 100% for Mango Pathogen Dataset and 99.16654% for Combination of Both Mango Pest and Mango Pathogen Dataset is the best model for Mango Disease Detection.

ConvNeXtTiny Model giving its accuracy of 90.908746% for Mango Pest Dataset, ConvNeXtSmall Model giving 96.97368% for Combination of Both Mango Pest and Mango Pathogen Dataset can be considered as Baseline models for Mango Disease Detection.

The models consistently improve their accuracy with each epoch, reaching near-perfect or perfect accuracy in classifying the mango pests and pathogens. The decreasing loss throughout the epochs demonstrates the models' ability to effectively minimize errors and improve their predictive capabilities.

This work is important in Mango Disease detection using transfer learning and ConvNeXT. The results show the potential of using deep learning models to accurately classify mango diseases, which can lead to more efficient and effective management of mango plantations. This can ultimately help farmers reduce crop losses and increase yields, leading to economic benefits for the agriculture industry.

Overall, the results show that deep learning models can be effective in classifying images of mango pests and pathogens with high accuracy, and larger models tend to outperform the smaller ones. However, it is important to note that the models' performance may depend on factors such as the quality of the dataset, pre-processing techniques and the choice of hyper parameters.

**Abstract**—Blockchain-based access control mechanisms have garnered significant attention in recent years due to their potential to address the security and privacy challenges in the Internet of Things (IoT) ecosystem. IoT devices generate massive amounts of data that are often transmitted to cloud-based servers for processing and storage. However, these devices are vulnerable to attacks and unauthorized access, which can lead to data breaches and privacy violations. Blockchain-based access control mechanisms can provide a secure and decentralized solution to these issues. This paper presents an improved Attribute-based Access Control (ABAC) approach with enhanced flexibility, which utilizes decentralized identity management on the Substrate Framework, codifies access control policies by Rust programming language, and executes access control policies on-chain. The proposed design ensures trust and security while enhancing flexibility compared to existing works. In addition, we implement a PoC to demonstrate the feasibility and investigate its effectiveness.

**Keywords**—Attribute-based Access Control (ABAC); Internet of Things (IoT); blockchain; substrate framework

## I. INTRODUCTION

Access control is a security approach that governs who or what has access to and uses resources in a computing environment. The primary objective of access control is to reduce the hazards of unauthenticated system access while protecting personal information. Therefore, most computing applications require access control services to control and prohibit unauthorized access to system resources such as networks, devices, files, or sensitive data. Meanwhile, the number of connected IoT devices is rapidly increasing due to the maturation of connecting protocols for IoT (e.g., BLE, LoRa, NB-IoT, LTE, 5G, and 6G). In addition, the growth of Big Data and Artificial Intelligence also motivates data collection from the physical environment by adopting IoT infrastructures. However, this means that security in IoT becomes more critical because IoT systems can yield a lot of sensitive data [1][2][3][4]. For example, a faulty firmware of a camera vendor caused millions of camera devices of clients to be exposed publicly to the Internet, and malicious parties can exploit resources legitimately. Therefore, access control employment is an essential solution to improve the security of IoT systems.

Most conventional access controls for IoT are based on a centralized architecture with many limitations, such as single-point-of-failure, trusted third-party requirements, and low scalability [5][6][7]. Meanwhile, the maturity of Blockchain drives

towards applying to numerous areas beyond cryptocurrencies to solve concerns of trust and security, such as digital certificate [8], smart factory [9], smart parking [10], healthcare [11], and traceability [12]. Additionally, there have been various research studies on the amalgamation of Blockchain to solve problems in existing IoT systems regarding scalability, interaction, security, privacy, and trust [13][14][15][16][17]. However, many aspects must be considered when applying Blockchain to conventional access control methods for IoT systems [18][19]. Due to heterogeneity and scenario variety in IoT, coarse-grained access control schemes, such as Discretionary Access Control (DAC), Mandatory Access Control (MAC), and Role-based Access Control (RBAC), become cumbersome in administration. Nevertheless, fine-grained access control schemes, such as Attribute-based Access Control (ABAC), not only provide flexible administration but also guarantee security [20].

In the ABAC scheme, access control is evaluated by attributes (e.g., subject, object, and environmental attributes) and instructed by codifiable policies. Those features produce ABAC's advantages but make it challenging to design, especially on Blockchain platforms. An ABAC design should consider two main parts: attribute management and policy execution. Besides the scheme aspect, identity management is also crucial in access control. Thanks to the decentralized identity (DID) standard, participants own DIDs associated with their human-readable information on Blockchain, which can be resolved to DID Document (DDO). This standard also facilitates authentication (DID Auth), which is generally necessary before authorization or access validation. Nowadays, existing Blockchain-based ABAC solutions for IoT still have several limitations. They do not ensure both security and flexibility. Moreover, several solutions based on ancient Blockchain platforms, such as Bitcoin and Ethereum, need to be improved in terms of scalability for massive IoT systems.

In this paper, we propose an improved ABAC-based approach developed on the Substrate Blockchain Framework, which ensures trust and security while enhancing flexibility compared to existing ABAC-based works. The main contributions of this paper can be summarized as follows:

- Propose an alternative design of a blockchain-based access control approach that includes improved features compared to similar works.
- Present the implementation of a proof-of-concept in detail to demonstrate the feasibility and evaluate the

effectiveness of the proposed design.

The rest of this paper is organized as follows. Section II summarizes related works to clarify the scope of our study. Then, Section III describes our proposed system. The implementation and evaluation are presented in Section IV. Finally, Section V provides concluding remarks and future works.

## II. RELATED WORKS

### A. Conventional Access Control Approaches

Discretionary Access Control (DAC) [21] is an identity-based access control model that gives users specific permissions to control their resources and data. Data owners can set access permissions for another user or group of users. These permissions are usually stored in an access control list. DAC is a simple and highly granular design because it allows users to freely configure access parameters on each data sample. However, it becomes a disadvantage and makes it for administrators more challenging to operate and maintain a more extensive system with a variety of users, data, and access configurations.

Mandatory Access Control (MAC) is a hierarchical model determined by the security level. In this model, each user is granted a security level, and each object is assigned a security label. A user can only access the according resource with a security label equal to or lower than that user's security level. In addition, this access control model also gives administrators complete control over access while users cannot configure their permissions. Therefore, the MAC model has a very high security. However, MAC-based systems can become quite unmanageable since administrators must configure permissions to all users and objects, leading to being overwhelmed if the system grows too fast.

Role-based Access Control (RBAC) [22] is a model based on user roles and responsibilities. Instead of granting access to users, RBAC gives access to roles that are then used to grant users the rights to access the system resources according to granted roles. RBAC has several variants, including flat RBAC, hierarchical RBAC, and constrained RBAC. The RBAC is suitable for small and medium systems because its static property is unsuitable for systems that grant access according to dynamic parameters.

Attribute-based Access Control (ABAC) [23] provides fine-grained and contextual access control capabilities based on attributes of users, system resources, and environment. The ABAC scheme allows administrators to define access control policies without prior knowledge of specific access objects. In addition, it can provide dynamic access control because it allows the use of environmental attributes, such as time, location, or IP address. Access decisions can be changed between access requests as attributes change. However, the ABAC scheme has low visibility (i.e., it is difficult to determine the privileges of a particular user) because it works based on attributes from many different sources. This also makes it challenging to identify security risks in the whole system.

Capability-based Access Control (CapBAC) [24] is an access control model based on the capability that is a token holding the privileges granted to users. When a user wants to

perform any actions on system resources, he has to send a request with his token to the service provider to check the validity of the token before deciding to allow or deny the request without verifying the requester's privileges because the token was published by a trusted server. This procedure makes the system not needing to maintain the users' list or the access policies list at the access points. However, issuing tokens by authentication servers and validating tokens at service providers might consume time in case of token withdrawal.

Access control models can be selected and deployed according to specific applications and conditions. Historically, centralized systems were often chosen to implement access control systems or through a third-party service provider. However, centralized systems are often limited regarding system scalability and the problem of single-point-of-failure, i.e., the risk at the centralized entity. In the meantime, allowing third parties to manage important security information, such as access control, can lead to information leakage risks and loss of user privacy. In addition, the system administrator has full control over the system, including manipulation of system usage history, which reduces the reliability and transparency of the entire access control system. However, Blockchain can tackle these limitations with prominent characteristics such as immutability, stability, audibility, and reliability.

### B. Blockchain-based Access Control Approaches

Applying Blockchain technology to access control management for IoT systems is a direction with many potential benefits. In [25], the authors proposed an access control solution by adopting smart contracts to define access control contracts (ACC). Each pair of a subject and an object in the system has one ACC that stores the subject's permissions with the object resources. This also means the number of ACCs will increase exponentially as the IoT system expands. Some other works [26][27] proposed blockchain-based authentication and authorization mechanisms for IoT with multiple domains and parties as access control solutions. Meanwhile, in [28], the authors proposed a capability-based access control on Blockchain, which applies the Decentralized Identifier standard to identify the parties involved in the system, including resource owners, resource access requests, and devices. However, this method does not have flexibility in access administration because it is a coarse-grained access control scheme that usually becomes cumbersome in access control management with large IoT systems, especially with many changes.

As mentioned above, fine-grained access control schemes are suitable for IoTs but more complex when developing on Blockchain. The six following works are the most closely related to ours. In [29], the authors proposed a fine-grained access control framework based on Hyperledger Fabric, called Fabric-IoT. Attribute fields for users, devices, and policies are pre-defined, and administrators specify their values. Meanwhile, values of environment attributes are dynamically detected at the request processing time. In this work, a policy definition is limited to only being set values of the pre-defined attribute fields. In addition, policy execution for the relationship between attributes and access decisions is hard-coded in a smart contract. A similar design was presented by Song et al. in [30], but user and device attribute fields in this

work do not need to be pre-defined. These two Blockchain-based approaches are generally simplified from the original ABAC scheme, making them less dynamic and flexible.

In [31], attributes and policies are stored on a Hyperledger Fabric blockchain and an InterPlanetary File System. A policy execution is performed at distributed nodes in a network, called off-chain execution, and its final result is reduced with the Practical Byzantine Fault Tolerance (PBFT) algorithm. This approach does not take advantage of Blockchain for policy execution. Meanwhile, Maesa et al. [32] proposed a manner to transpile ABAC policies with XACML language to smart contracts with Solidity language, which can be executed on EVM-integrated Blockchain. Similarly, in [33], the authors proposed a scheme to interpret ABAC policies with XAMCL language to Blockchain transactions in JSON and scripting-logic expression. Those can be executed as Bitcoin scripts with several extended commands dedicated to collecting attribute information in the ABAC scheme.

Besides policy execution, attribute management is crucial in ensuring the ABAC scheme's security. These above-mentioned works took attributes of subjects and objects provided by third parties or managed by an administrator. However, in [34], the authors proposed a model for endorsing subject attributes on Blockchain. An entity, so-called a trusted entity, can issue or revoke endorsements for other entities' attributes. An attribute's trust is a value accumulated from the trust levels of the entities endorsing it. Trust levels of entities are maintained by a reputation system deployed on Blockchain. Because of focusing on attribute endorsement, this work did not take policy execution in the scope of its study.

To the best of the authors' knowledge, existing ABAC designs for IoTs on Blockchain have yet to ensure trust, security, and flexibility simultaneously. Therefore, this paper proposes an improved ABAC design for IoTs, which utilizes decentralized identity management on Blockchain, applies attribute endorsement to ensure attribute trust and security, and leverage smart contract to codify policy for enhancing flexibility. We define four criteria to highlight the improvement of the proposed design in terms of flexibility compared to six related methods, as shown in Table I.

- C1: Attributes are modifiable.
- C2: Policies are codifiable.
- C3: Policies are executed on-chain.
- C4: Attribute values are endorsed.

TABLE I. COMPARISON OF RELATED WORKS AND OURS

Criteria	[29]	[30]	[31]	[32]	[33]	[34]	Ours
C1	No	N/A	Yes	N/A	Yes	Yes	Yes
C2	No	No	Yes	Yes	Yes	N/A	Yes
C3	No	Yes	Yes	Yes	Yes	No	Yes
C4	No	No	Yes	No	No	Yes	Yes

### III. THE PROPOSED APPROACH

IoT infrastructures typically consist of numerous devices deployed distributedly in the physical world. These devices can be categorized into end-devices, gateway, and IoT devices. As the largest and most distributed part among others, end-devices should be optimized in cost and energy consumption, letting them be neglected with battery power for a long time. In addition, end-devices are usually constrained in computing and storing capability, so they can not efficiently perform heavy cryptographic techniques to consolidate security. Moreover, low-power networks (LPWN) of wireless end-devices also have low bandwidth. Therefore, security methods will be mainly deployed on gateways since they employ electric grid power, high bandwidth internet connection, and more powerful computing and storage capacity. Besides, IoT devices, such as surveillance cameras, robots, or smartwatches, which have more powerful hardware configurations, are also considered to accommodate self-serving cryptographic security techniques. In the proposed design, we choose gateways as end-points for access control service, restricting requests from outside to inside resources for empowering security and privacy.

As the core of the proposed design, critical data and execution of access control are carried out on Blockchain to empower security and trust. We develop the proposed method on Substrate Framework and customize the Blockchain system for the access control services with three major obligations. First, Blockchain is an underlying infrastructure for a decentralized identifying system, facilitating authentication. Second, it provides methods for participants to manage their access control attributes on Blockchain. Third, it provides a distributed computing environment to manage and execute access control policies.

The proposed access control system comprises users with different roles and permissions, who can be divided into three types: regular users, trusted users, and administrators. The regular users include requesters who request access to resources and owners who own shared resources. The trusted users can endorse attributes of regular users, specifically requesters or subjects. The administrators are a minority in the system and are responsible for governing access to IoT resources through policies. With a large or global IoT system, there can be many multiple domains in which several administrators can manage each domain. This access control system is not tied to a specific IoT domain; in other words, it also supports multiple IoT domains. Furthermore, owners are considered to have sovereignty over their own IoT devices, which they may control locally and physically.

#### A. Security Assumptions

A security system is usually designed and built based on specific assumptions. Our proposed system will be developed based on four security assumptions (SA).

- SA1: Regarding physical devices such as IoT devices and gateways, they are assumed to operate reliably to protect themselves. It is noted that a device cannot be secured with only software solutions if a device is physically attacked and manipulated. However, a malicious device will not harm other trusted devices.

- SA2: The connection from IoT devices to the Blockchain system is also considered secure, allowing transactions from devices to reach the Blockchain or events returned from the Blockchain to propagate smoothly.
- SA3: Like other Blockchain systems, participants are responsible for the confidentiality of their Blockchain accounts and other private keys associated with their decentralized identity. In addition, users with special roles, such as administrators, are assumed to be trusted in their authority.
- SA4: Actual deployment conditions might influence Blockchain network topology and the selection of consensus algorithms. However, a Blockchain system must be distributed, immutable, and transparent as inherent characteristics.

Among these four assumptions above, except for the last one (SA4), when other assumptions are violated, it just locally affects; for example, a compromised IoT device or a disclosed Blockchain account, the security problems will be only affected locally.

### B. System Design

An access control system should have flexibility to be easily adopted for numerous scenarios. The flexibility also makes access management more convenient for administrators, particularly in granting or revoking permissions. Hence, we chose the ABAC scheme that a fine-grained access control scheme. In addition, to consider the flexibility of an access control system, we scope our study in two following use-cases.

- In smart agriculture, combining low-power wireless sensor networks with automatic control systems facilitates agriculture precision. Commonly, an agricultural product has to go through many stages before reaching its consumer, such as planting, harvesting, processing, transporting, and retailing, hence the need for traceability. Blockchain technology allows parties from those stages to participate in a system to share data in trust. Each farm or each factory can have numerous IoT devices, employees, several managers, and one possessor. To control access to IoT devices, a possessor can delegate to managers; in turn, they will manage access permissions for employees through ABAC policies. In this use case, managers could endorse employees' attributes or delegate to their assistants as trusted endorsers. Environment attributes like DateTime can grant temporary permissions for seasonal employees. Third parties, such as business partners and inspection centers, may also be granted appropriate permissions to access to monitor activity.
- Another use-case is to manage access controls for an IoT camera system on a campus. These cameras can be rented to students who want to conduct related experiments such as video streaming. A CapBAC-based Blockchain approach has been proposed in [28]. Owners control tenant access by issuing or revoking capability tokens, and each token issuing requires the participation of both the owner and the tenant. When

the system scales up, managing issued and revoked tokens becomes cumbersome and inflexible. Meanwhile, the ABAC design can provide more efficient access management for that case. Surveillance cameras can be divided into groups for easy management by defining attributes in a large system. Owners can grant permissions to tenants by endorsing their corresponding attributes. Note that a pre-defined policy just links the camera group to the tenant group. Besides that, environment attributes can help rent out based on time conveniently.

Fig. 1 depicts the system architecture of the proposed method on Substrate Framework that supports DID management and smart contracts via DID and Contract Pallets, respectively. In addition, we design the ABAC scheme as an **ABAC Pallet** and integrate it into the Substrate Framework. A typical Substrate's Pallet has two main parts: **storage declaration** and external methods (so-called **extrinsic definition**). Extrinsic calls only accomplish each update to pallet storage, and the change is also attached to Blockchain. As the core of the proposed design, the ABAC Pallet has three storage declarations for ABAC Attributes, Endorsements, and Policy Attachments, described as follows.

- The first one is to store attributes (**Attribute Storage**) of subjects and objects according to their decentralized identities. Each ABAC attribute is in the form of key-value pair. With self-sovereign design thinking, an owner of a decentralized identity also owns associated ABAC attributes on Blockchain.
- The second one is to store endorsements (**Endorsement Storage**), which trusted endorsers confirmed for reviewed attributes of subjects. The endorsements make trusty for the current values of the subject's attributes. The endorsers can specify a validity period for their endorsements.
- The third one is storing objects' attachments with ABAC policies (**Policy Storage**), which is in the form of a one-to-many relationship. In the proposed design, an ABAC policy is a deployed smart contract with a unique address on the blockchain system. For those policies to be valid to an object, attachments need to be committed by the corresponding owner or administrators. Each attachment also holds a reminiscent name and logs its author.

Based on the storage declarations above, necessary extrinsic are designed to control ABAC attributes, attribute endorsements, and policy attachments from outside Blockchain. To ensure the caller has authority with corresponding data on Blockchain, these extrinsic all require a decentralized identifier owned by the caller as the first parameter. Other parameters in a specific extrinsic are selected to fit multiple demands.

- There are two extrinsic for users to control attributes associated with their DIDs, including **setAttributes()** and **clearAttributes()**. Extrinsic **setAttributes()** allows users to create and modify one or more attributes on Blockchain. If an attribute with its key does not exist, a creation will occur, and vice versa, and an attribute-value update will be activated. Note that once the

Fig. 1. System architecture.

value of an attribute is modified, all of its previous endorsements will no longer be valid, and then it will be deleted. Otherwise, extrinsic clearAttributes() is to delete the existing attributes of a decentralized identifier by specifying the corresponding attribute names.

- There are two extrinsic for trusted users to control endorsements of subject attributes, including **endorseAttributes()** and **unendorseAttributes()**. Endorsers can use endorseAttributes() to endorse multiple existing attributes of a subject with a specific validity duration. In the Substrate Framework, the value of that validity duration can be represented by a multiplier of the block finalization interval (e.g., 6 seconds by default). Otherwise, unendorseAttributes() allow endorsers to proactively delete their endorsements before expiring.
- There are two extrinsic for owners or administrators to manage policies of corresponding objects, including **attachPolicy()** and **detachPolicy()**. As mentioned above, a policy exists on Blockchain as a smart contract with a unique Blockchain address. Extrinsic attachPolicy() allows owners or administrators to connect an object and a policy. Furthermore, a reminiscent name for the attachment is also enabled, and the caller's DID is logged. Meanwhile, extrinsic detachPolicy() deletes the connection between an object and its policy.

### C. Policy Execution Model

Access control policies define rules executed to make access decisions for requests. The policy execution should

help flexibility in management but ensure security. In our design, the policy execution model coordinates on-chain and off-chain parts as described in Fig. 2. The off-chain part is performed outside the Blockchain system and is usually conducted on gateways. Policy Enforcement Point (PEP) is a middleware for receiving and handling access requests. When receiving an access request, PEP will forward that request to the Off-chain Context Handle (OFF-CH), and the Environment Attribute Detection (EAD) will derive related information as environment attributes. Subsequently, OFF-CH invokes on-chain policy execution, which contains the subject's DID, the object's DID, and environmental attributes. Once on-chain policy execution is completed, access decisions are returned to OFF-CH, which will forward them to the PEP. Based on those decisions, PEP enforces denying or allowing for the corresponding request.

The on-chain part is performed distributedly on Blockchain, where attributes of subjects and objects are stored and managed via distributed identities. Authority participants, including device owners or administrators, define policies of objects, which are also stored and managed on Blockchain. All on-chain data modifications are attached to the blocks. When the system receives an invocation of on-chain policy execution, the On-chain Context Handle (ON-CH) will forward it to Policy Decision Point (PDP) to execute corresponding policies. Note that which policies will be executed can be specified in the invocation or derived from the object's DID. During the execution, the ON-CH is responsible for fetching necessary attributes from the Subject/Object Attribute Authority to the PDP. Once completed, access decisions go from the PDP to the ON-CH and propagate to the OFF-CH through Blockchain events.

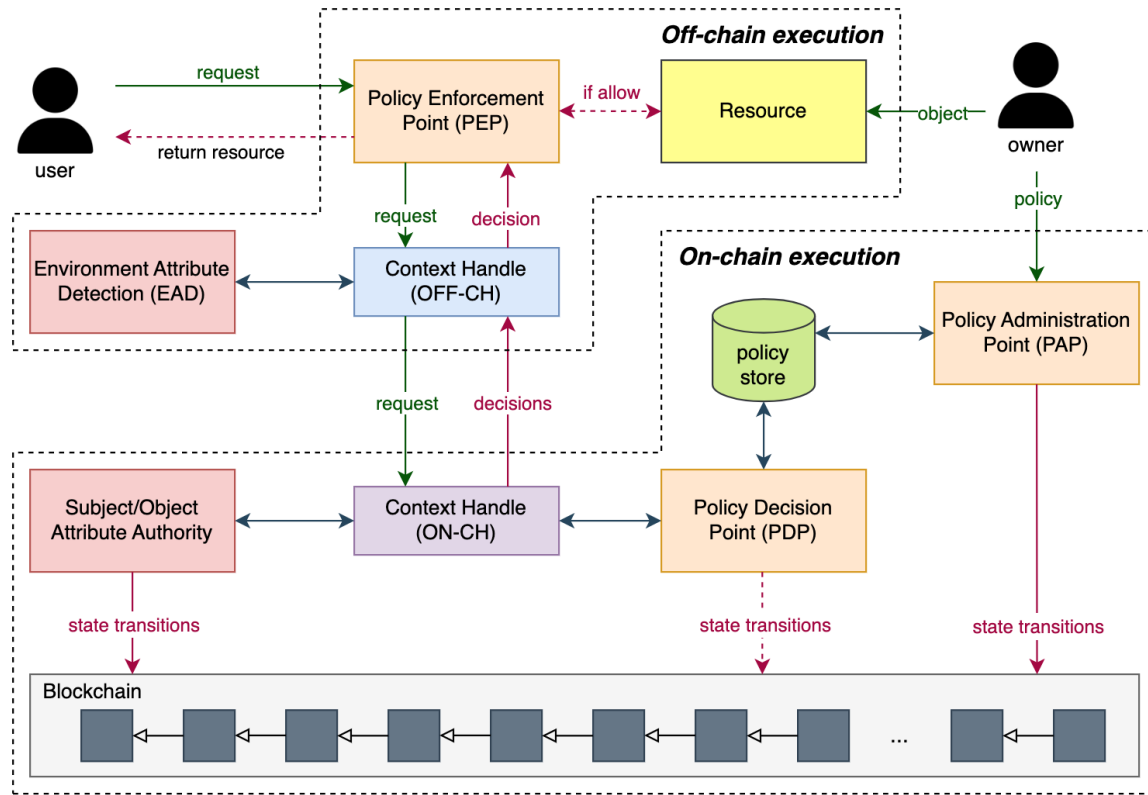

Fig. 2. Policy execution model.

A policy is a combination of programmable logic that defines the relationship among subject, object, environment attributes, and access decisions. In fact, policies can be expressed by procedural programming languages and deployed in appropriate computing environments. However, we leverage smart contracts in Substrate Framework to define policies.

#### IV. IMPLEMENTATION AND EVALUATION

##### A. Implementation

To investigate the proposed design, we implement and deploy a proof-of-concept (PoC) based on Substrate Blockchain Framework. Some abbreviations used to describe our algorithms are described in Table II. As presented in Section III-B, there are six main extrinsic for attributes management, attribute endorsement, and policy management in the proposed design. These six extrinsic belong to the ABAC Pallet (see Fig. 1) as interfaces to allow exterior to manipulate their on-chain data. We implement these extrinsic as Algorithms 1, 2, and 3. Some remarks are summarized as follows:

- In Algorithm 1, if an attribute is modified or deleted, all its endorsements shall be dropped automatically, as in lines 11 and 23.
- In Algorithm 2, before creating an endorsement for an attribute, its existence should be verified as line 6, and its value is calculated as line 7. For example, if  $EV$  is 3600 and the block generation interval is six seconds,

the corresponding endorsements will be valid for six hours.

- In Algorithm 3, the  $checkPerm()$  is used to make sure those who utilize these functions are the object's owner or administrators delegated, and a reminiscent name is also possibly associated with each attachment for later use.

To express the access control policy by a smart contract for general purposes, several rules in development should be proposed to scope it for access validation. Firstly, it needs a list of trusted endorsers so that its administrator can decide who is trusted with them. Secondly, it must have at least one method for access validation. Thirdly, those methods should take necessary arguments (e.g.,  $DID_s$ ,  $DID_o$ , and  $EA$ ), result in access decisions, and express policy logic in its body. Remarkably, there can be multiple policy logic expressions in one access validation method, and an access control template is proposed as Algorithm 4. A typical procedure should have five steps as follows.

- Step 1: Reading necessary attribute values.
- Step 2: Checking validity of the necessary attributes.
- Step 3: Evaluating defined policy logic.
- Step 4: Making a decision.
- Step 5: Saving the decision to the returning list

TABLE II. ABBREVIATIONS

Symbol	Description
$DID$	Distributed Identifier
$DID_a$	Administrator's DID
$DID_e$	Endorser's DID
$DID_o$	Object's DID
$DID_s$	Subject's DID
$ATL$	Attribute List
$AS$	Attribute Storage
$AV$	Attribute Value
$ANL$	Attribute Name List
$ES$	Endorsement Storage
$EV$	Endorsement Validity
$PS$	Policy Storage
$PAddr$	Policy Address
$PRN$	Policy's Reminiscent Name
$EA$	Environment Attribute
$ADL$	Access Decision List
$ACC_s$	The $i$ th Blockchain Account
$AEK$	Authentication's Encrypted Key
$APK_o$	Authentication's Private Key of An Object
$EAC$	Encrypted Authentication Challenge
$DDO$	DID Document

In case of failing to read attribute values or invalid endorsement, the corresponding expression should be bypassed, and no decision should be considered denying access.

Moreover, to demonstrate the feasibility of the entire system based on the proposed design, we also develop an example script of the off-chain access control as Algorithm 5, which works as an Express.js server running on an access control object (e.g., the Gateway) and opens REST API for listening access control requests. This module can communicate with Blockchain via a Web Socket connection manipulated by the Polkadot.js API library to query on-chain storage or listen to Blockchain events. Some remarks are summarized as follows.

- Lines 1 and 2 are to establish a Web Socket connection to Blockchain and to initialize a DID Resolver, respectively. As a service, the infinite loop handles every access request when it comes. The corresponding handler will be triggered based on the incoming request type.
- Lines 8 to 13 are to perform an authentication process between the sender (i.e., a subject) and an object. When this process finishes, an authentication challenge will return to the subject.
- Lines 14 to 20 are to complete the DID Authentication process. The request must include an authentication response corresponding to the previous authentication challenge for the subject. If the response matches the challenge, an encrypted key will be returned to the subject as a successful authentication. Otherwise, an error will be returned as a failed authentication.

### Algorithm 1 Attribute Management

must be verified before making an on-chain access validation to get access decisions (ADL) returned from Blockchain. At line 27, *OnChainValidation()* can collect environment attributes (EA) and encapsulate them into invoking on-chain policy execution.

The entire source code are freely shared at <https://github.com/substrate-iot>.

### B. Deployment

We adopt containerization to simulate a Blockchain network as a runtime environment because it is flexible in establishing a more decentralized Blockchain. Currently, we have established a network consisting of 12 Blockchain nodes. Notably, Substrate Blockchain uses a Proof-of-Authority consensus algorithm that does not press on computing capability. Therefore, deploying multiple Blockchain nodes on low-cost desktops or personal computers is convenient for experiments while guaranteeing all Blockchain features.

The deployment process of our implementation on containers in Substrate Blockchain Framework is summarized in four main steps as follows.

---

**Algorithm 4** The template to express the access control policy by smart contract

---

**Input:**  $DID_s, DID_o, EA[]$

**Output:**  $String[]$  (ADL: List of access decisions)

```
1: function validateAccess( $DID_s, DID_o, EA[]$ )
2:   Initialize ADL as an empty array of string
3:
4:   % Start of policy logic 1
5:   ...read attribute values ...
6:   ...check validity of attributes ...
7:   ...evaluate policy logic 1 ...
8:   ...make a decision for evaluation 1 ...
9:    $ADL.Push(\text{the result for logic 1})$ 
10:  % End of policy logic 1
11:
12:  % Start of policy logic 2
13:  ...
14:  ...  $ADL.Push(\text{the result for logic 2})$ 
15:  % End of policy logic 2
16:  ...
17:  % Start of policy logic n
18:  ...
19:   $ADL.Push(\text{the result for logic n})$ 
20:  % End of policy logic n
21:  return ADL
22: end function
```

---

- Step 1: Create a docker image (DI) which includes the executable file (EF) of the Blockchain node by compiling the source code (SC).

$$SC \xrightarrow{\text{compile}} EF \xrightarrow{\text{copy}} DI$$

- Step 2: Generate Blockchain accounts (ACC) for every node in the networks.

$$EF \xrightarrow{\text{generate}} \{ACC_1, ACC_2, \dots, ACC_{12}\}$$

- Step 3: Update the Default Chain Specification file (DCS), which would be loaded each the executable file boots up. A node must be aware of all other nodes and be updated with all other nodes' Blockchain addresses. Then, each particular node will have an Updated Chain Specification (UCS).

$$EF \xrightarrow{\text{generate}} DCS \xrightarrow{\text{modify}} UCS$$

- Step 4: Activate containers according to the number of Blockchain nodes from the docker image with the updated chain specification and their associated Blockchain account.

$$\{DI, UCS, ACC_i\} \xrightarrow{\text{activate}} BlockchainNode_i$$

### C. Evaluation

We conduct experiments to investigate the timing problem, a common design metric in most IoT systems. It measures how long it takes to complete a transaction, especially when many users utilize the Blockchain simultaneously. If it is too long, it will negatively affect to real-time demand and scalability of the IoT system. Therefore, our experiments investigate the amount of time elapsed to thoroughly submit transactions

---

**Algorithm 5** An off-chain access control JavaScript

---

**Input:**  $DID_o$ ,  $APK_o$

```
1:  $api \leftarrow PolkadotJS.ConnectTo(Blockchain)$ 
2:  $DidResolver \leftarrow BuildDidResolver(api)$ 
3: while true do
4:    $\langle req, type, data \rangle \leftarrow GetRequest()$ 
5:   if  $req == null$  then
6:     continue
7:   end if
8:   if  $type == "AuthRequest"$  then

34:    return  $Response(current\ data\ of\ resource\ X)$ 
35:   end if
36:   return  $Response(Error)$ 
37: end while
```

---

for seven main functions, including six extrinsic, as above-presented, and one for executing access policies. In each testing process, transactions have been submitted consecutively until a specific number of times is reached. The number of transactions for each process is increased by x10 times. Each testing process is performed five times to eliminate the effect of the natural unexpected random factor, and the final result is averaged. Fig. 3 summarises the experimental results, in which a logarithmic scale is utilized to present the value clearly due to the large differences.

Some findings are discussed based on the experimental results as follows:

- A single transaction's elapsed time, called response time, is roughly 1.0 to 1.5 on the logarithmic scale, equivalently from 10 to 30 milliseconds.
- When the number of transactions increases by x10 times, the elapsed times will also rise linearly by x10 times because it is equivalent to one unit on the logarithmic scale.

- At a specific number of consecutive transactions, the period of testing processes in different transaction types are almost the same, but one's  $validateAccess()$  is slightly greater than others. This is because invoking  $validateAccess()$  is a policy execution that leads to a smart contract execution behind the scenes, which is more complex than a normal extrinsic transaction.
- For application aspects, the average response time of 15 milliseconds is appropriate for the soft real-time IoT system. Besides, it can handle a vast number of transactions at a time, up to 10000, without any problems such as significant transaction failures or starvation. Therefore, the proposed design could meet the requirements of the IoT systems in terms of response time and accommodate more transactions compared to popular Blockchains like Bitcoin or Ethereum.

#### D. Security Analysis

The proposed design is trusted since it is inherently achieved by Blockchain compared to centralized systems. However, there is a trust-sharing model that is not mentioned before but exists implicitly in the proposed design. Device owners are considered the root of trust and can share it with other policy administrators through DID delegation. These administrators can manage ABAC policies of delegated devices or objects; in turn, they can specify who are trusted endorsers for ABAC policies. These trusted endorsers can endorse ABAC attributes of users or subjects to make them valid for access validation. The trust-sharing model makes access management more convenient but still maintains trust.

Additionally, the security of the proposed system is discussed on three typical security aspects of a software system: confidentiality, integrity, and availability (so-called CIA triad).

- **Confidentiality** is considered at IoT resources that should only be accessed by subject requests satisfying the requirements in the object's policies. For a malicious subject to access an IoT resource of an object, it has to modify its own ABAC attributes on blockchain to meet the object's policy. Nevertheless, such forged ABAC attributes have no meaning for access validation because they are not endorsed by one of the trusted endorsers specified in the policies. Furthermore, there are accident cases, for example, leakage of the blockchain account's private key. The previous trusted blockchain account and its DID become malicious. In such cases, endorsers can revoke their endorsements for that blockchain account. Similarly, device owners can also revoke delegations for policy administration in case administrators become malicious.
- **Integrity** is considered in on-chain data and policy execution. The data in the pallets' storages, such as ABAC attributes, attribute endorsement, ABAC policy attachment, etc., can only be modified by extrinsic signed by their owner's blockchain account. Regarding ABAC policies, once a smart contract is instantiated, the hash of both its source code and argument values passed into its constructor will be saved to the Pallet Contract's storage. This means that access validation

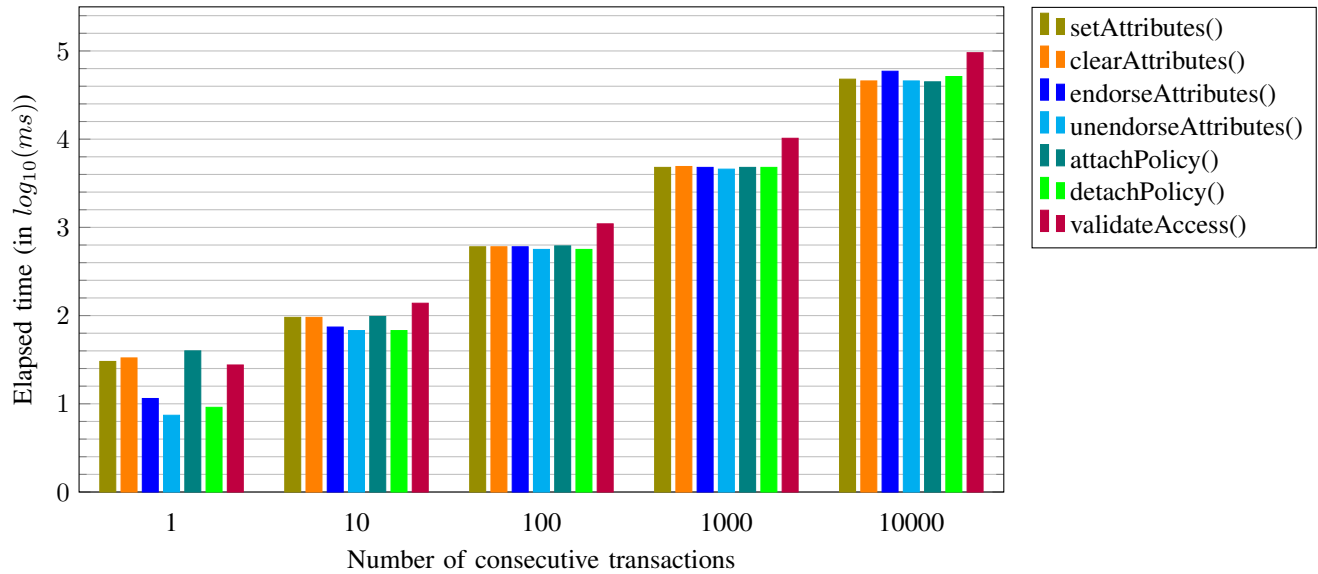

Fig. 3. Experimental results in terms of response time.

expressions of policy in the source code and trusted endorsers specified at the instantiating stage via the constructor are guaranteed to be consistent. Furthermore, policy execution can be distributedly conducted, and the result, which is access decisions, can be logged in the respective smart contract's storage. Generally, the integrity of policy execution is ensured by the smart contract. Moreover, in accident situations such as Blockchain account leakage, transactions originating from those leaked accounts are traceable because all transactions are kept in blocks.

- **Availability** is achieved by relying on a decentralized architecture with Blockchain technology. A decentralized system solves the single-point-of-failure problem in a centralized system; it can withstand a certain number of nodes failing simultaneously, and that number depends on the blockchain network topology and consensus algorithm. Each transaction has a certain fee in a blockchain system integrated with cryptocurrencies, so DoS or DDoS attacks by spamming transactions to disrupt the system are expensive for attackers.

As such, our proposed design achieves trust and security. However, these properties are also affected by the factors of a Blockchain system, such as network topology, consensus algorithm, and the number of honest nodes. Nonetheless, there is a horizontal scaling solution for the trust and security of a system by increasing the number of its Blockchain nodes. Meanwhile, consensus algorithm selection for a Blockchain is a trade-off between performance and security level, depending on assumptions of trust and security.

## V. CONCLUSION

This paper presents details of a Blockchain-based ABAC model that includes two main parts: attributes management and policy execution. Each decentralized identifier (DID) can be associated with attributes to verify access permission,

where attributes may need to be authenticated by trusted users (e.g., endorsers) via their DIDs. In our proposed model, the resource (e.g., IoT device or document) owner is considered the center, root-of-trust, who can delegate the authority to other administrators. Resource owners and administrators can also specify trusted endorsers for an access control policy for a particular object. Access control policies are codifiable by smart contracts, enhancing flexibility in access control management. Besides, policy validation is also executed on-chain, guaranteeing security in terms of the CIA triad. Therefore, our proposed design has demonstrated improved features compared to similar works based on four criteria, as shown in Table I. Furthermore, we also implemented the proposed model to investigate the performance regarding response time. The experimental results show that the proposed model could meet the soft real-time requirement for IoT systems.

In future work, intensive experiments be conducted to investigate other essential metrics, such as workload at the Blockchain node, storage cost, and transaction fee, before deploying it to practical applications.

**Abstract**—Fraud is the unlawful acquisition of valuable assets gained via intended misrepresentation. It is a crime committed by either an internal/external user, and associated with acts of theft, embezzlement, and larceny. The proliferation of credit cards to aid financial inclusiveness has its usefulness alongside it attracting malicious attacks for gains. Attempts to classify fraudulent credit card transactions have yielded formal taxonomies as these attacks seek to evade detection. We propose a deep learning ensemble via a profile hidden Markov model with a deep neural network, which is poised to effectively classify credit-card fraud with a high degree of accuracy, reduce errors, and timely fashion. The result shows the ensemble effectively classified benign transactions with a precision of 97 percent. Thus, we posit a new scheme that is more logical, intuitive, reusable, exhaustive, and robust in classifying such fraudulent transactions based on the attack source, cause(s), and attack time gap.

**Keywords**—Fraud transactions; fraud detection; deep learning ensemble; credit card fraud; cluster modeling; financial inclusion

## I. INTRODUCTION

The rise in the adoption of computing devices to aid effective data processing and resource sharing has continued to attract adversaries. This has necessitated the deployment of systems to avert such threats. The growth in these attacks has also resulted in higher costs associated with the safeguarding of valuable resources shared across networks [1]. Attackers have become more proficient at exploiting flaws with access to privileges, aimed at financial gains – even with advances made in the medium of data sharing [2]. This remarkable evidence advances a digital revolution such that day-to-day living is impacted therein with the proliferation of buying/selling via such mode, platform(s), and adoption of credit cards that have consequently, exposed many users to more clever and complicated methods to steal considerable money [3]–[5]. The growing complexity of ICT and the frequency of threats have also increased the data required to successfully detect them. There is also a rise in the adoption of multi-staged, subterfuge attacks targeted at various levels of security as provisioned in many organizations. Another barrier to detection is that adversaries often disguise the true forms and nature of their assault – and rarely, take up abrupt spurts of suspicious behavior that are easily recognized by simple intrusion detection schemes [6]–[9].

Previous studies have continued to acknowledge the rise in trend/alarming growth in credit card fraud, which has continued to lower user trust (irrespective of the rise in the adoption of credit cards) [10]. Studies also note that such fraudulent activities have caused greater losses to the financial services industry. This has thus, positioned as imperative – many researchers that adopted statistical models in detecting malicious credit card transactions [11]. Implementing a stochastic model has its bottleneck – as malicious transactions are aimed to evade detection, and their respective performance is often hindered by model over-fitting, parameter selection, etc [12].

The limited availability of data and ‘censored’ results from previous studies – have also led to difficulties to advance this field as datasets contain ambiguities, partial truth, and noise. These, have led to improper selection of features, data encoding, poor learning convergence, and incorrect results from over-parameterizing, overfitting, and overtraining. This increases false-positives and true-negatives error rates. We resolve this via a robust search that will effectively classify observations and yield the expected values [13]–[16].

The continued complexity in credit-card fraud detection has left us all in a frenzy with the continued quest to tweak methods to evade detection (for adversaries) as well as means to curb all attacks/threats (for security experts). This, in turn, has made and left such task and business, both a continuous and inconclusive feat [17]. In the quest therein for improved frameworks, some studies have shown that such tasks also, yield models whose performance is continually degraded at intervals due to improper selection of features within the used dataset for training and testing therein [18]–[20]. Even with the use and adoption of intelligent, stochastic, and dynamic classifiers, credit-card fraud persists as adversaries continue to evolve their techniques.

Thus, our study seeks to explore the use of feature selection [21]–[23] that is capable of addressing the issues of optimization with appropriate feature(s) selection, and adequately training the framework to avoid pitfalls from over-parameterization and overfitting of the model using deep learning. We propose a deep-learning cluster model to aid credit-card fraud detection. This will help to explore, exploit and use observed data as well as seek the underlying stochastic

feature of interest to yield a robust output and ensure qualitative knowledge.

## II. METHODS AND MATERIALS

### A. Credit-Card Fraud Detection: Review of Literature

The cost of financial crimes (globally) was estimated to be about \$ 42 billion in 2018. With this, is constantly on the rise – the financial services industry must employ systems that implement innovative fraud mitigation and prevention modes. Many methods for detecting abuse of a technical system [24], [25], are required. Fraud detection seeks to detect cases of fraud from logged data and user behavior [26]. Fraud *management thus* advances a step further to set up preventive measures. Oracle offers real-time detection and correlation capabilities of complex user behavior with use-case management – to result in its early detection and prevention via complex, multi-channel with reduced risk [27]. Fraudsters continue to seek effective means with improved complexity and circumvent border systems, which profile behavior at the point of access [28], and internal hacks that seek to steal client data and defraud valuable clients. Fraud monitoring should offer combined risk monitoring and detection analytics [29]. The system must intelligently correlate event alerts from various channels to offer optimal solutions via early fraud detection of multi-channel, and complex fraud, enhance client protection, and minimize risks [30]–[32].

Fraud is an unlawful act of possessing a valuable asset via intended misrepresentation. It is also associated with criminal cases such as embezzlement, theft, and larceny. It posits that an unknowing victim depends largely on a criminal's bogus claims for gains. It is committed by either an internal/external user. Today, credit cards have not only enhanced their usefulness in financial inclusion, but they have also attracted malicious attacks for gains [33], [34]. With credit cards easily targeted – crimes perpetrated with them are only discovered days afterward. Successful credit-card fraud techniques include (not limited to): (a) card-cloning and acquiring user's data, and (b) vendors' over-charge without cardholder's awareness [35], [36]. When banks lose money to card fraud, a cardholder is partly or wholly made to pay for such loss via many means that include higher interest rates, and reduced benefits. Thus, it is in both cardholders' and banks' interest to reduce fraudulent acts on a card [17], [37], [38].

In [39], the RBF model used 7 features and the trained RBF recognizes a packet as an attack, it is sent to a filter alarm. Else, it is classified as a normal packet. Profiles were constructed via stream sampling. Results showed that we can: (a) accurately profile packets, and (b) identify anomalies in low false-positive and false-negative. As routers exchange data, they capture key-feats in each packet – allowing them to profile the packets, and increase their rate and confidence in detection. Also [40] posited a distributed change aggregation trees (CATs) detection scheme. It lets the router detect minor shocks in data – which is then investigated and events correlated at the different sessions. The router then proactively terminates the session (if it detects an attack is imminent). In [41], the supervised memetic rule-based model used 7-feats to monitor, inspect and detect packet rates. However, [1] sought to extend the work [41] via deep learning, an unsupervised modular

network that captures a packet's key feats used as a profile to help analyze and classify packet patterns in a traffic session as either the normal or a DDoS attack.

### B. Data Gathering / Sample Population

Datasets are transactions generated through the Central Bank of Nigeria e-channel having 41,667 records with 15 feats as in Table I, which shows a description of the collected dataset including cardholder and transaction data. We split the dataset into training (70%) and Testing (30%) as in [18], [42], [43].

TABLE I. DATASET DESCRIPTION, DATA TYPES, AND FORMAT

Features	Description of Features	Data Type	Format
User Name	Account Holder's Name	Object	abcd
Bank Name	Bank of Account Holder	Object	abcd
NUBAN Account	Nigerian Universal Bank Number e-channel Trans.	Int	1234
Billing Address	Account holder's local bank address of withdrawal, hotel	Object	abcd
Transaction Amount	Amount of transactions adjusted in the bank's currency	Float	12.34
Transaction Type	Local, International, and/or e-Commerce as type	Object	Abcd
Date/Time	Transaction Date and Time	Float	M:D:Y
Transaction Channel	Channel (payment terminal and/or merchant application)	Object	Abcd
Merchant	Hotels, Restaurants, etc	Object	Abcd
Transaction Gap Time	Duration from last transaction to the current transaction	Float	M:D:Y
Daily Transaction	Daily average transactions performed by a cardholder	Int	1234
Daily Tran. Limit	The daily limit of the amount that cardholders can do daily	Float	12.34
Weekly Transaction	Weekly average transactions performed by the cardholder	Int	1234
Monthly Transaction	Monthly average transactions by the cardholder	Int	1234
Freq. Trans. Types	Average frequency of transactions by cardholder	Int.	1234

### C. Parameter / Features Tuning

A critical issue in machine learning is the formatting of data, the selections of feats/parameters of interest to understudy, properly encode the chosen dataset, and tuning the parameters to avoid model overfitting and overtraining to mention a few. Datasets are often riddled with inconsistencies, ambiguities, partial truths, and noise – such that selecting optimal parameters for a model, and encoding it by mapping to the required form a model understands – is a herculean feat and task. To transform our parameters and map them to the dataset, we use the Pandas data type Library as in the listing 1 algorithm [44]–[46].

**Algorithm 1: Data Description for DeLClustE Algorithm**

**Input:** Features are Selected  
**Output:** Features are Converted to Appropriate Data Type  
 Initialize DeLClustE with Select Parameters  
**For Each Selected Parameter do**  
     **if** Feature Selected is Non-Numerical **then**  
         Category for the Data Type is Generated  
     **End if**  
**End For**

**D. Experimental DeLClustE Ensemble**

Fig. 1 details our hybrid ensemble leveraging the work of [47]. The ensemble leans on two-components namely: the profile Hidden Markov model and deep-learning neural network. The selected training data forms a cluster of parameters that are passed via a PHMM represented as thus: (a) circles are delete-states for unclassified rules, (b) rectangles as accurately matched states that classify rules into class types, and (c) diamonds are insert-states to update the rules knowledgebase. As PHMM moves between the states, its insert and match states observe the emission state with probabilities corresponding to B. Thus, computes the probabilities via a forward algorithm, and computes the frequency of the number of rules each state emits [48]. Lastly, the delete state lets a PHMM pass through the gaps in the model to reach other emission states. The gaps in the model prevent it from over-fitting and over-parameterization [47], [49], [50].

DNN in its bid to learn, and adapt useful selected parameters via a carefully constructed deep, multilayer net that aims to improve forecast precision. Its hidden layer often transforms [51] data non-linearly and passes it on from a previous layer to its next [52]. With learning handed over to the DNN, [53] stressed that the DNN trains itself using 2-stages namely pre-training, and fine-tuning. It learns and resolves each task posed to it thus: (a) first, it groups all training data into cliques, to find the center point of each clique, (b) it then trains each clique of the DNN [54], learning the various features of each data subset, (c) third, it then applies a test data to previous clique centers to detect the outlier(s) in the pre-trained DNNs, and (d) lastly, it aggregates the output of each DNN as the final result of outliers [40]. A detailed description of the benchmark DNN is described in [55]. Also, the experimental ensemble yields a 3-phase model as in Fig. 1 [56]–[59].

The stages are as thus [14], [52], [53], [60]–[62]:

- Step 1:** Separates the data into clusters (train and test). DNN computes cluster centers and uses them as initialization centers to yield test datasets. The data attributes are structured as data points and aligned to meet the classes [63]. The model revises the cluster counts and sigma to improve its performance. The shortest distance between a data point and each cluster center is measured, and a data point's proximity to a cluster classifies it. DNNs use the training sets created by clusters as input. The number of DNNs in training equals the number of cliques. Each DNN consists of 5 layers (input, 2-hidden, softmax, and output). Each training subset is used to train the hidden layer, and the top layer is a 5D output vector. Each training created by the *k*th-clique center is sent back to the *k*th-DNN.

And each sub-DNN is trained, and labelled from 1 to *k* [64], [65].

- Step 2:** Generates a *k*-dataset of data via previous clique center obtained from clusters in Step 1. Test sub-datasets are represented by the letters Test-1 via Test-*k* [56].
- Step 3:** The test dataset is then, fed to the *k*-sub-DNNs that are trained as in step 1. Each DNN output is combined as the final result to analyze the positive detection [62].

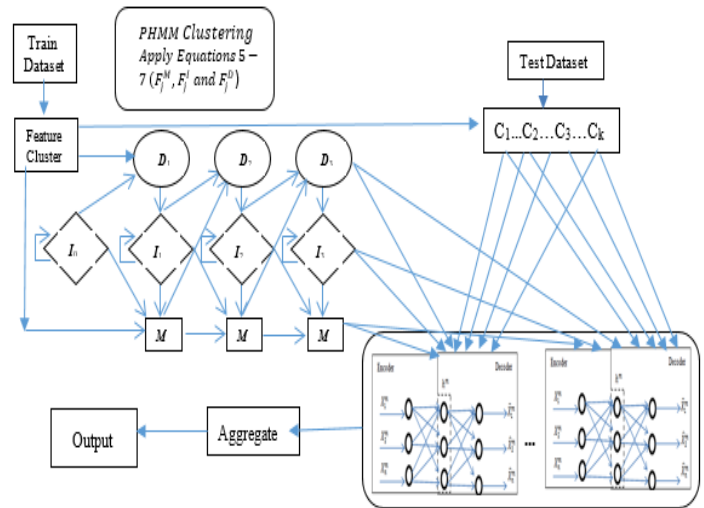

Fig. 1. DeLClustE: deep learning cluster hidden markov model trained deep learning neural network) ensemble.

**Algorithm 2: The DeLClustE Algorithm**

**Input:** Selected Features, **Output:** Converted Feature Data Type  
 Initialize DeLClustE with PHMM; states;  
 Discrete HMM with Random multinomial draw for each step  
 K-means cluster fits on *k*-sub DNNs  
**For Each Selected Parameter do**  
     Sample states using Forward Filtering  
     Compute Backward Sampling algorithm on states  
     Sample each transition parameters  
      $T_i = Mult(n_{ij} \setminus T_i) Dir(T_i \setminus c_k)$   
**End For Each**

**E. Hyper-Parameter and Ensemble Optimization**

A critical issue is that of tuning the parameters with values beyond the ensemble. They ripple across the model as hidden elements (hyper-parameters) [66]–[68] to impact its behavior – via targeted learning to optimize. Thus, we adopt the modular neural network [69]. As the model learns these feats directly via training data, it resolves the issues of over-parameterization, poor generalization, and model over-fitting [1], [70]–[72].

Handling these hyper-parameters is detailed in [57] thus:

- Learning Rate hyper-feat regulates what weight and how much of it on the network must be modified for gradient loss. A smaller value yields a slower slope. This feat defines how easily a network abandons learn beliefs, in favor of new ones. A small learning rate value implies that a network can quickly distinguish

between important feats and unimportant ones. A faster learning rate allows the net to adapt to change, more easily. To minimize over-fit and overtraining, the learning rate is suitably adjusted.

- 2) Batch Size defines the size of training used in iteration. There are three-modes namely: (a) batch is when its iteration and epoch values are equal, (b) Mini-batch denotes when the iteration size is greater than its epoch size, and (c) stochastic is when the gradient and network feats, which are updated after each iteration.

An epoch is the number of times when all training values were used to update a weight. A network can be trained in a single step. Training a network in a single pass, on a training dataset – implies that an epoch has been reached or exhausted. Training can span multiple iterations and/or eras. Thus, in batch training – a learning model process all samples simultaneously in one epoch, and update all the weights; While sequential training – adjusts all the weights after a training session.

### III. RESULTS AND FINDINGS DISCUSSION

#### A. Result Findings

We modeled the network's input layer with one neuron for each parameter to yield a total of 8 neurons; And used two neurons (to represent each possible outcome) for our output layer. The Deep learning parameters include the learning rate, our activation function, the hidden layer structure, and the number of epochs. We used the Rectified Linear Unit Activation Function with 500 epochs (optimal values reached 100, 300, and 500 epochs) – accounting for train convergence time and accuracy). Also, we note that there are no best practices for determining the number of neurons cum hidden layers – and additional hidden layers will give the ensemble capability to undertake more sophisticated functions on the data.

TABLE II. FIRST HIDDEN LAYER CONFIGURATION ANALYSIS

Hidden Layers	Precision	Recall	F1	Iteration	Train Loss	Epoch
1	0.94	0.94	0.92	18	1.400	500
2	0.86	0.53	0.63	4	2.230	500
3	0.90	0.84	0.86	16	2.071	500
4	0.92	0.93	0.92	18	1.140	500
5	0.92	0.92	0.90	16	1.779	500
6	0.88	0.91	0.89	7	2.134	500
7	0.91	0.92	0.89	8	2.320	500
8	0.87	0.87	0.87	13	2.006	500
9	0.92	0.92	0.90	8	1.970	500
10	0.92	0.92	0.90	5	1.730	500
11	0.85	0.85	0.85	10	1.540	500
12	0.90	0.84	0.86	15	2.320	500
13	0.91	0.92	0.90	8	1.440	500
14	0.92	0.93	0.90	14	2.160	500
15	0.91	0.91	0.91	5	1.772	500

We choose the number of neurons vis-à-vis the hidden layers via a trial-and-error mode that analyzes the results to achieve its best fit with the least amount of training error. The best number of layers to be used was discovered by first conducting experiments on a single layer with 1-to-15 neurons to determine which produces the highest f-score with the least (constant) amount of training loss time (see Table II)

As in Table III, the addition of a second hidden layer with the greatest number of neurons to generate the highest f-score resulted in the overall best feasible hidden layer arrangement.

TABLE III. SECOND HIDDEN LAYER CONFIGURATION ANALYSIS

Hidden Layers	Precision	Recall	F1	Iteration	Train Loss	Epoch
9, 1	0.91	0.92	0.89	10	1.996	500
9, 2	0.84	0.92	0.88	24	0.281	500
9, 3	0.93	0.93	0.92	11	1.884	500
9, 4	0.92	0.92	0.89	12	1.590	500
9, 5	0.90	0.92	0.90	12	1.731	500
9, 6	0.95	0.94	0.93	14	0.390	500
9, 7	0.93	0.93	0.91	12	1.130	500

9, 12	0.94	0.94	0.94	6	1.620	500
9, 13	0.93	0.94	0.92	7	1.760	500
9, 14	0.86	0.74	0.79	13	2.059	500
9, 15	0.92	0.92	0.89	8	2.421	500

#### B. Discussion of Findings

To evaluate how well the ensemble performed against known benchmarks, a comparative result(s) is seen in Table IV – with detection accuracies of 0.89 for PHMM, 0.78 for GANN, 0.91 for MNN, 0.96 for DNN, and 0.92 PHMM-DNN respectively. We also have that Fig. 2 shows the mean-time convergence for the various ensembles. We created a total of 22 rules. Table IV shows that rules can effectively identify/detect more than 60-to-82 percent of the cases in the dataset.

Fig. 2. Mean convergence time for experimental ensemble.

TABLE IV. CONFIGURATION ANALYSIS

Ensemble	Precision	Redundancy	Recall	F1	Average Support	Cost Estimate
DNN	0.92	0.52	0.94	0.92	12.449	140
PHMM	0.89	0.71	0.83	0.83	11.410	130
MNN	0.91	0.56	0.92	0.89	11.411	140
GANN	0.78	0.79	0.74	0.92	11.408	120
DeLClustE	0.96	0.52	1.00	0.97	12.500	140

That is, the test phase of the model with 12,500 records reveals that we accurately identified the majority of the models, 11,411 benign cases as agreed by [73], [74]. The result showed 11,410 benign threats from the test dataset are correctly grouped (i.e. true-positives). The result showed that 31-detected cases were erroneously labeled and agreed with [75]–[77] as false-positive; Also, 776 wrongly detected threats (i.e. false-negative) and 283-correctly recognized malicious instances labeled as true-negative. Thus, for true-positive cases, the model predicted positive (correctly) and also predicted negative (correctly) for true-negative cases. Conversely, sensitivity and specificity rates were computed with standardized tests for our test data [78], [79]. These proved, to be more efficient.

#### IV. CONCLUSION

We created a total of 22 rules, with classification accuracy range and fitness [0.6, 0.82] for the top rules (i.e. 60% of generated rules can sufficiently categorize the dataset). Thus, the ensemble effectively/correctly identifies fraudulent transactions and simultaneously improves the generality of rules to allow new datasets and their associated produced rules, to be added to the knowledgebase. Detection often filters all requests on a network, analyses all to separate compromised clients from those that are uncompromised, and also, provides security measures as appropriate actions. The performance of these ensembles may be hampered by error rates for erroneously classified and misidentified data points generated by the scheme and/or model.

Through trade-offs between the frequency of false positives and false negatives, an ideal approach correctly classifies all requests with nearly zero error rates of false positives or false negatives. With the increasing trend of intrusion threats and activities, it is critical to develop new methods and updated security monitoring systems that provide a high chance of detection and timely warning of intruder attacks. The goal of this research is to adapt a hybrid ensemble to monitor cardholder transaction flow patterns on a network, predict possible fraudster and adversary behaviors, and boost the effectiveness of banking platform (e-channel) network security when and if the level of threat changes.

# Proof of Spacetime as a Defensive Technique Against Model Extraction Attacks

Tatsuki Fukuda

Organization for Liberal Arts and Education, Shimonoseki City University, Shimonoseki, Japan

**Abstract**—When providing a service that utilizes a machine learning model, the countermeasures against cyber-attacks are required. The model extraction attack is one of the attacks, in which an attacker attempts to replicate the model by obtaining a large number of input-output pairs. While a defense using Proof of Work has already been proposed, an attacker can still conduct model extraction attacks by increasing their computational power. Moreover, this approach leads to unnecessary energy consumption and might not be environmentally friendly. In this paper, the defense method using Proof of Spacetime instead of Proof of Work is proposed to reduce the energy consumption. The Proof of Spacetime is a method to impose spatial and temporal costs on the users of the service. While the Proof of Work makes a user to calculate until permission is granted, the Proof of Spacetime makes a user to keep a result of calculation, so the energy consumption is reduced. Through computer simulations, it was found that systems with Proof of Spacetime, compared to those with Proof of Work, impose 0.79 times the power consumption and 1.07 times the temporal cost on the attackers, while 0.73 times and 0.64 times on the non-attackers. Therefore, the system with Proof of Spacetime can prevent model extraction attacks with lower energy consumption.

**Keywords**—Proof of spacetime; model extraction attacks; machine learning; security

## I. INTRODUCTION

In recent years, services known as Machine Learning as a Service (MLaaS), which utilize platforms such as Microsoft Azure and Amazon Machine Learning, have become increasingly popular. MLaaS enables users to pass input data to models stored on servers and receive corresponding output. In order for businesses to profit from MLaaS, they must allocate considerable resources towards training models on servers. However, there is a risk of model theft through attacks that target server-based models. These types of attacks, such as model extraction attacks that may not require training data [1], are increasing in frequency and severity.

Model extraction attacks involve repeatedly inputting data to a pre-trained machine learning model, obtaining many input-output pairs, and then training a local model based on that information in an attempt to replicate the original model. If a model is stolen, the MLaaS that was targeted could suffer a decline in revenue, and depending on the type of service, it may even be used as a foothold for other attacks.

There are various types of model extraction attacks, including Copycat CNN [2] and Knockoff Nets [3]. Copycat CNN involves creating a mimicked dataset by linking input data and their corresponding output from the targeted model,

and then using it to train a local model to steal the model. On the other hand, Knockoff Nets use reinforcement learning to efficiently select input images. There are also methods that steal the model by aligning the gradients of the targeted model and the local model [4].

As defense mechanisms against model extraction attacks, there are active defense, passive defense, reactive defense, and proactive defense.

Active defense is a method of hindering the training of the attacker's local model by altering the output of the targeted model. For example, it is possible to distort the probability of the output without changing the most probable class in the last activation layer of the targeted model [5] or intentionally poisoning the output to prevent the attacker from obtaining accurate output and obstructing the training of the local model [6]. However, these methods also affect the output accuracy of the model, which is a problem that also affects the output obtained by non-attackers.

Passive defense is a defense mechanism that protects the targeted model by truncating its output or detecting attacks. For example, there are methods that analyze the distribution of data that users have previously queried to detect attackers. However, existing methods are limited to research results based on assumptions such as the small distance between natural data and synthetic data [7] or the distribution of the attacker's dataset showing significant deviations as anomalies [8].

Reactive defense methods are techniques that aim to prove that the attacker's local model has stolen the victim model, rather than detecting the attack itself. There are methods that use digital watermarks [9] or verify whether the model suspected of theft has a certain level of common knowledge with the victim model [10]. However, these methods cannot prevent the theft of the model, and there is no guarantee that the stolen model will not be used for other attacks.

Proactive defense is a technique that increases the attacker's burden by imposing some form of cost on the users who query the model. For example, there are techniques that use Proof of Work [11,12], which requires computation, to demand costs in terms of electricity or time from attackers. This technique makes it difficult for attackers to acquire many input-output relationships at a low cost and is a method that does not affect output accuracy for non-attackers. Furthermore, since this defense technique does not require any changes to the learning model itself, there is no need to train the model with specialized data or retrain a pre-trained model, making the cost of introducing the defense technique relatively low.

However, the calculation required in the Proof of Work consumes a significant amount of electricity, which is not sustainable from the perspective of the United Nations' Sustainable Development Goals (SDGs). As a solution, applying the Proof of Spacetime into the defense method against model extraction attacks is proposed in this paper. The Proof of Spacetime aims to limit access by attackers without repeating high load calculation and can reduce the unnecessary consumption of electricity.

## II. LITERATURE REVIEW

Firstly, we describe the method of the Proof of Work and the Proof of Spacetime.

### A. Proof of Work

Proof of Work is mainly used in cryptocurrencies such as Bitcoin [13], where a reward can be received in exchange for solving a given problem through computation. Generally, a hashcash [14] is used in Proof of Work, which imposes a calculation to find a string of characters that has a certain number of zeros in the upper bits when the hash is converted. The difficulty of the calculation can be determined based on the number of zeros required.

By using Proof of Work's hashcash, it is possible to inhibit an attacker from obtaining the input-output relationship of a model by making MLaaS users perform calculations to obtain the model's output. However, since non-attackers also use MLaaS, it is necessary to increase the difficulty of hashcash, i.e., the number of consecutive zeros, as the suspicion of the attacker increases.

As a result, the attacker needs to perform many computations to obtain the output of the model, which imposes time and power consumption constraints. Additionally, because the computation occupies the CPU or GPU, it prevents the attacker from evading time constraints by using multiple accounts. However, Proof of Work calculations force unnecessary computations and power consumption, which leads to the consumption of fossil fuels, making it environmentally unfavorable.

### B. Differential Privacy

In a defense method using Proof of Work, it is necessary to distinguish between attackers and non-attackers, which can be achieved using differential privacy [15] as an indicator. Differential privacy is a concept that originally aims to protect personal information on a database and make statistical analysis possible. Differential privacy considers the privacy is secured if it is impossible to distinguish between the results obtained using a dataset that contains personal data and the results obtained using a dataset that excludes the personal data.

PATE [16] is a method for measuring differential privacy. PATE trains multiple models including personal data and builds a model that adopts the majority vote of their outputs. Then, the output of this model with noise added is used to train another model without using personal data. Through this process, the final model is trained without directly using personal data and with noise added, leading to the protection of differential privacy.

In our method, the differential privacy is used to judge the user whether or not an attacker and to determine how much cost to impose the user.

### C. Merkle Tree

Merkle tree [17] is a technique that uses hash functions to summarize and verify data. Multiple data are hashed and then the hash values are added together in pairs, which are then hashed again. This process is repeated until a tree is created with hash values on each node. Fig. 1 shows an example of a Merkle tree generated from four data sets. The root node,  $h_{ABCD}$ , is called the Merkle root. The hash values  $h_A$  and  $h_C$  that are needed to calculate the Merkle root from data  $B$  are called the Merkle path of data  $B$ .

Fig. 1. Example of Merkle tree.

### D. Proof of Spacetime

Proof of Spacetime [18] is a consensus algorithm used in virtual currencies such as Spacemesh. It is a method that occupies a certain amount of memory space for a certain amount of time. Specifically, it generates initial data in advance using a hash cache and considers the memory space and time occupied by that initial data as the cost.

Proof of Spacetime is a consensus algorithm used in virtual currencies such as Spacemesh. It is a method that occupies a certain amount of memory space for a certain period of time. It generates initial data using a hash cache and considers the memory space and time occupied by the initial data as costs. The Proof of Spacetime flow can be divided into initialization, proof, and verification stages. In the initialization stage, users save all hash-transformed data using a hash cache. In the proof stage, users create proof data using a Merkle tree. In the verification stage, the server verifies whether the proof data created in the proof stage is correct. The power consumed to build a Merkle tree is smaller than the power consumed to generate data in the initialization stage, because the hash transformation used to construct the Merkle tree is a repeated hash function that is faster than the hash function used in the initialization stage. The user-side cost in Proof of Spacetime can be represented as a monetary cost using (1) and (2),

$$C_{init} = p \times n \times C_p, \quad (1)$$

$$C_{proof} = s \times t \times C_{st}, \quad (2)$$

where  $C_{init}$  and  $C_{proof}$  are the cost in the initial and the proof stage, respectively. The cost in initial stage can be said also the cost of hash cash. Note that  $p$  is the amount of power consumed for one hash transformation,  $n$  is the number of times the hash is performed,  $C_p$  is the cost per power consumption,  $s$  is the size of occupied storage,  $t$  is the occupied time, and  $C_{st}$  is the cost per second for occupying 1 MB. A general flow of Proof of Spacetime is shown in Algorithm I.

The Proof of Work requires the user to perform a high-load calculation and continues until it is solved, whereas the Proof of Spacetime requires a relatively simple calculation and keeping the "evidence" of the calculation. In other words, the Proof of Spacetime does not require the user to keep moving at high power all the time, and power consumption can be suppressed.

#### Algorithm I:

1. function `init_stage(id)`:
2.      $\sigma = \text{hashcash}(id)$
3.     for  $i = 0 \dots t$ :
4.          $G[i] = \text{hash\_init}(i, \sigma)$
5.         if  $G[i]$  has  $\log_2 t$  or more leading zeros:
6.             return True
7.     return False
8. function `proof_stage()`:
9.      $\text{tree} = \text{Merkle}(G)$
10.     $\text{path\_list} = \text{all of the Merkle paths from all of leaves}$
11.    transmit  $G$  and  $\text{path\_list}$  to the server
12. function `verification_stage()`:
13.    for  $i = 0 \dots t$ :
14.       if  $G[i]$  has  $\log_2 t$  or more leading zeros:
15.           reconstruct tree from  $\text{path\_list}$
16.           return if tree is equivalent to  $\text{Merkle}(G)$
17.    return False

### III. METHODS

When using Proof of Work as a defense mechanism against model extraction attacks, excessive energy consumption and its negative impact on the environment have already been noted. Therefore, this study proposes a method using Proof of Spacetime. Specifically, the following steps STEP 1 to STEP 5 are taken:

STEP 1: Measure the differential privacy of the user that is

considered a non-attacker, denoted as  $D_n$ .

STEP 2: Measure the differential privacy of the current user,

denoted as  $D_c$ .

STEP 3: Calculate the difference  $D$  between  $D_n$  and  $D_c$ .

STEP 4: Calculate the temporal and spatial cost based on  $D$ .

STEP 5: Impose the temporal cost and spatial cost on the

current user using Proof of Spacetime.

The temporal cost reduces the efficiency of attackers obtaining input/output data, and the spatial cost prevents attackers from obtaining input/output data by parallel processing, i.e., using multiple accounts. However, there is a possibility that even non-attacker users may use the service multiple times, so it is desirable to minimize the initial hashcash as much as possible, which will also reduce unnecessary energy consumption. Therefore, the spatial cost for storage is fixed.

Compared to using the defense method with Proof of Work, using Proof of Spacetime provides the following four benefits:

- Power consumption can be reduced.
- Time costs imposed on users can be adjusted with little
- Change in computational complexity.
- Fine-tuning of costs is also possible.
- Costs can be demanded regardless of differences in machine resources.

The first benefit comes from the fact that Proof of Spacetime can reduce power consumption by using proof stages that require less power consumption than repeating hash calculations. This is because, as mentioned earlier, the hash conversion used for constructing a Merkle tree in the proof stage is a repetition of a high-speed hash function. Similarly, the second benefit is due to the small computational complexity of the proof stage, making it possible to adjust time costs without worrying too much about computational complexity.

The third benefit is due to the difficulty of adjusting difficulty levels when increasing the number of zeros in a hash cache from  $n$  to  $n + 1$ , as increasing the number of zeros results in an average computational complexity increase of  $2^n$ . With Proof of Spacetime, it is easy to simply change the occupied time.

The fourth benefit is that while costs that depend on computational complexity such as hash caches can be relatively reduced by increasing the performance of the attacker's machine, the time cost of Proof of Spacetime is not affected by the performance of the machine, and the space cost can be easily increased accordingly.

#### IV. EXPERIMENTS

Comparing the power consumption between Proof of Work and Proof of Spacetime:

##### A. Experimental Procedure

We prepared a target model for the attack: a ResNet34 for classifying cifar10 data (95.60% accuracy). Both of attackers and non-attackers randomly selected data from dataset not used for training the model to query. The number of queries is 5000 for each experiment. For the classification server, we implemented a defense method using Proof of Work and a defense method using Proof of Spacetime. We conducted the following measurements for a total of four servers:

- Power consumption of non-attackers.
- Power consumption of attackers using Knockoff Nets.
- Power consumption of attackers using Copycat CNN.

Power consumption was measured by measuring the overall power consumption of a computer shown in Table I with the minimum required processes running for program execution. In addition, the average power consumption during normal times when the program was not running was also measured.

TABLE I. COMPUTER USED FOR EXPERIMENTS

CPU	Core i5-9400F BOX
Memory	64GB
OS	Ubuntu Desktop 22.04

##### B. Results

The experimental results are shown in Table II. Fig. 2 to Fig. 4 illustrate the power consumption during program execution, where the vertical line shows the elapsed time from the query threw and the horizontal one shows the cumulative power consumption. Note that the power consumption while the computer is in idled for 30 minutes was  $3.0 \times 10^{-2}$  kWh and an average wattage is 60W.

TABLE II. RESULT FOR PROOF OF WORK

Client	Defence Method	Erapsed Time [Sec]	Power consumption [kWh]	Average wattage [W]
Non Attacker	PoW	48047	2.40	180
Knockoff	PoW	299563	9.36	112
Copycat	PoW	374146	11.52	110
Non Attacker	PoST	30685	1.75	205
Knockoff	PoST	360930	8.44	84
Copycat	PoST	358576	8.13	82

Fig. 2. Power consumption for a non-attacker.

Fig. 3. Power consumption for an attacker with knockoff nets.

Fig. 4. Power consumption for an attacker with copycat.

Fig. 5 to Fig. 7 show the monetary cost for each attack. Note that the unit prices in (1) and (2) were set to  $C_{st} = 2.50 \times 10^{-10}$  and  $C_p = 31$  [19-21], respectively. The vertical line shows the elapsed time from the query threw and the horizontal one shows the monetary cost.

Fig. 5. Monetary cost based on the online storage services for a non-attacker.

Fig. 6. Monetary cost based on the online storage services for an attacker with knockoff nets.

Fig. 7. Monetary cost based on the online storage services for an attacker with copycat.

## V. CONSIDERATION OF RESULTS

Now, we consider the results obtained from the experiment from the viewpoint of temporal cost and power consumption.

### A. Temporal Cost

According to Table I, the average time required per query for the defense mechanism using Proof of Work was 9.61 seconds for non-attackers and 67.4 seconds for attackers. On the other hand, when using Proof of Spacetime, the times were 6.14 seconds for non-attackers and 72.0 seconds for attackers. Therefore, the defense mechanism using Proof of Spacetime requires 0.64 times the temporal cost for non-attackers while

1.07 times for attackers, indicating its high performance as a defense mechanism.

### B. Power Consumption

For non-attackers, it can be seen that Proof of Spacetime reduces the total power consumption by 0.73 times compared to Proof of Work, but the average power required is 1.14 times higher. This is because Proof of Spacetime requires more computation in the initialization phase, which occupies a larger portion of the non-attacker's time cost.

For attackers, it can be seen that Proof of Spacetime reduces the total power consumption by 0.79 times compared to Proof of Work, and the average wattage required is also reduced by 0.75 times.

### C. Comprehensive Perspective

Comparing the defense mechanisms using Proof of Work and Proof of Spacetime, it was found that the latter has the following characteristics:

- Higher average power consumption for non-attackers
- Lower total power consumption for non-attackers
- Lower time cost for non-attackers
- Lower average power consumption for attackers
- Lower total power consumption for attackers
- Higher time cost for attackers

Since the goal of this study was to reduce unnecessary power consumption while preventing attacks, these results indicate that the goal was successfully achieved.

In addition, since the graphs of the monetary cost in Fig. 5 to Fig. 7 have a similar shape to the power consumption graphs in Fig. 2 to Fig.4, respectively. That means that it can be seen that storage costs are negligible compared to power costs. In other words, in terms of monetary cost, there is a trade-off between time cost and space cost in Proof of Spacetime. While storage was assumed to be the target of space cost in this study, cost-effectiveness can be improved by storing data in main memory.

When choosing between Proof of Spacetime and Proof of Work as defense mechanisms, the following points should be considered. Specifically, Proof of Work should be used to impose costs on attackers when the suspicion of an attack is low due to differential privacy. Proof of Spacetime should be used when the suspicion of an attack is high, to reduce power consumption while imposing time and space costs. By doing so, the costs imposed on non-attackers can be kept small, while the costs imposed on attackers can be increased.

## VI. CONCLUSION

This paper proposed the use of Proof of Spacetime as a defense mechanism against model extraction attacks. The existing defense method, Proof of Work, is effective in preventing attackers from obtaining the input-output relationship of the model for model extraction attacks. However, it imposes unnecessary power consumption, which is not environmentally preferable. With our method, the user has

to calculate a relatively simple calculation and keeps the "evidence" of the calculation, so the total power consumption decrease compared to Proof of Work. The cost to impose to the user is determined according to the differential privacy.

The only drawback of Proof of Spacetime is the large average wattage for the non-attackers. As the future work, it is necessary to consider efficient ways to use Proof of Work and Proof of Spacetime for attackers and non-attackers separately.

# Deep Learning-based Intrusion Detection: A Novel Approach for Identifying Brute-Force Attacks on FTP and SSH Protocol

Noura Alotibi, Majid Alshammari

Department of Information Technology-College of Computers and Information Technology, Taif University, Taif, Saudi Arabia

**Abstract**—As networks continue to expand rapidly, the number and diversity of cyberattacks are also increasing, posing a significant challenge for organizations worldwide. Consequently, brute-force attacks targeting FTP and SSH protocols have become more prevalent. IDSes offer an essential tool to detect these attacks, providing traffic analysis and system monitoring. Traditional IDSes employ signatures and anomalies to monitor information flow for malicious activity and policy violations; however, they often struggle to effectively identify unknown or novel patterns. In response, we propose a novel intelligent approach based on deep learning to detect brute-force attacks on FTP and SSH protocols. We conducted an extensive literature review and developed a metric to compare our work with existing literature. Our findings indicate that our proposed approach achieves an accuracy of 99.9%, outperforming other comparable solutions in detecting brute-force attacks.

**Keywords**—Artificial neural networks; machine learning; deep learning; intrusion detection system; detecting brute force attacks on SSH and FTP protocols

## I. INTRODUCTION

Over the past decade, network security has emerged as a major research area due to the growing interest and advancements in internet and communication technologies. The security of networks and their connected assets in cyberspace is primarily protected by various technologies, such as firewalls, antivirus software, and Intrusion detection systems (IDSes) [1]. However, as attacks become more sophisticated, non-traditional techniques are required to detect them. Consequently, existing IDSes have proven to be ineffective at detecting a wide range of threats, including zero-day attacks, and at reducing false alarm rates (FARs) [2].

Researchers have investigated the potential application of machine learning (ML), including deep learning, to aid in detecting these attacks. ML aims to extract valuable information from large volumes of data [3] and serves as a powerful approach for gathering useful data from network traffic and predicting normal and abnormal events based on learned patterns. Machine learning models rely heavily on feature engineering to learn essential information from network traffic [4]. Due to their structure, deep learning models do not require feature engineering and are capable of automatically learning complex features from raw data [5].

Although deep learning models are still in their early stages, there is considerable potential for advancing this technology. Recently, researchers have begun proposing deep

learning models to improve the effectiveness of attack identification. Among the most well-known attacks on networks are brute-force attacks on Secure Shell (SSH) protocol and File Transfer Protocol (FTP). The SSH protocol is used for secure remote login over an insecure network [6], while the FTP protocol is employed to transfer data between a client and a server [4].

Therefore, in this paper, we propose a deep learning-based model for detecting brute-force attacks on FTP and SSH protocols. Brute-force attacks targeting these protocols have become increasingly significant security risks to organizations. By leveraging the capabilities of deep learning, our model aims to overcome the limitations of traditional IDSes and improve the accuracy and efficiency of brute-force attack detection on FTP and SSH protocols. Through an extensive evaluation and comparison with existing literature, our findings demonstrate that the proposed model achieves an accuracy of 99.9%, outperforming other comparable solutions in detecting brute-force attacks.

The remainder of this paper is organized as follows: Section II provides a review of the literature. Section III presents the research methodology. Section IV discusses the proposed model. Section V presents the findings and analysis of the proposed model. Finally, Section VI concludes the paper.

## II. RELATED WORKS

Cybersecurity is a vast field designed to combat various attack pathways [7]. Since 2009, research has focused on utilizing artificial neural networks (ANNs) to improve anomaly detection and IDS identification. As a result, the application of ANNs in IDS and malware detection is still a relatively new concept [8]. Previous researchers have attempted to address issues related to overfitting, excessive memory utilization, and high overhead associated with traditional IDS detection. A two-layer, feed-forward ANN was suggested for this purpose. According to the authors, their method produced outcomes similar to traditional procedures but required less computational effort. This technique was tested using the benchmark dataset KDD'99. Since the machine requires time to process the data, the paper concluded that having fewer data points was preferable [9]. Researchers evaluated pruning an ANN as part of network optimization, which involved removing neural nodes from the input or hidden layers. As a result, their ANN became faster due to fewer computations

needing to be processed. When tested as an IDS, the ANN in [9] showed promising performance.

Rather than delivering the inputs directly from the dataset, [10] used principal component analysis (PCA) as a feature representation before feeding the data to the ANN. As the paper illustrated, this reduced the memory resources needed and the amount of training time required. In terms of accuracy, the two tested approaches produced similar results, making PCA the better alternative. Although using a kernel PCA improves ANN training time, it consumes significantly more memory than standard PCA, which is a drawback. Since the accuracy measures for both techniques are similar, the authors of [11] discussed the use of a combination of techniques as a superior alternative. Because GPUs are well-suited for ANN computations, research has explored using them to accelerate ANN-based IDSes. A performance boost has been demonstrated in [12]. The authors of [13] compared a support vector machine (SVM), Naïve Bayes (NB), and a C4.5 classifier to an ANN with one hidden layer. The ANN yielded equivalent or better results in attack detection than the other algorithms evaluated by the paper, and it did so with fewer computations due to the simplified structure of a three-layered ANN model. The tests were conducted on the NSL-KDD database, which replaced KDD'99 as the current benchmark.

Artificial intelligence-based IDS models continue to face two major issues. Traditional machine learning (ML) algorithms are generally fast but have a high false positive rate (FPR). Deep learning, on the other hand, offers excellent accuracy and low FPR but requires significant computation time. As a result, the authors of [14] proposed a solution that provided the best of both worlds. The suggested solution was an OS-based monitoring algorithm that used standard ML as a quick monitoring device, referred to as the standard stage; when a classification falls into the borderline state, the method's second stage is initiated. The second stage, dubbed uncertain, employs deep learning as the final decision-maker on a process. The authors of [15] examined malware detection flow based on a convolutional neural network (CNN). They found that detection approaches were overly reliant on specific packet elements, such as the port number, which created a blind spot in security, as some malware uses unpredictable port numbers and protocols. Instead of these packet elements, they proposed 35 features derived from the Stratosphere IPS project's data. To address the data balance problem, 2000 data points were selected in each class. Nestmate was used to extract 35-flow static features that were then fed into a CNN and three different machine learning methods for evaluation, including SVM, random forest (RF), and multi-layer perceptron (MLP). Data from the Stratosphere IPS project was used to train the models, as it is publicly available. The CNN architecture consisted of one input layer, five feature map layers, a flatten layer, two hidden layers, and one output layer. The authors concluded that the RF algorithm outperformed other approaches on all three examined indicators: accuracy, specificity, and sensitivity [16].

Table I and Table II display supervised algorithms, as well as autoencoder and deep belief network architectures used for intrusion detection, respectively.

TABLE I. COMPARISON OF INTRUSION DETECTION SCHEMES USING ANN AND CNN ARCHITECTURES

### III. METHODOLOGY

The methodology section outlines the process followed in developing the intrusion detection model using deep learning techniques. The chosen algorithm is based on previous studies, and the model utilizes ANNs with ReLU and SoftMax activation functions. The CSE-CIC-IDS 2018 dataset, specifically the FTP/SSH brute-force attacks, serves as the basis for the model. The entire process is broken down into distinct stages, as detailed below:

- 1) *Obtain the proposed benchmark dataset:* The CSE-CIC-IDS 2018 dataset is acquired, containing eight different attack types. Only FTP/SSH brute-force attacks are used in this study.
- 2) *Prepare the data:* Data preprocessing involves correcting issues such as missing values and outliers, ensuring that the dataset is clean and ready for analysis.
- 3) *Use exploratory analysis:* This step involves understanding the dataset's content and selecting the most suitable algorithm for the given problem.
- 4) *Train the model:* The best-performing algorithm from the literature review is used to train the model on the prepared dataset.
- 5) *Evaluate the model:* Evaluation techniques are employed to assess the model's performance and ensure that it meets the desired accuracy and detection standards.
- 6) *Optimize the model:* If the model's performance is unsatisfactory, alternative algorithms are considered or the current model's parameters are adjusted to improve its effectiveness.

The model is implemented using Google Colab, Python programming language, and the Scikit-learn library. The algorithm implementation is divided into four stages:

Stage 1: Input features are generated from the data preprocessing and representation stages and supplied to the neural network's input layer.

Stage 2: Neural network layers are initialized with random weights, which are used throughout the training phase.

Stage 3: The network accepts the input and begins the training process. The feature identifies the output probabilities by going through the forward propagation phases (dense, ReLU, and operations, as well as the forwarding propagation of hidden layer 3).

Stage 4: The intended output error value is computed and compared to the produced output. Validation is performed after every 50 iterations to assess the model's performance and make adjustments as needed.

This methodology provides a systematic approach to developing an effective intrusion detection model, from obtaining the dataset to training and evaluating the model.

### IV. PROPOSED MODEL

To implement the proposed algorithm, it is crucial to obtain the CSE-CIC-IDS2018 benchmark dataset. The data is organized in a CSV file with columns such as FlowID, Destination-IP, Source-Port, and Protocol. The dataset includes

over 80 network traffic features representing various attack types, including denial-of-service, Heartbleed, web attacks, botnet, and infiltration attacks.

Brute-force attacks are prevalent against networks as they exploit weak login and password combinations. Our model focuses on identifying SSH and MySQL accounts on the primary server targeted by dictionary brute-force attacks.

The following steps outline the data preprocessing:

- 1) *Data cleaning and normalization:* Convert all required features to nominal values and clean the data, depending on the created features.
- 2) *Normalization of data:* Normalize numeric feature values to a chosen scale, such as the [0, 1] range, to decrease data scale and improve model accuracy and processing time.
- 3) *Splitting data:* Divide the data into three parts: a training set with 60% of the data, a validation set with 20%, and a testing set with the remaining 20%.

Fig. 1 displays the architecture of the proposed model, while Fig. 2 shows the neural network architecture of our multiclass detection model. The ANN aims to minimize the number of information parameters needed by employing equivariant representation, parameter sharing, and sparse interactions. The network consists of multiple hidden layers, as well as an input and output layer.

Fig. 1. Architecture of the proposed model.

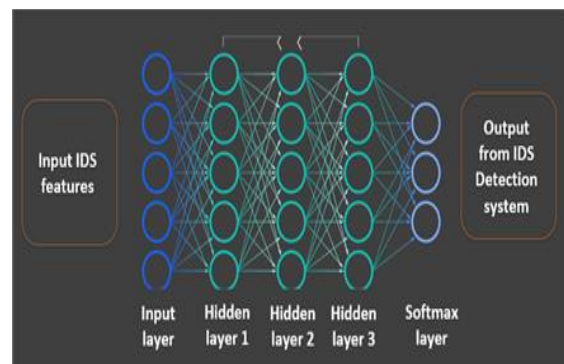

Fig. 2. Proposed neural network architecture of our multiclass detection model.

The model parameters are as follows:

- Input layer: Contains neurons equal to the number of input data features, utilizing the ReLU activation function.
- Hidden layers (1, 2, and 4): Dense layers with a specified number of neurons, also employing the ReLU activation function.
- Output layer: A softmax layer for classification with three output classes.

In this model, we use a softmax classifier for multiclass classification of brute-force attacks targeting SSH and FTP. The softmax layer effectively represents category distributions by normalizing the exponent of output values. It is primarily used in the output layer, providing a differentiable function that reflects the probability of the output.

### V. FINDINGS AND ANALYSIS

In the Findings and Analysis section, we present the performance of our proposed model and compare it with current research. Our proposed model achieved superior results with over 99.9% accuracy in comparison to the existing literature. Fig. 3, which shows the learning curves during the training process, demonstrates the performance of our proposed model.

Fig. 3. The accuracy of the proposed model.

Table III compares our proposed model with current research based on accuracy, precision, recall, and F-score. Our model produced superior results, with 99.9% accuracy, 98.3% F-score, 100% precision, and 98% recall.

The results of the proposed model, which employs an Artificial Neural Network (ANN) on the CSE-CIC-IDS2018 dataset, demonstrate a significant improvement in performance compared to existing research. With an accuracy of 99.9%, F1-score of 98.3%, precision of 100%, and recall of 98%, the proposed model outperforms other methods in the literature.

TABLE III. COMPARISON BETWEEN THE PROPOSED MODEL AND CURRENT RESEARCH

Scheme	Dataset	Model Architecture	Result in %
[26]	CSE-CIC-IDS2018	Broad Learning System	Accuracy: 97.08 F1- score : 77.89 Precision :NA Recall :NA
[27]	CSE-CIC-IDS2018	LSTM+ SMOTE algorithm	Accuracy :96.2 F1- score : NA Precision :96 Recall :96
[28]	CSE-CIC-IDS2018	Spark ML + Conv-AE	Accuracy : 98.20 F1- score : 98 Precision :NA Recall :98
Proposed Model	CSE-CIC-IDS2018	ANN	Accuracy : 99.9 F1- score : 98.3 Precision : 100 Recall : 98

In comparison, the Broad Learning System (BLS) achieved an accuracy of 97.08% and an F1-score of 77.89%, while the model using LSTM with SMOTE algorithm reached an accuracy of 96.2% and a precision and recall of 96%. Finally, the model employing Spark ML with Conv-AE obtained an accuracy of 98.20%, F1-score of 98%, and a recall of 98%. These results show that the proposed ANN model is significantly more accurate than other models, particularly in terms of precision.

The high precision of the proposed model indicates that it is particularly effective at correctly identifying true positives (i.e., correctly detecting attack instances) and minimizing false positives (i.e., misclassifying benign instances as attacks). This is an essential aspect of an intrusion detection system, as it ensures that genuine threats are identified while minimizing the risk of false alarms.

The recall rate of 98% for the proposed model, while slightly lower than its precision, is still noteworthy. This indicates that the model can successfully identify a high proportion of true positive instances from the total number of actual positive instances. In the context of intrusion detection, this means that the proposed model is effective at detecting most of the attacks in the dataset.

### VI. CONCLUSION AND FUTURE WORK

In this research, we introduced a novel model for detecting network intrusions using a deep neural network. Our proposed model demonstrates superior performance compared to other existing approaches, as evidenced by the results obtained.

We utilized the comprehensive CSE-CIC-IDS2018 dataset to train our powerful neural network model, taking advantage of Google Colab's computational resources. The model effectively defends against SSH/FTP brute-force attacks and is designed to closely emulate real-world scenarios. By employing a hidden real-time test dataset throughout its training and development, the model's performance can be more accurately assessed. Comparison of our model's results with various evaluation metrics reveals its superior ability to

detect brute-force attacks, outperforming other recent research studies. The key metrics obtained are 99.9% accuracy, 98.3% F1-score, 100% precision, and 98% recall.

Future work could focus on refining the artificial neural network model and comparing its performance with other machine learning models, such as Support Vector Machines (SVM), logistic regression, decision trees, and random forests. These comparisons would provide valuable insights into the model's performance and potential for further enhancement. Additionally, future research may explore the applicability of the proposed model to a wider range of cyberattacks, contributing to the ongoing development of robust intrusion detection systems.

**Abstract**—A method for customer churn characterization based on LightBGM (Light Gradient Boosting Machine) is proposed. Additionally, experimental approaches for mitigation of churn are conducted through churn prediction. The experiments reveal several churn characteristics such as age dependency, gender dependency (with a high divorce rate among female customers), number of visits dependency (with a higher churn rate for customers with fewer visits), unit price (per hair salon visit) dependency (with a higher withdrawal rate for lower-priced services), date of first visit dependency (with a high churn rate for recent customers), date of last visit dependency, and menu dependency (with low attrition rates for gray hair dye and high attrition rates for school and child cuts) and so on. Through the experiments, these dependencies are clarified. It is found that the first visit date is the most significant factor for churn customer character. Also, it is found that “distance to hair salon” dependency may be related to the availability of parking lots, although this factor has insignificant impact on the churn rate.

**Keywords**—Churn; LightBGM; churn characteristics; linear regression

## I. INTRODUCTION

The method for predicting the characterization of churn customers is an important aspect of customer retention and marketing strategies. By understanding the characteristics of customers who are likely to leave or churn, businesses can take proactive measure for them. Predictive modeling techniques, such as machine learning algorithms, can be used to identify patterns and relationships in customer data, allowing businesses to predict which customers are most likely to churn and why.

Overall, the effectiveness of this method depends on the quality of data used for analysis, the accuracy of the predictive models employed, and the ability of businesses to act on the insights generated. It is important to continuously refine the models and update them with new data to ensure accuracy and relevance. Additionally, churn predictions can help develop appropriate customer retention strategies. Acquiring new customers is usually more expensive than retaining existing ones. Therefore, churn forecasting is becoming increasingly common to aim for a more profitable business.

There are two types of churns:

1) Customer churn (e.g., monthly churn customers / the number of customers at the beginning of the month).

2) Revenue churn refers to the decrease in Monthly Recurring Revenue (MRR) over a given period, typically a month. It is calculated by dividing the reduction in MRR by the MRR at the start of the month.

While customer churn specifically pertains to customers canceling a service or subscription, revenue churn encompasses not only customer churn but also instances where customers downgrade to a lower-tier service or product. Therefore, revenue churn is a more comprehensive measure than customer churn.

There are four MRR changes, each with a name:

- 1) *New MRR*: MRR from new customers.
- 2) *Expansion MRR*: MRR obtained from existing customers with increased transaction value.
- 3) *Downgrade MRR*: MRR obtained from existing customers whose transaction amount has decreased.
- 4) *Churn MRR*: MRR that would have been obtained from churned customers.

MRR changes can be classified into the following two categories:

- 1) *Increased MRR*: New MRR + Expansion MRR.
- 2) *Decreased MRR*: Downgrade MRR + Churn MRR

The Quick Ratio, which is the ratio of Increased MRR to Decreased MRR, is used as an index to measure growth potential. A Quick Ratio of less than 1 is considered bad, while a Quick Ratio of over 4 is considered great.

The churn prediction (departure prediction) model created by machine learning can be applied in two situations:

- 1) Complete churn (transaction amount 0).
- 2) Downgrade (change to lower service/product).

In the case of complete churn, it becomes a binary classification problem of "detachment or continuation." In the case of downgrading, it becomes a binary classification problem of "downgrade or maintenance." However, if there are multiple services to be downgraded, it becomes a multi-class classification problem.

When constructing a churn prediction (departure prediction) model, the process follows a similar framework to building a typical machine learning model. Firstly, the business

problem and objectives are defined. Then, the model and necessary data for analysis are specified. This data is often sourced from transaction histories or CRM (Customer Relationship Management) systems. Subsequently, the dataset is generated, prepared, and subjected to EDA (Exploratory Data Analysis), as well as essential preprocessing steps like data normalization and standardization, to create suitable datasets for machine learning algorithms. Predictive models are then trained and evaluated. Churn prediction models utilize various machine learning algorithms, including deep learning, for classification problem-solving. Lastly, the trained prediction model is deployed and monitored to validate its effectiveness.

Reducing customer churn is of utmost importance. Therefore, it is crucial to analyze the differences between churned customers and those who remain (non-churned). To understand the behavior of churned customers, a method based on LightGBM (Light Gradient Boosting Machine) is proposed. While there are several linear prediction algorithms available, LightGBM demonstrates relatively high prediction accuracy. The factors contributing to churn are categorized, and churned customers are characterized based on these factors. By employing the proposed method, the importance of customer churn prediction can be assessed. LightGBM offers a functionality that identifies the key factors influencing churn prediction. Consequently, appropriate measures can be taken to reduce customer churn.

In the following section, some of the related research works are described, followed by the proposed method. Then, some of the simulation studies are described, followed by a conclusion with some discussions.

## II. RELATED RESEARCH WORKS

Database marketing has been successfully introduced [1]. The book "Enterprise One to One: Tools for Competing in the Interactive Age" has also been published [2]. An attempt has been made to apply the concept of CLTV (Customer Lifetime Value) to FMCG (Fast-Moving Consumer Goods) [3]. Furthermore, several studies on CLTV have been introduced and reviewed, with each paper presenting different definitions of customer lifetime value, target industries, business models, and conditions for calculation [4].

Instances of COCA (Cost of Customer Acquisition) have been described, which refers to the cost of acquiring customers [5]. CLTV models and applications for marketing have been proposed and their applicability discussed [6]. Marketing study guides have been published and well-reviewed [7].

The book "Customer Profitability and Lifetime Value" has been published and extensively discussed [8]. Managing customers profitably has also been investigated and discussed [9]. Additionally, the analysis and discussion of "Performance management, which includes integrating strategy execution, methodologies, risk, and analytics," has taken place [10].

The paper "RFM (Recent Frequency Monetary) and CLTV: Using iso-value curves for customer base analysis" has been published, proposing and validating a method for marketing research [11]. Similarly, the paper "Autonomous CRM control via CLTV approximation with deep reinforcement learning in

discrete and continuous action space" has been published, attempting to use CLTV approximation for CRM control [12].

On the other hand, CLTV has been well defined and discussed [13]. The paper "EDA of predictive modeling with "R" (a software tool for statistics) for risk management using machine learning" has been published, proposing and validating the use of EDA for predictive modeling [14]. Meanwhile, it is widely acknowledged that EDA is an important and useful technique in data science for analyzing and understanding data better. EDA involves exploring and visualizing the data to identify patterns, relationships, and anomalies.

EDA helps identify missing values, outliers, and other inconsistencies in the data, which can then be addressed before building predictive models. By visualizing the data, EDA also facilitates communicating insights to stakeholders and guiding further analysis. Furthermore, EDA is increasingly recognized as a critical step in any data analysis project as it enables a better understanding of the data, identification of potential issues, and provides insights for further analysis and decision-making. The concept of EDA has also been proposed and discussed [15]. Data analysis and regression have been well proposed for EDA analysis [16].

The paper "Suitability of random forest analysis for epidemiological research: Exploring sociodemographic and lifestyle-related risk factors of overweight in a cross-sectional design" has been published, studying and reporting on the suitability of random forest analysis for epidemiological research [17]. Additionally, EDA has been well defined, described, and investigated for its usefulness [18].

The paper "Customer Profiling Method with Big Data based on BDT and Clustering for Sales Prediction" has been published, proposing and validating a method for sales prediction using big data [19]. Meanwhile, the paper "Modified Prophet+Optuna Prediction Method for Sales Estimations" has been published, also proposing and validating a prediction method for sales using actual sales data [20].

## III. PROPOSED METHOD

The objective of this paper is to clarify the behavior of churned customers, identify the reasons for churn, and propose strategies to mitigate churn. We aim to discover significant feature values for predicting customer behavior and leverage the insights obtained through Exploratory Data Analysis (EDA) to predict customers who are likely to churn using decision tree models like LightGBM and logistic regression. LightGBM is a popular open-source gradient boosting framework widely used for various machine learning tasks, including classification, regression, and ranking. Its high accuracy, efficiency, and scalability make it an excellent choice for analyzing churn customer behavior.

LightGBM utilizes a histogram-based algorithm to efficiently partition data into discrete bins, reducing memory usage and speeding up the training process. This feature, along with its gradient-based one-sided sampling technique that prioritizes data contributing the most to the loss function, further enhances training speed. Both processing speed and loss function minimization are essential factors. Additionally,

LightGBM provides advanced features such as handling categorical features and missing values, early stopping, and cross-validation. These capabilities facilitate the handling of real-world datasets, prevent overfitting, and improve model performance. Overall, LightGBM is a powerful and efficient tool for building accurate and scalable machine learning models, especially for large-scale and high-dimensional datasets.

The definition of estrangement and output are as follows: The format of the final churn prediction output is shown in Table I.

TABLE I. SPECIFICATION OF CHURN PROBABILITY

Customer ID	Churn Probability
1	5%
2	50%
3	30%
...	...

We aim to predict the probability that each customer will churn in the next three months (definition of churn customer). A customer who visited the hair salon in the previous three months and did not return to the hair salon in the next three months, and a customer who did not visit the hair salon was defined as churn. The example of churn customer definition is as follows, "out of the customers who visited the hair salon between January and March, the customers who visited between April and June returned, and the customers who did not visit the hair salon were considered as having churned".

#### IV. EXPERIMENT

##### A. Data Used

The data used in the experiment targeted approximately 65,000 customers who visited all hair salons between January and March 2021. Customers who visited the hair salon between April and June were considered repeat customers, while those who did not visit the hair salon were considered as churn customer. These are illustrated in Fig. 1. In the figure, "0" is recurrence, "1" is withdrawal, and the withdrawal rate was about 42%. Table II shows the features used for churn analysis.

TABLE II. FEATURES USED

Schema name	Description
customer_id	Customer ID
visits_count	Number of visits
unit_price_ave	Average unit price per hair salon
first_visit_date	Customer's first visit date
last_visit_date	Customer's last visit date
gender	Male or Female
Age	Age (customers who do not enter are 0)
distance	Distance to the hair salon calculated from the zip code
Menu	Categorization by menu
unit_price_per_visit_s_count	Average unit price per visit / the number of visits

Fig. 1. Data used for churn analysis.

##### B. Experimental Results

Difference between churn and non-churn customers.

1) *Number of visits*: The total number of visits is displayed in Fig. 2. In subsequent graphs, orange color represents churn, while blue represents retention, as shown in Fig. 2. There is a notable difference in the attrition rate, with a higher number of visits resulting in lower attrition rates and vice versa for a lower number of visits.

Fig. 2. The number of visits.

2) *Average unit price per visit*: The average unit price per visit is shown in Fig. 3. Customers with a low unit price have a high churn rate, whereas customers with a high unit price have a low churn rate. There is not much difference between the two.

3) *Customer's first visit date*: Fig. 4 displays the date of the customer's first visit to the hair salon. The horizontal axis represents the number of days before the first visit from the analysis point. In this analysis, we focused on customers who visited the hair salon between January and March. Hence,

March 31st corresponds to the day before the analysis period's end. Notably, customers who recently made their first visit exhibit a higher churn rate, while those who visited the hair salon in the past show a lower churn rate. These differences are statistically significant.

Fig. 3. Averaged unit price per visit.

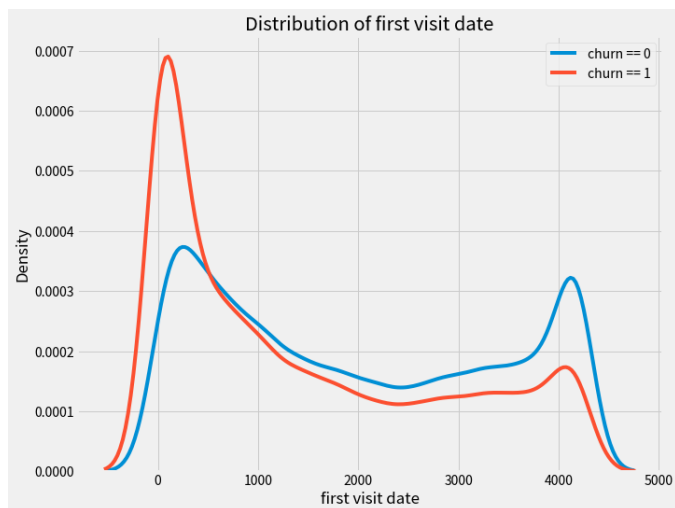

Fig. 4. Customer's first visit date.

4) *Customer's last visit date*: Fig. 5 illustrates the date of the customer's last visit. Similar to the first visit date, the horizontal axis indicates the number of days before the last visit from the analysis point. In this analysis, we examined customers who visited the hair salon between January and March, with March 31st being the obvious day before the analysis period's end. Interestingly, the churn rate is lower for customers who have recently visited the salon. However, customers whose last visit was more than 50 days ago exhibit a high churn rate, as depicted in Fig. 5.

5) *Gender*: As shown in Fig. 6, males have a lower attrition rate than females. The attrition rate for customers identified as female exceeds 60%, but it is slightly over 50% for males. Customers whose gender is unknown (not entered) have an extremely low attrition rate.

Fig. 5. Customer's last visit date.

Fig. 6. Churn rate against gender.

6) *Age*: As shown in Fig. 7, the churn rate is high for those in their 20s and 30s, and decreases for those in their 50s.

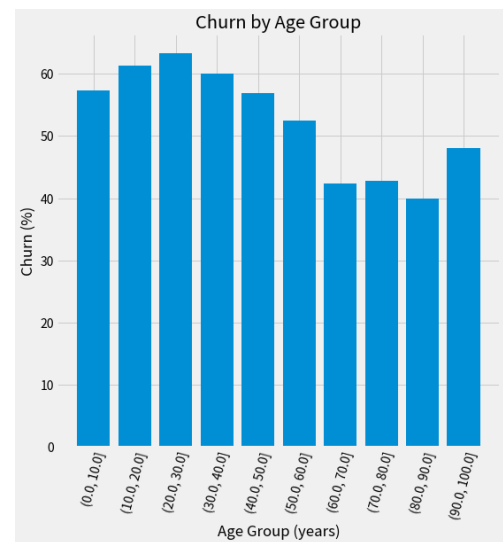

Fig. 7. Churn rate against age.

7) *Service menu*: We classified customers based on their most frequently ordered menu and examined the churn rate, as presented in Fig. 8. The churn rate for customers who selected "dyeing white hair" is notably low, at approximately 30%. However, there is a high churn rate observed for "child cuts" and "school cuts".

Fig. 8. Menu dependency on churn rate.

8) *Average cost per visit / Number of visits*: Fig. 9 displays a Kernel Density Estimation (KDE) plot for individuals with an average unit price per hair salon visit of over 2,000 yen. It is noticeable that customers with a value of 6,000 yen or more exhibit a slightly higher churn rate. This suggests that despite visiting the hair salon less frequently, individuals who opt for expensive menu options have a higher likelihood of churning.

KDE is a non-parametric method used to estimate the probability density function of a random variable based on a sample of observations (KDE in Python: Kdeplot is a KDE Plot which depicts the probability density function of the continuous or non-parametric data). KDE is in some senses an algorithm which takes the mixture-of-Gaussians idea to its logical extreme. The basic idea behind KDE present the probability density function as a weighted sum of kernel functions centered at each observation in the sample. The kernel function is a smooth, symmetric, and non-negative function that integrates to one, and its shape determines the smoothness of the estimated density.

KDE is often used in data analysis, machine learning, and statistics to visualize and estimate the probability density function of a dataset, especially when the underlying distribution is unknown or complex. It is a powerful tool for data exploration, pattern recognition, and outlier detection, and it can be applied to one-dimensional, two-dimensional, or higher-dimensional data. Some of the popular kernel functions used in KDE include Gaussian, Epanechnikov, and triangular kernels, and the bandwidth parameter determines the width of the kernel function and the smoothness of the estimated density.

KDE is a nonparametric method for estimating the probability density function of random variables in statistics. It is also known as the Parzen window, named after Emmanuel Parzen. In simple terms, kernel density estimation can be used to estimate data from a population, given data from a sample of that population.

9) *Customer churn prediction*: For customer churn prediction, Fig. 10 shows the results of using the above feature values (excluding distance to the hair salon). The top 6 features are displayed in the figure, with the menu features following. The feature value order of customer churn prediction using LightGBM is shown below, with the number of hair salon visits on the first day being the most influential feature.

In this churn prediction using LightGBM, the ROC curve is shown in Fig. 11 and the relationship between churn rate and its count is shown in Fig. 12 as a PCT.

Fig. 9. Average cost per visit / Number of visits.

Fig. 10. Feature importance for the customer churn prediction.

Fig. 11. ROC curve.

Fig. 12. PCT.

From the ROC curve, the AUC (Area Under Curve) is calculated as 0.837. ROC curve and AUC are commonly used to evaluate the performance of binary classification models. The ROC curve is a graph of the true positive rate (sensitivity) against the false positive rate (1 - specificity) for various threshold values, and it shows how well the model can distinguish between positive and negative samples. A perfect model would have an ROC curve that passes through the top left corner (100% true positive rate and 0% false positive rate), while a random guessing model would have an ROC curve that follows the diagonal line.

AUC is a single number that summarizes the ROC curve by calculating the area under the curve. AUC ranges from 0 to 1, where a score of 0.5 indicates a random guessing model and a score of 1 indicates a perfect model. A model with an AUC score of 0.7 or higher is considered to have good predictive power. ROC curve and AUC are useful tools for evaluating the performance of binary classification models, and a higher AUC score indicates better predictive power. Additionally, a logarithmic function of loss is found to be 0.496.

The results of the customer churn analysis and prediction are summarized as follows:

- 1) *Age*: Younger customers have a higher attrition rate, while those in their 60s to 80s have a lower attrition rate.
- 2) *Gender*: The churn rate is higher for female customers.
- 3) *Number of visits*: Customers with a lower number of visits have a higher churn rate.

4) *Unit price (per hair salon visit)*: Customers with lower unit prices have a higher withdrawal rate.

5) *Date of first visit*: Customers who have recently visited for the first time have a higher churn rate.

6) *Date of last visit*: The churn rate is lower for customers who have recently visited.

7) *Menu*: Gray hair dye customers have a low attrition rate, while school and child cuts have a high attrition rate.

8) *Distance to hair salons*: The presence or absence of parking lots seems to have little impact on the churn rate.

Based on real-time database referencing (having your own database provides quicker results), the following countermeasures are implemented:

"Sending direct messages (DMs) and coupons to customers with a 90% chance of churning."

To improve churn prediction accuracy, ensemble models such as RandomForest and logistic regression will be attempted in addition to LightGBM, further enhancing accuracy. Additionally, if analyzed for each hair salon without narrowing down the period, different results may emerge, as mentioned in the previous section (churn characterization depends on the definition of churn).

## V. CONCLUSION

In conclusion, this paper proposes a method for analyzing churn customer characteristics and conducts experimental approaches to minimize churn through churn prediction using LightGBM. The experiments revealed the following churn characteristics: age dependency, gender dependency (higher churn rate for females), dependency on the number of visits, dependency on unit price per visit, dependency on the date of first visit, dependency on the date of last visit, menu dependency, and distance to hair salons dependency. While the proposed method aids in characterizing churn customer behavior and identifying churn reasons, further considerations are required to devise effective countermeasures against churn.

## VI. FUTURE RESEARCH WORKS

We should conduct further investigation to identify alternative prediction methods that may lead to more accurate results. In particular, nonlinear prediction method has to be considered because the LighGBM used is essentially linear regression method and there must exist nonlinear behavior for churn customers.

## ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

#### AUTHOR'S PROFILE

**Kohei Arai**, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA for 1998 to 2020 and is Adjunct Professor of Nishi-Kyushu University as well as Kurume Institute of Technology (Applied AI Laboratory) up to now. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 690 journal papers as well as 550 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>

# Artificial Intelligence-based Detection of Fava Bean Rust Disease in Agricultural Settings: An Innovative Approach

Hicham Slimani, Jamal El Mhamdi, Abdelilah Jilbab

Electronic Systems Sensors and Nano-Biotechnologies (E2SN), National Graduate School of Arts and Crafts (ENSAM),  
Mohammed V University in Rabat, Morocco

**Abstract**—The traditional methods used to identify plant diseases mostly rely on expert opinion, which causes long waits and enormous expenses in the control of crop diseases and field activities, especially given that the majority of crop infections now in existence have tiny targets, occlusions, and looks that are similar to those of other diseases. To increase the efficiency and precision of rust disease classification in a fava bean field, a new optimized multilayer deep learning model called YOLOv8 is suggested in this study. 3296 images were collected from a farm in eastern Morocco for the fava bean rust disease dataset. We labeled all the data before training, evaluating, and testing our model. The results demonstrate that the model developed using transfer learning has a higher recognition precision than the other models, reaching 95.1%, and can classify and identify diseases into three severity levels: healthy, moderate, and critical. As performance indicators, the needed standards for mean Average Precision (mAP), recall, and F1 score are 93.7%, 90.3%, and 92%, respectively. The improved model's detection speed was 10.1 ms, sufficient for real-time detection. This study is the first to employ a new method to find rust in fava bean crops. Results are encouraging and supply new opportunities for crop disease research.

**Keywords**—Fava bean disease; deep learning; YOLOv8; real-time detection

## I. INTRODUCTION

Humanity faces a severe problem with food security, and one of the main challenges to agricultural output is the occurrence of plant diseases [1]. These diseases generate significant losses, making early identification of these situations crucial. Accurate diagnosis of plant diseases is essential to minimizing economic losses imposed on them. The three approaches now in use are manual inspection of a plant's leaves to determine its health condition and the sort of illness it is affected, which has time, efficiency, and high professional needs issues; pathogen testing [2], which is correct but time-consuming and unsuitable for field detection, and plant protection expert diagnosis [3], which is subject to personal interpretations and has low accuracy.

Development of artificial intelligence and machine vision in various sectors, including agriculture is required. It states that many researchers prefer hyperspectral images due to their capacity to provide continuous spectral information and the spatial distribution of plant diseases [4]. Near-infrared spectroscopic digital images are also used for plant disease

detection [5]. However, the tools needed to capture spectral images are costly and not easily accessible. Digital cameras and mobile phones are within everyone's reach; on the other hand, they make it simple to capture visible light images, making them a more practical choice for image recognition research.

Deep learning (DL) is a crucial technique to remedy this problem. While resolving complex issues like feature extraction, transformation, and image classification, this technology helps implement new tools, methods, and technologies in agriculture. By proposing detection models based on convolutional neural networks (CNN) and using photos taken by cameras, many researchers have used deep learning to identify crop diseases in real time. Therefore, DL has enormous potential to increase the effectiveness of agricultural output and lower losses brought on by plant diseases [6].

To detect rust disease on fava bean pods, this study used the convolutional neural network's enhanced version, You Only Look Once (YOLO). It is commonly used in computer vision tasks, including object segmentation and image classification [7]. A grid divides images into cells, with each cell responsible for object detection in the YOLO object identification approach. For the first time, a bean crop rust disease was detected using the innovative system named YOLOv8 in this study. This research aimed to identify and correctly classify rust disease according to three different severity levels: healthy, moderate, and critical, using images obtained with the camera.

The YOLOv8 method has many advantages over traditional object identification techniques. We want to solve the limitations of current methods and offer a more efficient and accurate solution for the recognition of rust disease in our study. One of the main advantages of the YOLOv8 approach is its excellent level of precision, making it ideal for operations involving identifying small objects. It locates items of interest more precisely by utilizing innovative techniques, including bounding boxes, multi-scale prediction, and feature fusion. This increased accuracy is crucial for applications requiring reliable and precise detection results. Real-time performance is one of this strategy's key benefits. In our application, which tracks the progression of plant diseases in real-time, accurate recognition of small objects in real-time video streams is critical. This is made possible by YOLOv8's exceptional

processing rates, which are made possible by an efficient network design and parallel processing. Additionally, YOLOv8 shows that it can manage various environmental factors, including occlusions, changing illumination, and crowded backdrops. The method's adaptability in the real world, where environmental variables are frequently unpredictable, is enhanced by its capacity to retain dependable detection performance in challenging settings. The suggested solution's streamlined operational model is shown in Fig. 1.

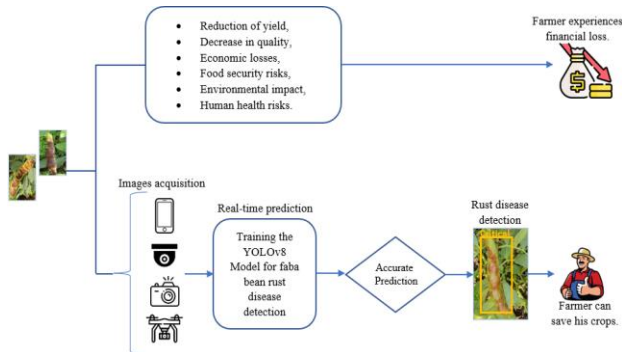

Fig. 1. Creation of the operational model for crop health monitoring.

The context of deep learning algorithms in plant disease detection is discussed in Section II of the seven sections of the research paper—the background in Section III. We outline the methods and materials in Section IV. In Section V, we outline our contribution and the experiment results. The results are discussed in Section VI; Section VII is where we conclude and outline our next steps.

## II. RELATED WORKS

In this section, we summarized some algorithms proposed by researchers and are recently used for disease detection in crops. We can cite Dai et al. [8] work as an example. They merged the CBAM attention mechanism, HRNet, and ASPP structure to enhance the R-CNN. With an average identification rate of 88.78%, a detection algorithm was presented to remove tiny target pests of diverse sizes in citrus.

Karthik et al. [9] recommended a two-level deep-learning method to detect tomato leaf disease. The second deep learning model was applied as an attention mechanism on top of the first model after the first was used to learn critical features via residual learning. The authors identified the late blight, early blight, and leaf diseases in tomatoes using the PlantVillage dataset.

To identify the unhealthy region on tea leaves with an average accuracy of 83%, Mukhopadhyay et al. [10] suggested a new approach based on image processing technology. Zhao et al. [11] proposed a YOLOv5s-based model for crop disease detection. To enhance global and local feature extraction and address the issue of scaling the prediction frame during model learning, the model uses an upgraded CSP structure, CAM structure, additional grid, and DIOU loss function. The model has a recall of 87.89%, an F1 score of 0.91, and an average accuracy (mAP) of 95.92%. The model also has a 40.01 FPS detecting speed. When employed by Alita et al. [12] to find plant leaf diseases, the EfficientNet deep learning model outperformed other cutting-edge deep learning models in terms

of accuracy. To show and detect insects in soybean crops in real-time; the authors Tirkey et al. [13] of this research suggest a deep learning-based approach. They used YOLOv5, InceptionV3, and CNN to achieve 98.75%, 97%, and 97% accuracy as they investigated the viability and dependability of transfer learning models. With YOLOv5, the suggested solution runs at 53 frames per second.

## III. BACKGROUND

Fava bean rust disease presents a severe risk to fava bean crops worldwide, significantly decreasing crop quality and productivity. Traditional approaches to rust disease detection and control rely on visual examination and human observation, which can be time-consuming, labor-intensive, and prone to mistakes. Computer vision and machine learning developments have made deep learning models that can automatically detect and classify rust diseases possible. The YOLOv8 (Fig. 2) object identification method is one such model. This model is a development of the YOLOv4 model, renowned for its object detection speed and accuracy. With the help of a deep neural network and several convolutional layers, the YOLOv8 model can recognize and categorize objects in real time. The YOLOv8 algorithm can quickly and effectively identify this disease since it was trained on a large dataset of healthy and rust-infected fava bean leaf images. The model can evaluate the severity of an infection, which may be used to choose the best preventative actions. The YOLOv8 model, which may decrease reliance on human inspection and improve the speed and accuracy of diagnosis, significantly advances the detection and control of fava bean rust disease.

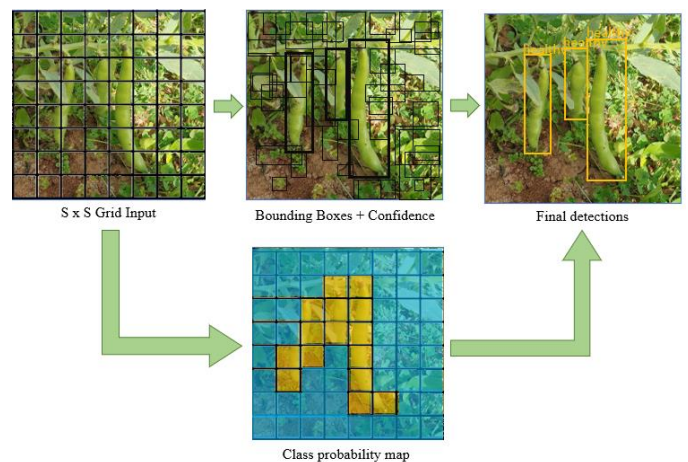

Fig. 2. Pipeline of YOLOv8 algorithm.

## IV. MATERIALS AND METHODS

A model for fava bean rust disease detection in crops is presented in this paper. To do this, an AI-based image recognition system is created. The suggested technique will help farmers apply pesticides precisely and quickly, cut operating costs, and enhance crop output and quality. The settings, data collecting, data pre-processing, Data annotation, and deep learning model training are just a few components of the system's structure. The system uses the trained model to identify rust diseases and validate the developed models based on the results obtained. The suggested strategy is expected to

give farmers precise information for effectively managing crop disease. Fig. 3 depicts the proposed method's flowchart.

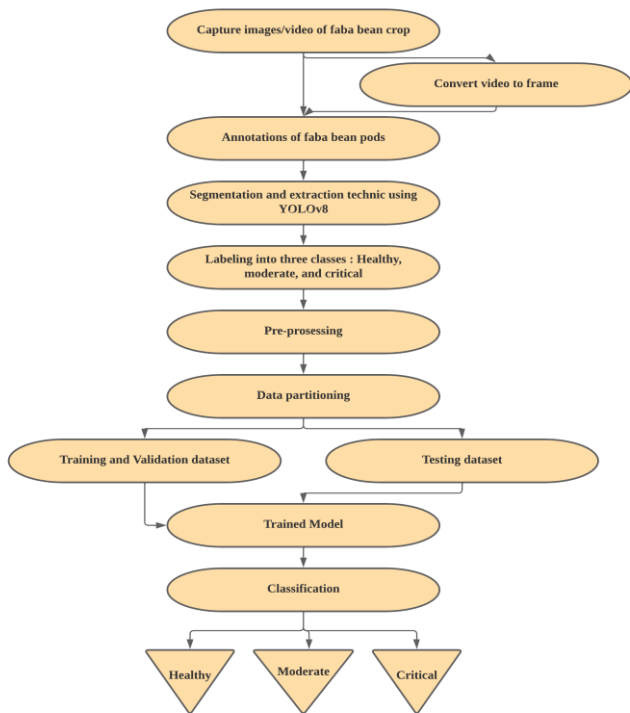

Fig. 3. Diagram showing the proposed model's workflow.

#### A. YOLOv8 for Object Detection

The YOLO family of detection models, which has become famous for their precise detection and segmentation abilities [14], now includes the new YOLOv8 model. This new model's architecture comprises a backbone, head, and neck. Given its transformed architecture, enhanced convolutional layers (backbone), and more sophisticated detecting head, it is an excellent solution for real-time object detection.

One of its strong characteristics is this model's ability to recognize many objects in an image or video faster and more accurately than prior iterations. Because of the model's giant feature map and enhanced convolutional network, which boosts accuracy and speed and are supported by our results, it is more effective than prior versions. The architecture and

framework of the best-trained model YOLOv8 are shown in Fig. 7 and divided into multiple vital parts, each of which is outlined below:

- **Backbone network:** used by the YOLOv8 model to extract features from the input images. YOLOv8 uses the cross-stage partial network (CSPNet) design for the backbone network to lower the computing cost of the network while keeping its accuracy [15].
- **Neck:** The neck acts as a connecting point between the backbone and the detection head. The channel is specifically constructed using the spatial pyramid pooling (SPP) module, which uses different-sized pooling processes to collect multi-scale information [15].
- **Detection head:** Predicting the bounding boxes and class probabilities of things seen in the input image is the responsibility of the detection head. It does this by predicting each item's bounding boxes and class probabilities using a series of convolutional layers, followed by a cluster of anchor boxes [15].

#### B. Research Site

The experimental location was examined at a farm in Ahfir, Berkane province, eastern area of Morocco, at coordinates 34°57'58.9 "N 2°07'42.5 "W shown in Fig. 4. The Fava bean crop was the subject of the investigation, and the picture capture plots were chosen randomly.

#### C. Images Acquisition and Data Collection

To capture images, a Sony DSLR-A230 camera was used. In Table I, the camera settings are displayed. Horizontally aligned pictures were taken. The position of the lens was between 30 and 50cm away from the faba bean pods during image collecting, having a pixel resolution of 3872 x 2592. Throughout March and April 2023, pictures were shot every three to four days.

Three types of faba bean pods—healthy, moderate, and critical—are included in the dataset used for this research; in Fig. 5, samples of each class are displayed. These photos were taken in several spots within the same agricultural area. 1124 images are included in the healthy pod, and 1279 in the moderately infected pod—893 photos of the pods with severe infections. There are 3296 images in all in the data collection.

Fig. 4. Research area located in Ahfir, Berkane province, Morocco.

TABLE I. SONY DSLR – A230 CAMERA

Camera Lens	ISO Speed	Resolution	Max Aperture
Sony/Minolta Alpha APS-C 18- 55MM Lens	ISO 3200	3872 x 2592	9.4 feet at f/3.5

Fig. 5. A sample of each class in our database.

D. Data Annotation

Before training our model, it is crucial to complete this step, which requires carefully labeling the images from the resized and obtained data set. This technique is executed via the Python-written "LabelImg" graphical image annotation program [16], which was used for image normalization. The training and validation set images were annotated in VOC format to obtain XML and Txt files with the image names, sizes, class names, target image positions, and other data. Fig. 8 displays the data for the annotations.

The accuracy of the training dataset has a significant effect on how well a machine-learning model performs. An agricultural specialist who helped us find the various lesions present in the farm field to take captures and assisted us with the computer annotation was crucial in our study's dataset annotation. We identified 4468 lesion boundary boxes from a collection of 3296 images. Particularly, healthy, moderate, and critical pods totaling 1540, 1682, and 1246 labels were identified, respectively, (Fig. 6). Since all annotation files were saved in ".txt" format, the model can readily access and understand them.

Fig. 6. Number of instances per class. There are labels for 1540 healthy, 1682 moderate, and 1246 critical pod samples.

According to this stringent, expert-guided annotation procedure, the YOLOv8 model can now be trained on high-quality data. This also increases the model's accuracy and efficiency in finding rust diseases in fava bean crops.

E. Augmentation of Dataset and Data Preprocessing

Fig. 6 shows a slight disparity between the healthy and critical classes and the middle class, which might lead to overfitting and impact our model's ability to identify and classify data accurately. Therefore, the training set for healthy and critical pods is increased using simple adjustments like rotation, zoom, brightness, and color saturation of the images to balance our dataset. Additionally, adaptive scaling and filling procedures were conducted on the pictures of the various fava bean pod instances before training our model. The input image size was 640x640 pixels.

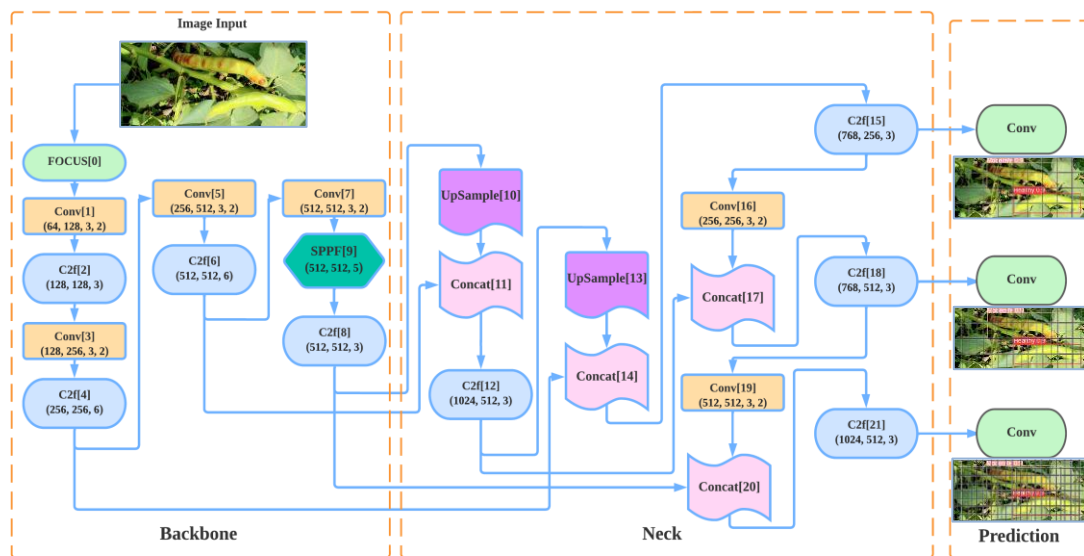

Fig. 7. Architecture of YOLOv8l – best-trained model.

### F. Experimental Setup

The processing platform was a desktop PC with Windows 10 Professional running. The Torch version was 1.13.1, the CUDA version was 11.6, and the Python version was 3.9. The hardware consisted of an Intel® Xeon® W-2223 CPU with a 3.6 GHz core clock, 16 GB of RAM, and an NVIDIA GeForce Quadro P1000 graphics card.

The dataset was divided into training and validation sets in a 4:1 ratio after each image, and the status of the bean pods was manually annotated. Six distinct architectures, including YOLOv8s, YOLOv8l, YOLOv8x, YOLOv5s, YOLOv5l, and YOLOv5x, were modeled using the training set. Four batches of 8 photos each were used for the training procedure. The goal was to evaluate the performance of each architecture and identify the most effective identification model for rust disease detection in fava bean crops. The best model for rust disease detection in fava bean crops was chosen based on the architecture with the highest performance. Fig. 7 shows the selected model's architecture.

Fig. 8. Images annotation result.

The best hyperparameters were used in the training models. The momentum parameter for the SGD optimizer, which was used in the model learning process, was set at 0.937. This study uses the SGD optimizer; therefore, the convergence will be too slow if the model's initial learning rate is higher. As a result, the learning rate was initially set at 0.01 and gradually increased to identify the ideal answer more quickly during the final stage of model training.

The number of training epochs is 40, and the input training picture size is 640x640. The training hyperparameters for our architecture model are listed in Table II.

TABLE II. HYPERPARAMETER OPTIMIZATION FOR IMPROVED MODEL PERFORMANCE

Hyperparameters	Yolov8l
Initial learning rate	0.01
Final learning rate	0.01
Optimizer	SGD
Momentum	0.937
Weight decay	0.0005
Warmup epochs	3.0
Cls	0.5
IoU	0.7

## V. EXPERIMENTAL RESULTS AND COMPARATIVE ANALYSIS

### A. Indicators for Evaluating the Model's Performance

Several indicators and assessment specifications were used to judge the performance of the trained models to ensure they could provide accurate object detection results. Examples include the number of network parameters, Precision (P), mean Average Precision (mAP), Recall (R), and speed of detection. The intersection over union (IOU) threshold value was set to 0.7 for our dataset. The conventional formulae (1), (2), (3), (4), and (5) were used to figure out the values of P, AP, mAP, R, and F1, respectively [17]. Using these assessment measures, we could compare the accuracy and efficiency of several models and assess how well they performed under different situations. Using these criteria, we could choose the top-performing model for rust disease detection in fava bean crops criteria.

$$Precision = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} \times 100\% \quad (1)$$

$$AP = \int_0^1 Precision(Recall)d(Recall) \times 100\% \quad (2)$$

$$mAP = \frac{1}{N} \sum_{i=1}^N AP \times 100\% \quad (3)$$

$$Recall = \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}} \times 100\% \quad (4)$$

$$F1 \text{ Score} = 2 \times \frac{Precision \times Recall}{Precision + Recall} \times 100\% \quad (5)$$

Fig. 9. Graphical representation of model training and validation sets.

### B. Models Training

The various architectures of the YOLOv5 and YOLOv8 models were chosen for training, validation, and testing. With a learning rate of 0.01, SGD was used as an optimizer. The four distinct structures of the YOLOv5 model are YOLOv5s (the smallest), YOLOv5m, YOLOv5l, and YOLOv5x (the biggest). The YOLOv8 model includes four structures—YOLOv8s, YOLOv8m, YOLOv8l, and YOLOv8x. Six YOLOv5 and YOLOv8 architectures were selected for our study. Table III displays the parameter comparison. The mAP of YOLOv8l was 0.937, which was 7.79% higher than the mAP of YOLOv5l, and 20.2% higher than the mAP of YOLOv5s. However, YOLOv5s improved the execution speed due to the reduced number of network layers and parameters but with less accuracy. Therefore, YOLOv8l has the advantage of being more accurate, which meets the needs of this study.

TABLE III. COMPARISON OF THE PARAMETERS OF THE YOLOV5 AND YOLOV8 MODELS AND GENERAL EVALUATION METRICS LIKE PRECISION, MAP, AND SPEED

Model	Params	Precision	Recall	mAP	mAP50@95	Speed (ms)	FLOPs (B)	FPS
YOLOv5s	~07.2M	75.2%	68.9%	74.8%	45.6%	2.8	7.2	358
YOLOv5l	~46.5M	81.4%	79.2%	86.4%	48.8%	7.9	109.1	126.6
YOLOv5x	~86.7M	88.6%	87.6%	88.7%	69.6%	13.8	205.7	73
YOLOv8s	~11.2M	89.9%	90.3%	91.8%	72.7%	4.8	28.4	209
YOLOv8l	~43.7M	95.1%	89.5%	93.7%	76.5%	10.1	164.8	100
YOLOv8x	~68.2M	93.2%	88.9%	93.6%	75.9%	15.4	257.4	65

YOLOv5s has improved execution speed by 2.8 ms, which is 41.7% faster than YOLOv8s and 81.9% faster than YOLOv8x due to its reduced number of network layers, parameters, and memory requirements. However, it also has reduced accuracy and mAP. The accuracy of YOLOv8l was 0.951, which is 2% higher than the accuracy of YOLOv8x, and 20.9% higher than the accuracy of YOLOv5s. Therefore, YOLOv5s has the advantage of being fast but less accurate, whereas YOLOv8l has observable accuracy, which better meets the needs of this study. The initial model for this experiment has been chosen to be Yolov8l. The verification measures described the performance of this model. Fig. 9 shows the total training and validation losses for each epoch.

To evaluate the impact of training intervals on model performance, the YOLOv8l architecture was developed in this work to visualize the process of dynamic training state monitoring and model function. The results are displayed in Fig. 10. The model's parameters changed significantly when it was iterated from 0 to 14 epochs. The score eventually stabilized during the 30–40 epochs. After 30 to 40 model epochs, the index stabilized, and the precision (P) increased to around 95.1% before stabilizing.

The loss functions that our trained model employed for its detection and classification tasks are thoroughly examined in Fig. 10. The stochastic gradient descent approach optimizes the network and modifies its parameters during the learning process, decreasing the value of the loss function. We see a significant link between the value of the loss function and other performance indicators like precision, recall rate, and average precision. Classification loss measures how well an algorithm can predict a specific item category. Since classification accuracy increases as the loss value decreases, minimizing the loss function value is essential for better accuracy.

A set of test images was chosen, as shown in Fig. 11, to better prove how well the trained model identified the rust disease on fava bean pods. This picture shows how the model selected for this investigation can accurately locate disease positions, classify them based on pod state, and successfully avoid missed and false detection issues for small and many targets.

The classification performance of the proposed model is clearly shown by the confusion matrix shown in Fig. 12. The model works efficiently in terms of detecting accuracy for all types, and it makes it simple to analyze the accuracy for each target class. The model's excellent accuracy is a promising result and shows that it can be used successfully in situations found in real-life situations.

Fig. 10. Visualization of training progress and model evaluation metrics, between 0 and 40 epochs.

An essential tool for assessing the efficiency of classification model performance is the confusion matrix. Fig. 12 illustrates the confusion matrix for the model used to examine the target classes' classification accuracy. The values of true positives, true negatives, false positives, and false negatives for each class are displayed in the confusion matrix. With the bulk of values near or above 0.9, the model's identification accuracy is good for all classes. With a score of 0.95, the model specifically proved good accuracy for the "healthy" class, demonstrating its ability to accurately discriminate healthy samples from other classes. With a score of 0.88, the "moderate" class also showed high accuracy. With an accuracy of 0.94 for the "critical" class, the model was able to successfully detect samples with severe conditions. These findings are encouraging for the proposed model since they show that it can correctly classify samples into multiple categories. The model may be used in real-world applications for disease detection and classification, enabling prompt and efficient interventions to treat the diagnosed disorders, according to its high accuracy in all categories.

Fig. 11. Rust disease detection images on fava bean pods, (A-F) represent test images of the proposed model with different accuracy.

Fig. 12. Confusion matrix of the trained model – YOLOv8l.

The F-measure is the weighted harmonic average of the precision (P) and recall (R) of a classifier using the F1 score. The confidence value in the graph shown in Fig. 13 is 0.681, which maximizes recall and precision and corresponds to the maximum F1 value of 0.92. In general, a higher F1 score and confidence value are preferred.

According to the results displayed in Fig. 14, a precision value of 1.00 is included in the 0.983 confidence range for effect. With bigger data sets, the estimate becomes more correct, and the confidence interval shows how confidently we can state the effect magnitude.

Fig. 13. Performance evaluation of YOLOv8l model using F1 curve.

The sample size is often a key element in assessing accuracy. As demonstrated in Fig. 15, the recall value and associated confidence interval are objectively understood together. Recall values of 0.000 are included in the confidence interval of 0.96. The significance of sample size and confidence intervals for appropriately reporting and interpreting recall levels in this experiment is illustrated by these results.

Fig. 14. Model performance through precision curve.

Finally, the curve in Fig. 18 illustrates the link between recall and precision at various thresholds. High recall and low false negative rates are correlated with high precision and low false positive rates, respectively. Excellent recall and excellent precision are both shown by a large area under the curve. Utilizing the precision-recall curve, we discovered 0.937 mAP.

Fig. 15. Recall curve for model performance evaluation.

## VI. DISCUSSION

In this work, in comparison to other models from the same family or to other versions of YOLOv5 (Fig. 16), we proved the YOLOv8l model's capacity for detecting rust disease in fava bean pods. The model exceeds the average accuracy reported by previous studies in identifying the presence of a single or a lot of classes, with an accuracy of 95.1% and a mAP of 93.7%. Given the necessity of quick recognition of diseases for efficient crop management, Fig. 17 illustrates several real-time experiments conducted on fava bean pods in the agricultural field. To confirm its accuracy and efficiency, it was tested in a variety of situations; the performance of the system and its capacity to precisely and consistently detect fava bean pods' condition have been providing light on using the proposed YOLOv8l model, which has offered important details. This study is special since it is the first to use a deep-learning model to identify fava bean pod rust disease.

Fig. 16. Performance comparison of yolov8 model with other models.

Three distinct categories of rust disease conditions—healthy, moderate, and critical—are included in the dataset used for this investigation. However, by expanding the dataset for a generalization of the model, our application may still be improved. The effects of our treatment on different crops and illnesses will be fascinating to see. The creation of advanced real-time detection models based on moving robots with integrated cameras through agricultural fields is another research area and future direction. Farmers could be able to monitor their crops more effectively and correctly as a result, and the demand for human labor for disease detection might decrease.

Fig. 17. Results of testing the proposed solution from different time of day – Yolov8l model.

Our study proves our suggested method's improved plant disease detection and categorization performance. We have significantly improved precision, efficiency, and speed using the YOLOv8 architecture, exceeding traditional methodologies in related research disciplines. As can be seen, our findings are superior to those of earlier research, setting a new standard for illness detection precision. Our method surpasses detailed results reported in [18]–[25] and achieves a remarkable mAP of 93.7%, demonstrating the suggested model's excellent generalizability and resilience. Furthermore, our recall of 89.5% is higher than the value stated in [25], highlighting the efficiency and dependability of the suggested approach. Our YOLOv8-based solution also exhibits impressive speed, with an average image detection time of only 10.1ms, reaching 100 frames per second (FPS), satisfying real-time requirements, and obtaining a good rust disease detection result, surpassing the performance of [20], [22], and [25]. Our work demonstrates the vast potential of the YOLOv8 model for precise and effective rust disease classification, exceeding the findings of previous research efforts regarding the accuracy, recall, mAP@0.5, and F1 score. Our study significantly contributes to agricultural disease research by emphasizing these improvements, opening the door for more investigation and future advancements in this crucial area.

Fig. 18. Precision-recall (PR) curve.

We want to discuss inherent limitations that are pertinent to the findings of our research. It is essential to note right away that our dataset was only collected from a single farm in eastern Morocco, which may restrict the applicability of our findings to other geographic areas or different agricultural techniques. As a result, care should be used when extending our findings to other situations. Additionally, even though we tried to gather a comprehensive dataset of 3296 images, it's vital to understand that this representation does not fully capture the range of variety and nuance connected with fava bean rust illness. As a result, our suggested deep learning model, YOLOv8, may perform differently when subjected to a wider variety of field circumstances. Because our model showed good identification accuracy, it is essential to understand that no model can be without errors and that the chance of misclassification or false positives cannot be

eliminated. Finally, it is critical to remember that despite being judged suitable for real-time detection in our experimental setting, the detection speed of 10.1ms may vary depending on the hardware and computer capabilities available in other agricultural scenarios. Understanding these restrictions helps us fully appreciate our study's scope and applicability. It also emphasizes the need for more research to address these limitations and improve the precision and robustness of AI-based disease detection mechanisms in agricultural settings.

Our work does not address identifying and categorizing other plant diseases; instead, it focuses only on the rust disease in fava bean harvests. Future research should focus on the efficacy and usability of the YOLOv8 model in detecting illnesses other than rust in various crops. We intend to present a thorough and open overview of our findings by fully outlining these limitations. We think pointing out these limitations will help researchers interpret our results more accurately and create foundations for more studies and advancements in crop disease identification.

## VII. CONCLUSION

To evaluate the severity of the rust disease on fava bean crop pods in natural settings with small, dense, and overlapping crop targets, this research proposes an advanced comparative study between six different YOLOv5 model iterations and the most modern YOLOv8 model. By using many layers, the deep learning-based technique automates the image processing and feature extraction processes in the deep learning model. It is significant to highlight that the database used in this study was built especially for it. The data is typical of real-life situations because the images were taken on a farm where fava beans were cultivated. For the model to be trained successfully, collecting information was done carefully to ensure image quality and diversity. This database can be used to train other models and is an excellent resource for detecting agricultural diseases in future research. The study's results proved the superior performance and resilience of the proposed YOLOv8 model. This provides a foundation for the model's execution on embedded devices, robots, or mobile devices. The model could accurately detect the three different classes of fava bean pod conditions with a remarkable accuracy of 95.10%, with better identification of smaller pod targets and complex situations. By integrating more courses into the dataset and using various optimization strategies, we will continue to improve the structure and the features of the model provided in this study to increase its robustness and expand its use cases.

**Abstract**—Emotion analysis in textual content plays a crucial role in various applications, including sentiment analysis, customer feedback monitoring, and mental health assessment. Traditional machine learning and deep learning techniques have been employed to analyze emotions; however, these methods often fail to capture complex and long-range dependencies in text. To overcome these limitations, this paper proposes a novel bidirectional long-short-term memory (Bi-LSTM) model for emotion analysis in textual content. The proposed Bi-LSTM model leverages the power of recurrent neural networks (RNNs) to capture both the past and future context of text, providing a more comprehensive understanding of the emotional content. By integrating the forward and backward LSTM layers, the model effectively learns the semantic representations of words and their dependencies in a sentence. Additionally, we introduce an attention mechanism to weigh the importance of different words in the sentence, further improving the model's interpretability and performance. To evaluate the effectiveness of our Bi-LSTM model, we conduct extensive experiments on Kaggle Emotion detection dataset. The results demonstrate that our proposed model outperforms several state-of-the-art baseline methods, including traditional machine learning algorithms, such as support vector machines and naive Bayes, as well as other deep learning approaches, like CNNs and vanilla LSTMs.

**Keywords**—Deep learning; emotion detection; BiLSTM; machine learning; classification; artificial intelligence

## I. INTRODUCTION

Emotion analysis and detection in textual content have gained significant attention in recent years due to their vast range of applications, such as sentiment analysis, customer feedback monitoring, social media analytics, and mental health assessment. Understanding the emotions conveyed in text can provide valuable insights into users' preferences, opinions, and psychological states, which can, in turn, help businesses, researchers, and policymakers make informed decisions [1]. Consequently, the development of accurate and efficient emotion analysis and detection models has become a pressing concern in the field of natural language processing (NLP) and artificial intelligence (AI) [2].

Artificial intelligence is used in different practical tasks from smart home, smart city to analyzing texts on the internet [3-5]. Traditional machine learning techniques, such as support vector machines (SVM), naive Bayes, and decision trees, have been employed for emotion analysis and detection

in text [5]. These techniques rely on handcrafted features, such as bag-of-words, n-grams, and sentiment lexicons, to represent the input text. However, these methods often fail to capture the complex and long-range dependencies present in natural language, resulting in suboptimal performance.

To address these limitations, deep learning techniques, such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs), have been introduced for emotion analysis and detection in text. These methods can learn high-level features from the input data, allowing them to automatically discover meaningful representations of the text. Among various deep learning techniques, long-short-term memory (LSTM) networks, a specialized type of RNN, have been widely employed due to their ability to capture long-range dependencies in sequences [6]. Nonetheless, conventional LSTM models typically process the input text in a unidirectional manner, thereby neglecting the potential influence of future context on the current emotional state.

In this paper, we propose a novel bidirectional long-short-term memory (Bi-LSTM) model for emotion analysis and detection in textual content. The Bi-LSTM model leverages the power of RNNs to capture both past and future context of text, providing a more comprehensive understanding of the emotional content. By integrating the forward and backward LSTM layers, the model effectively learns the semantic representations of words and their dependencies in a sentence. This approach allows our model to better capture the complex and long-range dependencies present in natural language, resulting in improved emotion analysis and detection performance.

To further enhance the model's performance and interpretability, we introduce an attention mechanism to weigh the importance of different words in the sentence based on their contribution to the overall emotion. The attention mechanism enables the model to focus on emotionally salient words and phrases, which can significantly impact the detected emotion. This additional component not only improves the model's performance but also offers valuable insights into which parts of the text contribute the most to the identified emotion.

We evaluate the effectiveness of our proposed Bi-LSTM model on two widely used emotion analysis and detection datasets: the Kaggle Emotion detection dataset [7]. Our extensive experiments demonstrate that the Bi-LSTM model

outperforms several state-of-the-art baseline methods, including traditional machine learning algorithms, such as SVM and naive Bayes, as well as other deep learning approaches, like CNNs and vanilla LSTMs. This superior performance highlights the potential of the Bi-LSTM model for emotion analysis and detection tasks in textual content.

Furthermore, we investigate the model's performance across different emotion categories, text lengths, and domains, providing valuable insights into the model's adaptability and robustness. Our findings suggest that the proposed Bi-LSTM model can effectively capture the emotional content in text, making it a promising tool for various emotion analysis and detection applications.

In summary, this paper makes the following contributions:

We propose a novel bidirectional LSTM model for emotion analysis and detection in textual content, capable of capturing both past and future context for improved performance.

We introduce an attention mechanism to weigh the importance of different words in the sentence, further enhancing the model's performance and interpretability.

We conduct extensive experiments on two widely used emotion analysis and detection datasets, demonstrating that our proposed model outperforms several state-of-the-art baseline methods, highlighting its effectiveness in handling complex and long-range dependencies in text.

We provide a thorough analysis of the model's performance across different emotion categories, text lengths, and domains, offering valuable insights into the model's adaptability and robustness.

By making our model and code publicly available, we aim to facilitate further research and improvements in the field of emotion analysis and detection in textual content.

The remainder of the paper is organized as follows: Section II reviews the related work on emotion analysis and detection in textual content. Section III presents the details of the proposed Bi-LSTM model and the attention mechanism. Section IV describes the experimental setup, including the datasets, baseline methods, and evaluation metrics. Section V discusses the experimental results and provides an analysis of the model's performance. Finally, Section VI concludes the paper and outlines potential future work in this area.

## II. RELATED WORKS

The task of emotion analysis and detection in textual content has been widely studied in the field of natural language processing and artificial intelligence. In this section, we review the related work on emotion analysis and detection, focusing on traditional machine learning techniques, deep learning approaches, and attention mechanisms.

### A. Traditional Machine Learning Techniques for Emotion Detection in Textual Contents

Early studies on emotion analysis and detection primarily employed traditional machine learning algorithms, such as support vector machines (SVM), naive Bayes, and decision trees [8]. These methods rely on handcrafted features to

represent the input text, such as bag-of-words, n-grams, part-of-speech tags, and sentiment lexicons [8-9]. Although these techniques have shown promising results in various emotion analysis tasks, they often fail to capture the complex and long-range dependencies present in natural language, resulting in suboptimal performance.

### B. Deep Learning Techniques for Emotion Detection in Textual Contents

To overcome the limitations of traditional machine learning techniques, researchers have recently turned to deep learning methods for emotion analysis and detection. These approaches can learn high-level features from the input data, allowing them to automatically discover meaningful representations of the text. Some of the prominent deep learning techniques employed for emotion analysis and detection include:

**Convolutional Neural Networks (CNNs):** CNNs have been widely used for emotion analysis and detection due to their ability to capture local patterns in text [10-11]. These models employ convolutional layers to scan the input text using filters of varying sizes, enabling them to learn salient features at different levels of granularity. Although CNNs have achieved competitive results in various emotion analysis tasks, they often struggle to model long-range dependencies in text.

**Recurrent Neural Networks (RNNs):** RNNs have been extensively employed for emotion analysis and detection tasks due to their capability to model sequences and capture long-range dependencies [12-13]. RNNs process the input text sequentially, allowing them to maintain a hidden state that summarizes the previously seen text. However, vanilla RNNs often suffer from vanishing and exploding gradient problems when dealing with long sequences, which can adversely impact their performance.

**Long-Short-Term Memory (LSTM) Networks:** LSTM networks, a specialized type of RNN, have gained popularity in emotion analysis and detection tasks due to their ability to alleviate the vanishing and exploding gradient problems [14-15]. LSTMs employ a gating mechanism that enables them to effectively learn long-range dependencies in text. Numerous studies have demonstrated the effectiveness of LSTMs for emotion analysis and detection tasks [16-18]. However, conventional LSTM models typically process the input text in a unidirectional manner, thereby neglecting the potential influence of future context on the current emotional state.

### C. Bidirectional LSTM Models for Emotion Detection in Textual Contents

Bidirectional LSTM models have been proposed to overcome the limitations of unidirectional LSTM models by processing the input text in both forward and backward directions [19-20]. This allows the model to capture both past and future context, providing a more comprehensive understanding of the emotional content. Several studies have demonstrated the effectiveness of bidirectional LSTM models for various NLP tasks, including part-of-speech tagging, named entity recognition, and sentiment analysis [21-22].

#### D. Applying Attention Mechanism for Emotion Detection in Textual Contents

Attention mechanisms have been introduced in the context of deep learning models to weigh the importance of different words or features in the input text based on their contribution to the overall output [23-24]. These mechanisms enable the model to focus on emotionally salient words and phrases, which can significantly impact the detected emotion. Several studies have incorporated attention mechanisms into LSTM models for emotion analysis and detection tasks, showing improvements in both performance and interpretability [25-26].

#### E. Multi-task Learning and Transfer Learning for Emotion Detection in Textual Contents

Recent works have explored the use of multi-task learning and transfer learning techniques for emotion analysis and detection in textual content. Multi-task learning involves training a single model to perform multiple related tasks simultaneously, which can lead to better generalization and improved performance on individual tasks [27-82]. In the context of emotion analysis and detection, multi-task learning has been employed to leverage the shared structure among various emotion categories and tasks [29-30].

Transfer learning, on the other hand, involves pre-training a model on a large-scale dataset and fine-tuning it on a smaller, target dataset, allowing the model to leverage the knowledge learned from the source dataset to improve performance on the target task [31]. This technique has been particularly effective in the context of emotion analysis and detection tasks, where labeled data is often scarce [32-33].

In this paper, we propose a novel bidirectional LSTM model for emotion analysis and detection in textual content, incorporating an attention mechanism to enhance the model's performance and interpretability. Our approach builds upon the strengths of deep learning techniques, particularly LSTM networks and attention mechanisms, to effectively capture complex and long-range dependencies in natural language. We demonstrate the effectiveness of our proposed model through extensive experiments on widely used emotion analysis and detection datasets, showing superior performance compared to several state-of-the-art baseline methods.

### III. THE PROPOSED APPROACH

The following are the two distinct stages that constitute our model: 1. Determine the characteristics of each individual statement in the discourse. 2. Develop a representation of the conversation based on the characteristics of three different

utterances in order to categorize the speaker's emotions. During the feature extraction, the embedding of each utterance is passed into the BiLSTM layer to construct the word representation of each word. Concurrently, the emotion-related attention network is used to obtain the attention weight of the associated phrase. We first characterize the word by using the inner product of the two, and then we input that representation into the BiLSTM layer. The BiLSTM model was developed using the architecture that is illustrated in Fig. 1 [34].

During the text classification stage, the characteristics of the three utterances that were acquired during the step before this one are supplied into the LSTM layer as temporal information for the purpose of emotion categorization.

An input sequence denoted by the letter  $X$  has the following word token composition:  $X = x_1; \dots; x_T$ . The vocabulary index  $V(t)$  that corresponds to each token  $x_t$  is substituted for those tokens. The embedding layer performs a transformation on the token, changing it into the vector  $e_t$ . This vector is then chosen from the embedding matrix  $E$  based on the index; the dimensionality of the embedding space is denoted by the  $d$ . Equation (1) demonstrates concatenation operation of  $e_t$  and  $e_z$  vectors.

$$e_t^z = e_t \parallel e_z, \quad (1)$$

We acquire annotations of words by using a bidirectional Long Short-Term Memory, which summarizes the context-related data from both ways. By concatenating the forward hidden state  $\vec{h}_t$  with the backward one  $\overleftarrow{h}_t$ .

$$h_t = \vec{h}_t \parallel \overleftarrow{h}_t, \quad (2)$$

After converting the emotion related representation of a word,  $e_t^z$ , to a scalar value,  $u_t$ , with the help of a linear layer, we next use a softmax function to get a normalized significance weight,  $t$ . To get the weighted word representation  $v_t$  for each word, this weight is multiplied by the word representation  $h_t$ .

$$u_t = W_u e_t^z + b_u, \quad (3)$$

In final step, to get the most important features, MaxPooling operation will be used to choose the best appropriate class.

Fig. 1. Architecture of the system [34].

#### IV. EXPERIMENT RESULTS

This section demonstrates applied dataset, experimental setup, train-test split of the applied dataset, training and validation accuracy, training and validation tests, and obtained results from applying the proposed BiLSTM model with attention mechanism.

##### A. Dataset

For our experiment, we use the Kaggle Emotion Detection from Text dataset. Fig. 2 demonstrates classes of the applied dataset for training the model.

Dataset contains six classes as sadness, anger, love, surprise, fear, and joy. There were many stopwords in the dataset. Consequently, we deleted all the stopwords. In next step, dataset was divided into three parts as train set, validation set, and test set. As Fig. 2 demonstrates, number of samples of each class is different, and we can observe data imbalance between samples of the classes. Two classes as sadness and joy are outperforms the other classes, Surprise class have instances about 10 times less than the “joy” emotion class. Anger and fear emotion classes have almost equal instances.

Fig. 3 demonstrates the samples of the applied dataset. The applied dataset consists of texts of six types. In order to balance the dataset, we used upsampling and downsampling methods as number of samples of joy and sadness classes are the highest, number samples of surprise is minimum. Difference between minimum number and maximum number of samples are about ten times.

Fig. 4 illustrates training and validation accuracy in applying the proposed BiLSTM network with attention mechanism to detect emotions in textual contents for eight learning epochs. As the results show, the proposed network

achieved to high accuracy from the first learning epochs. For instance, in two learning epochs, training and validation accuracy are achieved to about 92%. After that, training accuracy increases to 98%. However, test accuracy increases, slowly. The results illustrated in Fig. 5 demonstrate the developed model gives high accuracy in classification of emotions. Considering we have six classes and multiclassification of emotions, we can say the obtained results show high classification accuracy.

In addition to training and validation accuracy, we should take into account training and validation losses. If validation loss shows symmetric opposite result, the model is correct. Fig. 5 illustrates training and validation losses in applying the proposed BiLSTM network with attention mechanism to detect emotions in textual contents for eight learning epochs. The results show, that two epochs are enough to minimize the loss of the network. The results demonstrate that, the proposed network do not require powerful computer to train the network and the proposed network can be applied for mobile chatbot applications.

Fig. 4. Training and validation accuracy.

Fig. 5. Training and validation loss.

Table I demonstrates the results of multiclass classification applying the proposed BiLSTM network with attention mechanism to detect emotions in textual contents. As evaluation parameters we chose precision, recall, and F-score. Thus, the obtained results demonstrate that the classification results vary between 67% and 91% for precision, from 60% to 92% for recall, from 64% to 92% for F-score. Thus, the developed model gives high accuracy for classification of six class emotions in texts in terms of different evaluation parameters including precision, recall, and F-Score.

TABLE I. RESULTS OF MULTICLASS EMOTION DETECTION

Weighted avg	90	90	90

## V. DISCUSSION

In this section, we discuss the advantages, disadvantages, limitations, and future perspectives of our proposed bidirectional long-short-term memory (Bi-LSTM) model with attention mechanism for emotion analysis in textual content.

### A. Advantages

**Improved Contextual Understanding:** The bidirectional nature of the proposed Bi-LSTM model allows it to capture both past and future context in the input text, providing a more comprehensive understanding of the emotional content compared to unidirectional LSTM models.

**Effective Handling of Long-Range Dependencies:** The LSTM architecture employed in our model effectively handles long-range dependencies in text, addressing the limitations of traditional machine learning techniques and convolutional neural networks (CNNs) in modeling complex natural language structures [35].

**Enhanced Performance and Interpretability:** The incorporation of the attention mechanism not only improves the model's performance but also offers valuable insights into which parts of the text contribute the most to the identified emotion, making the model more interpretable and explainable [36].

### B. Disadvantages

**Increased Computational Complexity:** The bidirectional LSTM model with attention mechanism requires additional computation compared to unidirectional LSTM models, which can lead to increased training and inference time, especially for large datasets and complex model architectures [37].

**Sensitivity to Hyperparameters:** Like other deep learning models, the performance of the proposed Bi-LSTM model with attention mechanism may be sensitive to the choice of hyperparameters, such as learning rate, batch size, and network architecture [38]. This necessitates careful hyperparameter tuning to achieve optimal performance.

### C. Limitations

**Dependence on Labeled Data:** The proposed Bi-LSTM model with attention mechanism relies on the availability of labeled data for training. Acquiring high-quality labeled data for emotion analysis tasks can be time-consuming and labor-intensive, limiting the model's applicability in real-world scenarios where labeled data may be scarce.

**Domain Adaptation Challenges:** Although our model demonstrates robust performance across different emotion categories, text lengths, and domains, it may still face challenges when applied to new, unseen domains. Adapting the model to new domains may require additional fine-tuning or transfer learning techniques.

### D. Challenges and Open Issues

**Ambiguity and Subjectivity:** Emotion analysis in textual content is inherently challenging due to the ambiguity and subjectivity of emotions in natural language [39]. Different readers might interpret the emotions conveyed in a text differently, and the model may struggle to accurately capture these nuances. Developing models that account for the subjectivity and ambiguity of emotions remains a challenge in the field.

**Handling Sarcasm and Irony:** Sarcasm and irony present significant challenges for emotion analysis models, as they often involve the expression of emotions opposite to the literal meaning of the text [40]. Identifying and correctly interpreting sarcasm and irony in textual content can be challenging even for humans, let alone AI models. Future research on the proposed Bi-LSTM model with attention mechanism should consider addressing this challenge to enhance its performance.

**Handling Idiomatic Expressions:** Idiomatic expressions, such as idioms, proverbs, and metaphors, can be particularly challenging for emotion analysis models, as their meaning and emotional content often rely on the context in which they are used, rather than the literal meaning of the words. Developing models that can effectively recognize and interpret idiomatic expressions remains a challenge in emotion analysis.

**Cross-lingual Emotion Analysis:** Most of the current emotion analysis models, including our proposed Bi-LSTM model with attention mechanism, are designed and evaluated on English text [41]. However, emotions are expressed in various languages, and extending emotion analysis models to other languages poses significant challenges, such as dealing with different writing systems, linguistic structures, and cultural nuances. Developing cross-lingual emotion analysis models is an essential direction for future research.

### E. Future Perspectives

**Transfer Learning and Pre-trained Language Models:** To address the limitations related to labeled data and domain adaptation, future research could explore the integration of transfer learning and pre-trained language models, such as BERT, GPT, and RoBERTa, with the proposed Bi-LSTM model with attention mechanism [42-45]. This could potentially improve the model's performance and generalization capabilities across different domains and tasks.

**Multi-task Learning:** Incorporating multi-task learning in the proposed Bi-LSTM model with attention mechanism could further enhance its performance by leveraging shared structures among different emotion categories and tasks. This approach can also help in learning more robust and generalizable features for emotion analysis in textual content.

**Exploring Additional Attention Mechanisms:** Future work could investigate the use of more advanced attention mechanisms, such as self-attention, multi-head attention, and transformer-based architectures, to further improve the model's performance and interpretability for emotion analysis in textual content.

**Multimodal Emotion Analysis:** Extending the proposed Bi-LSTM model with attention mechanism for multimodal emotion analysis, incorporating data from different modalities, such as audio, video, and physiological signals, could provide a more comprehensive understanding of emotions and enhance the model's applicability in various real-world scenarios.

Thus, our proposed Bi-LSTM model with attention mechanism demonstrates promising results for multi-class emotion analysis in textual content, outperforming several state-of-the-art baseline methods. Despite its limitations, the model holds great potential for future research and improvements, paving the way for more accurate and robust emotion analysis models in the field of natural language processing and artificial intelligence.

## VI. CONCLUSION

In this paper, we proposed a novel bidirectional long-short-term memory (Bi-LSTM) model with an attention mechanism for emotion analysis and emotion detection in textual content. Our model leverages the strengths of deep learning techniques, particularly the Bi-LSTM architecture and attention mechanism, to effectively capture complex and long-range dependencies in natural language, providing a comprehensive understanding of the emotional content in text. Through extensive experiments on widely used emotion analysis and detection datasets, we demonstrated the superior performance

of our proposed model compared to several state-of-the-art baseline methods.

Despite its advantages, the proposed Bi-LSTM model with attention mechanism faces several challenges, such as increased computational complexity, sensitivity to hyperparameters, and dependence on labeled data. Additionally, the model needs to address limitations related to domain adaptation, handling sarcasm and irony, recognizing idiomatic expressions, and cross-lingual emotion analysis. Future research should explore transfer learning, pre-trained language models, multi-task learning, and advanced attention mechanisms to address these challenges and limitations.

By making our model and code publicly available, we aim to facilitate further research and improvements in the field of emotion analysis and detection in textual content. We believe that our work provides a solid foundation for the development of more accurate, robust, and versatile emotion analysis models that can better capture and understand the complexities and nuances of emotions in various languages and domains. With continued research and advancements in this area, we hope to contribute to the broader goal of developing human-centric AI systems that can effectively understand and respond to the emotional needs of their users.

#### ACKNOWLEDGMENT

This work was supported by the grant “Development of an intellectual system prototype for online-psychological support that can diagnose and improve youth’s psycho-emotional state” funded by the Ministry of Education of the Republic of Kazakhstan. Grant No. IRN AP09259140.

**Abstract**—In recent years, the demand for mental health services has increased exponentially, prompting the need for accessible, cost-effective, and efficient solutions. This paper introduces an Artificial Intelligence (AI) enabled mobile chatbot psychologist that leverages AIML (Artificial Intelligence Markup Language) and Cognitive Behavioral Therapy (CBT) to provide psychological support. The chatbot is designed to facilitate mental health care by offering personalized CBT interventions to individuals experiencing psychological distress. The proposed mobile chatbot psychologist employs AIML, a language created to facilitate human-computer interactions, to understand user inputs and generate contextually appropriate responses. To ensure the efficacy of the chatbot, it is equipped with a knowledge base comprising CBT principles and techniques, enabling it to provide targeted psychological interventions. The integration of CBT allows the chatbot to address a wide range of mental health issues, including anxiety, depression, stress, and phobias, by helping users identify and challenge cognitive distortions. The paper discusses the development and implementation of the mobile chatbot psychologist, detailing the AIML-based conversational engine and the incorporation of CBT techniques. The chatbot's effectiveness is evaluated through a series of user studies involving participants with varying levels of psychological distress. Results demonstrate the chatbot's ability to deliver personalized interventions, with users reporting significant improvements in their mental well-being. The AI-enabled mobile chatbot psychologist offers a promising solution to bridge the gap in mental health care, providing an easily accessible, cost-effective, and scalable platform for psychological support. This innovative approach can serve as a valuable adjunct to traditional therapy and help reduce the burden on mental health professionals, while empowering individuals to take charge of their mental well-being.

**Keywords**—Chatbot; artificial intelligence; machine learning; CBT; AIML

## I. INTRODUCTION

The World Health Organization (WHO) estimates that approximately one in four people will be affected by a mental or neurological disorder at some point in their lives, making mental health disorders one of the leading causes of global disability [1]. Despite the high prevalence of mental health issues, a significant proportion of affected individuals lack access to mental health care due to various barriers, such as cost, stigma, and inadequate resources. This creates an urgent

need for alternative, accessible, and cost-effective solutions that can help bridge the gap in mental health care.

Advances in artificial intelligence (AI) and natural language processing (NLP) have paved the way for the development of intelligent systems capable of understanding and responding to human language [2]. Chatbots, AI-powered conversational agents, have demonstrated potential in various domains, including healthcare, customer service, and education. In the context of mental health, chatbots can be designed to offer psychological support, guidance, and interventions to individuals experiencing psychological distress [3]. These AI-powered tools have the potential to complement traditional therapy, providing additional support and resources to those in need.

This paper presents an AI-enabled mobile chatbot psychologist that leverages Artificial Intelligence Markup Language (AIML) and Cognitive Behavioral Therapy (CBT) to offer personalized psychological interventions [4]. AIML, an XML-based language specifically designed for creating chatbots, enables the development of a conversational engine that can understand user inputs and generate contextually appropriate responses [5]. The use of AIML allows the chatbot to engage users in natural and effective conversations, fostering a sense of connection and rapport.

Cognitive Behavioral Therapy (CBT) is an evidence-based therapeutic approach that has been proven effective in treating a wide range of mental health issues, including depression, anxiety, stress, and phobias. CBT is based on the premise that maladaptive thought patterns and behaviors contribute to the development and maintenance of psychological distress [6]. By identifying and challenging these cognitive distortions, individuals can develop healthier thought patterns and coping strategies, leading to improved mental well-being. The integration of CBT principles and techniques into the chatbot's knowledge base enables it to offer targeted psychological interventions tailored to the specific needs of the user.

The development of the AI-enabled mobile chatbot psychologist involves the creation of an extensive knowledge base, comprising the core principles and techniques of CBT, as well as a conversational engine that leverages AIML for natural language understanding and generation [7]. To ensure the chatbot's effectiveness in delivering psychological

interventions, it is designed to adapt to the user's needs, recognizing their emotional state and providing personalized support accordingly. Furthermore, the chatbot is equipped with a user-friendly interface, allowing individuals to easily access and engage with the platform on their mobile devices.

To evaluate the effectiveness of the AI-enabled mobile chatbot psychologist, a series of user studies are conducted involving participants with varying levels of psychological distress [8]. These studies assess the chatbot's ability to engage users in meaningful conversations, deliver personalized CBT interventions, and improve mental well-being. The results of these studies provide valuable insights into the chatbot's potential as a scalable and accessible solution for mental health care.

The AI-enabled mobile chatbot psychologist offers a promising alternative to traditional therapy, addressing the need for accessible, cost-effective, and efficient mental health care solutions [9]. By providing personalized psychological support through a mobile platform, the chatbot can help reduce the burden on mental health professionals and enable individuals to take charge of their mental well-being. Moreover, this innovative approach can serve as a valuable adjunct to existing mental health services, offering additional support and resources to those in need.

The integration of AIML and CBT in the development of an AI-enabled mobile chatbot psychologist demonstrates the potential of AI-powered conversational agents in delivering effective mental health interventions. As artificial intelligence is applied in different aspects in our life from smart home, smart energy, smart city, natural language processing tasks to different applied problems [10-12], in this research, we try to use artificial intelligence to solve psychological problems. This paper contributes to the growing body of research on AI applications in mental health care, showcasing the potential of chatbots as a tool for providing accessible and personalized psychological support.

The remainder of this paper is organized as follows: Section II provides an overview of the background and related work in the fields of AI-powered chatbots, AIML, and CBT, highlighting the relevance and significance of these technologies in the context of mental health care. Section III describes the methodology employed in the development of the AI-enabled mobile chatbot psychologist, detailing the creation of the knowledge base, the AIML-based conversational engine, and the user-friendly interface. Section IV presents the user studies conducted to evaluate the chatbot's effectiveness in delivering personalized CBT interventions and improving mental well-being, discussing the findings and implications of the results.

Section V explores potential challenges and limitations associated with the implementation of the AI-enabled mobile chatbot psychologist, such as privacy concerns, ethical considerations, and the need for ongoing support and maintenance. Section VI outlines future research directions and potential enhancements to the chatbot, including the integration of additional therapeutic approaches, the incorporation of multimodal input and output channels, and the development of

advanced AI techniques for improved natural language understanding and generation.

Finally, Section VII provides a conclusion that summarizes the key contributions of the paper and highlights the significance of the AI-enabled mobile chatbot psychologist in addressing the global mental health care gap. By leveraging AIML and CBT, this innovative solution offers a scalable, accessible, and cost-effective platform for psychological support, empowering individuals to take control of their mental well-being and complementing existing mental health services.

## II. RELATED WORKS

This section provides literature review to artificial intelligence powered chatbots, AIML to develop chatbot applications, cognitive behavior therapy that can be applied in chatbot psychology applications, and overview of the existed chatbot applications and related works. As we now, machine learning is applied in different areas as home automation, smart city, image processing, computer vision, and other areas [13-15], in this section we review application of machine learning in a chatbot development.

### A. AI-Powered Chatbots

With the rapid advancements in artificial intelligence (AI) and natural language processing (NLP), the development of intelligent conversational agents, or chatbots, has gained significant momentum. Chatbots have been employed across various domains, including healthcare, customer service, and education, owing to their ability to understand and respond to human language in a contextually appropriate manner. In recent years, AI-powered chatbots have garnered attention for their potential application in mental health care, providing psychological support and interventions to individuals experiencing psychological distress. Studies have demonstrated the feasibility of using chatbots to deliver mental health support, highlighting their effectiveness in engaging users and reducing symptoms of anxiety and depression.

### B. Artificial Intelligence Markup Language (AIML)

AIML, an XML-based language specifically designed for creating chatbots, has emerged as a popular tool for developing conversational agents [16]. AIML allows developers to create rules that define the chatbot's responses to specific user inputs, facilitating natural and engaging human-computer interactions [17]. The language's flexibility and adaptability have made it a suitable choice for building chatbots in various contexts, including mental health care [18]. By leveraging AIML, chatbots can engage users in meaningful conversations, fostering a sense of connection and rapport, which is essential for effective psychological interventions.

### C. Cognitive Behavioral Therapy (CBT)

Cognitive Behavioral Therapy (CBT) is an evidence-based psychological treatment that has been widely researched and proven effective for a range of mental health issues, including depression, anxiety, stress, and phobias [19]. CBT is based on the principle that maladaptive thought patterns and behaviors contribute to the development and maintenance of psychological distress [20]. The therapy involves helping individuals identify and challenge these cognitive distortions,

promoting healthier thought patterns and coping strategies. As a structured and time-limited approach, CBT lends itself well to integration with technology, making it an ideal choice for AI-powered chatbot interventions.

#### D. Relevance and Significance of Chatbots, AIML, and CBT in Mental Health Care

The combination of AI-powered chatbots, AIML, and CBT offers a promising solution to address the growing need for accessible and cost-effective mental health care [21]. Chatbots can provide psychological support to a large number of individuals simultaneously, reducing the burden on mental health professionals and offering additional resources to those in need. By employing AIML, chatbots can engage users in natural conversations, enhancing the user experience and facilitating the delivery of effective interventions [22]. The integration of CBT principles and techniques into chatbots enables the provision of targeted, evidence-based psychological interventions tailored to the specific needs of the user.

Several studies have explored the use of chatbots in mental health care, with promising results. For instance, [23] evaluated the effectiveness of a chatbot utilizing CBT techniques in reducing symptoms of depression and anxiety, demonstrating significant improvements in participants' mental well-being. Similarly, [24] found that a chatbot-based intervention was effective in reducing symptoms of anxiety in a non-clinical population. These findings suggest that AI-powered chatbots, employing AIML and CBT, hold potential as an innovative solution to bridge the gap in mental health care, providing accessible, personalized, and scalable psychological support.

#### E. Related Work in AI-Enabled Mental Health Chatbots

Several AI-powered mental health chatbots have been developed and evaluated in recent years, showcasing the potential of conversational agents in providing psychological support. Some notable examples include:

**Woebot:** Developed by Stanford University researchers, Woebot is an AI-powered chatbot designed to provide CBT-based interventions for individuals experiencing depression and anxiety [25]. The chatbot has been shown to effectively engage users and significantly reduce symptoms of depression and anxiety.

**Wysa:** Wysa is a mental health chatbot that combines AI and human expertise to offer personalized support and evidence-based interventions, including CBT, dialectical behavior therapy (DBT), and motivational interviewing (MI) [26]. Wysa has been found to effectively reduce symptoms of anxiety in a non-clinical population.

**Tess:** Tess is an AI-powered chatbot designed to provide personalized mental health support, utilizing various evidence-based therapeutic approaches, including CBT, MI, and psychodynamic therapy [27]. Studies have demonstrated the chatbot's effectiveness in improving users' emotional well-being and reducing symptoms of depression and anxiety.

**Replika:** Replika is an AI-powered chatbot designed to provide companionship and support to users, helping them improve their mental well-being and cope with feelings of

loneliness [28]. The chatbot learns from the user's inputs, adapting its responses to match the user's preferences and communication style, fostering a sense of connection and rapport.

**X2AI's Tess:** Developed by X2AI, Tess is an AI-driven mental health chatbot designed to provide personalized psychotherapy using various evidence-based therapeutic approaches, including CBT, MI, and solution-focused brief therapy (SFBT) [29]. Tess has been shown to effectively reduce symptoms of depression, anxiety, and stress in various populations, including university students and healthcare workers.

**Ellie:** Ellie is a virtual human developed by the Institute for Creative Technologies (ICT) at the University of Southern California, designed to detect signs of depression and post-traumatic stress disorder (PTSD) in users through the analysis of their verbal and nonverbal cues [30]. While not strictly a chatbot, Ellie demonstrates the potential of AI-powered conversational agents in providing mental health support and interventions, particularly through the integration of multimodal input and output channels.

**Sibly:** Sibly is a mental health chatbot that combines AI with human expertise to offer personalized support and evidence-based interventions, including CBT, DBT, and mindfulness [31]. The chatbot has been found to improve users' emotional well-being and coping skills, suggesting its potential as a valuable adjunct to traditional therapy.

The background and related work in the fields of AI-powered chatbots, AIML, and CBT illustrate the relevance and significance of these technologies in the context of mental health care. AI-powered chatbots can offer accessible, cost-effective, and scalable psychological support, while AIML enables natural and engaging human-computer interactions [32]. The integration of CBT principles and techniques into chatbots allows for the provision of targeted, evidence-based interventions tailored to the specific needs of the user.

Previous studies and existing mental health chatbots have demonstrated the potential of AI-powered conversational agents in delivering effective psychological interventions. However, there is a need for continued research and development in this area, particularly in terms of personalization, user engagement, and the integration of advanced AI techniques [33]. The AI-enabled mobile chatbot psychologist presented in this paper seeks to address these challenges, providing an innovative solution to bridge the gap in mental health care and empower individuals to take control of their mental well-being [34].

These examples highlight the potential of AI-powered chatbots in providing accessible and effective mental health care. However, there is still room for improvement and innovation, particularly in terms of personalization, user engagement, and the integration of advanced AI techniques for natural language understanding and generation [35].

The related work in AI-enabled mental health chatbots demonstrates the potential of conversational agents in delivering effective psychological interventions and support. Several chatbots, such as Woebot, Wysa, Tess, Replika, Ellie,

and Sibly, have been developed and evaluated, with promising results in terms of user engagement and improvement in mental well-being [36-38]. These developments underscore the importance of AI-powered chatbots in addressing the growing need for accessible, cost-effective, and scalable mental health care solutions.

However, there is still room for improvement and innovation in this field, particularly in terms of personalization, user engagement, and the integration of advanced AI techniques for natural language understanding and generation. The AI-enabled mobile chatbot psychologist presented in this paper seeks to address these challenges and contribute to the growing body of research on AI applications in mental health care.

### III. METHODOLOGY

Awareness of the components of a chatbot is necessary before constructing one. The most fundamental parts for creating a chatbot are:

#### A. Chatbots of the Proposed Mobile Chatbot Psychologist

1) *Intents*. The path that the dialog will take according to the end-user's goals can be classified by utilizing the intent [39]. The collection of intentions is an excellent chance to facilitate a fruitful conversation. The process of mapping newly produced intentions is referred to as intent categorization. For instance, to create a knowledge agent for meteorological notifications, one would need to declare the intent "weather forecast," which would then be assigned to the user's query asking, "What is the weather forecast for today?" As can be seen in Fig. 1, it would be beneficial to the purpose to be able to determine things such as location and time based on information included inside a user message.

The fundamental intent is comprised of seventeen training expressions, which are examples of sentences that the user may write in their query and replies that the agent will provide when the intent has been identified. Textual content, video content, or audio recordings may be used to display replies, depending on the capabilities of the platform.

2) *Entities*. Contents are known as entities, and intentions are said to include entities [40]. For instance, in the custom offer "Book a movie ticket," "booking a movie ticket" may be an intent, and "movie" can be an entity; however, the "movie" entity can be substituted with another entity, such as "train," "airplane," or "other."

3) *Utterances*. Utterance is a variant of approximation recommendations or end-user inquiries that may be conveyed for a particular aim [41]. According to some sources, Utterance is classified as an independent part of the chatbot ecosystem. These kinds of remarks are, in essence, teaching terms, as was previously explained. It is advised that one should come up with anything from 5 (at least) to 10 assertions while writing for the internet.

4) *Instruction of the Robot*. Training is the procedure of constructing a model for categorizing intents and entities according to the intentions generated by the software

developer for novel assertions and assessing the correctness of the resulting model. This model relies on the intents generated by the programmer for new utterances.

5) *Confidence score*. When determining whether or not a user statement is associated with a certain purpose, the degree of trust serves as an indication of the strength of the categorization model.

#### B. Chatbot Psychologist Architecture

Fig. 2 provides a condensed overview of the steps that make up the functioning of a conversationalist. These steps are as follows: obtaining the input data, processing the input using a selection of multiple possible replies, calculating the confidence level of each response, and finally providing the user with the response that has the highest degree of trust level.

In order to create the virtual assistant, we utilized the RASA platform. RASA Open Source is a machine learning framework that may be used to automate conversational assistants that are based on data from either text or speech [42]. In contrast to Dialog flow, this framework gives developers the freedom to pick and represent categorization methods in whatever way they see fit.

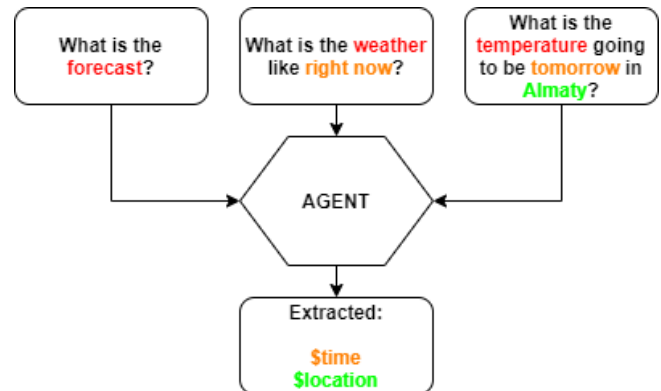

Fig. 1. Flowchart of the chatbot decision making process.

Fig. 2. Chatbot decision making architecture.

Fig. 3. Chatbot decision making architecture.

A tool for identifying intentions, searching for an answer, and extracting information, RASA NLU is a natural language processing system. Fig. 3 provides an illustration of the architecture of the conversational assistant that was constructed using Rasa. The message that is sent to the Interpreter from the user is then transformed into a dictionary by the Interpreter. This dictionary contains the text as well as any detected entities and intents. A tracker is an item that keeps track of the current state of the conversation and keeps a record of the fact that the message was received. Following the transmission of the

tracker state to the Policy, the subsequent action will be chosen. Following the recording of the action that was chosen in the tracker, the response is then delivered to the user.

C. Applying Natural Language Understanding Techniques

Rasa offers two primary approaches to the process of producing training data for bots:

Intentions that have already been taught Intent classifier: The categorization of the user's intentions will be based on pre-filtered datasets, which will then be used to represent every phrase in the user message as embedded words or in vector form (word2vec). The classification of the user's intentions will be accomplished. These datasets may be obtained via Spacy or MITIE, FastText, or any similar service; - controlled intents (Intent\_classifier\_tensorflow\_embedding). Because there is no training data readily available, the user of this method will be required to generate the data from scratch in order to use it.

A summary of the steps involved in the functioning of a chatbot can be seen in Fig. 4: after receiving the input data, the chatbot will analyze the data by choosing various alternative replies, calculating the amount of confidence associated with each response, and finally providing the user with the response that carries the greatest level of confidence.

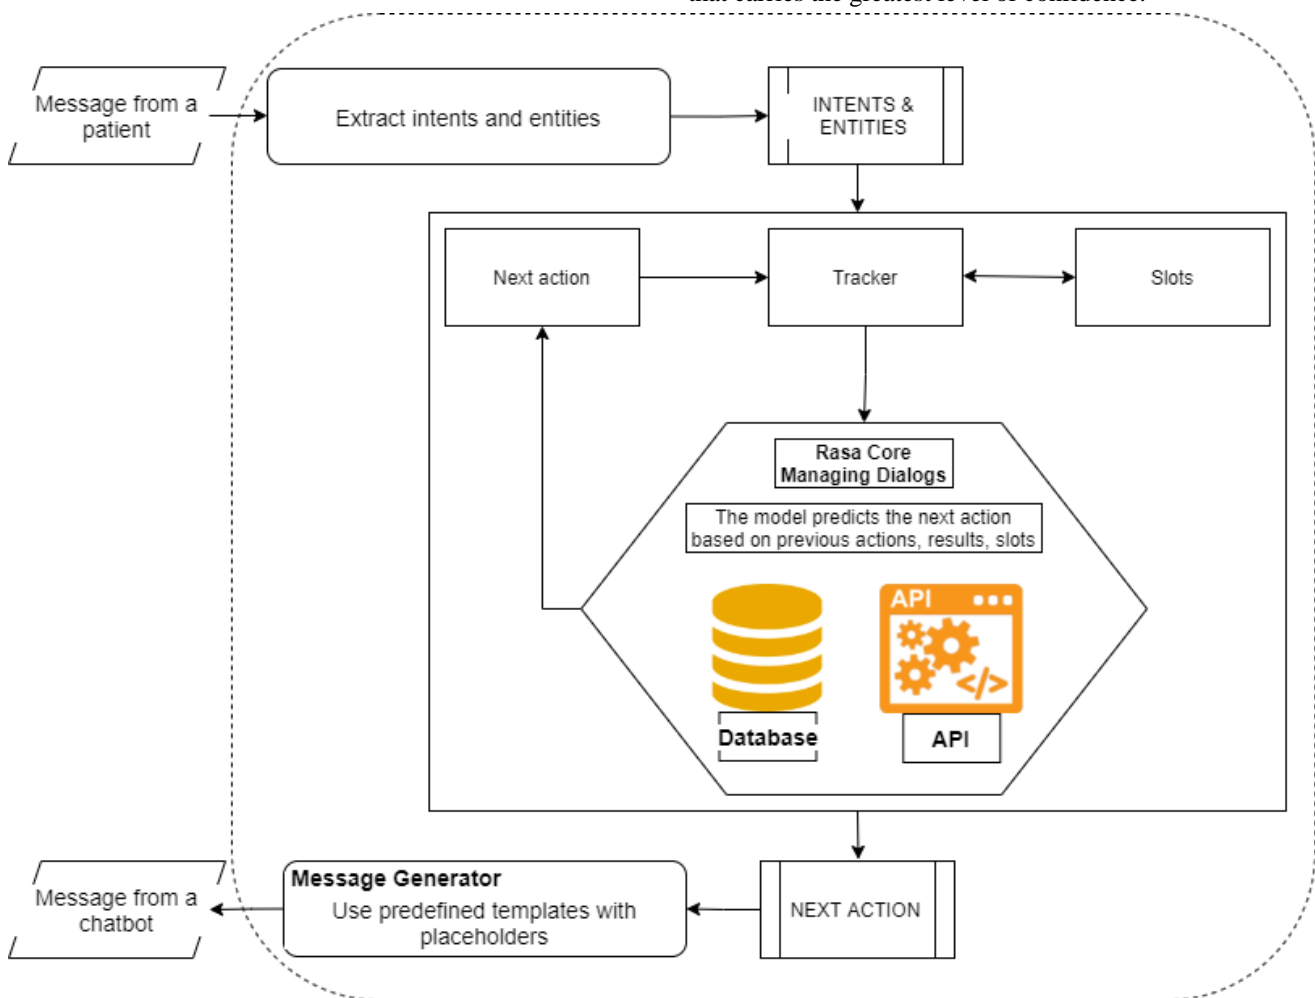

Fig. 4. Chatbot decision making architecture.

#### IV. EXPERIMENT RESULTS

In this section, we demonstrate the proposed mobile chatbot psychologist. Fig. 5 demonstrates a mockup of the proposed mobile chatbot. The display of the chatbot application is simplified to seem like a regular chat program that consumers interact with. The rationale for this is to ingrain a sense of familiarity in the user's mind towards the chatbot psychologist mobile application.

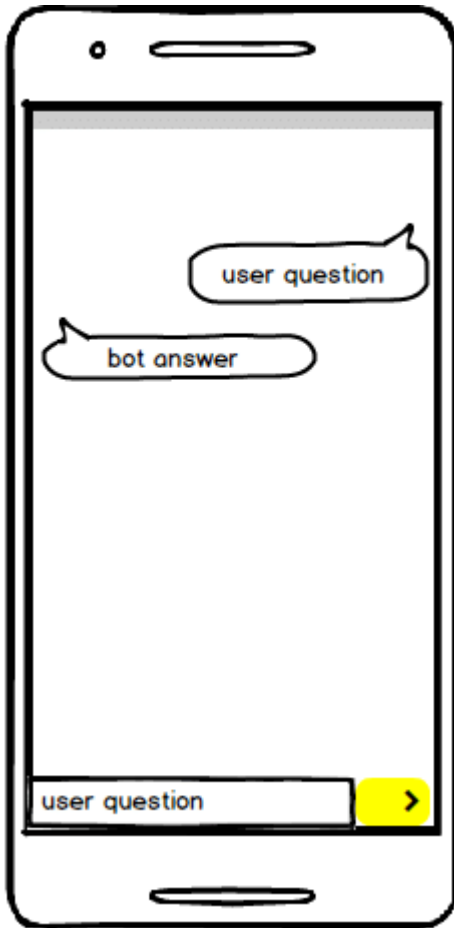

Fig. 5. Mockup of the proposed mobile chatbot.

##### A. Chatbot Psychologist in Practice

Using RASA technology, we constructed a chatbot (also known as a conversational agent) for the Kazakh language. This chatbot adheres to a restricted set of rules. The application of RASA Natural Language Understanding, also known as RASA NLU, is used to recognize entities and get the required response. The created chatbot takes into consideration a number of different topics, including "Greetings," "Confirm," and "Bye," as well as "Diagnosis." Fig. 6 demonstrates Menus of the proposed chatbot. It consists of several menus as take surveys, start chat, read, help, my info, about bot, and reset.

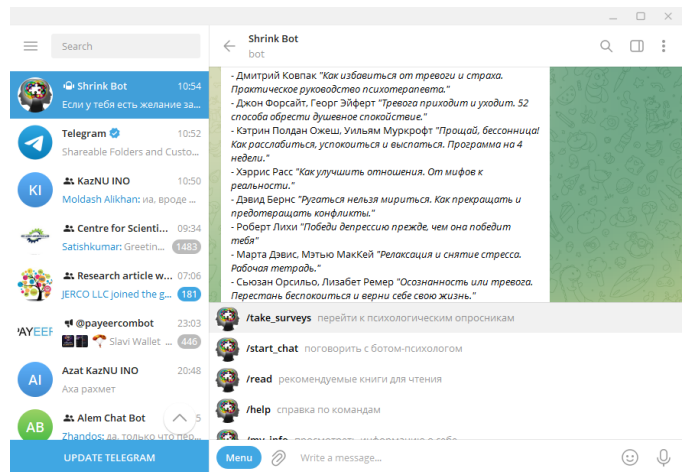

Fig. 6. Menu of the proposed mobile chatbot.

Fig. 7 demonstrates an example of the proposed mobile chatbot when the chatbot suggests different books that would be useful for users. Thus, the users can use the proposed chatbot to improve their knowledge. The users can choose the recommended literature in the chatbot, pass the different psychological tests to understand current psychological conditions, and use cognitive behavior therapy to solve their mental problems.

Fig. 8 shows current progress of a patient. There, we use different questionnaires as GAD-7 anxiety test, BPAQ-24 aggression test, Crafft screening test, Beck hopelessness test, NEO 5 factor inventory test, and open questions. In Fig. 8, we can see that a patient passed two tests as Beck depression test and questionnaire about the level of depression. Depending on the results of the psychology tests, the proposed mobile chatbot psychologist generates decisions and recommendations to the patient.

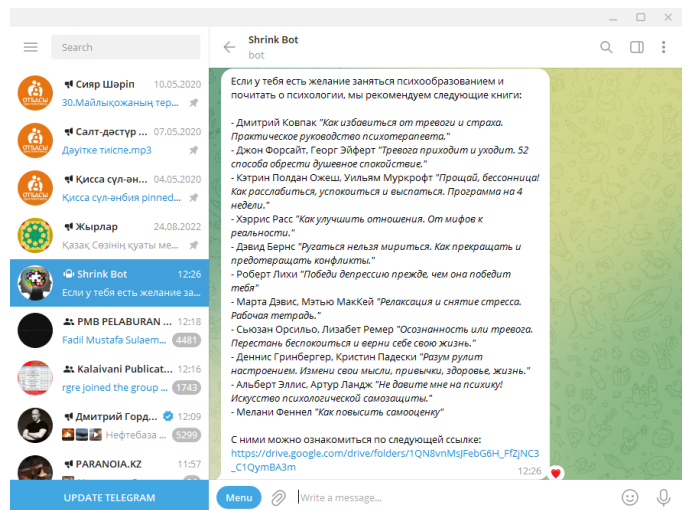

Fig. 7. An example of the proposed mobile chatbot.

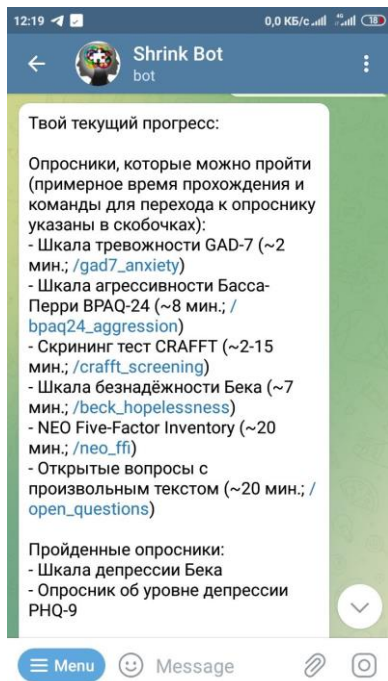

Fig. 8. Current progress of a patient.

## B. Analysis of the Results

According to the findings, the Rasa NLU system has an accuracy of 0.99375 with regard to its intended use. According to the training collection, there is a mistake: the meaning of "how are you?" is incorrectly recognized as "diagnosis," as displayed in Table I. It is quite probable that there is a mistake, since the training outcomes do not include any terms that are comparable. In the phrase "having a nice day," the term "time" is a contemporary machine term that replaces the phrases "day" and "day," and the experiment that was performed on it produced no errors.

We start out by doing an analysis of the RASA NLU procedure. The entity integrity of this particular training package is a score of 0.92, and the accuracy of the entity extract score is equal to one. If there are any grammatical flaws in the text, there is a possibility that errors will occur.

It has been shown that the process of extracting named entities using RASA NLU is very trustworthy since there are no mistakes in the entity extraction during the whole phase which utilizes appropriate training and test evidence.

In the subsequent stage of our investigation, we are going to use NLP strategies to datasets of databases that have been prepared in advance, such as, in order to recognize signals that are associated with depression.

TABLE I. OBTAINED RESULTS

Approach	Confirm	Greetings	Bye	Diagnosis	Total
Confirm	12	0	0	0	12
Greetings	0	5	0	4	9
Bye	0	0	16	0	0
Diagnosis	0	0	0	600	600
Total	12	8	12	600	632

## V. DISCUSSION OF CHALLENGES AND LIMITATIONS

In this section we discuss potential challenges and limitations associated with the implementation of the AI-enabled mobile chatbot psychologist, such as privacy concerns, ethical considerations, and the need for ongoing support and maintenance.

### A. Privacy Concerns

One of the main challenges associated with the implementation of the AI-enabled mobile chatbot psychologist is addressing privacy concerns. Users may be hesitant to share sensitive personal information with an AI-powered system due to potential data breaches, misuse, or unauthorized access [43]. To mitigate these concerns, developers must ensure that the chatbot adheres to strict data privacy and security standards, such as encrypting user data, implementing secure authentication protocols, and maintaining transparency regarding data collection, storage, and usage practices [44]. Additionally, compliance with relevant data protection regulations, such as the General Data Protection Regulation (GDPR), should be prioritized.

### B. Ethical Considerations

Ethical considerations are paramount when developing and deploying AI-enabled mental health chatbots [45]. The chatbot should be designed to respect users' autonomy, providing accurate information and unbiased support without imposing any particular perspective or course of action. Additionally, the chatbot should prioritize user safety, with built-in mechanisms to identify and respond to potential crises or emergency situations, such as active suicidality or severe distress. In such cases, the chatbot should be able to guide users to appropriate professional help or emergency services.

### C. Ensuring Clinical Effectiveness

While the AI-enabled mobile chatbot psychologist aims to provide evidence-based CBT interventions, the effectiveness of these interventions depends on the chatbot's ability to accurately interpret user inputs and deliver appropriate responses [46]. Ensuring clinical effectiveness requires ongoing evaluation and refinement of the chatbot's natural language understanding and generation capabilities. Moreover, it is important to recognize that the chatbot may not be suitable for all users or mental health conditions, and it should not be considered a replacement for professional psychological care.

#### D. Ongoing Support and Maintenance

The AI-enabled mobile chatbot psychologist requires ongoing support and maintenance to ensure its effectiveness and relevance [47]. This includes regular updates to the knowledge base, incorporating the latest research findings and clinical best practices in CBT. Additionally, the chatbot's AIML rules and conversational engine may need to be updated and refined to improve its natural language understanding and generation capabilities [48]. This ongoing maintenance requires dedicated resources, including a multidisciplinary team of mental health professionals, AI experts, and software developers.

#### E. Ongoing Support and Maintenance

While the AI-enabled mobile chatbot psychologist offers a convenient and accessible platform for psychological support, there is a risk that users may become overly reliant on the chatbot, neglecting the importance of face-to-face interactions and professional psychological care [49]. It is crucial to emphasize that the chatbot is intended to complement, rather than replace, traditional mental health services and should be used as an adjunct to professional care as needed.

### VI. DISCUSSION OF FUTURE PERSPECTIVES

#### A. Integration of Additional Therapeutic Approaches

While the current chatbot focuses on CBT principles and techniques, future research could explore the integration of other evidence-based therapeutic approaches, such as dialectical behavior therapy (DBT), acceptance and commitment therapy (ACT), and mindfulness-based cognitive therapy (MBCT) [50-52]. This would allow the chatbot to cater to a broader range of user needs and preferences, potentially enhancing its effectiveness and user engagement.

#### B. Incorporation of Multimodal Input and Output Channels

The chatbot could be further enhanced by incorporating multimodal input and output channels, such as voice recognition, speech synthesis, and emotion recognition through facial expressions or voice tone analysis [53]. This would enable the chatbot to provide more natural and immersive interactions, potentially improving user engagement and therapeutic outcomes.

#### C. Development of Advanced AI Techniques for Improved Natural Language Understanding and Generation

To improve the chatbot's natural language understanding and generation capabilities, future research could explore the integration of advanced AI techniques, such as deep learning algorithms and transformer-based models like OpenAI's GPT series [54]. These techniques could potentially enhance the chatbot's ability to process complex user inputs, generate more contextually appropriate and human-like responses, and adapt to individual users' communication styles and preferences.

#### D. Personalization and User Modeling

Future research could focus on developing more advanced personalization features and user modeling techniques, allowing the chatbot to better understand and adapt to individual users' needs, preferences, and emotional states [55]. This could involve the use of machine learning algorithms to

analyze user inputs, identify patterns in their behavior, and generate tailored interventions based on their unique characteristics.

#### E. Evaluation of Long-Term Outcomes and Real-World Implementation

Further studies should be conducted to evaluate the long-term outcomes of using the AI-enabled mobile chatbot psychologist, as well as its effectiveness in real-world settings [56]. This could involve large-scale, randomized controlled trials with diverse populations, as well as the analysis of user feedback and usage data to identify areas for improvement and potential barriers to adoption.

#### F. Collaboration with Mental Health Professionals and Stakeholders

Future research should prioritize collaboration with mental health professionals, users, and other stakeholders to ensure the chatbot's development is grounded in clinical best practices and addresses the needs of its target audience [57]. This could involve conducting focus groups, user interviews, and expert consultations to gather feedback and insights on the chatbot's design, functionality, and therapeutic content.

Future research directions and potential enhancements to the AI-enabled mobile chatbot psychologist include the integration of additional therapeutic approaches, the incorporation of multimodal input and output channels, the development of advanced AI techniques for improved natural language understanding and generation, personalization and user modeling, evaluation of long-term outcomes and real-world implementation, and collaboration with mental health professionals and stakeholders. These advancements hold the potential to further improve the chatbot's effectiveness, user engagement, and accessibility, ultimately contributing to a more robust and innovative solution for mental health care.

### VII. CONCLUSION

This paper has presented the development and evaluation of an AI-enabled mobile chatbot psychologist that leverages AIML and CBT to provide personalized psychological support and interventions. The key contributions of this work include the creation of an extensive knowledge base of CBT principles and techniques, the development of an AIML-based conversational engine for natural language understanding and generation, and the design of a user-friendly interface for seamless interaction on mobile devices.

The AI-enabled mobile chatbot psychologist addresses the global mental health care gap by offering a scalable, accessible, and cost-effective platform for psychological support. By making evidence-based CBT interventions readily available to users through their mobile devices, this innovative solution empowers individuals to take control of their mental well-being and complements existing mental health services.

Through the integration of advanced AI techniques and a comprehensive knowledge base of CBT principles, the chatbot has the potential to revolutionize mental health care delivery by providing users with immediate access to personalized psychological support, regardless of their geographical location or financial circumstances. This approach not only helps to

reduce the burden on traditional mental health services but also contributes to destigmatizing mental health issues by making support more readily available and approachable.

In conclusion, the AI-enabled mobile chatbot psychologist represents a significant advancement in the field of mental health care, harnessing the power of AI and evidence-based therapeutic approaches to provide accessible, cost-effective, and personalized psychological support. This innovative solution holds great promise in addressing the global mental health care gap and empowering individuals to take control of their mental well-being.

#### ACKNOWLEDGMENT

This work was supported by the grant “Development of an intellectual system prototype for online-psychological support that can diagnose and improve youth’s psycho-emotional state” funded by the Ministry of Education of the Republic of Kazakhstan. Grant No. IRN AP09259140.

**Abstract**—Hyperspectral image classification constitutes a pivotal research domain in the realm of remote sensing image processing. In the past few years, convolutional neural networks (CNNs) with advanced feature extraction capabilities have demonstrated remarkable performance in hyperspectral image classification. However, the challenges faced by classification methods are compounded by the difficulties of "dimensional disaster" and limited sample distinctiveness in hyperspectral images. Despite existing efforts to extract spectral spatial information, low classification accuracy remains a persistent issue. Therefore, this paper proposes a multi-branch feature fusion model classification method based on convolutional neural networks to fully extract more effective and adequate high-level semantic features. The proposed classification model first undergoes PCA dimensionality reduction, followed by a multi-branch network composed of three-dimensional and two-dimensional convolutions. Convolutional kernels of varying scales are utilized for multi-feature extraction. Among them, the 3D convolution not only adapts to the cube of hyperspectral data but also fully exploits the spectral-spatial information, while the 2D convolution learns deeper spatial information. The experimental results of the proposed model on three datasets demonstrate its superior performance over traditional classification models, enabling it to accomplish the task of hyperspectral image classification more effectively.

**Keywords**—Hyperspectral image classification; convolutional neural network (CNN); multi-branch network; feature fusion

## I. INTRODUCTION

Hyperspectral remote sensing is a cutting-edge technology that utilizes imaging spectrometry to remotely acquire the electromagnetic properties of objects, representing a revolutionary advancement in the area of remote sensing. The key to this technology lies in the utilization of a narrow and continuous spectral channel for remote sensing imaging of objects [1, 2], which can detect the two-dimensional spatial image and the third-dimensional spectral image of the object on earth at the same time and is a cube with the spectral and spatial information, and is also developed based on imaging and spectroscopy. Nowadays, hyperspectral imagery has found extensive application in the field of agriculture [3], military [4], chemistry [5], mineral identification [6], human health [7], and

other fields, playing an indispensable role in the development and progress of human society. The objective of hyperspectral remote sensing image classification is to accurately categorize target ground objects [8], integrate the categories with actual ground object information, and obtain specific category information for the target region [9]. This field of study represents a specialized application of image classification within the realm of remote sensing. However, hyperspectral images are plagued by "dimension disaster" [9], "Hughes phenomenon" [10, 11], the limited quantity of labeled training samples [12], and the inequality of data sample types, which will make hyperspectral images encounter great hardships in the course of extracting features and performing classification.

In the initial exploration of hyperspectral image classification, researchers primarily focused on the spectral information contained within these images, which can effectively capture and reflect the internal mechanisms and chemical composition of ground objects. Specifically, traditional classification methods have harnessed the abundance of bands in hyperspectral images to execute machine learning algorithms for classification purposes with great efficacy, including random forest [13], decision trees [14], support vector machine [15] and K-nearest neighbor [16] algorithms. Relying solely on spectral information, these methods are capable of performing simple classification without the need for feature extraction. Meanwhile, the problem of data redundancy has led subsequent researchers to focus their attention on dimensionality reduction and feature extraction methods. As a preliminary step to classification, the primary techniques of dimensionality reduction can be classified into feature selection and feature extraction [17]. The aim of feature selection is to identify representative spectral information from redundant hyperspectral data while preserving as much original band information as possible [18, 19]. Commercial feature selection methods, including principal component analysis (PCA) [20], independent component analysis (ICA) [21], and linear discriminant analysis (LDA) [22], are commonly used in hyperspectral image processing. PCA method is the most favored linear dimensionality reduction technique. With the continuous advancement and widespread application of deep learning in image processing,

target detection, and speech recognition, it has become a crucial tool for hyperspectral image classification research[23], some typical deep neural network models mainly include stacked autoencoders (SAE) [24], deep belief networks (DBN) [25], and convolutional neural networks (CNN) [26]. Compared to machine learning methods, deep learning models possess a hierarchical structure that enables the extraction of high-level semantic information during feature extraction. This allows for better approximation of the nonlinear structure present in hyperspectral image data and enhances algorithmic effectiveness and robustness [27], thereby facilitating the extraction of complex and high-level features. So far, several deep learning-based approaches have been accomplished within the field of hyperspectral image classification. Just as the application of stacked encoders (SAEs) [28] in hyperspectral image classification. PCA is used to reduce the spectral dimensions of the original data and expanded the data into one-dimensional (1D) vectors as the input of SAE model. Finally, the hyperspectral images were classified by SVM classifier. In 2015, a hyperspectral image classification method based on deep belief network (DBN) was proposed, which also combined PCA method, and used the hierarchical feature extraction and logistic regression classifier to complete the classification of hyperspectral images [29]. As the mentioned two methods expand the spatial neighborhood into a 1D vector, which destroys the correlation of spatial information, they cannot effectively extract the spectral-spatial information to achieve high precision classification of hyperspectral images.

Fortunately, convolutional neural networks, another major branch of deep learning, have demonstrated superior performance in handling hyperspectral data due to their ability to directly address high dimensionality and automatically extract hierarchical image features compared to SAE and DBN [30, 31]. In 2015, the first hyperspectral image classification algorithm based on CNN was introduced. Despite utilizing only the spectral dimension information of the image, its initial application in hyperspectral classification demonstrated superiority over traditional methods such as Support Vector Machine (SVM) [32]. The authors in [33] augmented the number of samples by rotating labelled training data. However, their model's feature extraction process solely relies on spatial domain information while disregarding spectral dimension information. Spectral information is complementary and essential as it indicates that adjacent pixels may belong to the same class [33]. Then, the 1D-CNN+2D-CNN network [34] utilizes a double-branch structure to connect spectral features learned from one-dimensional CNN (1D-CNN) and spatial features learned from two-dimensional CNN (2D-CNN), extracting joint spectral-spatial features for classification. However, this method fails to consider the interdependence between spectral and spatial features. The appearance of three-dimensional convolution just solves the problem of the above model. Using three-dimensional (3D) convolution to work concurrently on information in 3D directions could be more appropriate for the dimensionality of hyperspectral data. A three-dimensional CNN (3D-CNN) model proposed by [35] does not perform any pre-processing on hyperspectral data and uses the full spectral band as input, which retains complete information but actually has high band-to-band correlation and much redundant information. In recent years, an eight-layer

3D-CNN network structure [36] was also proposed for hyperspectral image classification, in which the convolutional layer and the pooling layer were placed alternately.

In this paper, we propose a multi-branch feature fusion model based on CNN for extracting features from hyperspectral images and achieving ground object classification. The present study makes noteworthy contributions in the following aspects:

1) In this paper, a multi-branch feature fusion classification model is proposed for hyperspectral image classification. 3D convolution operations are preferentially used to process special hyperspectral 3D data and extract features from different degrees of spectral and spatial dimensions by utilizing different scales of convolution kernels and number of filters. In addition, 2D convolution was added after 3D convolution to reduce the complexity of the neural network while still efficiently extracting deeper spatial features. Meanwhile, PCA method is used to solve "curse of dimension" of the hyperspectral image.

2) The model framework presented adopts a multi-branch feature fusion structure to integrate features extracted from different branches. By connecting the features extracted from various branches using the Concatenate function, network features can be more comprehensively supplemented, thereby addressing issues of inadequate feature extraction and low precision associated with single branch models, ultimately leading to improved classification performance.

3) The proposed method's effectiveness is demonstrated on three datasets, and the results indicate that it outperforms several other classical methods. The experiments validate that multi-branch feature fusion can significantly enhance classification accuracy. Additionally, various experiments were conducted to determine the model parameters' effects, such as patch size, learning rate, percentage of training samples, and number of branches.

## II. METHODS

The experimental study in this research primarily involves the acquisition of public hyperspectral datasets, preprocessing them, and randomly dividing them into training, validation, and testing sets. During model training, the validation set is utilized for verification to determine whether parameter retuning or training cessation is necessary. Finally, the test set input is used for prediction to obtain results. The specific classification process can be seen in Fig. 1.

Fig. 1. The hyperspectral image classification flow chart.

### A. Principal Component Analysis (PCA)

Hyperspectral images contain abundant spectral information, but a large number of bands exhibit strong correlation, leading to potential redundancy in the data. Therefore, employing PCA can effectively reduce dimensionality while retaining sufficient information for subsequent feature extraction and classification tasks. This approach not only saves time during model training and testing but also ensures that valuable information is preserved. Meanwhile, as sufficient information is preserved, the discarded band data is essentially superfluous and repetitive, thus exerting negligible influence on the ultimate classification outcomes. For further criteria and a comprehensive overview, refer to [37-39] and relevant literature therein.

To determine the appropriate number of principal components  $k$ , we analyzed the graph depicting the relationship between spectral information and the number of principal components after dimensionality reduction. The aim was to identify a value for  $k$  that would eliminate redundant bands while retaining most of the information in this experiment. Fig. 2 illustrates that even without PCA, the corrected removal of some noise bands does not result in a 100% retention of information across the three downloaded public datasets. After analyzing the outcome plots of these datasets following PCA and ensuring the proposed model's generality, we determined  $k$  to be 30.

Fig. 2. Relationship between the number of principal components and the amount of retained spectral information.

### B. Convolutional Neural Networks (CNN)

In 1989, LeCun introduced the concept of convolutional neural networks and proposed a multi-layer CNN model for handwritten digit recognition [40]. Since then, CNN, one of the typical feedforward deep neural network architectures, has seen extensive use in numerous computer vision domains. With its inherent advantages in local connectivity and weight sharing, the Convolutional Neural Network (CNN) has proven to be a powerful tool for image classification as well as other related fields. Consisting of an input layer, multiple hidden layers, and an output layer, deep CNN are capable of extracting features at different levels with remarkable efficacy.

As the most crucial operation in CNN, convolution realizes feature extraction of input data by utilizing various convolution kernels to perform sliding pixel extraction on the input image matrix. The nonlinear structure of activation function is then employed to enhance the similarity between image features and real features.

In 2D-CNN [41], both the convolutional kernel and input are in 2D format. When applied to hyperspectral image classification, the network typically takes the neighborhood block surrounding a center pixel as input, with the label of said

center pixel serving as that of the entire block. 2D convolution can effectively utilize neighborhood information, fuse the features of neighborhood samples, and extract spatial information. Its basic principle is to carry out weighted summation of image center pixel and neighborhood pixel according to the weights of convolution kernels and use the output of activation function as the value of center pixel. The output of  $j$ th feature map at  $(x, y)$  of the  $i$ th layer can be expressed as [42]:

$$v_{ij}^{xy} = f \left( b_{ij} + \sum_{k=1}^m \sum_{p=0}^{P-1} \sum_{q=0}^{Q-1} w_{ijk}^{pq} \cdot v_{(i-1)k}^{(x+p)(y+q)} \right) \quad (1)$$

Where in (1),  $f$  is the activation function,  $w$  and  $b$  are the weight and bias of the  $j$ th feature graph in the  $i$ th layer, respectively.

The 3D-CNN [41] is an extension of the 2D-CNN, where convolution is performed along three dimensions of input data simultaneously. This means that convolution is not only carried out in the height and width directions but also in the spectral channel. The output of the  $j$ th feature graph at  $(x, y, z)$  of the  $i$ th layer can be obtained by the formula [42]:

$$v_{ij}^{xyz} = f \left( b_{ij} + \sum_{k=1}^m \sum_{p=0}^{P-1} \sum_{q=0}^{Q-1} \sum_{r=0}^{R-1} w_{ijk}^{pqr} \cdot v_{(i-1)k}^{(x+p)(y+q)(z+r)} \right) \quad (2)$$

Same as (1),  $f$  is the activation function,  $w$  and  $b$  are the weight and bias of the  $j$ th feature graph in the  $i$ th layer, respectively.

In the convolution operation, utilizing an activation function can enhance the nonlinearity of the network. In this study, ReLU activation function[30] is employed for both convolution and full connection layers, while SoftMax classification function is exclusively used for final output classification layer. The formula is presented as follows:

$$f(x) = \max(0, x) \quad (3)$$

The ReLU function is relatively simple compared to other functions, yet it boasts faster operational efficiency and convergence speed. Consequently, it is widely utilized in deep learning models due to its ease of obtaining the required model.

### C. The proposed CNN Classification Model

In this research, a multi-branch feature fusion model based on CNN for extracting more profound and expressive spectral-spatial features of hyperspectral remote sensing images was discussed. To extract both spectral and spatial features from hyperspectral images, 3D convolutional operations are given priority to achieve this goal. This entails the utilization of convolutional kernels with varying scales and numbers to effectively capture features of different degrees, ensuring a comprehensive and efficient feature extraction process. As such, employing a network solely consisting of 3D convolution operations presents challenges in directly computing 3D data, resulting in excessive hyperparameters and prolonged feature extraction time due to its complexity. To augment the model's capacity for extracting spatial information features from data while simultaneously mitigating its complexity, the 3D data

resulting from convolution is transformed into simpler 2D flat data and subsequently subjected to additional 2D convolution operations.

On one hand, the conventional methods for enhancing the classification performance of the entire model involve deepening it, such as augmenting the number of convolutional layers. However, this often results in an increase in training parameters and complexity, as well as higher computational costs. While the classification performance may become better with a deeper network structure, the training difficulty also becomes greater. With consideration of these factors, this paper adopts a multi-branch convolutional neural network structure for the reason of improving the classification performance of the model as much as possible without increasing the overall model complexity and network depth. On the other hand, during the feature extracting procedure, the textural elements such as edge background of the hyperspectral image are mainly extracted by the low-level network, the regions of the image are extracted in the middle-level network, and the overall feature is partially extracted by the upper-level network, consequently, some essential feature contents are lost in the convolution process, which affects the final classification accuracy. In this paper, a multi-branch feature fusion approach is employed, whereby the same hyperspectral data is fed into multiple branches for processing and obtaining multi-scale feature information. Subsequently, the information obtained from each convolutional layer is integrated together. Compared to a single-branch structure, this architecture can capture a more diverse and comprehensive range of information by incorporating low-, middle-, and high-level features, thereby enhancing the overall classification performance of the model. Finally, a Dropout layer is appended after the fully connected layer to forestall overfitting. The specific model framework is illustrated in Fig. 3.

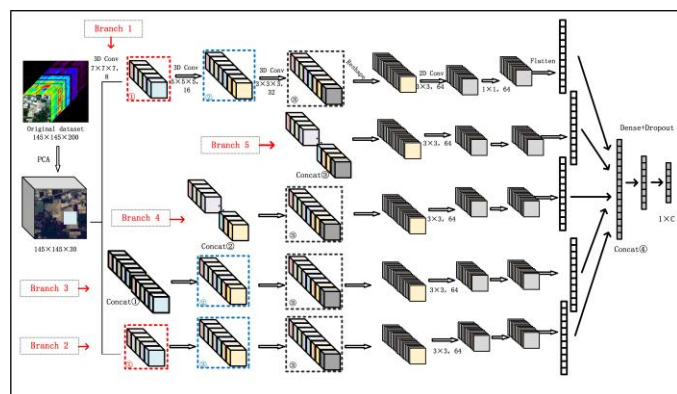

Fig. 3. The proposed network framework.

The proposed network framework is demonstrated using the representative Indian Pines dataset. The first stage of classification involves pre-processing the original hyperspectral dataset, wherein the spectral dimensionality is reduced, and redundant information is eliminated by applying PCA to reduce 200 spectral bands to 30. Afterwards, the reduced-dimensional dataset is fed into small cubes of size  $s \times s \times 30$  and slid from left to right and top to bottom as input for branch 1 and branch 2 of the same design in a convolutional network. These branches utilize three distinct 3D convolutional

layers with kernel sizes of  $7 \times 7 \times 7$ ,  $5 \times 5 \times 5$ , and  $3 \times 3 \times 3$  respectively, along with additional 2D convolutions using kernels of size  $3 \times 3$  and  $1 \times 1$ . As illustrated in Fig. 3, the output of the first convolution layer of the two branches, which is the feature map marked as number ① in Fig. 2, is connected together with the Concatenate function, and it is marked as Concat ①, and it is used as the input of branch 3. The two 3D convolution layers of the third branch are designated as  $5 \times 5 \times 5$  and  $3 \times 3 \times 3$ , respectively. 2D convolution kernel size is  $3 \times 3$  and  $1 \times 1$ , and the fourth branch in the same way.

The three output feature maps marked with number ② in the figure are also connected and marked as Concat ②, which is the input of branch 4, consisting of the second output feature map of branch 1 and branch 2 and the first output feature map of branch 3. The input of branch 5 is Concat ③, which is obtained by connecting the four outputs numbered ③. In this model, all branches finalize with two two-dimensional convolutional layers. Eventually, the one-dimensional vectors obtained by flattening all the branches are connected together again with the fully connected layer and the Dropout layer in turn. The extracted features are multi-classified and compared with the actual ground object map using the Softmax function in the final fully linked layer. The parameters of the complete model framework branches and convolutional layers are shown in Table I.

TABLE I. NETWORK STRUCTURES

### III. EXPERIMENT

The datasets, performance measurements, and experimental setting used in this work are briefly described in this section. It includes the partitioning of three publicly available datasets - Indian Pines, Pavia University, and Houston; as well as an explanation of the three objective evaluation metrics used in our experiments: OA, AA, and Kappa coefficients. Finally, we give a thorough explanation of the experimental setup and variables used in this research.

### A. Datasets

To execute the proposed model, three hyperspectral image datasets were utilized, namely Indian Pines, Pavia University and Houston, which differ in terms of band number, pixel count, feature classes and spatial resolution.

1) *Indian Pines(IP)*: The initial dataset comprises of Indian pine trees, captured by the infrared imaging spectrometer sensor AVIRIS in northwestern Indiana, USA. This image boasts a total of 220 bands, with 20 noise bands being eliminated to enhance its quality. Each individual band has a pixel size of  $145 \times 145$  and spatial resolution of 20 meters. It encompasses an impressive array of 16 feature species. In this paper, each feature class found in the Indian Pines dataset is painstakingly split into a training set, a validation set, and a testing set in the ratios of 1:1:8 in this research.

2) *Pavia University(PU)*: The second dataset captured by the ROSIS sensor over the University of Pavia is a stunning hyperspectral remote sensing image measuring  $512 \times 614$  with an impressive spatial resolution of 1.3 m. The image was imaged continuously in the wavelength range of 0.43-0.86  $\mu\text{m}$ , and after removing noise 12 bands that were severely affected by noise, the remaining 103 bands were used for classification. The dataset contains a total of nine categories of real features for classification, in the experiments of this paper 3% of the samples are selected as the training set and 3% as the validation set and the rest are used for testing.

3) *Houston (HT)*: The Houston dataset is acquired by the ITRES CASI-1500 sensor for ground feature information on the University of Houston campus and adjacent urban areas, and it is provided by the 2013 IEEE GRSS Data Fusion Competition with a spatial resolution of 2.5 meters. It contains  $349 \times 1905$  pixels, and this hyperspectral image consists of 144 spectral bands in the range of 380 nm to 1050 nm and contains 15 feature classes. As with the Indian Pine dataset, each class of features is divided into training set, validation set, and testing sets in the ratio of 1:1:8.

### B. Classification Index

To evaluate the effectiveness of our proposed model accurately and scientifically for classification, subjective perception alone is insufficient. Therefore, this paper employs evaluation indices including Overall Accuracy, Average Accuracy, Kappa coefficient [45].

- Overall Accuracy (OA): refers to the proportion of correctly classified test samples to the total number of test samples, reflecting the precision and effectiveness of classification performance.
- Average Accuracy (AA): refers to the ratio of the sum of classification accuracy of each type of ground object in hyperspectral images to the number of ground object classes.
- Kappa coefficient: It is an evaluation index used to test the consistency. It is used to test the consistency between the actual results and the predicted results in

hyperspectral images. Its value is generally between -1 and 1, and generally greater than 0.

### C. Experimental Environment

To verify the effectiveness of the proposed algorithm, this study was conducted in Python 3.8 environment with code written in TensorFlow framework and experiments on three publicly available datasets, including Indian Pines, Pavia University, and Houston. All experiments were run on NVIDIA RTX A6000 GPU servers.

## IV. EXPERIMENTAL PARAMETERS AND RESULTS

In this section, we first conduct experiments on the model's parameter settings, which involve adjusting parameters such as learning rate and epoch based on validation set results. We also analyse the effects of various settings on experimental outcomes, including training sample ratios across three datasets, input spatial region size for the model, and number of branches in the proposed multi-branch feature fusion model. When all the parameters were set, the results of the method proposed in this paper were analysed and compared with seven other different methods, including SVM[43], 1D-CNN[32], CDCNN[44], 3D-CNN[36], HybridSN[45], M3D-DCNN[46] and DBMA[47]. All the methods run in the same environment and use the same number of training set samples.

### A. Experimental Parameters Setting and Analysis

In this section, the primary objective is to optimize network parameters and determine the optimal configuration for the classification network by comparing experimental results, in order to achieve superior classification results. We ran experiments on three different datasets and picked the best network parameters after comparing them all. This resulted in the most accurate classification results for our network. The following comparative analysis presents learning rate, epochs, spatial size, training set ratio, and number of branches respectively.

1) *Learning rate and epochs*: It is crucial to ascertain the suitable learning rate for the model during training, as it is arguably the most critical hyperparameter to configure. The learning rate represents the magnitude of each parameter update in the network and dynamically adjusts during training with changes in epoch, following a specific update formula:

$$\omega_{i+1} = \omega_i - lr \nabla \quad (4)$$

Where  $\omega_{i+1}$  and  $\omega_i$  are the weight values of the  $i + 1$ st epoch and the  $i$ th epoch, respectively.  $lr$  is the learning rate and  $\nabla$  is the decay exponent.

As depicted in Fig. 4(a), with Adam optimizer and an initial learning rate of 0.001, both training accuracy and validation accuracy gradually improve as the number of epoch increases. The rising trend of both accuracies is consistent with the convergence trend, but there are certain fluctuations during the intermediate process, resulting in less stability. In Fig. 4(b), the relationship between epoch time and loss function is depicted, where an increase in epoch time leads to a gradual decrease and convergence of the loss function; however, it is evident that there exists a significant degree of fluctuation.

Fig. 4. Learning rate equals to 0.001. (a): Training and validation accuracy curves. (b): Training and validation of loss function curves.

With a reduced learning rate of 0.0005, the results depicted in Fig. 5 demonstrate faster convergence of both training and validation accuracy with smaller fluctuations, as well as quicker convergence of the loss function with less fluctuation compared to a learning rate of 0.001.

Fig. 5. Learning rate equals to 0.0005. (a): Training and validation accuracy curves. (b): Training and validation of loss function curves.

Furthermore, adjusting the learning rate to 0.0001 results in a clear convergence of the training and validation accuracy curves, with minimal fluctuations and improved overlap as shown in Fig. 6. This indicates a more stable convergence of the loss function. Therefore, following a comprehensive analysis of the relationship between the three learning rates and epochs, we have selected a more effective learning rate of 0.0001 and an epoch of 200 for experimentation in this paper. Based on these findings, we have set the optimizer's learning rate to 0.001 and the epoch to 200.

Fig. 6. Learning rate equals to 0.0001. (a): Training and validation accuracy curves. (b): Training and validation of loss function curves.

2) *Spatial size*: The spatial size refers to the dimension of the input sample after segmentation and dimensionality reduction of small cubes. For 3D CNN classification, the input data size is a crucial parameter that affects feature extraction and classification performance. Increasing spatial size captures more information but also introduces redundancy, which may affect final classification results. The experiments were conducted by setting  $15 \times 15$ ,  $17 \times 17$ ,  $19 \times 19$ ,  $21 \times 21$ ,  $23 \times 23$ ,  $25 \times 25$ ,  $27 \times 27$ ,  $29 \times 29$ .

Fig. 7. OA, AA, and Kappa values of three datasets at different spatial sizes. (a): Indian Pines. (b): Pavia University. (c): Houston.

The Fig. 7 shows the results of our experiments on the three datasets. As the space size increases, the OA, AA, and Kappa of the three datasets also increase. After the space size is larger than 25, the classification effect of the three datasets suddenly becomes worse, probably because the selected space is too large leading to more spatial contextual information, which brings redundancy leading to misclassification. And when the *spatial size* =  $25 \times 25$ , the datasets Indian Pines, Pavia University and Houston all reach the highest OA values of 98.92%, 99.16% and 99.30%, respectively. Therefore, combining the experimental results of the three datasets, the optimal parameter *spatial size* =  $25 \times 25$  was chosen in this study.

3) *Training set and ratio*: Deep learning-based classification models are highly reliant on the ratio of training samples. Generally, adding samples leads to improved performance in both training and testing. However, a significant challenge with hyperspectral data is the less labeled training samples. Furthermore, augmenting the size of the training dataset also results in prolonged training durations, which adversely affects model performance. Bearing these factors in mind, we will examine the impact of training set occupancy on classification outcomes. For the two datasets Indian Pines and Houston, training sets were used with 1%, 3%, 5%, 10%, 15%, 20%, 25%, and 30%, respectively; whereas for the larger dataset Pavia University, training sets with 0.1%, 0.5%, 1%, 3%, 5%, 10%, 15%, and 20% were used ratios were performed for the test.

Fig. 8. OA, AA, Kappa values of three datasets with different training set ratio. (a): Indian Pines. (b): Pavia University. (c): Houston.

From the Fig. 8, it is observed that as the training sample gradually increases, the OA, AA, and Kappa predicted by the classification model also improve, and when the training sample reaches 10%, the three evaluation indexes OA, AA, and Kappa of Indian Pines are 98.92%, 98.72%, and 98.76%, respectively, and the classification results of Houston were 99.30%, 99.44%, and 99.24%. In the case of Pavia University, owing to its large sample size, its OA, AA, and Kappa reached 99.16%, 98.53%, and 98.89%, respectively, when 3% was used for the training ratio, and the classification results were already better. In summary, our goal of minimizing the number of training samples and avoiding lengthy training time, was achieved by setting the training sample ratio to 10% for both

Indian Pines and Houston datasets, and 3% for Pavia University.

4) *Number of branches*: To validate the efficacy of branches in the proposed CNN, a series of comparative models have been devised to determine the optimal number of branches by assessing their impact on classification accuracy. The proposed model consists of five branches, Branch 1, Branch 2, Branch 3, Branch 4, and Branch 5 labelled in the network framework. This analysis explores the efficacy of branching in feature extraction and classification by examining the correlation between branch quantity and final classification outcomes.

In Fig. 9, where the meanings of the horizontal axes from 1 to 5, respectively, are:

- 1) (Branch1)
- 2) (Branch1  $\oplus$  Branch2)
- 3) (Branch1  $\oplus$  Branch2  $\oplus$  Branch3)
- 4) (Branch1  $\oplus$  Branch2  $\oplus$  Branch3  $\oplus$  Branch4)
- 5) (Branch1  $\oplus$  Branch2  $\oplus$  Branch3  $\oplus$  Branch4  $\oplus$  Branch5)

where the symbol  $\oplus$  denotes the Concatenate operation.

Fig. 9. OA, AA, Kappa values for three datasets with different number of branches. (a): Indian Pines. (b): Pavia University. (c): Houston.

As depicted in Fig. 9, the correlation between the number of branches in feature fusion and the three evaluation metrics (OA, AA, and Kappa) across three public datasets indicates that an increase in extracted features leads to higher OA, AA, and Kappa scores and improved classification performance. In this study, after analysing three sets of data and considering the number of branches and final results, the model ultimately selected five series branches to improve classification accuracy and enhance model robustness.

### B. Results

Table II to Table III and Fig. 10 to Fig. 12 show the results of three different datasets in seven classification methods, including the results of OA, AA and Kappa. In addition, Fig. 13 shows the confusion matrix for the three datasets acquired in this paper.

Table II and Fig. 10 reveal that SVM[43] exhibits the poorest classification results when using a training set of only 10% from the Indian Pine dataset, whereas DBMA[47] and HybridSN[45] demonstrate superior experimental outcomes in terms of classification accuracy compared to other methods. Amongst the seven compared methods, DBMA[47] stands out with its exceptional performance. Compared to DBMA[47], the proposed methods in this paper exhibit significant improvements in OA, AA and Kappa. Specifically, the classification accuracy of all types of ground objects is basically improved, eventually, OA is improved by about

0.88%, AA is improved by about 1.02%, and Kappa is improved by about 1.00%. It is worth mentioning that among the 16 features in Indian Pines, the classification results of five categories of features reached 100% under the classification method proposed in this paper.

TABLE III. CLASSIFICATION ACCURACY OF PAVIA UNIVERSITY

Classes	Accuracy (%): Pavia University (PU)							
	SVM	ID-CNN	CDCNN	3D-CNN	HybridSN	M3D-DCNN	DBMA	Ours
Dataset	PU	PU	PU	PU	PU	PU	PU	PU
1	92.06	92.88	92.92	93.11	97.51	94.56	98.12	98.52
2	97.94	96.98	97.75	98.01	99.95	99.31	99.90	99.86
3	72.74	83.06	89.44	91.01	97.69	78.88	90.70	99.51
4	93.78	85.77	97.81	89.70	92.50	94.68	95.94	95.63
5	99.46	99.46	100.00	99.16	99.92	100.00	99.61	100.00
6	83.68	75.34	91.30	88.60	100.00	72.67	100.00	99.94
7	85.04	78.22	94.07	82.64	100.00	82.64	100.00	100.00
8	89.83	82.50	91.26	89.36	97.31	98.40	99.30	99.08
9	100.00	99.67	99.44	90.42	82.05	99.78	99.54	94.23
OA	92.81	90.62	95.26	93.85	98.31	93.54	98.78	99.16
AA	90.50	88.21	94.89	91.34	96.32	91.21	98.12	98.53
Kappa	90.42	87.43	93.72	91.83	97.76	91.32	98.39	98.89

Based on Table III and Fig. 11, it is evident that among the six compared methods for the Pavia University dataset with only 3% training samples, 1D-CNN[32] exhibits the poorest classification performance while DBMA[47] remains superior in terms of classification accuracy. Furthermore, our proposed algorithm has demonstrated significant improvement compared to DBMA. OA, AA, and Kappa reached 99.16%, 98.53%, and 98.89%. Compared with the DBMA[47] algorithm, our method increases by about 0.38%, 0.41% and 0.50% for OA, AA and Kappa, respectively.

Table II and Fig. 12 present the experimental findings for the Houston dataset with a training sample of only 10%. It is evident that Houston's classification performance in 1D-CNN[32] was subpar, while it excelled in DBMA[47]. It is worth mentioning that the results obtained using the proposed

method show that seven of the fifteen classes of objects in the Houston dataset can achieve 100% classification accuracy, and compared with the best method DBMA[47], OA, AA and Kappa respectively increased by about 0.64%, 0.64% and 0.69%. Although the improvement results are modest, the classification metrics have reached 99.30%, 99.44%, and 99.24%.

From the above experimental results, we can see that DBMA [47] shows great superiority among the seven compared methods, which is the result of the development and application of the attention mechanism in recent years. Meanwhile, SVM [43] and 1D-CNN [32] exhibit poor results, confirming that the idea of using only spectral information is not enough, and the 3D convolution operation proposed in this paper is designed to make good use of both spatial and spectral information to improve accuracy. Therefore, it also enlightens

us to research and study the attention mechanism in the field of hyperspectral remote sensing image classification afterwards. And the model still has shortcomings and still needs to be studied and improved in depth. For the characteristics of small training samples of hyperspectral remote sensing data markers, the use of semi-supervised and unsupervised methods for classification in subsequent experiments is also one of the research directions. Moreover, with the development of attention mechanisms, the ability to suppress unimportant information as another improved feature of the model is one of the main points for continued learning in the future.

## V. CONCLUSIONS

A hyperspectral remote sensing image classification method based on multi-branch feature fusion is proposed in this paper to effectively extract spectral-spatial features of hyperspectral images and achieve efficient classification of ground objects. The proposed method, composed of multiple branches, yields more comprehensive and accurate extracted features. The 2D convolution layers are added to reduce the complexity brought by the 3D convolution, which makes the network not only more concise but also more deeply to extract spatial information. The experimental comparison results also demonstrate the preeminence of the proposed model over other methods, surpassing not only traditional classification techniques but also exhibiting significant advancements compared to other deep learning approaches. To sum up, the model approach proposed in this paper yields excellent classification outcomes across most datasets. Not only does it leverage 3D convolutional layers to simultaneously extract spectral-spatial features, but also reduces network complexity through the inclusion of 2D convolutional layers. Moreover, the multi-branch feature fusion structure enhances feature extraction adequacy and improves classification accuracy.

## VI. FUNDING STATEMENT

The research was financially supported by the Guangxi Key Laboratory of Precision Navigation Technology and Application at Guilin University of Electronic Technology, under grant number DH202208.

Universiti Teknikal Malaysia Melaka, Malaysia<sup>1</sup>

**Abstract**—Every organization uniquely adheres to security culture. Numerous studies have discovered that procrastinating, impulsive, forward-thinking, and risk-taking behaviors vary across organizations, which may help to explain why different organizations' adherence to security policies. This study describes the human aspect of a government organization in contributing to the successful implementation of a smart city by minimizing cybersecurity threats. Improper employee behavior and lack of understanding of cybersecurity will negatively contribute to the successful development of smart cities. The purpose of this research is to develop a framework to determine the factors to improve work behavior in terms of the contribution of social and technical factors. The use of a socio-technical approach to explain how socio-technical integration can contribute to improving work behavior by using mixed methods. The results indicated that several socio-technical factors which include technology, IT infrastructure, work organization, competency, training, and teamwork contribute to improving work behaviors which can be used as a basis for minimizing cybersecurity threats in smart city implementation.

**Keywords**—*Framework; socio technical; cybersecurity; behavior; threat; smart city*

## I. INTRODUCTION

Information and communication technology (ICT) has had an impact that can be felt in all sectors of human development. ICTs provide recent potential for the restoration soundness systems, new methods of citizens' authority, and active inclusion in their community at both charitable and political tiers. The elaboration of ICT has made a huge difference in the world. ICT affects many fields where it becomes a tool that enables the exchange of enormous information. ICTs deliver immensity and profound information to those who did not beforehand have this science and thus the chance for social and economic mobility.

Access to ICTs can have a profound influence on people's sense of empowerment and aptitude to be active participants in their society at both the political and social levels. ICT can intensify the empowerment of civil society by enhancing their proficiency to work as an organized network both within and beyond the frontier [1]. An ICT has altered the lives of society at the operative level. Technology gives people the operative power to commit, notify, create, study, perform, and demolish.

Technology also has its enchantment and attraction. Technology is not only an important means of human headway but also the most glorious human invention. Technological developments are difficult to stem because social entities show

a tendency to dominate and exploit operatively weaker entities [2]. The ICT has succeeded in improving the lives and broadening the horizons of society, but also facilitates the manipulation of society. Stunning sounds emanate from billions of screens and speakers around the world, and they shape people's thoughts and behavior.

Increasingly the means possessed by humans will be able to facilitate progress and human life but do not always lead to this goal. The effects of tool advancements depend to a large extent on the social and political environment that decides how these tools are used, and their operational strength. Society is getting stronger, but this does not mean that people's life has become preferable, wiser, and more beautiful. To make the world and life better, means must be used in a way that decrease misery, nescience, and devastation, for these are the basic dimensions by which human progress must be measured [2].

System improvement in urban areas based on the active use of information technology requires specialists with adequate qualifications, therefore, the methodological development of human resources needs to be considered from a bilateral approach position both in terms of executor and users [3]. Human resource development which is reviewed from two perspectives (executor and user) is necessary for the realization of smart city implementation.

The role of ICT is very substantial hence humans are very dependent on technology and humans cannot live without technology and it is very difficult and almost impossible to work without ICT. In everyday life, there are many cases where most people consciously or unconsciously use ICT purely [4].

Human teamwork in distributed knowledge-sharing groups relies on information and communication technology (ICT) functionality to support achievement. By adapting the level of detail of the information to the situation knowledge must be shared efficiently. In certain situations, information can be exchanged by involving people who work in collaboration [5].

Human development is one of the main factors that capture the core of livelihood in a community. In the current information age, the reach and diffusion of information and communication technology (ICT) that can reach remote countries in the world make it a stimulus to attain the preference for human development targets. The high population growth in urban areas will cause a lot of population problems as well as economic activity. [6].

Human factors contribute significantly to computer security, the human weaknesses that may cause unintentional jeopardize to the company or organization [7]. Cybersecurity is expanding to resolve the range of attack types while the attackers counter with their innovative hacking systems. Cybersecurity uses different approaches to upgrade detection of the threats [8].

Two things are the core elements of organizational culture, namely in the form of basic assumptions and beliefs. Collective norms and values will influence employee behavior. Organizational culture is consequently expressed in the collective values, norms, and knowledge of the organization. Several things are expressions of norms and values, namely artifacts and handbooks, rituals, and anecdotes [9]

Organizational culture can have dissimilar subcultures based on sub-organizations or purposes. Information Security Culture is a subculture concerning common company functions. It should support all activities so that information security becomes a natural aspect of the daily activities of every employee. Information security must become a natural aspect of employees' daily activities so that it can support all activities [9]

Another problem is cyberattacking have succeeded in defeating technical security solutions by utilizing human factor vulnerabilities related to security awareness, and skills and manipulating the human element to inadvertently grant access to important industrial assets. Knowledge and skills capability level contribute to human analytical proficiency to heighten cyber security readiness [10]

Human involvement is necessary to complement a technically based security approach to ensure overall cybersecurity. Human factors and organizational factors contribute to affecting the security of computing systems. The factors that appear on the user side are risk behavior, trust, lack of motivation, and inadequate use of technology while on the management side are inadequate workload and staff knowledge.

Information security violations can be classified in several different ways. The study [11] mentioned that based on several studies performed by other researchers provided thirteen attacks that cover all the computer security risk factors, and eventually defined "nine factors (that) can cover all risks as main factors". These factors are an excess privilege, error, and omission, denial of service, social engineering, unauthorized access, identity thief, phishing, malware, and unauthorized copy.

Information security practice accommodate all sociocultural quantify that support technical security methods, employee recognize that information security is a natural aspect to support daily activities. To utilize this socio-cultural behavior effectively and efficiently, management models and socio technical framework are required. The company must determine that the information security culture must be part of the organizational culture.[12] The contribution of the human factor in the failure to secure and protect systems, services, organizations, and information is tremendous [8]. The interrelationship of human and organizational factors and

computer and information security vulnerabilities is very significant. The factors that contribute to improving work behaviors to reduce cybersecurity threats and how the socio-technical factors contribute to improving work behavior is a discussion that will be explained in the results of study because human factors significantly influence people's interaction with information security hence generating many risks [13].

## II. LITERATURE REVIEW

### A. Smart City

The smart city concept continues to experience rapid development from year to year by following the flow of technological developments and innovations. The latest smart city concept, smart city 4.0, was just launched in 2017 by the innovation acceleration group from the University of Berkeley, California, United States. The Smart City 4.0 concept emerged as an action from the industrial revolution 4.0 by bringing initiatives to develop the skills of young innovators and entrepreneurs in the technology industry. Smart City 4.0 aims to develop skills for the industrial revolution 4.0 and accelerate technology development for young innovators, start-ups, and technology companies to create the best solutions to make cities smarter, safer, and more sustainable. [14].

Further, [15] identified two types of Japanese smart city initiatives: business-led initiatives conducted in conjunction with large-scale urban developments and government-led initiatives that are anchored within the vision statements of municipalities. Several experts have defined smart cities, [16] defined the smart city as a city that should integrate IT infrastructures, and social and economic issues to, more useful, and more flexible responses. Further, [17] mentioned that a smart city should be a city well performing in a forward-looking way with six smart characteristics (also called soft factors: smart economy, smart mobility, smart environment, smart people, smart living, smart governance), built on the smart combination of endowments and activities of self-decisive, independent, and aware citizens.

### B. Cybersecurity

Cyber security is an important issue in the infrastructure of every company and organization. A company or organization based on cybersecurity can achieve high status and countless successes because this success is the result of the company's ability to protect personal and customer data from competitors. Organizations and competitors' customers and individuals are rude. The company or organization must first and foremost provide this security in the best way to build and develop itself [18].

Cybersecurity includes practical steps to protect information, networks, and data from internal or external threats. Cybersecurity professionals protect networks, servers, intranets, and computer systems. Cybersecurity ensures that only authorized individuals have access to that information[19]. According to [19] Information Security is an effort to protect physical and digital data from unauthorized access, disclosure, misuse, unauthorized alteration, and deletion. Operational Security includes the processes and decisions made to control and protect data.

C. Behaviour

Behavior is the way a person or thing acts or reacts. The definition of behavior is based on the opinion of clinical psychologists and psychotherapists [20]. Behavior is an essential means for individuals to externalize information from their (entirely internal) psychological systems to their external surroundings. [21]

D. Socio Technical Concept

A socio-technical system (STS) consists of humans using technology to perform assignment through an operation within a social system (association) toward reaching a specified purpose. Numerous of the issues and losses of management information systems and administration science or operations research projects have been attributed to corporate behavioral concerns [29]. A socio-technical system (STS) consists of the complicated relations between sociable humans and technological systems. [22]

Socio-technical systems are distinguished by a high capacity of social complexity as well as technical intricacy to perform the essential positions of community [23] There was a synergistic combination of people, technology, organizational structures, and processes, including the operating environment in which all of this occurs [15]. The prefix socio is always associated with individuals and community in general, while 'technical' denotes something related to machines or technology. [22] The general structure of the STS and the elements that make up its complex social and technical dimensions are described differently by various researchers.

E. Related Works

Sociotechnical systems include physical and technical artifacts, organizations, scientific components, and legal [24]. Technical subsystems in an organization to solve complex issues [29]. The social subsystem consists of the organizational structure, which encompasses authority structures, reward systems, knowledge, skills, attitudes, values, needs and within the organization, employees can work by utilizing technological artifacts (tools, devices, and techniques) to achieve job satisfaction and economic performance [17]. As shown in Fig. 1, the socio-technical system, describes the interrelated nature of the organizational system, embedded in the external environment consisting of goals, people, buildings, technology, culture, and process [25].

Fig. 1. Socio-technical system, illustrating the interrelated nature of an organizational system, embedded within an external environment from [25].

Refer to Fig. 2. The information technology or information systems when developed require several social sub-system factors (user roles, social interaction) and technical sub-system factors (technical infrastructure, system access) [26].

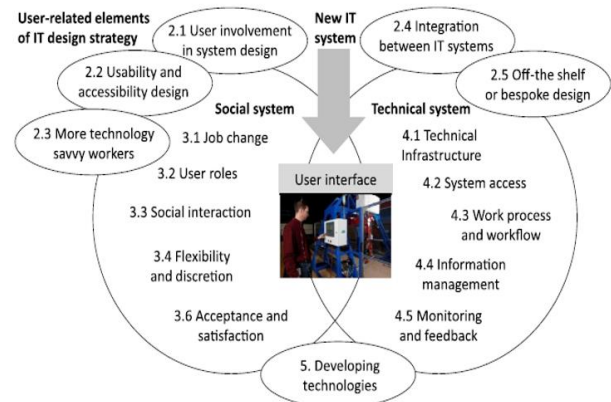

Fig. 2. Elements of the IT introduction and socio-technical system that may affect or be affected by the user-interface from [26].

The supporting elements in establishing a security system that is linked to Socio-technical will depend on the security requirements for the organization to determine the nature of ICT a culture of security to be cultivated. Apart from that, there are other defining requirements policies, and types of countermeasures (security systems) to be implemented. Next comes the security section requirements impose demands on the people who will interact with the system. Other activities such as motivation, training, and education need to be done thoroughly. In security culture issues, culture has effects on attitudes and beliefs, which in turn play a part in individual behaviors actions, and or reactions [30]

Based on Fig. 2, Fig. 3, a generic motif that can be accepted is the necessity and importance of work behavior to minimize cyber security threats. The questions here can rather be:

- 1) What are the factors that contribute to improving work behaviors to reduce cybersecurity threats?
- 2) How can socio-technical factors contribute to improving work behavior

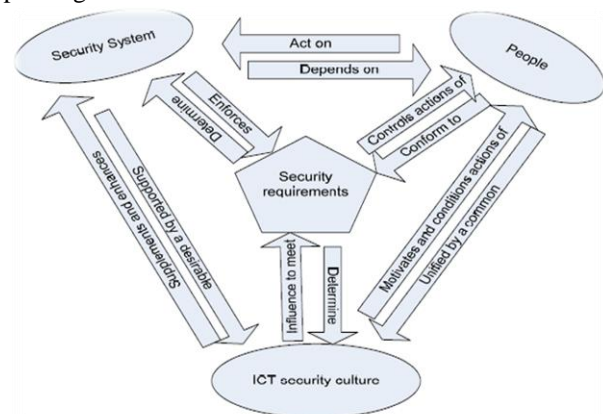

Fig. 3. An organizational framework showing ICT security culture in relation to other ICT security controls from [30].

### III. RESEARCH METHODOLOGY

The research methodology is described in Fig. 4.

1) *Literature review*: Literature reviews are more concentrated on the main studies according to the title of the research and those related to data collection both for interviews and research surveys. The literature review that emerged includes the concept and definition of smart city, definition of cybersecurity, concept of behavior, and socio-technical concept. The components and elements in the socio-technical will be used as a reference for building questions for qualitative studies and become question points in quantitative studies using the Likert scale model.

2) *Initial model*: This stage is the initial model used in this study. Referring to Fig. 1, the initial model adopts all socio-technical components, which consist of structure, technical, people, tasks, and environment. This initial model will then be used as a reference for processing questions for qualitative and point surveys for quantitative studies.

3) *Qualitative model*: The interview process is part of a qualitative study, namely by gathering as much information as possible from appointed and agreed sources. the results of this interview change the initial model by eliminating some of the components, namely by removing the environment hence that there will be four main components, namely structure, technical, people, and tasks.

4) *Quantitative model*: An interview to collect qualitative data will be carried out which is then followed by quantitative data collection by employing a survey questionnaire in the second phase [27]. Numerical data for quantitative research were collected and analyzed using statistical methods [28]. The model from the results of a qualitative study becomes a reference in a quantitative study the survey questionnaire will exclude an environmental component.

5) *Final model*: The final model is based on the quantitative finding. Data collection and data examination are essential when applying structural equation modeling (SEM). Several issues need to be addressed when utilizing a questionnaire survey. These issues include response rates, non-response bias, common method bias, missing data, and data distribution.

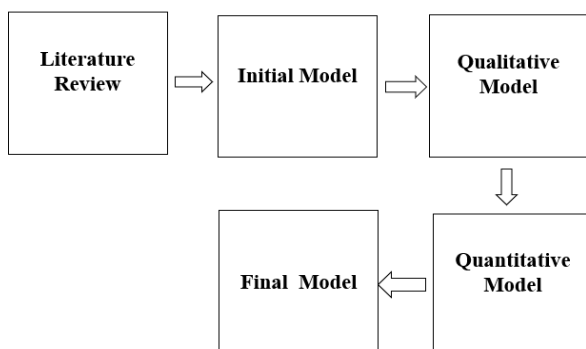

Fig. 4. Research methodology.

### IV. RESULT AND DISCUSSION

Being a part of continual research, this investigation is based on primary data origins gathered in West Java – Indonesia. Using mix-method research, is specifically primary analysis that contains the collection of data (interview and survey data), organizing it in some fashion (a social-technical framework) based on some factors of technological environment, personnel development, and organizational support. Fig. 5 shows the interaction between a social and technical system and the point interviews and questionnaires were made based on socio-technical components [29],[31] to obtain in-depth information about what factors influence improving work behavior. Each question and point questionnaire has been validated by several experts who are competent in their fields. Interviews were conducted thoroughly with several employees in the communication and information department which were conducted randomly and were conducted before the questionnaire process began.

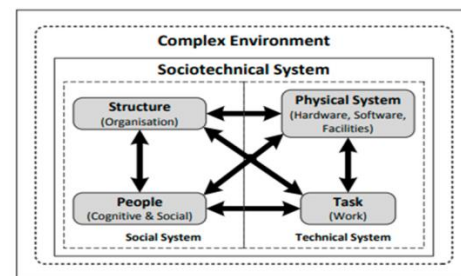

Fig. 5. Socio-technical perspective [29].

The initial model as shown in Fig. 6, propose includes technical, social, and environmental dimensions. Hypotheses that can emerge from the initial model which are displayed sequentially, are IT infrastructure has a positive influence on behavior, technology have a positive influence on behavior, IT infrastructure has a positive influence on competency, technology has a positive influence on work group, work organization has a positive influence on behavior, work organization has a positive influence on competency, competency has a positive influence on behaviors, company procedure have a positive influence on behaviors, IT awareness have a positive influence on behaviors, training have a positive influence on behavior, work group have a positive influence on behavior, environment have a positive influence on behavior, environment have a positive influence on competencies, and behaviors will give contribution and a positive influence for minimizing cyber security threat toward successful smart city implementation.

The interview process involved limited Ministry of Communication and Informatics (Kominfo) staff and employees; the number of interviewees was seven people. The interview process is carried out in stages and at different times according to the agreement. Some of the questions posed to them included:

- What is the impact of the external environment on competence?
- How does the organization provide direction regarding work behavior and culture?

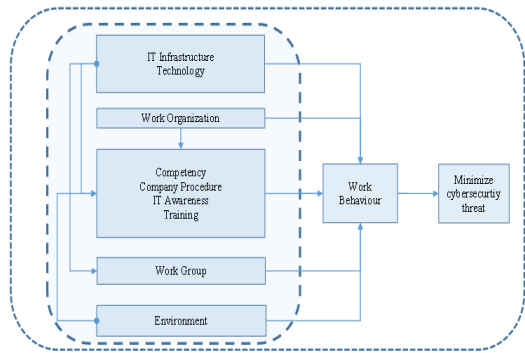

Fig. 6. Initial model.

The answer to the questions above is:

I believe the influence of the external environment on competency is not so significant that I can even say that there is no influence. (Respondent 1)

External factors do have the opportunity to contribute to employee competency but are very small and not significant (Respondent 3)

The qualitative method by using the interview process finally abolishes several hypotheses, as shown in Fig. 7 namely environment has a positive influence on behavior, environment has a positive influence on competencies, IT infrastructure has a positive influence on behaviors, and company procedure has a positive influence on behaviors.

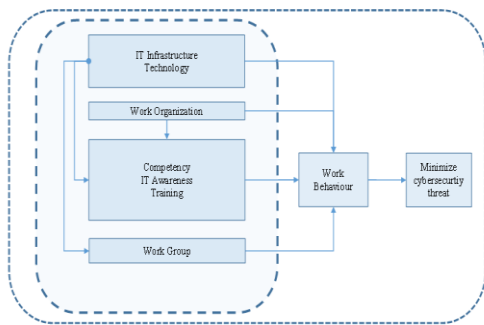

Fig. 7. New model based on qualitative result.

The questionnaires were delivered to employees who work at Kominfo. A total of 110 questionnaires were distributed to the Kominfo office in three districts, and 97 people filled out and returned the questionnaire form within two months. Table I shows the total questionnaire distributed which shows the data collected and which can be used.

TABLE I. DISTRIBUTION OF QUESTIONNAIRE

Office (District)	Distributed	Collected	Unusable	Usable
Karawang	55	43	0	43
Bandung	66	50	0	50
Purwakarta	10	4	0	4
Total	130	97	0	97

An example of a question sheet for a survey questionnaire is listed in Fig. 8.

**INSTRUCTION / ARAHAN:**  
 From Section B to F, please circle a number from 1 to 7 as an indication of the level of your agreement with the statement.  
 Dari Bagian B sampai F, harap lingkari angka dari 1 sampai 7 sebagai indikasi tingkat persetujuan Anda dengan pernyataan tersebut.

Strongly Disagree (1) Disagree (2) Somewhat Disagree (3) Neutral (4) Somewhat Agree (5) Agree (6) Strongly Agree (7)

Sangat Tidak Setuju (1) Tidak Setuju (2) Agak Tidak Setuju (3) Netral (4) Agak Setuju (5) Setuju (6) Sangat Setuju (7)

**SECTION B: COMPETENCY**  
**BAGIAN B : KOMPETENSI**

This section seeks to know your agreement on the level of your knowledge to optimize related to peripheral and application in IT  
 Bagian ini bertujuan untuk mengetahui persetujuan Anda tentang tingkat pengetahuan Anda terkait dengan periferal dan aplikasi di bidang TI

Items	Scales / Scala							
	Strongly Disagree	Disagree	Somewhat Disagree	Neutral	Somewhat Agree	Agree	Strongly Agree	
<i>As Employee in an Organization</i> Sebagai karyawan pada Organisasi ini								
1. Using ICT tools correctly is very important Menggunakan alat TIK dengan benar sangat penting	1	2	3	4	5	6	7	
2. The ability in the field of ICT is getting better with increasing years of work kemampuan di bidang TIK semakin baik seiring bertambahnya masa kerja		1	2	3	4	5	6	7
3. Understanding the office applications that are used in the organization is necessary Memahami aplikasi perkantoran yang digunakan dalam organisasi mutlak diperlukan		1	2	3	4	5	6	7
4. Knowing and understanding work culture is		1	2	3	4	5	6	7

Fig. 8. Form questionnaire.

The data represented in this area defines analysis data such as mean, minimum, maximum, standard deviation, median, and mode. Presentation of data descriptions starts from exogenous variables, namely IT infrastructure (X1), technology (X2), work organization (X3), IT awareness (X5), and training (X6) followed by endogenous variable competency (X4), workgroup (X7), behaviors (X8) and minimize cybersecurity threat (Y), descriptions of each variable are presented successively starting from variables X1, X2, X3, X4, X5, X6 X7, X8 and Y. As shown in Table II to Table X.

TABLE II. LATENT VARIABLE FOR IT INFRASTRUCTURE

	No.	Mean	Median	Min	Max	Standard Deviation	Excess Kurtosis	Skewness
X1.1	1.000	5.680	6.000	4.000	7.000	0.844	-0.540	-0.167

The quantitative process provides changes to the qualitative model by removing some of the attributes of the social dimension. The elimination of some attributes on the social dimension was due to the results of the questionnaire which was processed using structural equation modeling. Table XI shows the processing results of the quantitative method using SEM modeling. This hypothesis shows a negative result of IT awareness of work behavior, so the last model shown in Fig. 9 does not include the relationship between IT awareness and work behavior. The descriptive Analysis of Research Variables is shown in the table.

The framework created in this study is a communion of the framework composed by [30] and the research results resulting from the processing of structural equation models (SEM). The quantitative results show that the social dimension presents a great contribution than the technical dimension, this does not mean that social factors are more prominent, the contribution of both dimensions must still be required because both dimensions must continue to exist to be able to contribute to the development of the formation the work behavior. The factors that play a role in improving work behavior according to the research questions are as follows as shown in Fig. 5. The researcher divides the main factors contributing to increased work behavior into three parts, namely, personal development which consists of training and competency, organizational support which consist of teamwork and work organization, and

technological environment which consists of technology and IT infrastructure.

TABLE XI. HYPOTHESIS TESTING

Immediate impact	Path Coefficient	T count	Examination Conclusion
IT Infrastructure to competency (X1→X4)	0.335	3.462	H0 is refused, H1 is accepted. There is a positive direct effect of X1 → X4
Technology to work group (X2→X7)	0.270	2.918	H0 is refused, H1 is accepted. There is a positive direct effect of X2 → X7
Work Organization to competency (X4→X4)	0.283	3.274	H0 is refused, H1 is accepted. There is a positive direct effect of X3 → X4
Technology to behaviors (X2→X8)	0.219	2.860	H0 is refused, H1 is accepted. There is a positive direct effect of X2 → X8
Work Organization to behaviors (X3→X8)	0.160	1.992	H0 is refused, H1 is accepted. There is a direct positive effect of X3 → X8
Competency to behaviors (X4→X8)	0.167	2.135	H0 is refused, H1 is accepted. There is a positive direct effect of X4 → X8
IT Awareness to behaviors (X5→X8)	-0.204	2.502	H0 is refused, H1 is accepted. There is a direct negative effect of X5 → X8
Training to behaviors (X6→X8)	0.184	2.514	H0 is refused, H1 is accepted. There is a positive direct effect of X6 → X8
Work group to behaviors (X7→X8)	0.252	3.607	H0 is refused, H1 is accepted. There is a direct positive effect of X7 → X8
Behaviors to Minimize Cybersecurity Threat (X9→Y)	0.457	5.594	H0 is refused, H1 is accepted. There is a positive direct effect of X9 → Y

T Table = 1.96

Based on Fig. 9, the researcher makes a detailed elucidation by placing personal development as a fundamental basis then followed by organizational support and technological assistance. In most cases, personal development is a process of self-development owned by someone to achieve success in the world of work. In consort with personal development, employees can manage themselves well when working enterprise. The principal objective of this personal development is to dig up the potency that exists within oneself so that it can withstand to encounter all the alteration times that encircle it. Two factors need to be done for the self-development process, which can be through training and competency improvement.

According to [32] competence is the ability to act and think consistently that is owned by someone equipped with skills, basic attitudes, knowledge, and values. Competence is a person's skills and direct and indirect conduct that enable the person to effectively undertake a given assignment or assigned character. Hence, competence is not only about the capability or awareness that an employee has but the compliance to do what is known and can yield advantages.

According to [32] competence is the ability to act and think consistently that is owned by someone equipped with skills, basic attitudes, knowledge, and values. Competence is a person's skills and direct and indirect conduct that enable the person to effectively undertake a given assignment or assigned character. Hence, competence is not only about the capability or awareness that an employee has but the compliance to do what is known and can yield advantages.

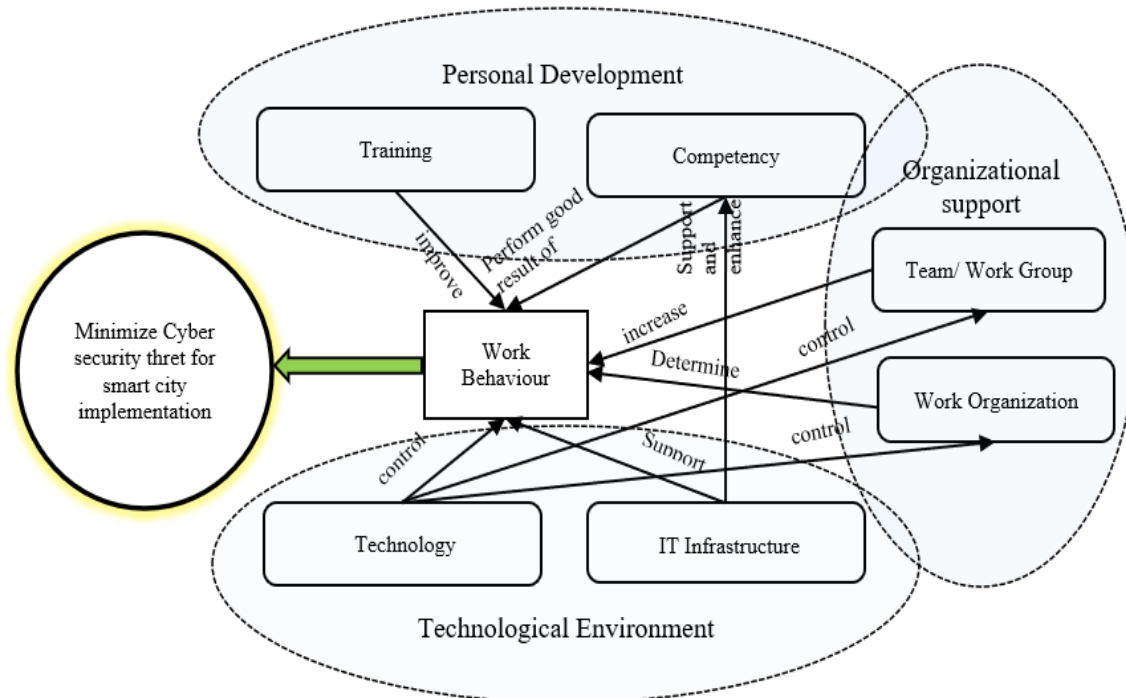

Fig. 9. Final model.

Training is one way to intensify competence [33]. Therefore, competence and training are two interconnected things. To rectify competency through training related to improving work behavior, there are several types of training that employees must obtain. Training is a key tool to increase the firm's organizational learning capability at individual, group, and organizational levels and, through this effect, training may affect performance. Some of the important training for employees, number one is the understanding importance of cybersecurity; cybersecurity is critical because it helps to protect organizations and individuals from cyber-attacks. Cybersecurity awareness is contributed to avert data breaches, identity stealing, and other types of cybercrime. Organizations are compulsory to apply strong cybersecurity measures to protect their data and customers. Behavior in the case of cybersecurity incidents, insider threats occur when an employee's careless behavior or lack of security awareness leads to a security breach.

For example, an employee might use an insecure password or fall for a phishing scam [34]. Malicious insider threats happen in case an employee intentionally causes a security breach.

Another compulsory training is how to defend against cyber-attack; this training will educate the employee to do some action against cybersecurity threats for example Turning on Multifactor Authentication. Implement multifactor authentication on your accounts and make it significantly less likely you'll get hacked [35].

Managing password security and a secure password is further important training for the user [36]. Robust passwords can assist defend against cyberattacks and reduce the hazard of a safety violation. The password generally is long—at least twelve symbols—and include uppercase letters, lowercase notes, digits, and certain symbols [37].

Robust passwords should not have any private data. Workplace protection directs to the measures put in place to save individuals, investments, and data from physical and digital threats. These hazards can reach in different shapes, running from robbery, roughness, and destruction to digital safety risks such as cyberattacks, data violations, and hacking.

Comprehending and protecting sensitive information is the other important training, the information needs to be protected to prevent that data from being misused by third parties for fraud, such as phishing scams and identity theft [38]. Data protection is also essential to help control cybercrimes by ensuring details (specifically banking) and reference report are covered to prevent deception.

The employee should know cyber-attack tactics [39], during a cyber-attack, the attacker gains unauthorized access to a computer system, network, or device for stealing, modifying, or destroying data. The attacker may use a variety of tactics, including malware, social engineering, or exploiting vulnerabilities in software or systems. Further incident response is an organized, strategic approach to detecting and managing cyber-attacks in ways that minimize damage, recovery time, and total costs. Detecting phishing emails, emails with bad grammar, and spelling mistakes, emails with

an unfamiliar greeting or salutation, inconsistencies in email addresses, links and domain names, and suspicious attachments, emails requesting login credentials, payment information, or sensitive data. [40].

Teamwork is part of the actor which is a social dimension. The objective of the entertainers in the organization is to emphasize the position recreated by human beings toward gaining protection. The actors include management and employees, and other stakeholders who execute or influence the way work organizational tasks are carried out and work organization is part of work activities. The purpose of work activities in the organization is to emphasize the purpose and implementation of suitable duties by individuals in extra operation and competency areas, using tools and resources, towards security. The work activities refer to the actual tasks and the way they should be carried out.

Technology and IT infrastructure are part of the technology from the technical dimension. The purpose of technology in the organization is to emphasize the tools and resources used by people in carrying out work activities towards achieving security. The technology includes any useful technical resources that can aid humans in performing their security duties, for example, information, equipment, frameworks, and computers.

In this research, the researcher uses two dimensions on the technical side, namely technology in general refers to Technology as the application of scientific knowledge to the practical aims of human life or, as it is sometimes phrased, to the change and manipulation of the human environment.

While IT infrastructure is part of the technology, more specifically the combined components needed for the operation and management of enterprise IT services and IT environments. The components of IT infrastructure are made up of interdependent elements, and the two core groups of components are hardware and software. The hardware uses software like an operating system to work, and likewise, an operating system manages system resources and hardware. operating systems also make connections between software applications and physical resources using networking components to produce a new framework, as shown in Fig.10., researchers adopted an ICT security framework from [30] as support and contribute to minimize cyber security threat for smart city implementation

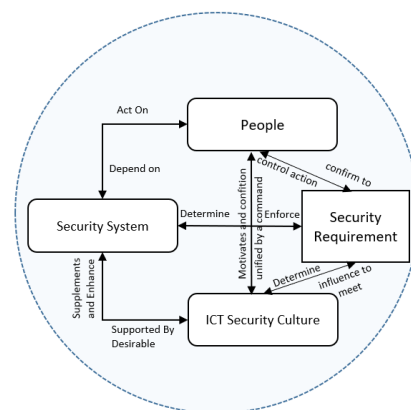

Fig. 10. ICT Security framework [30].

Fig. 11. Socio technical framework to improve work behavior.

Fig. 11 shows the relationship between the socio-technical components and their role in improving work behavior to minimize cyber security threats during smart city implementation. Planned training well and followed by all employees will improve work behavior. Training will contribute to employee competence and perform a good result to the work behavior. In addition, to be able to improve competency, good IT infrastructure support is needed. Organizational contributions make a dominant contribution, consisting of teams and organizational work that improve and determine work behavior. The level of success of the organization is determined by the support provided by the technology environment. The last component that contributes to improving work behavior is support from technology and IT infrastructure, implementation of backup systems, use of operating systems (OS), data communication devices, network security systems, anti-virus, and monitoring systems will have a major impact on work behaviors so that it is expected to be able to contribute to minimizing cyber security attacks in the framework of the successful implementation of smart cities.

## V. CONCLUSION AND FUTURE WORK

The results of the study show that social and technical factors contribute to increased work behavior; this is shown from the results of the quantitative method which produces a summary of hypotheses where there is only one hypothesis that shows negative results so that it cannot be used in the formulation of the framework proposed by the researcher. In this study, three main factors contribute to improving work behavior, namely personal development which consists of training and competency, organizational support which consists of teamwork and work organization, and technological environment which consists of technology and IT infrastructure to be able to contribute to minimizing threats cybersecurity.

In the future, organizations will experience many challenges, so to keep all problems better in the field of cybersecurity, a social-technical framework that is developed which aims to improve work behavior in a positive direction will be stronger when combined with a control framework by adopting a control objective for Information and related

technology (COBIT) and using the program and risk framework by implementing the NIST Cybersecurity Framework.

**Abstract**—In today's digital landscape, the identification of malicious software has become a crucial undertaking. The ever-growing volume of malware threats renders conventional signature-based methods insufficient in shielding against novel and intricate attacks. Consequently, machine learning strategies have surfaced as a viable means of detecting malware. The following research report focuses on the implementation of classification machine learning methods for detecting malware. The study assesses the effectiveness of several algorithms, including Naïve Bayes, Support Vector Machine (SVM), K-Nearest Neighbor (KNN), Decision Tree, Random Forest, and Logistic Regression, through an examination of a publicly accessible dataset featuring both benign files and malware. Additionally, the influence of diverse feature sets and preprocessing techniques on the classifiers' performance is explored. The outcomes of the investigation exhibit that machine learning methods can capably identify malware, attaining elevated precision levels and decreasing false positive rates. Decision Tree and Random Forest display superior performance compared to other algorithms with 100.00% accuracy. Furthermore, it is observed that feature selection and dimensionality reduction techniques can notably enhance classifier effectiveness while mitigating computational complexity. Overall, this research underscores the potential of machine learning approaches for detecting malware and offers valuable guidance for the development of successful malware detection systems.

**Keywords**—Malware; classification; machine learning; accuracy; false positive rate

## I. INTRODUCTION

In contemporary times, the Internet holds a crucial position in people's lives, functioning as a worldwide network of computers that employ the Internet Protocol for communication and information exchange. Nevertheless, the Internet is affected by multiple hazards, with malware being a prevalent issue [1]. The study [2] defines malware as harmful software, comprising viruses, worms, Trojans, Adware, and Ransomware. Most of the malicious software created in recent times poses a severe threat to an organization's information. Malware can infect any device that is connected to a computer network, causing damage to data, and facilitating theft that can be used for identity theft [3]. The widespread interconnectivity of modern devices has made this type of malware infection very common. Various forms of malicious software exist, such

as computer viruses, worms, Trojan Horses, spyware, rootkits, adware, and botnets.

Computer viruses are widely prevalent and propagate through files, infecting computer systems upon file access. Worms resemble viruses, reproducing rapidly and causing damage without user intervention [4]. Trojan Horses disguise themselves within programs, tricking users into downloading them to seize control and capture sensitive information. Spyware surveils and records user activities, including personal data [5]. Rootkits are purposefully designed to avoid detection, granting unauthorized remote access, and modifying system files. Adware generates intrusive ads while collecting personal information, and botnets disrupt computer networks by infecting multiple devices [6]. Hence, malware is classified as malicious software and presents significant risks that can result in substantial harm if not adequately protected [7].

The research paper makes several significant contributions as follows:

- A comprehensive dataset was obtained from a reputable source, [www.kaggle.com/datasets](http://www.kaggle.com/datasets). The dataset underwent thorough pre-processing to ensure its quality and suitability for analysis.
- Advanced techniques were employed to select the most relevant and informative features from the dataset. This process improved the accuracy of malware detection while reducing data dimensionality.
- The study employed various classification machine learning algorithms, including Naïve Bayes, SVM, KNN, Decision Tree, Random Forest, and Logistic Regression to detect and classify malware. These techniques enabled automated and efficient malware detection, saving valuable time and resources.
- The research aimed to improve the accuracy of malware detection. By leveraging the proposed methodology, the study contributes to reducing false positive rate, thereby enhancing the overall precision of malware identification.

The findings from this research have practical implications for the development of cybersecurity measures. By improving the accuracy of malware detection, organizations can enhance their defenses against cyber threats, ultimately safeguarding digital systems more effectively.

To ensure a well-structured approach to the research, this paper is divided into multiple sections. In Section II, a discussion of related work in the field is provided, with a particular focus on the research objectives of the study. Section III outlines the methodology utilized to complement the research, including details on data pre-processing and feature selection to optimize the performance of the classification machine learning techniques. Meanwhile, in Section IV, the outcomes of the evaluation on the machine learning classification techniques employed are presented, and a summary of the discoveries is provided in Section V.

## II. RELATED WORK

In this section, various investigations carried out by previous scholars on machine learning classification techniques are examined. Table I is provided to assist in this examination, summarizing the evaluated classification techniques in these studies. Classification is a valuable method for organizing objects according to their attributes and designations, and the insights gained from these investigations reveal the efficacy of different machine learning methods for this purpose.

To start, a method proposed by [8] for machine learning-based malware classification will be examined. Their approach involves analyzing packet information stored in a dataset. The team evaluated the accuracy and precision of four machine learning techniques, namely SVM, Decision Tree, Naïve Bayes, and Random Forest. While the researchers found Random Forest to have the highest accuracy of the four methods, they did not report on the false positive rate, a critical metric for assessing the efficacy of malware classification techniques.

A group of researchers [9] have conducted a study on identifying malicious network traffic in a cloud environment. They proposed a machine learning-based framework for intrusion detection, utilizing a dataset containing both normal and malicious traffic. The team extracted, selected, and added relevant features to train the machine learning models to differentiate between incoming traffic as either normal or anomalous. The researchers assessed the models using two methods: cross-validation and split-validation. The results indicated that KNN, Random Forest, and Decision Tree techniques achieved the highest detection accuracy. However, the SVM and Naive Bayes techniques had very low detection accuracy, resulting in a high false positive rate for both methods.

Research conducted in [10] focused on the identification of malware traffic through DNS over HTTPS connections. They employed four machine learning techniques: Random Forest, KNN, Logistic Regression and Naive Bayes, and tested them after selecting features. The results showed that Random Forest outperformed the other three techniques in detecting malware traffic. Consequently, the other three methods exhibited a relatively high false positive rate. Therefore, the study highlights the significance of selecting the appropriate machine learning technique for detecting malware traffic effectively.

Another technique designed by [11] aims to detect malware in a network environment using a visualization method involving 2D images and machine learning techniques. The

researchers evaluated the technique's accuracy for detecting malware using three different datasets. However, the technique did not achieve a high percentage of malware detection. For instance, the 2015 BIG dataset only achieved a 97.20% detection rate, which could indirectly affect the false positive rate.

TABLE I. PAST STUDY CLASSIFICATION TECHNIQUE

Malware detection & classification using machine learning	✗	✗	✗	✗	✓	✓
Malware analysis and detection using machine learning algorithms	✓	✓	✓	✗	✓	✓
Empirical study on Microsoft malware classification	✗	✓	✗	✓	✗	✓

In a recent academic paper by [12], a technique for detecting and categorizing malware was developed. The research process involved five phases, namely dataset creation, data preprocessing, feature selection, training dataset, and malware classification. The study aimed to discover fresh indicators of compromise through the utilization of machine learning methods to detect and classify malware. Nevertheless, the accuracy of the approach using Decision Tree and Random Forest models was found to be less than 99.50%, which implies that there is a high rate of false positives.

Researchers from [13] have proposed a robust and innovative methodology for effectively detecting malware by leveraging advanced machine learning algorithms. They discuss the challenges in analyzing and detecting malware due to its increasing complexity and sophistication. The proposed methodology involves three stages: data preprocessing, feature selection, and classification. The researchers use several machine learning algorithms such as decision tree, random forest, support vector machine, and logistic regression for malware detection. To evaluate the effectiveness of the proposed methodology, the authors used different evaluation metrics such as accuracy, precision, recall, and F1-score.

The research [14] discusses a study conducted on the Microsoft malware dataset to classify malware samples into

different families using four different classification algorithms: KNN, Decision Tree, Random Forest, and SVM. The algorithms' performance is evaluated using various metrics such as accuracy, precision, recall, F1 score, and AUC. The Random Forest algorithm is found to outperform the other algorithms, with an accuracy, precision, recall, F1 score, and AUC of 99.58% and 0.998, respectively. The SVM algorithm also performs well, with an accuracy, precision, recall, F1 score, and AUC of 98.74% and 0.994, respectively. Additionally, the authors analyze the algorithms' performance on different malware families, showing that the Random Forest algorithm performs consistently well across all families. The study concludes that machine learning algorithms are effective in classifying malware and provides insights into the performance of different algorithms on the Microsoft malware dataset.

The research [15] presents an empirical study of detecting malware families and subfamilies using machine learning algorithms. The study evaluates four different algorithms: Logistic Regression, KNN, Decision Tree, and Random Forest to classify malware samples into various families and subfamilies. The study evaluates algorithm performance using various metrics such as accuracy, precision, recall, F1 score, and AUC. Results indicate that the Random Forest algorithm outperforms others, achieving 98.7% accuracy in identifying malware families and 92.8% accuracy in identifying subfamilies. It also performs consistently across different type of malware. The study concludes that machine learning algorithms are effective in detecting malware and provides insights into their performance.

After reviewing previous studies in this field, it is evident that the feature selection present in the datasets utilized should be enhanced. It is crucial to decrease the false positive rate percentage to attain a high level of detection accuracy. This finding underscores the significance of selecting relevant and effective features for use in malware detection and classification techniques. By improving feature selection, the risk of generating false positive rates can be minimized, leading to more reliable and accurate results.

### III. PROPOSED METHODOLOGY

In this section, the stages required to finalize the research were covered. The process consists of a total of five stages, commencing with dataset preparation, and followed by the remaining four phases depicted in Fig. 1.

Fig. 1. Methodology of proposed malware detection.

#### A. Dataset Preparation

The initial stage involves preparing a dataset, which is critical as it enables the generation of data appropriate for machine learning techniques. The data will be utilized for classifying malware. Dataset preparation aids in establishing the proper data collection method. The dataset was procured from Kaggle, an open-source platform frequently employed by researchers in machine learning projects. Table II illustrates the 35 features that will be utilized in the study. To ensure high-quality data, data preprocessing will be conducted, and the refined data will be stored in a new file.

TABLE II. SAMPLE OF DATASET

hash	millisecond	classification	state	...	signal_nvcsw
abc.com	415	Benign	0	...	0
42fb5e	420	Malware	4096	...	0
024b27	90	Malware	4096	...	0
xyz.com	773	Benign	0	...	0

During the review process, some shortcomings were identified in the dataset, including redundant data and missing values. The fundamental principle is to ensure high-quality data for the study. To achieve this, two data preprocessing techniques will be undertaken: data cleaning and data reduction. The dataset will be inspected for missing values or empty cells, as illustrated in Fig. 2, in order to address these issues and ensure the data quality. A value of 1 denotes an empty cell in the hash, state, or prio columns, while a value of 0 indicates no missing values.

The secondary approach involves examining duplicated information, as depicted in Fig. 3. Whenever the result is affirmative, a duplicated record exists within the respective row. To illustrate, the application of this technique reveals the presence of replicated data on rows 3, 5, and 8.

```

In [4]: import pandas as pd
df = pd.read_csv('Desktop/malware_dataset.csv')
df.isnull().sum()

Out[4]: hash            1
millisecond            0
classification         0
state                 1
usage_counter         0
prio                  1
static_prio           0
normal_prio           0
policy                0
  
```

Fig. 2. Check for missing values.

```

In [13]: import pandas as pd
df = pd.read_csv('Desktop/malware_dataset.csv')
df.head(10).duplicated()

Out[13]: 0    False
1    False
2    False
3     True
4    False
5     True
6    False
7    False
8     True
9    False
  
```

Fig. 3. Check for duplicate data.

B. Features Selection

The subsequent stage of the research, referred to as feature selection, involves utilizing the correlation matrix to select the appropriate features. This is a crucial method for analyzing the connection between input and target data variables [16]. The correlation matrix enables the determination of whether the variable values are positive, negative, or zero. Out of the 35 features in the dataset, only 24 were selected based on the correlation matrix values that range from -0.39 to 1. Thus, 11 features had to be disregarded since the correlation matrix did not generate any values for them.

C. Data Splitting

Moving to the third phase of the study, data splitting is performed. This phase allows for the division of the dataset into two distinct parts: the training set and the testing set. The training set is critical in determining the suitability of machine learning techniques using data samples from the dataset, whereas the testing set is used to evaluate these techniques [17]. The train and test functions were implemented to segregate the two data categories. The dataset was split, with 80% of the data allocated to the training set and the remaining 20% to the testing set. The uneven allocation of data samples ensures an unbiased performance percentage for malware classification.

D. Build Techniques

Moving on to the fourth phase, which involves building machine learning techniques. This phase is dedicated to developing machine learning techniques using specific functions after providing training and testing sets. As an example, the SVC class was utilized to develop the SVM technique and evaluate its classification accuracy in detecting malware. All the developed techniques were trained and tested based on the selected features presented in the second phase.

E. Malware Classification Evaluation

The final stage of the study involves evaluating the malware classification. The techniques developed were evaluated using the confusion matrix, as illustrated in Table III, to assess their performance.

TABLE III. CONFUSION MATRIX

		Predicted Classification	
		Malware	Benign
Actual Classification	Malware	TP	FN
	Benign	FP	TN

The confusion matrix contains four parameters: true positive (TP), false positive (FP), true negative (TN), and false negative (FN). TP measures the correctly classified malware, while TN measures the correctly classified benign samples. On the other hand, FP measures the benign samples incorrectly classified as malware, and FN measures the malware samples incorrectly classified as benign. To measure accuracy and false positive rate, standard formulas were utilized. The results are presented in percentage form.

$$Accuracy = \frac{TP+TN}{TP+TN+FN+FP} \times 100 \tag{1}$$

$$FPR = \frac{FP}{FP+TN} \times 100 \tag{2}$$

IV. RESULT AND DISCUSSION

In this section, the experimental results for all the techniques involved are presented. The performance of the proposed malware detection method will be examined first, followed by a comparison with the performance of the previous techniques.

A. Performance Comparison in Proposed Malware Detection

Based on Fig. 4, it illustrates the performance of all the techniques tested in the proposed malware detection. The evaluation of each method's performance was done using two crucial metrics: accuracy and false positive rate. The results are presented in percentage format, providing a comprehensive overview of the achieved performance levels.

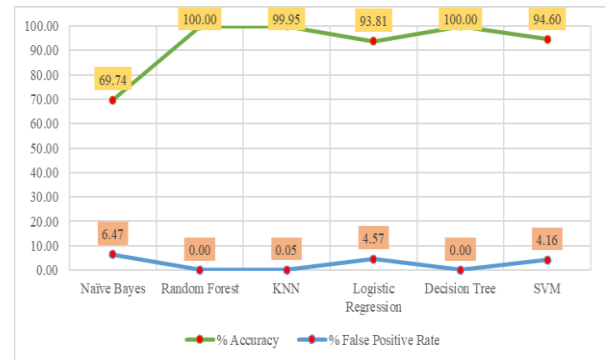

Fig. 4. Comparative analysis of classification techniques in proposed malware detection.

The obtained results demonstrate significant variations in the performance of the different techniques. Naïve Bayes achieved an accuracy of 69.74% with a false positive rate of 6.47%. Random Forest exhibited exceptional performance, attaining a perfect accuracy of 100.00% and a false positive rate of 0.00%. KNN achieved a high accuracy of 99.95%, with a minimal false positive rate of 0.05%. Logistic Regression demonstrated a balanced performance, with an accuracy of 93.81% and a false positive rate of 4.57%. Decision Tree matched Random Forest in terms of accuracy and false positive rate, both achieving perfect scores of 100.00% and 0.00%, respectively. SVM achieved an accuracy of 94.60%, with a false positive rate of 4.16%.

The results indicate that Random Forest and Decision Tree outperformed all other techniques in terms of accuracy and false positive rates, achieving perfect scores. However, it should be noted that achieving 100.00% accuracy may raise concerns of overfitting, especially if the dataset used for evaluation is relatively small or unrepresentative. Naïve Bayes exhibited a lower accuracy compared to other techniques, but it demonstrated a relatively low false positive rate. KNN and SVM also performed well, showcasing high accuracy rates with negligible false positive rates. The performance of all techniques is based on the experimental results presented in Table IV. The Naïve Bayes technique exhibited a correct identification of 3,401 malware packets and 6,921 benign packets. However, it also misclassified 4,478 packets, which indicates a relatively high misclassification rate. This suggests that Naïve Bayes may not be the most accurate approach for this specific task of identifying malware and benign packets.

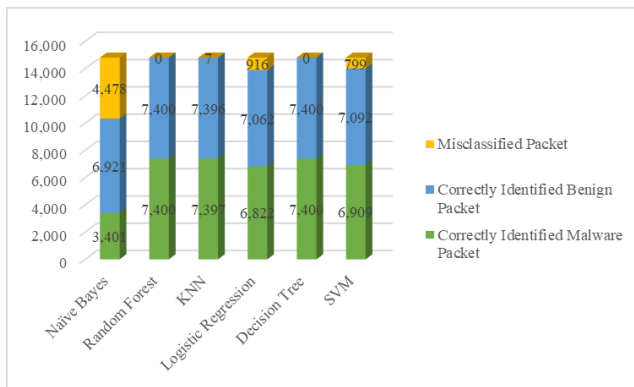

Fig. 5. Classification of the number of packets.

The Random Forest technique demonstrated impressive performance by correctly identifying 7,400 malware packets and 7,400 benign packets. It achieved a perfect classification rate with zero misclassified packets. This indicates that Random Forest is a robust and accurate technique for effectively identifying both malware and benign packets in this context. Meanwhile, KNN achieved high accuracy by correctly identifying 7,397 malware packets and 7,396 benign packets. However, it did misclassify a small number of packets, amounting to only 7 instances. This suggests that KNN may face some difficulty in accurately distinguishing certain types of packets. Following that, the Logistic Regression technique achieved accurate identification by correctly classifying 6,822 malware packets and 7,062 benign packets. However, it had a higher misclassification rate compared to other techniques, misclassifying 916 packets. This indicates that Logistic Regression may struggle with distinguishing between certain types of packets, leading to a relatively higher number of misclassifications (see Fig. 5).

Similar to Random Forest, the Decision Tree technique achieved perfect classification by correctly identifying 7,400 malware packets and 7,400 benign packets. It had zero misclassified packets, showcasing its effectiveness for accurately classifying packets in this task. Moving forward, the SVM technique demonstrated correct identification by accurately classifying 6,909 malware packets and 7,092 benign packets. However, it had a comparatively higher misclassification rate of 799 packets in comparison to certain other techniques. This indicates that SVM may not deliver optimal performance on this dataset, suggesting that it might not be the most suitable choice for accurately identifying malware and benign packets in this specific context.

### B. Performance Comparison between Proposed Malware Detection Technique and Previous Techniques

This section provides a performance comparison between the proposed malware detection method in this study and previous techniques. The comparison evaluates the accuracy achieved by different machine learning algorithms, as presented in Table IV. In the technique proposed by Harsha and Thyagaraja (2021), Random Forest emerged as the top-performing algorithm with an accuracy of 99.27%. This result highlights the suitability of Random Forest for this particular technique. Naïve Bayes also achieved a decent accuracy of 82.12%, suggesting its effectiveness as well. Decision Tree and

SVM demonstrated respectable performances with accuracy of 88.74% and 92.64% respectively.

TABLE IV. PERFORMANCE COMPARISON BETWEEN PROPOSED MALWARE DETECTION TECHNIQUE AND PREVIOUS TECHNIQUES

Technique	Machine Learning Algorithm					
	Naïve Bayes	Random Forest	KNN	Logistic Regression	Decision Tree	SVM
Harsha and Thyagaraja (2021)	82.12	99.27	NA	NA	88.74	92.64
Alshammari and Aldribi (2021)	59.87	100.00	98.94	NA	100.00	80.66
Singh and Roy (2020)	NA	99.99	99.31	96.86	NA	NA
Roseline et al. (2020)	52.14	91.22	85.28	62.59	86.41	89.25
Agarkar and Ghosh (2020)	NA	99.47	NA	NA	99.14	NA
Akhtar and Feng (2022)	89.71	92.01	95.02	NA	99.00	96.41
Chivukula et al. (2021)	NA	97	96.00	89.00	NA	NA
<b>Proposed malware detection</b>	<b>69.74</b>	<b>100.00</b>	<b>99.95</b>	<b>93.81</b>	<b>100.00</b>	<b>94.60</b>

For the technique introduced by Alshammari and Aldribi (2021), Random Forest and Decision Tree showcased perfect accuracy of 100.00%, indicating their strong performance in this context. KNN also performed well with an accuracy of 98.94%. However, SVM achieved a relatively lower accuracy of 80.66% in this scenario. Singh and Roy (2020) technique showed impressive results with Random Forest achieving an accuracy of 99.99% and KNN achieving 99.31%. Logistic Regression also performed well with an accuracy of 96.86%. Unfortunately, the accuracy for Naïve Bayes, Decision Tree, and SVM are not available.

In the study conducted by Roseline et al. (2020), Random Forest achieved a relatively high accuracy of 91.22%. Decision Tree and SVM also demonstrated respectable performances with accuracy of 86.41% and 89.25% respectively. However, Naïve Bayes and Logistic Regression achieved lower accuracy in this particular scenario. Agarkar and Ghosh (2020) technique showcased the effectiveness of Random Forest and Decision Tree, achieving accuracy of 99.47% and 99.14% respectively. Unfortunately, the accuracy for Naïve Bayes, KNN, Logistic Regression, and SVM are not available.

Akhtar and Feng (2022) technique demonstrated the strength of Decision Tree with an accuracy of 99.00%. SVM and KNN also performed well, achieving accuracy of 96.41% and 95.02% respectively. Naïve Bayes achieved a decent accuracy of 89.71% in this scenario. Meanwhile, Chivukula et al. (2021) technique showed strong results with Random Forest achieving an accuracy of 97.00% and KNN achieving 96.00%. Logistic Regression achieved a respectable accuracy of 89.00%. Unfortunately, the accuracy for Naïve Bayes, Decision Tree, and SVM are not available. Finally, in the proposed malware detection technique, Random Forest,

Decision Tree, and SVM achieved perfect accuracy of 100.00%, indicating their effectiveness in this context. KNN achieved a high accuracy of 99.95%, while Logistic Regression achieved a decent accuracy of 93.81%. Naïve Bayes achieved a relatively lower accuracy of 69.74% in this scenario.

Based on above discussion, it appears that Random Forest and Decision Tree consistently performed well across multiple techniques and datasets for malware detection. These algorithms achieved high accuracy rates, often reaching perfect or near-perfect accuracy in the studies mentioned. This suggests that Random Forest and Decision Tree are robust and suitable choices for malware detection tasks. KNN and SVM also showed good performance in some scenarios, achieving high accuracy rates. However, their performance varied across different techniques and datasets. It is important to note that the accuracy of Naïve Bayes, Logistic Regression, and SVM was not available in some studies, so it is difficult to make a comprehensive assessment of their performance.

Overall, the results indicate that the proposed techniques generally achieved high accuracy in detecting malware, highlighting their potential for enhancing cybersecurity measures. However, it is essential to consider that the performance of machine learning algorithms can vary depending on the specific technique, dataset, and evaluation metrics used in each study.

## V. CONCLUSION

A classification technique was developed by the research team to differentiate between malware and benign samples. Several machine learning methods were employed to train a dataset for this purpose. To evaluate the effectiveness of these methods, a comprehensive analysis consisting of five crucial stages was conducted, as outlined in Section III. Based on the analysis, it was found that the Random Forest and Decision Tree consistently performed well across multiple techniques and datasets for malware detection.

Future work in the field of malware detection should focus on several key areas. Firstly, enhancing feature engineering techniques can improve the representation of malware characteristics. This could involve exploring more sophisticated feature extraction methods or incorporating domain-specific features that capture nuanced patterns and behaviors unique to malware. Secondly, further investigation into ensemble methods can be valuable. While Random Forest and Decision Tree algorithms have demonstrated strong performance, exploring advanced ensemble techniques, such as boosting or stacking, may enhance the overall classification accuracy and robustness of malware detection models. Finally, the application of deep learning approaches, such as convolutional neural networks or recurrent neural networks to analyze malware samples and behaviors shows promise. Developing deep learning architectures that effectively capture intricate patterns and detect zero-day or polymorphic malware could significantly improve detection capabilities.

# Evaluation of the Accidents Risk Caused by Truck Drivers using a Fuzzy Bayesian Approach

Imane Benallou, Abdellah Azmani, Monir Azmani  
Intelligent Automation Laboratory  
FST of Tangier, Abdelmalek Essaadi University, Morocco

**Abstract**—Road accidents cause hundreds of fatalities and injuries each year; due to their size and operating features, heavy trucks typically experience more severe accidents. Many factors are likely to cause such accidents; however, statistics mainly blame human error. This paper analyses the risk of accidents for heavy vehicles, focusing on driver-related factors contributing to accidents. A model is developed to anticipate the probability of an accident by using Bayesian networks (BNs) and fuzzy logic. Three axioms were verified to validate the developed model, and a sensitivity analysis is performed to identify the factors that have the most significant influence over truck accidents. Subsequently, the result provided by the model was exploited to examine the effects of in-vehicle road safety systems in preventing road accidents via an event tree analysis. The results underlined a strong link between the occurrence of accidents and parameters related to the driver, such as alcohol and substance consumption, his driving style, and his reactivity. Similarly, unfavourable working conditions significantly impact the occurrence of accidents since it contributes to fatigue, one of the leading causes of road accidents. Also, the event tree analysis results have highlighted the importance of equipping trucks with these mechanisms.

**Keywords**—Heavy truck vehicle; road accident prevention; risk management; bayesian-fuzzy network; analysis tree event

## I. INTRODUCTION

The increase in road crashes is currently a significant concern for health and social policies in countries worldwide. Approximately 1.3 million people worldwide die on the roads yearly, while 20 to 50 million suffer serious injuries, most of which require lengthy and costly treatment [1]. Road crashes result in significant economic losses for victims, their families, and the nation. Most countries spend 1% to 3% of their gross domestic product on road crashes [2].

Collisions with heavy trucks are more critical than other traffic accidents [3]. In 2019, there were 510,000 crashes involving large trucks, of which 4,479 (1 per cent) were fatal [4]. Heavy trucks' large size and operational characteristics make the consequences of large truck crashes catastrophic: injuries are severe to disastrous and property losses are massive [5]. Various factors can contribute to an accident, including road, human, environmental, and vehicle-related factors [5]. However, human error accounts for 90% of fatal accidents [6].

This paper focuses on the driver-related parameters that contribute to accident occurrence. A predictive model incorporating the various causal links between the driver-related variables that influence the probability of an accident is

created. Using BNs, the propagation of probabilities on all possible states of each node within the network could be achieved. Also, various scenarios were tested using the configuration of the input nodes in the network. Finally, an event tree analysis was carried out to examine the impact of in-vehicle road safety systems in preventing road accidents.

The model developed will make it possible to estimate a driver's probability of causing an accident in advance, which will help implement preventive measures such as developing targeted awareness programs. These programs will inform high-risk drivers of unsafe behaviors and help them adopt safer driving practices. In addition, financial incentives can encourage drivers to adopt safer behaviors, whether by offering monetary rewards or applying penalties to higher-risk drivers.

The article's body has the following structure: Section II presents the related work. Section III explains the methodology used to build the proposed fuzzy Bayesian model; the results obtained are also discussed in this section. Section IV discusses the likely crisis scenarios relating to a truck accident through the application of event tree analysis. Finally, the conclusion is presented in Section V.

## II. RELATED WORK

Numerous issues about road safety have been investigated in earlier studies. In accident detection, several models based on machine learning and deep learning have been developed to detect road accidents ([7], [8], [9], [10], [11]). Concerning predicting the severity of accidents, neural networks have been used to create models capable of predicting the severity of road accidents [12], [13]. In accident prevention, Kabir et Roy [14] developed an algorithm based on deep learning for real-time collision avoidance. Fan et al. [15] used SVM and deep neural networks to develop an algorithm for identifying and analyzing traffic accident black spots. To predict accidents, neural networks have made it possible to build models capable of predicting the occurrence of road accidents [16], [17]. Sangare et al. [18] combined two approaches: support vector classifier (SVC) and Gaussian mixture model, to give a prediction of traffic accident occurrence.

Regarding BNs, they have been widely used to solve problems related to road safety. Sun et al. [19] used a hybrid method integrating a random parameter logit model and a BN to analyze accidents involving vulnerable road users and motor vehicles in Shenyang, China, focusing on seasonal differences. The study uses three accident datasets: the entire dataset, the "spring and summer" dataset, and the "fall and winter" dataset.

The random parameter logit model was used to identify significant factors and heterogeneity across the three datasets. The critical factors were then used to build a BN to investigate statistical associations between injury severity and descriptive attributes. Kuang et al. [20] proposed a two-level model, consisting of a cost-sensitive BN and a K-nearest neighbour weighted model, to predict the crash duration. Using the collected data, a cost-sensitive BN can qualitatively indicate whether the accident duration is less than or greater than 30 minutes. Then, the KNN regression model will give the precise duration value for each accident class. Karimnezhad et Moradi [21] considered learning the BN structure from the data collected on the accidents recorded on one of the highways in Iran. They could also calculate the probability of being injured by a driver based on some information about his node. They also examined the effect of seat belt use on the number of fatal accidents. Deublein et al. [22] developed a model to predict the number of injury accidents; this model can give the expected number of road users likely to be slightly, severely, or fatally injured. The model also identifies road sections with a high probability of accidents. The methodology combines three statistical methods: Gamma-updating, multivariate Poisson-lognormal regression analysis and BNs.

Despite the diversity of works that have addressed the road safety problem, the probability of a driver causing an accident has not been addressed in any work. Most of the parameters considered in these studies generally relate to road architecture, vehicle characteristics, and weather conditions. No advantageous interest was given to the human factor.

### III. SYSTEM MODEL

The proposed risk assessment model aims to estimate the probability of a driver causing an accident. To achieve this goal, a thorough literature search was conducted and experts were surveyed to discover all the variables that could affect the probability of an accident. These searches allow us to highlight the relationships between these variables and construct the BNs

structure. The conditional probability tables were produced using a Sugeno fuzzy inference system in the following phase. Finally, the probability of an accident was calculated by anticipating a few possible scenarios.

#### A. Construction of the BN

A BN is a graphical model representing probabilistic relationships between variables; it allows knowledge acquisition, representation, and use [23]. The principle of inference in BNs is based on Bayes' probability theory. The joint probability distribution of a set of nodes  $N = \{X_1, X_2, \dots, X_n\}$  can be expressed as follows [24]:

$$P(X_1, X_2, \dots, X_n) = \prod_{i=1}^n P(X_i | \text{Parents}(X_i)) \quad (1)$$

Where  $\text{Parents}(X_i)$  represents the set of parent nodes of  $X_i$

The availability of values on a child node  $X_i$ , allows us to express the posterior probability of the parent node  $X_j$  as follows [25]:

$$P(X_j | X_i) = \frac{P(X_i, X_j)}{P(X_i)} \quad (2)$$

To build our BN, we conducted an extensive literature review. Also, experts were surveyed to collect their opinions on the factors that can cause an accident and the causal relationships between the different parameters. Thus, a BN was set up in three levels represented in Fig. 1:

- The input nodes are described at the first level; they indirectly impact accident risk. As seen in Table I, they fall into five groups.
- The intermediate nodes (colored in yellow in Fig. 1) lead to the final impacts and make up the second level.
- The third level groups the last effects that directly influence the accident occurrence (colored in gray in Fig. 1).

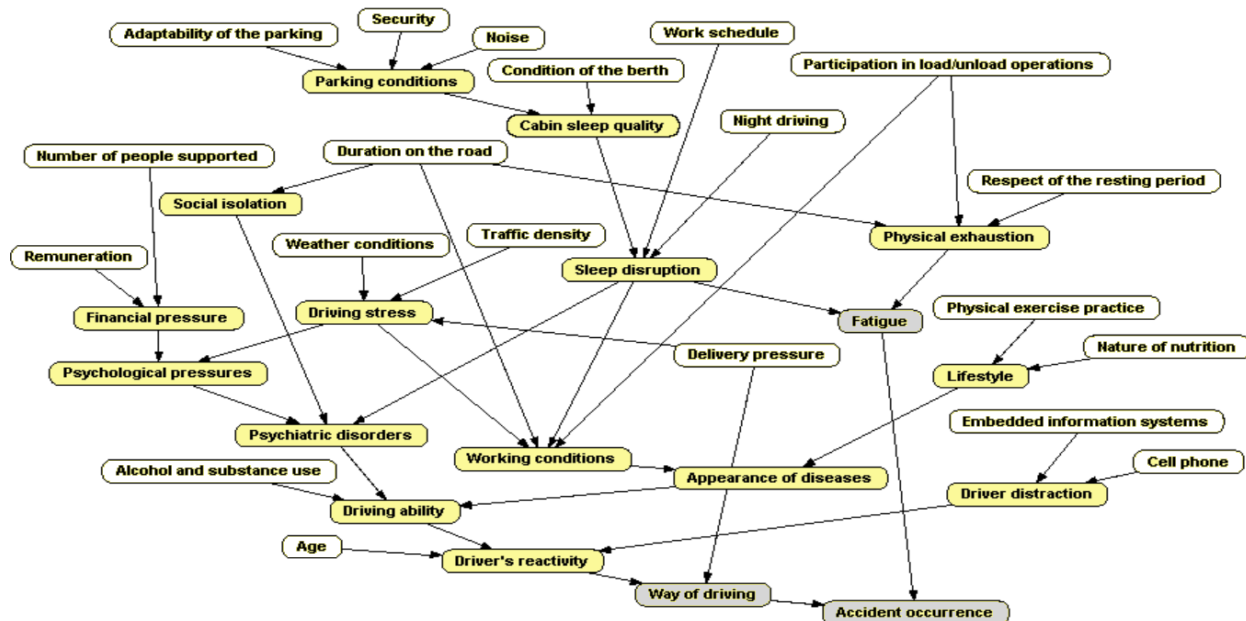

Fig. 1. Driver involvement in an accident model.

TABLE I. THE CAUSAL GRAPH'S INPUT PARAMETERS

Categories of parameters	Parameters	Description
Cabin sleep parameters	Adaptability of the parking	It refers to the ability of this space to meet the needs of drivers and carriers for safety, accessibility, and convenience [26].
	Noise	External noises can significantly affect the quality of sleep in the cabin [27].
	Security	It refers to compliance with parking spaces and safety standards concerning lighting, surveillance, and access control. [28].
	Condition of the berth	Creating a comfortable sleep environment depends on the condition of the berth, which significantly impacts drivers' sleep quality and their ability to rest properly. [27].
Personal driver settings	Physical exercise	Regular exercise improves the physical condition of drivers and helps reduce the risk of developing cardiovascular diseases, which are important risk factors for road accidents involving heavy goods vehicles [29].
	Age	Older drivers drive more safely and responsibly and are less likely to drive under the influence of alcohol compared to middle-aged drivers [30]. However, aging can lead to a decline in vision, memory, and coordination, which increases the risk of road accidents [31].
	Nature of nutrition	Poor nutrition leads to a deterioration in the general health of drivers, which can increase the risk of accidents ([32], [29]).
	Number of people supported	A significant number of people supported by the driver increases the financial pressures on the driver, which may encourage him to work overtime to support his family.
	Alcohol and substance use	Alcohol and substance use can cause reckless behaviour on the road and impair driver faculties [33].
Parameters related to driving conditions	Traffic density	High traffic density can irritate drivers, impairing their concentration and increasing the risk of driving errors and accidents. [34].
	Weather conditions	Weather conditions can disrupt the driver's abilities which can jeopardize their safety [35]
	Delivery pressure	Stress at work harms drivers' mental and psychological health [36]; it significantly reduces driving skills and consequently increases the risk of an accident [37].
	Respect of the resting period	Compliance with the rest range is essential to prevent driver fatigue and the resulting risks [38].
	Duration on the road	Increased time spent on the road increases driver fatigue levels, which may influence the probability of an accident [39].
	Night driving	Night driving can disrupt the sleep of truck drivers, which can have dangerous consequences and increase the risk of traffic accidents [40].
Working conditions parameters	Participation in loading and unloading operations	The duties of truck drivers also include non-driving labor. However, non-driver work is not necessarily remunerated [41]
	Work schedule	Irregular work schedules of truck drivers can increase fatigue and drowsiness at the wheel, which are vital factors in road accidents [42]
	Remuneration	Low pay incentivizes drivers to work overtime, affecting their safety performance [43].
Driver distraction settings	Embedded information systems	Misuse of in-vehicle information systems can distract drivers and thus increase the risk of an accident [44].
	Cell phone	The use of cell phones while driving is one of the critical factors in driver distraction, which can impair concentration and reduce their ability to react quickly to unforeseen events [44].

### B. Generation of Conditional Probabilities

Assigning conditional probabilities to the graph's nodes is necessary to exploit the developed BN. These probabilities can be determined using algorithms that learn from databases or by consulting subject-matter experts. Unfortunately, no database adapted to the identified variables was found in the literature. In addition, the large number of conditional probabilities in this network hindered the use of expert opinions. Then, fuzzy logic was used to generate conditional probability tables.

Fuzzy Bayesian networks result from the fusion between BNs and fuzzy set theory. This method is widely used to solve problems involving uncertain variables or when it is essential to understand and represent the causal dependencies between these variables [45]. This makes fuzzy BNs a particularly appropriate solution to the problem in question. Nevertheless, inference in fuzzy BNs can be costly in terms of computation time and computational resources, particularly for networks of

large size or with a large number of states. This complexity restricts its use for obtaining real-time answers or performing frequent updates.

The implementation of the fuzzy inference system goes through the following steps [46]:

- Fuzzification converts a crisp input value into a fuzzy value via membership functions, determining each fuzzy subset's membership degree [47].
- Inference deduces the result based on fuzzy rules [48].
- The defuzzification transforms the final answer of the fuzzy system into a numerical form [49].

We first define the fuzzy variables and their associated linguistic values to implement this method. Indeed, each variable has been qualitatively represented by natural language expressions illustrated in Table II.

TABLE II. LINGUISTIC VALUES OF NODES

Nodes	Linguistic values
Adaptability of the parking	Low, medium, important
Noise	Low, medium, important
Security	Bad, medium, good
Condition of the berth	Bad, medium, good
Parking conditions	Bad, medium, good
Cabin sleep quality	Bad, medium, good
Night driving	Low, medium, important
Work schedule	Regular, slightly irregular, irregular
Sleep disruption	Low, medium, important
Participation in loading and unloading operations	Low, medium, important
Driver distraction	Low, medium, high
Respect of the resting period	Low, medium, important
Social isolation	Low, medium, high
Time on the road	Small, medium, important
Physical exhaustion	Weak, medium, Strong
Fatigue	Light, medium, important
Delivery pressure	Low, medium, high
Number of people supported	Low, medium, important
Age	Young, medium, old
Traffic density	Low, medium, high
Physical exercise	Low, medium, important
Nature of nutrition	Bad, medium, good
Weather conditions	Normal, medium, extreme
Driving stress	Low, medium, high
Remuneration	Low, medium, important
Embedded information systems	Absent, light use, extreme use
Financial pressure	Low, medium, high
Working conditions	Bad, Medium, good
Appearance of diseases	Low, medium, high
Cell phone	Absent, light use, extreme use
Lifestyle	Bad, Medium, good
Psychological pressure	Low, medium, high
Psychiatric disorders	Low, medium, high
Alcohol and substance use	Low, medium, high
Driver's reactivity	Bad, Medium, good
Driving ability	Bad, Medium, good
Way of driving	Bad, Medium, good
Accident occurrence	Low, medium, high

Concerning the membership functions of all the nodes of the BN, the option was made for those of Gaussian type since the errors in the prediction of the data are minimal when compared to other forms, mainly triangular and trapezoidal forms [50]. The Gaussian membership function has been widely used in previous studies ([52] ; [53] ; [54]). It depends on two parameters: the mean m and the standard deviation k; the equation gives it [51] :

$$\mu_A(x) = e^{-\frac{(x-m)^2}{2k^2}} \quad (3)$$

Then, the fuzzy rule base was built based on the experts' judgments. These fuzzy rules are of the "IF-THEN" type; for example: IF 'Physical exhaustion' is weak and 'Sleep disruption' is medium THEN 'Fatigue' will be light. Here, linguistic values expressed in natural language represent the variable 'Fatigue'. It will accept one of the following values for all other rules: light, medium, or important.

As a result, we created a fuzzy inference mechanism that draws conclusions from input data and fuzzy rules. The Sugeno inference method was used because of its fast processing time and efficient defuzzification system [55]. In the Sugeno method, the inputs are linguistic variables.

The output of Sugeno inference  $z_i$  of an activated rule  $i$  is a linear combination of the input values ( $x_i$  and  $y_i$ ). It is written in the following form [55]:

$$z_i = f(x_i, y_i) = a_i x_i + b_i y_i + c_i \quad (4)$$

The final net output  $Z$  of Sugeno inference is computed by averaging the outputs of the fuzzy rules weighted with their weights in the following form ([56], [57]):

$$Z = \frac{\sum_r w_r * z_r}{\sum_r w_r} \quad (5)$$

With:

$r$ : the index of activated rules

$w_r$ : the implication result (the activation weight) of the rule  $r$

$z_r$ : the output of Sugeno inference of an activated rule  $r$

This fuzzy system incorporated 354 fuzzy rules, allowing us to produce 1062 conditional probabilities to feed the BN.

In what follows, the methodology will be explained by calculating the conditional probabilities of the 'Fatigue' node.

First, the membership functions and the fuzzy rules for the 'fatigue' node and its parent (physical exhaustion and sleep disruption) are defined. Then, the fuzzy system is initialized by input values close to the peak of the Gaussian distribution. Fig. 2 presents the inference of the variable 'Fatigue' knowing that 'Physical exhaustion' is weak and 'Sleep disruption' is medium.

Next, the max operator is applied to all the triggered conclusions of the activated rules. The following is thus had:

$$\text{Fatigue (light)} = \max (0.2, 0.98, 0.008) = 0.98$$

$$\text{Fatigue (medium)} = \max (0.006, 0.008) = 0.008$$

$$\text{Fatigue (important)} = 0.006$$

Thus, the variable 'Fatigue' will take the values 0.98, 0.008, and 0.006 for light, medium, and important, respectively. By computing the ratio between the probability of each state and the total probabilities of all states, the conditional probabilities table of the node 'Fatigue' can thus be obtained as follows.:

$$P(\text{Fatigue} = \text{low} \mid \text{Physical exhaustion} = \text{weak and Sleep disruption} = \text{medium}) = 0.98 / (0.98 + 0.008 + 0.006) = 0.986$$

$P(\text{Fatigue} = \text{medium} \mid \text{Physical exhaustion} = \text{weak and Sleep disruption} = \text{medium}) = 0.008 / (0.98 + 0.008 + 0.006) = 0,008$ .

$P(\text{Fatigue} = \text{high} \mid \text{Physical exhaustion} = \text{weak and Sleep disruption} = \text{medium}) = 0.006 / (0.98 + 0.008 + 0.006) = 0,006$ .

The generalization of this approach for all the nodes of the causal graph allowed us to obtain the conditional probabilities necessary to feed the BN.

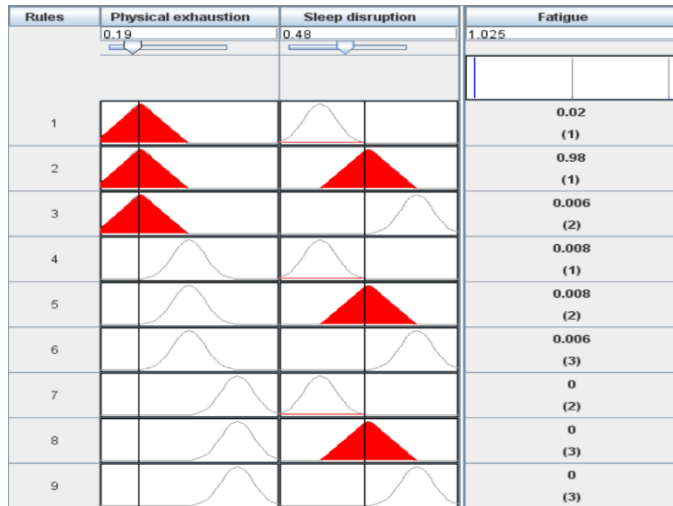

Fig. 2. Result of the inference mechanism.

C. Anticipation of Scenarios

Implementing the BN allowed us to examine the effect of the distribution of states for some nodes on the other nodes of the causal graph. In what follows, the probability of a driver causing an accident will be anticipated through the study of four scenarios listed below:

- Scenario 1 (S1): the parameters related to the driver are favourable and the parameters related to the work environment are favourable.
- Scenario 2 (S2): the parameters related to the driver are favourable and the work environment's parameters are unfavourable.
- Scenario 3 (S3): the driver parameters are unfavourable, and the work environment parameters are favourable.
- Scenario 4 (S4): the driver parameters are unfavourable, and the work environment parameters are unfavourable.

The driver-related parameters concern the driver's parameters and those that contribute to his distraction. On the other hand, the work environment parameters refer to the set of parameters related to the driving and working conditions and those related to sleep in the cab. Table III provides the configuration of the network input parameters according to the studied scenarios. The probabilities associated with the nodes were obtained using the inference of the fuzzy-Bayesian model. Since the network has many nodes (38), the probability of occurrence of some nodes has been presented in Table IV.

TABLE III. THE INPUT PARAMETER VALUES ACCORDING TO THE SCENARIOS STUDIED

	S1	S2	S3	S4
<b>Driver settings</b>				
Embedded information systems	Light use	Light use	Extreme use	Extreme use
Cell phone	Light use	Light use	Extreme use	Extreme use
Physical exercise	Important	Important	Low	Low
Age	Medium	Medium	Old	Old
Nature of nutrition	Good	Good	Bad	Bad
Number of people supported	Low	Low	Important	Important
Alcohol and substance use	Low	Low	High	High
<b>Work environment settings</b>				
Traffic density	Low	High	Low	High
Weather conditions	Normal	Extreme	Normal	Extreme
Delivery pressure	Low	High	Low	High
Respect of the resting period	Important	Low	Important	Low
Time on the road	Small	Important	Small	Important
Night driving	Low	Important	Low	Important
Participation in loading and unloading operations	Low	Important	Low	Important
Work schedule	Regular	Irregular	Regular	Irregular
Remuneration	Important	Low	Important	Low
Adaptability of the parking	Important	Low	Important	Low
Noise	Low	Important	Low	Important
Security	Good	Bad	Good	Bad
Condition of the berth	Good	Bad	Good	Bad

TABLE IV. DISTRIBUTION OF PROBABILITIES FOR BN VARIABLES

Variable	Value	S1	S2	S3	S4
<b>Working conditions</b>	Bad	0,0010	0,9908	0,0010	0,9908
	Average	0,0365	0,0082	0,0365	0,0082
	Good	0,9625	0,0010	0,9625	0,0010
<b>Psychiatric disorders</b>	Low	0,9837	0,0026	0,9712	0,0012
	Medium	0,0083	0,0111	0,0208	0,0115
	High	0,0080	0,9863	0,0080	0,9873
<b>Way of driving</b>	Bad	0,0110	0,9669	0,9799	0,9917
	Average	0,0526	0,0318	0,0121	0,0072
	Good	0,9364	0,0013	0,0080	0,0011
<b>Fatigue</b>	Light	0,9889	0,0011	0,9889	0,0011
	Average	0,0100	0,0086	0,0100	0,0086
	Important	0,0011	0,9903	0,0011	0,9903
<b>Accident occurrence</b>	Low	0,9357	0,0014	0,0083	0,0012
	Average	0,0523	0,0107	0,0391	0,0093
	High	0,0121	0,9879	0,9526	0,9896

Fig. 3. The probability of occurrence in the different scenarios.

The probability distribution for the occurrence of an accident for each scenario is displayed in Fig. 3.

#### D. Result Discussion

In the first scenario, the probability of fatigue and psychiatric disorders is low, with a probability of 98.89% and 98.37%, respectively. Also, the way of driving and the working conditions are good, with 93.64% and 96.25%, respectively. Therefore, the probability of an accident is low, with a value of 93.57%.

Regarding the second scenario, there is a 99.03% chance that the driver will become fatigued; the working conditions and the way of driving are bad, with 99.08% and 96.69%, respectively. In addition, a high probability of psychiatric disorders with 98.63% is observed, which leads to a high risk of accident occurrence of 98.79%.

For the third scenario, the probability of fatigue is low, with 98.89%. In addition, the working conditions are good at 96.25%, and the probability of psychiatric disorders is low at 97.12%. On the other hand, the way of driving is bad, with a probability of 97.99%. Therefore, the probability of an accident is high at 95.26%.

In the fourth scenario, we have a high probability of fatigue and the appearance of psychiatric disorders, with 99.03% and 98.73%, respectively. Regarding the way of driving, the working conditions are bad with 99.17% and 99.08%, hence a high probability of accident occurrence is with 98.96%.

According to the findings of the inference of the first and third scenarios, the probability of an accident increases if the driver's parameters are unfavorable. Additionally, unpleasant working conditions significantly influence the probability of accidents.

#### E. Sensitivity Analysis

Sensitivity analysis makes it possible to find the most dominant factors in the occurrence of a particular event [58]. This analysis would allow us to make the necessary prevention adjustments and reallocate resources more efficiently.

The results of the sensitivity analysis of the 'Accident occurrence' node are shown in Fig. 4. According to this figure, we can estimate that the preponderant factors in accidents are: alcohol and substance consumption, poor driving, fatigue, and distraction caused mainly by cell phones and embedded information systems. These results highlight the crucial role of the human factor in the occurrence of accidents.

#### F. Model Validation

The validation of the BN guarantees the reliability of the results provided by the model. In order to validate the developed BN, a method based on three axioms was used. This method was proposed by [59] and widely used by several researchers such as: [60], [61] and [62]. The principle of the three axioms is as follows [63]:

- Axiom 1: the increase or decrease in the probability of the parent node must result in a change in the probability of the child node.
- Axiom 2: The occurrence of a change in the probability distributions of the parent node must have a consistent impact on the child node.
- Axiom 3: The total effect of all parent nodes must be greater than either parent's effect.

Validation analyses were conducted on all nodes in the graph to confirm the verification of the three axioms. Tables V and VI show the verification results for axioms 1 and 2 for the 'Lifestyle' node. The impacts of the parent nodes 'Exercise Practice' and 'Nature of Nutrition' on the child node 'Lifestyle' were evaluated by increasing them by 10% and 20%, respectively, and then decreasing them by 5% and 10%. We found that the probability of the 'Lifestyle' node increased from 64.82% to 82.06% when the probability of the 'Exercise' node was increased by 20%. However, the probability of the 'Lifestyle' node increased to 56.20% when the probability of the 'Exercise' node was reduced by 10%. The 'Lifestyle' node replies for the other increments and decrements were consistent, supporting the developed network's stability.

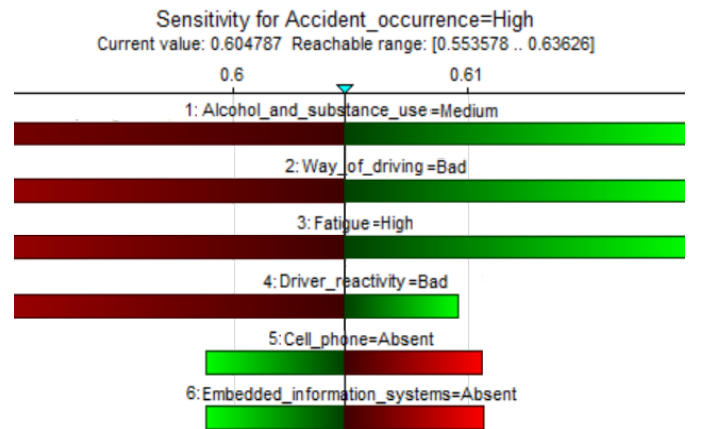

Fig. 4. Sensitivity analysis for accident occurrence.

TABLE V. AXIOM 1 VERIFICATION

	Parent node: Physical exercise		Child node: Lifestyle	
	Value	Probability	Value	Probability
20% increase	Low	95%	Bad	82,06%
10% increase		85%		73,44%
A priori probability		75%		64,82%
5% decrease		70%		60,51%
10% decrease		65%		56,20%

TABLE VI. AXIOM 2 VERIFICATION

	Parent node: Nature of nutrition		Child node: Lifestyle	
20% increase	Bad	97%	Bad	83,32%
10% increase		87%		75,06%
A priori probability		77%		66,80%
5% decrease		72%		62,67%
10% decrease		67%		58,54%

TABLE VII. AXIOM 3 VERIFICATION FOR THE 'LIFESTYLE' NODE

Nature of nutrition		Physical exercise		Lifestyle		Percentage change
Bad	90%	Weak	84%	Bad	77,53%	
	100%		84%		83,33%	7,48%
	90%		100%		92,20%	18,92%
	100%		100%		100%	28,98%

Regarding the verification of axiom 3, from the results presented in Table VII, we can say that the total effect of increasing all parents of the 'Lifestyle' node to 100% resulted in a more significant increase than when only one parent is increased separately, which is well in line with axiom 3.

G. Result Discussion

This article examines the importance of identifying and preventing risk factors in improving road safety. It focuses specifically on driver-related parameters that increase the risk of accidents. Based on bibliographical research and experts' opinions, road accidents cannot be attributed to a single type of cause but to a panoply of parameters linked together by causal relationships that ultimately give rise to a road accident. In order to prevent accidents, this article has developed an approach based on fuzzy BNs so that carriers can take the necessary precautions to avoid catastrophe. Adopting this model will ensure a high level of visibility and improve the efficiency of logistics deliveries. In addition, validating the proposed BN further guarantees the reliability of the results provided by the model. The scenarios studied highlighted the impact of working conditions on the occurrence of accidents. The sensitivity analysis results confirm that the most critical factors in accidents are: alcohol and substance abuse, poor driving style, fatigue, and driver distraction. These results underline the crucial role of the human factor in accident occurrence. This model has also created a synthetic database that can be used by learning models to predict the risks associated with road accidents.

The following section focuses on integrating in-vehicle safety devices to improve road safety. This aspect is explored through analysis of the proposed event tree.

IV. PREDICTIVE MANAGEMENT OF HEAVY VEHICLE ACCIDENTS BY APPLICATION OF EVENT TREE TECHNOLOGY

A. Event Tree Analysis

Event tree analysis uses a tree structure of events to provide potential probabilities of the outcomes of events that contribute to the success or failure of a management. The tree is constructed chronologically by predicting, in the first place, the probability of an initiating event. Then, a sequence of intermediate events occurs to prevent additional risk [64].

In order to develop the scenarios of probable crises related to a truck accident, different road safety devices installed were taken into account, such as:

- Adaptive cruise control: This system uses sensors to monitor the distance between the truck and other vehicles on the road and automatically regulates the speed to maintain a sufficiently safe distance.
- Driver Fatigue Monitoring System: This system uses sensors to monitor eye movements and the driver's head position. If the system detects the driver is tired or distracted, it can warn them to take a break.
- Automatic Emergency Braking System: This system uses sensors to detect objects near the truck and can automatically initiate emergency braking if the driver does not react quickly enough.

Then, the steps prescribed below were followed:

- Initiator event gave rise to the system's critical state; in our case, it is a road accident.
- Intermediate events aim to detect or prevent the initiating event or reduce its consequences as much as possible. The intermediate events that have been chosen are: adaptive cruise control system activated, driver fatigue monitoring system activated and automatic emergency braking system activated
- Identification of consequences specifies the expected outcomes of each series of events.
- Quantization of the tree assigns probabilities for each branch in order to calculate the probability of each sequence in the following form:

$$P(R) = \prod_1^n P(B_i) \tag{6}$$

With B<sub>i</sub>: Set of branches that make up the path to the result R.

Fig. 5 illustrates the event tree developed to study the probability of successful accident prevention based on the safety systems installed.

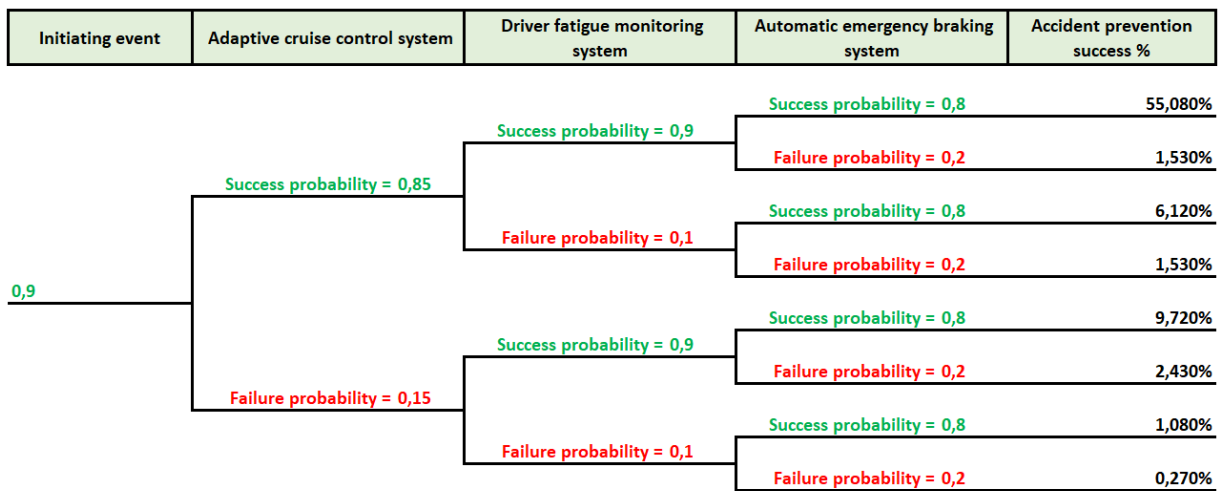

Fig. 5. Event tree showing the probability of success in preventing an accident based on the success rate or failure of the various safety systems installed.

### B. Analysis of Results

The quantification of our event tree allowed us to predict the probability of success of road accident prevention efforts according to the different operating rates of the safety systems installed. We found that the success rate is highest (55.08%) if all installed systems are working correctly and minimal (0.27%) for the opposite case. These results highlight the importance of equipping heavy goods vehicles with systems monitoring driver behavior to improve road safety.

### V. CONCLUSION

Road accidents involving heavy goods vehicles attract particular interest because of their devastating consequences of loss of life and property damage. In this article, the focus was placed on the prediction of heavy vehicle accidents in order to improve road safety and adequately manage this problem. To this end, BNs and fuzzy logic were combined to develop a model capable of scrutinizing the possibility of an accident.

The simulation of several scenarios allowed us to value the impact of the factors identified on the occurrence of accidents. In addition, the results deduced from the application of event trees allowed us to shed light on the importance of road safety mechanisms in preventing road accidents.

The developed system takes advantage of BNs and the strength of the fuzzy set theory, making it a robust and efficient model capable of providing reliable predictions. Similarly, this work may promote the development of new systems operating in research fields other than transport.

The limitations of the model developed lie in the complexity of road accident scenarios; the plurality of factors that can influence the occurrence of accidents makes it inappropriate to take them all into consideration, which could impact the accuracy of the predictions provided by the model.

One of the potential perspectives at work presented is the model's generalization to all occupational risks relating to truck drivers, such as work accidents the appearance aggravation of certain diseases; and we also intend to use deep learning methods in our future work to push back the prediction of the

risks mentioned above and manage the resulting crises appropriately.

### ACKNOWLEDGMENT

This research is supported by the Ministry of Higher Education, Scientific Research and Innovation, the Digital Development Agency (DDA), and the National Center for Scientific and Technical Research (CNRST) of Morocco (Smart DLSP Project - AL KHAWARIZMI IA-PROGRAM).

# Software Cost Estimation using Stacked Ensemble Classifier and Feature Selection

Mustafa Hammad

Department of Software Engineering  
Mutah University  
Al-Karak, Jordan

**Abstract**—Predicting the cost of the development effort is essential for successful projects. This helps software project managers to allocate resources, and determine budget or delivery date. This paper evaluates a set of machine learning algorithms and techniques in predicting the development cost of software projects. A feature selection algorithm is utilized to enhance the accuracy of the prediction process. A set of evaluations are presented based on basic classifiers and stacked ensemble classifiers with and without the feature selection approach. The evaluation study uses a dataset from 76 university students' software projects. Results show that using a stacked ensemble classifier and feature selection technique can increase the accuracy of software cost prediction models.

**Keywords**—Software project management; effort estimation; prediction model; machine learning

## I. INTRODUCTION

The process of developing software has evolved into a fundamental function of modern society as a result of the quick development of software in our days. However, a crucial step in the lifecycle of software development is software effort estimation. The goal of a software development task is to deliver the product on time and within budget. The planning process for any software project must therefore include early software cost estimation.

Predicting the amount of work required to create a software system is a part of software effort estimation. It is expressed in terms of the number of working hours or the number of hours needed to construct the software. Software testing, maintenance, requirements engineering, and other software operations are all included in the broad category of software effort estimation.

To produce software projects, various software development lifecycle models call for varying amounts of work at each stage. Software effort estimation is regarded as one of the most significant problems in software engineering. It affects the cost of the project and is a problem that many engineers and project managers encounter. A major issue that could harm software companies is the accuracy of the development effort estimation.

Several scholars as [1] have suggested various models to predict the effort of software development. Several researches have been done to determine the early software effort estimate to determine the significance [2]. Software companies need to

understand the work required to develop projects in addition to how they should proceed about accomplishing this.

In this paper, the software work is estimated based on project attributes using four machine learning techniques. This study's primary objective is to assess software effort estimation models created using machine learning techniques.

Before deciding to use a software component as a reusable asset, software engineers must analyze the software component. Assessing reuse potentials can be aided by predicting successful reuse. Datasets are used to train and test predictive models. Datasets, however, occasionally include attributes that are not useful. The performance of the model may suffer as a result of these characteristics. Therefore, choosing the key attributes improves the performance of the model and yields a more accurate output.

In this paper, an empirical study utilized a dataset to investigate and extract the essential features that lead to a successful reuse experience. Usually, the performance of a prediction model can be improved with an ideal subset of useful features. Feature selection algorithm selects a portion of the original dataset's most useful qualities. This subset can improve the prediction model's effectiveness and efficiency. Additionally, it avoids data overfitting. In this paper, six feature selection algorithms were utilized and evaluated to enhance accuracy. These algorithms are; Classifier Attribute Evaluation, Correlation Attribute Evaluation, InfoGain Subset Evaluation, Wrapper Subset Evaluation, Classifier Subset Evaluation, and CfsSubset Evaluation.

There are many benefits of using feature selection techniques. For instance, it reduces the training time, helps visualize the data, and optimizes the storage requirements. In this paper, the primary purpose of using feature selection techniques is to improve the prediction model's performance by removing the irrelevant attributes [3].

The organization of this paper is as follows; the next section discusses the literature that concerning software effort prediction. The proposed evaluation model is presented in Section III followed by a brief description about the used dataset in the evaluation process. The experimental results are presented in Section V. Finally, Section VI concludes the paper and highlights the future work.

## II. RELATED WORK

Many approaches have been presented in the literature about estimating the development's efforts of software projects. Most of these approaches utilize the machine learning and artificial intelligence techniques to predict the effort.

Rankovic et al. [4] proposed two different architectures of Artificial Neural Networks (ANN) for predicting software effort. They used exponent-scale factors, cost factors, and software size as control variables from COCOMO models. BaniMustafa [5] predicted the effort estimation by applying machine learning techniques and data mining. He applied Naïve Bayes, Logistic Regression and Random Forests. Priya Varshini et al. [6] proposed stacking using random forest for effort estimation. They used ensemble techniques to create and combine multiple models termed base-level classifiers. The works in [7, 8] applied Artificial Neural Network (ANN), Support Vector Machines (SVM), K-star, and Linear Regression to estimate software effort based on project features. Mahdie et al. [9] provided a detailed review about the application of Machine Learning in software project management which includes effort estimation. Another systematic performance evaluation study for software effort estimation accuracy prediction of ML techniques is presented in [2].

A different prediction technique has been presented by Nassif et al. [10]. They proposed an approach called regression fuzzy logic that is based on fuzzy logic models and regression analysis. Also, Fadhil et al, [11] used swarm intelligence techniques from the AI field. They applied two models based on dolphin algorithm and the hybrid dolphin and bat algorithm.

Rai et al. [12] proposed a hybrid model, based on team size using Support Vector Regression (SVR) and constructive cost model (COCOMO) approaches. Van Hai et al. [13] proposed a model called effort estimation using machine learning applied to the clusters (EEAC). The goal of the model is to evaluate the influence of data clustering on software development effort estimation.

## III. PROPOSED SOFTWARE COST PREDICTION MODEL

This work proposes an evaluation framework to evaluate the effectiveness of using basic machine learning and ensemble classifiers, as well as, feature selection algorithms to build a software cost estimation model. Fig. 1 depicts the proposed prediction framework. As shown in Fig. 1, the first prediction model is set with the basic standalone machine learning algorithms, while the second model is built using the stacked ensemble approach. Both models are evaluated using the full dataset and with a set of the selected features. The purpose of introducing feature selection to the proposed prediction models is to extract the most relevant features from the dataset. Since, the redundant and irrelevant features increase the data dimensionality without adding new information to the dataset. This could negatively affect the performance of the prediction models.

Fig. 1. The proposed software cost prediction framework.

Four machine learning algorithms were applied in the prediction process. These ML algorithms are:

- The Artificial Neural Networks (ANN): ANN system considers unsupervised learning as one of the training algorithms in a command to build an unlabeled data [14]. It consists of an input layer, hidden layers, and an output layer.
- K-Star: K-star is a machine learning algorithm that uses the entropic distance from the information theory to measure the similarities among the data elements and cases. [15].
- Support Vector Machine (SVM): SVM uses Sequential Minimal Optimization (SMO) algorithm, which transfers all nominal attributes and null values into binary ones. Then, the algorithms try to identify a margin that divides the data into different classes [16].
- Random Forest (RF): RF works by building multiple decision trees and then combining their results to make predictions. Each tree is trained on a randomly selected subset of the training data and a randomly selected subset of the features. By doing this, the algorithm can reduce errors and improve accuracy. To make a prediction, the algorithm takes in a set of features and passes them down each of the decision trees in the forest. Then it combines the results of all the trees to arrive at a final prediction [17].

Fig. 2. The proposed ensemble stacked cost prediction classifier.

Ensemble learning is a method that combines more than one learning classifiers. Combining machine learning classifiers is primarily done to reduce risks and errors associated with employing a single classifier [18]. Additionally, ensemble learning enhances prediction

performance by balancing out the shortcomings of a single classifier. Additionally, issues with training the classifier may arise due to the size of the dataset. For instance, using a single classifier on a sizable dataset is impracticable. The dataset should therefore be divided into subgroups, with each subset being used to train a different classifier. Additionally, ensemble learning might be able to alleviate issues brought about by utilizing a tiny dataset [19]. In ensemble learning, different classifiers can be added using Stacking, Bagging, and Voting approaches. In this paper, stacking ensemble approach is used to build different software cost prediction model.

Stacking ensemble classifier is one of the most used approach in ensemble learning to combines multiple classification algorithms. Fig. 2 shows the basic levels of the used stacking ensemble classifiers. The learning process of stacking learning consists of two levels. The first level combines different machine learning classifiers  $C = \{C_i(s, f), i = 1, \dots, l\}$ , which are called base classifiers. Each base classifier utilizes the training set  $f$ . In the second learning level, which is the meta-learning process, a single machine learning classifier  $\mu$  uses the outputs on the base classifiers as an input to generate the ensemble learning final prediction [20]. Therefore:

$$j_{stack}(s) = \mu(s, C) \quad (1)$$

where  $j_{stack}(s)$  is the final stacking prediction of the input  $s$ . As shown in Fig. 2, the used four basic ML classifiers are combined in the first learning level of the proposed ensemble classifier. For the meta learning level, each basic ML classifier is used as based meta-learner classifier to create different stacked ensemble prediction model. The goal is to evaluate all possible combinations of these basic ML classifiers. As a results, the generated ensemble classifiers are:

- ANN-based Stacked classifier
- K-star-based Stacked classifier
- SVM-based Stacked classifier
- RF-based Stacked classifier

All previous basic and ensemble software cost prediction models are evaluated using the full features of software projects, as well as, a set of selected features. In this paper the wrapper method algorithm is used by applying the Classifier Subset Evaluation (CSE) technique [21].

CSE approach is a popular feature selection technique that evaluates the performance of a specific classifier for each subset of features. Fig. 3 shows the basic steps for the used CSE approach. It starts by creating all possible subsets of software features. Then, randomly select a set of features to evaluate it using the target software cost prediction model. This process is repeated until achieving the optimal accuracy for this model. Once the best feature subset is recognized, it is used for the final model training process.

Fig. 3. The used wrapper CSE feature selection approach.

#### IV. USED DATASET

Due to the lack of software expense data, gathering public software effort data is a difficult undertaking. This is owing to the fact that software companies generally keep software cost data private. Usp05-tf, a publicly accessible dataset for empirical software engineering data, is made available online through the promise online repository (<http://tunedit.org/repo/PROMISE/EffortPrediction>), which was used in this study. Data from 76 university students' software projects are included in this dataset. Every project has 13 attributes. A list of these attributes is shown in Table I.

TABLE I. THE 13 ATTRIBUTES OF THE STUDIED PROJECTS

#	Project attributes	Description	Values
1	IntComplex	The complexity of the internal project calculations	1 (lowest) to 5 (highest)
2	DataFile	Total number of accessed data files	Positive integer
3	DataEn	The number of entry data items	Positive integer
4	DataOut	The number of output data items	Positive integer
5	Lang	The used programming language	C++, Java, HTML, etc.
6	UFP	Unadjusted Function Point Count	Positive integer
7	Tools	The used platforms and tools	VJ++, Delphi, Junit, etc
8	ToolExpr	The experience level of the developer team	Range of number of months, e.g. [3, 7]
9	AppExpr	The applications experience level	1 (lowest) to 5 (highest)
10	DBMS	The used database system	SQLServer, Oracle, MySQL, etc.
11	TeamSize	The size of the developer team	Range of min-max number of developers, e.g. [3, 6]
12	AppType	The used system architecture	B/S, C/S, Centered, etc.
13	Effort	The actual effort (in hours) expended on implementation tasks by all participating developers	Positive float

The features listed in Table I are not all numerical. This is crucial to verifying the machine learning approach's capacity for learning. The historical data is utilized as a learning tool to anticipate the work required for future software systems.

## V. EXPERIMENTAL RESULTS

The evaluation criteria and the results of the experiments are discussed in the following two sections.

### A. Evaluation Criteria

In order to assess the performance of the prediction algorithms, five statistical criteria were used. The following is a description of these criteria:

- Statistics Kappa (KS)
- Mean Absolute Error (MAE)
- Root Mean Square (RMSE)
- Error in Relative Absolute (RAE)
- Root Relative Squared Error (RRSE)

Statistics Kappa (KS) is the degree of agreement between the classifier's output and the actual classification is measured by KS. KS values vary from 0 to 1. The closer to 1 KS gets, the better. The following equation is used to compute KS:

$$KS = PA - PC / (1 - PC)$$

where PC is the percentage of agreement by chance and PA is the percentage of actual agreement.

Mean Absolute Error (MAE) calculates how well the actual classification matches the anticipated classification. The value of MAE is calculated using the formula below:

$$MAE = \sum_{n=1}^m |a_n - a'_n|$$

where  $n = 1$  through  $m$ ,  $m$  is the total number of instances,  $a_n$  is the actual reuse output, and  $a'_n$  is the predicated reuse output. The performance of the prediction model is good if the MAE value is low.

Root Mean Square (RMSE) is difference between data that was expected and actual data is measured by the quadratic mean known as RMSE. The accuracy of the model is inversely correlated with the RMSE. High precision is indicated by a low RMSE score. The error value can be calculated using the formula below:

$$RMSE = \sqrt{\frac{1}{m} \sum_{n=1}^m (a_n - a'_n)^2}$$

When  $n$  ranges from 1 to  $m$ ,  $a_n$  represents the observed values, and  $a'_n$  represents the anticipated values.

Error in Relative Absolute (RAE) is calculated by dividing the total absolute error by the total absolute error of the trivial model, RAE normalizes the total absolute error. RAE is obtained by the following equation:

$$RAE = \sum_{n=1}^m |a_n - a'_n| / \sum_{n=1}^m |a_n - a''_n|$$

where  $a_n$  is the predicted value,  $a'_n$  is the target value,  $a''_n$  is the mean of  $a_n$ ,  $m$  is the number of instances, and  $n = 1$  through  $m$ .

Root Relative Squared Error (RRSE) is calculated by dividing the total relative error of the naive model by the square root of the total relative error. Equation used to calculate RRSE is as follows:

$$RRSE = \sqrt{\sum_{n=1}^m (a_n - a'_n)^2 - \sum_{n=1}^m (a_n - a''_n)^2}$$

where  $a_n$  is the predicted value,  $a'_n$  is the target value,  $a''_n$  is the mean of  $a_n$ ,  $m$  is the number of instances, and  $n = \{1, 2, \dots, m\}$ .

### B. Experimental Results

The experiments were conducted using WEKA 3, a machine learning software platform written in Java (<https://www.cs.waikato.ac.nz/ml/weka/>). The ten folds cross-validation training technique was used to evaluate all software cost prediction models. In this technique, the training and testing the prediction models is repeated in iterations. Moreover, the dataset is divided equally into ten subsets called folds. In each iteration, the prediction model uses nine folds for training and one-fold for testing. This process is ended when the classifier tests all the dataset.

Table II shows the selected features of software projects after applying the feature selection approach for each base classifier. Number of the selected feature for K-star, RF, ANN, and SVM are 10, 5, 9, 13 respectively. The smallest number of selected features was produced with the RF classifier while the biggest number happened with SVM classifier.

TABLE II. THE SELECTED FEATURES FOR EACH CLASSIFIER

Classifier	Selected Features
K-star	ID, IntComplex, DataFile, DataEn, DataOut, UFP, Lang, ToolExpr, AppExpr, TeamSize
RF	ID, IntComplex, DataOut, Tools, TeamSize
ANN	ID, IntComplex, UFP, Lang, Tools, ToolExpr, AppExpr, TeamSize, Method
SVM	ID, IntComplex, DataFile, DataEn, DataOut, UFP, Lang, Tools, ToolExpr, AppExpr, TeamSize, DBMS, AppType

Table III presents the selected features of software projects using the feature selection approach for each stacking classifier. As shown in the table, the feature selection approach is more effective in reducing number of selected features needed to learn the stacking classifier than basic classifier. This can be helpful to software project engineers. It can point out a smaller set of key project features which can impact on the project's cost. In this study, number of the selected feature for stacking based K-star, RF, Stacking based ANN, and Stacking based SVM classifiers are 5, 6, 5, 9 respectively.

Fig. 4 shows the MAE values for the four basic classifiers in the used dataset before and after using the feature selection approach. As shown in the figure, the value of MAE is reduced when using the feature selection algorithm. The lowest MAE is obtained when using the RF classifier, were the MAE is

reduced from 2.5025 to 2.3154 after applying the RF on the selected feature instead of using the full features.

TABLE III. THE SELECTED FEATURES FOR EACH STACKING CLASSIFIER

Stacking classifier	Selected Features
Stacking based K-star	DataFile, DataOut, Lang, TeamSize, AppType,
RF	IntComplex, DataEn, DataOut, ToolExpr, TeamSize, Method
Stacking based ANN	IntComplex, DataEn, UFP, Lang, TeamSize
Stacking based SVM	ID, IntComplex, DataFile, DataOut, Lang, ToolExpr, TeamSize, Method, AppType

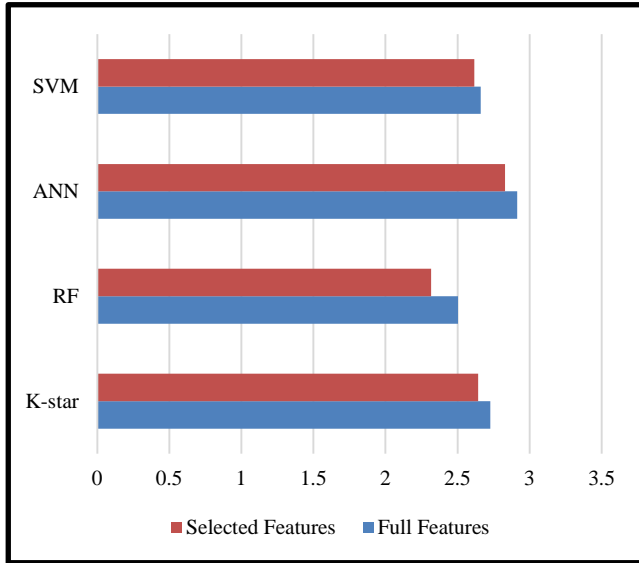

Fig. 4. MAE values before and after using feature selection.

Fig. 5 shows the values of RMSE for the four classifier on the full features and on the selected features. Same as MAE values, the RMSE values were reduced after selecting a subset of the software projects' features. The lowest RMSE value is produced when using RF classifier. For RF classifier the RMSE value was 4.8546 and 4.4979 with and without the feature selection algorithm respectively.

Fig. 5. RMSE values before and after using feature selection.

From pervious results, we can conclude the using the feature selection approach can increase the accuracy of software cost prediction model. Moreover, to evaluate other criteria, Table IV presents the KS, RAE, and RRSE evaluations before and after using feature selection method for the four classifiers. As shown in the table, RF is the best classifier among all others with highest KS and lower RAE and RRSE. However, feature selection approach is able to enhance the performance of all classifiers for all evaluation criteria.

TABLE IV. KS, RAE, AND RRSE EVALUATION RESULTS BEFORE AND AFTER USING FEATURE SELECTION

	KS- Full features	KS- selected features	RAE - Full features	RAE - Selected features	RRSE- Full features	RRSE- Selected features
SVM	0.7504	0.8098	44.3547 %	43.6098 %	64.6744 %	63.5698 %
ANN	0.7981	0.8098	48.8383 %	46.9337 %	64.6744 %	63.5698 %
RF	0.8441	0.8826	41.7323 %	38.6118 %	55.6778 %	51.5873 %
K-star	0.7797	0.7823	45.4795 %	44.0878 %	69.0658 %	67.9704 %

The second part of this experiment is set to evaluate the effectiveness of using stacked classifier on predicting the software cost. Fig. 6 and 7 show the MAE and RMSE evaluation values for the four possible combinations of stacked classifiers over the full features and the selected features. Stacked classifier with SVM is based classifier has the lowest MAE and RMSE with values of 2.4391 and 4.3705 respectively. After applying the feature selection approach, the MAE and RMSE values were reduced to 2.1801 and 4.0779 respectively. On the other hand, the ANN based stacked classifier has the highest MAE and RMSE values with 4.6594 and 8.1786 respectively.

Fig. 6. MAE evaluation of stacked classifiers for full and selected features.

Results in Fig. 6 and 7 show that the using the feature selection approach can increase the accuracy of software cost prediction model based on stacked classifier. Moreover, to evaluate other criteria, Table V presents the KS, RAE, and RRSE evaluations before and after using feature selection method for the four stacked classifiers. As shown in the table, the stacked based RF classifier is the best classifier among all others with highest KS and lower RAE and RRSE. Moreover, feature selection approach is able to enhance the performance of all stacked classifiers for all evaluation criteria.

Fig. 7. MAE evaluation of stacked classifiers for full and selected features.

TABLE V. KS, RAE, AND RRSE EVALUATIONS BEFORE AND AFTER USING FEATURE SELECTION

	KS – Full features	KS – selected features	RAE – Full features	RAE – Selected features	RRSE – Full features	RRSE – Selected features
Stacked based SVM	0.7504	0.8098	44.3547 %	43.6098 %	64.6744 %	63.5698 %
Stacked based ANN	0.5168	0.5506	77.7009 %	80.4054 %	64.6744 %	63.5698 %
Stacked based RF	0.8441	0.8826	41.7323 %	38.6118 %	55.6778 %	51.5873 %
Stacked based K-star	0.6635	0.7823	50.559 %	40.8892 %	75.5606 %	62.1436 %

## VI. CONCLUSIONS AND FUTURE WORK

An evaluation model has been presented for effort estimation. The model utilizes a set of machine learning algorithms and techniques to predict the effort. The model was evaluated using basic standalone machine learning algorithms and using the stacked ensemble ML approach. The evaluation is done on full features and a set of selected features that have been previously extracted using feature selection technique. Results showed that a stacked ensemble classifier with feature

selection technique achieved higher accuracy for software cost prediction. Our future work aims to expand the evaluation process by including deep learning techniques. Another issue under investigation is the utilization of more project attributes to enhance the prediction results.

# An Algorithm Based on Self-balancing Binary Search Tree to Generate Balanced, Intra-homogeneous and Inter-homogeneous Learning Groups

Ali Ben Ammar<sup>1</sup>, Amir Abdalla Minalla<sup>2</sup>

University College of Tayma, University of Tabuk, Tabuk, Kingdom of Saudi Arabia<sup>1,2</sup>

**Abstract**—This paper presents an algorithm, based on the self-balancing binary search tree, to form learning groups. It aims to generate learning groups that are intra-homogeneous (student performance similarity within the group), inter-homogeneous (group performance similarity between groups), and of balanced size. The algorithm mainly uses the 2-3 tree and the 2-3-4 tree as two implementations of a self-balancing binary search tree to form student blocks with close GPAs (grade point averages) and balanced sizes. Then, groups are formed from those blocks in a greedy manner. The experiment showed the efficiency of the proposed algorithm, compared to traditional forming methods, in balancing the size of the groups and improving their intra- and inter-homogeneity by up to 26%, regardless of the used version of the self-balancing binary search tree (2-3 or 2-3-4). For small samples of students, the use of the 2-3-4 tree was distinguished for improving intra- and inter-homogeneity compared to the 2-3 tree. As for large samples of students, experiments showed that the 2-3 tree was better than the 2-3-4 tree in improving the inter-homogeneity, while the 2-3-4 tree was distinguished in improving the intra-homogeneity.

**Keywords**—Learning group formation; balanced size groups; homogeneous groups; self-balancing binary search trees; greedy algorithm

## I. INTRODUCTION

The formation of learning groups is the first step to the success of the educational process, as it allows, depending on the tasks, students to be grouped into homogeneous or heterogeneous groups to be effective and lead to more effective learning. Heterogeneous groups are more effective on tasks that complete lessons and achieve specific learning outcomes, such as projects, assignments, and e-learning. In such a situation, students collaborate, learn from their peers, and share ideas to achieve common goals or accomplish group tasks that no one individual can complete alone. According to [1] and [3], more group heterogeneity has a negative impact on low-ability students, whereas peer effects were not found for high-ability students. Therefore, for such tasks, it is recommended to build groups with low heterogeneity. According to [19], homogeneous grouping is most useful for some types of learning activities, particularly those involving guided discovery, knowledge development, review of material already learned, or highly structured tasks to build competence, allowing students to progress at the same rate. In some cases, homogeneous groups are imposed due to the conditions and requirements of the courses.

Traditional methods that have been used to group students are basically random grouping, student-formed groups where the student chooses his group, and instructor-assigned groups where the teacher assigns the students into groups. There are many characteristics of the students on which the group formation depends, such as their knowledge level, personality traits, communication skills, etc. These characteristics were classified in [13] into static, such as gender, age, and knowledge level, and dynamic, such as interaction level or emotional status. The multiplicity of these characteristics and the multiplicity of students make the grouping process an NP-hard problem, as confirmed in [16], and so difficult to solve manually. Therefore, automated methods were required to form groups in an efficient manner based on several characteristics.

Most automatic grouping approaches studied in this paper have focused on the formation of heterogeneous groups for cooperative purposes and are of small size, with the number of members ranging between 3 and 5 in most cases. This may be due to their focus on e-learning and collaborative tasks. But, in fact, homogeneous groups are still needed in theoretical lectures and training courses, especially in in-person learning. The issue of forming homogeneous groups of large size was not addressed. Similarly, the balance between groups in terms of size and degree of homogeneity has not been addressed much, except in [2], where the authors examined the effect of group sizes on students in a gamification environment. They found that differing sizes between groups affected students' interest, comparison, and discouragement.

In this paper, an algorithm based on the self-balancing binary search tree is proposed to form learning groups. The goal is to build learning groups that are intra-homogeneous (a high level of similarity between the characteristics of the students within the group), inter-homogeneous (similarity or balance between the degree of homogeneity of the groups), and balanced in size. The idea is that we do not set intra-homogeneity as the sole goal of group formation because this will inevitably lead to groups with varying degrees of homogeneity, especially in the case of a high diversity of students before their distribution, which means groups that are highly homogeneous and others that are highly heterogeneous. In addition, if the focus is only on intra-homogeneity, then the issue of unbalanced sizes between groups is raised, as each student will be added to the group closest to him/her without any restrictions on group size. The connection between the three characteristics, namely intra-homogeneity, inter-homogeneity, and balanced size, is necessary for many uses,

such as lectures where instructors wish to deliver to more than one group with the same plan and progress at the same rate. The self-balancing binary search trees were used at an initial stage to achieve the objectives of group formation, as they contribute to the formation of student blocks (which are tree branches) with close performances and balanced sizes. Then, the groups are formed from these blocks. The proposed algorithm uses GPA (grade point average) as a key feature for grouping students.

Following this part, the paper is organized as follows: The following section discusses the literature review. The methodology used to construct the suggested algorithm, as well as the experimentation and outcomes of applying the proposed algorithm to some student samples, are then provided. The results and recommendations are explored in the concluding parts, which bring the article to a close.

## II. LITERATURE

In the past two decades, the formation of learning groups has been an important educational issue that researchers have addressed for the success of the educational process. This interest has multiplied in the past decade with the development of e-learning platforms, collaborative learning platforms, and collaborative work platforms. This section presents the related works and highlights the three essential aspects: the nature of formed groups (homogeneous vs. heterogeneous), forming methods, and forming characteristics or criteria.

Regarding the nature of groups, heterogeneous grouping is the most widely used grouping type because it can better satisfy diverse learning scenarios, especially in cooperative education, as used by [4], [5], [6], [8], [12], [13], [14], [15], [18], [26], and [28] whereas [19] developed an algorithm to generate homogeneous groups. Some research has focused on intra- and inter-group relationships. In this context, [16], [19], [25], and [27] propose approaches to achieve groups with members that are as similar as possible (inter-homogeneous) but also to enable individual differences among students within such groups (intra-heterogeneous).

There is a consensus that the issue of forming groups cannot be solved manually due to the multiplicity of formation criteria and the multiplicity of students. So, the relationship among these variables and possible grouping alternatives is factorial, making this an NP-hard problem, as confirmed in [16]. In these cases, it becomes necessary to use heuristic search methods to find a satisfactory solution with a considerably lower computational effort. A widely used heuristic method is the genetic algorithm (GA), which is used in [5], [11], [13], [15], [16], [19], [27], and [28]. The study [7] used simulated annealing (SA) to form student groups based on past academic records.

The main characteristics or criteria that were used in the related works to form the groups were knowledge levels, learning styles, communicative skills, leadership skills, gender, age, and self-confidence. Grouping algorithms assign different weights to these characteristics to generate optimized groups. The research [13] classified these characteristics as static and dynamic. Static characteristics are those that do not change or at least do not change during a short period of learning, such as

gender, age, previous levels of knowledge, or learning styles. Dynamic characteristics, which cannot be captured at a fixed point, are constantly changing during students' learning processes, such as levels of interaction or emotional status. According to [13], the main disadvantage of traditional non-automatic grouping methods, which include random grouping (used by [5]), student-formed groups (used by [11]), and instructor-assigned groups (used by [14]), is that they are generally based on static characteristics, and even if dynamic characteristics are used, they are not taken into account enough, which may lead to undesirable collaborative results. On the contrary, automatic grouping methods facilitated the use and good management of dynamic characteristics despite the problems associated with those characteristics, particularly how and when to measure them to form groups. [6], [12], [13], [16], [20], [21], and [25], developed automatic grouping methods that achieve collaborative learning outcomes. The phrase "cold start" was used in [13] to denote the problem of the inaccessibility of students' characteristics, such as personality traits, communication skills, and leadership capacities, at the starting point. Dynamic grouping is a solution to the "cold start" problem, in which groups are initiated and then modified by dynamic swapping. But its running time is expensive, and it takes time for groups to form and stabilize and for students to work on a regular basis. Thus, [6] proposes a dynamic grouping method where groups are initially formed based on students learning styles and knowledge levels, and then an activity-based dynamic group formation technique is proposed to swap students based on their knowledge levels. The authors in [17] propose a method to form dynamic groups for students who did not fit into any group and referred to them as "orphan students". In addition, [10] use dynamic grouping or partial grouping methods to enable students to find the most suitable partners.

The size of groups is less addressed in related works because the interest is in collaborative activities in which the group size ranges from 3 to 5 students. In the study conducted by [2] to investigate the effect of group sizes on students in a gamification environment, they found that varying sizes between groups affected students' interest, comparison, and discouragement but did not affect their perceived effort, perceived choice, perceived competence, tension, or motivation.

In summary, almost all grouping approaches have focused on collaborative tasks that have proliferated rapidly thanks to technological development. But collaborative activities and collaborative learning can be complementary to regular lectures in which the teacher contributes more than the student and in which the number of students is large. For this reason and to facilitate the role of lecturers in achieving the learning outcomes, it is necessary to form learning groups that are homogeneous and balanced in terms of size and homogeneity. We are not aware of any work using a self-balancing binary search tree for forming intra-homogeneous, inter-homogeneous, and size-balanced learning groups.

## III. METHODOLOGY

This section introduces an algorithm to automate the formation of learning groups. This algorithm aims to improve

the homogeneity of students' competence within learning groups for the same course and to achieve a balance between those groups in terms of size and degree of homogeneity. The algorithm relies on two types of self-balancing binary search trees due to its ability to classify and sort data. So, the first stage is to define the homogeneity of the groups and how it should be measured. The second stage introduces self-balancing binary search trees. Next, the steps of the algorithm that generates the learning groups are explained.

### A. Group Homogeneity

The proposed algorithm uses GPA (grade point average) as a key feature for grouping students. That is, students with a homogeneous GPA (closet GPA) are more likely to be in the same group. According to [9], [24], and [22], GPA is positively correlated with subsequent academic performance. The need for other grouping criteria, such as students' personality traits and communication skills, is unnecessary because this work does not address collaborative activities. Thus, the homogeneity of the learning group boils down to the homogeneity of the GPAs of its students. The used terminology and the calculated formula of homogeneity are as follows:

- $\mu(g)$ : The mean of the students' GPAs within a group  $g$
- $S(g)$ : The standard deviation of the students' GPAs within a group  $g$ . It measures the mean distance between each student's GPA and a reference point at the center of the range of GPAs, the  $\mu(g)$ . A small value of  $S$  means that the GPAs are distributed close to the central point,  $\mu$ , and are therefore close to each other, which means that they are homogeneous. Otherwise, they are far from each other and therefore heterogeneous.
- $CV(g)=(S(g)/\mu(g))\times 100$ : The coefficient of variation of the students' GPAs within a group  $g$ . The coefficient of variation measures GPAs' dispersion as a percentage of their mean to see how strong or weak that dispersion is. Hence, it is used as an indicator of both homogeneity and heterogeneity within a group  $g$ . The group  $g$  is considered heterogeneous from  $CV(g)=30\%$  and above because the GPAs of the students in it differ from each other by more than a third of the average. Otherwise, less than 30% ( $CV(g)<30\%$ ), group  $g$  is considered homogeneous. Therefore, the CV is used for measuring the homogeneity of student groups created in different ways, such as traditional methods and the proposed algorithm. Thus, the intra-homogeneity of a group  $g$  is calculated as follows:

$$H_{intra}(g)=(S(g)/\mu(g))\times 100 \quad (1)$$

Consider a set of  $n$  learning groups  $G=\{g_1, \dots, g_n\}$ , and their intra-homogeneity set  $H=\{(S(g_1)/\mu(g_1)), \dots, (S(g_n)/\mu(g_n))\}$  then the inter-homogeneity is calculated as follows:

$$H_{inter}(G)=S(H)/\mu(H) \times 100 \quad (2)$$

### B. Self-Balancing Binary Search Tree: Definition and use for Forming Learning Groups

A tree is a hierarchical data structure consisting of a set of nodes joined together by edges and having one node called the root. One of the most common tree types is the binary search tree (BST), also called an ordered binary tree. It has the property that the key (data) of each inner node is greater than all keys in its left subtree and less than those in its right subtree. One of its main benefits is speeding up data searches since the time complexity of operations on a BST is directly proportional to the tree's height. Fig. 1 provides an example of a BST that records the following list of GPAs for 17 students, where the GPA is measured on a 5-point scale: {1.88, 1.62, 3.3, 2.52, 4.13, 2.78, 3.75, 2.85, 2.56, 4.18, 1.83, 2.3, 4.05, 1, 3.7, 2.55, 3.29}. As it is shown below in Fig. 1, for a GPA search of 2.78, only the nodes with keys 1.88, 3.3, and 2.52 will be accessed.

Fig. 1. Example of a BST recording the GPAs of 17 students.

The use of the tree in this work is to build small blocks of students with convergent GPA levels that will be used later to build learning groups with improved homogeneity. Each tree branch (the path from the root to the leaf of the tree) is considered a student block that is represented by their GPAs. The elements of any BST branch are often convergent and homogeneous. For example, in Fig. 1, branches  $B1 = \{1.88, 1.62, 1\}$  and  $B2 = \{1.88, 3.3, 2.52, 2.78, 2.85, \text{ and } 3.29\}$  are two blocks of students represented by their GPAs. The homogeneities of these two branches, calculated according to formula 1, are 30.14% and 19.18%, respectively, which means that these two students' branches are homogeneous. However, the disadvantage of BST is that its branches are not always the same size. For example, the sizes (number of elements) of  $B1$  and  $B2$  are 3 and 6, respectively, which means they are completely different. This can lead to an imbalance in the size of learning groups being built. That is why we are going to use self-balancing BST instead.

A self-balancing BST is a tree that has the property of rearranging its nodes as necessary to ensure that it does not become too tall and thin. It generalizes the BST, allowing nodes to contain more than two children. There are several implementations for balanced binary search trees like AVL trees, 2-3 tree, 2-3-4 tree, and B-trees. For more information about balanced trees, you can review [23]. For the purpose of this work, 2-3 tree and 2-3-4 tree are applied to generate student blocks that will be used to form learning groups. The 2-3 tree allows each node to have one data element and two children, or two data elements and three children. The 2-3-4 tree allows each node to contain one to three data elements and

two, three, or four children. In both trees, if a node contains more than one key, the keys must be in order. Fig. 2(a) and 2(b) redraw the data set of Fig. 1 as the 2-3 tree and the 2-3-4 tree, respectively.

Fig. 2. Examples of self-balancing BST recording the GPAs of 17 students.

As shown in Fig. 2, the two trees are balanced so that all leaves are on the same plane. Using these two trees to form learning groups requires extracting all possible branches by decomposing nodes that are composed of more than one key and then associating each key with its children. The following table shows all possible branches of the 2-3 and 2-3-4 tree shown in Fig. 2.

TABLE I. BRANCHES GENERATED FROM THE 2-3 AND 2-3-4 TREES SHOWN IN FIG. 2.

	2-3 tree	2-3-4 tree
Branches	2.78, 1.88, 1.62, 1.0	2.78, 1.88, 1.0
	2.78, 1.88, 1.62, 1.83	2.78, 1.88, 1.62
	2.78, 1.88, 2.52, 2.3	2.78, 1.88, 1.83
	2.78, 1.88, 2.52, 2.55	2.78, 1.88, 2.3
	2.78, 1.88, 2.52, 2.56	2.78, 2.52, 2.3
	2.78, 3.75, 3.3, 2.85	2.78, 2.52, 2.55
	2.78, 3.75, 3.3, 3.29	2.78, 2.52, 2.56
	2.78, 3.75, 3.3, 3.7	2.78, 3.3, 2.85
	2.78, 3.75, 4.13, 4.05	2.78, 3.3, 3.29
	2.78, 3.75, 4.13, 4.18	2.78, 3.3, 3.7
		2.78, 3.3, 3.75
		2.78, 3.3, 4.05
		2.78, 4.13, 3.7
	2.78, 4.13, 3.75	
	2.78, 4.13, 4.05	
	2.78, 4.13, 4.18	

Table I shows that the branches generated from the 2-3 tree are few in number compared to the 2-3-4 tree but are longer than those produced from the 2-3-4 tree. This difference may play an important role in the formation of learning groups and affect their homogeneity, and this will be examined in the experiment section.

The common feature of the two trees, as shown in Table I, is that the produced branches often have homogeneous elements. However, sometimes the generated branches contain GPAs that are different or far from the majority within the branch, such as the branches {2.78, 1.88, 1.62, 1.83} and {2.78, 4.13, 4.18}, where the GPA 2.78 was far from the rest of the GPAs in the two branches. In this case, the homogeneity of the branch will not be highly affected because most of its

elements are close together. The homogeneity of branches and their balanced sizes in self-balancing BST serve the aims of this work, which is why these kinds of balanced trees were used.

### C. A Greedy Algorithm for Forming Learning Groups

To form learning groups that are intra- and inter-homogeneous and of balanced size, a greedy algorithm was developed using branches of self-balancing BST. This algorithm forms  $n$  learning groups, where  $n$  is predetermined. It processes recursively and, at each iteration, selects the appropriate branch  $br$  to add to the group  $g_i$ , where  $g_i$  is the group with the least size. If the number of groups of least size is greater than one, the lowest order group is selected. This procedure is applied to balance the size of groups.  $br$  is the branch that, when added to  $g_i$ , gives the best homogeneity to  $g_i$ , compared to the rest of the candidate branches for addition. At the end of each iteration, the algorithm reconstructs the candidate branches by removing the elements that are common with  $br$ . The following is the notation used to write the pseudocode for this algorithm:

- $GPAs$ : Students' GPAs that will be divided into groups.
- $TT$ : The used tree kind is either 2-3 or 2-3-4.
- $T$ : The self-balancing BST of kind  $TT$ , which will be constructed to contain GPAs
- $S$ : The generated branches from the  $TT$  tree
- $br$ : a branch in  $S$
- $n$ : The predetermined number of learning groups
- $G$ : The set of learning groups
- $g_i$ : The selected group to add an appropriate branch, where  $1 \leq i \leq n$ .
- $H_{intra}(g_j)$ : intra-homogeneity of the learning group  $g_j$

The pseudocode of the proposed algorithm, denoted for simplicity as the GF-SBT (Group Formation based on Self-Balancing Tree) algorithm, is presented in Fig. 3 below.

```

GF-SBT Algorithm(GPAs, TT, n)
INPUT:
- GPAs: List of students' GPAs
- TT: the type of balanced tree
- n: number of predetermined learning groups
OUTPUT:
- G: the set of created learning groups
BEGIN
1. T ← ConstructTree(GPAs, TT) // Construct the T tree of type TT from the list of GPAs
2. S ← generateBranches(T) // Extract all the branches of T
3. G ← ∅ // Initialize the Learning groups list to be empty
4. For i ← 1 to n do // Initialize all groups to an empty set and add them to G
5.   g_i ← ∅
6.   G ← G ∪ {g_i}
7. End For
8. While (S not empty) do // iterate to fill in the groups of G from S
9.   Find the group g_i ∈ G with the minimum size
10.  br ← first branch in S
11.  bestH ← H_intra(g_i ∪ br) // homogeneity of the GPAs in the set {g_i, U br}
12.  For each: b ∈ S // iterate to find the appropriate branch br to add to g_i
13.    hr ← H_intra(g_i ∪ b)
14.    if (hr < bestH) then
15.      br ← b
16.      bestH ← hr
17.    End if
18.  End For
19.  g_i ← g_i ∪ {br} // add the found appropriate branch br to g_i
20.  For each: b ∈ S // delete from any branch in S the elements in common with br
21.    b ← b - {b ∩ br}
22.  End For
23. Refresh S // Remove from S any branch that has become empty after deleting its elements in common with br
24. End While
25. Return G // return the set of created Learning groups
    
```

Fig. 3. GF-SBT Algorithm for forming learning groups.

#### IV. EXPERIMENTS

##### A. Experiment 1

This experiment investigates the ability of the 2-3 and 2-3-4 tree to help form intra- and inter-homogenous learning groups of balanced sizes. Moreover, it was used to measure the algorithm's ability to improve homogeneity and balance the size of learning groups compared to traditional group formation methods.

For this reason, five different tests were conducted to study the results of forming two learning groups in five different ways for 48 students enrolled in a computer programming course at the University of Tabuk. In the first three tests, traditional methods are used for grouping as follows: the first test keeps the same group formation that the university already made, which is self-formation (the student registered himself and chose the group). The other two tests were performed on random formations. The last two tests apply the algorithm GF-SBT using 2-3 and 2-3-4 tree, respectively. The results of these tests are summarized in Table II below. The mean intra-homogeneity is the average intra-homogeneity of the two groups.

Table II shows the learning group sizes generated by each test, the mean intra-homogeneity of the two groups, as well as the inter-homogeneity. For simplicity, in the rest of this paper, intra-homogeneity is used to denote mean intra-homogeneity.

TABLE II. RESULTS OF THE FIVE TESTS FOR FORMING LEARNING GROUPS FOR A SAMPLE OF 48 STUDENTS

	Self-grouping test	Random test 1	Random test 2	2-3 Tree test	2-3-4 Tree test
First group size	24	23	29	24	24
Second group size	24	25	19	24	24
Mean intra-homogeneity	20.50%	19.34%	21.16%	16.37%	15.63%
Inter-homogeneity	26.15%	50.88%	61.04%	31.95%	27.75%

The results in Table II showed that there was no correlation between the balance of group size and the improvement in homogeneity. For example, the first, fourth, and fifth tests produced groups of balanced size, with 24 students in each group. However, the intra-homogeneity was different between these three tests (20.50% for the first test, 16.37% for the 2-3 tree test, and 15.63% for the 2-3-4 tree test), which means that the contents of the groups differ from one test to another. In addition, the first test groups were balanced in size (24 per group) in contrast to the second test groups, which were not balanced (23 and 25), but the intra-homogeneity for the second test was better than the first.

The above readings of the results, presented in Table II, confirm that balancing group size is not sufficient to improve intra-homogeneity. Therefore, there is a need to use techniques that combine improving numerical balance with homogeneity when creating groups. In this context and based on the above results, the proposed algorithm, with the use of 2-3 and 2-3-4 trees, succeeded in meeting this need to adjust group sizes and improve group homogeneity compared to traditional methods.

Thus, group construction by applying the GF-SBT algorithm is more efficient than traditional formation methods in balancing the number of students between groups and improving intra-homogeneity. The use of 2-3-4 tree was better than 2-3 tree in improving intra-homogeneity (16.37% for 2-3 tree and 15.63% for 2-3-4 tree). Furthermore, the use of the 2-3-4 tree has improved the intra-homogeneity of the self-grouping test by 4.87 percentage points (from 20.50% to 15.63%), the intra-homogeneity of the first random test by 3.71 percentage points (from 19.34% to 15.63%), and the intra-homogeneity of the second random test by 5.53 percentage points (from 21.16% to 15.63%). Therefore, in terms of percentages, the use of the 2-3-4 tree improved the intra-homogeneities resulting from the three traditional tests studied by 23.76% (calculated as  $4.87/20.50$ ) for the first test, 19.18% (calculated as  $3.71/19.34$ ) for the second test, and 26.13% (calculated as  $5.53/21.16$ ) for the third test. The use of the 2-3 trees also improved the intra-homogeneity of the three traditional tests by 20.15% (calculated as  $(20.5-16.37)/20.5$ ), 15.35%, and 22.61%, respectively.

The inter-homogeneity showed that the GF-SBT algorithm was more efficient at narrowing the gap between the two group homogeneities than the randomized tests. In addition, the use of the 2-3-4 tree approach is more effective than the use of the 2-3 tree in adjusting the homogeneity between the two groups, given that the inter-homogeneity was 27.75% for the 2-3-4 tree and 31.95% for the 2-3 tree.

The bottom line from this experiment is that the GF-SBT algorithm, with its two trees, accurately balances learning group sizes and effectively improves intra-homogeneity caused by traditional grouping methods, with rates ranging from 15% to 26%. Also, compared to the random construction of groups, the GF-SBT algorithm is more efficient at balancing group homogeneity. For this small sample of students, the use of the 2-3-4 tree is more appropriate than the use of the 2-3 trees to create learning groups of equal sizes and optimized and balanced homogeneities.

##### B. Experiment 2

This experiment aims to investigate the effect of multiplying the number of students and the number of learning groups on the effectiveness of the GF-SBT algorithm in improving the intra- and inter-homogeneity of learning groups and balancing their size. To achieve this aim, five tests were conducted that used the GF-SBT algorithm with the 2-3 and 2-3-4 tree to construct learning groups for a broad sample of students. The number of groups differs in each test and ranges between 2 and 6. The sample consisted of 96 students who self-enrolled in four educational groups in the communication skills course at Tabuk University, as shown in Table III below.

TABLE III. CHARACTERISTICS OF 4 LEARNING GROUPS FROM A SAMPLE OF 96 STUDENTS

	Group size	Mean intra- homogeneity	Inter-homogeneity
Group 1	24	55.55%	9.05%
Group 2	25		
Group 3	32		
Group 4	15		

Table IV and Table V present the results of the five tests that apply the GF-SBT algorithm, with its two trees, to distribute this sample of students into 2, 3, 4, 5, and 6 learning groups.

TABLE IV. LEARNING GROUP SIZE IN A SAMPLE OF 96 STUDENTS

		Test1: 2 learning groups		Test2: 3 learning groups		Test3: 4 learning groups		Test4: 5 learning groups		Test5: 6 learning groups	
		2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree
Group size	Group 1	4 8	48	32	3 2	2 4	24	2 0	20	16	1 7
	Group 2	4 8	48	32	3 2	2 4	24	1 9	19	17	1 6
	Group 3			32	3 2	2 4	24	1 9	19	16	1 6
	Group 4					2 4	24	1 9	19	16	1 6
	Group 5							1 9	19	16	1 5
	Group 6									15	1 6

It is shown in Table IV that the GF-SBT algorithm yields groups of very balanced sizes, with some very slight differences resulting either from the non-divisibility of the total number of students evenly, such as in test 4, where 96 is not divisible by 5, or in cases where the number of groups is high, such as in the fifth test. It is also noted that the number of groups in the third test and in the formation proposed by the university are the same, but the groups produced by the third test are more balanced in size than the ones made by the university.

TABLE V. INTRA- AND INTER-HOMOGENEITIES OF LEARNING GROUPS IN A SAMPLE OF 96 STUDENTS

		Test1: 2 groups		Test2: 3 groups		Test3: 4 groups		Test4: 5 groups		Test5: 6 groups	
		2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree	2-3 Tree	2-3-4 Tree
Intra- homo- geneity	%	56.04	55.13	53.39	46.95	54.16	47.18	55.38	53.56	54.56	48.75
Inter- homo- geneity	%	3.25	2.52	10.87	36.86	13.67	32.80	9.22	19.04	18.30	23.26

Table V shows that the homogeneity of the groups is very high compared to the homogeneity of experiment 1. This is because this sample is characterized by the large number of its students and the great diversity of their GPAs. It shows that the difference between the intra-homogeneity of the two uses of trees in most tests was significant and ranged between 5 and 7

percentage points, except for the tests of two groups and five groups. It displayed that the use of the 2-3-4 tree was the best, compared to the 2-3 tree approach, in improving intra-homogeneity in all five tests for this heterogeneous sample. Compared to the self-grouping results presented in Table IV, the algorithm GF-SBT, with the two uses of trees, improves intra-homogeneity. In this respect, the use of the 2-3-4 tree approach yields an improvement of more than 8 percentage points (from 55.55% to 47.18%), which is equivalent to a 15.07% improvement. Thus, the algorithm GF-SBT with the two uses of trees can improve the intra-homogeneity for homogeneous samples, as in experiment 1, and heterogeneous samples, as in this experiment.

The results presented in the Table V did not show any clear correlation between the number of groups and the intra-homogeneity improvement in the two uses of trees. It is shown that intra-homogeneity does not follow the same pattern as the number of groups. For example, for the use of the 2-3 tree, the mean intra-homogeneity in the five-group test (55.38%) was greater than the mean intra-homogeneity for the three, four, and six group tests (53.39%, 54.16%, and 54.56%, respectively), but smaller than the mean intra-homogeneity in the two-group test (56.04%). The same phenomenon is observed with the 2-3-4 tree approach.

In Table V, by measuring the inter-homogeneity, it is shown that the use of the 2-3 tree was more capable compared to the use of the 2-3-4 tree in constructing homogeneity-balanced groups (well inter-homogeneous) in all tests except the two-group test. Fig. 4 below supports this finding and plots the intra-homogeneity of each test. It reveals that the results of the use of the 2-3 tree appear closer to each other than the ones of the use of the 2-3-4 tree, which appear disparate. However, despite their convergence, the levels of homogeneity resulting from the use of the 2-3 tree were mostly high, compared to the results of the use of 2-3-4 tree. This explains the excellence of the 2-3-4 tree in improving the mean intra-homogeneity. In addition, no correlation was observed between the inter-homogeneity and the number of groups.

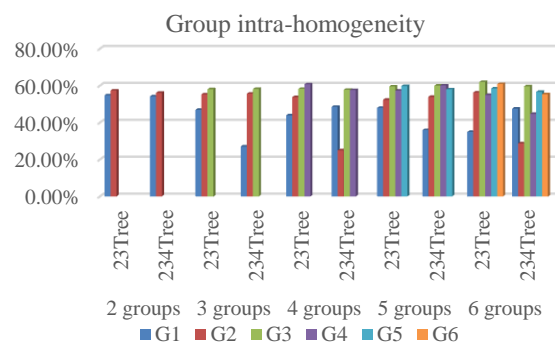

Fig. 4. Groups' intra-homogeneities of the five tests.

All three parameters measured and analyzed here above (group size, intra-homogeneity, and inter-homogeneity) depend on candidate branches (the initial contents of S set in the algorithm GF-SBT) that are used by the GF-SBT algorithm in the group formation process. Table VI below presents the

features of the candidate branches of the two trees used by the GF-SBT algorithm for this sample.

TABLE VI. FEATURES OF THE CANDIDATE BRANCHES GENERATED FROM THE 2-3 AND 2-3-4 TREES

	2-3 Tree	2-3-4 Tree
Branch size	6	5
Total Number of candidate branches	71	100
Standard deviation of homogeneities of candidate branches	8.17	9.05

It is evident in Table VI that the candidate branches of the 2-3-4 tree are shorter with dispersed homogeneities, i.e. its standard deviation is bigger than that of the 2-3 tree, and more numerous than those of the 2-3 tree. This is why using the 2-3-4 tree produces better intra-homogeneity than using a 2-3 tree and poorer inter-homogeneity between groups, as shown in Table V.

## V. DISCUSSION

Based on the results of the experiments presented in the previous section, the GF-SBT algorithm proved effective in forming learning groups of balanced size and improving their intra-homogeneity. In this regard, it exceeded the traditional methods (self-grouping and random grouping methods) that have been adopted in building learning groups. Similarly, these results agree with what is presented in [16], [19], [25], and [27], which propose to improve both the internal and external relationships of the groups. In spite of the similarities in the obtained results, the methods used for measuring the effectiveness of algorithms were different. For instance, [16], [19], [25], and [27] measure the effect of the grouping algorithm on the students' abilities, while this work measures intra- and inter-homogeneity of groups. The measure of students' ability was allowed for the former because they intended a small group made up of five students for collaborative work, whereas the latter was designed to deal with any size of group that may be greater than twenty students.

The results of using the two self-balancing BSTs, 2-3 and 2-3-4, with a small sample are nearly identical in terms of group size, intra-homogeneity, and inter-homogeneity. Thus, small samples are recommended to be used with any of both trees, with bit priority for 2-3-4 tree.

In the case of large samples, the algorithm produces different results for both trees because of the differences in structure of their candidate branches. The candidate branches of the 2-3-4 tree are more numerous than those of a 2-3 tree and are characterized by various homogeneities and short sizes. They allow the algorithm to create learning groups that are often better intra-homogeneous than the 2-3 tree groups but are less inter-homogeneous. Thus, the use of the 2-3-4 tree is preferable if priority is given to intra-homogeneity more than inter-homogeneity of learning groups. On the contrary, the 2-3 tree produces fewer candidate branches with less various homogeneity and a larger size. That is why the algorithm generates learning groups that are often less intra-homogeneous than 2-3-4 tree groups, but good inter-homogeneously. So, 2-3 tree use is beneficial if the priority of

group formation is given to inter-homogeneity. The summary of this paragraph is that the formation of groups through short student blocks improves the intra-homogeneity of learning groups at the expense of their inter-homogeneity, and the opposite occurs through large student blocks.

It has not been proven through experiments that the grouping process adopted by the GF-SBT algorithm is affected by the number of groups to be built. Therefore, the use of the algorithm is effective and recommended regardless of the number of groups to be formed.

The limitation of this work is that, with large samples, neither the use of the 2-3 tree nor the use of the 2-3-4 tree succeeded in integrating improvements in both intra- and inter-homogeneity of the generated learning groups. This limitation will be studied in future work.

## VI. CONCLUSION

In this paper, an algorithm based on self-balancing binary search trees has been implemented and experimented with to form intra-homogeneous (student performance similarity within the group) and inter-homogeneous (group performance similarity between groups) learning groups with a balanced size. The self-balancing binary search trees were used at an initial stage to achieve the objectives of group formation, as they contribute to the formation of student blocks (which are tree branches) with close GPAs and balanced sizes. Then, the groups are formed from these blocks. The algorithm uses two versions of self-balancing binary search trees (the 2-3 tree and the 2-3-4 tree), where the difference between them lies in the number and length of branches they produce.

The experiments have shown, with samples from different numbers of students, the efficiency of the proposed algorithm in balancing the size of the groups, balancing the homogeneity between them (inter-homogeneity), and improving their internal homogeneity (intra-homogeneity) compared to the traditional forming methods by up to 26%, whatever the kind of self-balancing binary search tree (2-3 or 2-3-4).

With small samples of students, using the 2-3-4 tree was more effective than the 2-3 tree for improving intra- and inter-homogeneity. However, with large samples, using the 2-3-4 tree was more effective than the 2-3 tree in improving intra-homogeneity but less effective for balancing homogeneity between groups. In this case, the choice between using 2-3 or 2-3-4 trees depends on the instructor's preference, whether intra-homogeneity or inter-homogeneity. The inability of the algorithm to combine intra- and inter-homogeneity optimization for large samples of students using both kinds of self-balancing binary search trees is a limitation that will be worked on in the future.

# Multi-Features Audio Extraction for Speech Emotion Recognition Based on Deep Learning

Jutono Gondohanindijo, Muljono\*, Edi Noersasongko, Pujiono, De Rosal Moses Setiadi  
Faculty of Computer Science, Universitas Dian Nuswantoro, Semarang, Indonesia

**Abstract**—The increasing need for human interaction with computers makes the interaction process more advanced, one of which is by utilizing voice recognition. Developing a voice command system also needs to consider the user's emotional state because the users indirectly treat computers like humans in general. By knowing the type of a person's emotions, the computer can adjust the type of feedback that will be given so that the human-computer interaction (HCI) process will run more humanely. Based on the results of previous research, increasing the accuracy of recognizing the types of human emotions is still a challenge for researchers. This is because not all types of emotions can be expressed equally, especially differences in language and cultural accents. In this study, it is proposed to recognize speech-based emotion types using multi-feature extraction and deep learning. The dataset used is taken from the RAVDESS database. The dataset was then extracted using MFCC, Chroma, Mel-Spectrogram, Contrast, and Tonnetz. Furthermore, in this study, PCA (Principal Component Analysis) and Min-Max Normalization techniques will be applied to determine the impact resulting from the application of these techniques. The data obtained from the pre-processing stage is then used by the Deep Neural Network (DNN) model to identify the types of emotions such as calm, happy, sad, angry, neutral, fearful, surprised, and disgusted. The model testing process uses the confusion matrix technique to determine the performance of the proposed method. The test results for the DNN model obtained the accuracy value of 93.61%, a sensitivity of 73.80%, and a specificity of 96.34%. The use of multi-features in the proposed method can improve the performance of the model's accuracy in determining the type of emotion based on the RAVDESS dataset. In addition, using the PCA method also provides an increase in pattern correlation between features so that the classifier model can show performance improvements, especially accuracy, specificity, and sensitivity.

**Keywords**—Deep learning; multi-features extraction; RAVDESS; speech emotion recognition

## I. INTRODUCTION

Speech is a form of information transfer commonly used in everyday life [1]. In everyday conversation, speech can provide a lot of information, not only words but also the emotions speakers convey. Knowing the level or type of emotion the other person is talking to is very important in building conversations in social life [2]. By understanding a person's emotional type, treatment and attitude towards that person will be adjusted to the current emotional state [3].

With the development of information technology and the increasing need for Human-Computer Interaction (HCI), the interaction process has become more advanced. One form of simple but effective advanced interaction is through speech

[4][5]. The development of a voice command system needs to consider the user's emotional state, because when interacting with a computer, users tend to treat computers like humans in general [6][7]. Therefore, developing a sophisticated HCI system requires the availability of a speech database that represents emotions as a basis for developing an artificial intelligence system capable of imitating human emotions.

Speech Emotion Recognition (SER) is a field of research that focuses on recognizing types of human emotions which can then be processed further in the form of feedback to users. Several studies have carried out research related to SER, one of which was put forward by Chowdary and Hemanth [8], who utilized the Mel Frequency Cepstral Coefficients (MFCC) and Convolutional Neural Network (CNN) extraction methods to identify types of emotions using the RAVDESS database. This research produced 92%, 95%, and 69% accuracy, specificity, and sensitivity values, respectively. Another study conducted by Kumala and Zahra [9] proposed a study using a cross-corpus technique to identify the types of emotions in Indonesian conversation. This study's results indicate that using a combination of two SER databases and feature extraction of MFCC and Teager Energy can provide an accuracy of 85.42%. Based on the achievement of the performance parameters of several studies above, it can be said that increasing the accuracy of recognition of types of human emotions is still a challenge for researchers. This happens because not all types of emotions can be expressed equally [10].

From the research above, it can be seen that the results of speech-based emotion recognition depend heavily on the database used, the number of balanced classes, the feature extraction process, and the machine learning method used [11]. The use of multiple features is one aspect of improving the performance of the classifier model in identifying types of human emotions, as stated in the research proposed by Iqbal et al [12], where this research utilizes the features of frequency, Pitch, Amplitude, and Formant which are combined with ANN models based on Bayesian Regularized (BRANN) to recognize the type of emotion using the Berlin Database of Emotional Speech (Berlin EmoDB) dataset. The evaluation results of this study obtained an accuracy value of 95%. These results indicate that the use of several features in recognizing the types of human emotions can have an impact, especially in increasing the value of performance parameters in the classifier model.

Therefore, this study proposes using multi-feature extraction and deep learning methods by utilizing the Deep Neural Network (DNN) architecture to recognize types of emotions based on speech. Deep learning is used because of its

ability to process large data and provide high-accuracy values [13]. Furthermore, the multi-features used in this study consist of Mel Frequency Cepstral Coefficients (MFCC), Chroma, Mel-Spectrogram, Tonnetz, and Contrast. These five features are related to the high and low frequency of speech associated with emotional expression [14]. In addition, PCA (Principal Component Analysis) and Min-Max Normalization techniques will be applied to determine the impact resulting from the application of these techniques. The evaluation results were then analyzed using the Confusion Matrix table to determine the accuracy, specificity, and sensitivity values.

This speech emotion recognition research contributes to:

- 1) Determine the features that affect the recognition of eight (8) classes of human speech emotions
- 2) Determine the optimal number of features for feature selection using PCA and feature normalization using MinMax
- 3) Improve performance parameters of accuracy, sensitivity and specificity.

The following section will explain related research, especially research on SER. Then, Section III will explain the methodology used in this study. Then in the next section, we will present the results of our experiment along with an analysis of these results, and Section V is this study's conclusion.

## II. RELATED RESEARCH

SER, or Speech Emotion Recognition, is a method of recognizing types of emotions through speech by utilizing several data processing techniques and machine learning. Based on the results of a literature study conducted by Singh and Goel [11], it shows that SER is a research area that has high interest, especially in real-world applications. From the results of this study, it was found that the development of SER has several factors that influence the results and performance of SER, namely the availability of datasets used in model development, the feature extraction process that is relevant to the type of emotion, and the type of classifier used in model training.

Several studies have carried out the development of models related to SER, one of which was suggested by research conducted by Chowdary and Hemanth [8]. This study proposes the development of SER by utilizing the RAVDESS and Convolutional Neural Network (CNN). The research phase starts from the MFCC feature extraction stage from the RAVDESS dataset. Then the feature extraction results were validated into 1642 data as training data and 810 data as test data. The training data is used as a reference for training the Conv1D-based CNN model. Next, the model is evaluated using test data. The evaluation results showed a model accuracy of 92%, sensitivity of 69%, and specificity of 95%.

Furthermore, Iqbal et al. [12] proposed speech emotion recognition based on Artificial Neural Networks (ANN). The Berlin Database of Emotional Speech (Berlin EmoDB) was used in this study as a speech-based emotion recognition dataset collection. Several feature extractions are used, including frequency, pitch, amplitude, and formant. While the

classifier model used is ANN based on Bayesian Regularized (BRANN). The model evaluation results obtained an accuracy performance of 95%. In addition, several studies also utilize multi-feature techniques such as MFCC [15], Cross Zero Rate, Root Mean Square (RMS) [16], Chroma, Mel-Spectrogram, Contrast, and Tonnetz [17][14]. The use of multiple features is one aspect of increasing the performance of the classifier model in identifying types of emotions [11].

The use of a different approach was also proposed by Kumala and Zahra [9]. In this study, it is proposed to use the Cross-Corpus technique to recognize speech emotions in Indonesian. This study utilizes several database sources, namely the Berlin Database of Emotional Speech (Berlin EmoDB), Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS), and Surrey Audio-Visual Expressed Emotion (SAVEE) so that there are three corpora, consisting of one corpus in German, and two corpora in English. The feature extraction process in this study uses the MFCC and Teager Energy methods. Using the Support Vector Machine (SVM) classifier, this study increased accuracy performance by 4.16% on MFCC and 2.09% on the Teager-MFCC combination. In addition, the three corpora used are in good agreement with Indonesian in terms of emotion recognition.

Using the multi-acoustic feature on the SER is one of the efforts to improve the performance of human emotion recognition. This study will use features such as MFCC, Chroma, Contrast, Mel-Spectrogram, and Tonnetz as emotion recognition features. Then Principal Component Analysis (PCA) and Min-Max Normalization techniques are implemented to see the impact of these processes on the performance of emotion recognition. Deep Neural Network (DNN) is used in this study as a classifier because of its ability to process large data and provide high accuracy values [13]. The model that has been trained is then evaluated using the confusion matrix to determine the performance of the model, especially in terms of accuracy, specificity and sensitivity values.

## III. METHODOLOGY

This study proposes to identify emotions based on RAVDESS voice data using multi-feature extraction and Deep Neural Network (DNN). An overview of this research can be seen in Fig. 1.

In Fig. 1 it can be seen that the RAVDESS dataset will extract its audio features using several types of audio extraction methods such as Mel Frequency Cepstral Coefficients (MFCC), Chroma, Mel-Spectrogram, Tonnetz, and Contrast. Then, PCA (Principal Component Analysis) and Min-Max Normalization techniques are applied to the extracted features to determine the impact of transformation and data reduction on the resulting model.

Fig. 1. Concept of proposed study.

After experiencing the pre-processing stage, the dataset can be grouped into training and testing sets using split validation. The Deep Neural Network (DNN) will use the training set as the model training reference data. After the training results model is obtained, the next step is to test using the testing set as the test data. From the testing process, the results of the emotion type prediction will be obtained by the trained DNN model, where these results will be transformed into a Confusion Matrix table as a reference table for determining the performance parameters of the proposed model. The parameters used to determine the performance of the proposed model are accuracy, specificity, and sensitivity.

#### A. Dataset

In this study, the Ryerson Audio-Visual Database of Emotional Speech and Song, or the RAVDESS dataset, was used [18]. The data set is a multi-modal database consisting of separate sound and video recordings showing certain types of emotions. The database is gender balanced, consisting of 24 professional actors, vocalizing lexically-matched statements in a neutral North American accent. Each actor recites a sentence or song in North American English lasting 3 to 4 seconds in a standardized recording scenario.

In this study, the focus will be on datasets in audio format. RAVDESS contains 2452 audio data divided into 1440 audio data for speech and 1012 audio data for songs. The data is also divided into 8 (eight) types of emotions: calm, happy, sad, angry, neutral, fearful, surprise, and disgust.

#### B. Feature Extraction

1) Mel Frequency Cepstral Coefficients (MFCC) is a feature extraction type commonly used in audio files [19]. MFCC is generally suggested to be used as an identifier for monosyllables in audio without identifying the speaker [20]. The MFCC feature extraction process [8] in audio begins with the Pre-emphasis stage, namely amplifying the audio signal at high frequencies. Followed by the framing and windowing stages, where framing stage aims to divide the length of the audio into several time intervals between 20 ms to 30 ms while the windowing technique is used to limit the occurrence of disturbances at the beginning and end of the audio, the next stage is the implementation of the Fast Fourier Transform, Mel Filter Bank, and Discrete Cosine Transform as a process of transforming the windowing results into MFCC. MFCC (Mel-Frequency Cepstral Coefficients) is a feature used in speech emotion recognition which has the advantage of representing the acoustic properties of the human voice. The MFCC uses the mel scale, which is similar to the human auditory perception of frequency. MFCC features are generated by taking the logarithm of the power spectrum and converting it to cepstrum, thereby helping to reduce feature dimensionality and processing complexity. MFCC can represent temporal information in speech signals through short-duration frame splitting techniques to capture variations in speech signals associated with temporal emotional changes.

2) Chroma is a feature extraction focusing on music-oriented audio tones [21]. This feature can provide a distribution of tonal variations in audio in the form of a simple feature. The Chroma feature's result is a chromagram built based on 12 (twelve) tone levels [22]. The use of chroma is expected to recognize the high and low pitch of the actor's speech in audio, where the tone of the speech can indicate a certain type of emotion.

3) Mel-Spectrogram is an audio feature extraction that was built to overcome the problem of limited human hearing ability in distinguishing high-frequency values [22]. The use of the Mel-Spectrogram in this study is to extract information on differences in frequency values, particularly in identifying the types of emotions expressed by actors.

4) Tonnetz is a feature extraction derived from Chroma that also focuses on audio harmony and tone classes [23].

5) Contrast is a feature extraction in audio that is useful for estimating the average sound energy based on each sub-band's peak and valley spectral values [24].

#### C. Principal Component Analysis (PCA)

PCA or Principal Component Analysis, is a statistical method that is widely used, especially in data processing such as dimension reduction, data compression, and feature

extraction [25]. PCA is conceptually able to identify new variables based on the main components, where these values are linearly the result of the combination of the original features used [26]. Simply put, PCA will project a new feature or variable whose representation is the same as the original feature where the number of components can be adjusted. In this study, PCA will be tested as dimension reduction to reduce the number of extracted features and increase the representation of feature values.

#### D. Min-Max Normalization

Normalization is the process of equalizing values among features with significant differences in value so that the weights and the effects on each feature are the same when used as a reference for classifier model training [27]. In this study, the Min-Max Normalization method will be applied where the value of each feature will be distributed over a range of values between 0 and 1. The application of this method will provide an overview of the impact of using normalization in the formation of classifier models. This method works by first determining the maximum ( $x_{max}$ ) and minimum ( $x_{min}$ ) values of each variable or feature. Then each original data ( $x_{old}$ ) is operated with the previously obtained value to produce a new value ( $x_{new}$ ) using the following equation [8]:

$$x_{new} = \frac{x_{old} - x_{min}}{x_{max} - x_{min}} \quad (1)$$

#### E. Deep Neural Network (DNN)

Deep Neural Network or DNN is one of the Deep Learning (DL) methods built on the basis of Neural Networks. DNN is the improved version of the conventional Neural Network method by adding some depth such as additional hidden layers at the input and output layers [28]. This method is generally used to predict or classify data according to class. In this study, the DNN structure used consisted of 1 (one) dense layer as input and 1 (one) dense layer as output with each activation, namely 'ReLU' and 'Softmax'. Then there are 3 (three) hidden solid layers. A detailed description of the proposed DNN structure in this study can be seen in Table I:

TABLE I. PROPOSED DNN STRUCTURE

Component	Layer Architecture	Activation Function
Input Layer	Dense Layer	RELU
1 <sup>st</sup> Hidden Layer	Dense Layer	RELU
Dropout	DROPOUT	-
2 <sup>nd</sup> Hidden Layer	Dense Layer	RELU
Dropout	DROPOUT	-
3 <sup>rd</sup> Hidden Layer	Dense Layer	RELU
Dropout	DROPOUT	-
Output Layer	Dense Layer	SOFTMAX

#### F. Performance Evaluation

The DNN model testing process results will be converted into a Confusion Matrix table as a reference for calculating model performance parameters. The performance parameters used are accuracy, specificity, and sensitivity. Determining the performance parameter values of the proposed model can use the following equation [8]:

$$Accuracy = \frac{TN+TP}{FP+FN+TN+TP} \quad (2)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (3)$$

$$Specificity = \frac{TN}{TN+FP} \quad (4)$$

In the equation above, TP (True Positive) is the number of test data correctly predicted as a positive class, TN (True Negative) is the amount of test data correctly predicted as a negative class while FP (False Positive) is the amount of test data with a negative class which is predicted as the positive class and FN (False Negative) is the number of test data with the positive class which is predicted to be the negative class. These four values can be generated from the Confusion Matrix table.

#### IV. EXPERIMENT RESULT AND DISCUSSION

Following are the steps in implementing the use of the RAVDESS dataset for speech emotion recognition:

- 1) Dataset exploration and understanding: understand the structure, metadata, and emotional information provided and examine the number of sound recordings, actors involved.
- 2) Feature extraction: uses the combined extraction technique and determines the feature extraction parameters.
- 3) Feature Selection: using the PCA technique
- 4) Data Normalization: using the MinMax Technique
- 5) Dataset division: divide the RAVDESS dataset into training, validation, and testing subsets.
- 6) Model training and evaluation: train a speech emotion recognition model using training subsets and validation splits.
- 7) Testing and final validation: using a subset of testing to test the model that has been trained and calculating the confusion of testing metrics to get accuracy, sensitivity, specificity.
- 8) Analysis of results and evaluation: analyze the results of speech emotion recognition obtained from the model, including performance in each emotion category.

In this study, the experimental phase was carried out using RAVDESS audio dataset which consisted of 1440 spoken audio data and 1012 emotional song data in \*.wav format. Furthermore, the data were extracted using several feature extraction techniques, consisting of MFCC, Mel-Spectrogram, Chroma, Contrast, and Tonnetz. From the extraction results that have been carried out, a total of 193 features were obtained consisting of 40 MFCC features, and 12 Chroma features, whereas Mel-Spectrogram, Contrast, and Tonnetz produced a total of 128 features, 7 features, and 6 features, respectively.

Furthermore, the features obtained are processed using the PCA technique with the total components used are the multiple of 10% of the total features. These results are then normalized using the Min-Max Normalization method to limit the data range that is too large, so that the same range of data for each feature can be achieved.

In the next stage, the normalization results using Min-Max Normalization were validated using separate validation with a ratio of 33% for 810 data as a test set and the remaining 1642

data as a training set. Next, the initialization of the sequential model is carried out by utilizing dense layers to form a Deep Neural Network (DNN) model.

The Deep Neural Network (DNN) model used consists of 5 (five) dense layers. Then the parameter specifications for each layer used consist of the first to fourth dense layers using the 'ReLU' activation function, while the fifth (last) dense layer uses the 'Softmax' activation function which acts as an inference in determining emotion classes. The proposed DNN model uses the 'Adam' optimizer parameter or the adaptive estimates of lower-order moments [29]. Then, the value of 0.1 is used for the dropout rate parameter, which means that the ratio of possible elimination nodes in the DNN is 10% at each embedded dropout step. The model of this sequential DNN uses dropout and parameters, which can be seen in Fig. 2.

```

Fig. 2. Specification of deep neural network (DNN) using 100% of features.

DNN model training using 1642 data distributed into 8 (eight) classes, namely calm, happy, sad, angry, neutral, afraid, surprised, and fed up has been carried out. The training process is repeated for 200 epochs. The model produced in the training process was tested using test data with 810 data. The experimental scheme in this study was carried out using several combinations of data pre-processing methods, especially PCA and Min-Max Normalization. The variations of the experimental schemes used consist of experiments with original features, experiments with applying the normalization method, experiments with applying the PCA technique, and experiments with a combination of PCA and Normalization techniques. In experiments that apply the PCA technique, the number of components used is 100% to 10% of the total features used, where the decrease in the number of components used is 10% for each test. Then, the experimental results for each scheme are transformed into a confusion matrix and evaluated using the performance parameters as shown in Table II.

Table II shows the test results for each experimental variation of the proposed method. The initial scheme that uses all original features can produce a Sensitivity of 69.53%,

Specificity of 95.93%, and Accuracy of 92.93%. This table also shows that the use of the Min-Max Normalization and PCA methods can have an impact on the performance value of the classifier model.

TABLE II. THE RESULT OF VARIATION EXPERIMENTAL OF THE PROPOSED METHOD

	Sensitivity (%)	Specificity (%)	Accuracy (%)
Original Features	69,53	95,93	92,93
Normalization	67,71	95,55	92,28
PCA	<b>73,80</b>	<b>96,34</b>	<b>93,61</b>
PCA + Normalization	73,00	96,33	93,61

The use of the Min-Max Normalization method in this study impacts decreasing performance values, although the decrease is not too significant. This can happen because Min-Max Normalization only projects the original feature values to be valued from 0 to 1, so there is a potential for important values to be omitted, which results in bias during pattern analysis in the model-building process.

The application of the PCA method can impact increasing the performance value of schemes with original features. In fact, applying the PCA method provided the best overall experimental performance with an accuracy value of 93.61%, a Sensitivity of 73.80%, and a Specificity of 96.34%. These results were obtained using 100% components or 193 components of PCA. The achievement of this value can occur because at the PCA stage, there is a Data Scaling process, which is similar to the transformation of feature values in the Normalization method. Furthermore, a statistical calculation process is carried out to form component values close to the original feature values, so that the distribution of feature values becomes the same and PCA can also increase the correlation of each component.

Then in the experiment that combined PCA and Min-Max Normalization, the highest results were obtained with sensitivity of 73%, specificity of 96.33% and accuracy of 93.61%. These results have similarities with the results achieved by experiments using PCA only. This can be indicated that the addition of normalization techniques to combined experiments between PCA and Normalization tends to have an impact in the form of decreasing the achievement of model performance values.

Furthermore, Table III displays the result of the PCA technique where a trial iteration is carried out with a 10% reduction in the number of components. It shows a change in the model performance value. As shown in Table III, the drastic reduction of each performance parameter starts from 50% of the components used or half of the total number of features.

This can happen because changes in the number of features or components affect the pattern analysis results from the classifier. The lower the number of PCA components used, the lower the model's accuracy, sensitivity and specificity performance. In the graphic, it can be seen in Fig. 3, 4, and 5.

TABLE III. THE IMPACT OF THE REDUCTION OF PCA FEATURES ON MODEL PERFORMANCE

Component Percentage (%)	Number of Features	PCA			PCA + Normalization		
		Sensitivity (%)	Specificity (%)	Accuracy (%)	Sensitivity (%)	Specificity (%)	Accuracy (%)
100%	193	<b>73.80</b>	<b>96.34</b>	<b>93.61</b>	73.00	96.33	93.61
90%	174	73.24	96.24	93.49	72.07	96.12	93.27
80%	155	72.44	96.10	93.21	73.12	96.24	93.46
70%	136	70.64	96.04	93.15	72.34	96.19	93.40
60%	116	71.32	95.98	93.02	70.45	95.91	92.90
50%	97	69.36	95.75	92.59	67.52	95.58	92.31
40%	78	67.24	95.47	92.16	67.71	95.51	92.22
30%	58	66.34	95.30	91.85	61.62	94.69	90.77
20%	39	58.21	94.30	90.09	58.08	94.20	89.97
10%	20	52.42	93.50	88.67	49.39	92.97	87.72

Fig. 3, 4, and 5 respectively explain the decrease in Accuracy (Fig. 3), Sensitivity (Fig. 4) and Specificity (Fig. 5) performance when using PCA or combined PCA + Normalization at each stage of the performance test with a feature reduction of 10% for each stage.

Fig. 3. Accuracy performance.

Fig. 4. Sensitivity performance.

Fig. 5. Specificity performance.

Overall, it was found that high-performance results were obtained with experiments implementing PCA only. Table IV shows a detailed description of the achievement of performance parameter values for each type of emotion in the experiment.

In Table IV, it can be seen that several types of emotions have an accuracy value above 94%, including happy, sad, fearful, and surprised. While the types of disgust and anger emotions obtained an accuracy value of 93.70% and 92.96%, respectively, followed by neutral and calm emotions with an accuracy value of 91.60%. The accuracy value is an indicator that shows how the model performs in predicting a data class correctly. The evaluation results show several differences in the accuracy value in each class. This can occur due to differences in the amount of data distribution according to each class [30].

Furthermore, the specificity parameter is a parameter that indicates the classifier's ability to predict a negative class among all data with a negative class. From the results of the specificity test, the proposed model is capable of producing performance above 95% with an average performance of 96.34%, so it can be said that the proposed model is capable of producing high specificity values.

TABLE IV. THE PERFORMANCE RESULT OF EACH EMOTION CLASS

Class	TP	TN	FP	FN	Sensitivity	Specificity	Accuracy
Neutral	89	653	26	42	67.94%	96.17%	91.60%
Calm	91	651	34	34	72.80%	95.04%	91.60%
Happy	48	718	24	20	70.59%	96.77%	94.57%
Sad	45	722	29	14	76.27%	96.14%	94.69%
Angry	88	665	27	30	74.58%	96.10%	92.96%
Fearful	110	657	21	22	83.33%	96.90%	94.69%
Disgust	92	667	27	24	79.31%	96.11%	93.70%
Surprised	40	730	19	21	65.57%	97.46%	95.06%
<b>Average</b>					<b>73.80%</b>	<b>96.34%</b>	<b>93.61%</b>

Then the sensitivity value is a parameter that shows the model's ability to predict the positive class correctly among all data that is in the positive category. The test results show that the sensitivity value for the type of fearful emotion has a value above 83%, indicating that the proposed model can identify test data with the type of fearful emotion well. Meanwhile, other types of emotions such as neutral, calm, happy, sad, angry, and surprised, can produce a sensitivity value of less or a little bit more than 70%, with an average value for all emotion classes of 73.80%. These results indicate that the RAVDESS dataset has a fairly high level of bias between classes. This can occur because the expression of several types of emotions tends to differ between actors [10].

TABLE V. THE PERFORMANCE RESULT OF EACH EMOTION CLASS

No.	Work	Dataset	Feature	Classifier	Accuracy Result
1	Chowdary and Hemanth [8]	RAVDESS	Mel Frequency Cepstral Coefficients (MFCC)	CNN	92%
2	Jothimani and Premalatha [16]	RAVDESS, CREMA, SAVEE, and TESS	Mel Frequency Cepstral Coefficients (MFCC), Zero Crossing Rate (ZCR), and Root Mean Square (RMS)	CNN+LSTM	92.60%
3	Alnuaim et al [31]	RAVDESS	Mel Frequency Cepstral Coefficients (MFCC), Short-time Fourier transform and Mel Spectrogram	MLP classifier	81%
4	Patnaik [32]	RAVDESS and TESS	Complex Mel Frequency Cepstral Coefficients (c-MFCC)	deep sequential LSTM model	91.60%
5	Proposed Method	RAVDESS	Mel Frequency Cepstral Coefficients (MFCC), Chroma, Mel Spectrogram, Contrast, Tonnetz	Principal Component Analysis (PCA) Deep Neural Network (DNN)	93.61%

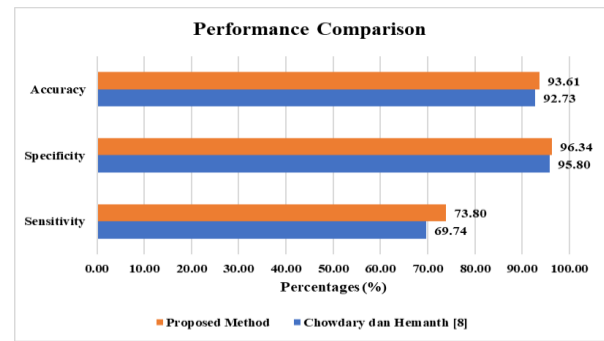

Fig. 6. Comparison of performance results with previous study.

Overall, the performance evaluation results of the proposed DNN model were able to produce the average values of accuracy, sensitivity and specificity of 93.61%, 73.80% and 96.34%, respectively, it can be seen in Fig. 6. These results were able to outperform the results of previous studies put forward by Chowdary and Hemanth [8], where this study also used RAVDESS dataset with MFCC feature extraction and CNN classifier. Comparison of performance results can be seen in Table V.

Based on Table V, the table compares the accuracy value of the proposed method with several previous studies. The comparison of the accuracy values used is the result using the RAVDESS dataset only. From Fig. 7, it can be seen that the proposed method is able to outperform the performance of previous studies. The use of multi-features in the proposed method can improve the performance of the model's accuracy in determining the type of emotion based on the RAVDESS dataset. In addition, the use of the PCA method also provides an increase in pattern correlation between features so that the classifier model can show performance improvements, especially accuracy, specificity, and sensitivity values.

Fig. 7. Accuracy comparison between proposed method with previous studies.

## V. CONCLUSION

Speech Emotion Recognition (SER) based on multi-feature extraction and Deep Neural Network (DNN) has been carried out. A total of 2452 audio data in .wav format taken from the RAVDESS database were used in this study. The data is extracted to produce several features, including Mel Frequency Cepstral Coefficients (MFCC), Chroma, Mel-Spectrogram, Contrast, and Tonnetz. From the extraction process, 193 main features were obtained. This study examines the impact of applying Principal Component Analysis (PCA) and Min-Max Normalization to the performance of the classifier model used. The DNN model is used in this study to determine emotions such as calm, happy, sad, angry, neutral, fearful, surprised, and disgusted. The test results for the DNN model with 200 epochs were able to obtain the accuracy of 93.61%, sensitivity of 73.80%, and specificity of 96.34%. The use of multiple features in the proposed method can improve the model's accuracy in determining the type of emotion based on the RAVDESS dataset. In addition, using the PCA method also provides an increase in pattern correlation among features so that the classifier model can show performance improvements, especially accuracy, specificity, and sensitivity. Moreover, the scheme that uses the PCA technique in which experimental iterations are carried out by reducing the number of components by 10% shows a change in the value of the model's performance, especially when the model uses features less than 50% of all components. The lower the number of PCA components used, the lower the performance of the model. The implementation of multiple features in this study can open opportunities for using other features related to certain types of emotions. Furthermore, the use of other dataset and classifiers can also provide a new approach in the development of this research in the future.

# Hierarchical Convolutional Neural Networks using CCP-3 Block Architecture for Apparel Image Classification

Natthamon Chamnong<sup>1</sup>, Jeeraporn Werapun<sup>2</sup>, Anantaporn Hanskunatai<sup>3</sup>

Data Science and Computational Intelligence Lab-Department of Computer Science-School of Science, King Mongkut's Institute of Technology Ladkrabang, Bangkok, 10520, Thailand<sup>1,2,3</sup>

**Abstract**—In fashion applications, deep learning has been applied automatically to recognize and classify the apparel images under the massive visual data, emerged on social networks. To classify the apparel correctly and quickly is challenging due to a variety of apparel features and complexity of the classification. Recently, the hierarchical convolutional neural networks (H-CNN) with the VGGNet architecture was proposed to classify the fashion-MNIST datasets. However, the VGGNet (many layers) required many filters (in the convolution layer) and many neurons (in the fully connected layer), leading to computational complexity and long training-time. Therefore, this paper proposes to classify the apparel images by the H-CNN in cooperated with the new shallow-layer CCP-3-Block architecture, where each building block consists of two convolutional layers (CC) and one pooling layer (P). In the CCP-3-Block, the number of layers can be reduced (in the network), the number of filters (in the convolution layer), and the number of neurons (in the fully connected layer), while adding a new connection between the convolution layer and the pooling layer plus a batch-normalization technique before passing the activation so that networks can learn independently and train quickly. Moreover, dropout techniques were utilized in the feature mapping and fully connected to reduce overfitting, and the optimizer adaptive moment estimation was utilized to solve the decaying of gradients, which can improve the network-performance. The experimental results showed that the improved H-CNN model with our CCP-3-Block outperformed the recent H-CNN model with the VGGNet in terms of decreased loss, increased accuracy, and faster training.

**Keywords**—Convolutional neural networks (CNN), hierarchical CNN (H-CNN), CCP-3 block (two convolutional layers (CC) and one pooling layer (P) per block), apparel image classification, fashion applications

## I. INTRODUCTION

In the Big-data era, social media platforms generate a tremendous volume of image data. There have been initiatives to utilize the valuable image data in a variety of industries, including the business and medical sectors. Due to a vast amount of accessible image data for training and the state-of-the-art technology that provides superior processing capability via the GPU, the unstructured visual data can now be implemented in statistical and data mining applications. Under the GPU technology, it is really simple and fast to analyze the image data. In a previous study, the image data were analyzed using traditional machine learning and image processing

techniques [1]. However, typical machine learning and image processing approaches are still limited in their processing capabilities when working with large image data. To overcome the processing restrictions associated with big picture data analysis, deep learning techniques such as Deep Neural Networks (DNN) are applied in the form of Convolutional Neural Networks (CNN) [2]. Currently, a deep learning model, when applied to the image data, provides a CNN architecture that performs well in classifying the image data.

Because apparel products in fashion applications are diverse and difficult to describe, the automatic CNN is frequently used to classify the apparel image data. A fashion-classification system uses a hierarchical structure that can be divided from the coarse to fine hierarchies. Each item in the fine hierarchy can be defined as a higher-level item, such as a t-shirt pullover and a shirt. These three different types of shirts are classified separately but can be combined in the same coarse layered Tops category because of their similarity. However, the classification of features for each hierarchy of items lacks the specific classification criteria and instead is classified based on similar features [3, 4]. As a result, the better categorizing the apparel products by using the CNN architecture is challenging. Applying the efficient CNN method of image classification, which has the advantage of assisting in filtering, categorizing, and product inspection, helps the apparel industry reduce the cost and time, while improving business efficiency [3, 5]. While CNN approaches are popular to the categorization of apparel image data, their tradeoff results (in terms of accuracy and speed) have been questioned. Therefore, many attempts have been made to develop more efficient strategies for optimizing the CNN models for the apparel classification. To improve the classification accuracy [6], a hierarchical classification strategy was used to classify the apparel image.

Recently, the fashion images were classified by using a hierarchical classification system [7]. In a hierarchical structure of fashion types, the Hierarchical Convolutional Neural Networks (H-CNN) was proposed and focused on the VGGNet architecture. The H-CNN was applied to the "Fashion-MNIST" dataset, an improved public image dataset for direct analysis. It is a 28 x 28 grayscale image of 10 classes comprised of 60,000 training photos and 10,000 test images, separated into 3 levels of coarseness: coarse 1, coarse 2, and fine. However, the existing H-CNN and the VGGNet were computed sequentially in deep architectures, where the VGGNet (many layers)

required many filters (in the convolution layer) and many neurons (in the fully connected layer), leading to computational complexity and long training-time. On the other hand, the H-CNN has not yet been implemented to improve the performance in shallow architectures.

Therefore, this study proposes to use the H-CNN in conjunction with our new CCP-3 block architecture, a minimalistic size founded on the concept of a shallow architecture (instead of a deep architecture) to achieve the better performance for not only the accuracy but also the computing time. Based on the popular models from the LeNet and AlexNet designs, the new CCP-3 block was introduced by reducing the number of layers in the network, the number of filters in the convolution layer, and the number of neurons in the fully connected layer, along with a new connection between the convolution layer and the pooling layer. In addition, a batch normalization technique was employed before passing the activation function so that networks can learn independently and train quickly. Moreover, dropout techniques were utilized in the feature map and fully connected to reduce overfitting, and the optimizer adaptive moment estimation was utilized to solve the decaying of gradients. In this study, the hypothesis is that “the integration of selected appropriate architectures in the H-CNN can improve the network performance”. In the performance evaluation, The CCP-3 Block architecture has been implemented in the H-CNN model to observe the improvement of the classification accuracy for the apparel image data and observe the speedup of the training time (on the GPU machine) in an experiment. Performance results showed that the CCP-3 Block architecture in the H-CNN model decreases training time significantly and improves the classification accuracy for apparel picture data over the recent VGGNet architecture in the existing H-CNN.

In summary, the main contributions of this study are as follows:

- This study proposes a novel CCP-3 Block architecture to optimize the H-CNN model for the efficient classification of the apparel images.
- This study compares the performance of the H-CNN models based on the existing VGGNet architecture and new CCP- 3Block architecture.

The remainder sections of this paper are organized as follows. Section II summarizes the CNN architectures and the related works. Section III presents the proposed CCP-3 Block architecture. Section IV illustrates the experiment on the fashion-MINIST dataset. Section V presents the experimental results and Section VI discusses the conclusion of this study and the future study.

## II. RELATED WORKS

In this section, an overview of the convolutional neural networks (CNN), the modern CNN architectures, and the optimization techniques of CNN are reviewed and a related work, called the hierarchical CNN (H-CNN) using VGG16 and VGG19 architectures, was presented to classify the apparel images.

### A. Convolutional Neural Network (CNN)

A convolutional neural network (CNN) is a neural network model of the human-vision emulation that perceives a space as sub-sectors and integrates the sub-sectors together to identify “what is visible”. Human perceptions of sub-areas are shaped by sub-area features, such as lines and color contrasts. Humans recognize that “the focused area is defined by a straight line or a contrasting color” because they combine both of the interested area and the surrounding area concurrently [8, 9]. The construction of CNN is divided into two main components [10-12]: 1. the first one is the feature extraction layer (for extracting features) and 2. the subsequent section is the classification layer (to educate and classify), which will ensure that the connection layer is fully connected. In the feature extraction layer, there are three sub-layers: Convolution Layer, ReLU (Rectified Linear Units) Layer, and Pooling Layer. In the classification layer, there is only one fully connected layer, which resembles a node in the neural network. Each of those layers has the particular and different functions.

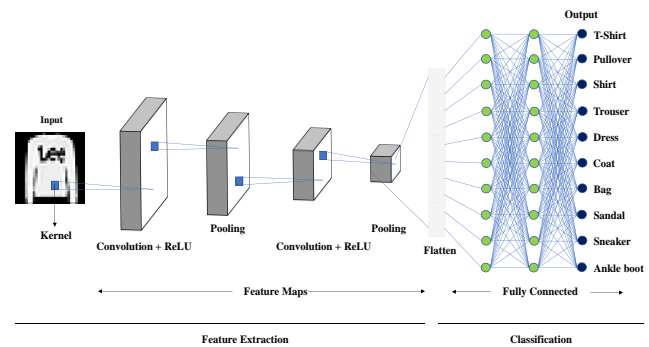

Fig. 1. Structure of CNN.

Fig. 1 describes the standard structure of the CNN, which consists of the following layers:

1) *Input layer*: Read the input data of the image and pass it to the neural network.

2) *Convolutional layer*: Create a sliding window (filter or kernel) that scans the input image to make a feature map. Initially, it scans the image to extract image elements such as borders, colors, and shapes, where the working principle starts with the convolution of the existing input image with the kernel and shifting it to the position of the next kernel. By scrolling the kernel position, the scroll distance can be adjusted. Repeat the same process, until all points of the input image are concerned. The convolution using the formula given below.

$$S_{ij} = (I * k)_{ij} \quad (1)$$

$$(I * k)_{ij} = \sum_{a=0}^{m-1} \sum_{b=0}^{n-1} I_{i+a,j+b} k_{a,b} \quad (2)$$

$S$  refers to the result of convolution at any position.  $I$  refers to image input.  $k$  refers to kernel.  $i, j$  refers to any position.  $m, n$  refers to the number of rows and columns.

3) *Rectified linear unit (ReLU)*: Perform a nonlinear activation function. The function given below

$$f(x) = \max(0, x) \quad (3)$$

4) *Pooling layer*: After the Convolutional layer(s) in the structure of a CNN, a Pooling layer is inserted. It calculates the maximum or average of the input and reduces the output of the Convolutional layers by sliding the filter with a specific shape and stride size.

5) *Fully connected layer*: Configure the output and display in the form of a multiclass logistic classifier.

6) *Output Layer*: Display the results of the classification. However, CNNs can have different layer elements in different architectures because each CNN consists of a layer convolutional for creating feature maps and pooling for the dimensionality of feature maps. By stacking these layers [7], we can formulate various CNN architectures.

### B. Architectures of Convolutional Neural Networks

1) *LeNet architecture*: The study to optimize the CNN model with a very well-structured architecture is another possibility to increase the performance of the CNN model. LeCun et al., [13] developed LeNet-5 in 1998, a network based on the CNN concept. In the convolutional layer, there are seven classification levels for numbers. Numerous banks employ it to identify the handwritten digits on digital checks using a 32x32 pixel image. Increasing the processing capability of higher resolution images requires a larger neural network layer and many layers. The LeNet-5 architecture is composed of two convolutional layers, two pooling layers, and three fully connected layers.

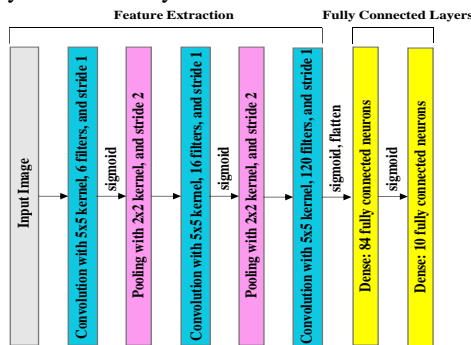

Fig. 2. Architecture of LeNet-5.

Fig. 2 describes the structure of LeNet-5 architecture. There are three convolution layers within the architecture, with two pooling and two fully connected. In each of the three convolution layers, the kernel size is 5x5 and the number of strides is 1. The distinction lies in the number of filters, with the first layer, second, and third having 6, 16, and 120 filters, accordingly. In the pooling layer, the kernel size is 2x2 and the number of strides is 2, which is identical to both layers. In a fully connected layer, the number of neurons in the first is 84, whereas the number of neurons in the second is dependent on the number of outputs. Sigmoid will be used as the activation function.

2) *AlexNet architecture*: AlexNet is a neural network, developed in 2012 by Krizhevsky et al., [14] which was intended to classify 1.2 million high-resolution images with

dimensions of 224x224x3, with images classified into 22,000 different classes. AlexNet achieves a top-5 test error rate of 16.4% in the ImageNet LSVRC-2012 contest. The AlexNet architecture is composed of 5 convolutional layers, 3 pooling layers, and 3 fully connected layers. In addition, it uses Rectified Linear Unit (ReLU) for the nonlinearity function, which is faster than Hyperbolic Tangent (tanh) function.

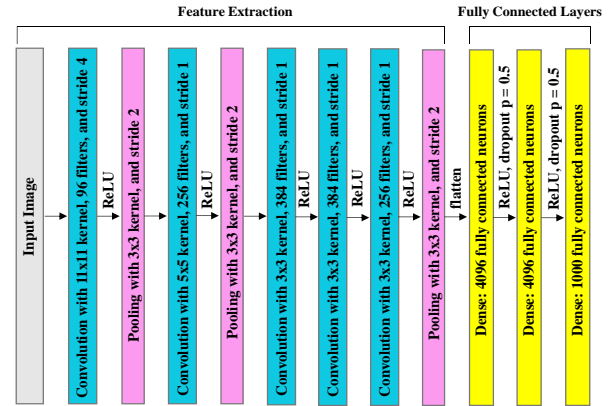

Fig. 3. Architecture of AlexNet.

Fig. 3 describes the structure of AlexNet architecture. There are five convolution layers in the architecture, with three pooling and three fully connected. The kernel sizes for the first and second convolution layers are 11x11 and 5x5, while the kernel sizes for the third, fourth, and fifth layers are all 3x3. In five convolution layers, there are 96, 256, 384, 384, and 256 filters, respectively, with the first layer the number of strides is 1, and in the remaining four layers, the strides are 4. In the pooling layer, the kernel size is 3x3 and the number of strides is 3, which is identical to all layers. In a fully connected layer, the number of neurons in the first and second is 4096, and the third is dependent on the number of outputs. However, in this architecture, the dropout rate is 0.5 and the activation function is used as ReLU.

3) *VGGNet architecture*: VGGNet was invented by the Visual Geometry Group as an architecture standard of deep convolutional neural network (deep CNN) with multiple layers. The most popular depth of the VGGNet architecture is VGG16 and VGG19 because the VGG16 and VGG19 architectures are the basis of ground-breaking object recognition models. The VGGNet architecture, developed as a deep neural network to surpass baselines on many tasks and datasets beyond ImageNet, consists of 16 and 19 layers of convolutional and fully connected layers. In competitive LSVRC-2014, the VGGNet won the 1<sup>st</sup> runner-up with less than 10% error rate and deeper layers containing 16 convolutional and fully connected layers. It uses 3 × 3 sized filters, a stride of 1 and 2 × 2 sized pooling, and a stride of 2 from the beginning to the end of the network. It also uses ReLU for nonlinearity function and is trained by batch stochastic gradient descent [15]. The structures of the VGG16 and VGG19 architectures are shown in Fig. 4 and Fig. 5.

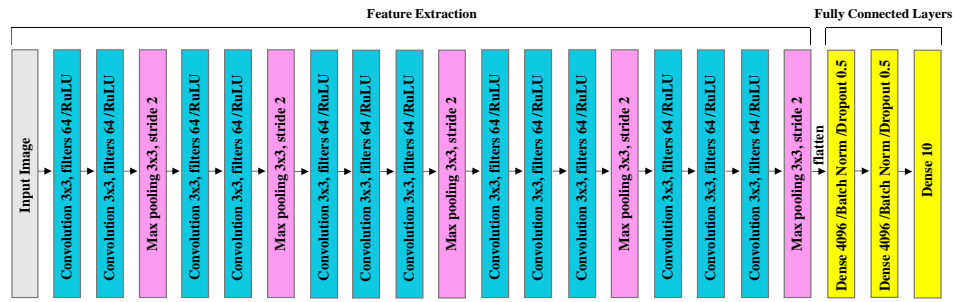

Fig. 4. Architecture of VGG16.

Fig. 5. Architecture of VGG19.

The number 16 and 19 in the name VGG (Visual Geometry Group) refer to the depth of 16 and 19 layers in the deep CNN. This means that VGG16 and VGG19 are extensive networks, where each of them has a total of around 138 million parameters. While VGGNet is popular in the modern standard, it is a huge network. However, the simplicity of the VGGNet architecture makes this network being more appealing. For example, there are a few convolution layers followed by a pooling layer that reduces the height as well as the width. When considering the number of filters, 64 filters are available and can be double to 128 filters and 256 filters. Finally in the last layer, we can use 512 filters.

In summary, the major differences of three architectures (LeNet, AlexNet, VGGNet) are focused on the architecture size and the activation function. In the initial periods of CNNs, the CNN architecture was a small structure with limited computational resources. Later, the larger CNN architectures have been constructed in response to the development of computational resources to be able to support the larger architecture designs. However, in this era the development of many CNN designs aims to decrease loss and increase accuracy, while being able to train models in fast or efficient time.

### C. Guide to Improving CNN

1) *Optimizer*: Optimizers can be explained as a mathematical function to modify the weights of the network, according to the gradients and additional information, which depend on the formulation of the optimizer. The optimizers are built upon the idea of gradient descent, the greedy approach of iteratively decreasing the loss function by following the gradient. However, different optimizers will affect the model sensitivity and learning accuracy [16-19]. As

a result, it is essential to use an appropriate optimizer for data and developed models.

2) *Regularization*: Regularization is the process of learning from the training datasets and modifying the model to be more efficient at predicting and reducing loss from the unseen data. The regularization is used to solve the issues of underfitting or overfitting. To address the underfitting problem of the neural network model, usually the number of layers and nodes in each layer can be increased but this can cause the overfitting [20-22]. Therefore, the regularization is a frequently mentioned solution, which is very simple to be implemented. The regularization technique consists of augmentation, batch normalization, and dropout, where their functions are defined as follows:

a) *Augmentation*: Augmentation is a technique to increasing the amount of data to train by generating the more data. In the case of image data, increasing a variety of images includes rotating images, zooming images, shifting images horizontally, shifting images vertically, and shear images.

b) *Batch normalization*: Batch Normalization is a technique for scaling the data to adjust their values to the specified limits before exporting from the node to the next layer input. For example, a feature engineering procedure converts the grayscale image from 0-255 to 0-1 by dividing the original color value by 255. For data normalization, several well-known methods can be utilized, such as min-max normalization or standardization.

c) *Dropout*: Dropout is an effective process of regularizing neural networks to avoid the overfitting. During training, the dropout layer cripples the neural network by removing the hidden units stochastically.

3) *Efficient shallow learning as an alternative to deep learning*: In 2022, Y. Meir et al. [23] discusses the realization of complex classification tasks using deep learning architectures with many convolutional and fully connected hidden layers. The authors demonstrate that with a fixed ratio between the depths of the first and second convolutional layers, the error rates of shallow architectures like the LeNet and VGG-16 can decay as a power law with the number of filters in the first convolutional layer. This phenomenon suggests a quantitative hierarchical time-space complexity among machine learning architectures and calls for further examination using various databases and architectures. The conservation law along the convolutional layers is found to minimize error rates. The study emphasizes the efficient shallow learning and its potential for implementation using dedicated hardware developments.

D. Hierarchical Classification

Hierarchical classification is a system of grouping things (or objects) according to a hierarchy, such as levels and orders. A hierarchical classifier classifies the input data according to the output categories, which are defined subsumptively. Classification begins at a basic level with the fine-detailed input data. The classifications of the separate bits of the image data are then integrated and elevated to a higher level iteratively until a single or defined output is obtained. This final output represents the overall result of the data classification.

In 2015, Yan et al. [24] proposed the first trial of hierarchical image classification using a deep learning approach. To resolve class confusion in the proposed model, Hierarchical Deep Convolutional Neural Networks (HD-CNN) employed an initial coarse classifier CNN to differentiate easily separable classes (or coarse classes) from fine classes. Additionally, the HD-CNN model could be implemented without increasing the training complexity. However, that model encountered some limitations, which were that it required two steps of training. The first step was to train the coarse and fine categories and the second step was to fine-tune the coarse and fine categories. Moreover, the HD-CNN model could not be used to classify many levels of hierarchy since it included one coarse category and one fine category only for an overall of two levels.

Later in 2017, the Branch Convolutional Neural Network (B-CNN) was proposed by Zhu and Bain [25] to solve the limitation of HD CNN.

Due to previous CNN research during 2015 - 2019, the hierarchical CNN study along with the particular application could improve the accuracy in the experiment. Therefore, implementing the hierarchical classification to optimize the CNN models to respect the diversity of datasets, applications, and CNN architectures is interesting.

In 2019, Seo and Shin [7] introduced the Hierarchical Convolutional Neural Networks (H-CNN) for the categorization of fashion images in the Fashion MNIST image data, where the fashion imagery obtained from Zalando is similar to the MNIST Dataset's handwritten numeric dataset, a refined fashion image.

That study employed the large-scale VGGNet neural networks as an experimental model. In performance evaluation (on the Fashion-MNIST dataset), accuracy results of the usage of H-CNN under the VGGNet architecture outperformed those of the simple VGGNet network.

In 2021, Q. Zhu et al. [26] discusses the use of drone imagery in automated inspection for surface defects in infrastructure. The proposed approach in the paper is a deep learning method that uses hierarchical convolutional neural networks with feature preservation (HCNNFP) and an intercontrast iterative thresholding algorithm for image binarization. The technique is applied to identify surface cracks on roads, bridges, or pavements, and is compared with existing methods on various datasets using evaluation criteria including the average F-measure. The proposed technique outperforms existing methods on various tested datasets, especially for the GAPS dataset, demonstrating the merits of the proposed HCNNFP architecture for surface defect inspection.

This study is interested in developing the H-CNN (Hierarchical CNN) under the more efficient architectures for the fashion applications (in Section III). Therefore, the previous study [7] is the main related work, see detail in Section II E.

E. Original Hierarchical Convolutional Neural Network (H-CNN) Model

With regards to the original H-CNN model under VGG16 and VGG19 architectures [7], both VGG16 and VGG19 are composed of five building blocks as shown in Fig. 6 and Fig. 7.

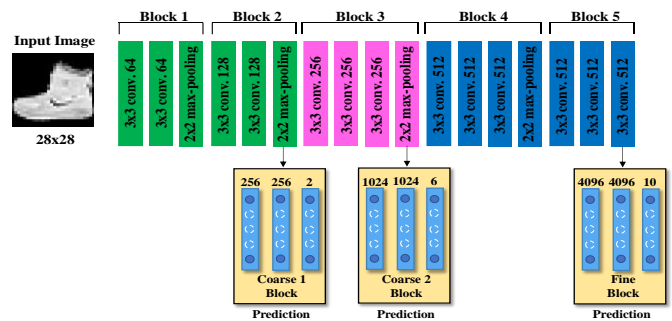

Fig. 6. Architecture of VGG16 H-CNN model.

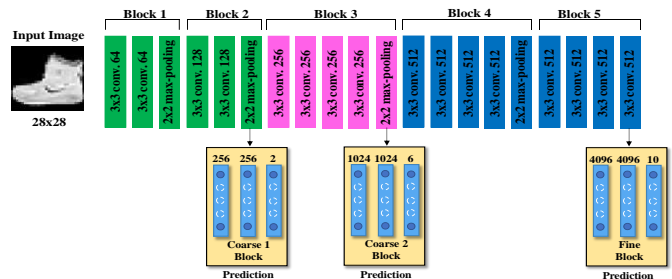

Fig. 7. Architecture of VGG19 H-CNN model.

In the VGG16 H-CNN model, the first and second building blocks consist of two convolutional layers and 1 pooling layer, the third and fourth blocks consist of 3 convolutional layers and 1 pooling layer, and the fifth building block has 3 convolutional layers.

In the VGG19 H-CNN model, the first and second building blocks have 2 convolutional layers and 1 pooling layer, the third and fourth blocks have 4 convolutional layers and 1 pooling layer, and the fifth building block consists of 4 convolutional layers.

The filter size and number of filters in the convolution layer are the same for both VGGNet architectures, with the filter size being 3x3 throughout the model. For the number of filters, they can be divided as follows: In the first block, there are 64 filters, the second block 128 filters, the third block 256 filters, and the fourth and fifth blocks 512 filters.

Moreover, these H-CNN models also use ReLU for activation function, batch normalization for initialization, and dropout for regularization. In the final block denoted as the fine prediction block, the softmax function is used to classify 10 fine classes.

However, this model has three additional blocks below followed by a prediction block. In each block, there are labels for 3 levels of classification, which makes it different from the basic model. The first block is for course-level, the second block is for course-level, and the last block is for fine-level. All three additional blocks are composed of fully connected neural networks. As the input image goes through the H-CNN model, three prediction values of coarse 1 level, coarse 2 level, and fine level will be computed in order. For example, when an input image of a sweater is inserted, the first coarse level block will indicate ‘clothes’, the second coarse level block will indicate ‘tops’, and the final block will indicate ‘pullover’ as output predictions.

### III. PROPOSED METHOD

Applying the convolutional neural network (CNN), especially the efficient deep learning, to fashion applications (to achieve not only the high accuracy but also the fast training) is challenging under the massive visual data emerged on the current social networks. Recently (2019), the hierarchical CNN (H-CNN) was proposed to classify the fashion-MNIST datasets with a capability of high accuracy. However, in that H-CNN the applied VGGNet (the deep architecture) is composed of many layers, many filters (in the convolution layer), and many neurons (in the fully connected layer), leading to computational complexity and long training-time.

According to the hypothesis (in the fashion classification) believe that the shallow architecture plus a few proper functions can yield good results as the deep architecture, while can take faster training-time to solve computational complexity problems. In benefit summary of existing architectures, the (deep) VGGNet architecture requires many layers, many filters, and many neurons with long training-time for high accuracy, while the (shallow) AlexNet architecture require less training time (with shallow layers) but less accuracy. Therefore, we focus on studying the novelty and strength of the architecture for the H-CNN model to decrease loss, increase accuracy, and fast training-time.

This study proposes to classify the apparel images with the H-CNN model using the new CCP-3 Block architecture to retain the accuracy as the VGGNet architecture within the less

training-time as the AlexNet architecture, where each building block consists of double convolutional layers (CC) and one pooling layer (P). As mentioned earlier, our proposed CCP-3 Block architecture was inspired by the fast LeNet and AlexNet microarchitectures (with shallow layers).

In Section III A, the new CCP-3 Block architecture is proposed first for classifying the apparel/fashion image. In Section III B, the H-CNN model using the CCP-3 Block architecture is presented for the completed classification. In Section 4, the experiment is conducted on the fashion-MNIST datasets to compare the performance of CCP-3 Block architecture. Finally, the experimental results are presented in Section V.

#### A. CCP-3 Block Architecture

The CCP-3 Block architecture is a shallow-layer architecture, see details in Fig. 8, which can reduce the number of layers (in the network), the number of filters (in the convolution layer), and the number of neurons (in the fully connected layer) of the deep-layer architecture, while adding a new connection between the convolution layer and the pooling layer.

The CCP-3 Block architecture has only three blocks shown in Fig. 9. Each building block consists of two convolutional layers and one pooling layer. The 3x3 sized filters with a stride of 1 are used in all convolutional layers. In the first building block, 64 filters are concatenated and in the second block, first convolution has 128 filters, second convolution has 256 filters and 512 filters in the third block. For the pooling layers, the 2x2 size max-pooling is done with a stride of 2. In a fully connected layer, there are 3 layers, where in the first and second layers we define the number of neurons as 1024 neurons, and in the last layer, we define 10 neurons into 10 classes using the softmax function.

Moreover, ReLU was used for the activation function, batch normalization for initialization, and dropout for regularization. In the structure of CCP-3 Block architecture, batch normalization will be implemented in order to ensure that for any parameter value after the convolution layer, the network always produces activations with the desired distribution. So, the batch normalization layer is inserted right after the convolution layer, but before feeding into ReLU activation [27]. To reduce overfitting, dropout was added into both building blocks and the fully connected layer. In the building block, dropout was defined between the convolution layer and after the pooling layer. The fully connected, dropout was defined after batch normalization layer. Throughout the architecture, we set the dropout value to 0.3.

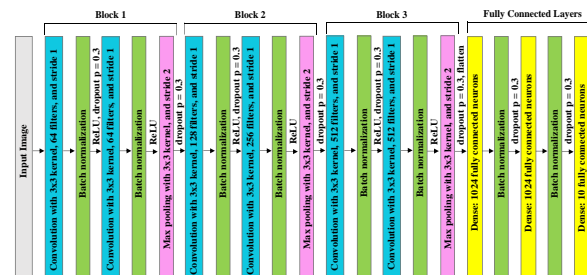

Fig. 8. Details of CCP-3 block architecture.

### B. H-CNN using CCP-3 Block Architecture

The H-CNN model was implemented in conjunction with CCP-3 Block architecture by adding additional blocks below each main block, followed by a prediction block, shown in Fig. 9. The additional blocks have the same functions and properties as those blocks in the original H-CNN. Each additional block contains labels indicating one of three classification levels. The first block is intended for course-level instruction, the second block is intended for course-level instruction, and the final block is intended for fine-level instruction. Each of these three blocks is composed entirely of fully connected neural networks. As the input image passes through the H-CNN model, three prediction values will be computed in order: coarse 1 level, coarse 2 levels, and fine level.

Fig. 9. Architecture of H-CNN CCP-3 block model.

## IV. EXPERIMENTS

To evaluate the performance of CCP-3 block architecture, the H-CNN model was implemented in incorporated with CCP-3 Block architecture. The experimental results were compared to those of the original H-CNN model using VGG16 and VGG19 architectures on the same environment. See the improved results in Section V in terms of increased accuracy and decreased computing-time.

### A. Environment Setup

This experiment implemented and operated the above 3-model programs on the google colaboratory. This programming environment investigated a GPU runtime (speed up execution), the GPU machine used in this operation is the Tesla P100-PCIe.

### B. Dataset

This paper uses Fashion MNIST image dataset (see Table I). This fashion image dataset is collected from Zalando, which is similar to the MNIST dataset handwritten digit classification. In this standard dataset, each grayscale image is a square size of  $28 \times 28$  pixels and all images are divided into 10 classes: t-shirt, trouser, pullover, dress, coat, sandal, shirt, sneaker, bag, and ankle boot. Each class contains an equal number of samples. The 60,000 samples are used for training and the 10,000 samples are used for testing. In the hierarchical

structure, these 10 classes can be restructured into two coarse classes and one fine class as shown in Fig. 10.

Each first-level coarse class consists of the second-level coarse classes and each second-level class consists of the fine-level classes. The first-level coarse class consists of 'clothes' and 'goods'. In the second-level coarse class, the 'clothes' contain 'tops', 'bottoms', 'dresses', and 'outers' as well as the 'goods' contain 'accessories' and 'shoes'. Below the second-level coarse classes, there are fine-level classes consisting of 't-shirt', 'pullover', and 'shirt' in 'tops', 'trouser' in 'bottoms', 'dress' in 'dresses', 'coat' in 'outers', 'bag' in 'accessories'; 'sandals', 'sneaker', and 'ankle boots' in 'shoes'. For hierarchical matching in the H-CNN models, the first-level coarse classes are represented by green, second-level classes are represented by pink, and fine-level classes are represented by blue [7]. Each color in Fig. 10 matches the original H-CNN models in Fig. 6 and Fig. 7 and the H-CNN using CCP-3 Block architecture in Fig. 9.

### C. Parameter Setting

1) *Parameter setting of the original H-CNN using VGG16 and VGG19* [7, 16, 28, 29]: To train two original H-CNN models, the parameters were set as follows: A number of epochs were set to 60 times and the size of the batch was set to

128. There were variations in learning rate as 0.001 used in the initial stages, 0.0002 after the 42<sup>th</sup> epoch, and 0.00005 after the 52<sup>th</sup> epoch. Stochastic gradient descent was applied by using 0.9 of momentum. To reflect differences in the importance of each level of the class the loss weight values were added when training models. The changes in loss weights were set to [0.98, 0.01, 0.01] in the first epoch, [0.10, 0.80, 0.10] in the 15<sup>th</sup> epoch, [0.1, 0.2, 0.7] in the 25<sup>th</sup> epoch, [0, 0, 1] in the 35<sup>th</sup> epoch.

2) *Parameter setting of the H-CNN using CCP-3-Block:* In this study, we set similar parameters as the original H-CNN models, such as a number of epochs, learning rates, the changes in loss weights. However, the stochastic gradient descent is not used in the model because the architecture of the CCP-3 block is small. In addition, an appropriate optimizer was used to reduce overall losses and improve accuracy [30, 31]. Adaptive moment estimation is applied by using 0.9 of beta1, 0.999 of beta2, and 1e-07 of epsilon.

## V. RESULTS

In order to evaluate the performance of the H-CNN model using CCP-3 Block architecture, the performance was compared of the H-CNN CCP-3 Block model to the original H-CNN models using VGG16 and VGG19 architectures. Table II shows the results (the final loss, accuracy of the test, and the training time) of each model. The CCP-3 Block architecture has a loss of 0.2714, while the VGG16 and VGG19 architectures have the loss of 0.3781 and 0.3863. About the accuracy of 0.9490, while the others have the accuracy of 0.9352 and 0.9341. The CCP-3 Block model has the fastest training time of 18.21 minutes, while the others have 20.33 and 27.28 minutes (H-CNN CCP-3 Block is 10.32 percent faster than H-CNN VGG16 and 32.87 percent faster than H-CNN VGG19.). In comparison, the CCP-3 Block model has lower loss, greater accuracy, and less training time than the other two models.

Table III shows the test accuracy results (0.8970-0.9410) of previous researches (i.e., data mining methods and other CNN models), compared to the test accuracy (0.9490) of the CCP-3 Block architecture on the Fashion MNIST dataset. The existing CNN2 and CNN2 + BatchNorm + Skip models were presented by Bhatnagar, Ghosal, and Kolekar (2017), where the CNN model consisting of two convolutional and max-pooling layers (or CNN2), trained by batch normalization (or BatchNorm) with residual skip connections (or skip) to compare the results with those of Support Vector Classifier (SVC) and Evolutionary Deep Learning (EDEN). Later, the accuracy results were improved by the VGG16 and VGG19 based models. Finally, the accuracy result was improved by the CCP-3 Block based model and in this study the CCP-3 Block architecture could generate the best test accuracy when combined with the hierarchical CNN (H-CNN) model.

This study focused to improve the H-CNN model by using the CCP-3 Block architecture over the VGGNet architecture (VGG16 and VGG19). Overall, the loss and accuracy were compared (in training and testing) of each H-CNN model in Table IV. For testing set, the H-CNN using the CCP-3 Block

architecture (H-CNN CCP-3 Block) has lower loss (0.2714) than those (0.3781 and 0.3863) of VGG16 and VGG19 and higher accuracy (0.9490) than those (0.9352 and 0.9341) of VGG16 and VGG19. However, when looking at the training set, the H-CNN CCP-3 Block model had a loss of 0.0218 and an accuracy of 0.9920, while the original H-CNN (VGG16, VGG19) models have the better training results because in the H-CNN CCP-3 Block model we added the dropout to both of the building block and in the fully connected layer to solve the overfitting problem, leading to a reliable final-loss and a realistic accuracy (0.9920 < 1.0 (overfitting)) in the training but the better performance in the testing (on the unseen data) with the less final-loss and the higher accuracy.

TABLE II. THE COMPARISON OF FINAL LOSS, ACCURACY, AND TRAINING TIME OF THE EXISTING H-CNN MODELS (H-CNN VGG16, H-CNN VGG19) AND OUR H-CNN CCP-3 BLOCK MODEL

Model	Test		Training Time (minutes)
	Loss	Accuracy	
H-CNN VGG16	0.3781	0.9352	20.33
H-CNN VGG19	0.3863	0.9341	27.28
<b>H-CNN CCP-3-Block</b>	<b>0.2714</b>	<b>0.9490</b>	<b>18.21</b>

VGG19 based model	0.9290
<b>CCP-3 Block based model</b>	<b>0.9410</b>
<b>H-CNN CCP-3 Block model</b>	<b>0.9490</b>

TABLE IV. THE TRAIN AND TEST COMPARISON (IN FINAL LOSS AND ACCURACY) OF THE EXISTING H-CNN MODELS (VGG16 H-CNN, VGG19 H-CNN) AND OUR CCP-3 BLOCK H-CNN MODEL

	Train		Test	
	Loss	Accuracy	Loss	Accuracy
H-CNN VGG16	0.0002	1.0000	0.3781	0.9352
H-CNN VGG19	0.0004	1.0000	0.3863	0.9341
<b>H-CNN CCP-3-Block</b>	<b>0.0218</b>	<b>0.9920</b>	<b>0.2714</b>	<b>0.9490</b>

Moreover, observe that the H-CNN CCP-3 Block model could converge faster than the H-CNN VGG16 and VGG19 models, as shown in Fig. 11 (H-CNN VGG16), Fig. 13 (H-CNN VGG19), and Fig. 15 (H-CNN CCP-3 Block). The more epochs the less in loss until 60 epochs the losses were stable. Meanwhile, the accuracy value of our H-CNN CCP-3 Block model was greater and converged more quickly than the existing models, as shown in Fig. 12 (H-CNN VGG16), Fig. 14 (H-CNN VGG19), and Fig. 16 (H-CNN CCP-3 Block). In

particular, Table V shows the improved performance (a numbers of specific loss and accuracy values) in each epoch (from epoch 1 to epoch 60) of each model.

In summary, the H-CNN CCP-3 Block model can achieve the better performance than the H-CNN VGG16 and VGG19

models (Table II, Table IV, Table V) and other state-of-the-art models (Table III) to classify images in the Fashion-MNIST dataset based on deep learning architectures. The CCP-3

Block design starts with a shallow-layered architecture (combine two convolution layers followed by a pooling layer) and redesign with only three blocks followed by the fully connected layers and add the batch normalization before the activation function so that networks can learn independently and train quickly as well as add the dropout layer in feature extraction and fully connected to reduce the overfitting. Moreover, an optimizer (adaptive moment estimation) was used to solve the decaying of gradients, which can improve the network performance. As a result, the H-CNN CCP-3 Block model has a faster training time and the better performance in testing (decreased loss and increased accuracy). For the image classification in the Fashion-MNIST dataset, the problem of multi-class classification error can be solved by the H-CNN CCP-3 Block model.

## VI. DISCUSSION

As presented in the test results section, the H-CNN model uses a shallow layered CCP-3 Block architecture, which provides the best performance in both training speed and classification accuracy. However, when considering the CCP-3 Block architecture used in the classification of apparel images, our design is simplified combine two convolution layers followed by a pooling layer, designed with only three blocks followed by fully connected layers, and adding batch normalization before the activation function. Moreover, adaptive moment estimation is also used to optimize the model (see detail in Section III A). We call this the CCP-3 block base model. Table V shows the test accuracy of the CCP-3 Block base model is 0.9410, which is more accurate than the H-CNN used VGG16 and VGG19 architectures but we perceive something in the table confusion matrix of the CCP-3 Block base model.

Table VI shows the confusion matrix of the CCP-3 block base model. In the case of the shirt category, misclassification samples of 88 T-shirt images, 43 pullover images, and 49 coat images reveal that these three categories locate closer among the 10 categories. The same is the case for the ankle boots category, with misclassification samples of 6 sandal images,

and 34 sneaker images; when these categories are similar. It is reasonable to categorize similar images into a hierarchy.

Observing Table VI, it is possible that the accuracy of the CCP-3 block base model could be increased further if the training images were hierarchically categorized. Therefore, we have applied the Seo and Shin [7] fashion image classification inference to categorize images into a hierarchy as shown in Fig. 10. It is used in conjunction with the CCP-3 Block architecture, which we have designed to support hierarchical classification (see detail in Section III B). The results showed that with the use of hierarchical image classification in combination with the CCP-3 block architecture, accuracy increased to 94.90%. (shown in Table III). When considered in the confusion matrix of the H-CNN CCP-3 Block model (shown in Table VII), in the case of the shirt category, the misclassification was reduced. T-shirt, pullover, and coat were previously misclassified from 88, 43, and 49 images reduced to 66, 33, and 40 images respectively. The same is the case for the ankle boots category, the misclassification is reduced as well. Sandal and sneaker were previously misclassified from 6 and

34 images and reduced to 4 and 26 images respectively. Therefore, categorizing similar images into a hierarchy for classification can increase their accuracy.

The CCP-3 Block base model, a simplified version of the H-CNN model, achieves high accuracy in apparel image classification. However, the model experiences misclassifications within visually similar categories such as shirts and ankle boots. To address this, we propose a hierarchical classification approach using the Seo and Shin fashion image classification inference. By combining this approach with the CCP-3 Block architecture, the model's accuracy improves significantly to 94.90%. The hierarchical classification effectively reduces misclassifications within similar categories, demonstrating the value of categorizing visually similar images into a hierarchy for improved accuracy. Additionally, pre-defining hierarchical labels of the dataset can also be done by the data-driven method before training the model we want. By considering the classification of the data based on the consideration of the result of the confusion metric.

## VII. CONCLUSION

CNN has been applied in a wide variety of fields as a powerful result of the development of deep learning techniques. In fashion application, CNN can support human tasks in image detection, apparel classification, apparel retrieval, and automatic apparel tagging, while the complexity of hierarchy and categories is a challenge in fashion classification. In the past, a hierarchical image classification process was considered in previous studies to improve the accuracy of the classification of apparel. Recently, a hierarchy was used in the Fashion-MNIST data which is  $28 \times 28$  sized grayscale images of 10 classes consisting of 60,000 training images and 10,000 test images, where the Hierarchical Convolutional Neural Network (H-CNN) was proposed in combination with VGGNet architectures (VGG16 and VGG19). Each of these deep VGGNet architectures consists of five building blocks of multiple convolutional, max-pooling, and fully connected layers. However, many filters (in the convolution layer) and many neurons (in the fully connected layer) of each VGGNet (for the Fashion-MNIST data) a required the long training-time.

This study focuses on designing a new efficient architecture for H-CNN to improve not only the accuracy of apparel classification but also the training time. Therefore, the CCP-3-Block architecture was proposed, a shallow-level architecture. A new design combines two convolution layers followed by a pooling layer, designed with only three blocks followed by fully connected layers, and adding batch normalization before the activation function so that networks can learn independently and train quickly, as well as adding the dropout layer in feature extraction and fully connected to reduce overfitting. Moreover, an optimizer (adaptive moment estimation) is added to solve the decaying of gradients, which can improve the overall network performance. In the experiment, the performance was compared of the H-CNN CCP-3-Block model and the original H-CNN VGGNet model (using VGG16 and VGG19 architectures). The results showed that the H-CNN CCP-3Block model performed the better performance with lower loss, higher accuracy, and faster training time than the original H-CNN (VGG16, VGG19) models. This result confirmed the hypothesis that the shallow layered CCP-3 Block architecture performs better performance than the deep VGGNet architectures in the hierarchical classification (H-CNN) of apparel images on the Fashion-MNIST dataset. Thus, for fashion business/applications, the H-CNN CCP-3-Block model can be applied on a variety of real online apparel images with the hierarchical classification.

## ACKNOWLEDGMENT

The authors wish to gratefully thank the School of Science, King Mongkut's Institute of Technology Ladkrabang (KMUTL), Bangkok, Thailand for the scholarship to Mr. Natthamon Chamnong, a master student in Computer Science, during 2020 – present.

**Abstract**—Deep Learning (DL) based point cloud classification techniques now in use suffer from issues such as disregarding local feature extraction, missing connections between points, and failure to extract two-dimensional information features from point clouds. A point cloud classification network that utilizes multi-layer feature fusion and point cloud projection images is suggested to address the aforementioned problems and produce more accurate classification outcomes. Firstly, the network extracts local characteristics of point clouds through graph convolution to strengthen the connection between points. Then, the fusing attention mechanism is introduced to aggregate the useful characteristics of the point cloud while suppressing the useless characteristics, and the point cloud characteristics are fused by multi-layer characteristic fusion. Finally, a 3D point cloud network plug-in model based on point cloud projection image (3D CLIP) is proposed, which can make up for the defects of other 3D point cloud classification networks that do not extract two-dimensional information characteristics of point clouds, and solve the problem of low accuracy of similar category recognition in datasets. The ModelNet40 dataset was used for classification studies, and the results show that the point cloud classification network, without the addition of a 3D CLIP plug-in model, achieves a classification accuracy of 92.5%. The point cloud classification network with a 3D CLIP plug-in model achieved a classification accuracy of 93.6%, demonstrating that this technique can successfully raise point cloud classification accuracy.

**Keywords**—Point cloud; classification; graph convolution; attention mechanism; CLIP

## I. INTRODUCTION

As Artificial Intelligence (AI) has continued to advance, point cloud data has also evolved into a type of fundamental data [1-3]. To gather point cloud data and perform 3D reconstruction, the classification of point cloud data is crucial. As a result of the disorderly and irregular nature of data from point clouds, this poses a challenge to the task of point cloud classification.

Early Deep Learning (DL) based point cloud classification methods transform raw point cloud data into pictures or voxels before extracting point cloud characteristics using traditional classification networks. However, some of the point cloud information disappears during the point cloud transformation procedure, which lowers the network classification accuracy [4-6]. Researchers have presented point cloud classification methods using original point cloud data, which don't require

the transformation of the point cloud data, in response to the drawbacks of the point cloud classification methods. The extraction of local information characteristics from the point cloud is ignored by the present classification methods. Channel information and spatial information in the point cloud are not extracted. It is neglected how points relate to one another. The point cloud two-dimensional information is not taken into consideration. Aiming at the above problems, the primary contributions of this research paper are described below:

- A network GFANet based on fused attention mechanism and graph convolution is proposed for existing point cloud classification networks that do not extract point cloud features well. Using the ModelNet40 dataset, experimental findings demonstrate that the suggested network obtains 92.5% classification accuracy.
- A point cloud classification approach that utilizes a 2D point cloud projection image is proposed because current point cloud classification networks are not focused on the two-dimensional information of the point cloud. According to experimental findings, 3D CLIP can be plugged into a 3D point cloud classification network to increase the network classification accuracy.
- For the proposed two-point cloud classification network models, GFANet and 3D CLIP are combined to produce superior point cloud classification outcomes. On the ModelNet40 dataset, experimental findings show the point cloud classification method utilizing GFANet and 3D CLIP achieves 93.6% classification accuracy.

Based on the above, the focus of this research paper is on ways to improve the extract of the point cloud's local and global features as well as its two-dimensional information features in hopes of improving the accuracy of the point cloud classification network.

The paper is organized as follows: Section-II presents the related works for point cloud categorization. Section-III describes the proposed methodology of GFANet and 3D CLIP. Section-IV discusses the experimental results. Section-V concludes the overall research paper.

## II. RELATED WORKS

The point cloud is a collection of points that can be represented as a collection of three-dimensional points ( $x, y, z$ ). In addition to the information on each point location, point clouds also include details about its color, illumination level, category labels, normal vectors, grayscale values, and other characteristics. Applications for classifying point cloud data include automated driving [1], facial recognition [2], 3D reconstruction [3], and many more. The conventional point cloud categorization methods cannot be used directly on point clouds due to their irregularity and disorder.

Considering the disadvantages of conventional point cloud categorization techniques [7-9], deep learning techniques are now widely used in research to categorize point cloud data [10]. Early researchers transformed irregular 3D point cloud data into regular 3D grid data or images [11], [12] and then used 3D CNN for classification. Voxeling a point cloud primarily involves converting the point cloud data fed to the network into a grid, after which 3D CNN is used to extract features. The point cloud classification task is realized after obtaining global features through feature stitching. Other networks that convert point clouds into voxelated representations include FPNN [13], OctNet [14], and KD-NET [15]. The point cloud is projected onto a two-dimensional picture such as MVCNN [16], which projects 3D point cloud data from multiple perspectives to obtain two-dimensional images, uses a convolutional neural network to process and extract features, and then inputs the aggregated features into the convolutional neural network to realize point cloud classification. Other similar networks include GVCNN [17], SnapNet [18], and View-GCN [19].

The above two point cloud classification methods will lose some information during the conversion of point cloud data, resulting in a decline in classification accuracy. The point cloud classification method that utilizes original points may process the original point cloud directly, maximizing the retention of original point cloud data and significantly enhancing classification accuracy and algorithm performance compared to the other two point cloud classification methods mentioned above. Qi et al. suggested applying a model using deep learning on the PointNet [20] of the original point clouds, which performs well in both classifications [21] and segmentation tests [22] for point clouds. The network employs maximum pooling aggregate point features to ensure displacement invariance of point clouds and three-dimensional spatially transformed network STNs [23] to guarantee rotational consistency for point clouds. Although PointNet has several benefits, it simply extracts the point cloud global information properties. Based on the shortcomings of PointNet such as its inability to obtain local feature information and poor classification ability. Qi et al. then proposed an optimized network PointNet++ [24]. This network suggests a multi-level structure based on the PointNet for layer-by-layer extraction of local characteristics from a point cloud. However, PointNet++ also independently handles points in the point cloud, without paying attention to the connection between points. After that, researchers have also proposed some point cloud classification networks, such as ECC [25], DGCNN [26], LDGCNN [27],

and GAPNet [28], but the categorization accuracy of point clouds has not been significantly improved.

Although the categorization of the point cloud method based on original points solves the shortcomings brought by some characteristics of point clouds [29], there are still shortcomings such as insufficient feature extraction and lack of point cloud feature information. To efficiently extract both local as well as global characteristics of point clouds, enhance the network feature extraction capabilities, and make up for the lack of two-dimensional information in the point cloud include an extraction process, a point cloud classification network constructed using multi-layer feature fusion and projected images is presented in this paper.

## III. METHODOLOGY

There are two main components to the entire network, the network of one part is called GFANet, and the plug-in network of the other part is called 3D CLIP.

The GFANet, mainly includes the input transformation module, Graph Conv module, F-Attention module, and multi-layer feature fusion module. In the input transformation module, the input point cloud data is multiplied with a transformation matrix that the T-Net network has learned in order to ensure the consistency of the input point cloud data sequence and standardize the point cloud. In the Graph Conv module, its input is pointing to cloud features of  $N \times f$ ,  $N$ , and  $f$  represent the number and dimension of points respectively. The KNN algorithm is used to create a graph out of data from a point cloud. Then the graph of point cloud data is passed through  $n$  multilayer perceptions ( $\text{mlp} \{L_1, L_2, \dots, L_n\}$ ) to extract edge features. And finally, the  $N \times L_n$  dimension features are obtained. The spatial and channel information characteristics from the point cloud are extracted using F-Attention to improve the network's feature extraction capabilities. Obtain global and local features of point clouds using multi-layer feature fusion. Three completely connected layers were used to achieve the point cloud final classification outcome.

The existing 3D point cloud classification network mainly extracts 3D point cloud features and then performs classification tasks. The point cloud 2D information properties are not its primary concern, so some single categories with similar features cannot be classified well. The 2D information features can provide more object representations in the network classification task and improve the network classification accuracy. A point cloud categorization approach called 3D CLIP is proposed as a result of this issue and relies upon 3D point cloud projection images. The point cloud projection image features are extracted and categorized using a 2D image classification network to increase the 2D representations available for 3D point cloud classification tasks and boost network accuracy. The key components of 3D CLIP are the text encoder and the image encoder. The network mainly uses the trained text encoder and image encoder in 2D CLIP to obtain the text description features and the projected image features of the point cloud. In the text encoder, using text-transformer to obtain the point cloud's textual description features. In the image encoder, the point cloud projection image features are extracted using ResNet. Then the

correspondence between text features and image features is found from the pre-trained model. Finally, the final

classification results are obtained. The network is shown in Fig. 1.

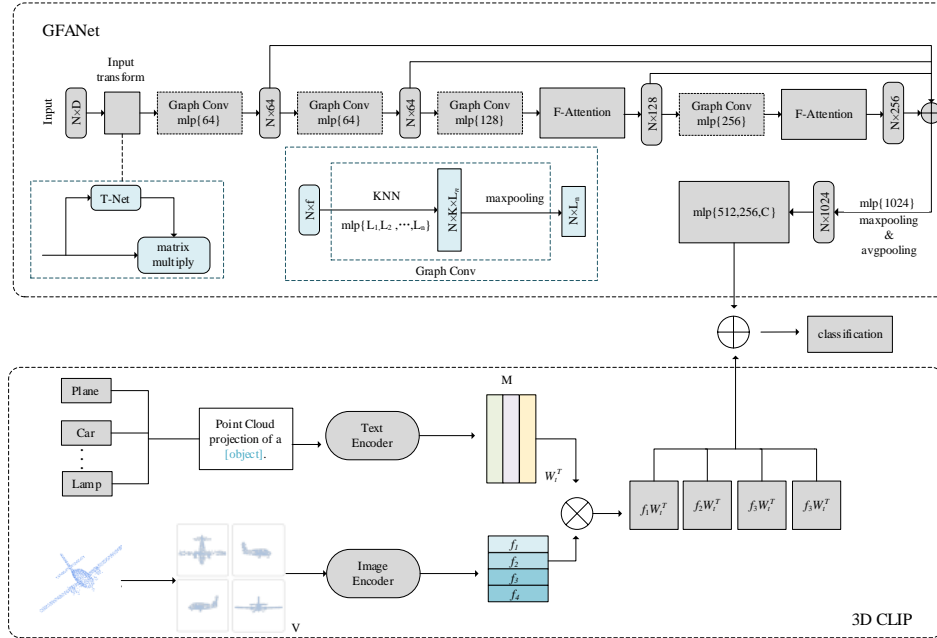

Fig. 1. GFANet and 3D CLIP structure.

### A. The GFANet

1) *Graph conv module*: There are two types of graph convolution: spatial domain convolutions of graphs [30] and spatially domain graphs convolution [26]. Additionally, the information properties of the area of the node can be better obtained using the spatial dimension of graphs convolution. Therefore, the spatial dimension of convolutions of graphs is used to build this model.

For GFANet, model inputs can be expressed as:

$$X = \{x_1, \dots, x_n\} \subseteq R^D \quad (1)$$

Where  $X$  is the point clouds collection,  $x_i$  is a point in the collection, and  $D$  is each point's distinctive dimension.

A directed graph with the formula  $G = (V, E)$  represents the point cloud local arrangement. where  $V$  represents a collection of  $N$  point locations and  $E$  represents the collection of edges connecting nodes.

The directional graph  $G$  for GFANet is built using the k-nearest-neighbor classification (KNN) technique. The central node of a point cloud and the  $K$  nearest neighbor points which include the central node can be calculated using the KNN algorithm.

In the Graph Conv module, local features of point clouds are extracted using the edge function and the aggregation process. As below:

$$h_\theta(x_i, x_j) = h_\theta(x_i) \quad (2)$$

Where  $x_i$  and  $x_j$  are the attributes of node  $i$  and its neighboring nodes  $j$ ,  $h_\theta$  is a linear product of parameter  $x$  that

can be learned, and  $\theta$  is the collection of weight and other parameters in the network.

However, point cloud global information is the sole focus of the edge function. The local information was ignored. In Formula 3, a new edge function is created that takes into account the point cloud local as well as global information.

$$h_\theta(x_i, x_j) = h_\theta(x_i, x_j - x_i) \quad (3)$$

For aggregation operation,  $x_i'$  is the collection of edge characteristics for the central node  $x_i$  at the  $k$  points about it.

$$x_i' = \sum_{j:(i,j) \in E} h_\theta(x_j - x_i) \quad (4)$$

In Fig. 2, to create a graph structure, the KNN method is utilized. And the Graph Conv module is used to learn aggregating edge characteristics from one set of point clouds to another [31].

Fig. 2. Graph convolution process.

2) *F-attention module*: The attention mechanism [32] is divided into the space attention mechanism and the channel attention mechanism. In order to emphasize useful information features for classification tasks while suppressing useless information features, a new fusion attention mechanism was

designed, which incorporate the point cloud channel information characteristics with spatial information characteristics.

The structure of the new fusion attention mechanism (F-Attention) is shown in Fig. 3.

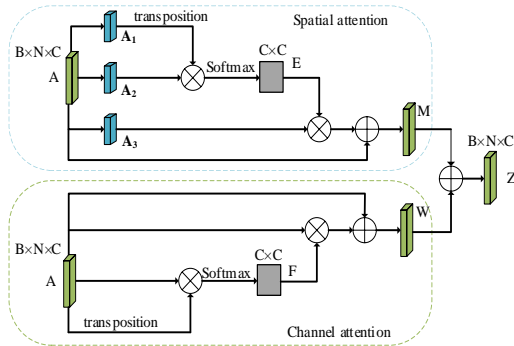

Fig. 3. Fusion attention module (F-Attention).

a) *Spatial attention module:* In Fig. 3, A is defined as the input point cloud feature matrix and  $B \times N \times C$  is the dimension of A in the Spatial attention module. The new feature matrices  $A_1$  and  $A_2$  can be obtained by linear transformation by A, which contains more spatial features. The two matrices have the dimensions  $B \times N \times C$ . Matrix  $A_1$  is transposed and multiplied with matrix  $A_2$ , and then the spatial attention coefficient matrix  $E (C \times C)$  is got using the SoftMax function, which is calculated as follows:

$$a_{ji} = \frac{\exp(A_{1i} \cdot A_{1j})}{\sum_{i=1}^N \exp(A_{1i} \cdot A_{1j})} \quad (5)$$

Where  $a_{ji}$  is the outcome of the SoftMax function calculation, which depicts the effect of the location  $i$  on  $j$  within matrices  $E$ .

$A_3$  is a new feature matrix, which is got by inputting A into the  $1 \times 1$  convolutional layer. The dimension of  $A_3$  is  $B \times N \times C$ . By multiplying matrices  $A_3$  and  $E$ , an outcome feature with a dimension of  $B \times N \times C$  is obtained. In order to adjust weights during training, the output feature is given a linear variable  $\lambda$ . As illustrated in Formula 6, the final output  $M$  of feature A is created by adding the elements of the characteristic matrix refreshed on the attention mechanism to those of the initial characteristic matrix A one by one.

$$M_j = \lambda \sum_{i=1}^N (a_{ji} A_{3i}) + A_j \quad (6)$$

To assign more weights by training the network,  $\lambda$  is initialized to 0. Both the initial point cloud characteristics and the location in space characteristics of the point cloud are included in the final feature  $M$ .  $M$  more effectively aggregates the information about the global context.

b) *Channel attention module:* The channel attention module input feature matrix is also defined as A. And the dimension of A is also  $B \times N \times C$ . The matrix A is first inverted.

After that, the original matrix is multiplied by the transposed matrix. The SoftMax function is then used to produce a channel attention factor matrix F having a size of  $C \times C$ .

As shown in Formula 7:

$$b_{ji} = \frac{\exp(A_i \cdot A_j)}{\sum_{i=1}^N \exp(A_i \cdot A_j)} \quad (7)$$

Where  $b_{ji}$  represents the impact of channel  $i$  on channel  $j$ .

The characteristic matrix A and the attention factor matrix F are multiplied to obtain a feature output with  $B \times N \times C$ . A parameter  $\chi$  is introduced to adjust the weights in the network training. The final result W of characteristic A is derived by adding the elements of the original characteristic matrix A and the updated feature matrix produced by the channel mechanism, as illustrated in Formula 8:

$$W_j = \chi \sum_{i=1}^N (b_{ji} A_i) + A_j \quad (8)$$

Similarly, to assign more weights by training the network,  $\chi$  is initialized to 0.

The final characteristic Z is obtained by fusing the characteristic M with point cloud spatial information and the characteristic W with point cloud channel information.

3) *Multi-layer feature fusion module:* In 3D point cloud classification tasks, fusing information features of different scales can effectively improve the classification performance of the network. Low-level features contain more location and detail information from point cloud data, but low-level features do not undergo much feature extraction, resulting in more noise and decreased semantic content. A high-level characteristic has more robust semantics, but they have poor feature resolution and poor detail perception. Therefore, before obtaining global features of point clouds through the network, it is necessary to perform feature fusion for features of 64, 128, and 256 dimensions.

In terms of the feature fusion method, select the concat feature fusion method, which essentially combines the number of feature channels, as shown in Fig. 4.

Fig. 4. Concat feature fusion.

For the two input features X and Y, if their feature dimensions are  $m$  and  $n$ , the output feature dimension after the concat operation is  $m+n$ . If the channels of input are  $X_1, X_2, \dots, X_c$ , and  $Y_1, Y_2, \dots, Y_c$ , respectively, the result after concat can be written as follows:

$$Z_{concat} = \sum_{i=1}^c X_i * K_i + \sum_{i=1}^c Y_i * K_{i+c} \quad (9)$$

The 64, 128, and 256-dimensional features obtained from the network are spliced using a multi-level feature fusion method, enabling the final global features to better focus on the global context information of the point cloud, enabling the network to achieve better classification accuracy. The fusion method is shown in Fig. 5.

Fig. 5. Multi-layer feature fusion.

### B. The 3D CLIP

The 3D CLIP plug-in network can directly perform classification tasks without pre-training. In order to obtain the text description characteristics of point clouds as well as the image features for point cloud projection images, this model primarily uses the trained text encoder and image encoder in the two-dimensional CLIP [33] and finds the corresponding relationship between text features and image features from the pre-trained model. Then, each image feature is weighted and summed with all text features, and the cosine similarity is calculated. The category corresponding to the maximum similarity text is the final classification result.

1) *Text encoder*: First, construct an appropriate descriptive text for each object class in the dataset. Then input these description texts into the text encoder to extract text features.  $M$  text features will be obtained after extracting the features through the text encoder. The text features extracted by the text encoder can be represented as  $W_t \in \mathbb{R}^{M \times C}$ . The model text encoder employs text-transform, and the primary method of extracting textual characteristics is depicted in Fig. 6:

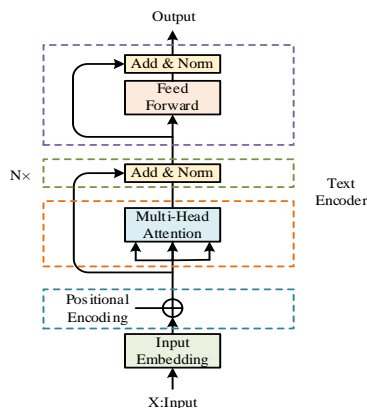

Fig. 6. Text feature extraction.

In this structure, the input of the text encoder is  $X$ , which represents a sentence. The final text features of the sentence are obtained after feature extraction from several modules of the encoder.

The input embedding module, the main purpose of this module is to transform the characters in a sentence into a vector.  $X$  can be converted into a  $X_{embedding}$  vector after this module. This vector's three dimensions stand for the total number of sentences, the number of words in a sentence, and the size of each individual word.

In the positional encoding module, the position of each word in the input sentence is encoded and marked. The encoding calculation process can use the sine and cosine function, which is calculated as:

$$PE(pos, 2i) = \sin(pos / 10000^{2i/d_{model}}) \quad (10)$$

$$PE(pos, 2i+1) = \cos(pos / 10000^{2i/d_{model}}) \quad (11)$$

where  $i$  indicates the size of the word vector and  $pos$  the position of each word within the phrase.

After the position encoding module, an encoding array  $X_{pos}$  with the same dimension as the input sentence can be obtained. And the new word vector can be obtained by superimposing  $X_{pos}$  with the original vector:

$$X_{embedding} = X_{embedding} + X_{pos} \quad (12)$$

In the multi-head attention module, this module enables the model to learn the expression of multiple meanings. The module uses the self-attention attention mechanism to linearly map the inputs to obtain  $Q, K, V$ :

$$\begin{aligned} Q &= X_{embedding} * W_Q \\ K &= X_{embedding} * W_K \\ V &= X_{embedding} * W_V \end{aligned} \quad (13)$$

where the dimensions of  $Q, K,$  and  $V$  are the same as the  $X_{embedding}$  dimensions.

In the add and norm module, the main operations are residual concatenation and normalization. The preceding layer input  $X$  is added to the output via the residual join. The normalization operation is to subtract the mean value of each row and divide it by the standard deviation of the row to obtain the normalized value.

The feedforward module contains two layers of linear mapping and activation using the activation function. The final output is obtained after the same add and norm operation.

2) *Image encoder*: Because the images input by the CLIP model when using the image encoder to extract image features are all two-dimensional, it is necessary to perform two-dimensional processing of three-dimensional point cloud data. The specific operation is to project the three-dimensional point cloud data in the dataset from multiple perspectives into a two-dimensional depth image.

The spatial coordinates of a point cloud for 3D data in a dataset can be represented as  $(x, y, z)$ . When projecting in the  $z$ -direction, the point can be transformed into  $([x/z], [y/z])$ . The advantage of this projection is that it can make the image closer to a natural image. Because the image encoder of the CLIP

model processes three-channel RGB images, to obtain point cloud-related features from the projected image, the projected image is copied twice to become a three-channel image before being input to the image encoder.

The mapping formula for projecting 3D point cloud data point  $A$  to 2D coordinate system point  $B$  is as follows:

$$\vec{A} = \begin{bmatrix} x \\ y \\ z \end{bmatrix} \rightarrow \vec{B} = \begin{bmatrix} \alpha \cdot \frac{x}{z} + C_x \\ \beta \cdot \frac{y}{z} + C_y \end{bmatrix} \quad (14)$$

In the selection of the image encoder, since the ResNet [34] is used in the 2D CLIP to achieve better results in classification tasks, the ResNet will also be used for feature extraction in the 3D CLIP selection of the image encoder.

ResNet is a residual network, and a residual network is composed of a series of residual blocks. For ResNet, it contains two basic modules, identity block, and conv block, and the module structure is shown in Fig. 7:

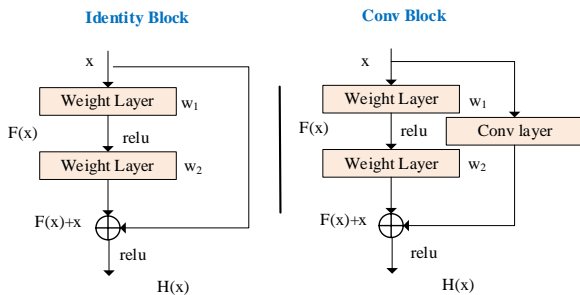

Fig. 7. ResNet main module.

In the identity block module,  $x$  is the input and  $H(x)$  is the output:

$$H(x) = F(x, \{w_i\}) + x \quad (15)$$

where  $F(x, \{w_i\})$  denotes the residual, which is the target to be learned. It represents the operator relationship between the weights and the input,  $F(x) = H(x) - x$ .

Unlike the identity block module, the conv block module adds the conv layer convolution operation on top of it. The shape of the input matrix can be adjusted so that the residual edges and the convolution in the module can be summed.

For depth, images projected from  $V$  different angles of view, use an image encoder to extract image features. The extracted image features have a total of  $f_i$ , where  $i = 1, \dots, V$ .

During the classification process, since the 3D CLIP has already obtained  $w_i$  text features and  $f_i$  image features, it is only necessary to calculate the classification  $logits_i$  of each projection view separately. Finally, weighted summation can be used to get the point cloud final classification  $logits_h$ , and the classification outcome. The calculation formula is as follows:

$$logits_h = \sum_{i=1}^V f_i W_i^T, i = 1, \dots, V \quad (16)$$

$$logits_h = \sum_{i=1}^V logits_i \quad (17)$$

## IV. EXPERIMENTS AND RESULT

### A. Datasets

For accurately assessing the network categorization performance for this article, the open dataset ModelNet40 proposed by Princeton University was selected for training and testing the network. There are a total of 12311 CAD models in the dataset, with 9843 models used for training and 2468 models used for testing. Each model has its corresponding category and is divided into 40 categories of artificial objects. Select four categories from the ModelNet40 dataset: airplane, plant, chair, and person for visualization. The results are shown in Fig. 8:

Fig. 8. Partial category visualization.

Because the point cloud set contains a sizable number of useless and noise points. The point cloud categorization network capacity to extract features will decline. In addition, when the number of points used to input the network is too large, it can generate many parameters during training. It will affect the training speed of the network. The subsampling algorithm can remove noise points and ensure the same number of points input to the model.

Fig. 9 displays the visualization of point cloud data following sampling. The original point cloud contains 10000 points. After sampling, 1024 points can be obtained. These points can represent the object well and contain rich object details.

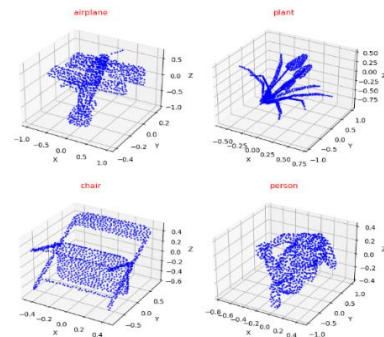

Fig. 9. Point cloud data sampling.

### B. Experimental Setting

The hardware environment required for this model is Intel core i5-9400, the software environment consists of Python 3.7,

CUDA10.1, PyTorch 1.6, and Ubuntu 20.04.2 LTS. The learning rate for the experimental parameters has been set to 0.001. There are 250 iterations in total. 32 is the set batch size. The Adam optimizer is used.

The evaluation metrics of the network are the overall classification accuracy (OA) and the average classification accuracy (mAcc). As follows:

$$OA = \frac{TP + TN}{TP + TN + FP + FN} \quad (18)$$

$$Precision = \frac{TP}{TP + FP} \quad (19)$$

$$mAcc = \frac{\sum_{m=1}^M Precision_m}{M} \quad (20)$$

where *TP* is the number of samples with accurate predictions. *TN* represents the number of samples with incorrect predictions. The sample quantity of false positives is denoted by *FP*. The sample quantity of false negatives is denoted by *FN*. *Precision* is the accuracy rate. *M* is the classification number.

### C. Experimental Results Analysis

1) *Pooling method selection*: To study the effects of various pooling methods on the classification precision of network models, max pooling, average pooling, and a combination of the two pooling methods were compared in the process of getting the global feature. Assume that method A uses only average pooling, method B uses only max pooling, and method C uses both average pooling and max pooling. Where  $\checkmark$  indicates using this method,  $\times$  indicates that this method is not used, and the classification accuracy is shown in Table I.

TABLE I. GFANET CLASSIFICATION ACCURACY UNDER DIFFERENT POOLING MODES

Pooling method	Avg. Pooling	Max Pooling	mAcc/%	OA/%
A	$\checkmark$	$\times$	89.3	91.5
B	$\times$	$\checkmark$	89.2	91.6
C	$\checkmark$	$\checkmark$	<b>90.2</b>	<b>92.5</b>

According to the test results of AvgPooling and MaxPooling in Table I, the combined use of max pooling and average pooling improves classification accuracy compared to utilizing either pooling approach alone. The average classification accuracy of using method C is 0.09% and 0.1% higher than that of method A and method B, respectively. And the overall classification accuracy of method C is 0.1% and 0.09% higher than that of method A and method B, respectively. This demonstrates that the information lost during the global feature selection process can be reduced by combining average pooling and max pooling. As a result, for

feature extraction during the construction of GFANet, average pooling, and max pooling are combined.

2) *Analysis of network classification accuracy*: To compare with the GFANet, many traditional point cloud classification networks are used. The ModelNet40 dataset is selected as the testing dataset. The classification accuracy of different networks on the ModelNet40 dataset is shown in Fig. 10 and Fig. 11.

Fig. 10. Average classification accuracy of different networks.

Fig. 11. Overall classification accuracy of different networks.

In contrast to traditional point cloud categorization networks, the GFANet has higher classification accuracy. Compared with PointNet, the GFANet has an overall classification accuracy improvement of 3.8% and an average improvement in classification accuracy of 4.4%. The reason is that GFANet concentrates on the point clouds local and global information characteristics. The GFANet exhibits an overall classification accuracy improvement of 2.0% when compared to PointNet++. The reason is that the connection between points is strengthened and the information feature between point pairs is focused in GFANet. While PointNet++ just processes points separately. Compared with DGCNN, the GFANet has an overall classification accuracy improvement of 1.2% and an average improvement in classification accuracy of 1.1%. The reason is that the information of point pairs is focused on GFANet. And a fusion attention mechanism is added in GFANet. In addition, the spatial and channel information properties of point clouds are extracted by GFANet.

Fig. 12. Network classification accuracy.

For the ModelNet40 dataset, the classification accuracy curve obtained through 250 iterations for PointNet, PointNet++, DGCNN, and GFANet is shown in Fig. 12.

The GFANet has significantly better classification accuracy than the other three networks in most training cycles, especially in the middle and late stages of training. It has been demonstrated that GFANet can increase the classification accuracy of point clouds.

3) *Comparative experiments of different categories:* Like the PointNet, the GFANet is a classification net that accepts data from point clouds directly. And the construction of the GFANet also refers to the PointNet. The comparison results of GFANet with PointNet and PointNet++ on ModelNet40 data set for individual classification of each category are shown in Table II.

Compared with PointNet and PointNet++, the GFANet has higher accuracy for most categories. For the categories with obvious features, such as the Bench, Guitar, and Lamp, the classification accuracy of GFANet is 5%, 2%, and 1.3% higher than that of PointNet, and is 3%, 0.5% and 0.7% higher than that of PointNet++. For the categories with no obvious features, such as the Bathtub, Door, and Wardrobe, the classification accuracy of GFANet is 5%, 1.2%, and 4% higher than that of PointNet, and is 3%, 1%, and 3% higher than that of PointNet++.

The reason is that both the local information characteristics and the global information characteristics for data points are considered in GFANet. Additionally, GFANet takes into account the channel information features as well as the spatial information features for data points.

TABLE II. COMPARISON RESULTS FOR 40 CATEGORIES

Category	PointNet	PointNet++	GFANet	Category	PointNet	PointNet++	GFANet
Airplane	1.000	1.000	1.000	Laptop	1.000	1.000	1.000
Bathtub	0.870	0.890	0.920	Mantel	0.930	0.940	0.950
Bed	0.960	0.964	0.970	Monitor	0.950	0.960	0.980
Bench	0.700	0.720	0.750	Night_stand	0.742	0.753	0.776
Bookshelf	0.910	0.918	0.930	Person	0.920	0.930	0.950
Bottle	0.940	0.952	0.960	Piano	0.900	0.910	0.930
Bowl	0.900	0.920	0.940	Range_hood	0.920	0.930	0.952
Car	0.960	0.971	0.980	Sink	0.780	0.800	0.850
Chair	0.970	0.974	0.980	Sofa	0.960	0.963	0.970
Cone	0.950	0.960	1.000	Stairs	0.800	0.840	0.900
Cup	0.780	0.790	0.800	Stool	0.850	0.860	0.800
Curtain	0.900	0.910	0.920	Table	0.800	0.830	0.870
Desk	0.800	0.880	0.900	Tent	0.950	0.951	0.953
Door	0.800	0.860	0.920	Toilet	0.980	0.982	0.970
Dresser	0.696	0.700	0.726	Tv_stand	0.800	0.830	0.860
Flower	0.220	0.230	0.250	Vase	0.820	0.825	0.830
Glass	0.950	0.960	0.970	Wardrobe	0.750	0.760	0.790
Guitar	0.980	0.985	1.000	Xbox	0.650	0.680	0.750
Keyboard	1.000	1.000	1.000	Plant	0.760	0.770	0.780
Lamp	0.950	0.956	0.963	Radio	0.750	0.770	0.800

4) Analysis of adding 3D CLIP classification accuracy:

The effectiveness of the 3D CLIP network is demonstrated by comparing the accuracy of point cloud classification with and without adding 3D CLIP in PointNet, PointNet++, DGCNN, and GFANet. The classification accuracy is shown in Table III.

TABLE III. CLASSIFICATION ACCURACY OF DIFFERENT NETWORKS

Method	3D CLIP	mAcc/%	OA/%
PointNet [20]	×	85.8	88.7
	√	87.3	90.1
PointNet++ [24]	×	—	90.5
	√	—	91.4
DGCNN [26]	×	89.1	91.3
	√	90.4	92.7
GFANet	×	90.2	92.5
	√	<b>91.1</b>	<b>93.6</b>

The overall accuracy of classification of PointNet is 1.4% higher and the average accuracy of classification is 1.5% higher when the 3D CLIP is used. The overall accuracy of the classification of PointNet++ is 0.9% higher when the 3D CLIP is used. The overall accuracy of classification of DGCNN is 1.4% higher and the average accuracy of classification is 1.3% higher when the 3D CLIP is used. The overall accuracy of classification of GFANet is 1.1% higher and the average accuracy of classification is 0.9% higher when the 3D CLIP is used. The experiment results indicate that point cloud classification networks with 3D CLIP have a certain improvement in classification accuracy compared to networks without 3D CLIP. The reason is that 3D CLIP can extract two-dimensional feature information of point clouds. The GFANet with 3D CLIP has the highest classification accuracy compared to other networks with 3D CLIP. It proves the effectiveness of the GFANet and 3D CLIP. It also demonstrates the potential of 3D CLIP to enhance the classification accuracy of point cloud categorization networks.

5) Analysis of 40 categories classification results of GFANet adding 3D CLIP: According to Table II, for the categories with similar characteristics in the ModelNet40 dataset, such as cup and vase, flower\_pot and plant, nightstand, and wardrobe. GFANet and the existing classical point cloud classification network cannot be well classified, and these categories are shown in Fig. 13. The primary cause is that the network only concentrates on the three-dimensional information feature information of the point cloud and does not extract the two-dimensional information feature of these categories, making it difficult for the network to distinguish and identify, and resulting in a relatively small improvement in the classification accuracy of these single categories. In this experiment, the 3D CLIP is added to the GFANet to prove that the 3D CLIP can help the GFANet to better distinguish

different categories with similar features and improve the classification performance of the network. The findings of the experiment are displayed in Table IV.

Table IV shows that in comparison to GFANet alone, the network comprising GFANet and 3D CLIP has somewhat increased the classification accuracy of the 40 categories of the ModelNet40 data set. For the cup and vase categories with similar features, the accuracy of classification is increased by 2% and 1.8%, respectively. For the flower\_pot and plant categories with similar features, the accuracy of classification is increased by 3% and 2%, respectively. For the nightstand and wardrobe categories with similar features, the accuracy of classification is increased by 3% and 2%, respectively. The classification accuracy of the network is improved by 2.6% and 3%, respectively. This is so that the network can both extract the three-dimensional information features of the point cloud and learn the two-dimensional information representation of the point cloud. The 3D CLIP is an addition to the GFANet that can provide more two-dimensional information about the point cloud for the network. Thereby the network can better distinguish between different categories with similar features and raise the classification accuracy of various categories. Improve the classification accuracy of the network.

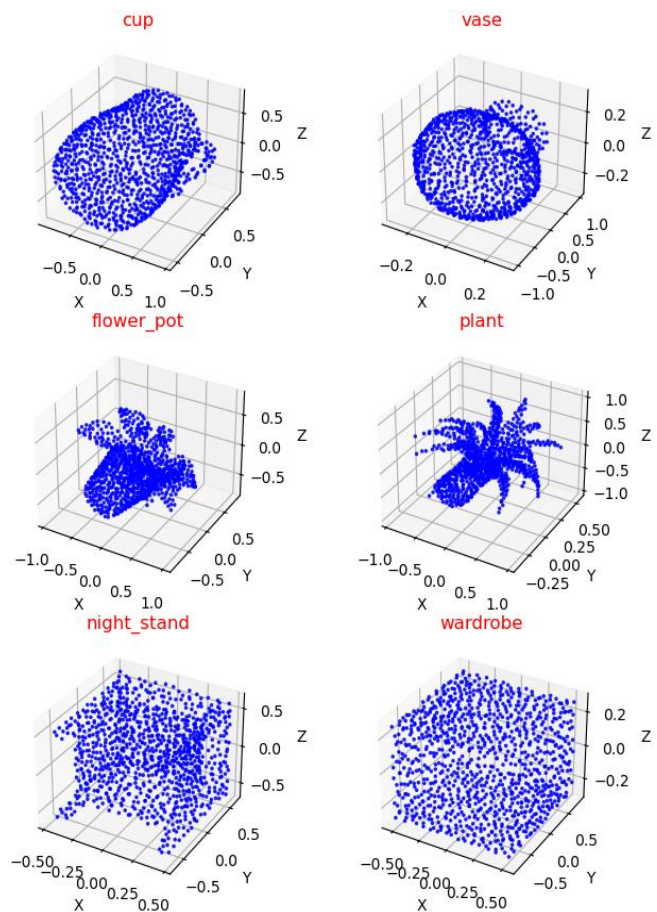

Fig. 13. Different categories with similar features in the ModelNet40 dataset.

TABLE IV. ANALYSIS OF 40 CATEGORY CLASSIFICATION RESULTS

Category	GFANet	GFANet+3D CLIP	Category	GFANet	GFANet+3D CLIP
Airplane	1.000	1.000	Laptop	1.000	1.000
Bathtub	0.920	0.930	Mantel	0.950	0.960
Bed	0.970	0.978	Monitor	0.980	0.983
Bench	0.750	0.800	Night_stand	0.770	0.802
Bookshelf	0.930	0.940	Person	0.950	0.960
Bottle	0.960	0.970	Piano	0.930	0.940
Bowl	0.940	0.950	Range_hood	0.952	0.962
Car	0.980	0.987	Sink	0.850	0.860
Chair	0.980	0.983	Sofa	0.970	0.980
Cone	1.000	1.000	Stairs	0.900	0.920
Cup	0.800	0.820	Stool	0.800	0.850
Curtain	0.920	0.930	Table	0.870	0.900
Desk	0.900	0.910	Tent	0.953	0.961
Door	0.920	0.926	Toilet	0.970	0.980
Dresser	0.726	0.862	Tv_stand	0.860	0.880
Flower	0.250	0.280	Vase	0.830	0.848
Glass	0.970	0.975	Wardrobe	0.790	0.820
Guitar	1.000	1.000	Xbox	0.750	0.800
Keyboard	1.000	1.000	Plant	0.780	0.800
Lamp	0.963	0.986	Radio	0.800	0.880

#### V. CONCLUSION

Targeting the issues that the current point cloud classification methods disregard the point cloud's local feature extract, lack the connection between points and points, and do not extract the two-dimensional information features of the point cloud when obtaining the point cloud features. To obtain a more precise classification result, a point cloud categorization network using a multi-layer fusion of features and point cloud projection image was proposed. The network employs dynamic graph convolution to enhance the association between points by extracting local characteristics from the point cloud. The point cloud features were fused via multi-layer feature fusion, and the fusion attention method was devised to collect the useful characteristics of the point cloud while suppressing the useless features. Finally, a 3D point cloud network plug-in model based on a point cloud projection image, 3D CLIP, is used to make up for the lack of extracting two-dimensional information features of the point cloud, to increase the network accuracy at classifying objects.

#### FUNDING STATEMENT

This Research was funded by the National Key R&D Program of P.R. China under project number: 2022YFE0107300.

#### ACKNOWLEDGMENT

The authors are grateful to the anonymous referees for their insightful comments and suggestions.

#### CONFLICTS OF INTEREST

The authors declare that they have no conflicts of interest to report regarding the present research paper.

**Abstract**—Autism Spectrum Disorder (ASD) is a mental disorder among children that is difficult to diagnose at an early age of a child. People with ASD have difficulty functioning in areas such as communication, social interaction, motor skills, and emotional regulation. They may also have difficulty processing sensory information and have difficulty understanding language, which can lead to further difficulty in socializing. Early detection can help with learning coping skills, communication strategies, and other interventions that can make it easier for them to interact with the world. This kind of disorder is not curable but it is possible to reduce the symptoms of ASD. The early age detection of ASD helps to start several therapies corresponding to ASD symptoms. The detection of ASD symptoms at an early age of a child is our main problem where traditional machine learning algorithms like Support Vector Machine, Logistic Regression, K-nearest neighbour, and Random Forest classifiers have been applied to parents' dialog to understand the sentiment of each statement about their child. After completion of the prediction of these models, each positive ASD symptoms-related sentence has been used in the cosine similarity model for the detection of ASD problems. Samples of parents' dialogs have been collected from social networks and special child training institutes. Data has been prepared according to the model for sentiment analysis. The accuracies of these proposed classifiers are 71%, 71%, 62%, and 69% percent according to the prepared data. Another dataset has been prepared where each sentence refers to a particular categorical ASD problem and that has been used in cosine similarity calculation for ASD problem detection.

**Keywords**—Support vector; logistic regression; cosine similarity; K-nearest neighbor; random forest

## I. INTRODUCTION

People with ASD [1] often have difficulty in understanding the social cues and expectations that are necessary for meaningful conversations and relationships with others. This can lead to isolation, difficulty in forming relationships, and, in some cases, difficulty in gaining recognition in society as in [2]. Early detection can help identify the illness sooner, allowing for personalized treatments or preventive measures to be put in place that can help reduce the severity of the illness and improve the chances of recovery as in [3]. It is caused by a combination of genetic and environmental factors that affect the development of the brain. It is characterized by difficulty in social interaction, communication, and repetitive behaviors. Research has been done to identify the causes of this syndrome, which include

genetic predisposition, environmental factors, and lifestyle choices. Although the exact cause is still unknown, the available evidence shows that it is a multi-faceted condition. In addition, the lack of trained professionals and resources to diagnose and treat ASD [1] has created a huge gap in access to care. Furthermore, due to the complexity of the disorder, it can be difficult to diagnose and properly classify it, leading to misdiagnosis or delayed diagnosis. This is because autism is a complex disorder, and it can manifest itself differently in each affected individual [4]. As such, it is difficult to create a single biomarker that can accurately detect the disorder. Additionally, research into developing tools and applications, data analysis, and pattern recognition [5][6] to help identify children with autism is challenging, as it requires creating a comprehensive program that can detect subtle signs of autism across a range of contexts as in [7]. People with autism may struggle with understanding social cues, interpreting and responding to others' emotions, and forming relationships. They may also have difficulty with processing sensory information or have strong interests in certain topics or activities. Diagnosis is based on observed behavior, and the process can involve interviews and questionnaires, cognitive assessments, physical examinations, and genetic and neurological tests. All of these evaluations can take time and money, and the cost can be prohibitive for some families. These tests are designed to identify patterns of behavior and symptoms associated with autism, by asking parents and professionals to observe the individual. They then analyze the responses and compare them to a set of criteria established to identify autism or other developmental disorders. For example, if a person is using a metal detector, they must have an understanding of the type of metal they are looking for and the size of the object they are searching for. The quality of the metal detector will also have an impact on the accuracy and efficiency of the screening method. Such systems can use algorithms to analyze large amounts of data and detect patterns with high accuracy, potentially leading to earlier and more accurate diagnoses. Additionally, such systems can help to automate certain labor-intensive tasks and reduce the amount of time needed to complete diagnostic tests. This is because machine learning algorithms can analyze large amounts of data and identify patterns and correlations that would be difficult or impossible for humans to find. The algorithms can then be used to develop predictive models that can accurately identify potential diagnoses and suggest

therapies as in [8]. Some research scholar has done some work on ASD diagnosis using machine learning. The aim of this research is to reduce the classification time of ASD diagnosis process after the detection of the most influential ASD diagnosis items as in [9][10][11][12]. Machine learning (ML) is a powerful tool that can be used to analyze vast amounts of data and identify patterns that can be used to detect mental health issues. ML can also be used to develop personalized treatments based on individual patient characteristics. This could potentially lead to more targeted and effective treatments for mental health issues. Through the use of data-driven techniques, ML enables the analysis of large amounts of data to uncover previously unknown patterns, trends, and correlations. ML can be used to develop predictive models or to recommend interventions that may be tailored to individual needs. These challenges include the need to ensure responsible data collection and storage, to develop equitable access to ML-enabled solutions, to ensure ethical and responsible use of ML and AI, and to ensure that privacy and confidentiality are maintained as in [13].

The proposed work is based on the detection of ASD symptoms from the parents' dialogue. Parents of autistic children have the best experience with their autistic children's symptoms. The data has been collected from many social sites and organizations for special children. The data is related to the parents' dialogue in text mode and a dataset has been prepared using these parents' text inputs. Traditional machine learning models like SVM, Logistic Regression, K-nearest neighbor (KNN), and Random Forest have been used to detect the symptoms from the parents' text. The sentiment analysis process has been used to detect sentences from the parents' text. After completion of the prediction using the proposed machine learning models, the positive sentences have been used as input in the cosine similarity model. This model will calculate the cosine similarity of input sentences and ASD symptoms sentences to detect ASD problems. Many machine learning-based applications related to mental disorders have been discussed in Section II. The proposed dataset, detailed architecture of the proposed system, and machine learning models have been discussed in Section III. The results of this proposed system have been discussed in Section IV. The limitation has been given in Section V whereas conclusion has been discussed in Section VI and ends with the future work in Section VII.

## II. RELATED WORKS

Today, Autism Spectrum Disorder (ASD) is a highly prevalent disorder problem among children. Now it is one of the main components in the healthcare domain and much research has been done using Artificial Intelligence (AI). A few important AI-based research works on Mental Health related issues have been included in this related work section.

These NLP software tools use a combination of natural language processing (NLP) algorithms and domain-specific ontologies to identify and extract biomedical concepts from unstructured texts. The ontologies provide an organized representation of biomedical concepts and the NLP algorithms enable the software to accurately identify the concepts in the text. This is due to the fact that the existing literature on these

disorders is often written in a complex, highly technical language that is difficult to parse and interpret with natural language processing tools. Additionally, many of the diseases are multi-faceted and involve a variety of clinical terms that need to be identified by the NLP tools in order to accurately extract relevant information. The authors evaluated the predictive performance using precision, recall, and F1 score. We also ran a manual evaluation to compare the manual annotation of ASD-related terms with the tools' extracted terms, and found that CLAMP outperformed the other two tools in terms of precision, recall, and F1 score on both the abstracts and full-text articles. The F1 score combines the precision and recall of a system, so it takes into account both the accuracy and completeness of the system. In this case, CLAMP had the highest F1 score, meaning it had both a higher precision and a higher recall than the other two systems. This type of analysis protocol allows researchers to better identify, classify, and quantify the symptoms of a disorder, even when there is not a well-defined terminology set to describe it. This makes it easier to compare the presentation of the disorder across different populations and can help to identify potential biomarkers for the disorder as in [14]. People with ASD had more difficulty in expressing emotions and abstract concepts than typically developing individuals, as well as difficulty in using language to describe events and convey information. This suggests that impairments in the use of pragmatic language are an important aspect of ASD and should be addressed in interventions. This suggests that the differences in narrative production between ASD and control groups are related to difficulties in understanding and expressing emotions, as well as producing more abstract language. The individuals with typical development had a more varied range of vocabulary, which included more words with both positive and negative sentiments, while the participants with ASD displayed a limited vocabulary, resulting in a greater tendency to use negative words. The lower level of language abstraction in the ASD narratives could be due to the limitation of their vocabulary and the difficulty of expressing abstract concepts. This suggests that language abstraction and emotional polarity can be used to measure the narrative abilities of individuals with ASD without relying on age or IQ scores. The strong positive correlation between linguistic abstraction and emotional polarity indicates that the more abstract language used, the more likely it is to contain emotional content. The difference in emotional polarity between the two groups could be due to the fact that individuals with ASD may have difficulty recognizing and expressing emotions. In addition, they may have difficulty understanding abstract language concepts, which could explain why they used fewer abstract words in their narratives as in [15]. One of the most promising areas for developing assistive tools is the use of artificial intelligence (AI) and machine learning (ML) algorithms. These algorithms can be used to analyze data from various sources and can provide insights that may help diagnose ASD earlier and more accurately. The proposed approach is expected to find the underlying patterns in the eye-tracking records which can be used to accurately diagnose the disorders. The results of this study could provide clinicians with a powerful tool that could potentially improve the

accuracy and speed of diagnosis. By applying NLP methods to the raw eye-tracking data, the study was able to extract meaningful features from the data that could be used to train classification models. The experiment showed that using these features could yield better results than using the raw data alone. The authors [16] used a customized loss function to adjust the weights of the model, which allowed them to achieve a high level of accuracy. Additionally, authors [16] utilized transfer learning to fine-tune the model, allowing us to further improve the accuracy of the model. The author's [16] approach could realize a promising accuracy of classification (ROC-AUC up to 0.8) as in [16]. Social behavior issues are often the most noticeable in children with autism, and they may include difficulty forming relationships, lack of eye contact, and difficulty understanding nonverbal communication. Clinical tests can also be used to look for developmental delays, such as difficulty with speech and language, as well as repetitive behaviours like hand flapping or rocking. The assessment process is designed to identify key characteristics of autism in individuals, such as difficulty in communication and social interaction, and to determine the severity of the condition. By using semi-structured data posted in Twitter, the team of doctors can gain insight into the individual's behavior, which can then be used to develop a more accurate and effective assessment. Analyzing the tweets, it allows researchers to detect the sentiment of people's opinions on autism, the topics that are most commonly discussed, and the language used to discuss autism. This helps researchers gain a better understanding of how people think and talk about autism, and can help inform policy decisions. NLP and topic modeling allow for more efficient processing of data by automatically recognizing patterns and keywords, saving time and effort. Furthermore, the results of the analysis are highly accurate, making them an ideal choice for studying topics such as genetic analysis, the effect of vaccination, and behavior analysis. The 10k tweets dataset is enough to provide in-depth analysis and insight into these topics. The analytical results are used to learn the genetic impact on ASD, the vaccination effect on ASD and also used to learn the behavior changes and population of autistic children as in [17]. It is characterized by a persistent pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development. It is often accompanied by other mental health disorders, such as anxiety and depression, which can further impair functioning and quality of life. We applied the CNN model to the EEG data in order to distinguish between ADHD patients and healthy controls. The CNN was able to accurately classify the EEG data with an accuracy of 90.3%, significantly outperforming other methods, particularly of event-related potentials (ERP) from ADHD patients ( $n = 20$ ) and healthy controls ( $n = 20$ ) collected during the Flanker Task, with 2800 samples for each group. By exploiting invariances, deep networks are able to classify data even when there are variations in the data, such as changes in lighting or orientation of an image. Compositional features are combinations of basic elements that form a more complex representation of the data, such as edges and shapes in an image. Deep networks are able to identify these features, which enables them to accurately classify data. This was achieved by using a Convolutional Neural Network (CNN)

that was trained on EEG data from patients with Parkinson's Disease in order to classify them as either having the disease or not. The CNN was able to extract relevant features from the data without any manual input, resulting in a higher accuracy than other machine learning approaches. This is because CNNs can learn more complex patterns from the data and have the ability to generalize to new data. Event-related spectrograms capture more information about the events of interest, which can be used to extract more accurate features than resting state EEG spectrograms. This suggests that these techniques can be used to identify and visualize the underlying physiological differences between neurological disorders and healthy brains, potentially leading to a better understanding of their underlying pathophysiology. Deep networks are useful because they can extract meaningful patterns from EEG signals and are capable of handling large amounts of data. These results suggest that deep networks can also be used to analyze EEG dynamics from smaller datasets, which could be used to develop biomarkers for clinical use as in [18]. EEG can provide valuable information to help diagnose ADHD in children because it can measure electrical activity in the brain and detect any abnormal electrical activity that may be indicative of ADHD. Additionally, EEG can help to differentiate ADHD from other mental disorders that may be present in the child. Symptoms of ADHD include difficulty paying attention, impulsivity, and hyperactivity. These symptoms can interfere with a child's ability to learn, manage emotions, and interact with peers. Video long-range EEG monitoring can provide more accurate and detailed information about the brain activity of children with ADHD compared to ambulatory EEG monitoring, as it allows for more frequent data collection and better visualization of the EEG data. It also helps to identify abnormal brain electrical activities which may be associated with ADHD, thus aiding in the diagnosis of the condition. By doing this, they were able to accurately identify children with ADHD and study their behavioral patterns in order to better understand and treat the disorder. This allowed for a more precise and detailed analysis than traditional methods of observation. Comparing the results of various models can help to identify which model is best suited for recognizing signs of ADHD in EEG data. By selecting the most accurate and appropriate model, researchers can then use it to build a recognition method that can diagnose children with ADHD more accurately. This is because long-term video EEG can detect the abnormal EEG patterns associated with ADHD, such as slow wave activity, and can also detect the degree of attention fluctuation in children with ADHD as in [19]. With the recent advances in artificial intelligence, computers can now analyze EEG data and provide results much faster than a neurologist. This has enabled the field of neurology to become much more efficient and provide more accurate results in a fraction of the time. This is made possible because AI is able to quickly analyze and process large amounts of data. It can quickly identify patterns and draw conclusions from the data that would take human hours or even days to detect ADHD. Additionally, AI can look for indicators of diseases or abnormalities that would be difficult for humans to find on their own. This is because it can automate the process of analyzing EEG signals, thus allowing neurologists to quickly and accurately identify

patterns associated with different neurological diseases. Furthermore, this technology can also help neurologists to identify subtle changes in EEG signals that could potentially signal the onset of a neurological disorder. The ML model can process the EEG signals quickly and accurately to detect patterns that may indicate ADHD. By making use of the data generated from the EEG signals, the ML model can diagnose ADHD more accurately and quickly than traditional methods. By analyzing the EEG signals, the ML model can identify patterns that are indicative of ADHD. Additionally, the ML model can be trained to recognize these patterns more quickly and accurately than traditional methods. With the right pre-processing techniques and machine learning algorithms, the ML model can provide a more accurate diagnosis of ADHD than traditional methods as in [20]. This allows individuals to stay connected with their friends and family and to keep up with what is going on in the world. Additionally, it makes it easier to stay in touch with people who are not in the same physical location, making it a great way to stay connected during this time. The pandemic has had a negative impact on the mental health of many people, and it has become harder for them to access in-person support. As a result, online tools and resources have become more important than ever for those struggling with mental health issues, allowing them to get the help they need even when they are unable to leave their homes. Mental health conditions can have a significant impact on an individual's overall well-being, affecting their ability to work and their relationships with others. Additionally, research has found that mental illnesses can increase an individual's risk of developing chronic physical health conditions, such as heart disease and diabetes. AI methods can help mental health providers to detect patterns in patient data that might otherwise go unnoticed, as well as to generate insights into the patient's current state. This can lead to more accurate diagnoses and better treatment plans, leading to better overall outcomes for the patient. AI can help to analyze patient data quickly and accurately, identify patterns and correlations, and make predictions about the best course of action for a patient's diagnosis and treatment. AI can also help reduce the time and resources required for manual data analysis and provide more efficient and cost-effective care. The models were tested on a labeled dataset of Reddit posts from users with self-reported mental illnesses and compared against a baseline model. The results showed that the machine learning, deep learning, and transfer learning models outperformed the baseline model in correctly classifying the different mental illnesses. This will help to reduce the amount of time it takes to identify and respond to medical emergencies, which will ultimately lead to more lives being saved. Additionally, it will also help to reduce the burden on healthcare workers, which will make the public health system more efficient and cost-effective as in [21]. A variety of factors can contribute to depression, such as genetics, brain chemistry, environmental influences, traumatic experiences, and other medical conditions. Additionally, depression can be caused by a combination of these factors, making it difficult to pinpoint a single cause. Genetics and brain chemistry can predispose someone to depression, while environmental factors and traumatic experiences can trigger its onset. Other medical conditions such as chronic illnesses can also be

associated with depression. Recognizing the early signs of depression can help to identify and address the issue before it becomes a more serious problem. The CNN is used to extract high-level features from speech signals, while the SVM classifier is used to classify the extracted features. The hybrid model is trained on a dataset of Arabic speech from people with depression and those without, to produce a model that is capable of distinguishing between the two. The hybrid model uses a combination of convolutional neural networks (CNNs) and support vector machines (SVMs) to analyze while 30% of data were used to test the proposed model. A hybrid model (CNN + SVM) attained a 90.0% and 91.60% accuracy rate to predicting the depression from the data and make predictions. This combination of techniques allows for the model to process the data quickly and accurately, resulting in the high accuracy rates it achieved. This is likely because the hybrid model combines the strengths of both models. The RNN can accurately make predictions based on the context of the data, while the CNN can detect the most important features in the data. By combining both models, the predictive power of the hybrid model is enhanced, the RNN achieved an 80.70% and 81.60% accuracy rate. This indicates that the combined model was more effective in classifying depression than either of the individual models alone. The results suggest that incorporating multiple models into one prediction system can increase the accuracy of the diagnosis. This is because the achieved findings can be used to identify key indicators of depression in spoken Arabic, such as speech patterns, intonation, and pauses. These indicators can then be used to identify individuals who may be suffering from depression and help physicians, psychiatrists, and psychologists provide more effective treatment as in [22]. The mental health issues, such as depression and anxiety, are becoming more common, and people are recognizing the need to prioritize their mental health as well as their physical health. Additionally, with the development of telehealth services, it's become easier for people to access mental health services regardless of their location. This means that most people who suffer from mental health issues are unable to get access to the right diagnosis and treatment, resulting in an overall decrease in the mental health of the population. The model will be trained on a dataset of speech samples from people with and without depression. Exploring the acoustic features and patterns in the speech samples of people with depression will help to identify the differences between those with and without depression. By doing so, it will be possible to detect signs of depression in an individual and provide an initial diagnosis of mental health problems. This model uses Natural Language Processing (NLP) techniques to analyze the text and determine the sentiment of the posts. The sentiment of the posts is then used to assess an individual's mental health status as in [23].

A comparative analysis has been done on proposed systems that are equipped with machine learning models and similar types of systems that are also based on machine learning models. Table I contains 'Models' as the first attribute where each model name is defined. The 'Description' attribute contains details about the models. The third attribute is 'Dataset' which refers to the dataset details and the fourth attribute is 'Accuracy' where each model's accuracy has been given. The last attribute is 'Remarks' about each model. Fig. 1

shows the accuracy graph of similar machine learning models and proposed machine learning models.

TABLE I. COMPARATIVE STUDY OF PROPOSED MODELS WITH SIMILAR TYPE MODELS IN MENTAL DISORDERS

Sl.No.	Models	Description	Dataset	Accuracy	Remarks
Similar Type Machine Learning Models in Mental Disorders					
1	CNN, RNN, SNN [18]	Deep learning CNN, Recurrent Neural Network, and Recurrent Neural Network are used for classification and comparison to detect Attention deficit hyperactivity disorder (ADHD).	EEG data has been used.	88%, 86%, and 78%	EEG is a medical test that measures electrical activity in the brain. This data is a very high volume and time and cost-effective.
2	Fully connected neural network model [19]	Neural Network-based Deep Learning Model to detect disorders like ADHD.	Deep learning long-range EEG big data.	97.7%	The data is long-range EEG big data which is a very high volume data for analysis.
3	KNN, SVM, and RF [20]	KNN, SVM, and RF Models are used trained with the EEG signals data to detect ADHD.	EEG signals data of ADHD	69%, 72%, and 74%	Much time has to be given for preprocessing to improve the quality of EEG signals.
4	Linear Support Vector Classifier, LR, NB, and RF [21]	Depression, anxiety, bipolar disorder, ADHD, and PTSD detection from unstructured data.	Unstructured user data on the Reddit platform has been used.	79%, 79%, 74%, and 75%	Reddit's post-dataset cleaning process is related to removing personal information, punctuation marks, and URLs.
5	CNN+SVM[22]	Intelligent system to detect depressive symptoms using speech analysis	Basic Arabic Vocal Emotions Dataset (BAVED)	90 and 91.60	The dataset has been prepared from the audio format for sentiment analysis.
6	RNN+CNN [22]	Intelligent system to detect depressive symptoms using speech analysis	Basic Arabic Vocal Emotions Dataset (BAVED)	88.50 and 86.60	The dataset has been prepared from the audio format for sentiment analysis.
Proposed Models in Mental Disorder (Autism Spectrum Disorder)					
7	Proposed SVM	SVM model to predict positive ASD symptoms from parents' dialogue.	Parents' Dialogues of Autistic Children in text format from SAHAS- Durgapur, India, and Social Sites.	71%	The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns.
8	Proposed Logistic Regression	SVM model to predict positive ASD symptoms from parents' dialogue.	Parents' Dialogues of Autistic Children in text format from SAHAS- Durgapur, India, and Social Sites.	71%	The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns.
9	Proposed K Nearest Neighbor (KNN)	SVM model to predict positive ASD symptoms from parents' dialogue.	Parents' Dialogues of Autistic Children in text format from SAHAS- Durgapur, India, and Social Sites.	62%	The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns.
10	Proposed Random Forest	SVM model to predict positive ASD symptoms from parents' dialogue.	Parents' Dialogues of Autistic Children in text format from SAHAS- Durgapur, India, and Social Sites.	69%	The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns.

Fig. 1. Accuracy graph of similar ML models and proposed ML models.

### III. ARCHITECTURE OF PROPOSED MODELS

A few traditional machine learning classifiers have been used to identify ASD symptoms from parents' dialogues. SVM has been used as the first classifier to identify the symptoms from the parents' dialogue. Logistic regression is a second classifier that is also identifying the ASD symptoms from the given dataset. KNN and Random forest are the last two classifiers that are also used to identify ASD symptoms from a given dataset.

#### A. Dataset of Proposed System

The Dataset has been prepared using the parents' dialogue where parents are describing their thoughts and experiences about their own autistic child. These data have been collected from several different social networks and organizations where special children are taking their therapies on communication, speech, and behavior. A few parent dialogue example has been given in Table II. Parents' dialogues are very important data from where all possible symptoms of ASD can be identified. The given dialogues are used to make the dataset for proposed machine learning models training and testing.

TABLE II. EXAMPLE OF PARENTS' DIALOGUES

Sl. No.	Parents' Dialogues
1.	My second son is 4 and also autistic; he's on the move always and always into something and he's also a big momma's boy, loves hugging and cuddling me. I'm nervous about bringing baby home. Idk how he'll handle it. Any advice?
2.	Hi. Please I need some advice. My son is 10 and from a few years is very hard to make him do some activities (writing and staff like that) At school he refuse. They are not able to make him do anything. At school just play and if say no to him he just scream. He doesn't want to do anything; (in terms of studying or activities). I really don't know what to do.
3.	I'm currently having problems with washing my (almost 2 year old) daughter's hair. Whenever i try, she basically goes ballistic and throws a fit. She's scared and I'm trying to figure out how to support her and make her feel safe because she does have to get hair washed. Any suggestions and things that have worked for you?

4.	My youngest with autism, learning disabilities and is non-verbal, will be 4. She has to be in a pushchair whilst out and about for safety as has zero sense of danger. I'm struggling to find a double pushchair suitable for a newborn and my will be 4 year old. If anyone can send any links or pictures that would be great.
5.	From few days my son eye movements strangely like keeping head down n seeing up and moving eye balls to the corners of the eyes. Can anyone suggest why he is doing so? Please... thanks!

The Dataset has been prepared from the text in Table II. Each sentence has been taken into consideration to identify whether it is a symptom of ASD or not. There are no fixed symptoms in ASD for identification. Increment of those parents' dialogues who are actually parents of autistic children can be a good idea to identify more symptoms as well as a good advantage to train the machine learning models for better accuracy. A few examples of data from the proposed dataset have been given in Table III.

TABLE III. EXAMPLE DATA IN THE PROPOSED DATASET

Sl. No.	Comments	Sentiment
1.	because all they do there is play with toys with him every time	1
2.	I'm confused guys help my son is 3years old now	0
3.	My little girl is 3 and a half and still non verbal	1
4.	he does is mumbles only no proper words	1
5.	I was really surprised when he came home with iep papers	0

The dataset structure in the proposed research has been described in Table III where the first column is Serial Number, the second column is Comments, and the third column is Sentiment. Paragraph text from parents' dialogues has been taken to prepare the dataset. Each sentence has been taken from the paragraph text and identifies whether it is a symptom of ASD or not. If it is a symptom of ASD then it is labeled as 1 (true) otherwise 0 (false). According to Table III, Sentences in the Comments column with serial numbers 1, 3,

and 4 are true symptoms of ASD whereas serial numbers 2 and 5 are false symptoms. Now this ASD symptom-based dataset has been prepared to train some traditional machine learning models like SVM, Logistic Regression, KNN, and Random Forest.

TABLE IV. LIST OF LABELS WITH ASD PROBLEMS

Sl. No.	Label	ASD Problems
1.	1	Speech Problem
2.	2	Sensory Problem
3.	3	Behaviour Problem
4.	4	Special Education
5.	5	Social Interaction
6.	6	Eye Contact
7.	7	Cognitive Behaviour
8.	8	Hyper Active Problem
9.	9	Child Psychological Problem
10.	10	Attention Problem

Table IV shows that each ASD problem is associated with the label. Label 1 denotes the “Speech Problem” whereas Label 2 and 3 denotes the “Sensory” and “Behaviour” problems. The other problems also mention in the label in Table IV. This table has been used after the prediction of the sentiment of a sentence according to the ASD symptoms. If the sentence is positive (1) then the proposed system will use this positive sentence as input of the Spacy cosine similarity model. Table V shows a dataset that contains a number of positive sentences with labels. Each label indicates an ASD problem according to Table V. Each sentence will be used for a similarity check with predicted positive sentences in the cosine similarity model and that has been discussed in the Proposed System Flow sections.

TABLE V. DATASET FOR COSINE SIMILARITY CHECK

Sl. No.	Positive Sentences	Label
1.	I can't show him how to potty during the day while his dad is at work	7
2.	he does is mumbles only no proper words	1
3.	when I call him he doesn't come to me	10
4.	He needs to visualize what I'm saying	6
5.	She gets so frustrated it breaks my heart I guess I'm looking for success stories	9

Each model has been described with the proposed algorithm in the next sections where this dataset has been utilized to train these models and the result of each model has been discussed in the Result and Discussion section.

**B. Support Vector Machine (SVM)**

Support vector machine (SVM) is the first approach to identify the symptoms of ASD. SVM is a supervised machine learning algorithm that can be used for classification or regression problems. It is a good idea to use SVM on a small

dataset and it generates good predictive results according to the problem. SVM is based on the finding of the best hyperplane that divides data points either in two classes or multiclass. The proposed approach is binary classification where data points either true (1) or false (0).

Fig. 2. Support Vector Machine (SVM).

It can be observed according to the above image that it is a two features classification problem. The optimized hyperplane has been drawn to linearly separate support vectors. The support vectors can be seen as red and green circles in Fig. 2. It is a binary classification problem where the SVM algorithm draws many lines to separate vectors according to true and false. After optimization, the SVM algorithm returns the best-fitted line for classifying the support vectors.

According to the equation of hyperplane:

$w \cdot X + b = 0$  Where X is a vector and w is a vector normal to hyperplane and b is an offset value.

The decision rules have been applied to classify the positive and negative value.

$$\vec{X} \cdot \vec{w} - c \geq 0$$

putting  $-c$  as  $b$ , we get

$$\vec{X} \cdot \vec{w} + b \geq 0$$

Hence,

$$y = \begin{cases} +1 & \text{if } \vec{X} \cdot \vec{w} + b \geq 0 \\ -1 & \text{if } \vec{X} \cdot \vec{w} + b < 0 \end{cases}$$

According to the above equation as in [24], the value  $w \cdot X + b > 0$  then it will be detected as a positive value (1) otherwise it will be a negative value (0). The proposed algorithm is used the ASD symptoms dataset to train the SVM model. The proposed algorithm to train the SVM model for the prediction of ASD symptoms has been given below.

*Proposed SVM Algorithm:*

*Pseudo Code:*

*Step 1: Read data from csv file.*

Step 2.  $X$ =data from csv

$x_1=[a_1,a_2, a_3,a_4,a_5, \dots \dots a_n]$  is a user text column inside the dataset.

$x_2=[r_1,r_2, r_3,r_4,r_5, \dots \dots r_n]$  is a label data column inside the dataset.

Step 3. Split the dataset as train data and test data.

```
train, test = train_test_split(X, test_size=0.2,  
random_state=1)  
X_train = train['text'].values  
X_test = test['text'].values  
y_train = train['label']  
y_test = test['label']
```

Step 4. Define NLP functions to pre-process text from  $X_{train}$  and  $X_{test}$ .

```
//Text tokenization  
tokenize_text=tokenizer(text)  
// Stop Words removal from text  
fresh_text = stopwords.words(text)  
// text to vector conversion using vectorization method  
vectorizer = CountVectorizer(  
    analyzer = 'word',  
    tokenizer = tokenize_text,  
    lowercase = True,  
    ngram_range=(1, 1),  
    stop_words = fresh_text)
```

Step 5. Call method to train SVM model.

```
// kfold has been used to send data as a bunch into the SVM model.  
kfold = StratifiedKFold(n_splits=5, shuffle=True, random_state=1)  
// Make the pipeline to send data inside the SVM model.  
pipeline_svm = make_pipeline(vectorizer, SVC(probability=True,  
kernel="linear", class_weight="balanced"))  
// SVM model initialization with parameters  
grid_svm = GridSearchCV(pipeline_svm,  
    param_grid = {'svc__C': [0.01, 0.1, 1]},  
    cv = kfold,  
    scoring="roc_auc",  
    verbose=1,  
    n_jobs=-1)  
// fit data inside the model to train  
grid_svm.fit(X_train, y_train)
```

Step 6. Predict the result using SVM model.

```
model= grid_svm.best_estimator_  
prediction = model.predict(X_test)
```

The result of this proposed algorithm has been discussed in the Result and Discussion section.

### C. Logistic Regression

The next approach is logistic regression which is able to identify ASD symptoms from user text. This is another machine-learning algorithm for binary classification problems. The logistic regression model works on finding the value between 0 and 1 and this algorithm is bounded. The logistic regression does not contain any relationship between input and output variables because of the nonlinear transformation to the odds ratio. Logistic regression can be defined as-

$$\text{Log}(p(M)/1-p(M))=\beta_0+ \beta_1X$$

$p()$ -> refers to the probability function.

$M$ -> refers to the input

Where  $p(M)/1-p(M)$  in the left side is termed as odds and the left side is called logit. The odds are the ratio of chance of success according to the chance of failure. In logistic regression, the linear input combination is transformed to  $\text{log}(\text{odds})$ .

The inverse of the above function will be:  $p(M)=(e^{\beta_0+\beta_1x} / 1+ e^{\beta_0+\beta_1x})$

This function is a sigmoid function that can be produced an S-shaped curve and it returns a value between 0 and 1. The main work of the sigmoid function is to generate a probability value from the expected value and this value always will be bounded between 0 and 1. The mathematical representation of the sigmoid function can be  $f(m) = 1/(1+e^{-m})$

Fig. 3 shows the S-shape curve according to the function-  
 $f(m) = 1/(1+e^{-m})$

Fig. 3. Sigmoid function according to the equation.

The proposed algorithm which is based on logistic regression has been given below.

Proposed Logistic Regression Algorithm:

Pseudo Code:

Step 1: Read data from CSV file.

Step 2:  $X$ =data from csv

$x_1=[a_1,a_2, a_3,a_4,a_5, \dots \dots a_n]$  is a user text column inside the dataset.

$x_2=[r_1,r_2, r_3,r_4,r_5, \dots \dots r_n]$  is a label data column inside the dataset

Step 3: Features generation using Vectorizer function.

// Vectorizer function converts the string value to number values.

```
vectorizer = CountVectorizer(  
    analyzer = 'word',  
    lowercase = False,)
```

// Feature creation using vectorizer.fit\_transform function

```
features = vectorizer.fit_transform(x_1)
```

// Feature array creation

```
features_nd = features.toarray()
```

Step 4: Model creation and training

//Logistic model creation

```
log_model = LogisticRegression()
```

// Logistic model train

```
log_model = log_model.fit(X=X_train, y=y_train)
```

Step 5: Prediction using Logistic Regression model  
 $y_{pred} = \log\_model.predict(X\_test)$

The output as a result of this proposed algorithm has been discussed in the Result and Discussion section.

#### D. K-Nearest Neighbor (KNN)

The third approach to identifying ASD symptoms from user text. KNN is a supervised algorithm that can be used in classification problems. This algorithm uses feature similarity to predict the value for a new data point that comes as input. KNN uses the similarity between new data points with available categorical data points and identifies this data point in a particular similar data point's category. KNN is very popular in binary classification. Fig. 4 shows before KNN prediction the new data point plotted on a graph where two categories of data points are present. Category A and Category B have been classified according to the nearest data points. According to Fig. 5, after applying the KNN algorithm, the new data point has been assigned as Category B because the nearest neighbor of the new data point is the data point of Category B.

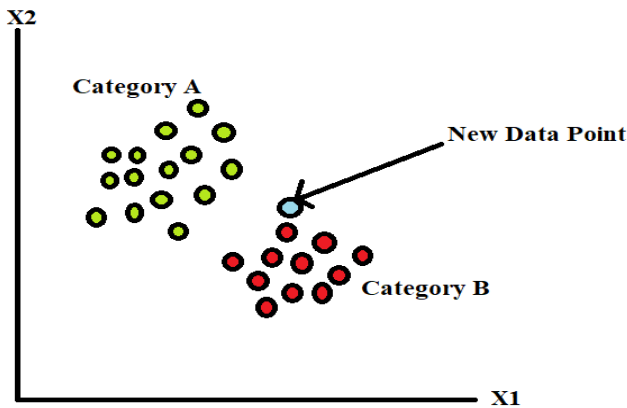

Fig. 4. Before the KNN algorithm is applied on a new data point.

Fig. 5. After the KNN algorithm applied on a new data point.

K is a parameter in KNN that is related to the number of nearest neighbors that are used to count the majority process. The first step of KNN is to transform data points into vectors where the KNN algorithm will calculate the distance of these vectors. KNN computes the distance of each data point of training data then it will calculate the probability of a new data point is similar to the training data. Euclidean, Minkowski or

Hamming distance functions can be used here to calculate the distance. The proposed algorithm is based on KNN that uses the proposed dataset.

Proposed KNN Algorithm:

Pseudocode:

Step 1: Read data from CSV file.

Step 2:  $X = \text{data from csv}$

$x_i = [a_1, a_2, a_3, a_4, a_5, \dots, a_n]$  is a user text column inside the dataset.

$y_i = [r_1, r_2, r_3, r_4, r_5, \dots, r_n]$  is a label data column inside the dataset

// Split the data in train and test format

$x\_train, x\_test, y\_train, y\_test = \text{train\_test\_split}(x_i, y_i, \text{stratify} = y_i, \text{test\_size} = 0.33)$

Step 3: String value to Vectorizer transformation.

// Vector function declaration

vectorizer = CountVectorizer()

// Vector transformation of x\_train

$x\_train\_bow = \text{vectorizer.fit\_transform}(x\_train)$

// Vector transformation of y\_train

$x\_test\_bow = \text{vectorizer.transform}(x\_test)$

Step 4: KNN Model creation

$\text{grid\_params} = \{ 'n\_neighbors': [40, 50, 60, 70, 80, 90], 'metric': ['manhattan'] \}$

$\text{knn} = \text{KNeighborsClassifier}()$

Step 5: KNN model training using prepared dataset

$\text{clf} = \text{RandomizedSearchCV}(\text{KNN}, \text{grid\_params},$

$\text{random\_state} = 0, \text{n\_jobs} = -1, \text{verbose} = 1)$

$\text{clf.fit}(x\_train\_bow, y\_train)$

Step 6: Prediction using KNN model

$\text{Prediction} = \text{clf.predict\_proba}(x\_test\_bow)$

The result of this proposed KNN-based algorithm has been discussed in Result and Discussion section.

#### E. Random Forest

The last approach is a Random forest machine learning algorithm to identify the ASD Symptoms from user text. This is one of the important machine learning algorithms which is constructed from decision tree algorithms. The Random forest algorithm is used to solve regression and classification problems. This algorithm is trained through bagging which is an ensemble algorithm. The ensemble algorithm is used to improve the accuracy of the machine learning algorithms. The outcomes of the random forest are based on the prediction of the decision tree. The mean of various decision trees is used to calculate the prediction value by the random forest algorithm. Decision trees in random forest algorithms use the tree view to generate prediction value from a series of feature-based splits where it starts from a root node and ends in a leaf node with a decision. Feature selection and the splitting process is depending on the impurity which means either result will be 'yes' or 'no'. To know about the impurity of the dataset, the Gini index [25] is a good option and that can be written mathematically-

$$\text{Gini Index} = 1 - \sum (P_i)^2$$

$$= 1 - [(P_+)^2 + (P_-)^2]$$

Where  $P_+$  is denoted as a probability of positive class and  $P_-$  is denoted as a probability of negative class. Gini Index will find out all the possibilities of splits and will choose the root node and this root node will be a low impurity means the lowest Gini index.

The proposed random forest-based algorithm has been given below which is utilizing the proposed dataset to train the model for the prediction of ASD symptoms from user text.

*Proposed Random Forest algorithm:*

*Pseudo code:*

*Step 1: Read data from CSV file.*

*Step 2: X=data from csv*

$x_1=[a_1,a_2, a_3,a_4,a_5,.....a_n]$  is a user text column inside the dataset.

$x_2=[r_1,r_2, r_3,r_4,r_5,.....r_n]$  is a label data column inside the dataset

*Step 3: Features generation using TFIDF Vectorizer function.*

*// Split data and assign for training and testing purpose*

$X_{train}, X_{test}, y_{train}, y_{test} = \text{train\_test\_split}(x_1, x_2, \text{test\_size} = 0.90, \text{random\_state}=42)$

$X_{train}, X_{test}, y_{train}, y_{test} = \text{train\_test\_split}(X_{train}, y_{train}, \text{test\_size} = 0.5, \text{random\_state}=42)$

$X_{val}, X_{test}, y_{val}, y_{test} = \text{train\_test\_split}(X_{test}, y_{test}, \text{test\_size} = 0.5, \text{random\_state}=42)$

*// TFIDF Vectorizer Function declaration*

*def vectorize(data,tfidf\_vect\_fit):*

$X_{tfidf} = \text{tfidf\_vect\_fit.transform}(data)$

$words = \text{tfidf\_vect\_fit.get\_feature\_names}()$

$X_{tfidf\_df} = \text{pd.DataFrame}(X_{tfidf}.toarray())$

$X_{tfidf\_df}.columns = words$

$\text{return}(X_{tfidf\_df})$

$\text{tfidf\_vect} = \text{TfidfVectorizer}(analyzer=\text{clean})$

$\text{tfidf\_vect\_fit}=\text{tfidf\_vect.fit}(X_{train}[\text{'text'}])$

$X_{train}=\text{vectorize}(X_{train}[\text{'text'}],\text{tfidf\_vect\_fit})$

*Step 4: Random Forest model initialization*

$\text{model}=\text{RandomForestClassifier}(\text{bootstrap}=\text{True}, \text{ccp\_alpha}=0.0, \text{class\_weight}=\text{None},$

$\text{criterion}=\text{'gini'}, \text{max\_depth}=20, \text{max\_features}=\text{'auto'},$

$\text{max\_leaf\_nodes}=\text{None}, \text{max\_samples}=\text{None},$

$\text{min\_impurity\_decrease}=0.0,$

$\text{min\_samples\_leaf}=1, \text{min\_samples\_split}=2,$

$\text{min\_weight\_fraction\_leaf}=0.0, \text{n\_estimators}=100,$

$\text{n\_jobs}=\text{None}, \text{oob\_score}=\text{False}, \text{random\_state}=\text{None},$

$\text{verbose}=0, \text{warm\_start}=\text{False})$

$X_{val}=\text{vectorize}(X_{val}[\text{'text'}],\text{tfidf\_vect\_fit})$

$\text{rf1} = \text{RandomForestClassifier}(\text{n\_estimators}=100,\text{max\_depth}=20)$

$\text{rf1.fit}(X_{train}, y_{train}.values.ravel())$

*Step 5: Prediction of Random Forest Model.*

$\text{Prediction} = \text{model.predict}(X_{val})$

The result of this algorithm has been discussed in the Result and Discussion section.

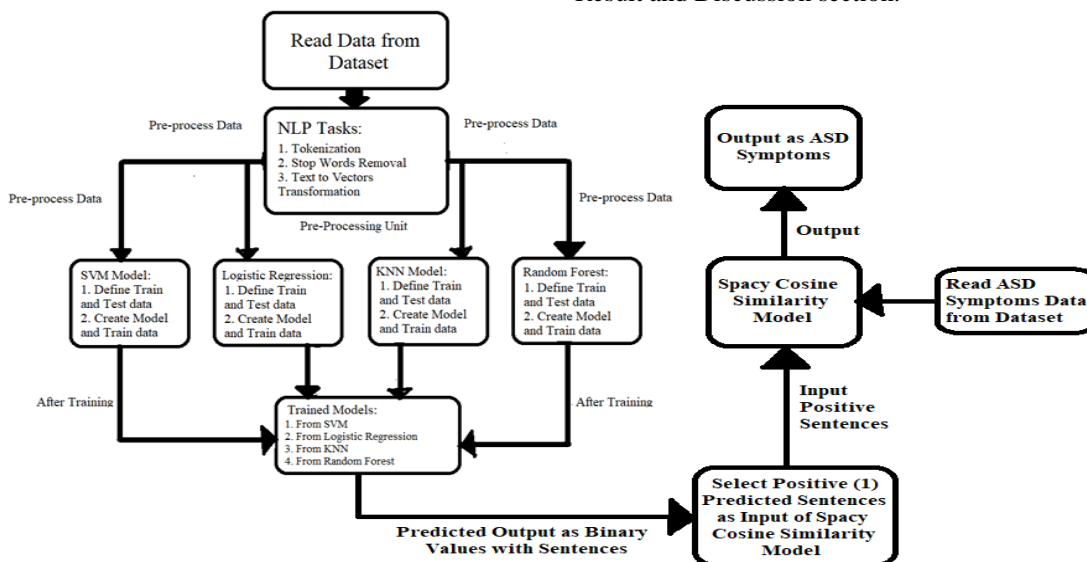

Fig. 6. Flow diagram of Proposed System Architecture

### F. Proposed System Flow

Fig. 6 shows the overall architectural diagram of the proposed system to identify ASD symptoms from user text. The proposed system will read data from the ASD symptoms dataset in the first step. Each sentence will be passed through some NLP tasks like tokenization, stop words removal, and text-to-vector transformation. Sentences are tokenized by the tokenization process of NLP where stop words mean unwanted words (tokens) like ‘am’, ‘is’, ‘a’, ‘an’, etc. are removed from the sentence. The final task is to transform each token into vectors. These vectors are the main input in each machine-learning model with labeled data. After vector transformation, data are separated into two parts which are training and testing data. According to Fig. 6, SVM, Logistic Regression, KNN, and Random Forest models are trained with the training data, and testing the prediction results with test

data. After completion of the model training and testing, the proposed system is ready to accept new paragraph text from the user to identify a number of positive sentences from the given text that denotes ASD symptoms. The predicted sentences will be in two modes either it will positive (1) or negative (0). The proposed system will select only the sentences that are positive and the negative sentences will be discarded in the next step. The selected positive sentences will be the input to the Spacy Cosine Similarity Model. This model will read each positive sentence from the ASD symptoms dataset (Table V) and calculate the cosine similarity with the input sentence. The Spacy cosine similarity model will check a sentence that has the highest cosine similarity score with the input sentence and the Label will be selected of this sentence by the system. The Label will indicate the ASD problem according to Table IV. Each input sentence will be handled by

this cosine similarity model to identify ASD problems. The algorithm has been given below.

```
Proposed Cosine Similarity algorithm:  
Pseudo code:  
Step 1: // Declare Python and Spacy packages  
import spacy  
import pandas as pd  
nlp = spacy.load('en_core_web_lg')  
// Initialize positive ASD symptoms data in a Dataframe  
Step 2: df = pd.read_csv("ASD_Smptoms.csv")  
// Three list variable has been declared to store each cosine  
similarity value with sentence and label  
comments=[]  
sentiment=[]  
cosine_value=[]  
Step 3: Define Cosine Similarity Calculation Method  
def Spacy_Cosine(strs):  
for ind in df.index:  
sen1 = nlp(df['Comments'][ind])  
sen2 = nlp(strs)  
  
sen1_no_stop_words = nlp(' '.join([str(t) for t in sen1 if not  
t.is_stop]))  
sen2_no_stop_words = nlp(' '.join([str(t) for t in sen2 if not  
t.is_stop]))  
  
comments.append(df['Comments'][ind])  
sentiment.append(df['Sentiment'][ind])  
  
score=sen2_no_stop_words.similarity(sen1_no_stop_words)  
# score=sen2.similarity(sen1)  
cosine_value.append(score)  
  
dfc=pd.DataFrame(  
{  
'Comments': comments,  
'Sentiment': sentiment,  
'Cosine_Scores': cosine_value  
})  
  
dfc.to_csv(r'ASD_Cosine_Data.csv')  
dfc['Cosine_Scores']=dfc['Cosine_Scores'].astype('float64')  
i = dfc['Cosine_Scores'].idxmax()  
  
return dfc['Sentiment'][i]  
Step 4: // Select only predicted positive (1) sentences as input  
Strs= List of predicted positive sentences  
for st in str['Comments']:  
result=Spacy_Cosine(st)  
print(st,"=",result)
```

The output of this proposed algorithm has been given and discussed in Result and Discussion section.

#### IV. RESULT AND DISCUSSION

The proposed system uses multiple traditional machine learning models which are SVM, Logistic Regression, KNN, and Random Forest. The proposed dataset has been utilized to train and test these models. The result of each model according to the dataset has been discussed here one by one.

##### A. Result and Discussion of SVM Model

Table VI has been given here to show the SVM model metrics after training and testing.

TABLE VI. SVM MODEL METRICS

Sl. No.	Metrics	Value
1.	AUC	0.77
2.	F1	0.74
3.	Accuracy	0.71
4.	Precision	0.71
5.	Recall	0.77

The SVM model has multiple metrics to understand the model's performance and scalability. According to Table VI, the AUC score is 77% which is a good score for any trained SVM model. The AUC refers to the area under the ROC curve that is a popular metric of SVM. If  $AUC = 1$ , then the model can distinguish correctly between positive and negative. If the condition is  $0.5 < AUC < 1$  then there is a high chance to distinguish between positive and negative. The F1 score of this proposed SVM model is 74% which refers to the combination of precision and recall scores which are 71% and 77% respectively. The overall accuracy of this proposed SVM model is 71% and this score is a good approach. According to the ROC curve, the higher Y-axis value denotes a higher number of true positives than false negatives as well as the higher X-axis value denotes a higher number of false positives than true negatives. According to Fig. 7, the ROC curve of this proposed SVM model shows a higher true positive rate than the false positive rate. This signifies that the proposed is able to generate good prediction results and this ROC curve indication satisfied this.

Fig. 7. ROC curve of proposed SVM model.

According to Fig. 8, the training scores line on the graph is between 0.99 and 0.94 (approx.) and the cross-validation scores line is between 0.70 and 0.79 (approx.). The gap between the two score lines is not very high. This proposed model is able to generate good prediction results according to the given Fig. 8.

Fig. 8. Training scores and cross-validation scores of SVM.

A few sentences have been sent to the proposed SVM model for the prediction. According to Fig. 9, the proposed model shows the output as 1 or 0, which is attached to each sentence. One (1) refers to a positive sentence regarding ASD detection whereas zero (0) refers to a negative sentence.

```

Result:How does speech therapy help with a nonverbal to speak=[1]
Result:because all they do there is play with toys with him every time=[1]
Result:I'm confused guys help my son is 3years old now=[0]
Result:he does is mumbles only no proper words=[1]
Result:but he goes to speech therapy every month=[1]
Result:Does it help=[0]
Result:My son is 5 and started speech therapy at 3=[1]
Result:My Son can't speak and always spin the wheels of a toy car=[1]
Result:She is 4 years old and reaping words=[1]
    
```

Fig. 9. Prediction result of SVM model as output.

### B. Result and Discussion of Logistic Regression

According to Fig. 10, a confusion matrix has been represented that refers to how many are true actual 1s, actual 0s, predicted 0s, and predicted 1s.

According to the test data, the proposed logistic regression model selects 75 sentences as actual 0s and predicted as 0s. Fifteen (15) sentences are actual 0s but predicted as 1s whereas 31 sentences are actual 1s and predicted as 0s. Forty (40) sentences are actual 1s and predicted as 1s. The following metrics for model evaluation have been given in Table VII. The AUC value is 0.69 (69%) which covers the ROC curve. The F1 score is 0.63 (63%) which combines the precision and recall values. The precision value is 0.72(72%) and the recall value is 0.56 (56%). The overall accuracy of the proposed Logistic regression model is 0.71 (71%). According to Fig. 11, the ROC curve, the higher Y-axis value denotes a higher number of true positives than false negatives as well as the higher X-axis value denotes a higher number of false positives than true negatives. The training accuracy is 0.97 (97%) whereas the testing accuracy is 0.70 (70%) on the proposed dataset according to Fig. 11.

Fig. 10. Confusion matrix of logistic regression model.

TABLE VII. LOGISTIC REGRESSION MODEL METRICS

Sl. No.	Metrics	Value
1.	AUC	0.69
2.	F1	0.63
3.	Accuracy	0.71
4.	Precision	0.72
5.	Recall	0.56

Fig. 11. ROC curves of logistic regression.

### C. Result and Discussion of KNN model

According to Fig. 12, two ROC curve has been represented that shows the accuracy of the proposed KNN model.

Fig. 12. ROC curves of KNN training and testing.

The AUC value of the proposed KNN model is 0.67 (67%) which refers to the high chance to distinguish positive and negative sentences. The AUC refers to the area of the ROC curves. The given two ROC curves stated that they are moving in almost the same manner from 0 to 1. The training accuracy is 0.80 (80%) as well as testing accuracy is 0.65 (65%) on the proposed dataset. It is another good metric that shows the ability of the prediction of the proposed KNN model. Accuracy is an important metric for machine learning model determination according to the task. The popular metrics have been given in Table VIII are useful to evaluate the machine learning model. The AUC value is already given as 0.67 (67%). The F1 score is 0.65 (65%) which combines the precision and recall values. The precision value is 0.65 (65%) and the recall value is 0.66 (66%). The overall accuracy of the proposed KNN model is 0.62 (62%).

TABLE VIII. KNN MODEL METRICS

Sl. No.	Metrics	Value
1.	AUC	0.67
2.	F1	0.65
3.	Accuracy	0.62
4.	Precision	0.65
5.	Recall	0.66

#### D. Result and Discussion of Random Forest model

The last proposed model is Random Forest which is a good classifier. The proposed dataset has been applied to this model to predict the sentiment of the sentences from the parents' dialogues. This model trains with the features after extracting these from the sentences.

Fig. 13. ROC curves of random forest.

Fig. 13 shows the two lines that are showing the accuracy graph of the proposed Random Forest model. The blue color line shows the accuracy of the training data as well as yellow line shows the accuracy of the testing data. According to Fig. 13, the accuracy score of this model on the testing data is 0.98 (98%), and 0.68 (68%) accuracy score on the testing data. According to Table IX, the F1 score is 0.73 (73%) which is combined two metrics values that are Precision and Recall. Precision refers to the measurement of the positive prediction of a model whereas recall refers to the positive cases that are correctly predicted by the model. The Precision value is 0.70 (70%) and the Recall value is 0.76 (76%). These two values have been defined in Table IX. The overall accuracy value of the proposed model is 0.69 (69%).

TABLE IX. RANDOM FOREST METRICS

Sl. No.	Metrics	Value
1.	AUC	0.68
2.	F1	0.73
3.	Accuracy	0.69
4.	Precision	0.70
5.	Recall	0.76

Fig. 14 shows the top 20 important features from all sentences of the prepared dataset that are also used in the model training. The frequency of each feature can be seen in Fig. 14. "poo", "autism", and "toilet", are three noted words with the highest frequencies. Other words are also given in Fig. 14.

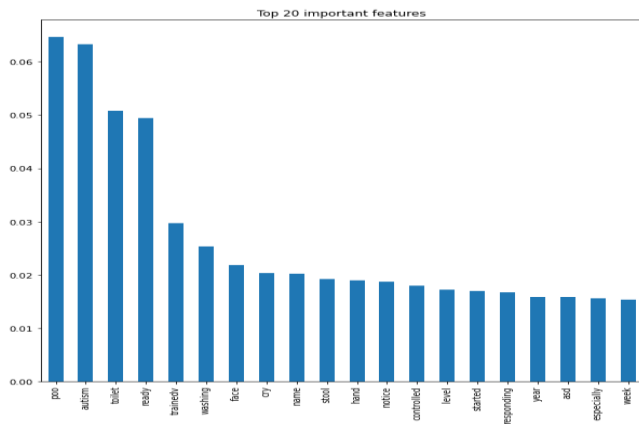

Fig. 14. Important features of proposed dataset.

### E. Result and Discussion of Spacy Cosine Similarity Model

The proposed model returns the ASD problem according to the positive sentences that contain ASD symptoms.

```
In [51]: runfile('F:/DeepL/Spacy_Cosine.py', wdir='F:/DeepL')
she cant understand where to do pee = 7

In [52]: runfile('F:/DeepL/Spacy_Cosine.py', wdir='F:/DeepL')
She is very aggressive and throwing objects to other = 8

In [53]: runfile('F:/DeepL/Spacy_Cosine.py', wdir='F:/DeepL')
Eyes are scrolling and hand flapping = 6
```

Fig. 15. Output of spacy cosine similarity model.

The output can be seen here in Fig. 15 where the sentence “she can’t understand where to pee” is labeled with 7. The sentences like “She is very aggressive and throwing objects to others” and “Eyes are scrolling and hand flapping” are labeled with 8 and 6. According to Table IV, 7 denotes Cognitive Behaviour problems whereas 8 refers to Hyper Active problems and 6 refers to the Eye contact problem. After the detection of ASD problems, therapies can be started according to the detected problem and that will be very helpful to reduce the ASD symptoms.

### V. LIMITATION OF THE PROPOSED SYSTEM

The proposed system has been equipped with traditional machine-learning models. The Probabilistic model like Naïve Bayes or ensemble model like XGBoost models can be applied to this dataset for better accuracy. More data can be collected for the training score and testing score enhancement. More accurate ASD-related parent dialogs-related to ASD are needed to train the model. If the dataset is large then this traditional machine learning model will not work better and that will downgrade the proposed system. If one part of this system is not responding then the cosine similarity part will not work perfectly.

### VI. CONCLUSION

The proposed system will accept natural language text from the parents’ dialogues. The proposed system will

generate positive or negative sentences using sentiment analysis. A sentence that contains ASD symptoms is 1 and a sentence that does not contain any ASD symptoms is 0. The sentiment analysis has been done using SVM, Logistic Regression, KNN, and Random Forest models. These models are trained with the proposed dataset. After prediction, the proposed system will select all positive sentences as input for the cosine similarity model. An ASD symptoms dataset has been proposed where each sentence is labeled with a value that indicates particular ASD symptoms. The proposed system will calculate the cosine similarity value between the input sentence and each ASD sentence of the ASD symptoms dataset. The proposed system will select a label value of an ASD symptoms sentence that has the highest cosine similarity value with the input sentence and this label value will indicate the ASD problem. This system is based on text and does not need to use MRI or Image data for the prediction of ASD at the early age of a child. This system may be used in many health centers in rural areas because people in rural areas are not aware of ASD as well as many of them are financially weak to spend money for MRI or other ASD diagnosis processes.

### VII. FUTURE WORK

The proposed dataset can be utilized to train the Naïve Bayes and XGBoost models for better output and accuracy. The cosine similarity model of this system depends on the prediction result of the traditional machine learning models. These models are good for small datasets but these models will not work with the best performance when the dataset is large. XGBoost is an ensemble model which is a very powerful model for prediction as well as the Naïve Bayes model is a probabilistic model that works on Bayes theorem. These two models implementation using a proposed dataset for ASD detection is the future development of this proposed system.

### ACKNOWLEDGMENT

The authors extend their appreciation to the Manipur International University, Imphal, India for supporting this Post-Doctoral (D.Sc.) research work on Autism.

Presently, He is working as a Data Scientist at Vodafone Intelligent Solutions, Pune, Maharashtra, India, and doing his Post Doctoral (D.Sc.) in Computer Science from Manipur International University, Imphal, Manipur, India.

Sourav Sadhukhan has above 5 years of experience in Law and Management. He completed his Graduation in LLB from Calcutta University, Kolkata, India, and Post Graduate Diploma in Management from Pune Institute of Business Management, Pune, India. Presently he is a student of Executive Post Graduation in Data Science and Analytics from the Indian Institute of Management, Amritsar, India.

Dr. Manish Godse has 27 years of experience in academics and industry. He holds Ph.D. from Indian Institute of Technology, Bombay (IITB). He is currently working as an IT Consultant in the Bizamica Software, Pune in the area of Artificial Intelligence and Analytics. His research areas of interest include automation, machine learning, natural language processing and business analytics. He has multiple research papers indexed at IEEE, ELSEVIER, etc.

Dr. Baisakhi Chakraborty received the Ph.D. degree in 2011 from National Institute of Technology, Durgapur, India in Computer Science and Engineering. Her research interest includes knowledge systems, knowledge engineering and management, database systems, data mining, natural language processing, and software engineering. She has several research scholars under her guidance. She has more than 60 international publications. She has a decade of industrial and 22 years of academic experience.

# Speaker Recognition Improvement for Degraded Human Voice using Modified-MFCC with GMM

Amit Moondra<sup>1</sup>, Dr Poonam Chahal<sup>2</sup>

Researcher<sup>1</sup>, Professor<sup>2</sup>

Department of Computer Science Engineering, Manav Rachna International Institute of Research and Studies, Faridabad, Haryana, India<sup>1,2</sup>

**Abstract**—Speaker’s audio is one of the unique identities of the speaker. Nowadays not only humans but machines can also identify humans by their audio. Machines identify different audio properties of the human voice and classify speaker from speaker’s audio. Speaker recognition is still challenging with degraded human voice and limited dataset. Speaker can be identified effectively when feature extraction from voice is more accurate. Mel-Frequency Cepstral Coefficient (MFCC) is mostly used method for human voice feature extraction. We are introducing improved feature extraction method for effective speaker recognition from degraded human audio signal. This article presents experiment results of modified MFCC with Gaussian Mixture Model (GMM) on uniquely developed degraded human voice dataset. MFCC uses human audio signal and transforms it into a numerical value of audio characteristics, which is utilized to recognize speaker efficiently with the help of data science model. Experiment uses degraded human voice when high background noise comes with audio signal. Experiment also covers, Sampling Frequency (SF) impacts on human audio when “Signal to Noise Ratio” (SNR) is low (up to 1dB) in overall speaker identification process. With modified MFCC, we have observed improved speaker recognition when speaker voice SNR is upto 1dB due to high SF and low frequency range for mel-scale triangular filter.

**Keywords**—GMM; artificial intelligence; MFCC; fundamental frequency; mel-spectrum; speaker recognition

## I. INTRODUCTION

Voice as a human identity is still a challenge for machine. Now businesses need to have effective speaker recognition though his/her voice in silent or in noise environment. Medical industries are also moving toward human voice based medical diagnosis. So human voice is not only identity of a person but also an aid in medical problem diagnosis. A human’s voice is identical to himself and always different from each other. Human creates audio from mouth and throat. Fundamental frequency is prime frequency, and it is transformed due to different vocal cord shapes and that create every human’s voice as identical voice.

Any speaker recognition process starts with voice feature extraction which is highly dependent on voice characteristics. Speaker recognition system is always designed similar to the mechanism that humans use to recognize two different speakers. A human generally identifies another human’s voice based on few classifications. Generally, humans first identify speaker’s gender, whether it’s male voice or female voice. Key differentiation between female and male voice is tone/pitch and

frequency. After gender identification human brain considers multiple voice features to classify speaker. Every person’s voice is identical, and it’s based on different voice characteristics like amplitude, pitch, frequency, jitter and spectral power. Male voice has 0-900 hz as prime or fundamental frequency and similarly fundamental frequency for female voice is 0-1500Hz. If we average out male fundamental frequency, then it is 110 hz and female average fundamental frequency is 211 Hz [1].

Human lungs generate air pressure to start sound and this sound is articulated by vocal cord. Teeth, jaw, and tongue are main articulators of vocal tract which modulate fundamental frequency (F0) [2][3]. This air pressure creates sound with prime or fundamental frequency. Fundamental frequency sound is transformed by the vocal tract to generate different sound changes. Human prime frequency or fundamental frequency is base frequency for any speaker recognition system. Following sub sections define different key voice features which are used for feature extraction in speaker recognition process.

### A. Fundamental Frequency and Pitch

Human voice signal consists of different sine waves with multiple frequencies. If we segregate all these waves and identify lowest sinusoidal wave frequency, then that frequency is considered as fundamental frequency (F0) of the human voice signal. F0 is also considered to calculate the pitch of the human audio signal. The perception of F0 and equivalent harmonics is generally known as voice pitch. The fundamental frequency value should come into a certain frequency range. Else, the pitch of the human voice signal is either extremely high or extremely low. Basically, fundamental frequency is indirectly proportional to the period of the human voice signal or directly proportional to sampling frequency [4]. If N is number of overlapped segments which divide complete voice signal and  $T_i$  denotes  $i$ th-segment period, then

$$F0 = \frac{1}{N} \sum_{i=1}^N \frac{1}{T_i}$$

### B. Jitter

Jitter is another audio characteristic of voice signal. It analyzes as periodic variation in F0 of voice signal. Frequency variation in voice signal is represented by Jitter. Jitter can be calculated as per [5]

$$Jitter = \frac{\frac{1}{N-1} \sum_{i=1}^{N-1} |T_i - T_{i+1}|}{\frac{1}{N} \sum_{i=1}^N T_i}$$

### C. Shimmer

Shimmer also represents variation, but focuses mainly on amplitude. When a speaker generates voice then that voice amplitude may vary. It may be high or low. This amplitude variation is the shimmer of the voice signal. If  $A_k$  is amplitude of cycle  $k$  and  $M$  is number of cycles of the voice signal then shimmer defined as

$$Shimmer = \frac{1}{M-1} \sum_{k=1}^{M-1} 20 \log_{10} \frac{A_k}{A_{k+1}}$$

Shimmer, fundamental frequency, pitch, and jitter are voice characteristics and are helpful during voice feature extraction process, which is defined in next section.

Speaker recognition is not easy when high background noise comes with speaker voice. When high noise comes with speaker voice then key human voice feature subsides and creates issue in speaker recognition. Most of previous research work uses MFCC as feature extraction method but it's still challenging with degraded human voice to extract optimized human voice features. The purpose of this research is to identify optimized feature extraction.

The paper is organized as follows: Section II is more about related work in same research topic; base model for speaker recognition is discussed in Section III which defines all necessary steps for speaker recognition system. In this section we also discuss about what is degraded human voice, and the data set. In Section IV we present baseline model results, proposed model with modified MFCC and results comparison, then we have concluded discussion in Section VI.

## II. RELATED WORK

N. V. Tahliramani and N. Bhatt [7] study presents that speaker can be recognized by a machine from the speaker's voice. MFCC is used to extract voice features during training and can also be used for speaker identification. Silence and noise can also be present alongside the speaker's actual voice during speaker recognition. According to the proposed model, noise and silence (between words) are removed before comparing the voice for similarity with the stored voice sample of the same speaker. Framing, windowing, low-pass filtration, and transformation techniques are employed to identify voice features. GMM is used during training and testing for speaker recognition. GMM increases the probability of correctly recognizing the speaker, even when noise is present in the speaker's voice.

S. Park, Y. Park, A. Nasridinov and J. Lee [6] study presents that conference call (closed user group) over any conference application requires gender identification. Gender can be recognized based on frequency of the speaker's voice and effectiveness of the speaker recognition process. Correct meeting notes can be created based on gender and speaker recognition methods. Female voice frequency (average 188-221Hz) is commonly high as compared to the male voice frequency (average 100-146Hz). Difference in frequency is used to recognize gender and correctly assign the person's ID.

"Text To Speech" API from Google is used to transform voice to text and create runtime Minutes of Meeting (MoM).

N. Gupta and S. Jain [21] presented that speaker recognition is possible through Convolutional Neural Network (CNN) based speaker recognition system. Siamese and CIFAR network architecture are used in speaker recognition. CNN base layers, convolutional, pooling and dense, are used in the model for pattern matching, recognizing deviation and pattern categorization. Negative and positive voice samplings are used for better speaker identification. Positive human voice sample is recorded when there is less distance between speaker and the microphone. When recording is done with some distance then it is considered as negative sample. Presented model for speaker recognition is built on "CIFAR" network architecture with shared weightage on "Siamese Network". Main purpose of "Siamese Neural Network" (SNN) is to learn the feature vectors. This type of speaker recognition system can be used more in places like bank and telecom.

M. M. Mubarak al Balushi, R. V. Lavanya, S. Koottala and A. V. Singh [23] proposed denoising technique for better speaker recognition. Study proposed that denoising can be performed in transformation domain and it gives different results with different wavelet transformation techniques. Denoising means suppression of the noise from speaker's voice. Denoising filter can suppress either the low frequency in the human voice when it notices it or increase in the voice where identifying that SNR is low. In addition, wavelet filter can filter the voice in the frequency domain. Proposed work is applicable for human and animal voice. Authors used Matlab programming tool to simulate results. Fejer- Korovkin wavelet filter has been compared with other available wavelet transformation filter to analyze noise elimination for better speaker recognition. Fejer- Korovkin & Dmey wavelets were verified for denoising. SNR and Mean Square Error (MSE) used as a parameter to check voice signal quality. Fejer-Korovkin results are 5% better than Dmey wavelet in terms of SNR.

R. M. Lexuşan [16] presented that, which voice features are the best features for human voice. Some of the key features of human voice are MFCC coefficient, energy of the voice signal, fundamental frequency of voice signal, duration and ratio of voice and unvoiced segment. This study also performed experiment which used 172 voice samples with happiness, sadness, and neutral states. Study also using "Support Vector Machine" (SVM) and decision tree as a classification method. Study shown that decision tree gives better recognition rate as compared to liner SVM. Study also concluded that algorithm provides approximately 85% recognition rate. With help of Nao robot, it's capable to recognize speaker emotions from the recording. Similarly, R. Chakroun, L. B. Zouari, M. Frikha and A. Ben Hamida [24] presented that Support Vector Machine (SVM) is more supportive with GMM for speaker recognition. GMM is more successful for speaker recognition when speaker voice is text independent. Study used GMM supervector in SVM, it's combining SVM results with GMM supervectors.

J. G. Liu, Y. Zhou, H. Q. Liu and L. M. Shi [25] studied multiple methods for noise elimination from speech for single channel speech betterment. It's observed that most of speech

enhancement analysis performed in frequency domain. The authors first analyzed Chi priori effects with weighted Bayesian estimator on speech and then incorporated “Speech Presence Uncertainty” (SPU) into the proposed estimator to derive an efficient hybrid priori SNR (HSNR) estimator. These methods give effective result to eliminate musical noise from speech and better speaker recognition process.

Thimmaraja Yadava G et al. [26] presented a pre-processing method for noise elimination which can be used in any speech recognition system specifically for Kannada speech (One of the Indian languages). It’s based on spectral subtraction “voice activity detection” (VAD). As per spectral subtraction, noisy speech data first need to segment first, and that segment need to overlap up to 50% in subsequent frames. The authors analyzed the noisy speech using autocorrelation spectral subtraction and periodogram methods and that is in Linear Prediction Coefficient (LPC). Noise elimination observed when subtracts the periodograms of additive noisy signal from corrupted speech signal.

M. N. A. Aadit et al. [27] have proposed white and colored noise suppression method with adaptive Kalman filter approach. The authors analyzed stationary and dynamic nature noise to retrieve the desired information from noisy Bangle speech. Proposed method is using recursive filter which is based on Kalman filter approach to improve speech signals which is corrupted by both static and dynamic noises. The authors also compare speech signal before noise elimination and after noise elimination to validate performance of proposed filter and it’s based on pitch value of speech, mean square error before and after noise elimination was between -0.4 to 0.2dB where SNR vary from -35 to -20.

Most of the researchers have suggested different type of filters, which are mostly effective when noise before and after human voice or when noise have different frequency which is not in human voice range. It’s easy to eliminate noise when noise has low frequency or high frequency as compared to male and female voice frequencies. Main concern is when human voice and noise comes together, and noise signal strength is high. Our experiment is focused in this area to address this issue.

### III. RESEARCH METHODOLOGY

This section details the speaker recognition baseline model, what is degraded human voice and details of dataset.

#### A. Speaker Recognition Base Model

When speaker voice come with high background noise then it is challenging to identify speaker with any speaker recognition system. Fig. 1 is showing basic process for any Speaker Recognition system.

Fig. 1. Speaker recognition process blocks.

1) *Preprocessing*: Preprocessing step is used to clean speaker data. When speaker voice come for identification then it can have high or low frequency noise. Generally different types of filters used to remove such kind of noises. Band Stop Filter (BSF) and “Low Pass Filter” (LPF) are common to filter noise from speaker audio. Butterworth filter is commonly used as band-stop filter [1].

2) *Voice feature extraction*: Voice feature or characteristics extraction is utilized to extract feature from speaker’s audio file. Extracted feature is used for speaker classification. There are multiple voice feature extraction methods and MFCC [6][7][8][9] is widely used. Linear Predictive Coding (LPC) [10] is also used for feature extraction. For feature extraction, MFCC uses following key steps [7][11][12] to identify cepstral coefficients. MFCC converts human voice into cepstral coefficient in matrix form and it is easy to use in classification step. Following steps may be used in combination also, based on application and source speaker voice.

- Framing and Blocking
- Windowing
- Fast Fourier Transform (FFT)
- Triangular Bandpass Filter (Mel Scale)
- Invers FFT

In our experiment we have also used MFCC and modify it for better speaker classification results.

3) *Classification*: MFCC output works as an input for speaker classification. Classification process differentiates one speaker from another speaker through speaker’s voice features. Speaker classification can be performed based on different type of available classifier. Different researcher used GMM [13][14], “Hidden Markov Model” (HMM) [15], “Support Vector Machine” (SVM) [16][17][18][19] and deep learning based “Convolutional Neural Network” (CNN) [10][20][21][22] classifier. In this article we have focused on most common classifier as GMM.

4) *Gaussian mixture model*: GMM is a probabilistic model and it’s another type of clustering algorithm. GMM creates different types of clusters, and every cluster is modeled as per different Gaussian distribution. In another word GMM generates data points which are derived from a mixture of a limited Gaussian distributions that has no known parameters. There are two approaches which help to drive these paraments. One is maximum a posteriori estimation and another is prior trained “Expectation-Maximization” algorithm. Generally, “Expectation-Maximization” clustering aka EM clustering is mostly used for speaker recognition.

#### B. Degraded Human Voice

Nowadays we can’t expect silence in public places and generally lot of background noises are also come with in speaker voice. Current need of speaker recognition system is to identify speaker from noisy environment. Efficiency of good

speaker recognition is dependent on the speaker’s audio quality. If speaker’s voice comes without any background noise, then it’s easy to recognize by machine as compared to high background noise human voice. We consider human voice as degraded human voice when high background noise with human voice. Such degraded human voice is not easy to recognize by machine. There are multiple articles [1][26][27][28] which used frequency-based noise elimination methods. If background noise is continuous and low as compared to speaker’s voice, then probability to recognize the speaker is high. But if background noise is impulsive (sudden high) and high as compared to speaker voice then probability of speaker recognition will decrease. This article mainly focuses on noise between words and sentences.

Generally, voice degradation is defined based on human voice and noise power. SNR signifies ratio of voice signal power to the noise power. SNR is indirectly proportional to the noise signal power. SNR is low when high noise signal power. Low values of SNR indicate highly degraded human voice. For example, if SNR is high like 12dB then that voice signal is good and have almost no noise in other if SNR is 1dB then this signal has lot of noise and hard to recognize speaker from this voice signal. If  $P_s$  is voice signal power and  $P_n$  represent noise signal (background) then SNR is

$$SNR(dB) = 10\log_{10} \left( \frac{P_s}{P_n} \right)$$

OR

$$SNR(dB) = P_s(dB) - P_n(dB)$$

### C. Data Set

In major speaker recognition applications, customer (speaker) training sample recorded in the silent environment or without noise environment but testing sample comes with lot of background noise.

In our experiment we have also used same mechanism that training sample is recorded in silent environment when no background noise is there but testing sample comes with different background levels. In general, two different datasets are used (human audio and noise) and merged them to create degraded human voice dataset. In our experiment we have not mixed two signals (human voice and noise) even instead we have created dataset as per real life scenario like human speaks in noisy environment. We have recorded human voice in noisy environment. It means in same room we have noise source and human voice. It’s not mixed of human voice and noise through any application. We have used 10x10 feet room and recoded human voice with air friction noise. During data creation we have recorded voice through “Microsoft Conexant ISST Audio” with driver version 10.0.18362.1

We have defined five different categories and each category has multiple male speaker voice for training and testing purpose. We have used voice sample from five categories based on SNR range as defined in Table I. SNR calculation is based on voice signal strength (with python noisereducer library) and noise signal strength as principally explained in sub section B of Section III.

TABLE I. DATASET SNR RANGES FOR TRAINING AND TESTING

Voice sample Category	SNR (dB) Range
A	10 to 12
B	8 to 10
C	3 to 5
D	2 to 3
E	1 to 2

Category A data has been used for training purpose and remaining four categories voice samples have been used for testing purpose. Speaker voice from Category-A has SNR in range of 10-12dB and power spectrum as define in Fig. 2.

Fig. 2. Power spectrum category-a sample.

Category B data has been used for testing purpose. Speaker voice from Category-B has SNR in range of 8-10dB and power spectrum as defined in Fig. 3. Category-B voice signal has slightly high background noise as compared to Category-A voice signal.

Fig. 3. Power spectrum category-b sample.

Category C data has been used for testing purpose. Speaker voice from Category-C has SNR in range of 3-5dB and power spectrum as defined in Fig. 4. Category-C voice signal has high background noise as compared to Category-A and Category-B voice signal.

Category D data also has been used for testing purpose. Speaker voice from Category-D has SNR in range of 2-3dB and power spectrum as define in Fig. 5. Category-D voice signal has high background noise as compared to Category-A and Category-B voice signal but there is not much different as compared to Category-C voice signal.

Fig. 4. Power spectrum category-c sample.

Fig. 7. Power spectrum analysis.

Fig. 5. Power spectrum category-d sample.

Category E data is also used for testing purpose. Speaker voice from Category-E has SNR in range of 1-2dB and power spectrum as defined in Fig. 6. Category-E voice signal has high background noise as compared to Category-A and Category-B voice signal but there is not much different as compared to Category-C and Category-D voice signal.

Fig. 6. Power spectrum category-e sample.

When we analyze power spectrum of Category-E sample then as per Fig. 7, yellow highlighted power is noise power before and after human voice and green highlighted is showing noise between words.

#### IV. EXPERIMENT AND RESULTS

##### A. Baseline Model and Results

As discussed in Section III, MFCC is used as voice feature extraction method and GMM for learning and pattern matching. We have used same device to produce different strengths of air friction noise. In all samples voice recorder remains same.

With baseline model, Samples from category A is used for training and other categories sample are used for testing purpose. As per experiment results, if SNR is reduced by 2dB then baseline model can't identify speaker voice as per Table II.

TABLE II. EXPERIMENT RESULT WITH BASELINE MODEL

Voice sample Category	SNR (dB) Range	Identify correctly
A	10 to 12	Training Sample
B	8 to 10	No
C	3 to 5	No
D	2 to 3	No
E	1 to 2	No

##### B. Proposed Model and Results

Proposed model is also based on MFCC and GMM. On top of baseline model, we have performed three steps modification at MFCC level. We proposed GMM model with modified MFCC for feature extraction. When feature extraction provides more information at MFCC coefficient level then GMM also adopts this information and improves speaker recognition performance. Similar approach is used with TIMIT dataset and CNN [28]. Environment and data set are also remaining same as in baseline model. Only modification is performed at feature extraction level.

##### Step-1: High Sampling Rate

Sampling rate is key factor to identify voice feature. High sampling rate captures more signal dissimilarity info as compared to low sampling rate. We have increased sampling rate from 22050 to 44100 and identified test result as per Table III.

TABLE III. EXPERIMENT RESULT WITH PROPOSED MODEL STEP-1

Voice sample Category	SNR (dB) Range	Identify correctly
A	10 to 12	Training Sample
<b>B</b>	<b>8 to 10</b>	<b>Yes</b>
C	3 to 5	No
D	2 to 3	No
E	1 to 2	No

Table III shows slight improvement in test result for classification of the speaker when SNR in range of 8-10dB.

Step-2: Frequency Range for mel-scale triangular filter bank

As per Section III, MFCC uses Mel-scale triangular bandpass filter. These filters use low and high frequency range to create triangular filter bank. Human male fundamental frequency comes in range of 0-900Hz. If we create mel filter bank in just twice from male fundamental frequency ~1800Hz then it mostly captures human voice relevant information for speaker recognition process and avoid noise information which occurs in between the words. Optimization of frequency range for triangular bandpass filter gives benefit to filter out background noise.

Table IV shows results when we create mel-scale filter bank from 0 to 1800 Hz (high frequency as 1800 Hz) during MFCC coefficient calculation.

TABLE IV. EXPERIMENT RESULT WITH PROPOSED MODEL STEP-2

Voice sample Category	SNR (dB) Range	Identify correctly
A	10 to 12	Training Sample
<b>B</b>	<b>8 to 10</b>	<b>Yes</b>
<b>C</b>	<b>3 to 5</b>	<b>Yes</b>
D	2 to 3	No
E	1 to 2	No

Table IV shows good improvement in test result for classification of the speaker when SNR in range of 8-10dB, 3-5dB and 2-3dB sample category. But still Category-E sample is not classified correctly because of very low SNR.

Step-3: Pre-emphasis Effects

Humans generate sound with fundamental frequency at 0-900Hz for male and up to 1500Hz for female. Vocal tract modulates this voice and generates modulated voice. This modulated voice is suppressed by high frequency voice. The objective of pre-emphasis is to compensate on the high-frequency part that was suppressed during the sound generation by the humans [29]. When we look voice power spectrum of data set in Fig. 4 to 7 then we can realize that spectrum power is more on lower frequencies and it's reducing at high frequency. So, it is required to boost the energy levels at the high frequencies. Pre-emphasis is one of the key steps in feature extraction process and is considered during MFCC coefficient calculation. Fig. 8 is showing low power level when frequency is more than 1500Hz (approximately).

Fig. 8. Power spectrum freq > 1500Hz.

In general, when MFCC coefficient is calculated by different libraries like "python\_speech\_features" then standard value is 0.97 and when we used same pre-emphasis values then we have not received much gain in speaker recognition accuracy. In our experiment we optimized pre-emphasis value and make it at 1.00 then we have received results as per Table V. It's also observed that if we tune pre-emphasis values from .90 till 1.10 then result values getting changed and is not much effective like at pre-emphasis = 1.00.

TABLE V. EXPERIMENT RESULT WITH PROPOSED MODEL STEP-3

Voice sample Category	SNR (dB) Range	Identify correctly
A	10 to 12	Training Sample
<b>B</b>	<b>8 to 10</b>	<b>Yes</b>
<b>C</b>	<b>3 to 5</b>	<b>Yes</b>
<b>D</b>	<b>2 to 3</b>	<b>Yes</b>
<b>E</b>	<b>1 to 2</b>	<b>Yes</b>

## V. CONCLUSION

Different speaker recognition systems are required for various applications. Most applications seek a speaker recognition system that functions well without any background noise during training, but same system should recognize speaker even with degraded human voice. In our experiment, we addressed this issue and utilized speaker voices with minimal background noise (SNR = ~11dB) during training, and tested the system's performance with degraded human voices at SNRs as low as 1dB. According to Section IV of our experiment, we observed that high sampling rate, optimized frequency range for the triangular mel bandpass filter, and optimized pre-emphasis value, all contribute to the effectiveness of the feature extraction mechanism for calculating MFCCs in the speaker recognition process. In future, this experiment could be expanded to include different datasets comprising voices of various genders and languages. Modified MFCC can also tested with K-Nearest Neighbor (KNN) and Random Forest [30].

#### AUTHORS' PROFILE

Amit Moondra received the Master of Engineering degree in Communication Engineering from the Birla Institute of Technology and Science, Pilani, India (BITS - Pilani). He has more than 20 years of industrial and research experience with 10+ across countries. He is currently working in Ericsson Global India Limited as Senior System Manger in Product Development Unit and pursuing his Ph.D. at Manav Rachna International Institute of Research and Studies. India. His research focuses on artificial intelligence, deep learning model in speech area. He is an active member of IEEE.

Poonam Chahal received her Ph.D. in 2017 from YMCA University of Science and Technology, Faridabad India, in the field of Artificial Intelligence. Presently she is working as Professor in Department of Computer Science and Engineering at FET, Manav Rachna International Institute of Research and Studies, Faridabad. She is actively involved in research activities and is on the reviewing panel of many journals and conferences.

# Application of Conv-1D and Bi-LSTM to Classify and Detect Epilepsy in EEG Data

Chetana R\*, A Shubha Rao, Mahantesh K

Department of Electronics and Communication Engineering,  
SJB Institute of Technology, Bangalore, Karnataka, India

**Abstract**—EEG is used to study the electrical changes in the brain and can derive a conclusion as epileptic or not, using an automated method for accurate detection of seizures. Deep learning, a technique ahead of machine learning tools, can self-discover related data for the detection and classification of EEG analysis. Our work focuses on deep neural network architecture to visualize the temporal dependencies in EEG signals. Algorithms and models based on Deep Learning techniques like Conv1D, Conv1D + LSTM, and Conv1D + Bi-LSTM for binary and multiclass classification. Convolution Neural Networks can spontaneously extract and learn features independently in the multichannel time-series EEG signals. Long Short-Term Memory (LSTM) network, with its selective memory retaining capability, Fully Connected (FC) layer, and softmax activation, discover hidden sparse features from EEG signals and predicts labels as output. Two independent LSTM networks combine to form Bi-LSTM in opposite directions and appreciate added visibility to upcoming information to provide efficient work contrary to previous methods. Long-term EEG recordings on the Bonn EEG database, Hauz Khas epileptic database, and Epileptic EEG signals from Spandana Hospital, Bangalore, assess performance. Metrics like precision, recall, f1-score, and support exhibit an improvement over traditional ML algorithms evaluated in the literature.

**Keywords**—1D CNN; bidirectional LSTM; dataset (DS); deep learning; electroencephalogram (EEG); LSTM

## I. INTRODUCTION

Epilepsy is a neural sickness portrayed by a sudden attack called seizures due to strange initiation by the networks of neurons [1]. The abrupt behavior of electrical movement causing disorder inside mind is due to abnormalities, lack of oxygen during labor, and reduction in blood sugar. A seizure is a time of irregular excitation of neurons lasting from seconds to a minute [2] and upsets the body. These seizures are not quickly perceived, which is a significant issue. Now researchers are exploring and assessing seizures in the beginning phase utilizing Electroencephalogram (EEG). The strange enactment is the voltage alteration due to the flow of current by the ions in the neurons, demonstrating the cerebrum's bioelectric phenomena [3] converted to electrical action and looked through electroencephalography (EEG). The recording is done to gauge the voltage motions in brain and changed to time series data called signals, characterized by spikes, sharp waves, or a combination of both. EEG signals are preferred in the frequency domain since they are convenient and give clarity [4]. Diagnosing epilepsy with EEG signals is tedious and arduous, and human mistakes are a

possibility, so that a machine-based determination would be better.

Therefore data-preprocessing is done by normalizing the input variables. Features are extracted and selected from EEG signals in time, frequency, or in the time-frequency domain, like spectral, amplitude, entropy, wavelet, statistical, non-linear features, etc., and passed to the classification process. Because EEG patterns are exceptionally unique and may be unsuccessful for slight differences, time-series information is considered for dynamic examination since methodologies based on domain features have impediments.

Machine learning and deep learning strategies are predominant for learning, to prove the model with complex real-world information. We achieve crucial data collection by creating robust features [5], so the deep neural network can distinguish between seizure and non-seizure events. It concentrates on computational models and learns through non-linear transformations like neural networks. Initially, neural networks required more calculation time. Subsequently, they didn't get consideration, yet presently, due to enormous datasets and complex Graphic Processing Units (GPUs), it has given scientists an economical and robust arrangement, permitting them to examine deep learning models. Without prior knowledge of the dataset, neural networks have improved their boundaries repeatedly.

Work here demonstrates a one-dimensional Convolution Neural Network (1D-CNN) model to learn high-level representations from filtered EEG signal data for seizure detection and classification after reviewing the available research. However, increasing the convolutional layers can eventually obtain strong and conclusive features, with simplicity and efficiency being the most important advantages of this type of network. 1D-CNNs are naturally apt for handling biological signals like EEG for seizure detection [6] by using pooling and convolutional layers. In addition to that, signals are 1D in nature, and using preprocessing methods there is no information loss.

Next, the one-dimensional Convolution Neural Network Long Short-Term Memory (1D CNN-LSTM) model is proposed, with preprocessing applied to the raw EEG signal and normalized features effectively extracted by 1D-CNN. The obtained characteristics handled by LSTM layers extract temporal features and passed to fully connected layers before conclusion as epileptic or not. Results obtained demonstrate the proposed model exhibits identification recognition correctness in classifying epileptic seizure recognition tasks as

binary and multiclass, respectively. The 1D CNN-LSTM model comprises one input layer, six convolutional layers, three pooling layers, two LSTM layers, one fully connected (FC) layer, and three dropout layers.

The modified version of the Recurrent Neural Network (RNN) is LSTM, and it is tough to train standard RNNs because of vanishing and exploding gradient problems [7]. The identity function of derivative 1 happens as the activation function, thus preventing the gradient from vanishing or exploding. The Bi-LSTM architecture selected consists of 64 forward and 64 backward LSTM cells per layer. Bidirectional long short-term memory (Bi-LSTM) network explores seizure detection and classification in this research. Bi-LSTM evolved considering the merits of LSTM and Bi-RNN [8]. Processing happens in two opposite directions, thereby improving performance. When compared with CNN models and Bi-LSTM models on time series data, the time dependencies of the signal are described poorly in CNN models but well in Bi-LSTM models.

## II. LITERATURE SURVEY

Numerous procedures are employed to obtain EEG signal features for seizure detection. In [9], integrating with extreme learning machine (ELM), features like approximate entropy and sample entropy are employed. In [10], non-sampled wavelet-Fourier features are incorporated for seizure detection, with a considerable quantity of continuous EEG recordings being the limitation. Combining wavelet decomposition with directed transfer function (DTF) for feature extraction is used in [11]. Still, the limit here is the existence of muscle artefacts in scalp EEG recordings. However, better results can be expected if an intracranial electrocorticogram (ECoG) uses subdural grid electrode implementation. In [12] authors suggested a unique feature as a matrix determinant for EEG analysis. For noise removal, researchers proposed a Bandpass filter to enhance SNR in intracranial EEG signals to obtain a sensitivity more significant than 80% and specificity ranging between 75% and 88%. Correspondingly, sensitivity, specificity, and accuracy of 77.10%, 71.63%, and 75.07% are obtained [13], demonstrating weak execution. Linear Discriminant Analysis (LDA) [14] and Bayesian classifier [15] comprise the machine learning classifiers and Convolutional Neural Networks (CNN) [16] as deep learning classifiers with no perfect prediction available. Positive results are obtained using Long Short-Time Memory Units (LSTMs) [17]. However, the investigation by collecting additional experimental data and fusing it to develop new AI algorithms improves upon existing applications.

Robust features [18] with single-channel epileptic EEG signals automatically learn using machine learning and deep learning techniques. Research should focus on algorithms capable of handling complex multichannel epileptic EEG signals. Using discrete wavelet transform (DWT) and K-means with multilayer perceptron (MLP) for classification in [19] is implemented. Though deep CNN-based architecture obtains prominent features from raw EEG data to detect seizures, overlapping among seizure and non-seizure events happens. It becomes tedious to construct a generic technique

to obtain high sensitivity [20]. In [21] a hybrid ensemble learning framework that systematically combines pre-processing methods with ensemble machine learning algorithms specifically, principal component analysis (PCA) and t-distributed stochastic neighbor embedding (t-SNE) combined along k-means clustering followed by ensemble learning such as extreme gradient boosting algorithms (XGBoost) and random forest is considered. However, in [22], using 13 layers, deep CNN architecture is considered.

Nevertheless, the drawback is the lack of a vast EEG database. Researchers demonstrated the deep belief nets (DBN) mechanism for modelling EEG data [23]. The training time using K Nearest Neighbor (KNN) and Support Vector Machine (SVM) took a few hours to a few days, but with DBNs, it took a few days to more than a week.

Using two parallel 1D-CNN blocks, a stacked 1D-CNN model is implemented with a random selection and data augmentation (RS-DA) strategy to overcome sample imbalance in [24] but with Two-Dimensional Convolution Neural Network (2D-CNN) and LSTM, collectively with RS-DA, thorough assessments with statistical, entropies, frequency, or time-frequency domain features, etc., can be derived and combined to 1D-CNN model as input. A generic auto-detection method, robust to noise, is used in [25]. Inputs are the digital version of the EEG recordings to the model, which aids the neurologists in detection. The limitation is the SNR value decreases the classification accuracy. A key reason for using Bi-directional LSTM in [26] is they look after the time dependencies both in a forward and backward direction. The authors in [27] use spectral feature-based two-layer long short-term memory (LSTM) model. The segments considered are in the frequency domain. In [28], an automated epilepsy detection system implementing wavelet decomposition and a 1D-CNN, along with Bi-LSTM, is incorporated. But the limitation is its inability to detect the occurrence of seizure at 512 Hz as the sample rate. However, the decimation of samples can enable the model at 256 or 512 Hz sampling rate to identify epileptic seizures.

## III. DATASETS

Before we begin the experiment with the results and analysis, discussion on the various datasets being used in the work is being dealt with.

### A. Bonn EEG – UCI Machine Learning Repository: Epileptic Seizure Recognition Dataset

We expect to characterize the different classes of the Bonn EEG dataset into five categories named class1, class2, class3, class4 and class5, each having 100-single channel sections of EEG. Every single channel is 23.6s recording at a sampling frequency of 173.61 Hz. The comparing time series inspects 4097 data focused on separating and rearranging into 23 pieces, each containing 178 data of interest every second. The data of interest is the EEG recording at the alternate moment. The recording is of both healthy and epileptic patients. Class 1 contains EEG signals from epileptic seizure sections, and EEG signals originating from the tumor zone belong to Class 2. Class 3 has signals from the healthy brain area of the tumor found in the brain. Class 4 contains EEG information on

healthy volunteers with closed eyes. EEG data of subjects with open eyes belong to Class 5 (Fig. 1).

The 178 information are X1, X2, X3... X177, X178 the logical factors with various classes labeled y (Fig. 2). For 500 patients, we get 11500 columns (23X500= 11500). Each of the 178 pieces of information is put in sections as columns and 11500 examples as lines or rows and named the information from [1-5] as the last segment (segment y). People other than one category, i.e., 2,3,4,5, classes are non-epileptic.

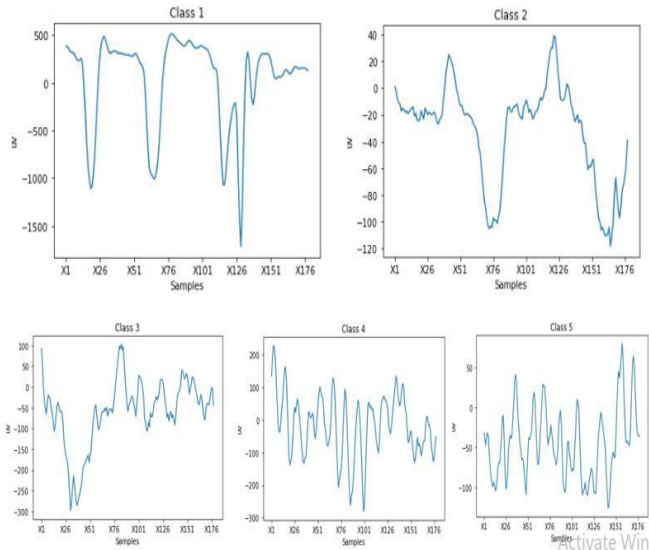

Fig. 1. Plot of each class.

Unnamed: 0	X1	X2	X3	X4	X5	X6	X7	X8	X9	...	X170	X171	X172	X173	X174	X175	X176	X177	X178	y	
0	X21.V1.791	135	190	229	223	192	125	55	-9	-33	...	-17	-15	-31	-77	-103	-127	-116	-83	-51	4

2	X8.V1.1	-32	-39	-47	-37	-32	-36	-57	-73	-85	...	57	64	48	19	-12	-30	-35	-35	-36	5

3 rows x 180 columns

Fig. 2. Datapoints with label.

**B. Neurology and Sleep Centre, Hauz Khas, New Delhi**

The EEG recording uses the Comet AS40 EEG machine and 200 Hz as the sampling rate. Signals ranging between 0.5 to 70 Hz undergo filtering and are divided into pre-ictal, interictal and ictal stages. The duration of the EEG portion in this archive is 5.12s with 1024 examples.

There are three folders that are named according to the epileptic seizure stages and each folder contains fifty files of EEG time series. Each segment is considered as an instance. In total, 150 instances are considered belonging to each intended class.

**C. Spandana Nursing Home Dataset, Bangalore**

An ongoing EEG Data is being utilized for the location of epilepsy. Twenty EEG accounts of epileptic patients with 10 EEG signals during seizures and 10 EEG data from a sound volunteer with open eyes are considered. The sampling rate is 175 Hz. Filtering for signals ranging between 0.5 to 60 Hz is done. The universally perceived technique to portray areas of various electrodes on the scalp is utilized, which depends on

the connection between the primary regions of the cerebral cortex. The number '10' - '20' suggests the distance between every terminal from each other is 10% or 20% of the absolute right-left or front-back space of the skull. A letter has been assigned to each site for lobe recognition, and a number is assigned to distinguish the cerebral hemisphere area. Even numbers 2, 4, 6, and 8 indicate the right of the brain for the electrode position of the brain, and odd numbers 1, 3, 5, and 7 mean terminals on the left part. The crude signals acquired are switched over entirely to ASCII design. EDF (European Data Format) Browser programming is utilized, an open source, universal viewer, multiplatform, and tool kit for conversion. The classifier tool is in such a way if the output is '0', it is epileptic or abnormal EEG, and '1' indicates normal EEG or non-epileptic EEG.

**IV. PROPOSED METHODOLOGY: DEEP LEARNING ALGORITHMS AND MODELS**

The proposed technique introduces three different methodologies for adequate recognition and classification of an epileptic seizure. EEG as input is a Comma Separated Values (CSV) document. When the input document is perused and switched over entirely to a python data frame, the information is standardized, split for training, validation, and testing in the proportion of 6:2:2 and labels are changed over into One Hot Encoded design. The architecture's performance is analyzed for Multiclass (1,2,3,4,5) and Binary Classification (1/0). All the presented models are examined by training for up to 40 epochs using Categorical Cross Entropy as a loss function.

**A. Method-1: Based on Conv1D**

In the proposed method 1, the EEG information is examined by applying Convolution, and a deep learning method is prominently used to analyze time series data. Direct and quicker design models are presented because the boundaries are low. Pooling and convolutional layers with bigger size are utilized in 1D models and, when applied, produces a kernel of determined size(m) which is convolved with the input(x) to create the filtered output(y) whose dimensionality will be equivalent to the number of kernels(n). Conv1D is fit for learning features (w) concealed in the series of time sequence data.

$$y_i = \sum_{-m}^m x_{i-k} w_k \tag{1}$$

In the output expressed as the above equation, k is the counter value ranging from -m to +m, covering the length of the kernel. Initially, considering 1D data of the EEG signal with the feature vector, it is convolved along with the filter to acquire a feature map. 1D data is ordered along a single line data organized by time and fits on a 1D line. Convolution takes a kernel (internal weights) of a filter and a sliding dot product with the signal. The process of multiplying each aligned pair of points and adding all products is called the dot product.

Since we are sliding, the data gets overlapped, and the representation is as below.

$$x = \{x_0, x_1, x_2, \dots \dots x_{m-1}\} \tag{2}$$

$$w = \{w_0, w_1, w_2, \dots, w_{n-1}\} \quad (3)$$

$$y = \{y_0, y_1, y_2, \dots, y_{m-1}\} \quad (4)$$

Losses are overcome by backpropagation, and the above equations are explicitly differentiated concerning gradients through layers. The partial derivative of loss for y is propagated back to calculate the partial derivative of loss for x through every network using the chain rule and the loss to each input given by.

$$\frac{\partial L}{\partial x_i} = \sum_{j=0}^{m-1} \frac{\partial L}{\partial y_j} \frac{\delta y_j}{\delta x_i} \quad (5)$$

Therefore, input gradient = output gradient (W), where  $W = \frac{\delta y_j}{\delta x_i}$  should be known and so the layer is differentiable. The architecture consists of a series of Conv1D layers followed by MaxPool layer. It reduces spatial size, number of parameters and computation while aggregating the dominant features, thereby reducing the dimensionality. The most well-known pooling strategy is max pooling. Max pooling alludes to getting maximum value after each pooling activity and the data is flattened. Flatten concatenates the results from the convolution layers to frame a flat structure taken as input to dense layer. A fully connected layer or Dense network helps to classify based on features. It is a dense network of neurons, and every neuron is connected to the previous and subsequent layers. If there are multiple dense layers, then the last layer has output as the same number of the classes or categories. The linearity principle is used in Dense Layer, where the outcome depends on every input. The activation function utilized is the SoftMax activation which adds learning capacity to neural networks by learning complex patterns and multiplying weights with the input features and concluding regarding firing. Activation functions make the network non-linear, else it becomes linear. For example, output relies

linearly upon the input features. SoftMax activation is the most ordinarily busy work as final layer in neural network for multiclass classification, being a blend of different sigmoid which works out the general probabilities and standardizes neural network results to fit between 0 and 1. The SoftMax probabilities will constantly aggregate to 1. The architecture of the proposed Method-1 can be seen in Fig. 3. The results obtained using Method-1 to determine the metrics like Accuracy, Precision, Recall, F1- Score and Support with DS1, DS2 and DS3 for multiclass and binary classification are shown in Table I (A) and Table II (B) respectively.

$$S(Y)_i = \frac{e^{Y_i}}{\sum_{j=1}^n e^{Y_j}} \quad (6)$$

**B. Method-2: Based on Conv1D+LSTM**

The architecture with a mix of Convolution (Conv1D) and Long Short-Term Memory (LSTM) is proposed as method 2. Input is passed to Convolution, MaxPool, and dropout layer before executing with the next layer, where it invalidates a portion of the neurons towards the following layer by randomly setting the input units to 0, thus forestalling overfitting and consequently evades the network from depending on a single neuron. Typically, dropouts are put on fully connected layers. Dropout might be carried out on any hidden layer or input layer in the network, yet not utilized on the output layer.

Fig. 3. Architecture of the proposed method-1.

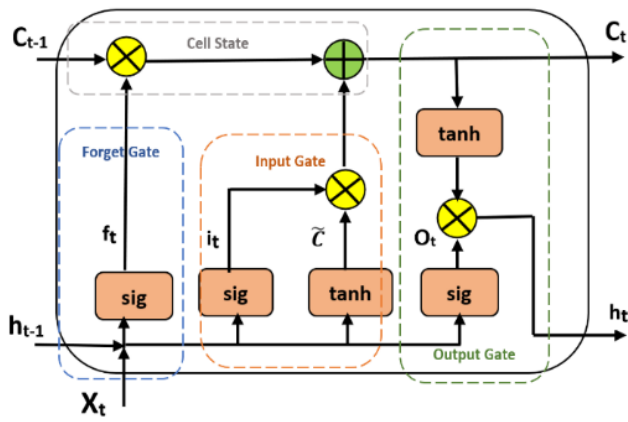

Fig. 4. Cell of LSTM.

Fig. 5. Architecture of the proposed method-2.

LSTM is based on recurrent neural networks capable of learning, remembering, and processing information from a series of data distributed over time and, accordingly, is slow. LSTMs, with their specially designed gates, process the data linearly while deciding against retaining the learnt feature is good or forgetting it and moving forward. The LSTM gates use sigmoid activation ( $\sigma$ ) as shown in Fig. 4. The architecture of the proposed method 2 is seen in Fig. 5. It has been observed in the conducted research that using many filters results in hindering the model from learning. Long Short-Term Memory (LSTM) networks are fit for learning to rely on the sequence and handle the disappearing gradient issue.

Sigmoid and tanh functions are two normalizing conditions utilized in LSTM. The sigmoid function implies a mechanism attempting to compute a bunch of scalars in the range of 0 and 1. The tanh function tells a system trying to change the information into a standardized data encoding between - 1 and 1. Inputs are multiplied by different frameworks of weights and added together. Feature extraction is done when the sigmoid function crushes the outcome between 0 and 1 when added with bias and applied. Though training is lengthy, it glances at the long sequence of inputs without expanding the network size. An LSTM network empowers to include sequence information in the network and makes forecasts relying on individual time stamps.

The LSTM cell is shown in Fig. 4. To replace memory, the Input gate finds the value. The second sigmoid function accepts current state  $x_t$  and previously hidden state  $h_{t-1}$  and concludes values to let through as 0 (critical) or 1(not critical).

Furthermore, the tanh function gives weightage to the qualities which are passed to create a vector  $\tilde{C}_t$  concluding their degree of significance from - 1 to 1.

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \quad (7)$$

$$\tilde{C}_t = \tanh(W_c[h_{t-1}, x_t] + b_c) \quad (8)$$

where  $t$  = timestamp,  $i_t$  = input gate at  $t$ ,  $W_i$  = Weight matrix of sigmoid operator between input gate and output gate,  $b_i$  = bias vector,  $\tilde{C}_t$  = value generated by tanh,  $W_c$  = weight matrix of tanh operator between cell state information and network output,  $b_c$  = bias vector concerning  $W_c$ .

Based on the block's input and memory, the output gate result is chosen, and current and previous hidden state values are passed to the third sigmoid. The function tanh accepts new cell state generated, and outputs are multiplied point-by-point. The final value decides the hidden state to carry the information. Therefore, a new cell state and a new hidden state are passed to the next timestamp.

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \quad (9)$$

$$h_t = o_t * \tanh(C_t) \quad (10)$$

where  $t$  = timestamp,  $o_t$  = output gate at  $t$ ,  $W_o$  = Weight matrix of output gate,  $b_o$  = bias vector with respect to  $W_o$ ,  $h_t$  = LSTM output.

Related data from the earlier process is found by forget gate. The sigmoid function is passed with the current input  $x_t$  and hidden state  $h_{t-1}$ , and value derived is implemented for point-by-point multiplication.

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_o) \quad (11)$$

where  $t$  = timestamp,  $f_t$  = forget gate at  $t$ ,  $x_t$  = input,  $h_{t-1}$  = previous hidden state,  $W_f$  = weight matrix between forget gate and output gate,  $b_o$  = bias at  $t$ .

The data needs to be stored from the new state in the cell to obtain the end output. The product of previous cell state  $C_{t-1}$  and forget vector  $f_t$ , if found to be 0, then values are eliminated, and point-by-point addition is performed to get a new cell state  $C_t$ .

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (12)$$

where  $t$  = timestamp,  $C_t$  is cell state information,  $f_t$  is forget gate at  $t$ ,  $C_{t-1}$  is previous time stamp,  $i_t$  is the input gate,  $\tilde{C}_t$  is a value generated by tanh.

The boundaries in LSTMs are learning rates, information, and result predispositions. In forget gate, a duplicate of the time-stamp information is separated, and in input gate a copy is passed. Using the above method, various metrics like Accuracy, Precision, Recall, F1- Score and Support for various datasets DS1, DS2 and DS3 are calculated and demonstrated in Table III (A) and Table IV (B) for multiclass and binary classification.

C. Method-3: Based on Conv1D+BiLSTM

In the proposed method 3, a more meaningful output is produced by using a powerful tool for modeling the sequential dependencies in both directions. The architecture is planned with a blend of Convolution and Bidirectional Long Short-Term Memory (Bi-LSTM). It offers preferable expectations by two LSTMs. Every component of an input sequence computes the input arrangement from the reverse path to a hidden forward sequence and a backward hidden sequence. Concatenation of the final forward and backward outputs leads to an encoded vector. Thirty-two units of LSTM of 0.2

dropouts, are utilized in a bidirectional manner as depicted in Fig. 6. At every timestamp, each hidden layer yield is created alongside the memory cell state and passed to a 1D convolutional layer of 64 filters of kernel size four as shown in Fig. 7. The past LSTM network trails the remainder of the network. The results show that Bi-LSTM based modeling offers better predictions than regular LSTM based models. Accuracy, Precision, Recall, F1 Score and Support for datasets DS1, DS2 and DS3 for both multiclass and binary classification using Conv1D+ Bi LSTM are referred in Table V (A) and Table VI (B) accordingly.

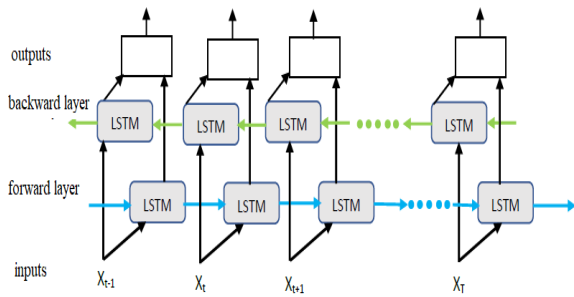

Fig. 6. Bidirectional LSTM.

Fig. 7. Architecture of the proposed method-3.

V. RESULT AND DISCUSSION

Precision is defined as the quality of a correct prediction given by the model and is the number of true positives divided

by the total positive predictions. Precision is how good the model is at predicting a specific category. It does not predict negative class, called false negatives [30-32].

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP})$$

Recall is a measure computing the number of correct predictions from all positive predictions possible. In binary class, recall is computed as the number of true positives divided by the sum of true positives and false negatives.

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$$

The F1 score or F-measure gives the harmonic average of precision and recall together to measure the efficiency of two classifiers.

$$\text{F-Measure} = (2 * \text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall})$$

Support: The support is several actual occurrences of the class in the specified dataset and got by summing the rows of the confusion matrix.

However, comparing three models with Bonn EEG Dataset, displayed in Table VII illustrates the proposed Deep learning methods with added layers have a higher score than simple CNN approaches, suggesting high classification accuracy.

TABLE VII. COMPARISON OF ACCURACY WITH EXISTING AND PROPOSED METHODS OF DATASET1(BONN), DATASET2(HAUZ KHAS) AND DATASET3(SPANDANA) WITH BINARY CLASSIFICATION

Dataset1(Bonn)								
DL Algorithm and Models	Accuracy (%)	Proposed	Sensitivity	Proposed	Precision	Proposed	F1- Score	Proposed
Conv1D [29]	88.70	98.83	95.00	98	90.00	96	--	97
Conv1D+ LSTM	---	99.04	---	97	---	98	--	97
Conv1D+ BiLSTM	---	99.40	---	96.5	---	98	---	97
Dataset2 (Hauz Khas)								
Conv1D [29]	---	77.42	---	86	---	86	--	77
Conv1D+ LSTM	---	80.65	---	82	---	82	--	83
Conv1D+ BiLSTM	---	80.65	---	93	---	92	---	80
Dataset3 (Spandana)								
Conv1D [29]	---	75.00	---	100	---	100	--	80
Conv1D+ LSTM	---	100.00	---	100	---	100	--	100
Conv1D+ BiLSTM	---	100.00	---	100	---	100	---	100

VI. CONCLUSION AND FUTURE WORK

In Proposed Method 1 (Conv 1D), a CNN model is built on a 1D time series, and architecture consists of a series of Conv1D layers followed by MaxPool. Flatten forms a flat structure which acts as input to dense layer with SoftMax activation adding learning capacity to neural networks for classification. A fully connected layer or Dense network helps to classify based on features. The metrics are improved compared to ML algorithms. A dense or Fully Connected layer is used as a classifier based on extracted features. Generally, the performance of the CNN classifier can be improved by the right choice of parameters like pooling size, learning rate, activation function and optimizer. Our approach

uses CNN to detect epileptic seizures and has improved the classification accuracy along with the generalization ability of the classifier. The tabulated results from Table I (A) and Table II (B) significantly shows the improvement compared to Machine Learning based algorithms.

In Proposed Method 2 (Conv1D + LSTM), the LSTM is based on recurrent neural networks capable of learning, remembering, and processing information from a time series data. LSTMs have gates that process the data and decide on retaining the known feature if it is sound, forgetting if imperfect, and moving ahead. Gates use sigmoid activation ( $\sigma$ ) and are fit for learning order. Though the training time is lengthy, LSTM glances at a long sequence of inputs without

expanding the network size. An LSTM network empowers to include sequence information in succession. It is evident from the measured metrics shown in Table III (A) and Table IV (B) that LSTM, with its selective memory, can successfully empower the network with the retained essential features. This model can also be implemented on different domain signals like frequency and time- frequency domain signals and can compare the performance accuracy. Furthermore, LSTM layers can implement the data in classifying with multiclass exclusively on the Bonn EEG epileptic dataset deeply and classifying better seizure states.

In Proposed Method 3 (Conv1D + Bi LSTM), the Bi-LSTM based model is much better than usual LSTM based models as per the results obtained. Bi- LSTM takes a step further ahead from LSTMs with its capability to view and understand the data in both directions. In contrast, they are utilizing the knowledge of the past and future data present in the time series. Bi-LSTMs can extract the best describing feature vectors from the data. While the proposed methods prove their ability with the Bonn and Hauz Khas dataset, it leads to overfitting with Spandana dataset due to its smaller size. As part of further work, improvement is made by enhancing the dataset from medical agencies, building deeper models, regularization with Batch normalization, augmentation techniques, and reinforcement-based learning remains unexplored. Moreover, when operated to multi-class classification, the present approach does not have a good recognition accuracy that is principally exceptional. Results prove that Bi-LSTMs are an ideal choice for time sequence data as demonstrated in Table V (A) and Table VI (B) correspondingly.

**Abstract**—Customers' feedbacks are necessary for an online business to enrich themselves. The customers' feedback reflects the quality of the products and the e-commerce services. The companies are in a position to concentrate more and analyze the customers' feedback or reviews carefully by applying new techniques for predicting the current trends, customers' expectations, and the quality of their services. The e-business will succeed when one accurately predicts customer purchase patterns and expectations. For this purpose, we propose a new fuzzy logic incorporated sentiment analysis-based product recommendation system to predict the customers' needs and recommend suitable products successfully. The proposed system incorporates a newly developed sentiment analysis model which incorporates the classification through fuzzy temporal rules. Moreover, the basic level data preprocessing activities such as stemming, stop word removal, syntax analysis and tokenization are performed to enhance the sentiment classification accuracy. Finally, this product recommendation system recommends suitable products to the customers by predicting the customers' needs and expectations. The proposed system is evaluated using the Amazon dataset and proved better than the existing recommendation systems regarding precision, recall, serendipity and nDCG.

**Keywords**—Classification; e-commerce; preprocessing; recommendation system; recurrent neural network; sentiment analysis

## I. INTRODUCTION

E-Commerce technology is growing fast due to rapid population development and technological adaptation. Most people are willing to complete their purchase from their place without visiting the shops online for an affordable cost. Today, people save their money and time with the help of e-commerce technology. They can purchase their items anytime online even though the e-commerce technology is in the position to fulfil the customers' requirements conveniently by providing good quality products. For this purpose, many e-commerce platforms are collecting feedback from their customers and trying to rectify the flaws, if there are any, by analyzing their feedback through sentiment analysis. This sentiment analysis can provide the customers' opinions on services and goods. Moreover, it is useful for enhancing service quality and fulfilling the customers' requirements as per their expectations. Moreover, the customers share their experiences, expectations, and comments about product quality. The sentiment analysis is applied to the review comments of the products and also

predicts the customers' expectations and the current purchase trends [1].

Sentiment analysis is an important part of Natural Language Processing (NLP) which learns the exact meanings and the useful features of a review comment. The major objective of the sentiment analysis is to extract the sentiment entities and the features available in their review comments. Recently, social media usage has been drastically increasing daily, and people are sharing their purchase experiences by posting comments. Moreover, they spread their comments about their purchase experience and opinions to their friends and unknown circle through social media. So that every customer review comment also plays a role in the e-commerce platform, and if the specific product receives negative comments from a few customers, it also affects sales. Therefore, the e-commerce applications incorporated a sentiment analysis phase capable of categorizing the review comments such as an object, features of the object, meaning, holder and time of expression. Generally, the sentiment analysis finalizes the customer reviews as positive, negative, and neutral comments [2].

The sentiment analysis is categorized into three categories: statistics-based, knowledge-based, and hybrid. Among them, the knowledgebase-based method helps extract the features from the customer's reviews. Then the classification is performed over the reviews by applying the different Machine Learning (ML) algorithms such as the Naïve Bayes classifier, Support Vector Machine (SVM) and Maximum Entropy algorithm. Customers may have different sentiments over the various products using different entities and emotions. In this scenario, the system must apply multi-sentiment analysis to handle the different sentiments expressed in review comments and predict customer opinions on products. This kind of analysis is done by considering customer reviews collected from e-commerce websites, blogs, Facebook, Twitter, etc. Data preprocessing is also necessary before performing the sentiment classification. The basic data preprocessing [3] on review comments include syntax analysis, semantic analysis, tokenization etc. The data preprocessing steps can enhance the classification algorithm's performance.

**Research Gaps:** People are interested in purchasing products online. Here, people need help to choose their interests like products from the vast number of products.

To help society use e-commerce websites frequently, this paper proposes a new fuzzy aware sentiment classifier incorporated product recommendation system to recommend suitable products to the customers to satisfy their requirements. The contributions of this paper are listed below:

- 1) To propose a new product recommendation system to recommend suitable products to customers.
- 2) To apply basic level data preprocessing steps such as tokenization, syntax analysis and semantic analysis to extract the raw data from reviews.
- 3) To analyze the customers' reviews by applying the proposed sentiment analysis technique to know the customers' opinions on the products.
- 4) To introduce fuzzy temporal rules for making effective decisions on product recommendation.
- 5) Proved as better than the available systems regarding the precision value, recall value, f-measure value and prediction accuracy by conducting various experiments.

The remainder of this paper is formulated below: Section II explains the available works in the direction of sentiment analysis and recommendation systems. Section III provides an overall architecture of the system for understanding the entire system. Section IV explains the proposed model by providing the necessary backgrounds, data preprocessing, fuzzy rules and classification. Section V demonstrates the effectiveness and efficiency of the proposed product recommendation system. Section VI concludes the work with future direction.

## II. RELATED WORKS

Sentiment analysis, content recommendation systems, product recommendation systems, feature selection and classification incorporated systems in the past by many researchers. Among them, Li and Feng [4] developed a new clustering algorithm using the Latent Class Regression method capable of considering product ratings and opinions for identifying the reviewer's choice. They have enhanced their method by considering the products' weighted features and proved them as better through experimental results. Jawa and Hasija [5] designed a new model that works according to the interest-aware graphs with the sentiment analysis to calculate the correlation value of different entities, and it also supplies suitable and relevant products in e-commerce.

Zhang et al. [6] built an aspect-based sentiment collaborative filtering model that combines sentiment analysis with fuzzy Kano. They have obtained the various attitudes of the customers according to the results of sentiment scores. Moreover, they have incorporated a new similarity measure technique with user choices for a collaborative filtering method. Ultimately, their model is proved better than other models by conducting experiments by applying the Amazon datasets. Karthik et al. [7] proposed a novel Feature aware Product Ranking and Recommendation Algorithm to provide suggestions for customers interested in purchasing good quality products. Their algorithm analyses the various products and their ranks based on the review comments provided by the customers who purchased and used the product. Ultimately, the algorithm suggests the products that are more suitable for the

customers. It evaluates through experimental results and is also proven superior to the classical ML algorithms, including random forest and SVM.

Irfan et al. [8] proposed a hybrid framework that uses context-aware recommendation based on product ratings and customer reviews. They have used text mining methods over large-scale user item feedback to calculate the sentiment scores. Moreover, they have proposed a greedy heuristic method for producing the item ranks according to the customers' similarities. The major advantage of their framework is the consideration of purchase similarities and the greedy search method. Dau and Salim [9] developed a new sentiment analysis incorporating deep learning technique-based recommendation system that considers the various aspects of products and the customer's sentiments that are used to improve the recommendation accuracy. They have mainly designed a semi-supervised topic modelling model for extracting product aspects associated with lexicons from customer reviews. They also have used long short-term memory (LSTM) encoder to achieve better product recommendation performance than other models.

Wang et al. [10] proposed sentiment matrix factors, sentiment scores and the reviews-based recommendation model to predict suitable content. Initially, they analyzed various topics and reviewed comments by applying the lexicon construction and Latent Dirichlet Allocation (LDA) methods. Then, they combined the user consistency computed using their review comments on products and the ratings. Next, they have integrated the reliability measurement of topics and sentiment analysis on review comments. Finally, they proved that their model is superior to other product recommendation systems. Hu et al. [11] proposed an enhanced recommendation model that considers the interests, credibility and sentiment scores. Their model consists of five different modules for performing the recommendation process, feature sentiment assignment, user interests, credibility analysis and feature extraction process. They have considered the customer's opinions on their liked products and the trust scores of the customer's review comments. Finally, they have made product decisions using weighted sentiment scores and features.

Mohammad et al. [12] developed two new lexicon generation approaches to handle aspect-based issues that use statistical methods and genetic algorithms. They have proved that their models as better than the existing approaches. Karthik and Ganapathy [13] developed a new approach called Multi scenario demographic hybrid with necessary and useful features, including users' ages and locations. Moreover, they have ranked the available products according to age group and purchase locations. Finally, their system is proven superior based on prediction accuracy.

Zarzour et al. [14] designed an architecture incorporating deep learning technique-based sentiment analysis to predict review comments. Their architecture has two major components: LSTM and Gated Recurrent Unit (GRU) methods. Finally, they evaluated their architecture by conducting experiments using the actual purchase and Amazon datasets and achieving better prediction accuracy. Munuswamy et al. [15] developed a novel rating and sentiment-aware

content prediction method to build a recommendation system to mine valuable data from customer reviews or product feedback. Their algorithm helps predict the people who liked products by considering the ratings. Their algorithm uses a dictionary to calculate the sentiment scores to recommend the exact items. In the end, their method obtained superior prediction accuracy than available methods. Karthik and Ganapathy [1] developed a fuzzy aware product recommendation system capable of predicting the suitable products for the customers based on their interests in e-commerce. They calculated the sentimental score for each product, used them to form fuzzy rules, and stored them in an ontological table for making final decisions. Finally, they have proved that their system is superior by achieving better results in the majority of experiments on various sizes of datasets.

Wenxiong et al. [16] built a novel multi-level graph-based neural classifier for performing the sentiment analysis over their review comments. They have applied node connection windows to consider local and global features. Specifically, they have integrated a message-passing system that considers the scaled dot-product attention to fuse the features. Huiliang et al. [17] proposed a new neural classifier that applies an improved Bat Algorithm and Elman Neural Network to analyze the reviews of the products. Their method consists of four important steps: data collection, feature selection and sentimental classification. In their work, they have used Web Scrapping Tool to extract customer reviews about the products from e-commerce websites. The preprocessed data is categorized as positive, negative and neutral. Finally, they have achieved superior prediction accuracy than the available systems.

Abolfazl et al. [18] designed an automated model for performing effective sentiment analysis of customer review comments. They have considered the feature extraction process by incorporating the Term frequency, Inverse document frequency. They also speed up robust and local binary patterns to extract the features from pre-processed data. Finally, they have integrated the Deep Belief Network and Whale Optimization Method to perform feature optimization and sentiment classification. They have obtained around 97% classification accuracy, which is superior to other classifiers. Antony et al. [19] proposed a novel product recommender to predict suitable customer products. Their recommendation system incorporates the bidirectional encoder and the attention-based sequential recommendation system for effective classification. They have compared their system with other models and proved it superior.

Yao et al. [20] proposed a deep product recommender that considers the sentiment analysis of review comments and the product ranking. They applied the deep learning technique to map the extracted features and the ranking-based latent factor. Many experiments have been conducted using Amazon datasets and obtained higher accuracy than the available models in this direction. Rosewelt and Renjith [21] built a new method for enhancing the product recommendation systems' performance by deeply analyzing product reviews and the customer's purchase behaviours. They have considered the product features, feedback, and not-liked product features to improve prediction accuracy.

### III. SYSTEM ARCHITECTURE

Fig. 1 demonstrates that the proposed product recommendation system's workflow consists of four important components: Amazon Dataset, User Interaction Module, Decision Manager and Product Recommendation System, which has three different phases Sentiment Analysis, Data Preprocessing and Sentiment Classification Module.

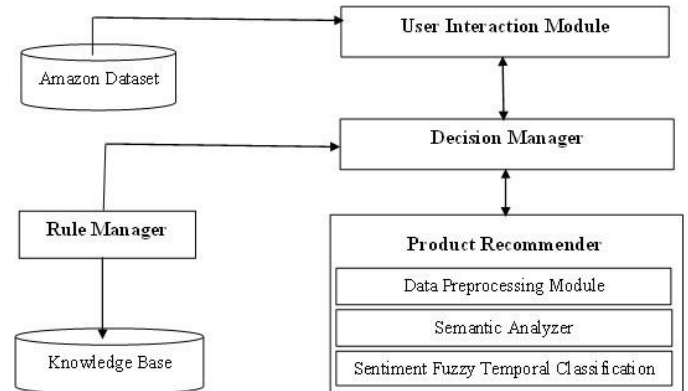

Fig. 1. System architecture.

The user interaction module extracts the necessary data from the Amazon dataset. The decision manager receives the extracted data and forwards them to the product recommender. The product recommender has three important phases: data preprocessing, sentiment analyzer and sentiment classification. The data preprocessing module performs the data preprocessing tasks, including stemming, stop word removal, tokenization and syntax analysis. Finally, the preprocessed data is to be moved to the sentiment analyzer capable of analyzing the data as per sentiments. The sentiment analyzer performs the sentiment analysis and forwards it to the sentiment classification by applying the classifier and considering fuzzy temporal rules. The decision manager makes effective decisions on the sentiment classification process by applying the fuzzy temporal rules stored in the knowledge base through the rule manager. Generally, the knowledge base contains the rules and facts. The rule manager is used to manage the rules available in the knowledge base based on the suggestions of the decision manager. The Amazon dataset contains the customers' purchase history and feedback as review comments.

### IV. PROPOSED WORK

This work proposes a new product recommendation system that incorporates the data preprocessing technique and classification. The data preprocessing technique incorporates the newly developed weighted topic-aware lexicon expansion for performing effective preprocessing. The sentiment classification is also adopted for enhancing the data preprocessing processes capable of identifying the effective features to enhance the classification accuracy. The classification adopts the newly developed Fuzzy Temporal Product Recommendation Algorithm to identify suitable liked products for customers according to their interests.

### A. Data Preprocessing

Data preprocessing consists of two important preprocessing tasks: lexicon expansion and sentiment classification. Before that, the basic data preprocessing, including tokenization, POS (Parts of Speech) tagging and parsing, are useful for performing effective data preprocessing tasks in this work. Here, a new data preprocessing method called Fuzzy Weighted Product based Lexicon Expansion Method (FWP-LPM) is finalizing the preprocessed content. First, it explains this work's fuzzy logic and rules for performing data preprocessing and classification tasks.

1) *Fuzzy logic and fuzzy rules:* The fuzzy set theory was proposed by Zadeh [22]. Many applications in the real world cannot make decisions with certainty. This is because many phenomena in this world are fuzzy in nature. The crisp sets make decisions by manipulating formulas that can hold values of 1 and 0 only. Therefore, the logic, such as propositional logic and the first order predicate logic can only manipulate the formulas to make a true or false decision. However, the world consists of facts that are probabilistic in nature. Hence, it is necessary to perform the gradation of truth values. This type of gradation can help to perform qualitative reasoning as well as quantitative reasoning. Fuzzy logic provides operators and membership functions for converting the crisp set values into fuzzy linguistic values so that it is possible to perform reasoning under uncertainty.

A fuzzy inference system is capable of performing qualitative reasoning through the effective application of fuzzy rules. The fuzzy rules are formed according to the fuzzy membership functions like triangular, trapezoidal and Gaussian membership functions. Moreover, the fuzzy rules are represented in the form of IF.... THEN rules. The other type of format used for representing rules are Event, Condition and Action rules which are also represented using ON Event, IF (Cond) THEN rules and both these types of rules can be used for making inferences. In a fuzzy inference system, there are two modules in which the first module performs the fuzzification process. Here, the quantitative values are converted into qualitative and linguistic variables. In the defuzzification process, the qualitative rules and values are converted into quantitative values. The fuzzy rules can be used to adjust weight in the neural network-based classification algorithms to increase classification accuracy. In other classifiers, fuzzy rules can aid in decision-making by handling the uncertainty in the classification process.

2) *Basic data preprocessing tasks:* This subsection explains the tokenization, POS Tagging and Parsing in detail. These preprocessing tasks help perform effective classification.

a) *Tokenization:* The feedback is categorized into various tokens or words or terms. The sequence is identified and grouped as meaningful content according to the term relevancy. The review comments contain the terms "fantastic product", "good", "liked products" and "Worthy products" to perform the processes of morphological analysis and tokenization. Here, the tokenization is done and you get the terms like good, fantastic, like, and worthy. In addition, the

stop words are also removed from the feedback or comments on products.

b) *POS tagging:* It provides the data on how the terms are applied in a sentence and also identifies the "Nouns", "Pronouns", "Adjectives" and "Verbs" are tagged on tokens. Moreover, it labels the terms over the POS tagging. Every token is identified and tagged with POS, which is used for identifying the suitable terms to predict the user's interest.

c) *Parsing:* It provides a standard grammatical structure for any input sentence. Here, the parsing model groups the words according to their relevancy. In this work, the parsing model constructs a parse tree by considering the words relevancy in terms of subject or object.

3) *Weighted topic (product) based lexicon expansion:* The lexicon analysis is used to find the difference between the input content and the common opinion or meaning of the term. This work considers the relevancy between two terms with closure sentiment scores and relevant meaning. In this work, the polarity of the expression with less emotion is also calculated as the value of Weighted Point based Mutual Information (WPMI) simply between any two input terms using the formula given in (1).

$$WPMI(t1, t2) = \log_2 \left( \frac{p(t1, t2)}{p(t1)p(t2)} \right) * WT \quad (1)$$

Where, t1 and t2 are the different input terms or words, p indicates the probability, and WT represents the weight that is the common difference between the two terms.

The term's or word's orientation value semantically is demonstrated by using (2).

$$SOT(T) = WPMI(T, Pos) - WPMI(T, Neg) \quad (2)$$

Where, Pos means positive (+ve) and Neg means negative (-ve), T represents the token.

Generally, two different assumptions are considered in this work. First, the sentiment orientation of emotions such as "(:)" and ":((" is stable relatively throughout the entire comments. Here, the positive and negative signs and comments on products are useful for knowing the two extreme statuses of the product in the market. Second, the comment on a product is not valid over the products with negations. For example, "I don't like this product". This comment is a negative comment about a product. Now, the polarity value of their opinion is measured by computing the relevancy score between the terms. The sentiment orientation on a product is calculated using (3).

$$SO(T) = \log_2 \left( \frac{H(T, Pos) \times H(Neg)}{H(T, Neg) \times H(Pos)} \right) \quad (3)$$

Where, H indicates the hits. The sentiment may not be applicable to some terms in comments. In this scenario, the POS tags of the terms can be applied for identifying the potential and useful terms that include "Adjectives", "Nouns", "Pronouns", "Verb" and "Intersections". This set of tags was identified and selected after conducting the experiments with various combinations of tag sets and applying this set to perform the classification effectively.

Fuzzy Weighted Product based Lexicon Expansion Method (FWP-LPM)

**Input:** Feedback or Review Comments and sales data

**Output:** Preprocessed Content

Step 1: Read the feedback about a specific product {FBp1, FBp2. . . .FBPn}

Step 2: Perform the tokenization process and extracts the terms as tokens.

Step 3: Perform the POS Tagging process and extracts the terms with parts of speech.

Step 4: Perform the Parsing process and construct the parse tree to provide the useful terms.

Step 5: Find the value of Weighted Point based Mutual Information (WPMI) for the two adjacent terms of the input terms using (1).

Step 6: Find the orientation of the sentiment score for the input term of a product by using (2) and (3), and also consider the sales history of the input data.

Step 7: Apply the Fuzzy Rules to finalize the terms.

Step 8: Return the preprocessed terms/contents.

The newly developed FWP-LPM is applied for performing the data preprocessing and is useful for extracting the preprocessed content.

4) *Sentiment classification:* This section describes the sentiment score calculation procedure used in this work to identify users' interest in the products through their comments/feedback. The product rating is calculated using the relevant feedback by applying the newly developed product ranking algorithm (PRA). Here, the sentiment polarity and product rank in the form of a score is summed up as a sentiment score. First, the product ranking process is explained in this section.

a) *Product ranking:* The average product score ( $PS_{p,u}$ ) is computed by applying (4). Fuzzy Weighted Product based Lexicon Expansion Method (FWP-LPM)

$$PS_{p,u} = \sum_{i=1}^{TP_{p,u}} (SSi_{p,u}) \quad (4)$$

Where,  $TP_{p,u}$  represents the number of feedbacks received and considered for the respective product. The overall ranking of the product is computed by applying (5).

$$POR_{p,u} = \frac{OR_p * NOF}{PS_{p,u}} \quad (5)$$

Where, the variable  $OR_p$  indicates the overall rank of the specific product and the variable  $NOF$  indicates the number of feedbacks considered for the specific product in this work.

In this way, the rank is to be identified for each product according to the feedback and also consider the current

purchase behaviour of the users. Moreover, the similarity between the products is also considered in this work by applying the Cosine similarity formula that is given in (6).

$$CosineSim(p_i, p_j) = \frac{p_i \cdot p_j^T}{\|p_i\| * \|p_j\|} \quad (6)$$

The cosine similarity value between the two products is useful for finalizing the specific product rank and product classification processes. This cosine similarity also plays an important role in the decision-making process in the various recommendation systems. In this work, the similarity value of each product must be below the threshold. The average cosine similarity value is considered a threshold value.

### B. Classification

The classification is performed by applying a newly developed Fuzzy Temporal and Sentiment awareness Product Recommendation Algorithm (FTS-PRA) in their work to predict the user's interests and to recommend suitable products. The fuzzy logic is applied in this work for making effective decisions over the product recommendation process. Moreover, this paper uses the standard triangular fuzzy membership function to generate the fuzzy rules. In the process of fuzzy rule generation, time is also considered an important parameter. The reason is for considering the temporal feature for enhancing the prediction accuracy. The steps of the FTS-PRA are as follows:

Fuzzy Temporal and Sentiment aware Product Recommendation Algorithm (FTS-PRA):

**Input:** Feedback or Review Comments, sales data

**Output:** Recommended product

Step 1: Read the feedback about a specific product {FBp1, FBp2. . . .FBPn}

Step 2: Apply basic preprocessing tasks

Step 3: Apply Weighted Product based Lexicon Expansion along with sentiment score.

Step 4: Check whether the specific product similarity value is below the threshold and sold out reasonable numbers.

Step 5: Calculate the product ranking score for the product by applying (3) and (4).

Step 6: Apply the Fuzzy Temporal Rules

Step 7: Perform the sentiment classification and initiate the product recommendation process

Step 8: Recommend a suitable product to the customer/user.

The newly developed FTS-PRA is used to predict the user purchase pattern and the suitable products by analyzing the feedback of the customers who purchased the product early. First, it reads the product's feedback and performs the preprocessing tasks including Tokenization process, POS Tagging process and Parsing. Moreover, this algorithm applies the newly developed weighted product-based Lexicon expansion with a semantic score method to retrieve the most useful contents from feedback. Next, the product similarity is calculated by considering the feedback analysis. Then, based

on the sentiment classification result, find the product score for the products and also recommend the product to the users. Finally, it recommends the product to the customer.

## V. RESULT AND DISCUSSION

This section demonstrates the experimental results for evaluating the proposed system and the relevant discussion. First, it explains the dataset used in this work.

### A. Dataset

The proposed system is evaluated using the famous benchmark dataset, the Amazon dataset. The Amazon dataset is considered the Kindle store items, books, magazines, CDs, Toys, Greeting Cards, Crafts and Video games, grocery, office products, pantry, home and gourmet food. All these items are categorized into different datasets according to the type of products.

Amazon Sales Dataset 2023: The Amazon sales dataset 2023 [25] has sales records. The sales records contain the details about the products, sales time and date and the frequency of sales with the number of items sold out for the specific time duration [25].

### B. Performance Metrics

The proposed system is evaluated by considering the standard evaluation metrics including Precision and Recall metrics shown in (7) and (8).

$$Precision = \frac{Relevant\ Recommended\ Products}{Total\ Recommended\ Products} \quad (7)$$

$$Recall = \frac{Relevant\ Recommended\ Products}{Total\ no.\ of\ relevanted\ products\ to\ be\ Recommended} \quad (8)$$

This work focuses on the precision value and recommends the same product repeatedly that may be different from what users liked. In this scenario, the product recommendation can be based on metrics such as Serendipity and nDCG.

a) *Serendipity*: This metric is very useful for recommending a suitable product to the user. Serendipity value is computed by applying the formula shown in (9).

$$P_x = \frac{no.-rank_x}{no.-1} \quad (9)$$

b) *nDCG*: This metric is useful for identifying the user's liked products and recommending them for purchase. The nDCG value helps check the correctness of the recommended product described in (10).

$$nDCG(L, k) = \frac{1}{|L|} \sum_{x=1}^{|L|} Z_{kx} \sum_{m=1}^k \frac{2^{R(x,m)-1}}{\log_2(1+m)^l} \quad (10)$$

### C. Experimental Results

The experiments are done with different sets of records as separate datasets such as DS1, DS2, DS3, DS4, DS5 and DS6. These datasets contain different products with various numbers of records. Fig. 2 demonstrates the precision value analysis between the proposed model and the existing models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Fig. 2. Precision value analysis.

Discussion: Fig. 2 demonstrates that the performance of the proposed model is proved as better than the available models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Reason for the Enhancement: The performance is using a weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

Fig. 3 shows the recall value analysis between the proposed model and the existing models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Fig. 3. Recall value analysis.

Discussion: Fig. 3 shows the performance of the proposed model that is proved as superior in terms of recall value than the available product recommendation systems such as Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Reason for the Enhancement: The reason for the enhancement here is the use of weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

Fig. 4 shows the Serendipity value analysis between the proposed model and the available recommendation systems like Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Fig. 4. Serendipity value analysis.

Discussion: Fig. 4 shows the serendipity value of the proposed model which achieves superior value than the available models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Reason for the Enhancement: This better enhancement is applying weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

Fig. 5 demonstrates the nDCG value analysis between the proposed model and the available models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

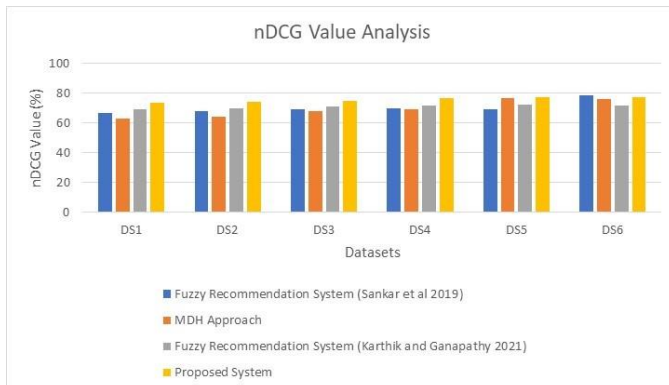

Fig. 5. nDCG value analysis.

Discussion: Fig. 5 shows the achievement of better nDCG value than the available models like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]).

Reason for the Enhancement: This betterment applies a weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

Table 1 shows the comparative outcome analysis between the proposed and available product recommender models. The proposed product recommendation system considers the evaluation metrics such as precision, recall, serendipity and nDCG. It implies that a new product is recommended based on the context and relevant to current user interest. This improves user satisfaction as well. Table 1 shows the consolidated results

with the conducted results. Both recommendation-specific metrics Serendipity and nDCG are improved without impacting or compromising the precision and recall.

TABLE I. COMPARATIVE OUTCOME ANALYSIS

Recommendation system	Precision	Recall	Serendipity	nDCG
FBPRR	0.32	0.15	0.022	0.23
Fuzzy rule	0.52	0.32	0.024	0.25
MDH	0.45	0.45	0.02	0.21
Fuzzy recommendation	0.49	0.49	0.04	0.34
Product Recommendation System	0.50	0.49	0.041	0.36
Personalized Recommendation System	0.51	0.51	0.042	0.37
Proposed System	0.52	0.52	0.045	0.38

Discussion: Table 1 shows the better achievement of the proposed recommender model according to the evaluation parameters such as precision value, recall value, serendipity value and nDCG value than the available recommenders like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]), Product Recommendation System [23] and Personalized Product Recommendation System [24].

Reason for the Enhancement: This achievement applies a weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

Table 2 shows the time analysis between the proposed and existing product recommendation systems. Here, the experiments have been done with randomly selected 700 records as training datasets and 300 records are given as testing datasets from the Amazon sales dataset 2023 and Amazon Product Review Dataset for this time analysis.

TABLE II. TIME ANALYSIS

Recommendation system	Training Time (sec)	Testing Time (sec)
FBPRR	0.41	0.19
Fuzzy rule	0.40	0.18
MDH	0.39	0.17
Fuzzy recommendation	0.39	0.17
Product Recommendation System	0.38	0.16
Personalized Recommendation System	0.37	0.15
Proposed System	0.34	0.14

Discussion: Table 2 shows the better achievement of the proposed recommender model with respect to the training and testing time than the available recommenders like the Fuzzy recommendation system (Sankar et al. [2]), MDH Approach (Karthik and Ganapathy [13]), Fuzzy Recommendation System (Karthik and Ganapathy [1]), Product Recommendation System [23] and Personalized Product Recommendation System [24].

Reason for the Enhancement: This efficiency betterment is considering time constraints and applying a weighted topic-based lexicon expansion method, sentiment analysis and fuzzy temporal rules.

## VI. CONCLUSION AND FUTURE WORKS

In this work, a new fuzzy logic incorporated sentiment analysis-based product recommendation system is developed to predict the customer's need and recommend suitable products successfully. The proposed system incorporates a newly developed sentiment analysis model which incorporates the classification through fuzzy temporal rules. Moreover, the basic level data preprocessing activities such as stemming, stop word removal, syntax analysis and tokenization are performed to enhance the sentiment classification accuracy. Finally, the proposed product recommendation system recommends suitable products to the customers by predicting the customer's needs and expectations. The proposed system is evaluated using the Amazon dataset and proved superior to the existing recommendation systems in terms of precision, recall, serendipity and nDCG values. This work can be further enhanced by introducing a deep learning algorithm for classification instead of a normal machine learning classifier.

# Information Technology Technical Support Success Factors in Higher Education: Principal Component Analysis

Geeta Pursan<sup>1</sup>, Timothy. T. Adeliyi<sup>2</sup>, Seena Joseph<sup>3</sup>

ICT and Society Research Group-Department of Information Technology, Durban University of Technology,  
Durban, 4000 South Africa<sup>1,3</sup>

Department of Informatics, University of Pretoria, Gauteng, 0028, South Africa<sup>2</sup>

**Abstract**—The use of information and communication technologies at higher education institutions is no longer an option, but rather a need. Information Technology support is an essential factor that entails giving end users assistance with hardware and software components. Technical support for information technology has been recognized as a crucial element linked to student happiness because it helps students understand, access, and use technology efficiently. The successful implementation of IT technical support will be aided by identifying the essential success criteria that enable efficient and effective support for students and instructors. Hence the main aim of this study is to identify and rank the key success factors for the successful implementation of IT technical support at higher education institutes. 81 key success factors identified from 100 research papers were analyzed using principal component analysis. The findings led to the identification and ranking of 25 PCs. 95.35 percent of the observed variation was accounted for by the first 25 PCs with eigenvalues higher than 1. The percentages for the first 6 PCs were, in order, 11.87%, 22.21%, 30.64%, 38.25%, 45.12%, and 51.47%. This research provides useful information highlighting factors that can be used to examine areas in educational institutions that need to receive continuous and special care to generate high student satisfaction; ensure future success and gain a competitive advantage. These factors can assist the management of HEI to determine the success or failure of an institution in terms of the technical support provided to students and student satisfaction.

**Keywords**—Information technology; technical support services; key success factors; principal component analysis; higher education institutions

## I. INTRODUCTION

Information Technology technical support is an important part of the implementation and integration of technology in education [1]. Technical support is needed by students who are not familiar with information and communications technology and need to use online learning effectively [2]. Support from technical staff is not limited to infrastructure, hardware, and software issues; when academic staff is supported by technical staff are most likely to explore different online tools that will aid in multi-modal teaching [3]. Technical support is needed to assist and enhance the efficient delivery of academic content. [4]. To study, students depend on the technical team's constant and prompt reactions. [5].

Lack of technical support and advice leads to unsuccessful projects [6].

Higher education institutions all across the world were utilizing a range of measures to sustain their academic programs as the COVID-19 virus started to spread in early 2020. To avoid losing the academic year, the academics had to come up with creative ways to teach. To assist academic staff and students who were compelled to use technological tools like Moodle, Blackboard, email, and MS Teams and to help mitigate the problems experienced, there was an immediate and great need for IT technical support services[79]. According to [7] the pandemic made access to technical support services at all higher education institutions an even bigger problem. Email, Microsoft Teams, WhatsApp, and several other online channels were used to deliver technical support services. Students required technical support and advice to enable them to understand how this new technology will benefit them [5].

Technical support has been cited by numerous researchers [84,85,86,87] as a crucial success component that is linked to student contentment. Reference[87] cited technical support as a key element that influenced distant learners' satisfaction with their courses at Malaysian universities. According to studies [84, 85, 86], students who received technical support felt more at ease and inspired to use the e-learning systems. To create a successful IT technical support services satisfaction model and reduce the risk of failure, key success factors (KSFs) must be recognized [8, 9]. It is crucial to emphasize that KSFs will evolve as both the environment and users' perceptions of them do. To attain or sustain optimum benefit, identified KSFs will need to be continually assessed [9]. The most important success variables ought to be small, manageable, and measurable [10].

Principal component analysis (PCA), according to Hanci and Cebeci [12], is a multidimensional statistical technique that can split similar relevant variables into a cluster of fewer key determinants as principle components (PCs). It helps draw attention to differences and spot patterns that may be concealed in a dataset [11]. The PCA method, a mathematical methodology based on eigenanalysis, calculates the eigenvalues and equivalent eigenvectors of a square symmetric matrix using sums of squares and cross-products [13]. The author in [81] used PCA to reduce the number of

evaluation criteria for learner support services provided to undergraduate students at remote education centres. The PCA method was used by Reference[82] to identify the service quality indicators among Ghanaian graduates of a higher education institution. PCA was utilized in the study [83] to identify the aspects of service quality at a Kenyan university. The main objective of this study is to use the PCA method to identify the key success factors for IT technical support services in higher education institutions. The following section of this paper is organized as follows: Section 2 related works; Section 3 materials and methods; Section 4 the results and discussion and Section 5 conclusion.

## II. RELATED WORKS

Technical aid some of the services offered to students and academics to lessen the workload of the instructor and improve student performance include having the knowledge and abilities to assist students and instructors with technical issues, providing support using online tools (WhatsApp), being able to resolve issues quickly and effectively, understanding the specific needs of students, and being available 24/7. Over the years, numerous research measuring the service quality of HEIs were carried out utilizing the Service Quality (SERVQUAL) 5 dimensions technique (tangibility, reliability, responsiveness, empathy, and assurance). The author in [14] discovered that the institution in Thailand did not live up to the expectations of the 350 study participants. Perceptions received lower scores than anticipated. This suggests that significant service enhancements are required to improve service quality. Similarly, in [15], they determined that it was important to assess the level of service at a university in Ghana, particularly from the perspective of the students, given the growing demand for investment in the management and administrative areas of HEIs. Data was gathered and examined by 384 students. The study's findings indicated that most students were happy with the services provided by the institution to the point where they would suggest it to others. Contrary to the other four dimensions, the tangibility dimension was performing well in terms of its services. The author in [16] at Valley View University in Ghana surveyed 100 students to gauge their satisfaction with the services provided. The findings demonstrated that the university's assurance, tangibility, and responsiveness services were satisfied; however, the empathy dimension was only moderately satisfied. A Tanzanian university's service quality and student happiness were the subjects of the study described in [17]. The findings indicated that the reliability dimension was the most favourable aspect of the study, while the other dimensions obtained low scores, indicating that the services provided to the students were unsatisfactory.

The author in [18] sought to investigate how service quality was implemented at an Indonesian university. We conducted interviews, observations, and document analyses. The outcomes demonstrated that the university's implementation of service quality was of poor quality. The SERVQUAL instrument was used in the study [19] to compare literature reviews and assess service quality in HEIs. The outcomes of the literature review were triangulated, and they were evaluated for certain quality aspects that would be

typical of public HEIs and might need to be improved. In terms of the services being provided, the perception of the students was lower than expected. The study by [20] looked at how the five service quality factors impacted Indonesian university students' satisfaction. The sample group included 125 students. The sampling process was straightforward and random. According to the findings, tangibility, dependability, and responsiveness had a good impact, whereas empathy scored reasonably, and assurance had no impact.

The study in [21] assessed the level of services offered at Albanian HEIs. According to the study's findings, none of the services provided to students satisfied them, as evidenced by the fact that all five SERVQUAL dimensions obtained low scores. The reliability factor received the most negative evaluations from students who thought that staff members were unwilling to help them with issues, failed to notify students in advance of schedule changes, and did not give them the necessary support. A study [22] looked at the relationship between student happiness and the caliber of services provided to Sri Lankan students in private foreign HEIs. The key SERVQUAL dimensions that were most important in determining student satisfaction were looked at. The results of the study demonstrated a significant link between student happiness and service quality. In this study, the qualities of assurance and responsiveness had a substantial contribution to student happiness. This research will fill a gap since no earlier studies have concentrated especially on the technical support services offered to students at HEIs.

## III. MATERIALS AND METHODS

The techniques for data extraction and dimensionality reduction are thoroughly explained in this section. To obtain the pertinent data, this investigation used the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) technique recommended by [23]. One of the finest techniques for helping researchers do systematic reviews and meta-analyses correctly and review a structure like a road map is PRISMA. This approach is well-liked in systematics literature and has been widely applied in a variety of research [24-28, 80]. The scientific literature that can be obtained using a structured approach that is based on objectives that are set so that different authors can utilize them can be summarized and analyzed by the researcher in a systematic review, which provides significant evidence [29].

All published studies reporting on IT technical support services were found through a search of the literature. Identification of pertinent research, screening, and selection of those studies, eligibility, and inclusion stages were all completed following the PRISMA methodology.

1) *Identification*: Scientific articles are chosen relating to IT technical support service key success factors in higher education institutions published in scholarly journals listed on the SCOPUS database (368) and ScienceDirect (749). Databases were searched by using the keywords “key success factors”, “IT technical support services”, “higher education”, limited to years greater than 1985 and less than 2022, limited to “journals”, limited to “computer science” subject area and limited to the “English” language. The Next step of the

PRISMA method is to remove duplicate articles.

2) *Screening*: A review of articles relevant to IT Technical Support Service Key Success Factors in Higher Education, the articles were screened by analyzing the title and abstract. The articles were put into the Mendeley citation management software. From a total of 1,117 articles 303 duplicate articles were removed. Finally, 814 articles remain.

3) *Eligibility*: Eligible criteria are needed to select appropriate articles [30], therefore articles are filtered based on inclusion and exclusion criteria as shown in Table 1.

TABLE I. INCLUSION AND EXCLUSION CRITERIA

Criteria	
Exclusion Criteria	
EC1	Papers in which only abstract is available.
EC2	Duplicate records.
EC3	Review and survey papers.
EC4	Papers not written in the English language.
EC5	Papers not relevant to IT technical support services.
EC6	Papers not applying PCA or Factor Analysis or SERVQUAL dimensions.
EC7	Papers not reporting sample size.
Inclusion Criteria	
IC1	Articles published in English.
IC2	Papers in Computer Science subject area only.
IC3	Papers relating to IT technical support service key success factors in higher education.
IC4	Journal papers only.
IC5	Papers between 1985 to 2022

Table 1 shows that only publications that satisfy the criteria are chosen; chapter books, brief reports, articles, non-English papers, and works from before 1985 are all excluded. In this instance, 25 items were eliminated since they did not meet the requirements and 789 articles are still present. Another 749 pointless articles have been eliminated at this point.

4) *Included*: Overall, 100 articles that match the inclusion

criteria remain. The 100 papers that can contribute to this study are examined in this final step. The papers are carefully read through to extract and condense key information. The information gathered will be used for this study. The flow of a database search using PRISMA is shown in Fig. 1.

This section aims to provide the key success factors that will be used to assess the IT technical support services provided to students at HEIs.

a) *Dataset*: For this study, a total of 81 factors have been identified from 100 research studies. They have been gathered and presented in binary form to display the attribute of the factors identified for further analysis.

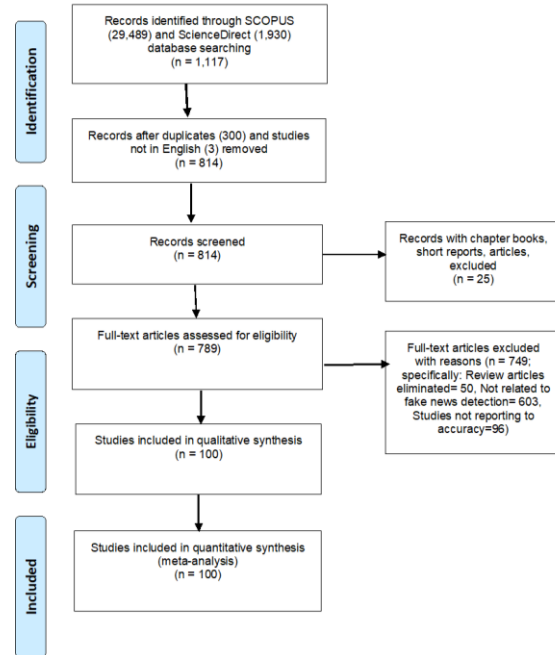

Fig. 1. Flow diagram of database search using PRISMA [31].

TABLE II. QUALITATIVE AND QUANTITATIVE IT TECHNICAL SUPPORT SERVICES (ITSS) FACTORS FOR PCA

ITSS FACTORS	NAME	DESCRIPTION	ADAPTED FROM SOURCE
F1	reliability	The student is assured that support staff to help resolve queries promptly.	[14] [32] [33] [15] [16] [18] [17] [19] [20] [21] [22]
F2	responsiveness	IT technical support staff's willingness to assist students and provide them with prompt service.	[34] [14] [32] [35] [15] [16] [18] [17] [19] [20] [21] [22]
F3	tangibility	Communication medium used to provide support services to students. Friendliness of staff.	[14] [33] [35] [15] [16] [18] [17] [19][20][21] [22]
F4	empathy	IT technical support staff gives students personal attention and understanding of the student's specific needs.	[14] [35] [15] [16] [18] [17] [19] [20] [21] [22]
F5	assurance	IT technical support staff being courteous to students as well as staff knowledge to answer students' queries.	[14] [35] [15] [16] [18] [17] [19] [20] [21] [22]
F6	trustworthy and loyalty	Loyalty requires developing a solid relationship with students.	[33]
F7	commitment	Students' likeliness to contact the same technical staff for assistance in the future.	[33]
F8	competence	IT technical staff have the appropriate knowledge and skills.	[14]
F9	reputation	IT technical staff are consistent in terms of	[34] [33]

		service delivery.	
F10	technical support staff	Timeliness and effectiveness of solution provided.	[34] [36] [37] [38] [39]
F11	communication material	Documents provided to students are easy to follow and are easily accessible and accurate.	[40] [32] [33]
F12	communication method	Effective use of modern online tools and services. WhatsApp service is reliable and easy to use. Technical staff is easily accessible by this service.	[40] [36] [33]
F13	location	Remote technical support provided is very convenient. Remote technical support is available 24/7.	[40]
F14	customer orientation	The student is very satisfied with the service provided.	[41]
F15	competitor orientation	IT technical staff has a competitive advantage over others in terms of providing excellent service to students and knowledge of the technical staff.	[41]
F16	inter-functional orientation	Inter IT technical department communication.	[41]
F17	performance orientation	IT technical staff's commitment to service.	[41]
F18	employee orientation	IT technical staff choose to provide service excellence.	[41]
F19	long term orientation	IT staff continuously improving student services.	[41]
F20	academic aspects	IT staff assist students with queries thereby increasing student academic performance.	[42] [43] [44] [45] [40] [46] [47]
F21	non-academic aspects	Support services, financial aid, security, etc. are considered non-academic aspects.	[42] [43] [44] [45] [40] [46]
F22	dependability	Students rely on IT technical staff to assist with technical queries.	[48]
F23	effectiveness	Effective use of modern online tools and services.	[48]
F24	capability	The technical staff has the knowledge, skills, and experience to assist promptly with student queries.	[48]
F25	efficiency	Promptness of delivery.	[48] [49] [50]
F26	assurance	Courtesy of technical staff; ability to encourage confidence and trust.	[48] [51]
F27	unusual situation management	unusual situation management.	[48]
F28	semester	Usually, six months.	[48]
F29	syllabus	Course content.	[48] [49] [50]
F30	teaching methodology	The method used to conduct lecturers e.g., using blackboard.	[52] [49] [51] [53] [54]
F31	disciplinary action	Reprimand in response to rule violation or misconduct.	[52]
F32	environmental change in study factor	Universities' involvement in reducing their carbon footprint.	[52]
F33	mediating self-actualization placement	Fulfillment of one's talents and potential.	[52]
F34	NSE as a service quality measure	NSE dimensions of service quality include but are not limited to content and structure of the study, acquired general skills, acquired scientific skills, testing, and assessment, program schedules, etc.	[55]
F35	customer focus and need-based	The customer is driven by a specific need.	[56]
F36	channels of communication	Examples: university website, WhatsApp communication, Facebook, Twitter, alerts, and reminders.	[56,57]
F37	instructional competence	Important practices that lecturers must grasp for effective instruction to students to maximize knowledge and skills.	[56] [50] [57] [58]
F38	specific policies and procedures	Guidelines for development, implementation, monitoring, and evaluation of HEIs.	[56]

F39	evaluation and control system	Implemented through the preparation of emergency policies and a crisis management team.	[56]
F40	curriculum design	Relevance of materials to students. Enthusiasm and methodology used by lecturers.	[40] [47] [51]
F41	effective leadership	Efficient guidance.	[56]
F42	periodic review	Assessing regularly.	[56]
F43	resource allocation	Equipment provision.	[56]
F44	operational planning	Department goals, capabilities, and budgets.	[56]
F45	competence	Theoretical knowledge, practical knowledge, up-to-date, teaching expertise, and communication.	[59] [54]
F46	attitude	Understanding the needs of students.	[59] [43] [58] [53] [54]
F47	content	Documents given to students are easily obtainable and accurate. Adherence to course objectives.	[59] [43] [58] [53] [54]
F48	delivery	Easy access to IT technical support staff.	[59] [43] [58] [53] [54]
F49	academic services	Includes admissions, financial aid, disability services, etc.	[60] [58] [61] [54]
F50	leisure	Relaxation.	[60]
F51	industry links	HEIs in contact with outside companies	[60]
F52	cost	Cost of facilities.	[62, 60]
F53	facilities	Tangibles, ease of access, support services, recreational facilities, library services, staff availability	[63] [49] [64] [65] [62] [66]
F54	flexibility	Ability to assist out of normal hours.	[67] [62] [68]
F55	availability	Reachable.	[50] [57] [62] [65] [69] [68]
F56	personnel quality	Ability and skills of staff.	[50] [57] [62] [65] [70]
F57	sufficiency of resources	Adequate facilities available for students to use, e.g., computer laboratories, and libraries.	[50] [57] [62] [71]
F58	quality of faculty	Value of faculty.	[50] [66] [62] [71]
F59	access	Right to use.	[61] [53] [42] [70] [72] [43] [44] [40]
F60	courtesy	The staff is courteous with students.	[70] [72] [53]
F61	communication	Between lecturer and student.	[70] [72] [53]
F62	credibility	Trustworthiness.	[70] [72] [53]
F63	security	Campus facilities are safe.	[70] [72] [53]
F64	understanding	Both students and lecturer appreciate each other.	[70] [72] [53]
F65	standards of organizations	Each organization has its policies and guidelines.	[70]
F66	assessment	Evaluation methods.	[70]
F67	feedback	Opinions from staff and students.	[70]
F68	human resources quality	Capability and promptness of staff.	[46]
F69	privacy	Any information given by students (e.g., passwords) to technical staff is kept confidential.	[69]
F70	contact	Communication method.	[69]
F71	administrative services	Student support services.	[49] [64] [53] [61]
F72	campus infrastructure	Setup of HEI.	[49] [53] [73]
F73	leadership	Authority.	[74] [73]
F74	perishability	A service that cannot be made in advance	[75]

		and stored.	
F75	intangibility	A service has no physical substance.	[75]
F76	variability	Service may vary in quality from one provider to the next.	[75]
F77	lack of ownership	Shortage or absence of something required.	[75]
F78	inseparability	Makes customer-provider collaboration compulsory.	[75]
F79	infrastructure	Setup of an organization.	[76]
F80	teamwork	Colleagues working together.	[76]
F81	institutions management	Process of planning and organizing resources to run a successful organization.	[77]

a) *Principal Component Analysis:* Principle component analysis (PCA) is a multivariate statistical technique that summarizes the data by breaking it down into principle components (PCs), which are smaller elements that may be used to assess the construct more precisely without sacrificing any of the data's information [12]. Using built-in R stats package functions, PCA was applied to R-Studio.

b) *Data Standardization:* In PCA, data normalization is referred to as scaling. Here, the dataset is altered using an equation (1). This indicates that the attribute's mean is zero and that the resulting distribution has a unit standard deviation. The dataset was standardized as follows:

$$X_{ij} = (X_{ij} - X_m) / \sigma \quad (1)$$

where  $i = 1, 2, 3, \dots, 100$  (research no.) and  $j = 1, 2, 3, \dots, 81$  (factor no.),  $X_{ij}$  represents the original value of the  $i$ th research rating of the  $j$ th factor,  $X_m$  is the mean, and  $\sigma$  represents the standard deviation of the series formed by values of the  $i$ th research for all 81 factors. To standardize the data the R-Studio function `scale()` was used. The numeric matrix is entered as input and then the scaling on the columns is performed [78].

Table 2 displays the study dataset, which includes 100 quantitative examples and 81 qualitative cases for each element, and describes them all. To show the factors and determine the weights of each element, PCA was used to analyze the dataset. The dataset was standardized into items of classes and attributes using the PCA approach known as scaling in R-Studio to ascertain the transformation of the factors. The Kaiser criteria, which uses a minimal eigenvalue of unity, was used to calculate the number of PCS. Factors 1 through 81 were included in the dataset as @ ATTRIBUTE F1–F81 and their extraction was coded as @ ATTRIBUTE class PC 1–PC 100. R-Studio 2022.07.01 Build 554 and WEKA 3.8.6 were used to obtain the statistical methods for analyzing the transformed dataset. By using these two statistical approaches, we were able to assess the contributions of multiple factors and uncover transformations among the factors with increased validation. WEKA's PCA was employed to order the attributes.

As can be seen in Table 3 there are now 25 factors from the original 81 factors that have been identified as the key

success factors to determine students' satisfaction in terms of the IT technical support services that are provided at HEIs.

TABLE III. A 5-FACTOR LOADING RANKING OF THE QUALITIES

Rank	Attribute	Contribution

The WEKA statistical software identified 25 PCs with eigenvalues of 9.615 to 0.630, a variance of 0.119 to 0.008, and a cumulative variance of 0.119 to 0.957. The percentage ranges for each of the 81 PCs found by R Studio were as

follows: eigenvalue 9.615 to 0.001, variance 1.187 to 0.002, and cumulative variance 11.871 to 100. The 81 components, like other research that have used PCA to address various real-world issues, only take into account eigenvalues bigger than unity. The 81 PCs' eigenvalues, on the other hand, ranged

from 9.615 for the first component to 0.001 for the last. Moreover, for PCs 81 and 25, respectively, the 56 consecutive PCs had eigenvalues that ranged from 9.615 to 0.630, which is less than unity. A cumulative variance of 11.871 and an eigenvalue of 9.615 for PC1 explain the same total variance of 11.871.

The Institutions Management (F81) extraction value for PC represents 0.001, while the maximum 0.997 extracted values are for F14 – Customer Orientation, F15 – Competitor Orientation, F16 - Inter Functional Orientation, F17 – Performance Orientation, F18 – Employee Orientation, F19 – Long term Orientation. These factor loadings were integrated to account for the high eigenvalue, as seen in the first component.

According to Table 4, the cumulative variances for the first six PCs are 11.87%, 22.21%, 30.64%, 38.25%, 45.12%, and 51.47%.

As depicted in Table 5, Empathy has an eigenvector value of -0.224 and is one of the KSFs in the first group of PC1. Compared to subsequent components, this one describes the dataset's largest irregularity. In PC2, F41(effective leadership), F42(periodic review), F39(evaluation and control system), F38(specific policies and procedures), F43(resource allocation), F44(operational planning) and F35(customer focus and need based) have an eigenvector value of -0.292. F36(channels of communication) has -0.245; F40(curriculum design): -0.182 and F63(security): 0.168. The highest eigenvector value of +0.18 for PC3 is F61(communication) and F62(credibility). The highest eigenvector value of 0.371 for PC4 is F16(inter functional orientation), F15(competitor orientation), F18(employee orientation), F19(long term orientation), F14(customer orientation) and F17(performance orientation). For PC5, F22(dependability), F28(semester), F27(unusualsituation management), F23(effectiveness): 0.247. For PC6, F46(attitude), F47(content), F48(delivery): 0.093. The contribution of 10 factors identifying the different groups for the 6 PCs can be seen in Table 5.

The individually weighted factor values contribute to the PC from the factors in Table 6 that are shown there. The communalities shown in Table 6 show each factor loading that was employed for extraction, as observed between the extracted component's minimum and highest ranges of 0.089 and 0.997. Table 6 also displays the outcomes of each factor's presentation of its contribution to the communality.

Fig. 2. Ranking of 25 PCs.

The 25 PCs are ranked in Fig. 2, with the top six components scoring, respectively, 88.13%, 77.79%, 69.36%, 61.75%, 54.88%, and 48.53%.

A scree plot is a diagnostic tool that determines whether or not PCA performs properly on the data. The most variety is captured by PC1, followed by PC2, and so on. Although there are as many primary components in PCA as there are qualities, each one gives some information about the data. Information is lost if PCs are not present. The number of PCs is on the x-axis, while the eigenvalues are on the y-axis. The screen plot in Fig. 3 illustrates these PCs.

The graphic depiction of PCA is shown in Fig. 4. The graphic illustrates the correlation between the variables in the dataset; it indicates that if two variables point in the same direction, they are correlated; if they create a 90-degree angle, there is no connection; and if they point in the opposite directions, there is a negative correlation. For instance, variables F49, F55, and F56 are correlated because they all point in the same direction; variables F4 and F30 are negatively linked because they point oppositely; and variables F36 and F64 are uncorrelated since they form a 90-degree angle.

'Rotated' loading score is where each PC has its loading score, creating a matrix of eigenvectors. From this, it can be determined which factor has a positive or negative loading score. Fig. 5 depicts the 10-factor loading scores for the first 5 ranked attributes.

Fig. 3. Scree plot of the PCs.

Fig. 4. Contribution of each variable.

Fig. 5. Bar plot of the rotated component matrix for the 10-factor loadings.

According to these results, several KSFs that are used to specify the KSF diversity of the IT technical support satisfaction model based on the taxonomy of the groups that may have been discovered by the selection of these KSFs exhibit significant morphological variance. In this study, we attempted to explain the morphological diversity and map the KSFs to numerous relevant IT technical support satisfaction model components. These findings indicate that taxonomic groups could have been created by selecting certain characteristics. PCA was used in studies [81,82,83] to locate KSFs. According to different identity categories, the current study shows how KSF diversity differs. Several KSF studies have selected particular KSFs to contextualize their results. However, to offer a thorough nature of KSFs with varied morphologies, the results from this research were achieved by including all the KSFs that were found. A hybrid PCA and factor analysis technique was used in this study to identify, validate, rank, and categorize a dataset of 25 inputs as critical, leading to the discovery and description of all KSFs. The results of this study demonstrate that tangibility, reliability, responsiveness, empathy, and assurance are the KSFs that are most frequently used to categorize IT technical support services.

## V. CONCLUSION

By examining the physical traits that serve as a crucial preliminary method for evaluating various KSFs and simultaneously clarifying their effectiveness when utilized successfully, diversity was computed using many KSF markers. The range of KSFs that may be used for diverse IT technical support service satisfaction model implementations

is the important information offered by the study's findings. From the 81 factors for evaluating student IT technical support services provided to students at HEIs, only 25 of the most substantial have been uncovered. The first six primary components' low variances demonstrate unequivocally that the highest KSFs considerably increased the pool's diversity having eigenvectors not limited to values 0.23, 0.224, 0.247, 0.292, 0.371, and 0.402. The results of this study significantly advance our understanding of KSFs for IT technical support. With a special emphasis on the morphological traits of a divergent model that was created from a variety of distinct morphological taxonomies of the KSFs that were found. The study's conclusions can help practitioners avoid neglecting any KSF and help them consider their roles in creating a successful technical support service model. To date, no study has concentrated on studying the key success factors of

student IT technical support services in HEIs. It is recommended that the identified key success factors be used to evaluate IT technical support services that are being rendered to students at HEIs so that services can be improved and/or maintained. HEIs will be able to attract and retain more students. Future studies will focus on providing IT technical support services to staff and students and secondary schools (public and private).

Finally, The findings of this study make an essential contribution to the body of knowledge, with special emphasis on the identified CSFs of IT technical support services provided to students at HEIs. The study findings can assist HEI policymakers and IT practitioners in HEIs in not overlooking any essential success factors, therefore attaching a substantial consideration to providing the effective delivery of IT support services provided to students.

# Effect of Distance and Direction on Distress Keyword Recognition using Ensembled Bagged Trees with a Ceiling-Mounted Omnidirectional Microphone

Nadhirah Johari, Mazlina Mamat\*, Yew Hoe Tung, Aroland Kiring  
Faculty of Engineering, Universiti Malaysia Sabah, Kota Kinabalu, Malaysia

**Abstract**—Audio surveillance can provide an effective alternative to video surveillance in situations where the latter is impractical. Nevertheless, it is essential to note that audio recording raises privacy and legal concerns that require unambiguous consent from all parties involved. By utilizing keyword recognition, audio recordings can be filtered, allowing for the creation of a surveillance system that is activated by distress keywords. This paper investigates the performance of the Ensemble Bagged Trees (EBT) classifier in recognizing the distress keyword "Please" captured by a ceiling-mounted omnidirectional microphone in a room measuring 4.064m (length) x 2.54m (width) x 2.794m (height). The study analyzes the impact of different distances (0m, 1m, and 2m) and two directions (facing towards and away from the microphone) on recognition performance. Results indicate that the system is more sensitive and better able to identify targeted signals when they are farther away and facing toward the microphone. The validation process demonstrates excellent accuracy, precision, and recall values exceeding 98%. In testing, the EBT achieved a satisfactory recall rate of 86.7%, indicating moderate sensitivity, and a precision of 97.7%, implying less susceptibility to false alarms, a crucial feature of any reliable surveillance system. Overall, the findings suggest that a single omnidirectional microphone equipped with an EBT classifier is capable of detecting distress keywords in a low-noise enclosed room measuring up to 4.0 meters in length, 4.0 meters in width, and 2.794 meters in height. This study highlights the potential of employing an omnidirectional microphone and EBT classifier as an edge audio surveillance system for indoor environments.

**Keywords**—Distress speech; ensemble bagged trees; audio surveillance; machine learning; distance; directions

## I. INTRODUCTION

Screaming, yelling, or shouting is a natural way to express agony. They are particularly useful for detecting distress events in audio-based surveillance and monitoring applications that use the pitch and intensity of voice. The audio key-event detection system using Gaussian Mixture Model (GMM) presented in [1] uses acoustic references to detect and examine abnormal events based on a binary classification technique of shot and normal classes. In [2], a monitoring service technology was developed to determine the stress level from the voice tone changes. An anomalous audio event detection using GMM in [3] discriminates screams and gunshot sounds from noises. Another study in [4] utilizes the personal computer equipped with a sound card and microphone to detect distress sounds like a cry for help or glass breaking. Real-time

sound analysis was developed using eight mic channels to distinguish stress from normal situations [5]. Audio data are advantageous in assistive awareness systems for emergency recognition of falls and distressed speech expression in elder or patient care [6-7]. In [8], a two-stage learning-based method was proposed to detect screams and cry in urban environments. Indoor context based on Receiver Operating Characteristic (ROC) result gives the least false alarm rate compared to the other five contexts; Gathering, conversation, outdoors, machinery, and multimedia. Detection of speech distress was also conducted through remote monitoring [9]. According to the results obtained in [10], it can be concluded that in various interaction scenarios, voice pitch may serve as an accurate biosocial and individual identifier. The distress call is useful in emergencies, especially tracking a person by detecting cries for help in an enclosed environment [11].

However, people might also talk, laugh or scream loudly and high-pitched when they get excited. Surveillance systems triggered by the voice's pitch and intensity will create false alarms in those circumstances. Moreover, the existing surveillance system may also intrude on an individual's privacy and invasion of civil rights [12]. For example, always-listening devices like smartphones may accidentally wiretap the information of the surroundings [13]. Hence, the privacy-aware architecture was proposed to prevent privacy violations and potential recordings [14, 15]. The risks are apparent due to the availability of technology that can access sensitive data such as audio [16]. Overcoming these issues requires a simplified surveillance system that intelligently recognizes distress keywords apart from the voice's pitch and intensity. Such a system will enable a crime detection automation system that recognizes targeted distress speech and non-distress (high-toned) speech. This idea has been explored for outdoor surveillance [8] and should be extended to indoor environments when video surveillance is not viable [17-19]. Places like shared bathrooms and nursery rooms should be equipped with audio surveillance to reassure safety [20-21].

Having indoor audio surveillance that is always recording in the cloud is not well accepted by many due to privacy and security concerns. Edge Artificial Intelligence (AI) could be employed as a solution. Audio surveillance with edge AI will be able to detect specific keywords and trigger the system at the device level (locally). Among the AI algorithms, the Ensemble Bagged Trees (EBT) is one of the supervised machine learnings explored in audio data classification for safety-related applications. EBT has been applied to non-

speech data to investigate false speakers via spoofing sounds [22], classify non-speech audio data [23], monitor babies [24], and classify sounds [25-26]. EBT has also recently been employed to differentiate multiple emotions; anger, disgust, fear, joy, neutral, surprise, and sad from speech audio signals [27-29].

These studies show that EBT performs considerably better than other classifiers, such as Boosted Trees, Bagged Trees, Subspace K-Nearest Neighbor (KNN), Support Vector Machine (SVM), Quadratic SVM, and Quadratic Discriminant [24,29]. EBT can be a good option for real-time distress keyword recognition due to its ability to handle noise and variability in speech data. In speech recognition, there can be significant variation in speech patterns due to individual differences, accents, and other factors. Bagged trees can capture this variability by creating multiple decision trees and combining their outputs. Thus, it can improve accuracy and robustness in recognizing spoken keywords. EBT is computationally efficient and can be easily parallelized, making it a good option for real-time speech recognition applications. It can also be trained using small amounts of data, which is beneficial for scenarios where large amounts of labeled data may not be available.

Employing EBT in the edge audio surveillance system requires careful evaluation to get robust performance. To the best of our knowledge, there is still a shortage of work on distress speech detection using EBT because most studies focus on non-speech and non-distress signals. Moreover, the effectiveness of EBT on distances and directions of the sound sources from the microphone is still undiscovered. This paper investigates the effect of speech distance and direction on the EBT recognition performance, which was proven superior in a previous analysis [30]. For that, two experiments were conducted in a room that resembled a typical nursing room size. Experiment 1 studies the performance of EBT to detect a distress keyword from three different distances: 0m, 1m, and 2m. Experiment 2 analyzes the effect of different directions, facing toward and away from the microphone.

This paper is arranged as follows. Section II covers the materials and research methodology. Section III presents and discusses the results. Finally, Section IV concludes the findings, research's limitations, and future recommendations.

## II. MATERIALS AND METHODS

### A. Experimental Setup

The experiment was conducted in a low-noise room with a dimension of 4.064m (Length) x 2.54m (Width) x 2.794m (Height). An omnidirectional microphone was installed at the center of the room's ceiling to capture audio signals from various angles at equal coverage and in a short range. However, omnidirectional microphones collect more noise than directional microphones [31]. Thus, it was suggested to place the omnidirectional away from the reflecting areas [32-33]. Speeches were uttered from horizontal distances of 0 m, 1 m, and 2 m by speakers in sitting condition, facing toward the microphone and away from it, as shown in Fig. 1 to 3. The microphone was connected to a Vivo V17 smartphone

(Android 9.0 Pie & Octa-core processor) that performed as a speech recording device.

Guidelines:

- ✗ - Position of the audio sources
- - Microphone

Fig. 1. Distance between speaker and microphone in a closed room.

Fig. 2. Position of the speaker during data collection facing toward the microphone.

Fig. 3. Position of the speaker during data collection facing away from the microphone.

### B. Signal Preprocessing – Audio Filtering

The recorded audio signal was initially stereo with MP4a format, 44100 Hz sampling rate, and 32-bit rate. The audio signal was then exported in WAV format with 44100 Hz for further processing. WAV format audio files are stored in a large space because the signals are uncompressed, maintaining strong sound quality [34]. Due to the differences in time-frequency representation, both left and right channels were calculated to find their average to produce only a mono data channel instead of separating the channels into two parts [35-36].

### C. Feature Extraction and Feature Reduction

Each preprocessed audio signal was divided into smaller frames using a Hamming window of 1024 ms and an overlap length of 512 ms [37-39]. For every frame, thirteen Mel-Frequency Cepstral Coefficients (MFCCs) were extracted and organized into an  $f \times c$  matrix, where  $f$  is the number of frames and  $c$  is the thirteen MFCCs. The total number of frames was set to 120 by adding or deleting frames at regular intervals, resulting in a matrix of  $120 \times 13$  MFCCs representing the audio signal features [30]. Principal Component Analysis (PCA) was used to reduce the features to  $13 \times 13$  [40]. The pseudocode for feature extraction is given in Fig. 4.

```
Obtain a speech signal of 1.5s length, and do the following:
  Detect Endpoints, obtain the voiced part
  Divides into f frames (Hamming window: 1024ms, overlap 512ms)
  For n = 1 to f
    Extract 13-MFCCs
    Construct an  $f \times 13$  matrix
  End For loop
  If  $f > 120$ , do the following,
    Obtain number of rows to be removed, r
    Determine the interval, d
    For i = 1 to f
      Delete the 13-MFCCs at every d
    End for loop
  Else
    Obtain number of rows to be added, r
    Determine the interval, d
    For i = 1 to 120
      For every d, compute new MFCCs using the average
        of MFCCs(d-1) and MFCCs(d+1)
      Add the new MFCCs at row d
    End For loop
  End if-else
```

Fig. 4. Pseudocode for feature extraction.

### D. Data Collection

The distress keyword "Please" was chosen for analysis, as it was found to be the most distinct compared to other distress keywords such as "Oi", "Help", "Tolong", and "No [30]. A total of 3600 speeches containing the targeted distress keyword "Please" and non-targeted speeches were collected and divided

into four datasets: Dataset 1, Dataset 2, Dataset 3, and Dataset 4. Dataset 1 comprises 100 samples for each distance and 300 for each direction of distressed "Please" speeches, recorded by five female speakers, with each speaker producing 20 samples for each distance and direction.

Dataset 2 includes 600 samples of recorded distressed "Please" speeches played at three different distances and directions. Dataset 3 has the same design as Dataset 1, except the speakers uttered "Please" in a non-distressed tone. Dataset 4 contains 20 samples of each of the five words "One", "Two", "Three", "Okay", and "Yes", spoken in a distressed or high tone captured from three female speakers at each position. Each dataset was labeled '1' for the targeted "Please" and '0' for the non-targeted speeches. The datasets were then divided into training and testing data in an 80 to 20 ratio, as shown in Table I. The EBT was trained using a combined training data of 2880 speeches and tested on various groups of unseen speeches.

TABLE I. DATA COLLECTION OF DISTRESS KEYWORD "PLEASE"

Dataset	Characteristic	Label	Sample	Data Partition	
				Training (80%)	Testing (20%)
1	Distress "Please"	1	600	480	120
2	Distress "Please"	1	600	480	120
3	Non-distress "Please"	0	600	480	120
4	Distress/High-tone Words	0	1800	1440	360

### E. EBT Classifier

Z Breiman presented the ensemble technique in 1996, intending to improve the Decision Trees (DT) classification performance [41]. The word 'Bagging' itself is a Bootstrap Aggregation that reduces the decision tree variance.

The bootstrap method randomly creates minor groups of data with replacements from the overall dataset from the training dataset. Each set created with equal probability will undergo a parallel training of DT classifiers. It produces a robust performance compared to an individual DT model [42]. Each DT model will independently produce different features. Then, the aggregation process was applied by accumulating the predictions of all different DT groups and taking the mean of the outcomes to get the final bagging result. Likewise, this machine learning classifier is a highly precise model combining various decision trees [43]. For this study, 30 DT classifiers were used for the parallel ensemble technique, as illustrated in Fig. 5.

Equation (1) defines its principle where DT learners,  $f_d(x)$  are trained based on the architecture in Fig. 5 with the bootstrapped dataset. The mean of the total predictions from every DT learner is taken as the result.

$$f(x) = \frac{1}{D} \sum_{d=1}^D f_d(x) \quad (1)$$

Where; D = sets of bootstrapped data, d = DT learners.

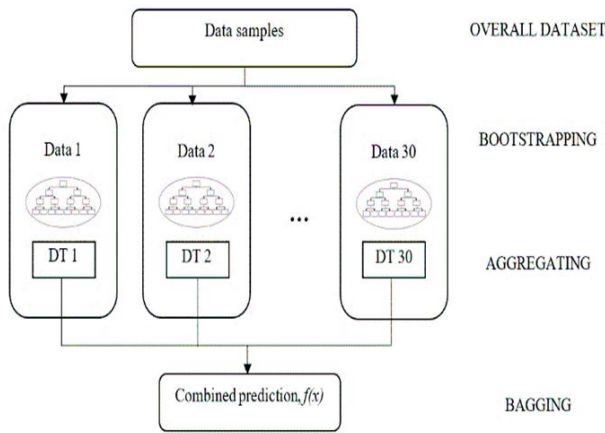

Fig. 5. The ensemble bagged trees.

F. Evaluation Metrics

The efficiency of the EBT as a distress keyword recognizer is measured based on the following metrics: accuracy, precision, recall, and F1 score, as stated by equations (2) until (5). In an audio-based surveillance application, all metrics are important, but precision and recall are two indicators defining performance. Precision and recall values will determine whether such an audio-based surveillance system would have minimal false alarms or unidentified incidents.

1) *Accuracy*: It measures the overall correctness of the EBT's output. The calculation of accuracy is based on the following formula:

$$Accuracy = \frac{No.of\ samples\ predicted\ correctly}{Total\ number\ of\ samples} \times 100\% \quad (2)$$

2) *Precision and recall*: These metrics provide information on how effectively the EBT performs when categorizing specific classes. Precision measures the proportion of true positives among all the positive results. In other words, precision measures the percentage of correctly identified events out of all the events detected by the EBT. The recall measures the percentage of true positives that were accurately detected.

In an audio-based surveillance system, precision is important to avoid false alarms, which can be a nuisance and result in unnecessary responses by security personnel. On the other hand, recall is important to identify all critical events, even if they are rare or infrequent. The precision and recall are given by equations 3 and 4, respectively:

$$Precision = \frac{True\ Positive\ (TP)}{True\ Positive\ (TP)+False\ Positive\ (FP)} \times 100\% \quad (3)$$

$$Recall = \frac{True\ Positive\ (TP)}{True\ Positive\ (TP)+False\ Negative\ (FN)} \times 100\% \quad (4)$$

3) *F1 Score*: It is considered a weighted average based on precision and recall and is calculated with the following:

$$F1\ Score = \frac{2(Precision*Recall)}{(Precision+Recall)} \quad (5)$$

In an audio-based surveillance system, the F1 score can be a useful metric to optimize a balance between precision and recall, especially when there is a trade-off between the two.

III. RESULTS AND DISCUSSION

All four datasets described in Table I were merged to form a training data set of 2880 samples. This combined data set was used for EBT training and validated with a 20-fold technique. To evaluate the performance of the trained EBT, 720 unseen samples were tested based on the distances and directions as defined in the subsequent subsections. Table II presents the results that were deduced from the confusion matrices in Fig. 6. Excellent accuracy, precision, and recall values exceeding 98% were observed during validation.

Of the testing data, the EBT has a satisfactory recall rate of 86.7%. It means the system has moderate sensitivity to every possible incident, adequate but not achieving the desired characteristic of a surveillance system. Nevertheless, a precision of 97.7% was observed, indicating the system is less susceptible to generating a false alarm, a feature of a trusted surveillance system.

TABLE II. PERFORMANCE ON DIFFERENT DISTANCES AND DIRECTIONS

Validation Performance (%)					
Metric	Accuracy	Precision	Recall	F1-Score	
	99.4	99.2	99.9	99.5	
Testing Performance (%)					
Metric	Accuracy	Precision	Recall	F1-Score	
Distance: 0m	Facing Toward	97.5	95.1	97.5	96.3
	Facing Away	87.5	96.3	65.0	77.6
Distance: 1m	Facing Toward	95.0	97.2	87.5	92.1
	Facing Away	93.3	100.0	80.0	88.9
Distance: 2m	Facing Toward	99.2	97.6	100.0	98.8
	Facing Away	96.7	100.0	90.0	94.7
Average					
Testing data	94.9	97.7	86.7	91.9	

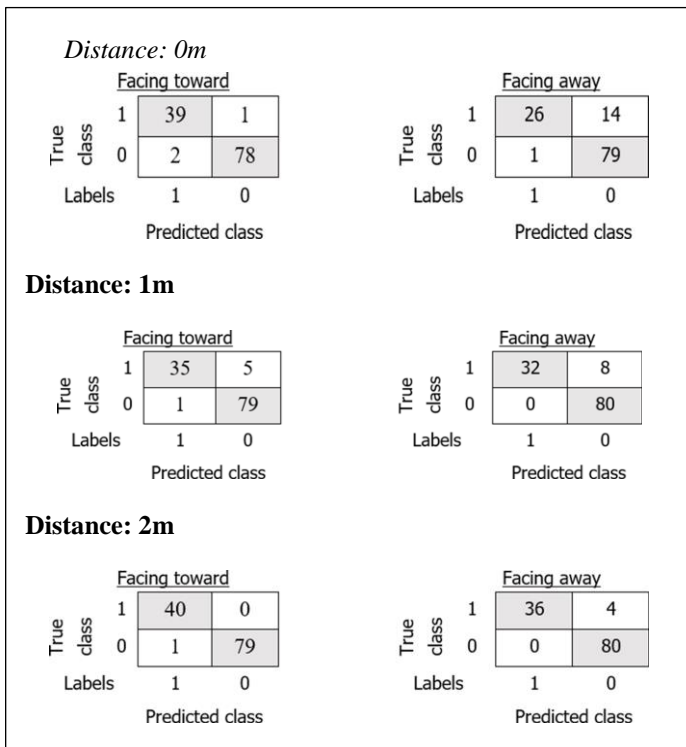

Fig. 6. The confusion matrices for different distances and directions.

#### A. Effect of Sound Distance

Fig. 7 shows the evaluation metrics versus distances of the testing results in Table II. Overall, EBT demonstrated high recognition accuracy with excellent precision for all distances examined. The lowest accuracy was observed at a 0 m distance, right under the microphone, possibly due to sound energy spreading from the speaker. When moving a little farther, the recognition performance improved. It is interesting to note that recall values are lowest at 0 m, slightly increased at 1 m, and highest at 2 m from the microphone.

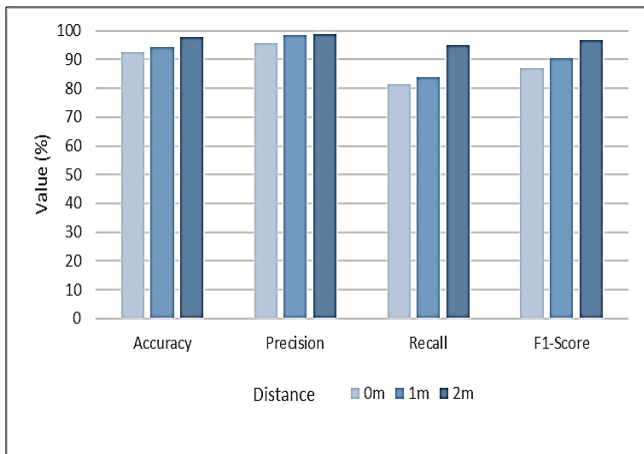

Fig. 7. Evaluation metrics versus distance.

This observation indicates that the system is more sensitive and could better recognize the targeted signals when the signals are a little farther, at one or 2-meter from the microphone. The findings corroborate that the omnidirectional microphone can capture signals from a wider distance, contributing to EBT's recognition performance in this study.

#### B. Effect of Sound Direction

Fig. 8 displays the evaluation metrics values for the facing toward and facing away directions. Based on the chart, it can be observed that facing toward the microphone will produce a better recognition rate. This is expected as the coverage area of the signals emitted toward the microphone is much wider. Sounds emitted from sources facing toward the microphone contain higher intensity than the sounds emitted from sources facing away.

Facing away from the microphone apparently affects the sensitivity of the system to recognize the targeted keyword. The overall recall value falls under 80%, in which a distance of 0 m scores the lowest. However, the recall value is gradually improving as the distance increases. At closer distances, facing away from the microphone can result in a weaker signal-to-noise ratio, which can make it more difficult to distinguish speech from background noise or interference. This can result in a lower recall of speech and a lower overall quality of the recording. However, at farther distances, the reduction in speech intensity due to facing away may be less pronounced, and the ambient noise level may also be lower, resulting in a clearer and more intelligible recording.

#### C. Proposed Edge Audio Surveillance

From the results, it can be inferred that a single omnidirectional microphone equipped with an EBT classifier is adequate for capturing audio in a low-noise enclosed room measuring up to 4.0 meters in length, 4.0 meters in width, and 2.794 meters in height. An audio surveillance system with an omnidirectional microphone and a processing unit that contains algorithms for signal preprocessing, feature extraction, feature reduction, and a pre-trained EBT can be developed. Fig. 9 presents the proposed edge audio surveillance.

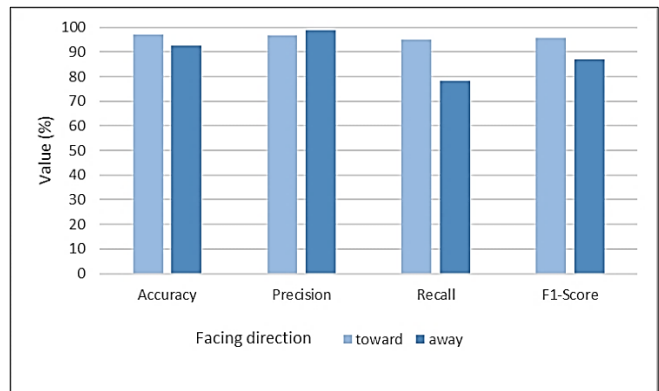

Fig. 8. Evaluation metrics versus direction.

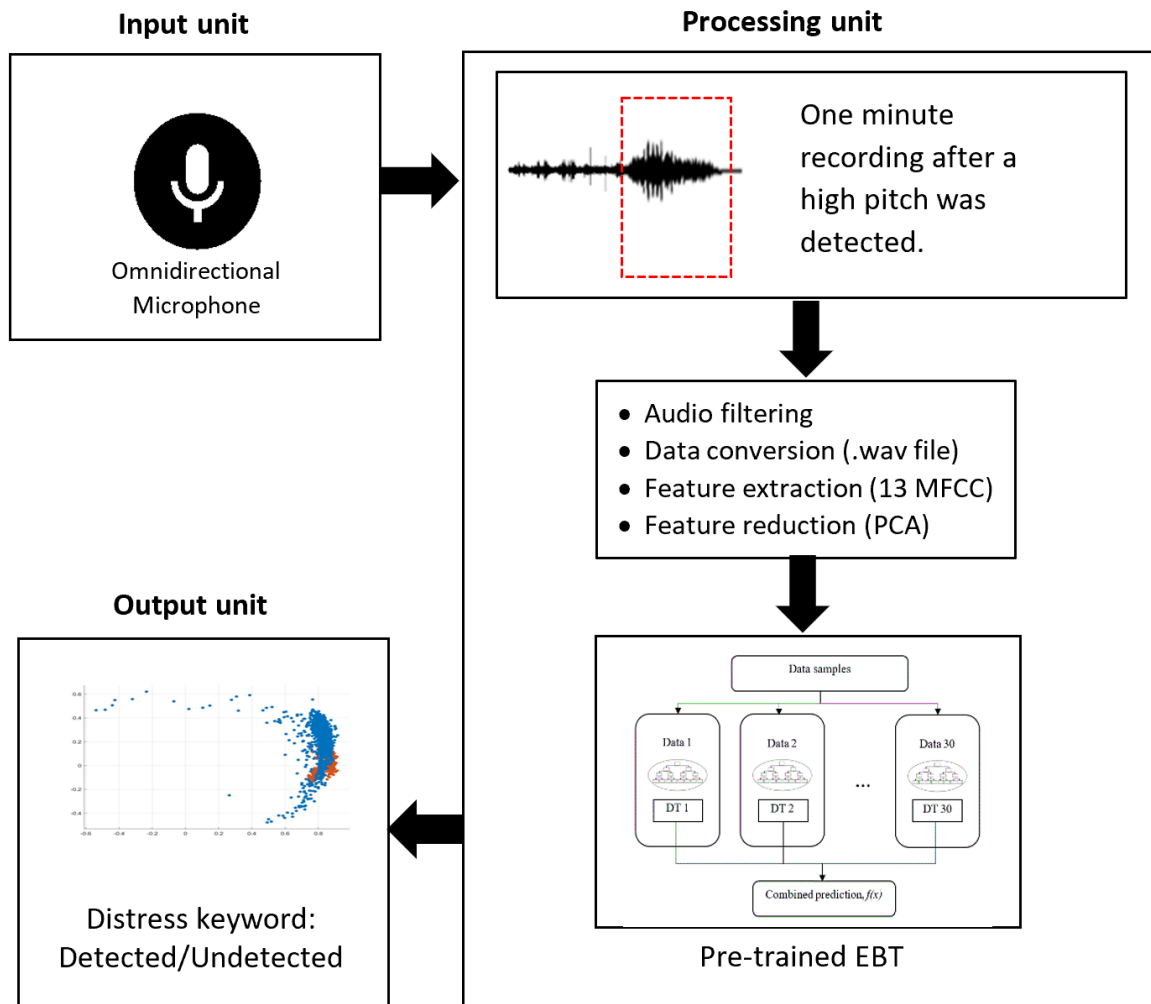

Fig. 9. Block diagram of the proposed audio surveillance system.

The processing unit can be assembled into several devices to form an edge surveillance system. A potential device would be the Raspberry Pi 4. Raspberry Pi 4 is a low-cost, small-sized computer that can run various operating systems and programming languages. The Raspberry Pi 4 has up to 8GB SDRAM and is clocked at 1.5GHz, enough processing power and memory to run simple speech preprocessing and pre-trained EBT, and can be easily connected to microphones and other output devices. The efficiency of the pre-trained EBT on the Raspberry Pi 4 will depend on factors such as the size of the EBT, the complexity of the individual trees, and the available resources on the Raspberry Pi. However, with proper optimization and tuning, it is possible to achieve efficient and accurate inference on the Raspberry Pi 4 with a pre-trained EBT model.

#### IV. CONCLUSION

This paper presents audio-based surveillance based on distress keyword recognition using an EBT classifier and an omnidirectional microphone. The experiments were conducted in a setting similar to a typical nursing room, enclosed and low-noise. The recognition performance of EBT was evaluated

under different conditions, explicitly varying distances and directions of the sound sources from the microphone. Results show that the system is more sensitive and could better recognize the targeted signals when the signals were a little farther, at a one or 2-meter distance, and facing toward the microphone. It can be inferred that a single omnidirectional microphone equipped with an EBT classifier is adequate for capturing the distress keyword "Please" in a small, low-noise enclosed room.

To further enhance the sensitivity of the developed audio surveillance, expanding the dataset by incorporating various sources of both targeted and non-targeted signals is recommended. This approach will help to mitigate the occurrence of false alarms. Additionally, it is advised to increase the number of samples with background noise to address common issues related to high-pitched vocalizations, such as screaming in joy or surprise, that may trigger the distress event detector. Furthermore, implementing an adaptive noise filtering mechanism can facilitate the system's learning about the surrounding noises associated with the threshold of the distress signal speeches, thereby enhancing recognition accuracy.

**Abstract**—In the big data era there are some issues regarding real-world classification problems. Some of the important challenges that still need to be overcome to produce an accurate classification model are the data imbalance, difficulties in labeling process, and differences on data distribution. Most classification problems are related to the differences in the data distribution and the lack of labels on some datasets while other datasets have abundant labels. To address the problem, this paper proposes a weighted-based feature-transfer learning (WbFTL) method to transfer knowledge between different but related domains, called cross-domain. The knowledge transfer is done through making a new feature representations in order to reduce the cross-domain's distribution differences while maintaining the local structure of the domain. To make the new feature representation we implement a feature selection and inter-cluster class distance. We propose two stages of the feature selection process to capture the knowledge of the feature and its relation to the label. The first stage uses a threshold to select the feature. The second stage uses ANOVA (Analysis of Variance) to select features that are significant to the label. To enhance the accuracy, the selected features are weighted before being used for the training process using SVM. The proposed WbFTL are compared to 1-NN and PCA as baseline 1 and baseline 2. Both baseline models represent the traditional machine learning and dimensionality reduction method, without implementing transfer learning. It is also compared with TCA, the first feature-transfer learning work on this same task, as baseline 3. The experiment results of 12 cross-domain tasks on Office and Caltech dataset show that the proposed WbFTL can increase the average accuracy by 15.25%, 6.83%, and 3.59% compared to baseline 1, baseline 2, and baseline 3, respectively.

**Keywords**—Feature-transfer learning; image; feature selection; weight; distance

## I. INTRODUCTION

In this big data era, the use of machine learning is growing and expanding into various purposes and uses, including image classification. The success rate of machine learning in image classification is generally determined by the accuracy value. Although nowadays there are already many public datasets [1], some challenges associated with image classification still exist. The first challenge arises because there are some unlabeled or limited labels of datasets [2] [3] [4]. Meanwhile, on the other side there are many other datasets with a very abundant labels. The second challenge is related with the labeling process which needs much effort to make a label for the dataset [3] [4] [5] [6]. Whereas the availability of the labeled data training determines the success of the classification model [7]. The third challenge is

associated with the limited ability of the traditional machine learning method, which requires the training and inference data come from the same dataset that has the same distribution. Even though this ability is needed to produce an accurate classification model [2] [3] [8]. Unfortunately, traditional machine learning methods such as: NN (Nearest Neighbor) and PCA (Principal Component Analysis) do not show good results on the third challenge [9].

To overcome the challenges, we can make a classification model by using knowledge from different but related datasets (domain) [4] [10] [11] [12]. The method is called transfer learning, which is an extension of traditional machine learning. The different but related dataset (domain) used in transfer learning is often called cross-domain. The use of cross-domain terms indicates the existence of the source domain ( $D_S$ ) and the target domain ( $D_T$ ). The original idea of transfer learning is to utilize the knowledge from the labeled domain often called the source domain, to predict the correct label for an unlabeled domain often called the target domain. Before transferring the knowledge, we need to conduct the similarity measurement between the cross-domain to avoid negative transfer. Negative transfer is when the classification model trained using a combination of the cross-domain gives poorer performance than the one trained using the source domain only. Generally, the similarity measurement in the cross-domain is performed using Maximum Mean Discrepancy (MMD).

There are many transfer learning approaches, such as feature-based, instance-based, parameter-based, and relational-based transfer learnings [3] [10] [11]. Our work focuses on feature-transfer learning, considering this approach is mostly used for image domain [12] [13] [14] [15] [16] [17]. Research on the feature-transfer learning began with the discovery of the Transfer Component Analysis (TCA) method which only focuses on overcoming marginal distribution differences in cross-domains [13]. After TCA, several other feature-transfer learning methods were found, such as Geodesic Flow Kernel (GFK) [16], Joint Distribution Adaptation (JDA) [14], Subspace Alignment (SA) [17], Transfer Joint Matching (TJM) [15], and Balanced Distribution Adaptation (BDA) [9]. Moreover, the success key for knowledge transfer in the cross-domain can be done by focusing on the instances in  $D_T$  and conducting the features matching to minimize data distribution difference [18]. Feature-based also can be improved the classification accuracy when it is used with the classifier like SVM [19] [20] [21]. However, one of the weakness of SVM is restricted the

data precision and requires computational cost, so it needs an additional step, such as features reduction to minimize cost [22] [23]. Many techniques can be applied in feature-transfer learning, for example, the use of the Grassman manifold as the geometric property[16], adding balance unit parameter to overcome the data imbalance problem[9], or the formation of subspace features to minimize the distribution difference[17]. In general, the previous feature-transfer learning method works by adapting the dimensional reduction approach and generating an adaptation matrix which is a projection of the cross-domain's features. These techniques need an iteration process to get the best result and add some parameters in the model, where the parameters have to be tuned up to give optimal results. These previous feature-transfer learning methods need large computational requirements due to the complex process and the use of many parameters. CORAL [24] proposed simpler feature-transfer learning without using many parameters. It used the second-order statistical approach to overcome the distribution differences in the cross-domain. However, this method did not consider the label information contained in the source domain. Though some important information can also be obtained from the label.

Therefore, in this paper we propose a simple feature-transfer learning method without using many parameters while still adopting a dimension-reduction approach and utilize the label information from the source domain. We name this proposed approach as Weighted-based Feature-Transfer Learning (WbFTL). The dimension reduction in the method is more towards the formation of new features subsets through the implementation of features selection techniques. Implementing the features selection has several benefits. First, it can reduce the search space and generate significant features for the classification [25]. Second, the features selection also has a simpler way of working without the need to do features projection of the cross-domain, thus retaining the original form of the features and maintaining the explicit meaning of the selected features [26]. Lastly, the features selection method in the classification problem also can enhance the classification results [27] [28] [29] [30]. To optimize the model, the proposed feature-transfer learning adds some weight to the selected features and also use the closest distance between instances to the center of the class label. These combination techniques allow the proposed method to make a new features representation that can minimize the distribution differences between cross-domain while still maintaining the local structure of each domain to get an efficient and accurate classification model.

The experiment showed WbFTL increasing the accuracy by 15.25%, 6.83%, and 3.59%, respectively, against the 1NN, PCA, and TCA baseline models. WbFTL is also superior to the previous feature transfer method and provides a higher average accuracy than those of GFK, JDA, SA, and TJM. Compared to BDA, WbFTL has a competitive accuracy. However, our proposed WbFTL is more superior in the parameters used than BDA. Unlike BDA, WbFTL supports minimal use of parameters that can be run on limited machine resources.

Overall, the contribution of our work can be summarized as follows:

1) WbFTL is an easy feature-transfer learning approach that can overcome the distribution difference in the cross-domain without using many parameters in the training and inferring process.

2) WbFTL is a novel feature-transfer learning method that uses feature selection as the strategy to make transformation of the features. Combined with the feature weighting, the experiment results show that the proposed method get better results compared to other feature-transfer learning methods.

3) WbFTL also the first feature-transfer learning method that utilize the label information in the source domains in the transformation process.

## II. METHODS

Machine learning has two important components: domain and task. In transfer learning we have source domain, source task, target domain, and target task. The source domain or  $D_S$  contains source features space ( $\mathcal{X}_S$ ) and marginal probability ( $P(x_S)$ ), written as  $D_S = \{\mathcal{X}_S, P(x_S)\}$ , where  $x_S \in \mathcal{X}_S$ . The source task or  $\mathcal{T}_S$ , consists label space  $\mathcal{Y}_S$  and classification function  $f(\cdot)$  to determine the label for instances in  $D_T$  based on the knowledge from  $D_S$  and  $D_T$ . The source task can be written as  $\mathcal{T}_S = \{\mathcal{Y}_S, f(\cdot)\}$ . Same as the source domain and task, the target domain, and target task can be written as  $D_T = \{\mathcal{X}_T, P(x_T)\}$  and  $\mathcal{T}_T = \{\mathcal{Y}_T, f(\cdot)\}$ .

The WbFTL method is included in the category of transductive transfer learning. In this category, only instances in  $D_S$  have the label, meanwhile  $D_T$  are unlabeled. There are 800 features in each  $D_S$  and  $D_T$ , and the number of instances on  $D_S$  and  $D_T$  can be different. The goal of the WbFTL is to do feature transformation and make a new feature representation that represents the cross-domain,  $D_S$  and  $D_T$ . The overview of WbFTL in carrying out the transformation can be seen in Fig. 1.

From Fig. 1 it can be seen that the WbFTL method emphasizes the problem of distribution equalization in the cross-domains. Distribution equalization is conducted by making a new features representation that reflects both domains. The process of equalizing this domain begins by measuring the similarity between domains, followed by features selection and features weighting to create a method that is cost effective while still being able to produce a good accuracy. WbFTL also overcomes the conditional distribution differences by utilizing the label information in the features transformation process.

As depicted in Fig. 1 below, the new features representation should minimize the distribution difference between  $D_S$  and  $D_T$ , while still preserving the local structure of the domain itself. The new features representation formed will be used for the training and inference process with SVM, as depicted in Fig. 2. Before being processed by SVM, the data used will be converted into a features vector using statistical calculations [31].

Fig. 1. The overview of WbFTL

There are three steps of features transformation in WbFTL as shown in Fig. 3. The first step is features selection using a threshold to select the features. The second transformation step is the features selection using ANOVA. The third step is only transforming the features in  $D_T$ , by calculating the minimum distance between instances in  $D_T$  to the class label of  $D_S$ .

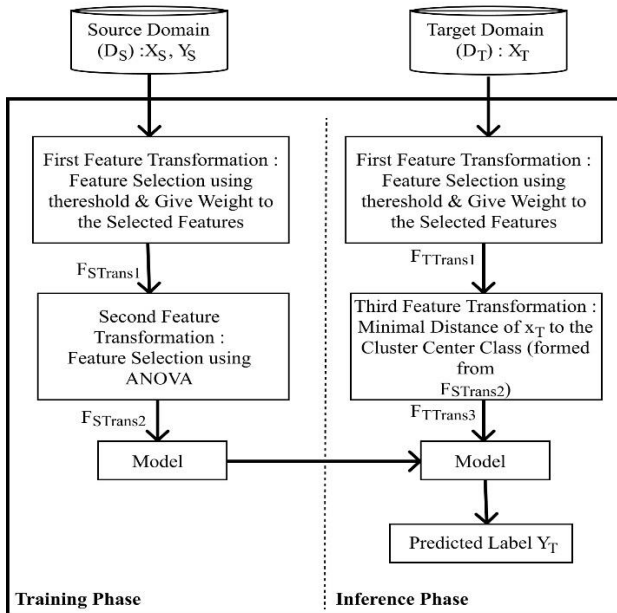

Fig. 2. The training and inference process in the WbFTL.

The features selection method is one of the strategies to form a new features representation besides features mapping, features clustering, features encoding, features alignment, and features augmentation [32]. This strategy can preserve the

local and important structure of the domain, besides, also reducing the distribution difference of the cross-domain.

Fig. 3. Feature transformation steps in WbFTL.

Before doing the features transformation, there is a similarity measurement process between  $D_S$  and  $D_T$  using MMD, as a non-parametric method [9] [13] [14] [15] [16] [18] [32]. In the non-parametric method, the measurement is done using approximation distribution value, because it is difficult to get the real distribution value. In the proposed feature-transfer learning, MMD is used in conjunction with the kernel which will map the original value of the features space of each domain to a new features representation using a mapping function. Our proposed method uses a distance function as the mapping function, that is the Euclidean Distance and Reproducing Kernel Hilbert Space (RKHS) [13] [14] [15] [16] [18] [32]. The use of MMD and kernel makes it sufficient to calculate the similarity of the cross-domain using density estimation. The density estimation is done using average features values in the features space  $X_S, X_T$ . The formulation of the mapping function on feature-transfer learning can be seen in (1).

$$Sim(D_S, D_T) = \|F_{S_i} - F_{T_i}\|_{\mathcal{H}}, \quad (1)$$

where  $Sim(D_S, D_T)$  is the similarity measurement result using MMD and RKHS in the cross-domain,  $F_{S_i}, F_{T_i}$  is the vector of the mean value of the  $i$ -features in  $D_S$  and  $D_T$ , sequentially.

The new features space formed from MMD and kernel will be the input for the first step of features transformation. The shape of the features space resulting from the application of MMD and the kernel can be seen in (2).

$$F = \{f_1, f_2, \dots, f_n\} \in R^n, \quad (2)$$

where  $F$ , is the new features space which is the result of  $D_S$  and  $D_T$  features mapping,  $n$  is the amount of the original features, that is 800 features.

### A. Features Selection and Weighting

Feature selection is the process of generating a feature subset based on its relevance and redundancy [33]. The purpose of feature selection is to select the right features in order to get a better understanding of the characteristics of the data. Therefore, selecting significant features will assist the model in studying the data and producing the right label [23]. Feature selection can also enhance classification accuracy [29] [30]. Moreover, feature selection can also be used to reduce

the dimensionality while maintaining the local structure of the dataset and reducing the model complexity.

WbFTL applies the feature selection technique in the first and second steps of the feature transformation process. The two steps of feature selection in WbFTL use a statistical-based approach, i.e., average and varians.

1) *Feature selection using thresholds and feature weighting*: The first step in feature transformation is adopting the filter method. The filter method can work faster and simpler in the implementation and does not depend on the classifier used [34] [35]. The average value will be used as the threshold value, which serves as a stopping criteria. Features with a value under the threshold will be selected because they are considered similar or significant features between  $D_S$  and  $D_T$ . The feature subset that is formed can be written as in (3)

$$A = \{a_1, a_2, \dots, a_k\} \in R^k \quad (3)$$

where  $A$  is the feature subset and  $k$  is the amount of the selected features, with  $k < n$ .

Previous feature-transfer learning also reveals that feature weighting can enhance classification accuracy [27] [36]. Feature weighting is the generalization of feature selection [37] [38]. Therefore, the selected features in the feature subset will be weighted according to their degree of similarity. The smaller the feature value, the greater the weight given. The weight value describes the level of similarity. The formula for the feature weight can be seen in (4). This weighting method is similar to Fisher's criteria, which are used in various cases.

$$w(a_i) = \frac{\frac{1}{k} \sum_{i=1}^k a_i}{a_i}, \quad (4)$$

where  $w(a_i)$  is the weight for the  $i$  –features.

The first feature transformation is generated as a dot product between the selected features in (3) and the weight according to formula (4). The dot product can be written as in formula (5) and the representation of the first feature transformation can be written in (6).

$$b_i = w(a_i) \times f_i, \quad (5)$$

$$F_{Trans1} = \{b_1, b_2, \dots, b_k\} \in R^k \quad (6)$$

where  $b_i$  is the first features transformation for the  $i$  –feature,  $w(a_i)$  is the weight for the  $i$  –feature,  $f_i$  is the original value for the  $i$  –feature, and  $F_{Trans1}$  is the first feature transformation.

2) *Feature selection using ANOVA*: The disadvantage of the first-step feature transformation above is that it does not involve label information. Therefore, to select the features that are significant to the label, the second feature transformation is carried out using ANOVA. The ANOVA technique uses variants, a statistical property, to select the features. Previous research shows that the use of ANOVA with SVM gives good accuracy in image classification [28] [39] [40].

The second step of feature transformation in WbFTL applies ANOVA to select features. The first feature

transformation ( $F_{Trans1}$ ) above became the input for the second feature transformation ( $F_{Trans2}$ ), which is used for the training process. The second feature transformation has the same value as the first feature transformation, only different in the number of features. The representation of the second feature transformation can be seen in (7).

$$F_{Trans2} = \{b_1, b_2, \dots, b_a\} \in R^a \quad (7)$$

where  $F_{Trans2}$  is the second feature transformation that uses ANOVA, and  $a$  is the selected features from the implementation of ANOVA with  $a < k$ .

### B. Inter-Cluster Class Distance

The third feature transformation is done by calculating the distance from instances of  $D_T$  to the center of the class label. The Euclidean distance will be used for the distance calculation. The third feature transformation adopts the gravity law, which is also similar to the general works of classification [41]. The use of distance has also been widely used in feature-transfer learning, such as for determining the weight proportion [8], determining the similarity between cross-domain [13] [14] [15], and the implementation of metric learning [32].

The input for the third feature transformation ( $F_{Trans3}$ ) comes from the first feature transformation ( $F_{Trans1}$ ). The formula to calculate the distance of each instances in  $D_T$  is written in (8). While the formula to get the third feature transformation can be seen in (9). The representation of the the third feature transformation written on (10).

$$d_i = \frac{x_T \times h_C}{Dist(x_T, h_C)^2} \quad (8)$$

$$z_i = d_i \times F_{Trans1}, \quad (9)$$

$$F_{Trans3} = \{z_1, z_2, \dots, z_k\} \in R^k \quad (10)$$

where  $d_i$  is the distance between the  $i$  –instance of  $x_T$  and the cluster center  $h_C$ .  $z_i$  is the third feature transformation for the  $i$  – feature of  $x_T$ .  $F_{Trans3}$  is the third feature transformation which is only applied to  $D_T$ ,  $h_C$  is the center of the cluster class label calculated by average formula.  $Dist(x_T, h_C)$  is the euclidean distance between  $x_T$  (instances in  $D_T$ ) and  $h_C$ .

### C. Dataset and Experimental Setup

The dataset for the proposed feature-transfer learning was taken from the image domain, which is the real-world object category. There are 10 class labels in each dataset: calculator, laptop, keyboard, mouse, monitor, video projector, headphones, backpack, mug, and bike [13] [14] [15] [16]. We use four datasets in the experiment. A detailed description of each dataset is shown in Table I. All the datasets used already implemented SURF as the feature descriptor. The features descriptor algorithm will extract the superior degree of the pixels in the original image so that it can capture stable features from each image [39]. Fig. 4 is an example of some images from the class label monitor, backpack, mug, and mouse in each dataset.

TABLE I. DESCRIPTION OF THE DATASET USED

Dataset	Instances #	Features #	Class #	Domain
Office-Amazon	958	800	10	A
Office-Webcam	295	800	10	W
Office-DSLR	157	800	10	D
Caltech-256	1123	800	10	C

Fig. 4. Example of dataset used.

Different from previous research on feature-transfer learning, which uses many parameters in its classification model, this proposed method does not use parameters. The only parameter needed in the proposed feature-transfer learning is the C parameter in the classifier SVM. The C value is set to 0.001 with a linear kernel. This value setting follows previous feature-transfer learning research [17]. Moreover, the proposed feature-transfer learning in this paper has a simpler feature transformation process. By using feature selection and feature weighting approaches and employing statistic properties like average and variance, the proposed method can be done with limited resources while still providing good accuracy results.

### III. RESULT

The experiment result of the WbFTL will be compared with three baselines and five previous feature-transfer learning methods, namely: Geodesic Flow Kernel (GFK) [16], Joint Distribution Analysis (JDA) [14], Transfer Joint Matching (TJM) [15], Balanced Distribution Adaptation (BDA) [9], and Subspace Alignment (SA) [17]. All the datasets used in WbFTL were also used in the comparison methods, including the use of SURF as the feature descriptor.

#### A. Comparison with the Baselines and Previous Feature-Transfer Learning Methods

The difference between WbFTL and previous feature-transfer learning methods mainly lies in the feature transformation process performed, the optimization process, and the use of pseudolabels, as shown in Fig. 5. The red box indicates the feature transformation steps. Fig. 5(a) is the

previous feature-transfer learning method. Meanwhile, Fig. 5(b) shows the steps of WbFTL. Even though both of the methods use a dimensionality reduction approach, WbFTL chooses feature selection rather than forming a projection matrix as used in previous methods. WbFTL also uses feature selection and feature weighting as optimization processes. This approach makes WbFTL simpler and more cost-effective. Moreover, WbFTL does not need to go through an iterative process to find a stable pseudolabel that will be considered the predicted label.

All the methods will be compared based on their accuracy values. The accuracy values from the baselines and the previous feature-transfer learning methods will be taken from the original paper for each method. The comparison results for the accuracy of each pair of datasets can be seen in Table II. Meanwhile, Fig. 6 shows the comparison graph between WbFTL and the baselines model.

This research used three baselines, and the results of the baselines gained from the original paper [9]:

- Baseline 1: INN as the representation of the traditional machine learning method
- Baseline 2: PCA as the representation of the dimensional reduction method
- Baseline 3: TCA as the first feature-transfer learning method

There is no feature transfer or knowledge transfer in the implementation of baseline 1 and baseline 2.

In addition, the experiments also compare the average accuracy from 12 pairs of datasets between the WbFTL method, the baselines, and the comparison methods. The comparison results of the average accuracy are shown in Table III, and the visualization will be shown in graphical form in Fig. 7 and Fig. 8. From the experiment results in Table III, it can be seen that the WbFTL gets 46.62% for the average accuracy. This value overcomes the baselines and previous feature transfer learning methods, except for BDA. Although the average accuracy value of the WbFTL is comparable with the average accuracy of the BDA, the WbFTL uses fewer parameters, as shown in Table IV. So, it is possible to use it with limited resources.

Table II shows 12 pairs of datasets formed from four datasets: A, W, D, and C. These twelve pairs of datasets are formed by swapping the positions of the datasets that will become  $D_S$  and  $D_T$ . For example, the  $A \rightarrow W$  means dataset A becomes  $D_S$  and dataset W becomes  $D_T$ . Another example is  $W \rightarrow A$  which means dataset W becomes  $D_S$  and dataset A becomes  $D_T$ . Because the principle of transfer learning is that there are no definite rules on which datasets must become  $D_S$  or  $D_T$ . The best value for each dataset pair is written in bold, and the second best value is written in underline. From the value yield, we can see that WbFTL gives a better accuracy value on  $A \rightarrow C$ ,  $C \rightarrow A$ , and  $C \rightarrow W$ , where dataset C becomes one of the processed domains.

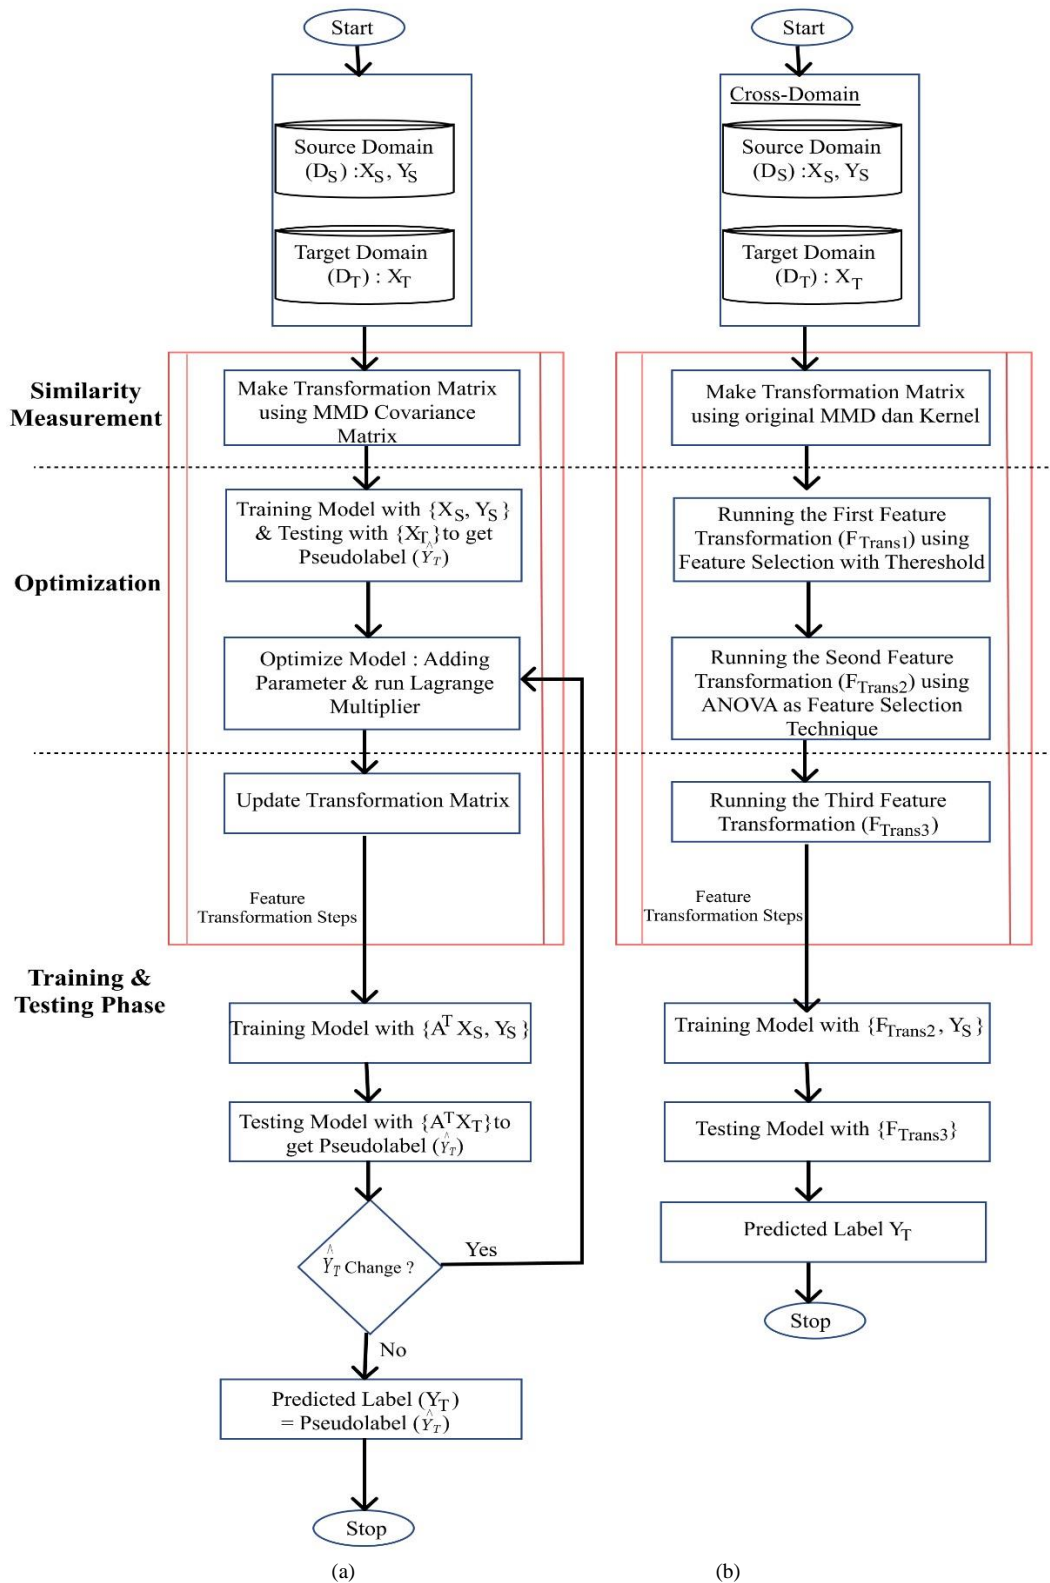

Fig. 5. Comparison method between previous feature-transfer learning and WbFTL.

### Accuracy Comparison for Dataset Pair

Fig. 6. Accuracy comparison between baselines and WbFTL for dataset pair.

TABLE II. ACCURACY COMPARISON PER DATASET PAIR

Dataset	Baselines			Previous Feature-Transfer Learning Methods					Proposed Method
	<i>INN</i>	<i>PCA</i>	<i>TCA</i>	<i>GFK</i>	<i>SA</i>	<i>JDA</i>	<i>TJM</i>	<i>BDA</i>	<i>WbFTL</i>

Fig. 7. Average accuracy comparison between WbFTL and previous feature-transfer learning.

Fig. 8. Average accuracy comparison between WbFTL and the baselines.

Based on the accuracy value in Table III, we can see that the average accuracy of WbFTL exceeds the average value of all baselines. This value also shows an increase in accuracy of 15.25%, 6.83%, and 3.59% when compared to baseline 1, baseline 2, and baseline 3. This result also shows that the implementation of feature-transfer learning has proven to improve image classification accuracy across domains. Even when compared to using a simple classification model such as 1NN, which is baseline 1, WbFTL is far better at generating predictive labels. Compared to PCA, the commonly used dimensionality reduction method, WbFTL also provides better accuracy results. Although WbFTL also uses a dimensionality reduction approach, the process used in WbFTL is simpler than PCA. WbFTL does not take iterative steps to generate a stable transformation matrix, as can be seen in Fig. 5. This result also indicates that feature selection can be applied to form new feature representations to produce a better classification model without applying dimension reduction as in baseline 1. Feature selection as a form of dimensionality

reduction has also proven to be applicable to transform features and produce good classification models at a cost-effective rate.

When compared with the previous transfer learning methods, such as TCA, which is baseline 3, it is also seen that WbFTL provides an increase in yield of 3.59%. This result indicates that the feature transformation process in WbFTL is able to minimize more differences in data distribution compared to that carried out in baseline 3. This is because TCA works to reduce marginal distribution differences without considering label information. While WbFTL reduces the difference distributions between cross-domains by utilizing label information through the second and third transformations.

The experiment results prove that the distribution difference in the cross-domain can be reduced by making a new feature representation that reflects both domains. The formation of this new feature representation can be done by

using a dimensionality reduction approach to reduce the searching space. Concerning the implementation of dimensional reduction techniques, the feature selection method is proven to be implemented and gives good results for transfer learning cases.

The use of the feature selection method makes the WbFTL simpler compared to other feature-transfer learning methods, which have to make a projection matrix. Other than being complex, the use of the projection matrix in the previous feature-transfer learning method also requires optimization, which involves many parameters to be tuned, requiring more resources. A comparison of the number of parameters used in the previous feature-transfer learning method with the WbFTL can be seen in Table IV.

### B. Ablation Study

The ablation study will show accuracy for each step of feature transformation, which is conducted in WbFTL. In this research, the ablation study will compare the accuracy of the second feature transformation with the third feature transformation. The first feature transformation will not be seen in particular because it uses the same approach as the second feature transformation, namely feature selection. By looking at the accuracy of the second feature transformation, it already includes the first transformation. The result of the ablation study can be seen in Table V. Where  $F_{Trans2}$  is the accuracy using only feature selection to transform features, and  $F_{Trans3}$  is the final accuracy value after carrying out all stages of feature transformation.

TABLE V. ABLATION STUDY FOR DATASET PAIR

Dataset	$F_{Trans2}$	$F_{Trans3}$
W→D	84.62	84.62
D→W	76.53	76.53
A→D	39.10	39.10
D→A	33.86	34.38
W→A	38.87	38.77
A→W	36.73	37.41
A→C	41.44	41.71
C→A	50.68	50.57
D→C	31.91	31.91
C→D	44.23	44.23
W→C	34.49	34.58
C→W	46.26	45.58

Based on the ablation study result in Table V above, we can see that the third feature transformation has a better result than the second feature transformation, although it is not showing a significant difference. When viewed from the 12 pairs of the existing datasets, the increase in accuracy values occurs in pairs D→A, A→W, A→C, and W→C. While several dataset pairs experience a very small decrease in accuracy after doing the third feature transformation, namely at W→A, C→A, and C→W.

By looking at these results, it can be seen that the majority of degradation was found when the Amazon dataset became  $D_T$ . Accuracy values also tend to decrease when the Caltech dataset becomes  $D_S$ . The biggest decrease was in C→W, which decreased by 0.68.

Meanwhile, when the Amazon became  $D_S$ , the accuracy value tended to improve at each step of the feature transformation performed, as shown in A→W and A→C. The increase in accuracy is also seen when the dataset that becomes  $D_T$  has more instances than the number of  $D_S$ , as shown in D→A, A→C, and W→C. The biggest increase in A→W was 0.68.

### C. Discussion

The experimental results in Table V above show that the classification results are better when using large datasets as  $D_S$ . This can be seen from the accuracy value, which tends to be high when Amazon becomes  $D_S$ . Similar results are also shown in Table II. In Table II, the accuracy value of A→D is 39.1%; this value is greater than the accuracy of D→A, which is only 34.38%. As mentioned in Table I, the Office-Amazon dataset is larger than the Office-DSLR. Other dataset pairs, such as C→A, also have 9% higher accuracy than A→C because the Caltech-256 dataset is larger than Office-Amazon.

In addition, the imbalance of instances between  $D_S$  and  $D_T$  also affects the accuracy value of each pair of datasets. Better accuracy is obtained on pairs of datasets with an almost equal number of instances. As shown in Table II, where the highest accuracy is D→W and W→D of 76.53% and 84.62%, respectively. The pair with the next highest accuracy is C→A at 41.71% and A→C at 50.57%. In this case, the number of instances between the Office-DSLR and Office-Webcam datasets is more evenly matched than the number of instances between Office-Amazon and Caltech-256. Conversely, when the number of instances of the two domains is very different, the accuracy value will deteriorate, as shown by the D→C pair, which only has an accuracy of 31.91%.

The condition of the original image in the dataset pair used also affects the accuracy value. In Fig. 4 above, it can be seen that the original images between the Office-Amazon and Caltech-256 datasets are quite different in terms of background color, objects in the image (original and cartoon objects), and lighting. This background color difference will affect the value of the resulting feature extraction results, so it can affect the level of image similarity. So the accuracy value between the Office-Amazon and Caltech-256 dataset pairs tends to be small, only in the range of 40%–50%. Meanwhile, the Office-DSLR and Office-Webcam datasets have more similar original image conditions, resulting in higher accuracy in the range of 75%–85%. Given that the original image conditions are almost the same, the feature extraction values will be more similar, so the resulting accuracy will also be better.

## IV. CONCLUSION

In summary, we have proposed a simple feature-transfer learning method called WbFTL. The proposed method is more efficient than the previously reported feature-transfer learning methods because it employs a feature selection strategy for

making a new feature representation. In addition, the WbFTL involved weighting on the selected features to improve the accuracy. The proposed method is also simple since it utilizes statistical properties such as averages and variance to transform the features. There are three steps of feature transformation in the proposed feature-transfer learning method. The first step was feature selection which used a threshold obtained from the feature averaging value as the stopping criteria. The second step was feature selection using the ANOVA technique. Finally, the third step was calculation of the distance between the target domain and the center of the class label employing the Euclidean distance.

This experiment was carried out using only one type of classifier, namely SVM, with SURF as a feature extraction technique. There are still many other types of classifiers that can be used. Another limitation in the experiment is the category of dataset used, which is limited to real-world objects only.

From the experiment result using 12 pairs of the dataset, we have shown that the WbFTL provides a better result than the previous method, except for the BDA. Although the WbFTL gives a comparable result to the BDA, it is superior in terms of simplicity because it does not use any parameters to run the model. Allowing it to use in the conditions of limited resources. We also showed that WbFTL get higher accuracy of 15.25%, 6.83%, and 3.59% when compared to 1-NN, PCA, and TCA model baselines.

We can improve the results and accuracy of the WbFTL in the future by combining it with CORAL as one of the feature transformation steps in WbFTL. Furthermore, the accuracy can also be increased by optimizing the feature transformation steps, such as optimizing the feature weighting process or applying the weighting to the distance.

**Abstract**—The amount of data being exchanged over the internet is enormous. Attackers are finding novel ways to evade rules, investigate network defenses, and launch successful attacks. Intrusion detection is one of the effective means to counter attacks. As the network traffic continues to grow, it can be challenging for network administrators to detect intrusions. In huge networks connected with millions of computers Terabytes/Zettabytes of data is generated every second. Deep Learning is an effective means for analyzing network traffic and detecting intrusions. In this article, distributed autoencoder on the CSE-CIC-IDS2018 dataset is implemented by considering all the classes of the dataset. The proposed work is implemented on Azure Cloud using distributed training as it helps in speeding up the training process, thereby detecting intrusions faster. An overall accuracy of 98.96 % is achieved. By leveraging such parallel computing into the security process, organizations may accomplish operations more quickly and respond to risks and remediate them at a rate that would not be possible with manual human capabilities alone.

**Keywords**—Network intrusion detection systems; deep learning; autoencoders; cloud computing; distributed training; parallel computing

## I. INTRODUCTION

Organizations must prioritize cybersecurity as they begin their digital transformation initiatives. The availability, confidentiality and integrity of the data has to be maintained irrespective of whether the deployment was on the premises or on the cloud. Therefore, while organizations want to ensure that they keep up with technological changes, they also need to prioritize security. In a matter of seconds, the amount of exchanged data can multiply dramatically, increasing the risk to sensitive data. And as the Internet of Things (IoT) expands beyond consumer electronics and into industrial machinery, there is concern over both the number of attacks and how sophisticated they are becoming. Human welfare is at risk as attackers are targeting hospitals, cars, and power plants. Given the stakes, it is crucial that IT directors put the practical approach in place to protect this valuable data. Security managers are implementing significant changes as they embrace new technology and security measures. Rather than making systems secure, the emphasis is on ensuring that the data they contain is secure. As a result of digital transformation, attackers are exploring vulnerabilities to launch attacks. Today, any vulnerability in the supply chain has a catastrophic effect that costs millions of dollars thus, immediately destroying the credibility.

Digitalization, connected cars, connected homes and IoT has enhanced the digital footprint. The world is transitioning from a physical to a digital experience. The ever increasing threat landscape brings in more challenges in the security domain. This led to the integration of Artificial Intelligence (AI) and Machine Learning (ML) in cyber security. To protect their organizations from novel attacks, companies are increasing their investments in cyber security automation. Few decades ago, companies used to invest very less on security. With the increase in the incidents and breaches post the covid pandemic period, the world has transitioned into a remote network which operates without geographical boundaries. Attackers are finding new ways to breach the security, posing significant threat to organizations. Deep Learning (DL) models can leverage cloud computing services. This paradigm shift helps train DL algorithms on distributed hardware more easily.

DL has been quite a game-changer for several companies and organizations during the recent years. As a result, it is not surprising that many specialized, cloud-based solutions have developed to aid data scientists in their work multiple ways. The global ML market is projected to grow from \$7.3 billion in 2020 to \$30.6 billion in 2024. This would lead to a substantial growth of 43% according to Forbes. To continue with the constantly changing business requirements of consumers, data scientists and ML engineers have to create more sophisticated models. ML experts have found MLaaS to be extremely useful and powerful in designing more sophisticated models.

Organizations have to leverage DL techniques to quickly identify, evaluate and treat risks to evade major attacks on their networks. The consequences after a network attack are devastating. Attacks might be one or more of the following;

- Loss to government, private and public parties
- Legal and regulatory impact
- Financial implications
- Impact to essential services
- Loss of trust
- Socio-psychological impact.

Decades ago, computing was completely self-managed with respect to hardware, software and configuration. The location of the data center was dedicated to a physical location and customization was based on requirements. Ring fence security was used to block or control external access. These

techniques are no longer suited in the present digital era as they are expensive because of the capital and operational costs. Also, the complexity with customization has increased. Another major disadvantage of traditional computing is their inability to scale. Thus, there is a complete paradigm shift towards cloud computing.

Traditional methods of storage are no longer suitable because of the following requirements.

- Exponentially growing data.
- Very expensive, not scalable and slow
- Loss of data.

Compared to traditional storage methods, there are numerous advantages of storing data on the cloud.

- Ease of use and access
- Easy sharing
- Disaster recovery
- Scalability and elasticity
- Cost efficient
- Security

There are numerous advantages of cloud computing over traditional computing

- Shared infrastructure that are logically separated.
- No access to the underlying hardware.
- Optional customization of software and configuration.
- Geographically dispersed points of presence
- Suited for performance and scalability.
- As-a-service (aaS) subscription model.

MLaaS refers to a group of different cloud-based systems that combine ML tools with solutions to assist ML team in various tasks such as deploying and running orchestration models, data pre-processing, model training and tuning predictive analysis for a variety of problem statements. It leverages cloud computing's flexibility to provide ML services on the go. The MLaaS industry is pretty substantial. Valued at \$1.0 billion in 2019, it is anticipated to grow to \$8.48 billion by 2025. Azure Machine Learning Studio offers a development environment. It helps create ML models both for entry-level and professional data scientists. Most actions in Azure ML Studio may be accomplished using a GUI interface, just like with Microsoft Windows.

The key contribution of this research is to perform distributed training. This research article emphasizes on the fact that training time can be drastically reduced when distributed training is used. As the size of the dataset increases, the traditional methods of training DL models using single machine are no longer suitable. In the context of NIDS, the main aim is to help the network administrators to detect intrusions at a faster rate. In terms of training time, the proposed distributed autoencoder model improves the

performance by reducing the training time. This helps the network administrators to take necessary steps before the attacker is successfully able to launch an attack on the network.

The manuscript is organized as follows. Section II gives a detailed description of the literature review carried in the area of Network Intrusion Detection (NIDS). Section III gives the details of the proposed methodology. Section IV gives the details about the experimental setup. Section V gives the details on the results. Finally, Section VI discusses about conclusion, limitations and future enhancements.

## II. RELATED WORK

Ketulkumar et al. implemented 'Multiclass Decision Forest' on the UNSW-NB15 dataset using. The ML algorithm was run on Azure ML platform. The author has achieved an average overall accuracy of 96.33% [1]. Youngrok et al. carried out their research on three datasets namely NSL-KDD, N-BaTot and IoTID20 datasets by using auto encoders. The authors opined that stacked encoders work better when their model size is increased [2]. Pooja Rana et al. implemented their FCM-ANN and SVM-ANN and FCM-SVM, SVM-ANN algorithms. The authors concluded that FCM-SVM methodology outperforms other classifiers on the UNSW\_NB15 dataset. SVM-ANN methodology outperforms other classifiers on the NSL-KDD dataset [3]. Kanimozhi et al. implemented various ML algorithms and ANN (MLP) on the CSE-CIC 2018 dataset. The authors concluded that ANN (MLP) outperforms other ML Classifiers. Using ANN (MLP) the authors achieved an accuracy of 99.97% along with other metrics. The authors also used a Calibration curve [4]. Smitha Smitha Rajagopal et al. proposed a meta-classification approach. The authors tested their proposed model on UNSW NB-15, CICIDS 2017 and CICDDOS 2019 datasets [5]. Jan Lasky et al. carried out an extensive literature review on NIDS and concluded that DL techniques outperform shallow ML techniques [6].

Kanimozhi et al. used the combination of Random Forest and Decision Tree classifiers. The authors used ANN algorithm on the UNSW-NB15 dataset with an accuracy of 89% [7]. Zeeshan Ahmed et al. carried out an extensive literature survey on ML and DL approaches used in NIDS. The authors conclude that a majority of the researchers detested their models on outdated datasets like KDD cup'99 and NSL-KDD. Another important finding from their work is most of the researchers have not addressed the class imbalance problem in their datasets. This affects the accuracy and detection rate of the minority attack classes [8]. Satish et al. carried out a detailed review of research trends in NIDS. The authors conclude that KDD Cup'99 is the most used dataset for NIDS. However, KDD Cup'99 does not reflect the current attacks. The authors encourage researchers to carry out their research using datasets that reflect the current day attacks [9]. Narayana et al. implemented the Stacked Auto encoded- Deep Neural network (SAE-DNN) on KDD, NSL-KDD and UNSW-NB15 datasets. Their hybrid model on UNSW-NB 15 achieved an accuracy of 99.5% [10]. Sultan Zavrak et al. used Variational Auto Encoder (VAE). The metrics used by authors were Receiver Operating Characteristics (ROC) and Area Under ROC curve [11]. Sydney Mambwe et al. used Simple RNN,

LSTM and GRU on NSL-KDD and UNSW-NB15 datasets [12].

Zichan Ruan et al. used visualization algorithm to gain insights into the KDD99 cup dataset [13]. Matthias Langer et al give a taxonomy of Distributed Deep Learning Systems (DDLs) [14]. Asif et al. in their research paper detailed about the strategic importance of NIDS [15]. Abhishek Divekar et al. in their research work conclude that UNSW-NB 15 dataset is an alternative to KDDCup 99. The authors also highlighted that class imbalance of KDD-99 and NSL-KDD. Class imbalance hampers the efficacy of the classifiers on the minority class [16]. Mahdi Soltani et al. proposed model on Deep Intrusion Detection (DID) system. The authors evaluated their work on CIC-IDS2017 and CSE-CIC-IDS2018 datasets [17]. Joffrey L Leevy et al. carried out a detailed survey of IDS models on CSE-CIC-IDS2018 dataset. The authors opined that most of the researchers who carried out their work on CSE-CIC-2018 dataset did not address the class imbalance [18]. Sukhpreet et al. used eXtreme Gradient Boosting (XGBoost) on the NSL-KDD dataset. Jiyeon Kim et al used Convolutional Neural Network (CNN) and focussed only on DoS (Denial of Service) attacks. They used the KDD and CSE-CIC-IDS 2018 datasets [20]. Said Ouiazzane et al proposed snort signature based NIDS on the CICIDS2017 dataset. They implemented their proposed model using ML algorithms [21]. Haripriya et al carried out a literature review on NIDS datasets. They implemented Deep Autoencoder by including all the files of CSE-CIC-IDS2018 dataset. An overall accuracy of 97.79% was achieved [22-23].

Attackers are finding novel ways to launch sophisticated attacks. Studies from literature review show that there is an increasing necessity to not only detect intrusions accurately but also more quickly. Once intrusions on the network are detected, necessary steps should be taken so that the attacker is not successfully able to launch the attack. Considering the enormous amount of data generated on the network, training the DL algorithm on a single machine is no longer suitable. This research work mainly focuses on distributed training of deep autoencoder model to speed up the training.

### III. PROPOSED METHODOLOGY

There are two means to achieve parallelism namely model parallelism and data parallelism. Model parallelism is when the same data is used for each thread but the model is split among them. In data parallelism, same model is used for each thread but operating on different portions of the data.

This research article focuses on data parallelism. Fig. 1 illustrates data parallelism [24]. Initially, a compute cluster with two nodes is created. Each node contains a replica of the model. However, each node processes a different portion of the data. The errors between each node's predictions for its training samples and the labeled outputs are individually calculated. Each node then modifies its model in response to the errors. This information is communicated to all the other nodes to update their related models. The worker nodes need to synchronize model parameters on every batch computation. This ensures the consistency of the training model.

Fig. 1. Data parallelism.

#### A. Autoencoders

The proposed work uses autoencoders. An autoencoder is a special type of neural network architecture, used for unsupervised learning. The main idea of using an autoencoder is to learn a lower-dimensional representation for a higher-dimensional data.

#### B. CSE-CIC-IDS2018 Dataset

CSE-CIC-IDS 2018 dataset is used on the proposed autoencoder model [25]. The dataset is obtained from AWS S3 bucket. It consists of seven types of attack scenarios along with 80 features. The dataset was created as joint venture between the Communications Security Establishment (CSE) and Canadian Institute of Cybersecurity (CIC).

#### C. Preprocessing

Preprocessing helps network traffic data to be easily processable by the DL algorithm. It also helps speeding up the training process. Rows containing NAN and infinite values were dropped. Label encoding and one-hot encoding were used. The CSE-CIC-IDS2018 dataset suffers from class imbalance. The classifier tends to be more biased towards the majority class leading to inaccurate results. This has a major negative impact on the performance. The class imbalance was addressed Synthetic Minority Oversampling Technique (SMOTE). It is an augmentation technique for the minority class.

#### D. Configuration in Azure Machine Learning Studio

Fig. 2 illustrates the Azure ML Resource group. The following steps were carried out.

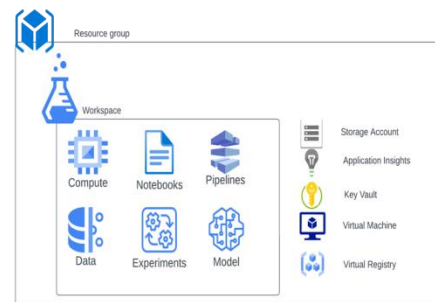

Fig. 2. Azure ML resource group.

- Sign in to Azure Machine Learning Studio and select create workspace. Give the workspace name. In addition to this provide subscription type, resource group and the region. After providing all the details a workspace is created.
- Microsoft Azure Blob (Binary Large Objects) was employed to store CSECICIDS 2018 dataset. Blob storage is best suited for large scale unstructured data.

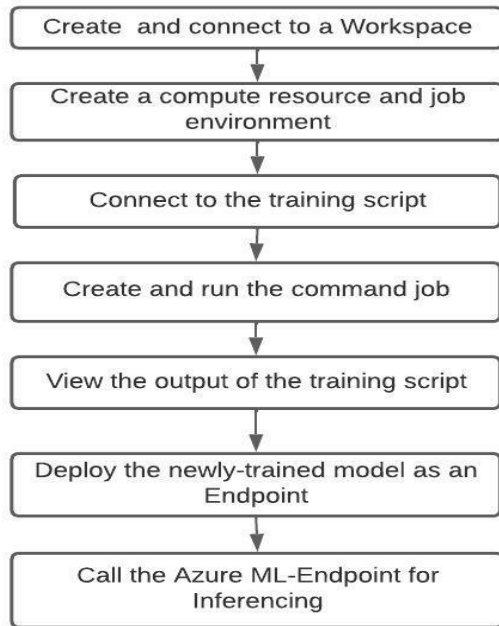

Fig. 3. Flowchart depicting model deployment on Azure cloud.

Fig. 3 clearly illustrates the different steps to be followed while deploying the DL model on the cloud.

#### IV. EXPERIMENTAL SETUP

##### A. Details on the Implementation

Fig. 4 illustrates accelerated networking. The configured Virtual Machines (VMs) supports accelerated networking. It greatly improves network performance by reducing latency,

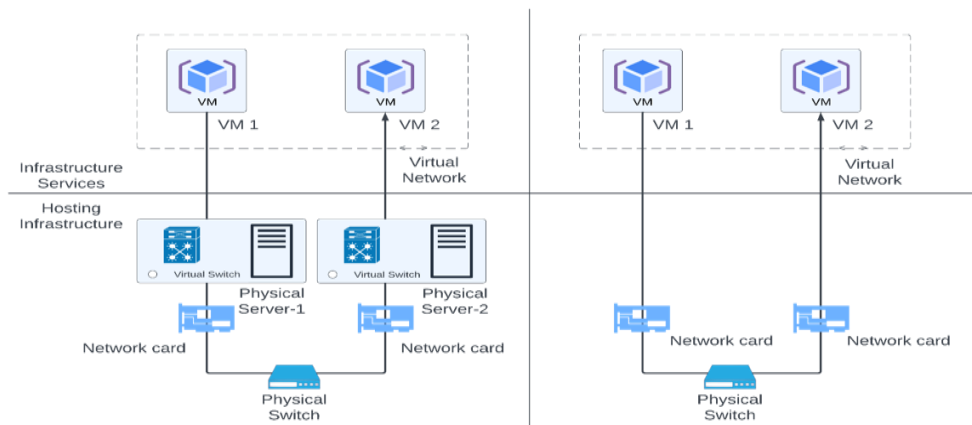

Fig. 4. Accelerated networking.

jitter and CPU utilization. This is suitable in scenarios with most demanding network workloads.

Premium Solid State Drive (SSD) disks were used for storage. The main advantage of using SSD is that they have access speeds of 35 to 100 microseconds. Compared to Hard Disk Drives (HDD) they are 25 to 100 times faster. SSDs are more suitable in I/O intensive workloads and deliver high-performance and low-latency disk support for VMs.

Locally Redundant Storage (LRS) was used as illustrated in Fig. 5. The key advantage of using LRS is, it replicates the storage account three times within a single data center located in the primary region. Thus, the application is restricted to replicate data only within a country/ region. This is more suitable in scenarios where data governance requirements are being imposed. Table I illustrates the configuration of the VMs used in the training model.

Synchronous distributed training is implemented across the worker nodes, each having two CPUs. All variables and computations are replicated to every local device. In order to enable collaboration of multiple workers, it utilizes a distributed collective implementation (such as all-reduce).

First the ScriptRunConfig is created. This is used to specify the training script arguments, the environment and the cluster to run on. The training script in this experiment uses a Multi-Worker Distributed training of the Keras model. This can be done using the `tf.distribute.Strategy` API. `tf.distribute.Experimental.MultiWorkerMirroredStrategy()` is used to leverage distributed training. The tensor flow configuration is used to run a multi-worker tensor flow job. The number of nodes in the training job is specified by setting the worker count variable. In tensor flow, to enable the training on multiple machines, the `TF_CONFIG` environment variable is used. This allows the training code on each Virtual Machine (VM) instance used in the training job, to gain access to information about the training job and the VM's operation. Thus, to comply with the requirements set forth by Tensor Flow for distributed training and to enable communication between VMs, `TF_CONFIG` environment variable must be present on all the VMs configured for the training job. Next, a distributed config is created by specifying the number of worker count. The number of worker nodes is set to two. The train - test split is set is to 70 % and 30 % respectively.

Fig. 5. Replication of storage account using LRS.

TABLE I. VM CONFIGURATION - DV2 11SERIES

VM Configuration	VM 1	VM 2
Size	Standard_D11_v2	Standard_D11_v2
vCPU	2	2
Memory GiB	14	14
Temporary Storage(SSD)GiB	100	100
Max temp storage throughput:IOPS/ ReadMBps / Write MBps	6000/93/46	6000/93/46
Maxdatadisks/ throughput IOPS	8/8*500	8/8*500
Max NICs	2	2
Expected network bandwidth (MBps)	1500	1500

TABLE II. HYPERPARAMETERS USED IN THE PROPOSED DISTRIBUTED DEEP AUTOENCODER

Sl. No.	Hyper Parameters	Value
1	Activation Function: Hidden layer	ReLU
	Output layer	Softmax
2	Batch Size	128
3	Number of Epochs	15
4	Loss function: Multi Classification	Categorical Cross Entropy
5	Optimizer	Adam
6	Learning Rate	0.01

Table II gives the details of hyper tuning parameters in training the proposed distributed autoencoder model.

## V. RESULTS AND DISCUSSION

In our experimentation two scenarios are considered. In the first scenario, single VM is used for training. In the second scenario, two VMs are used to train the model.

Fig. 6 illustrates the time taken when the autoencoder model is run on a single VM without distributed training. Fig. 7 illustrates the time taken when the autoencoder model is run on two VMs by leveraging distributed training. Time taken to

train is plotted on the X-axis and CPU Utilization is plotted on the Y-axis. In this research work, by using data parallelism, Deep Auto-encoder algorithm is trained on two VMs (distributed training), which speeds up the training process. An overall accuracy of 98.96% is achieved.

Fig. 6. CPU utilization and Time taken when a single node is used.

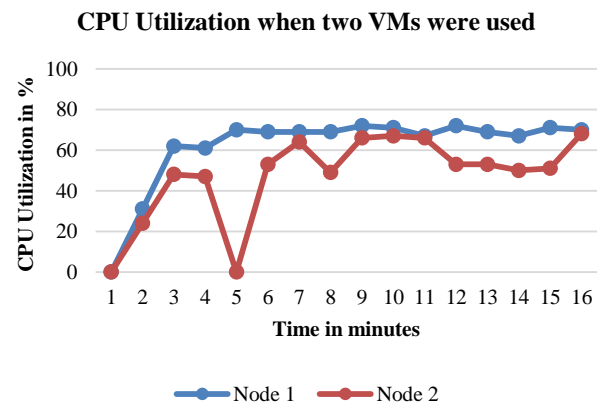

Fig. 7. CPU utilization and time taken when multiple nodes are used.

Fig. 8 depicts the training time when single node and distributed training is used. Time taken to train when single VM is used is 67 minutes while the time taken to train when two VMs (Distributed Training) is 43 minutes. 24 minutes reduction in terms of training time was observed when distributed training was used. Table III gives the comparative analysis of the proposed work with other techniques.

Fig. 8. Single node training vs. distributed training.

TABLE III. COMPARATIVE ANALYSIS

Sl.No	Authors	Algorithm Used	Dataset Used	Accuracy	Year	Attacks detected	Whether Distributed training was used?
1	V. Kanimozhi et al [4]	Artificial Neural Network and Multi-Layer Perceptron	CSE-CIC-IDS 2018	99.97%.	2019	Only Botnet attack	No
2	Alzughabi et al [26]	Multi-Layer Perceptron with Back Propagation	CSE-CIC-IDS 2018	98.41 %	2023	All the attacks of the dataset	No
3	Farhan et al [27]	Deep Neural Network	CSE-CIC-IDS 2018	90 %	2020	All the attacks of the dataset	No
4	Proposed Work	Deep Auto Encoder	CSE-CIC-IDS 2018	98.96 %	2023	All the attacks of the dataset	Yes

## VI. CONCLUSION

With the pace at which internet is growing, the amount of data exchanged over it is increasing, paving way for novel network attacks. Detecting intrusions early to avoid network attacks is the need of the hour. Considering the huge size of dataset, classifying all the attacks is a compute-intensive task. The main contribution of this research work, is to perform distributed training on the autoencoder model using the latest benchmark dataset by classifying all the classes of the dataset. Performance on the model proved to more efficient when distributed training was used. For compute and data intensive tasks, DL combined with distributed training is the most appropriate solution. Promising results were achieved with an overall accuracy of 98.96% and 24 minutes reduction in training time when distributed training was used. To the best of our knowledge, this is indeed the first research work done in this area. As a future work, other DL algorithms suitable for distributed training for NIDS can be explored. The training time can further be reduced by using high configuration VMs. Also, services from various cloud service providers can be leveraged for distributing training. A comparative study of various ensemble methods for DL algorithms suitable for NIDS can also be carried out.

# An Arabic Intelligent Diagnosis Assistant for Psychologists using Deep Learning

Asmaa Alayed, Manar Alrabie, Sarah Aldumaiji, Ghaida Allhyani, Sahar Siyam, and Reem Qaid

College of Computer and Information Systems,  
Umm Al-Qura University,  
Makkah, Saudi Arabia

**Abstract**—Mental illnesses have increased in recent years, especially after Covid-19 pandemic. In Saudi Arabia, the number of psychiatric clinics is small compared to the population density. As a result, psychologists encounter a variety of difficulties at work. The main goal of the current research is to develop a system that assists psychologists in the diagnosis process, which will be based on the DSM-5 (Diagnosis and Statistical Manual of Mental Disorders). The work on this research started with collecting the requirements and identifying users' needs. In this matter, several interviews have been conducted with Saudi Psychologist and then a questionnaire was developed and distributed to psychologists in Saudi Arabia. Following an analysis of the needs and requirements, the system was designed. A deep learning technique was applied during the diagnosing process to address the issues mentioned by psychologists. Additionally, the proposed system helps psychologists by quickly calculating the results of psychological tests. The system was built as a website. The Convolutional Neural Network (CNN) algorithm was used with 96% accuracy to automatically predict the appropriate diagnosis and suggest the most suitable psychological test for the patient to take. System testing and usability testing were also conducted by involving patients and Saudi psychologists to test the usability of the system and the accuracy of the CNN model. The results indicate that the diagnosis prediction was accurate, and that each activity was completed faster. This demonstrated the model's high degree of accuracy and the system's interfaces' clarity. Additionally, psychologists' comments were encouraging and positive.

**Keywords**—Mental health; psychologist; mental illness diagnosis; psychological test; deep learning; CNN algorithm

## I. INTRODUCTION

Health care is an important aspect of human life, such as eating and drinking. Mental disorders are one of the most important health problems that are beginning to increase recently. According to the latest Saudi National Mental Health Survey report published by King Salman Center for Disability Research [1], two out of five young Saudi nationals have been diagnosed with mental disorders at a certain time in their lives. Around 80% of Saudi nationals have been diagnosed with severe mental disorders. However, they do not seek to receive any type of mental health treatment. Moreover, the number of mental health clinics in Saudi Arabia does not exceed 100 [1], which is a very small number compared to the population density in the country.

As noticed in [1], the number of patients is large compared to the number of clinics which would put more pressure on

psychologists. Limited number of patients would be seen daily due to the time each session takes. Sometimes, psychologists need more time to diagnose the patient's condition, either due to the lack of experience or because the patient complains of rare or similar symptoms that require careful consideration to be diagnosed appropriately. Additionally, the psych-diagnostic may differ from one psychologist to another due to the difference in their references and method of diagnosis. The psychologist's human nature would also affect the final diagnosis.

During an interview with an experienced Saudi psychologist [2], he pointed out that there is a problem faced by psychologists, which is most people in our society do not prefer to visit a psychiatric clinic, either due to the unavailability of clinics close to the area in which they live or for personal reasons. Instead, they prefer attending counseling sessions online. However, it is difficult to complete all stages of diagnosis from a distance since there is another stage after the initial diagnosis, which is taking psychological tests. These tests are usually done manually, so the patient has to visit the clinic to take them, which makes the diagnosis go back to the starting point. The calculation of the tests results takes a long time to analyze and reach complete and correct diagnosis results. A number of these tests would take more than a day to analyze and understand the results. Moreover, the calculation and analysis process are prone to human mistakes since the tests have many questions and the way of calculating the results is complicated.

The main goal of the current research is to help psychologists in Saudi Arabia to overcome these problems, and hence facilitate their work. The contribution of this paper is twofold:

First, it proposed a new machine learning model to assist Arabic psychologists in diagnosing three prevalent mental disorders, namely Anxiety, Depression and OCD, based on DSM-5 [3].

Second, it automates the Arabic psychological tests based on APA [4].

This paper is structured as follows: Section II sheds light on the research background. Section III describes related work. Section IV clarifies the adopted research methodology including the results. Section V discusses the results. Section VI concludes the paper.

## II. RESEARCH BACKGROUND

The purpose of the research is to develop a diagnosis assistant for Arabic psychologists. Psychological tests are considered essential elements in this diagnosis process. Therefore, a brief background is provided to clarify what mental illness and psychological test are. In addition, the three most important prevalent psychological disorders that are covered in this research will be briefly explained.

### A. Psychological Test

Psychological testing (psychometrics) is the systematic use of tests to quantify psychophysical behavior by allowing the person to answer some questions about a particular test. The test is determined by a psychologist, to make predictions about psychological performance. It is one of the tools that helps psychologists to measure how much of a specific psychological construct a patient has. Although psychological tests are available on some websites, they are tools like any other tools, if they are not in the hands of a trained professional, they might not achieve their intended goals [5].

### B. Mental Illness

The term "mental illness" or "mental disorder" refers to a health condition that results in emotional, behavioral, or thinking changes it also can be combination of them. Mental illnesses are often accompanied by distress and/or problems functioning at home, work, or in social settings. It can affect anyone regardless of age, gender, social status, or any other aspect. Developing a mental health treatment plan requires collaboration between a mental health clinician (psychologists and psychiatrist) and the patient (and family members if desired). There are many types of treatment available, including psychotherapy (talk therapy), medication, and others. Medication and therapy are often most effective when combined. In this work, the focus is on three mental illnesses, namely Anxiety, Depression, and Obsessive-Compulsive Disorder (OCD)

Anxiety is considered one of the most common mental disorders. According to the Saudi National Survey [1], anxiety is the most prevalent disorder among individuals in Saudi Arabia. Around 12% were diagnosed with separation anxiety disorder, which is the largest percentage compared to the rest of the disorders. In the current project, Taylor Manifest Anxiety Scale[6] will be used. This scale is a test of anxiety as a personality trait to measure the severity of anxiety.

Depression is the second prevalent mental disorder in the world. The latest national survey indicates that 6% of people suffer from depression in Saudi Arabia [1]. It is a serious mental disorder that may lead to a suicide thought. Therefore, discovering the problem and knowing the severity of depression may help in creating a treatment plan that would help people to recover and get rid of this disorder. In the current work, the Beck Depression Inventory [7] will be used to measure characteristic attitudes and symptoms of depression.

Obsessive-Compulsive Disorder (OCD) is considered one of the most common mental disorders in the world [8]. It was rarely diagnosed in the past, but nowadays it is seen as a neuropsychiatric disorder mediated by specific neural circuits

and closely related to neurological conditions such as Tourette's syndrome and Sydenham's chorea [8]. OCD could be observable behavior or mental rituals. The obsessions and compulsions of obsessive-compulsive disorder are qualitatively different from obsessive-compulsive personality traits such as perfectionism and excessive conscientiousness. The psychologist can professionally diagnose the patient to determine the type of disorder. In the project, Brown Obsessive Compulsive Scale will be used [5].

## III. RELATED WORK

In this section, the systems and web applications that serve the field of mental health and offer services to assist psychologists in the diagnoses process are discussed.

Labayh [9] is a Saudi mobile app approved by the Saudi Ministry of Health. It is considered as a virtual clinic that provides immediate or scheduled consultation with many different psychologists and psychiatrics allow the patient to choose any of them. Because it is not charitable or free platform, the patient must pay for each session. The app also provides two uncertified psychological tests for depression and anxiety, offered to all people who want to try.

Shezlong [10] is an Arabic website that gathers a group of therapists and presents their information in a clear manner with the cost and duration of the counseling session. This gives the users the opportunity to choose the therapist appropriate to their psychological status and budget. The website offers six psychological tests that initially diagnose the patient's condition and make recommendations for the best psychologist to follow up with. However, the patient takes a test based on what he thinks about his situation, not according to specialized advice from a therapist.

Mentalines [11] is a profit-based Arabic website that provides several psychological tests. The user can choose any of them to purchase and take online under the supervision of a psychologist. The website also provides many services related to the mental health like articles, training sessions, therapy trips, and group therapy sessions.

In [12], assistance was provided to psychologists to diagnose Anorexia using natural language processing to assess the expressed emotions by the patient through body description according to DSM criteria [3]. The diagnosis is made by processing the patients notes about their body. To achieve it, researchers used a dataset from a collection of opinions from the Stanford Amazon Dataset service and trained the model using the RNN (Recurrent Neural Network) algorithm. According to [12], the results showed the relationship between psychologists and patients had improved; writing notes made them feel safe, less resistant, and more credible. Although the good results, the model did not recognize some words, which influenced the diagnosis.

In [13], a machine learning model was built to assess five levels of three disorders, namely, anxiety, depression, and stress, without the need for a psychologist's intervention. The dataset was collected through online questionnaires filled out by different participants. The researchers applied eight algorithms that belong to four different categories: bayes, neural networks, lazy, and tree. The results of this research

showed the neural networks RBFN (Radial Basis Function Network) model was the best with depression disorders, while random forest was the best with anxiety disorders. It had a 100% accuracy rate, this occurred due to an imbalanced dataset.

A Machine Learning Approach to detect Depression and Anxiety using Supervised Learning was proposed in [14]. This paper suggested completing the diagnosis process without the need for a psychologist's intervention. It can be done by the patient choosing the disorder, answering the questionnaire, and then the system shows the result to the patient. The dataset was collected through a standard, structured questionnaire. The researchers used four algorithms to develop the model, which are: linear regression, LDA (Linear Discriminant Analysis), CNN (Convolutional Neural Networks), SVM (Support Vector Machine), and KNN (K-Nearest Neighbor). The results of this research showed that the CNN model was the best for depression with 96% accuracy and anxiety with 96.8% accuracy. However, there were limitations in its work. The questionnaire was too long, and there was a potential that the patient would not complete it. Also, according to [14] without a psychologist's help, patients will be less honest.

In [15], a predictive model was built to predict two disorders: Major depressive disorder (MDD) and generalized anxiety disorder (GAD). The researchers used an existing EHR dataset containing biometric and demographic data collected from 4184 undergraduate students. The model was trained using varied non-psychiatric input features such as blood pressure, heart rate, housing, status, and public insurance. The participants were assessed for full Diagnostic and Statistical Manual of Mental Disorders Fourth Edition (DSM IV). For the prediction accuracy, the sensitivity and specificity for MDD were 55% and 70%, and for GAD were 70% and 66% respectively. Additionally, the positive predictive value for MDD was 20% and for GAD it was 16% and the negative predictive value for MDD was 92% and for GAD it was 96%.

From the reviewed literature, it is clear that many different approaches have been proposed to automate the process of diagnosis in the field of mental health. However, they mainly focus on one part of the process, and sometimes without supervision from specialized personnel. In the next sections, our proposed approach is explained. It aims to help psychologists in the whole diagnosis process including the initial diagnosis phase using deep learning, and final diagnosis phase involving automated Arabic psychological testing. Table I compares the reviewed systems and proposed system.

According Table I, there are several systems and research have been created and developed to improve the diagnostic process in the field of mental health. Three of them [6] [7] [8] are actual real system platforms that connect psychologists with patients. They provide a number of psychological tests without any utilization of artificial intelligence algorithms to facilitate the initial diagnosis process. Moreover, they do not have a standard reference for the diagnosis process, but they depend only on the Psychologist's experience.

TABLE I. COMPARING THE REVIEWED SYSTEMS AND THE PROPOSED SYSTEM

System	Analyze the symptoms based on DSM-5	Using AI in the diagnosis process	Provide psychological test	Software system	Digital diagnosis assistant for psychologist
[9]			*	*	
[10]			*	*	
[11]			*	*	
[12]	*	*			*
[13]		*			
[14]		*		*	
[15]		*			
Proposed System	*	*	*	*	*

Four of the reviewed papers, [9], [10], [11], [12] were conducted with the aim of using different algorithms in the diagnosis process. However, they did not rely on DSM-5 [3] on the symptoms analysis process. All of these four researches have not been deployed as an actual system yet.

As noticed, each of the related work focused on a specific side and ignoring others. For example, helping psychologists reach beneficiaries and offering psychological tests without using any new techniques. Other systems [12], [13], [14], [15] adopted artificial intelligence algorithms on the initial diagnosis, but they did not offer any other services, such as offering and calculating psychological tests which can help psychologists to expedite and facilitate the diagnosis process.

The proposed system aims to leverage these limitations. It uses deep learning algorithm (CNN) in the diagnosis process based on a standard reference which is DSM-5 [3]. Additionally, it offers appropriate physiological tests according to the result of the diagnosis.

#### IV. RESEARCH METHODOLOGY

The research methodology comprises several steps as summarized in Fig. 1 and clarified in the following subsections.

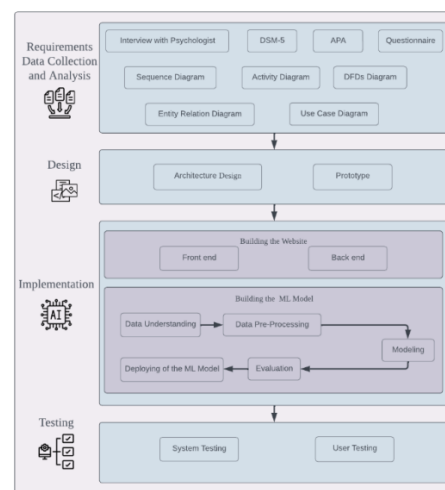

Fig. 1. Research methodology.

A. Requirements Collection and Analysis

In the process of collecting the requirements, we had several online and face-to-face interviews with psychologists from Saudi Arabia in the period between August 27, 2022 and October 18, 2022. Through these interviews, the most important needs of psychologists were identified, and the diagnostic mechanism was fully understood. Additionally, to investigate the significance of this system, an online questionnaire was designed for the experts in the field of mental health [2], and distributed to the psychologists in the Saudi Arabia in the period between 28 Sep 2022 and 8 Oct 2022. Since the target user group was precisely defined in terms of the field, country and specialization, there has been a struggle to reach them in the given timeframe. A total of 70 responses were received. They pointed out that they suffered in terms of time and accuracy to diagnose each patient. They agreed that they are in need of an Arabic system to assist them by automating the process, but at the same time not excluding them.

After full familiarity with the diagnosis process, the functional requirements, including user and system requirements, for the proposed system were identified. The requirements of three main actors namely, Admin, Psychologist, and Patient were analyzed thoroughly using data flow diagrams, use cases and scenarios, activity diagrams, sequence diagrams and Entity Relationship Diagram (ERD) [16] to clarify different aspects of the requirements. Fig. 2 illustrates scenario for the actors including psychologists and patients.

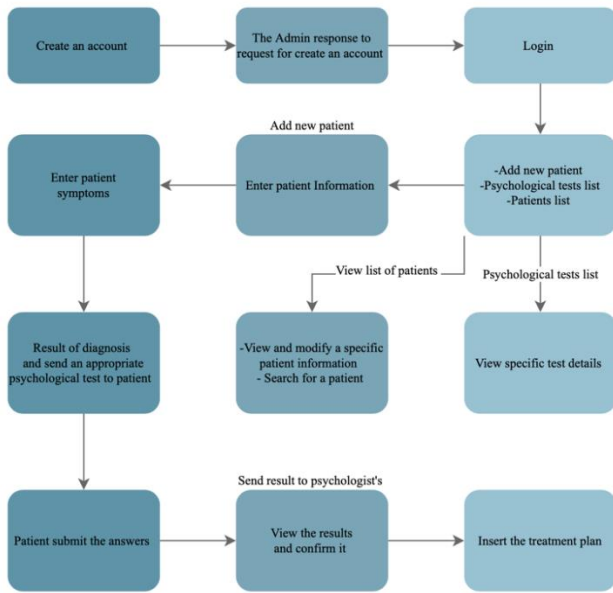

Fig. 2. System scenario to clarify the steps and the main functions of the system.

B. System Design

In this step, the system architecture was designed as illustrated in Fig. 3. Client-server architectural pattern was used to represent the architectural design of the system. Each client was considered as an end-user of the system. The functionality of the system was organized into services, with each service

delivered from a separate server. Each client can access the services through the Internet; therefore, the most suitable architectural pattern is the Client-server [16].

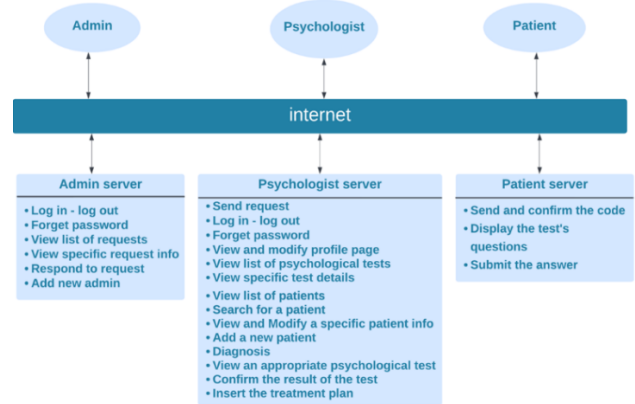

Fig. 3. Client-Server architecture for the proposed system displayed all functions for each actor.

The interfaces of the website were designed as well. Fig. 4 shows the homepage and how it looks on different devices. Fig. 5 and Fig. 6 show two pages that would assist the psychologists during the diagnosis process.

Fig. 4. The proposed website applies responsive design to work properly on different devices.

Fig. 5. This page is displayed to psychologists allowing them to enter patient's symptoms.

Fig. 6. Result of diagnosis and suggested psychological test for patient to take.

### C. Implementation

This section clarifies the implementation step and its details. This step constitutes three main activities, building the website, building of machine learning model, and deployment.

1) *Building the Website:* To build the website, the frontend and backend were implemented. Frontend implementation involved,

- Writing the content of the website by using HTML.
- Styling the interface by using CSS.
- Making the website interactive by using JavaScript.
- Backend implementation involved,
- Creating website's database in Amazon cloud (AWS).
- Connecting the database to Django.
- Creating tables of the website's database.
- Writing functions of CRUD (Create, Read, Update, and Delete) operations. These operations are implemented in Python. Example of such operations include, calculating the test score and saving the result to be displayed to the psychologist.

2) *Building the machine learning model:* To build the ML model, the following steps were followed:

- Collecting dataset.

For this research, the dataset was provided by psychologists from Saudi Arabia. There were 305 observations with 13 symptoms. The symptoms were food problems, sleep problems, conscience, communication, face features, speech, mood, behavior, fears, thoughts, focus, attention, and duration. The psychologists provided balanced observations, where around 62 observations were collected for each disorder: anxiety, obsessive-compulsive disorder, and depression. Fig. 7 shows a sample of the collected dataset.

Disorder	Eating Problems	Sleeping Problems	Conscience	Communication expression	Facial expression	Speech	Mood	Behavior	Fears?	Thoughts	Focus	Attention	Duration
الخوف	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع

Fig. 7. Sample of the collected dataset showing the symptoms being analyzed.

Pre-processing the data. The first step was to ensure that the dataset did not have missing data. This can be done by using the Python function `data.isnull().sum()`. A total of 38 missing cells were found as illustrated in Fig. 8.

```
path = 'withmissing.xlsx'
DF = pd.read_excel(path)
print("Number of Missing Data:", DF.isnull().sum().sum())
print("Dataset Shape: ", DF.shape)
```

Number of Missing Data: 38  
Dataset Shape: (305, 14)

Fig. 8. The dataset before solving the missing data problem.

To fix this problem using Python method `fillna(method="bfill")` from pandas' library and the way of filling missing data was (backward) method that uses next data point to fill the gap [17], as depicted in Fig. 9.

```
new_df = DF.fillna(method="bfill")
new_df.to_excel('dataset.xlsx')
print("Number of Missing Data:", new_df.isnull().sum().sum())
```

Number of Missing Data: 0

Fig. 9. The dataset after solving the missing data problem.

Since the dataset was categorical, the pre-processing was done by using one hot encoding technique. One hot encoding is a common approach for transforming categorical features into suitable binary vectors to be used as input in machine learning models [18]. This can be achieved by writing `get_dummies` Python method from Pandas' library. The dataset was converted into binary vectors and the features increased from 13 to 35 as shown in Fig.10.

الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع	الوجع
0	1	0	0	1	0	0	0	0	0	0	0	0	1	0	0	1	0	0

Fig. 10. The result of One Hot Encoding shows that all dataset converted into binary vectors.

The dataset was checked again to make sure that there was not any missing data, using Python Pandas `data.isnull().sum()` and the result was printed as shown in Fig. 11.

```
data = pd.read_excel('dataset_encoded.xlsx')
print("Number of Missing Data:", data.isnull().sum().sum())
X = data.drop(["اوساس فكري", "القلق", "اكتئاب"], axis=1)
y = data[["اوساس فكري", "القلق", "اكتئاب"]]
print("X shape:", X.shape)
print("Y shape:", y.shape)
```

Number of Missing Data: 0  
X shape: (305, 35)  
Y shape: (305, 3)

Fig. 11. The result of data preprocessing.

- Training the model.

Two machine learning algorithms were chosen namely, SVM and KNN and one deep learning algorithm was chosen which is CNN.

Support Vector Machine (SVM) is a supervised machine learning algorithm. The goal of the SVM algorithm is to create the best line or decision boundary that can segregate n-dimensional space into classes so that putting the new data point in the correct category in the prediction will be easy [19]. This best decision boundary is called a hyperplane [19]. SVM has multiple kernels: linear, polynomial, and RBF. Kernels are different in making hyperplanes. Linear works with linearly separable data, and polynomial and RBF work with non-linearly separable data [20]. The SVM algorithm was implemented in the current work using the Python Scikit-Learn package.

K-Nearest Neighbor (KNN) is a supervised machine learning algorithm. It is one of the simplest machine learning algorithms, it assumes the similarity between the new case/data and available cases and put the new case into the category that is most like the available categories [13]. This means when new data appears then it can be easily classified into a well suited category by using KNN. The KNN algorithm was implemented in the current work using the Python Scikit-Learn package.

Convolutional Neural Networks (CNN) is a type of artificial neural network. CNN contains multilayer convolutional, and each layer's output feeding into the next layer's input until out layer [21]. Keras model was used, which is a high-level, deep learning API developed by Google for implementing neural networks. It is written in Python and is used to make the implementation of neural networks easy. Keras is an open-source software library that provides a Python interface for artificial neural networks [22]. Keras also supports multiple backend neural network computation. Keras was chosen to implement CNN adopted 20 layers, the rectified linear unit (ReLU) as the activation function and optimized with a learning rate of 0.5.

The training process started by splitting the dataset into 70% for training data and 30% for testing data to ensure the same data is trained and evaluated in each model.

The SVM and KNN models were trained by fitting the training data to the model using fit() Python method as shown in Fig. 12 and Fig. 13.

```
model = OneVsRestClassifier(SVC(kernel="linear"))
model.fit(X_train,y_train)
```

Fig. 12. Training the SVM model.

```
knn = KNeighborsClassifier(n_neighbors=5)
knn.fit(X_train, y_train)
```

Fig. 13. Training the KNN model.

In training KNN, the neighbor that was chosen after more than one attempt which was five neighbors showed the best accuracy.

The CNN model was built with 20 layers, activation function (softmax,relu), and a learning rate of 0.5, and the dataset was trained 20 times using 20 epochs as shown in Fig. 14.

```
# Build The structure of Model
model = keras.Sequential()
# here we define 20 nodes with input shape 35 and activation function called relu
model.add(keras.layers.Dense(20, input_shape=(input_shape,), activation='relu'))
#then the output 3 node because we have multiclassifiaction (anxiety/ desperation /OCD)
#and the activation function called softmax
model.add(keras.layers.Dense(3, activation='softmax'))

#compile the model
optimizer = keras.optimizers.Adam(lr=0.5)
model.compile(loss='categorical_crossentropy', optimizer='adam', metrics=['accuracy'])
```

Train model

```
history = model.fit(X_train, y_train, epochs=20,
                    validation_data=(X_test, y_test),
                    verbose=1)
history_df = pd.DataFrame(history.history)
history_df.loc[:, ['loss', 'val_loss']].plot();
```

Fig. 14. Building and training the CNN model.

- Evaluating the models

To measure the quality of predictions for each model, accuracy, precision, recall, and F1 score were calculated using the confusion matrix, as clarified in Eq. (1) to (4). The confusion matrix represents the true positives (TF), false positives (FP), true negatives (TN), and false negatives (FN) from predicted and actual values [23].

$$Accuracy = \frac{TP+TN}{(TP+TN+ FP+ FN)} \quad (1)$$

$$Precision = \frac{TP}{(TP+ FP)} \quad (2)$$

$$Recall = \frac{TP}{(TP+ FN)} \quad (3)$$

$$F1\ Score = 2 \times \frac{Precision*Recall}{Precision+Recall} \quad (4)$$

Table II presents accuracy, precision, recall, and F1 score results of the SVM, KNN and CNN models.

TABLE II. COMPARISON OF THE MODELS' PERFORMANCE

Models	Accuracy	Precision	Recall	F1-score
SVM (Linear)	92.48%	96.8%	97.2%	97%
SVM (poly)	92.48%	96.8%	97.2%	97%
SVM (RBF)	94.48%	96.8%	97.2%	97%
KNN	89.48%	96.9%	96.9%	96.9%
CNN	96.74%	96.8%	97.2%	97%

The results are discussed in Section V below.

- Model Deployment.

Since the results were similar in terms of precision, recall, and F1 score, the CNN model was chosen as the best model to deploy it the website taking into consideration its accuracy result which was 96.74%.

The CNN model was deployed to the website by importing all the required Python libraries, the three target disorders were specified. The user-defined Python function inidiag() is used to connect the input data to the model and makes the prediction of specific diagnosis process then saves the result. After that, the input data was processed by converting it to the binary vector.

**D. Testing**

The proposed system was evaluated using system testing and usability testing.

1) *System testing*: System testing is the level of testing that validates a complete and integrated software product. To check how the components interact with each other and with the system as a whole and check the comprehensive test for each input in the system to verify the required output [15]. Four different scenarios were used to conduct the system testing. The results indicate that all errors were minor, and they were related to the front-end part. Upon completing the system testing, the errors were resolved.

2) *Usability testing*: A total of nine users participated in the testing, five of them represented the role of patients and the other four were psychologists. Each participant was given a number of tasks to perform on the system, and they were observed during the testing. The total time to complete each task for each participant was recorded along with the number of errors per task. After the testing session, the participants were interviewed and asked about the system and their experience in using it. The feedback was positive, and they pointed out the usefulness and ease of use of the system.

**V. DISCUSSION**

Table II indicates that the results of the three models were almost similar in precision, recall, and F1 score, however, accuracy differences were noticed. SVM performed better than the KNN model, with accuracy of 92.48%. SVM with kernel RBF has performed better than poly and linear models, with accuracy of 94.48%. Among all models, the CNN model performance was the best, with accuracy of 96.74%. CNN uses epoch, and the higher the epoch, the greater the accuracy. When an epoch is executed, it compares the earlier validation result to the original result. As a result, if an issue is discovered, it attempts to minimize the problem by upgrading the layer function.

Fig. 15, 16, and 17 illustrate the curve of training loss and validation loss in the three models. They show that CNN has a better fit compared to SVM and KNN.

In the confusion matrices illustrated in Fig. 18 to 22, 0 refers to Depression, 1 to Anxiety, and 2 to OCD.

The accuracy results were averaged after 20 epochs for CNN and averaged cross-validation [24] with 10 Kfold to avoid overfitting for SVM and KNN. Overfitting is the term for a model that does not generalize properly from observed data to unobserved data and defeating its purpose [25].

## VI. CONCLUSION AND FUTURE WORK

In this paper, an Arabic system was proposed to assist Saudi psychologists in making the diagnosis process of mental disorders accurate, easier, and faster. The methodology followed involved requirements collection and analysis, design, implementation, and testing. The machine learning approach was adopted to diagnose the patient based on the symptoms, prior to deciding which psychological test to take. The focus was on three popular mental disorders namely, Depression Anxiety, and OCD. The dataset was built from scratch for them by collecting anonymous data from psychologists. The ML model was trained by using three different algorithms SVM, KNN, and CNN. The CNN algorithm was chosen to deploy on the system, because it was the most accurate algorithm with a minimum number of errors. Two main limitations were encountered during the work on this research. The proposed system did not cover all mental disorders; it covered three prevalent mental disorders. In addition, the collected dataset was limited to 305 observations. The dataset was balanced with around 100 observations for each mental disorder. The main symptoms needed to diagnose the disorders were considered as features in the dataset. The dataset did not contain the less important features such as the background and history of the patient.

As a future work, we are planning to add more mental disorders that can be diagnosed, add more psychological tests that can be taken by patients, and suggest a treatment plan to the psychologist using a machine learning approach.

# The Evaluation of a Persuasive Learning Tool using Think-Aloud Protocol

Muhammad ‘Aqil Abd Rahman<sup>1</sup>, Mohamad Hidir Mhd Salim<sup>2</sup>, Nazlena Mohamad Ali<sup>3</sup>  
Institute of IR4.0 (IIR4.0), Universiti Kebangsaan Malaysia, Selangor, Malaysia

**Abstract**—e-Learning has become a platform for students to gain and expand their knowledge through mobile applications or web-based systems. Even though e-learning systems usually aim to facilitate students' understanding of the subject, some fail to convey the underlying learning outcomes. These circumstances emerge as most e-learning methods or tools fail to attract students to engage in their studies continuously. Therefore, to overcome the problem, the Persuasive Learning Objects and Technologies (PLOT) model comprises persuasive design elements for online learning, is developed. A web-based statistical analysis assistant system called TemanKajianKu (Study Buddy) has been developed based on PLOT elements to assist students in identifying the correct approach to conduct and analyze their experiment. This paper aims to evaluate users' experience and examine the effectiveness of the persuasive design elements of the system. Ten participants were involved in interviews using the Think-Aloud protocol method. The study results showed that most participants conveyed positive opinions by giving good feedback on the system design. Most also stated that the system could help them make decisions by utilizing persuasive elements such as reduction, social signal, tunnelling, tailoring, and self-monitoring. This concludes that the Persuasive Learning Tool is effective in helping develop an e-learning application or web-based system that helps students in decision-making concerning their studies.

**Keywords**—Learning technology; persuasive technology; persuasive learning; persuasive design

## I. INTRODUCTION

Technology can solve many problems by enhancing students' learning capacity using mobile applications and web-based platforms. According to Ahmad [1], computing technologies are intended to assist individuals with daily activities like conducting administrative work or teaching in a classroom and to influence and drive people to change their attitudes or behaviors toward specific issues or things. Numerous applications from various fields must be developed to support students' learning in helping to produce students who are sensitive to using internet platforms as tools to gain knowledge. Problems can arise when students cannot make timely decisions, and their workload grows. With the help of digital learning technology, which can change students' attitudes and improve knowledge content, especially in decision-making aspects like methods, strategies, or selection in research activities, this problem can be resolved. Decision-making and critical thinking are essential in solving a problem, especially in the student's learning process. It has been discovered that technology-assisted learning can influence attitudes, improve research performance, and offer learning experiences for making critical decisions. The need to enhance

the research and student learning level was determined to be met by multimedia components alone, such as audio, video, and interactivity. Student performance must improve to raise learning motivation.

Even though experience is one of the most essential factors in building a technology or application, and if each technology or application is designed to persuade people, the user's decisions are still influenced by experience [2]. Effective persuasive designs are essential when developing an e-learning system [3]. Because e-learning programs are flexible enough to meet needs, this saves students who already understand some concepts in a course from having to review them. On the other side, they might like more complex material, whilst individuals just discovering a field would choose to concentrate on the basics [4]. After that, to better comprehend student decision-making in their study, a system called TemanKajianKu was developed to assist students in understanding statistical analysis. The main aim of this study is to evaluate the persuasive learning tool implemented in the system using a think-aloud protocol for the students. According to studies, failing to think critically might delay or prevent graduate students from finishing their studies and impede the advancement of research [5]. Although universities provide courses designed exclusively for graduate students, including Research Methodology, some students find them too general because each student's studies are unique based on the topic of their studies. Examples of research tasks requiring analytical skills include selecting research methodologies and statistical analysis approaches for user studies and evaluations. Then, the material and methods used in the evaluation study will be further described in the following section of this paper. Next, the result and discussion are presented to explain the evaluation system. The final part of this paper is the conclusion.

## II. BACKGROUND WORK

### A. Persuasive Technology

Persuasive technology is designed to change user attitudes and behavior without coercion [6]. Persuasive technology can be used and implemented to help students adjust and at the same time be able to accelerate their attitude changes without any coercion [7]. This technology can bring people together through computer interaction [8]. It could trigger positive emotions in users by employing various persuasion principles or methods to gain trust and successfully persuade them to adopt the desired attitude or behavior [9]. Persuasive technology has been used in various fields, such as e-commerce, health, and marketing. Persuasive technology is also applied in education by focusing on changes in learning

behavior towards students on e-learning [10]. According to the table below, Gram-Hansen and Sandra Burri (2012) identified nine persuasive design principles for system development.

Persuasive learning experiences, such as being actively involved in learning, could be established with persuasive design ideas or principles applied in education [11]. A persuasive learning design framework is also explicitly developed to target changes in student attitudes toward learning technology [12]. Table I shows the persuasive elements of system design outlined under the learning design framework [13]. Each of these persuasive elements has its application design function in decision-making to produce a more compelling user experience.

### B. Persuasive Technology in Education

As the world strives for new technologies and the IR4.0 era, education must be prepared to provide content through mobile applications. Using persuasive technology in education can significantly benefit students' language learning, stress management, school safety, and other areas. An application called VocabGame was created in Arab nations using persuasive design elements to assist students in understanding word meanings and so expanding their vocabulary. Additionally, it supports educators working to enhance their country's systems for teaching and studying English as a foreign language [14].

Most students in Canada experience stress and anxiety, which is likely related to poor time management. SortOut is an application developed with seven persuasive strategies integrated as six essential elements that assist students in time management and time savings by encouraging organizational behavior [15]. Then, it may be challenging for students and teachers to enhance language learning and raise learners' motivation when English is a second language. From the 17 review frameworks for mobile education applications, the Vocabulary Game EVG prototype has been offered. It uses persuasive design elements to focus on three criteria (mobile, game, and language learning) [16].

1) *Persuasive learning*: According to Gram-Hansen (2015), persuasive learning and design can be related to facilitating the learning process by inspiring learners to engage in the learning experience and encouraging a sustainable behavior change [17]. Furthermore, through learning opportunities provided by online platforms, persuasive learning can develop an emotional bond between users and systems. Using persuasive design features in websites and applications, persuasive learning can also aid in motivating users and students to learn.

2) *Educational technology*: Educational Technology creates a way to broaden the scope of education and learning by disseminating information using online platforms. According to Voronov (2021), educational technology gives advantages to students throughout their studies, such as online learning, and needs to be in a place with a stable network [18]. Pham (2022) stated that technology is a field of study that investigates analyzing, designing, developing, implementing,

and evaluating the instructional environment and learning materials to improve teaching and learning [19].

Although utilizing educational technology can improve student decision-making in learning and teaching skills, this problem can be solved with learning technology that could change students' attitudes and increase their knowledge. Learning technology is a broad category of communication, information, and related technologies used to support the learning process, teaching, and assessment. Tools such as tutorials, simulations, productivity tools, and communication tools such as email were used as materials for students' activities. After that, to ensure that learning technology is widely implemented on websites and applications, persuasive design should be employed to assist higher education and school learner in learning things more quickly and efficiently as well as accurately decision-making in their study.

TABLE I. PERSUASIVE DESIGN PRINCIPLE (GRAM-HANSEN & SANDRA BURRI, 2012)

Principles	Description
Reduction	Reduction is a design method for reducing a process that might otherwise be difficult. For example, Shopee purchase allows users to skip many time-consuming navigations and tiresome form filling to make an immediate purchase.
Tunnelling	Tunneling is a design method in which the user is placed inside a process with a predetermined path. For example, most installation processes necessitate the completion of multiple stages by the user before the installation can be completed.
Tailoring	The degree to which a site or application offers appropriate content to users or user groups is referred to as tailoring. User demographics can be reflected in navigational options, filtering processes, and labeling systems.
Suggestion	Suggestion is a persuasion design method that involves conveying a message at the right time. For example, when Kindle suggests several books that are linked to the one you were going to purchase.
Self-monitoring	Self-monitoring is a design method that enables users to keep track of progress. For example, sites that need a login before allowing the user to track their weight reduction progress.
Surveillance	Surveillance is like self-monitoring, except the monitoring is done by the system or the system's owners, not by the user. Users of a weight-loss website, for example, may be encouraged not just by tracking their success, but also by sharing their experiences and receiving feedback from other users who are dealing with similar problems.
Conditioning	The method of incorporating emotional input into a design is known as conditioning. It is frequently presented in the form of praise and prizes, but more subtly than with Persuasive Social Actors.
Simulation	Simulation is a design method that allows users to experiment and explore in a safe, non-threatening setting. It plainly and immediately demonstrates a link between cause and effect, and it may look like a subtle form of persuasion as the user gains personal experience through the simulation.
Social Signals	Social signals are a form of the design principle that, like conditioning, incorporates emotional feedback into a design but is more direct. For example, delivering positive feedback and social support to users. Chatbots, which can be seen on websites providing advice and comments in a human-like manner, are examples of persuasive social actors.

### III. MATERIALS AND METHOD

A semi-structured interview was conducted with participants in a lab, or some were in a room free from distractions. All participants were given information about the objectives of the TemanKajianKu system and instructions to implement the think-aloud protocol throughout the interview session. There are three different tasks, the first one being the scenario task. The scenario task is divided into two different scenarios and participants need to solve all the scenarios given by using functions in the TemanKajianKu system.

There are two objectives throughout this pilot study:

- To evaluate the user experience on persuasive learning object technology (PLOT) in the TemanKajianKu system.
- To evaluate the effectiveness of persuasive design elements in a TemanKajianKu system.

Next, a total of ten questions will be asked on persuasive elements that are applied in the system. Each persuasive element will have two related questions; all participants must answer the questions through conversation. Besides that, three open-ended questions were asked about user experience when using the TemanKajianKu system. All these questions are used to study the effectiveness of persuasive design elements and users' feedback for system improvement.

A think-aloud protocol is a technique that is implemented during the interview session. A think-aloud protocol is a technique that encourages participants to share their opinions with interviewers while engaging with the product [20]. Usually, this technique was applied while doing qualitative empirical data collection. Participants verbally conveyed their opinions about the interaction experience, including their goals, justifications, and impressions of UX difficulties, to identify UX weaknesses [21]. Everything said by the user and the interviewer was documented and audio-recorded during the interview since the aim is to identify the response the user gave precisely.

#### A. Instructions and Scenarios

The first scenario asks participants to use the system sequentially following the eight steps set. Second, participants are given three types of storylines to solve to get the answers for each situation.

Table II shows all the steps for participants to follow and finish it. These are standard steps for a new user in understanding the functions and use of the system, which is from signing into the system, utilizing it, and logging out from the system. Therefore, Table III below shows three different situations for participants to solve. The situation asks the participants to use chatbots and charts to know the methods used in statistical analysis and sampling analysis.

Scenario one shows Ali, a post-graduate student who wants to use parametric analysis in his studies; participants are asked to help Ali find the appropriate statistical analysis method. Then, scenario two shows Fatimah, an undergraduate student who has just studied the subject of statistics and wants to know

about the quota sample; the participants are asked to help Fatimah find the appropriate method for sampling analysis. The last scene shows that participants are asked to find the most distant statistical analysis techniques in the diagram using chatbot help. All participants can ask questions about the scenarios if they don't understand them well.

TABLE II. LIST OF 8 STEPS FOR USERS TO USE THE SYSTEM

Step 1	Users are asked to register a new account to log into the system.
	↓
Step 2	Users are prompted to create a new project for Sampling Analysis.
	↓
Step 3	Users are asked to use the chatbot on the left side of the screen.
	↓
Step 4	The user is prompted to save the project and return to the home page.
	↓
Step 5	Users are prompted to create a new project for Statistical Analysis.
	↓
Step 6	Users are asked to use the chatbot on the left side of the screen.
	↓
Step 7	The user is prompted to save the project and return to the home page.
	↓
Step 8	Users are asked to test the edit and delete buttons.

TABLE III. LIST OF THREE SCENARIOS USERS NEED TO FINISH

Scenario	Description
Scenario 1	Ali is a postgraduate student who conducts research using analytical statistics. Ali used different 'continuous' data and means methods in his study. The study did not exceed two groups and the parametric analysis technique was the main technique used.  <u>Participant Task</u> Users are asked to use the chatbot to guide Ali to get information about parametric analysis.
Scenario 2	Fatimah is an undergraduate student who has just studied statistics. She still does not understand the information about analysis sampling. She wants to know more about the quota sample method.  <u>Participant Task</u> Users are asked to use the chatbot to guide Fatimah to get information about quota samples.
Scenario 3	The user is asked to select the most distant statistical analysis technique in the diagram and use the chatbot to get the steps to achieve the selected technique.

#### B. Questionnaires

This system implements five persuasive elements from the persuasive learning object technology (PLOT): reduction, tunneling, self-monitoring, tailoring, and social signal. Table IV shows that two questions were asked to the participants for each persuasive element used in the system to determine the effectiveness of the elements implemented. Next, three more open-ended questions were asked to get user feedback and experience in upgrading the system more efficiently.

TABLE IV. LIST OF QUESTIONS USED DURING THE INTERVIEW

Scenario	Description
Reduction	Is the TemanKajianKu system easy to use even if it is your first time using it?
	Are there any design elements in the TemanKajianKu system that are not required?
Tunneling	Does the TemanKajianKu system show you the steps to get the statistical method you need?
	Do you think the statistical method search process diagram shows easy-to-understand and accurate steps?
Self-monitoring	Does the TemanKajianKu system indicate your level of progress in obtaining the required statistical methods?
	Do you think statistical method search process diagrams help you figure out where you are right now?
Tailoring	Does the TemanKajianKu system provide the statistical methods you need?
	Do you think the use of chatbots in this system suggests a statistical method that matches your research needs?
Social Signal	Does the TemanKajianKu system use language that is easy to understand and clear?
	Does the chatbot used use positive language, complement, and give you good comments?
Open-ended Question	What do you think of this system?
	Does the system save you time and help you make decisions to find coincidental statistical analysis methods?
	Are there any other feature additions or system problems that can be updated in the system?

### C. Thematic Analysis

This section presents the results and findings from the pilot study data analysis. The data collected includes semi-structured interviews and recorded videos of users explaining their experiences with the TemanKajianKu system. We categorized transcriptions and arranged the themes of the findings based on thematic analysis after transcribing the recorded videos and interviews [22].

Clarke & Braun, (2017) defined thematic analysis as a method for analyzing qualitative data that entails searching across a data set to identify, analyze, and report repeated patterns [23]. Data familiarization was first applied by reading and re-reading the selected articles and marking early ideas or perceptions [24]. Then, coding was included in the data collection by using the Nvivo software to identify the themes. The preliminary themes were discussed and improved until the finalized themes were identified.”

### D. System Interface Design

The sign-in page for the TemanKajianKu system is seen in Fig. 1. To use the system, a user must first register a new account. Fig. 2 and 3 depict the system's dashboard, which lists two different analysis methods that users may select for their research methods, and a chart page where users can determine the most suitable strategy for the chosen analysis method from the information displayed on the page.

TemanKajianKu system applied a user-friendly design interface by implementing a suitable color theme to ensure users understand each tool or function available.

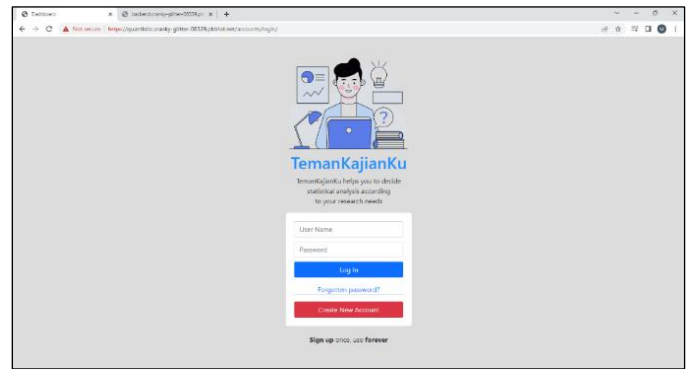

Fig. 1. Sign in page temankajianku system.

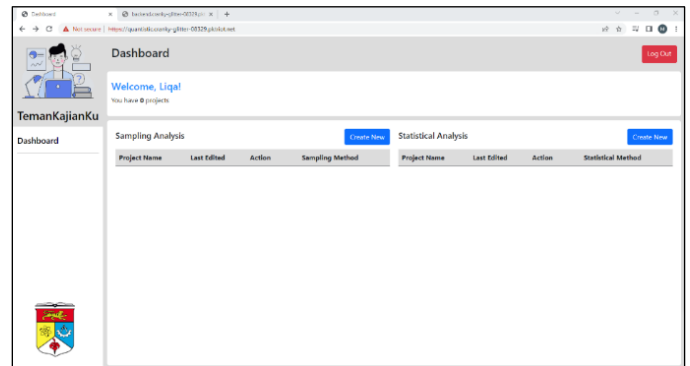

Fig. 2. Dashboard page temankajianku system.

Fig. 3. Flow/chart diagram page temankajianku system.

## IV. RESULTS

In this system evaluation, 10 postgraduate students from the National University of Malaysia (UKM) with different backgrounds study were recruited as system users in this research. All system users must follow the system instructions and steps, where three different tasks must be completed by exploring the whole system. They were requested to finish the task within a maximum of 30 min using the laptop given while doing the interview.

Most of the participants were male (60%), postgraduate students (100%), and studied in the engineering field (50%). Most of the participants have learned statistics subjects (90%) and suggested platforms for online learning study. The demographic of users' information is presented in Table V.

TABLE V. DEMOGRAPHIC OF USERS' INFORMATION

Users (n=10)	n (%)
Gender	
Male	6 (60%)
Female	4 (40%)
Age	
18-20	-

A. The Effectiveness of Persuasive Element used, and User Experience based on TemanKajianKu

There are three different results of the persuasive using think-aloud experiment. First, think aloud about the result of the user using the TemanKajianKu system. Second, think-aloud results on persuasive questions that were asked during the pilot study, and third, think-aloud results on persuasive open-ended questions to know users' feedback about the TemanKajianKu system (see Fig. 4).

B. User Experience in Utilizing the TemanKajianKu

Understanding user experience is essential to understand how people think about the system from start to finish. User experience, according to Rex Hartson (2019), is the sum of the effects a user feels before, during, and following engagement with a system or product in ecology [25]. Additionally, user experience influences how interested users are in using the system long- or short-term. Three themes with eight subthemes were identified after data analysis. The themes include user-friendly, improvement of system functions and disadvantages of system tools. Based on the identified themes, the analyzed data is discussed below:

- User-friendly

The majority of users preferred to have complete access when using the system. As a result, users are free to use every

system component without needing permission. Furthermore, the system is simple to use and comprehend, making it simple for users to understand its function, how to utilize it, and obtain the required information. For example, participant 2 said, "Simple, easy to understand, the system has an easy-to-understand flow".

- Improvement of system function

The design of the system interface also contributes to users having a clear view of the system. Due to incorrect color selections, small text fonts, and displayed graph diagrams that need to be enlarged, some system components need to be visible. For example, participant 3 said, "This diagram must be enlarged a little because I cannot even read the one below. This diagram should be larger. Like below, the information cannot come out immediately because it cannot even be read". In addition, users recommend enhancing the system by including a zoom feature and a selection of system color themes.

- Disadvantages of system tools

Every system inevitably has flaws that must be fixed to increase usability. Some users of the system need clarification on the instructions and diagram provided. Based on the statement, the size and tool position of the part in the system is too close to one another and too small. Users said the systems occasionally required system instruction and were challenging to use. "It is difficult to move to the flowchart and drag the slider on the bottom page," says participant 4.

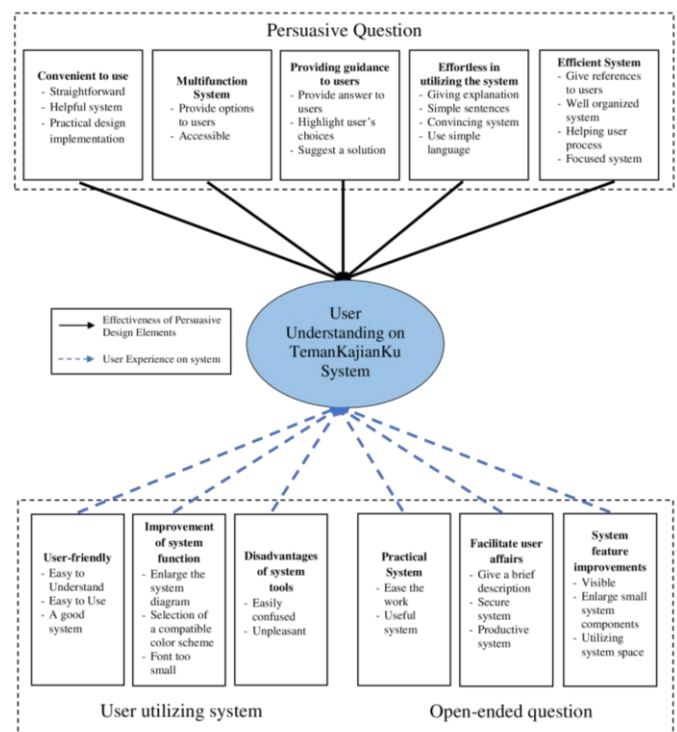

Fig. 4. User experience and the effectiveness of persuasive design implementations.

### C. User Experience based on Open-ended Question

After users had completed the persuasive questions, they were invited to answer three open-ended questions to know the user experience when using this system and give their opinions or suggestions about the TemanKajianKu system. As a result, three themes have emerged for each submitted question, which are practical systems, facilitate user affairs, and system feature improvements.

- Practical System

A practical system consists of good functions and features with various exciting elements. Based on user perceptions, this system is beneficial and makes it easier for users to achieve user goals. For example, participant 5 said: *"It is beneficial for statistical methodology, for those involved in this field, beneficial."* Participant 1 and participant 2 made a similar point.

- Facilitate user affairs

A system facilitates user affairs by saving the user time, explaining methods, and assisting the user in making decisions to locate compatible statistical analysis methods. Furthermore, a secure and productive system makes users feel more enthusiastic and safer. For example, participant 4 said, *"Yes. Because there is a definition, and it has an efficient flow chart, so time goes faster."* Other users also agreed that this system could save time and help make decisions about the statistical analysis method for their research.

- System features improvements

System features should be improved to ensure that the system is maintained and managed with better quality. There are several remarks made by users about their interactions with the systems. For instance, it may be necessary to expand small system components to be more visible. Additionally, complex features can be clarified to make them simpler to grasp, and voids in the system can be filled with fresh, more useful features. During the interview session, participant 10, said: *"I think for the flow diagram, it should be bigger than now. As for me, I can't see it clearly. For anyone short-sighted, they need to focus more to see the diagram."* Participant 7, Technology Student, makes similar thoughts.

### D. The Effectiveness of Persuasive Design Elements Used

Five persuasive elements from Persuasive Learning Object Technology (PLOT) were implemented in the TemanKajianKu system: reduction, tunneling, self-monitoring, tailoring, and social signal. Each persuasive element has a specific purpose in assisting and simplifying user system utilization. During the pilot study, the user was given a set of ten questionnaires, two of which were related to each persuasive element employed in the system. Users must answer all the questions. The interviews were recorded. 16 subthemes were created, which led to the formation of five themes. Each one of the five themes will represent each persuasive element implemented.

- Convenient to use

The first persuasive design elements approach in the system was a reduction, intending to make it simpler for users to utilize the system in line with their preferences and comfort

levels. The system is beneficial and comprehensive in providing a selection method that makes users feel easier to use and practical with the design found in the system. For example, participant 5 said, *"The system already has guidelines, and the website is also running smoothly. This diagram is also complete, it helps"*.

- Multifunction System

A design method called tunneling means inserting the user inside a process that follows a predetermined path. Users believe the system is straightforward and has an easy-to-follow flow that guides the user by displaying a simple and understandable user interface with instructions, labels, and page titles. Participant 8 gave positive feedback: *"The diagram shows the easy-to-understand steps"*.

- Efficient system

The aim of self-monitoring is a design method that enables users to keep track of progress. According to user comments, the system is simple to understand regarding the features and design that assist users in identifying the system's structure and comprehending the graph display. For example, participant 4 stated, *"Because there is a chatbot, so we don't have to worry about the flow, the flow as a reference."* Participant 2 had the same opinion, which is *"Changing the color helps, the system helps us to focus more on our purpose"*.

- Providing Guidance to Users

A website or application employs tailoring to give users or user groups the information suitable for them. According to the user, the system presents users with a choice between an option and an answer related to or applicable to their research, which can assist users in making more precise and effective decisions faster. *"The system gives suggestions. Because the system gives us a choice."* said participant 6.

- Effortless in Utilizing the System

Social signal is a design principle that combines emotional feedback into a design more directly than conditioning. This system was implemented by using clear and good language, large text, simple sentences, and color picks that correspond to the user's view. This system also helps users feel more secure in their answer options or methods through clear and comprehensive explanations. For example, participant 1 said, *"Okay, the chatbot language is very clear because it's just a short sentence"*, and participant 9 agreed, *"The chatbot boosts my confidence in making decisions. The explanation provided is simple and understandable"*.

## V. DISCUSSIONS

Generally, educational technology is a scientific and ethical practice of boosting learning and improving performance by creating, using, and managing appropriate technological processes and resources [26]. This study has developed a system based on persuasive design elements that assist students in research decision-making. The study continued by asking ten users to participate in semi-structured interviews to determine their thoughts on the system. Think-aloud protocol interviews were conducted to understand more about users' viewpoints and their benefits from using the system. This in

continuously helps to attain the study's research objectives which consist of; the effectiveness of implementing persuasive elements and user experience while using the system. This was done by utilizing thematic analysis to examine the data that had been gathered.

In this section, we will discuss two components of the findings from the conducted interviews. First, how effectively the system's persuasive design aspects work, followed by how well users experience utilizing the system. According to the first theme created by the persuasive elements' effectiveness, most users offer the system positive feedback and believe that the system's persuasive design elements can aid them in making research decisions. Because the human brain is not a rational information processor or decision-maker, persuasive information design helps influence user decision-making [27], and reduction aids in developing a more positive attitude about the behavior, [6] which persuades people to choose the best action. Next, the user identified that the system provides simple guidelines for understanding the appropriate statistical methods for research through graphs, explanations, and focusing on the objectives of the user's study. The persuasiveness of information offered by computing technology will increase if it is catered to the requirements, interests, personality, usage context, or other characteristics relevant to the individual [28]. In the process of tailoring, the relevant information is provided to the individual to meet their needs in a context unique to that instant in time [29]. After that, some users stated that the system did a great job motivating them to grasp statistical analysis using straightforward language and short, basic sentences. According to Oinas (2008), a system should use compliments expressed through words, visuals, symbols, or sounds to provide positive feedback to a user [30]. Because positive feedback might affect users' perceptions of social support [31], and by utilizing social influence, social support aims to inspire people [32], where it is employed in persuasive design elements of social signal.

Furthermore, some users have expressed dissatisfaction with the system's usability due to its functional limitations. They thought using system tools like graphs and chatbots was occasionally challenging because the system is often too confusing. Even if Lukas (2022) asserts that a user-friendly design solely focuses on making a task as simple as possible for the user to complete and does not try to change the action the user wants to accomplish, a persuasive design must be kept apart from a user-friendly design [33]. Nevertheless, persuasive design can enhance the user experience by making a website simple and engaging user by understanding psychological triggers and their behavior. Most users then claim the system's functionality and toolkit can be enhanced further. For instance, the text and graph are too small, the theme color choice is inappropriate, and more features are added to the available area. Users' feedback on system upgrades makes us more sensitive to ensuring the system is more functional and user-friendly. As a tool, the system should identify user preferences and offer solutions to problems while guiding the user through a step-by-step procedure (Fogg, 2002) because the user experience is crucial to an information system's success (Li & Samir, 2010). In addition, users described each statistical or sampling analysis result briefly, demonstrating the system's

stability in managing users' information. Fogg (2002) claimed that persuasive software could understand humans because it is more persistent than humans and employs various influencing modalities [6]. Oinas (2009) asserts that a system should appeal to its users and offer information that is accurate, impartial, and fair [28].

To the best of our knowledge, Malaysia universities should also provide additional training to improve academics' online teaching skills to ensure more successful lesson performance [34]. Concerning that, using systematic platforms or applications, such as TemanKajianku, would be a plus point in enhancing online learning. Based on the study, it can be concluded that TemanKajianKu is a system objectively developed as an online learning platform to assist students in selecting the most effective research methods. E-learning enables people to meet their educational needs through various digitally enabled services [35] and a web-based system that makes information or knowledge available to users or learners without regard to time constraints or geographic proximity [36]. In meeting this objective, this system implemented a chatbot as a user and system communication platform. One of the key tools in this system is the chatbot, which helps users find recommended methods that are appropriate for their research. Another key tool in the system is the graphs for statistical analysis or sampling analysis methods, highlighting the steps to be performed in user research. In general, it was discovered that persuasiveness has a significant role in facilitating users and is beneficial in helping users reach their desired goals in this system based on the discussion. The findings were gained through the study of system usage.

## VI. CONCLUSION

The results of this study conclude that our participants liked the TemanKajianKu system because it helped them in decision-making for statistical analysis for their research study. This system provides two different analyses, sampling, and statistical analysis, for users to choose the corresponding and appropriate method. As predicted, PLOT helps motivate, increase confidence, and engage users to achieve users' goal. Therefore, some participants said the system could be improved with more effective functions or features. Future developments of the TemanKajianKu system will emphasise the efficiency of user-system communication through the current chatbots. The present chatbot will be upgraded further to identify the objective and goals of the user research in greater depth, hoping that the system's proposed analysis approach is more suitable to the user. Additionally, it is feasible to enhance the persuasive design elements to make the system more organized, productive, inventive, and efficient. All the recommendations will be considered for the improvement of the TemanKajianKu system.

## ACKNOWLEDGMENT

We would like to thank all participants involved in this study. The work was supported by a university research grant GGPM-2022-065.

**Abstract**—Industrial control systems (ICS) play a crucial role in various industries and ensuring their security is paramount for maintaining process continuity and reliability. In ICS, the most damaging cyber-attacks often come from trusted insiders rather than external threats or malware. Insiders have the advantage of bypassing security measures and staying undetected. This research focuses on developing a real-time intrusion detection system for ICS workstations that effectively detects insider threats while prioritizing user privacy. The approach employs file integrity monitoring to identify suspicious activities, particularly file violations such as data tampering and destruction. The model presented in this research demonstrates low system resource consumption by utilizing an event-triggered approach instead of continuous polling of file data. The model leverages built-in operating system functions, eliminating the need for third-party software installation. To minimize disruptions to the ICS network, the model operates at the supervisory level within the ICS architecture. Through extensive testing, the model achieves a high level of accuracy, detecting insider intrusions with a high true positive rate. This reliable detection capability contributes to enhancing the security of ICS and mitigating the risks associated with insider threats. By implementing this real-time intrusion detection system, organizations can effectively protect their control systems while preserving user privacy.

**Keywords**—Industrial control system; insider threats; intrusion detection; file integrity monitoring; SCADA security

## I. INTRODUCTION

The industrial control system is very important for various industries in our life. As with any other system, security is now a top priority, and it must be achieved without affecting process continuity and reliability. ICS faces different kinds of threats from outside the system as well as threats from insiders. The security threat from within can be even more powerful than many external attacks [1], [2]. This is particularly the case with ICS networks, which manage critical infrastructure and manufacturing plants. A smart, motivated, perhaps disgruntled employee or ex-employee with knowledge of a plant and access to the network, can cause a variety of disruptions that may result in information breaches, financial losses, equipment damages, and even threaten human lives [3]. Industrial control systems should be very secure to ensure plant resource availability and integrity without any disturbance or production loss. The system should imply a very secure means of

protection including fast detection of insider intrusion, to avoid exploitation getting even worse.

An insider threat occurs when someone close to a company with authorized access misuses that access to harm the company's key information or systems [1]. This individual does not have to be an employee; third-party vendors, contractors, and partners may represent a threat as well. Privileged employees, such as IT team members, superusers, knowledge workers, resigned or dismissed people, and managers are all possibilities to be insiders [4].

Several recent security surveys report a high increase in insider threats. In the report [1] more than half of organizations have experienced an insider threat in the last year. Based on the survey, 74% of insider attacks have become more frequent over the last 12 months. In the report of [5], about 4700 reported attacks were subjected to analysis and it showed that 23% of attacks were attributed to malicious insiders while 63% were attributed to employee and contractor negligence. In [4] survey report The negligent insider is the root cause of most incidents that come from insider threats. According to the Kaspersky 2019 Status of industrial cybersecurity study, staff mistakes and accidental activities were responsible for 52 percent of incidents affecting operational technology (OT) and industrial control system (ICS) networks in 2018 [5]. Sometimes, unaware or negligent employees can unintentionally cause security breaches without knowledge of doing so [1]. According to a recent Ponemon Institute (2022) research sponsored by ObserveIT and IBM Insider, risks have increased in the last two years [4]. As a result, enhancing the approaches of early identification of any source of insider attack requires more security controls and solutions.

Network intrusion detection, Firewall, and antivirus systems have been shown to be ineffective to detect attacks coming from insiders. Large security operations centers have started to implement endpoint-based sensors that give their organizations broader visibility into low-level occurrences [6]. Therefore, employing techniques and tools specifically designed to address the threat of insiders will be more effective. Furthermore, these tools should consider the phenomena and requirements of the industrial system.

In the field of (ICS), applying traditional IT countermeasures and solutions blindly is not recommended due to several differences between the two environments. While IT systems prioritize confidentiality, ICS focuses on availability

as its major priority. Additionally, the expected reaction time in ICS should be below a millisecond, compared to a few seconds in IT systems [7]. Outages in ICS can have severe consequences, including production stoppage and financial losses. In ICS, security will include ensuring safety for company assets and personnel as well as the environment [8].

## II. LITERATURE REVIEW AND RELATED WORKS

Industrial control system (ICS) is a term used to describe different control systems and related instrumentation, including the devices, networks, and controls used to operate and automate industrial manufacturing processes [7]. It includes a distributed control system (DCS), supervisory control and data acquisition system (SCADA), Safety Instrumented Systems (SIS), Emergency Shutdown Systems (ESD), and programmable logic controllers (PLC) [9], [7]. They are core parts of every technical infrastructure globally, ranging from the small controller used in air conditioning in our cars and homes to the extensive control networks used in factories [10]. These factories include power production and distribution, oil and gas, chemical production, water distribution systems, and even nuclear plants[3]. These systems help control and automate industrial operations, providing remote monitoring and recording for different data and parameters on the field side.

A typical IACS design seen in any modern facility might have a DCS as the primary control system, with interfaces to additional systems such as PLCs and SCADA System. The plant data is sent to a central control room to be used for monitoring and controlling purposes [9]. These data are saved on a workstation known as the Historian to help the panel operator view historical trends. Panel operator workstations are used by plant operators to monitor the process. Besides operator workstations, Engineering Workstations are used to configure the DCS controllers and maybe the subsystems such as PLCs, as well as the associated systems such as SIS [11].

The architecture of ICS is hierarchical and has several operational levels as in Fig. 1 including Process Level, Basic Control Level, Supervisory Control Level, Process Management, and Corporate Network Levels by ISA 99 (control system automation security and safety standard) [8]. To guarantee greater security, security measures should be implemented at every level. The intrusion might have taken place at any level of this hierarchy or on multiple levels at once. Understanding the components of these levels enables more professional security measurement implementation.

The first level of the architecture is called Process Level, and it interfaces with the physical process through actuators and sensors instrumentation. The second level, known as Basic Control Level, is where the system's overall control takes place. The primary goal of the basic control level is to use controllers to regulate the physical process that interfaces with instrumentation components [8]. The supervisory level is the following level in the hierarchy. This level is in charge of interacting and gathering data from the process and control levels so that the operator workstations can monitor and view the control state and field reading of the process [8]. In this level, engineering workstations also exist which are used to access controllers setting and programs. Supervisory level

workstations have a good supply of memory and processors in comparison with two lower levels, which make them more suited to deploy a security intrusion detector than the previous two levels.

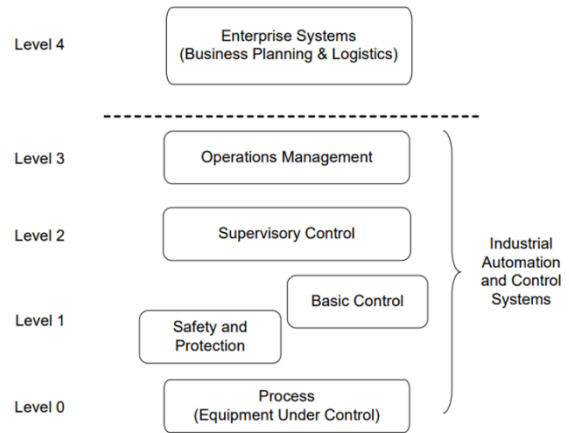

Fig. 1. Reference model for ISA99 standards.

Source: [8]

There is a lack of research and studies done on the field of ICS insiders, because of the gap between IT security researchers and operating technology [8]. In this part, we discuss the research which discusses insider intrusion detection solutions in IT system and ICS system as well. In the last few years, many ICS-oriented intrusion detection approaches have been explored in the research community. Several ICS-oriented IDS taxonomies with various categorizations are found in the literature. Some approaches attempt to detect insider threats by using machine and deep learning approaches and other approaches which depend on monitoring internal logs and system commands.

Some research on insider threat detection shows that potential insider threats can be proactively identified through psychological changes and language habits before the execution of malicious activities. These researchers argue that variations in an individual's behavior and communication patterns can serve as early warning signs of potential threats. The studies that focus on psychological changes and language habits are primarily designed to identify potential malicious insiders such as traitors. They can be very effective at detecting individuals who might be planning to intentionally harm an organization [12]. However, when it comes to negligence or unintentional insiders, these psychological and linguistic-based detection methods may not be as effective.

Another research discusses insider intrusion detection through user behavior monitoring. By monitoring user activities during using the system like login and logoff beside other activities during doing normal task and then deploying these data by using deep learning to detect insider [13]. Keystroke and mouse dynamics have a lot of information about how a user operates the host [14]. Because this type of data source contains information that can be used to identify legitimate users using behavioral biometrics, it is best suited for detecting masqueraders [15]. Although such a log may be

verbose at times due to a significant number of duplicated entries, the information contained within it may still be worth investigating. A particularly extended sequence of authentication failures, for example, may indicate a brute-force password attack [15].

In the paper [16], the authors propose a method that combines deep learning techniques with mouse biobehavioral features to detect insider threats. This approach achieves both rapid user authentication and high accuracy. The study focuses on five fundamental mouse actions: click, move, drag, stay, and scroll. These actions, along with authentication events, are used to extract features that capture the user's unique behavioral characteristics. Support Vector Machine (SVM) classification methods are then employed to categorize and analyze these features, enabling effective insider threat detection.

As per the survey of 2023 insider threats most businesses possess end-to-end user activity monitoring, which includes both access logging and automatic user behavior monitoring and is even more alarming. One big obstacle to this technology is that it violates user privacy and does not comply with the EU's general data protection law (GDPR), which leads to many businesses avoiding utilizing it [1]. The survey shows also that cybersecurity units within organizations are intensifying their employment of User Behavior Analytics (UBA) tools. These sophisticated instruments are utilized to identify, categorize, and raise alerts in response to aberrant behavior. An impressive 86% of organizations are reported to actively observe user behavior via one methodology or another [1].

Another research discusses using audit log windows detection of fraudulent behavior. The research suggests that Windows audit logs provide sufficient information to enable the reliable detection of fraudulent behavior while generating manageable data streams on endpoints. Audit logs offer a cost-effective and efficient alternative to more expensive breach detection systems that rely on agent-based approaches [6]. Another research explores the utilization of Multi-Source Logs for detecting insider behaviors. The security logs are converted into text format and compiled as a corpus. By training a model using Word2vec with the corpus, the researchers were able to approximate the posterior probabilities associated with insider behaviors. The proposed approach proves to be effective and scalable for practical applications in insider threat detection [17]. The problem with this method is detecting malware incidents that will happen after they have bypassed perimeter security layers. Audit logs, like any other endpoint software, can be modified or destroyed once malware has administrative access to the target endpoint. This issue is reduced in part because most enterprise setups store audit logs on a remote server, and the audit logs' integrity can be verified using cryptographic protocols [18].

Another research discusses creating a USB-Watch which is a Generalized Hardware Assisted Insider Threat Detection. The statement suggests that the framework utilizes hardware to capture real-time USB traffic, enabling the collection of data before advanced attackers have the opportunity to tamper with it within a compromised operating system. Additionally, the framework employs a decision tree anomaly detection

classifier, which is implemented in the hardware itself. This classifier analyses the behavioral patterns of connected USB devices, allowing for the detection of anomalous behavior [19]. However, this method is not effective with insider threats which do not need USB connections.

A new research focuses on the proactive detection of insider threats through the application of graph learning and psychological context [20]. The MEWRGNN utilizes graph neural networks to capture the contextual relationship of user behaviors and achieve accurate anomaly identification. It ranks the contribution of different edge-representation features, providing interpretability and understandable insights for security analysts. Experimental results show that the MEWRGNN can learn from limited sample data sets and achieve quick and accurate insider threat detection [20].

There are many researches which try to implement machine learning in intrusion detection such as in [21], [22]. With respect to ICS, studies based on machine learning normally faced the difficulty of finding a real dataset from an industrial control system. The industrial company always tries to reveal any data related to industrial control as a kind of security [23]. In our research, our objective was to create a model that does not rely on machine learning but rather utilizes signature-based anomaly detection, primarily functioning at the host side. This model is designed to operate independently of the operating system security logs file. Our focus is specifically on detecting unauthorized changes that occur in the monitored files.

In our model, we will try to utilize an important point related to industrial workstations which is: these workstations will be provided by a system vendor with the required installed software. The vendor will ensure its security configuration and hardness. It is not allowed to install new software or change configuration filled by any unauthorized person [24]. Many application software activities depend on the configuration which is stored on known paths and directories. Any change in working application configuration will affect the working of related services and could have a bad effect on some process working set points or on the panel operators monitoring screens. Determining the underlying cause of the intrusion or any file system problem is critical, but manual analysis extends the time it takes to resolve threats [25]. Finding a model which can detect any changes for these files on any one of the operator and engineer workstations will help to detect if there are some suspicious activities from an insider.

There are Many Files Integrity Monitoring (FIM) tools available today developed by private companies in response to these industry needs. Some examples include Tripwire [26], Samhain [27], and OSSEC [28]. FIM tools can help in detecting file integrity intrusions in monitored host computers [29]. These tools continuously monitor the file system for changes, including changes to file attributes, content, and timestamps. They can generate alerts when unauthorized or unexpected modifications occur [30], [26].

Monitoring file integrity in ICS environments can be challenging due to the unique requirements and constraints of these systems. For example, ICS often use specialized hardware and software that may not be compatible with standard FIM tools. Additionally, ICS typically have strict

performance requirements, making it important to minimize the performance impact of monitoring activities [31]. FIM solution has its own drawbacks and issues such as Delays in detection, and Complex deployment. Current FITs work off-line pattern which means these tools will monitor the files at scheduled times to check the integrity of the system. Delay in detection is the biggest issue because this will create an opportunity for the intruder to take advantage of the system [30].

One of the main challenges when building a FIM is real-time detection, which should have minimal performance overhead to ensure it can be used effectively in real production environments. High-performance overhead can cause system slowdowns, reduced productivity, and user frustration, which could lead to the tool being disabled or ignored [30]. Implementing a FIM in an ICS poses specific challenges due to the constraints of computing resources and the need for continuous system operation. The installation of third-party software may also introduce compatibility issues and potentially disrupt the system's functionality. Therefore, it is crucial to carefully evaluate and minimize any adverse effects on system performance during the implementation of any intrusion detection tools.

A good File Integrity Tracking (FIT) tool should collect comprehensive information about file changes, enabling administrators to make informed decisions and use the tool effectively. Detailed information can help identify the root cause of an issue, track unauthorized changes, and mitigate potential security risks. In the process of selecting files for monitoring, priority should be given to those that are integral to your system and applications. Emphasis should be placed on files that are not anticipated to undergo changes without premeditated scheduling. Opting to monitor files that are frequently altered by applications or the operating system, such as log files and text files, could generate a surplus of data, subsequently obscuring the identification of a potential attack [32].

### III. RESEARCH METHODOLOGY

We propose an intrusion detection approach that centers around the automated identification of unauthorized alterations in Monitored File lists. These modifications may occur intentionally or unintentionally, involving employees or contractors, and can stem from both legitimate and malicious intents. Whether resulting from human actions or software interventions, any such changes are regarded as potential security concerns. To address this, our model generates alerts to promptly designated personnel to review and assess these alterations for suspicious activity.

The supervisory level In ICS architecture is the best place to implement the Intrusion detection model. This is the primary level of interest in our research. At this level, operational operators and engineers interact with physical system programming and configuration. This study aims to improve the detection of intrusions at the level of operator and engineering workstations. The other higher layers are often managed by IT and should be kept separate from the ICS system. This isolation is already accomplished with a hardware firewall and DMZ, or with a data diode.

At the supervisory level, the operators' and engineers' workstations and servers existed [8]. These workstations are equipped with a group of certain software and tools which are already provided by the system vendors. A limited number of services should be working with a minimum number of listening open ports [8]. Many working software depends on configuration files to define their working environment as well as their responses. In addition to that, many system engineers depend on written text file scripts to automate daily tasks with the help of operating system task schedules. Improving a technique to monitor the integrity of these files and services and providing a mechanism to notify the right people in case of suspicious changes, and providing data to help cybersecurity teams take the best possible course of action is very important. Such tools will contribute to enhancing and maximizing the ability to stop incidents from occurring or getting worse. The data collected by this model will provide a good data source for other troubleshooting activities in case of a security incident happening, because it will save a history record for the monitored file and the changes that happened to them.

The following flowchart in Fig. 2 describes how the philosophy of the model works to detect any malicious activities on monitored files. The initial phase of our methodology involves establishing a baseline by creating a comprehensive list of crucial files that need to be monitored for potential malicious alterations in the targeted industrial workstations. This process requires identifying the critical systems and software applications operating on these workstations, as compromising them could have significant operational consequences. When selecting which files to monitor, it is important to consider the files that are vital for the proper functioning of the system and applications. These are the files that you expect to remain unchanged unless planned modifications are made. On the other hand, monitoring files that are frequently changed by applications or the operating system, such as log files, can introduce unnecessary noise and make it more challenging to detect an actual attack.

When selecting files related to industrial control systems, it is important to include operational and configuration files of the main component such as SCADA software, PLC programming tools, and other specialized applications. To effectively understand the critical components of the system and the primary software, a thorough examination of the OT system vendor's documentation is necessary. This documentation provides insights into the system's architecture and the essential software components, including vital configuration files, and data files that are crucial for the system's proper functionality. To gain further insights, engaging with system administrators, operators, and other experts within the organization is highly valuable. These individuals possess specialized knowledge and experience with the system, allowing them to provide valuable input on the most crucial files that should be included in the monitored list.

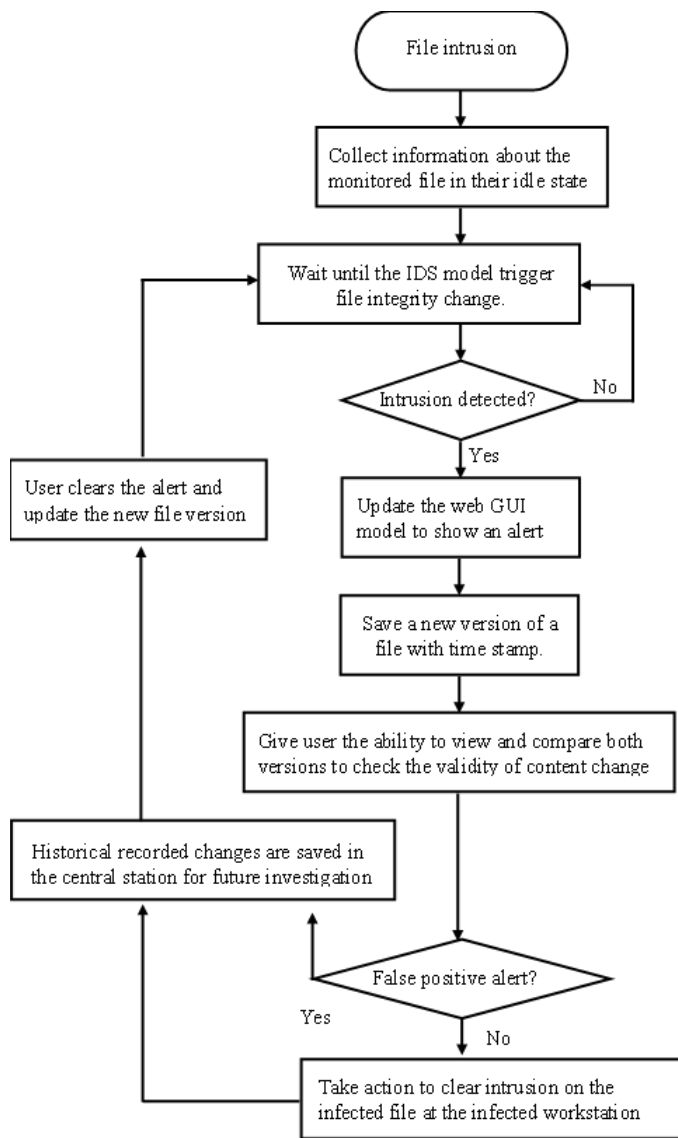

Fig. 2. Flowchart describes the methodology.

Various types of data can be collected for files to monitor their integrity and detect potential malicious activities. Some of these data attributes encompass file metadata such as filename, file path, file size, file extension, file permissions, file owner, file attributes, file content hash, and file timestamps. While the date-modified timestamp is a valuable data attribute for detecting file changes, its reliability can be compromised due to timestamp tampering. Timestamps can be effortlessly manipulated or spoofed, enabling an attacker to alter the timestamp following modifications to conceal their activities. Consequently, timestamps alone become an unreliable source for detecting unauthorized changes. To address this issue, file content hashes can be employed in conjunction with timestamps. A file content hash is a unique, fixed-length string generated from a file's contents using a cryptographic hash function. This hash functions as a digital fingerprint of the file, facilitating the effortless identification and verification of the file's contents. Cryptographic hash functions, such as SHA-256, SHA-1, or MD5, accept an input (in this instance, the file

contents) and generate a fixed-length hash value. Moreover, a file content snapshot of the monitored value can be stored in a secure location, which can be utilized in the event of intrusion detection to revert to a healthy condition. A file content snapshot is a copy or representation of the file's content at a specific moment in time, which can be employed for comparison with subsequent versions of the file.

The focus of the model developed in this research is on insider attacks involving file content changes or file deletions within industrial control systems (ICS). These attacks encompass several categories, including data tampering, data destruction, unauthorized access with modification, malicious code injection, accidental data modification, negligence, and accidental file deletion. Data tampering refers to the deliberate alteration of critical ICS configuration files, program files, or databases by insiders with the intent of manipulating process data or creating falsified records. Data destruction involves insiders intentionally deleting or corrupting critical ICS files or backups. Unauthorized access with modification occurs when insiders misuse their legitimate access credentials to gain unauthorized entry to sensitive ICS files or systems and then make unauthorized changes to the content. Malicious code injection involves insiders introducing malicious code or scripts into ICS files where this malicious code is designed to compromise the system, extract sensitive process data, or disrupt industrial operations. Accidental data modification can occur when insiders inadvertently modify the content of ICS files due to human error or a misunderstanding of the system or processes; these unintentional modifications can have adverse effects on process control, safety systems, or data integrity. Accidental file deletion refers to instances where insiders unintentionally delete important ICS files, resulting in data loss or disruptions in industrial processes. By focusing on these various types of insider attacks involving file content changes or file deletions, the model aims to enhance the detection and mitigation of such threats within industrial control systems, thereby improving overall system security and integrity.

To ascertain the efficacy of our model, we conducted tests in an environment that mirrored the workgroup network for workstations at the supervisory level. This was achieved either by creating a small, real local network or constructing a virtual network using VMware Workstation virtual machines. In this research, we utilized a group of workstations operating on the Windows operating system.

For the real-time testing of the intrusion detection system model in a Windows OS environment, we employed the Register-ObjectEvent cmdlet in PowerShell. The Register-ObjectEvent cmdlet is designed to monitor events on .NET objects with minimal system resource usage. It employs an event-driven model, triggering an action when a specified event transpires, as opposed to continuous polling for changes, which can be more resource-intensive. Despite the comparatively low resource usage of the Register-ObjectEvent cmdlet, especially when contrasted with continuous polling methods, it is crucial to manage event subscriptions meticulously and unregister them when no longer required, to avert unnecessary resource consumption.

To illustrate the operation of our model, we predefined a list of files requiring monitoring. Initially, the model collects data such as the last modified time and file content hash value of these files, storing this information in a remote station. This data serves to confirm file integrity violations in case of intrusion detection and is preserved for subsequent incident investigation. To gauge the model's effectiveness, we devised a comprehensive list of 100 potential scenarios that could compromise file integrity and observed the model's capacity for intrusion detection. These scenarios encompass all conceivable insider threats, whether originating from employees or contractors, and whether they are intentional or unintentional. Concurrently, we recorded the model's response to these scenarios to measure its performance. In the event of intrusion detection, the data is transmitted to a remote station that maintains a database to record file information and the history of recorded attacks. This station also manages the display of alarms in a Graphical User Interface (GUI) form. This GUI can be accessed from any network station using a standard web browser.

#### IV. RESULT AND DISCUSSION

After conducting 100 simulated insider intrusion scenarios targeting file integrity violations, the model demonstrated a high true positive score, as depicted in Table I. These results indicate its high sensitivity in detecting this type of intrusion. This outcome aligns with expectations within the context of industrial control system workstations, where configuration files should be modified under a management of change (MoC) process, thereby minimizing the risks associated with these changes. Any modification outside of the MoC will be detected.

On occasion, the model might flag false positives. However, this is an expected occurrence, as these false alarms may be generated during an authorized modification of any of the monitored files. In the context of industrial control systems, alterations to any configuration file or settings are ideally conducted within a structured (MoC) process. Consequently, the occurrence of such false alarms is anticipated. Moreover, the model possesses the ability to enter a state of inhibition during approved changes, thus preventing the triggering of unnecessary alarms. Significantly, the model reported a rarely false-negative rate. This result is consistent with the operational characteristics of the model, which is designed to raise an alarm whenever there is a change or deletion in the file content. In all other instances, the model remains inactive, thus ensuring no false negatives are reported.

By analyzing the results of the model test, it can be observed from the data presented in Table I that the model demonstrates a notable level of efficiency and precision when it comes to detecting alterations in file content. The percentage of true positive detections is significantly high, indicating the model's ability to accurately identify instances of insider intrusion in real-time. However, it is important to note that there were occasional occurrences of false positives during the testing phase. Despite this, the model's overall performance remains strong, highlighting its capability to effectively identify unauthorized changes in file content and mitigate the risk of insider threats. This successful detection and prompt

response contribute to enhancing the overall security of the system.

TABLE I. INTRUSION DETECTION PERFORMANCE

Scenario	Actual Intrusion	Model Detection	Result
Scenario 1	Yes	Yes	True Positive
Scenario 2	Yes	Yes	True Positive
Scenario 3	Yes	Yes	True Positive
.....	Yes	Yes	True Positive
Scenario 99	Yes	Yes	True Positive
Scenario 100	No	Yes	False Positive

By focusing on file integrity monitoring, the model avoids the need to scrutinize user behavior, offering a distinct advantage for organizations that prioritize privacy. This approach ensures that employees' personal habits and actions remain confidential while still effectively safeguarding the system. This respect for privacy, combined with robust intrusion detection, supports a balance between security and individual privacy rights, aligning with best practices for ethical workplace monitoring. Therefore, this model possesses an advantage over other research approaches that rely solely on monitoring user behavior and actions.

In the initial phase of the methodology, identifying the files to be monitored in their optimal state allows for the establishment of a signature-based detection approach specific to those files. The model can readily detect intrusions by identifying deviations from the expected state of the files, without the need for implementing machine learning algorithms. Therefore, this approach offers the advantage of effective intrusion detection with low false positive rates, in contrast to research that relies on anomaly algorithms and data training. However, it is important to note that the model may encounter challenges in detecting new or unknown attacks that do not match any existing signatures, as well as attacks that do not involve file content violations. In the context of machine learning research, acquiring specialized datasets for (ICS) also poses significant challenges due to the complexities involved in accessing data from industrial environments. These challenges are primarily driven by security concerns, which restrict the availability and sharing of such datasets.

The model works based on an event-driven approach. This means it only springs into action when a specific event - in this case, a change to a file - occurs. This is different from a continuous polling approach where the system would constantly check the files for changes. The benefit of the event-driven response model is its remarkable efficiency in utilizing system resources, while also enabling real-time detection of intrusions as they occur. There's no need to wait for the next round of checks or polling cycle. As soon as a file changes, the model knows about it and can respond immediately. This real-time detection is crucial for catching and responding to intrusions as quickly as possible.

Leveraging the inherent capabilities of the PowerShell Register-ObjectEvent cmdlet, the model confines its operation

to the monitored workstation, thus eliminating the need for the installation of additional third-party software. The model's avoidance of third-party software installation is indeed a substantial advantage, particularly given the specific needs and constraints of industrial control systems. The introduction of third-party systems can lead to compatibility issues with existing software and configurations. Typically, the installation of any new software on industrial workstations requires explicit vendor permissions, thus adding another layer of complexity. Moreover, the introduction of new software necessitates the implementation of patching and updating plans, potentially imposing additional burdens on maintenance operations. Hence, a model that operates effectively without the need for additional software installations alleviates these potential challenges, thereby enhancing the model's applicability and ease of use in an industrial control system environment.

Storing file information and the history of file changes in a remote station negates the need to use the local storage of the workstation under normal conditions. The storage of file modification time and file hash value in a remote station enhances security by mitigating the risk of file metadata tampering by an attacker. The secure remote storage of file information enhances accessibility, enabling the review of history from any network station. This feature simplifies the investigation of file event history in the event of incident response following attack detection. Moreover, the storage of file content snapshots effectively supports system continuity by facilitating the restoration of files to a healthy condition.

The decision to implement the intrusion detection model at the supervisory level of the Industrial Control System (ICS) architecture offers numerous benefits. This level, in contrast to the control and field levels beneath it, has an abundance of system resources. Crucially, the operation of the model at this level does not burden the bandwidth of the control and field-level networks, which are known for their resource limitations. Further, the supervisory level is uniquely positioned as the sole access point to both the control and field levels. These lower levels are particularly sensitive to disruptions due to their resource limitations, and any interference could lead to significant production process impacts. By placing the intrusion detection model at the supervisory level, we ensure minimal intrusion, optimal use of resources, and maintain the integrity of the lower levels, safeguarding the overall production process.

## V. CONCLUSION

The implementation of file integrity monitoring has proven to be a highly effective and accurate method for detecting insider intrusion involving file violations in control system workstations. These violations include data tampering, data destruction, unauthorized modifications, malicious code injection, accidental data modifications, negligence, and accidental file deletion. The model also facilitates the detection of other types of attacks that involve file content alteration, such as ransomware and remote code execution. The detection process is performed without the necessity of monitoring user behavior and actions, thereby upholding user privacy.

While the model examined in this research demonstrates its efficacy in detecting insider threats related to file integrity violations, it does not possess the capability to identify other forms of insider threats that do not involve modifications to file content, such as Intellectual Property Theft and Unauthorized Data Access. Exploring and addressing these additional categories of insider threats could serve as a promising area for future research. Another crucial aspect to consider is that the model solely focuses on detecting intrusions and does not possess the capability to independently prevent their consequences. Therefore, to achieve maximum effectiveness, it is essential to seamlessly integrate a file integrity monitoring strategy with an organization's incident response plan. This integration ensures that timely and appropriate measures are taken to mitigate the impact of file integrity intrusions, thereby preventing further unwanted consequences.

# Clustering Based on Gray Wolf Optimization Algorithm for Internet of Things over Wireless Nodes

Chunfen HU<sup>1</sup>, Haifei ZHOU<sup>2\*</sup>, Shiyun LV<sup>3</sup>

Changzhou College of Information Technology, School of Cyberspace Security, Changzhou 213000, China

**Abstract**—The Internet of Things (IoT) creates an environment where things are permitted to act, hear, listen, and talk. IoT devices encompass a wide range of objects, from basic sensors to intelligent devices, capable of exchanging information with or without human intervention. However, the integration of wireless nodes in IoT systems brings about both advantages and challenges. While wireless connectivity enhances system functionality, it also introduces constraints on resources, including power consumption, memory, and CPU processing capacity. Among these limitations, energy consumption emerges as a critical challenge. To address these challenges, metaheuristic algorithms have been widely employed to optimize routing patterns in IoT networks. This paper proposes a novel clustering strategy based on the Gray Wolf Optimization (GWO) algorithm. The GWO-based clustering approach aims to achieve energy efficiency and improve overall network performance. Experimental results demonstrate significant improvements in key performance metrics. Specifically, the proposed strategy achieves up to a 14% reduction in energy consumption, a 34% decrease in end-to-end delay, and a 10% increase in packet delivery rate compared to existing approaches. The findings of this research contribute to the advancement of energy-efficient and high-performance IoT networks. The utilization of the GWO algorithm for clustering enhances the network's ability to conserve energy, reduce latency, and improve the delivery of data packets. These outcomes highlight the effectiveness and potential of the proposed approach in addressing resource limitations and optimizing performance in IoT environments.

**Keywords**—Internet of things; energy consumption; clustering; optimization; gray wolf optimization

## I. INTRODUCTION

As technological advances advance, instruments and objects in our environment can exchange data through technologies such as Radio-Frequency Identification (RFID) and Wireless Sensor Networks (WSNs) [1, 2]. The emergence of wireless communication and seamless integration of different technologies between devices has resulted in the concept of the Internet of Things (IoT) that facilitates data exchange among a variety of items and their associated things over a network protocol or standard at any time [3-5]. All IoT devices and things are assigned unique IP addresses. The devices can be configured to sense and collect raw data from the physical environment to process it and make decisions [6]. The integration of Blockchain [7], humanitarian logistics [8], cloud computing [9], machine learning [10-14], and artificial intelligence [15, 16] within the IoT ecosystem plays a crucial role in enabling secure and efficient data exchange, optimizing resource allocation, improving decision-making processes,

and enhancing overall system resilience, making it a transformative force in various domains such as healthcare, transportation, energy management, and disaster response.

In such energy-constrained networks, clustering has proven to be an effective method of designing energy-efficient routing algorithms [17, 18]. This method groups the nodes together in clusters. Each cluster is headed by a Cluster Head (CH) whose responsibility is to gather the data of its members. Clustering can provide scalability, conserve bandwidth, and reduce the routing problem among all sensors [19]. The CHs are responsible for relaying the data to the sink node, thus reducing the total number of hops needed [20]. This way, the energy consumed by relaying data is reduced since the nodes only need to relay data over short distances. Furthermore, clustering helps in balancing the load on the network, which in turn improves the network performance. Moreover, clustering ensures efficient data aggregation, which further minimizes the amount of data that needs to be transmitted to the sink node. The result is an efficient use of the available resources and a better overall experience for all participants [21].

Clustering approaches currently available are primarily time-based. A clustering approach can be static, dynamic, or hybrid. Static clustering is used when the data points and clusters can be defined ahead of time and do not change over time. Dynamic clustering automatically adjusts the clusters as the data points change [22]. Hybrid clustering combines the two approaches, using static clustering to define the initial clusters and then dynamic clustering to adjust them over time. There is minimal overhead associated with a static performance network, and it is stable for a short period of time. Although dynamic performance increases the lifetime of a network, it has a high overhead cost. Hybrid clustering allows for a more flexible approach to clustering, as the clusters can be adjusted over time without having to start from scratch. This helps to reduce the computational overhead associated with clustering, as well as the time it takes to create an optimized clustering solution [17].

## II. RELATED WORKS

A mechanism is proposed by Said [23] for dividing the IoT environment into various zones based on the characteristics of the network. Afterward, the ACO algorithm is applied to the areas in order to resolve the routing problem. It is evident from the results of NS2 that the proposed routing algorithm meets the target energy consumption, packet loss rate, latency, bandwidth consumption, and overhead criteria. By using the genetic algorithm, Fouladlou and Khademzadeh [20] developed an effective routing approach and extended the

lifetime of a network by clustering IoT objects. Several experiments have shown that the proposed scheme performs better than IEEE 802.15.4 in terms of transmission rate, energy consumption, delay, and bit error rate.

Mohseni, et al. [24] proposed a cluster-based routing strategy in the IoT by combining the fuzzy logic system and the Capuchin search algorithm, called CEDAR. It involves two stages, namely the clustering process and intra- and extra-cluster routing. This strategy significantly cuts energy consumption by IoT devices through clustering the nodes in the network, and each cluster is responsible for routing the packets of the nodes in its own cluster. Additionally, the fuzzy logic system allows the nodes to adapt to the changing network conditions, and the Capuchin search algorithm ensures that the packets are routed in the most efficient way. Simulation results reveal that CEDAR is superior to comparative approaches regarding energy consumption, delay, and network lifetime. An optimized routing strategy based on neuro-fuzzy rules has been proposed by Thangaramya, et al. [25]. The results of the experiments conducted in this study demonstrate that the modeled routing protocol performs well in terms of network lifespan, latency, delivery rate, and energy consumption.

Geetha, et al. [26] propose a new energy-aware future load prediction and cluster communication strategy for IoT networks. It determines an optimal number of CHs and forecasts the incoming load on the network. It comprises two main phases: clustering with the satin bowerbird algorithm and load estimation using deep random vector functional link networks. A comprehensive analysis of the results and discussion indicates that the proposed method of regulating renewable energy usage in IoT networks is extremely effective.

Lakshmana, et al. [27] introduced a novel cluster-based IoT routing protocol. The objective of this design is to ensure optimal energy utilization and network lifetime. This is achieved by developing an enhanced Archimedes optimization algorithm-driven clustering approach to facilitate the selection of CHs and establishing cluster structures. The suitability function takes into account the number of hops that the data must take to reach its destination, how far apart the nodes are from each other, and the amount of energy consumed. The teaching-learning-based optimization algorithm then uses this information to determine the best route for the data to take. As a result, the network is more efficient and reliable, leading to improved performance.

### III. PROPOSED METHOD

The proposed method divides a network's lifespan into multiple cycles. It operates under two distinct stages, namely, initialization and stabilization. During the initialization stage, the base station collects location and energy information about nodes and determines CHs based on this information and the Gray Wolf Optimization (GWO) algorithm. Data collected by the cluster heads are sent to the base station during the steady state phase. In the proposed method, to conserve energy, the initialization stage is performed when the current cluster heads are close to death. This process eliminates the need to send and receive control packets during the setup phase, reducing

energy consumption. The proposed method is illustrated in Fig. 1.

Fig. 1. The process of the proposed method.

#### A. Cluster Head Selection

In this subsection, the clustering problem is modeled as an optimization problem, and an optimization algorithm is employed to select cluster heads. A parameter called dead time ( $T_D$ ) is defined for each node. The number represents the maximum number of iterations a node may survive, given its role in the network and its remaining energy. This definition can be formulated as Eq. (1), in which  $E_r(i)$  stands for energy remaining on node  $i$ , and  $E_c(i)$  denotes the amount of energy consumed by a given node per iteration.

$$T_D(i) = \frac{E_r(i)}{E_c(i)} \quad (1)$$

$T_D$  values differ between nodes based on the solution. Maximizing the average  $T_D$  between all nodes is the most effective solution. As an optimization problem, this definition can be expressed as follows:

$$\text{maximize } f = \text{avg}(T_D) = \frac{1}{|\text{nodes}|} \sum_{i \in \text{nodes}} T_D(i) \quad (2)$$

which presupposes the following assumptions:

$$Er(CH_j) > \frac{1}{|\text{nodes}|} \sum_{i \in \text{nodes}} E(i), 0 < j \leq m \quad (3)$$

The above condition states that the residual energy of all cluster heads should surpass the average energy of all nodes. This is necessary to ensure that the cluster heads have enough energy to effectively manage the clusters and maintain effective communication between the cluster heads and the other nodes in the network. The death time for each node in the network is determined according to the role of that node in the network. This calculation excludes the energy spent on sensing and data processing since these activities are negligible compared to communication. The energy consumption of each normal node is calculated by Eq. (4). This calculation does not include the energy associated with the exchange of control packets since our goal is to determine the maximum number of cycles a node may survive before re-clustering.

$$E_c^{member}(i) = E_{Tx}(L, \text{dis}(i, CH_i)) \quad (4)$$

In Eq. (4),  $ch_i$  is the cluster head of node  $i$ ,  $\text{dis}(i, j)$  indicates the distance between two nodes,  $L$  specifies the size of the data packet in bits, and  $E_{Tx}$  represents the transmission energy. The amount of energy consumed by a cluster head is calculated by Eq. (5).

$$E_c^{CH}(j) = E_{RX}(L \times CM_j) + E_{DA} \times L \times (CM_j + 1) + E_{TX}(L, dis(j, next(j))) \quad (5)$$

In Eq. (5),  $E_{RX}$  refers to the energy consumed for receiving a packet,  $CM_j$  is the number of cluster nodes,  $E_{DA}$  is the required energy for data aggregation per bit, and next represents the next hop, which can be another node or the base station. Some cluster heads may act as a relay for another cluster head. The energy consumption for relaying data by relay node is given by Eq. (6).

$$E_c^{relay}(r) = E_{RX}(L) + E_{TX}(L, dis(r, BS)) \quad (6)$$

The proposed method finds an optimal solution to this problem using the gray wolf optimization algorithm. This algorithm is described in detail in the following section.

### B. Selection of Relay Nodes

To avoid the rapid exhaustion of the energy source of cluster heads far from the base station, each cluster head is assigned a relay node, which is used by only one cluster head at a time. Therefore, several cluster heads lack relays and transmit data to the base station in a direct manner. To assign relays to the cluster heads, we choose a suitable relay for each cluster head, from the farthest cluster head to the central station to the closest cluster head to the central station. The desired goals in choosing the cluster head are to minimize the total energy consumption and create the greatest balance between the energy consumption of the cluster head and the relay. Fig. 2 shows the central station, a cluster head, and a hypothetical relay.

Fig. 2. Process of relay nodes selection.

It can be proved that there is a specific and fixed value for  $r_0$  to guarantee the lowest energy consumption and the greatest balance between the energy consumption of the cluster head and the relay. Furthermore, a private point exists on the line segment linking the cluster head and the base station that serves as the optimal relay point. The calculated value for  $r_0$  is 1.8. To select a relay for each cluster head, first, according to the value of  $r_0$ , the best point for the relay, located on the segment of the line between the cluster head and the central station, is calculated. The nearest cluster head, not previously selected as a relay, is calculated as the desired cluster head relay is chosen. Also, when no relays are located within a threshold of the desired point, the cluster head sends messages immediately to the base station. This process is advantageous in several ways:

- It significantly reduces the energy used to transmit packages to the base station.

- It minimizes the problem of being spot-hot. This is because the balance of energy consumption between the cluster head and the relay is guaranteed, and different relays are selected periodically.
- The relay is selected for the maximum possible number of cluster heads.

An example of the result of this process to select relays is shown in Fig. 3. There are 100 cluster heads in this network, and the base station is in the middle. Notably, some cluster heads do not have relays; these cluster heads are displayed as crosses without lines.

Fig. 3. An example of assigning relays to CHs.

### C. Formation of Clusters

During the initialization stage, the nodes send a node-MSG message to the central station. This message contains the remaining energy and the location of the node. This information is needed for clustering by the base station. In the next step, the base station selects the cluster heads using the presented method based on the gray wolf optimizer that leads to the maximization of the fitted function given in Eq. (2). Then the base station sends a broadcast message that contains the ID of the selected cluster heads and the corresponding relays. After the cluster heads receive this message and realize their selection as the cluster head, each cluster head broadcasts a CH-ADV message to introduce itself to the network. The remaining nodes choose a nearby cluster head based on the strength of the received CH-ADV signals and transmit a Join-MSG message. Relays also broadcast the Relay-ADV message to the network. At this stage, since each cluster head already has its relay ID, it waits for the Relay-ADV sent by its relay and sends an RJoin-MSG message in response. After completing these steps, all nodes will be aware of their role in the network, and the network will enter the stabilization stage. The initialization stage will not be performed unless one of the nodes has consumed 50% of its energy since the last initialization stage.

### D. Clustering with GWO Algorithm

In the proposed method, the gray wolf optimizer is used to maximize the fitting function shown in Eq. (2). For this purpose. Each solution should be displayed as a

multidimensional vector. In other words, because the wolves represent the solutions in the gray wolf optimizer and have a multi-dimensional position vector, then the clustering solutions should be displayed as multi-dimensional vectors. To perform this mapping, we consider a vector with the number of dimensions expressed as the number of network nodes. Each dimension of this vector indicates the chance of a node becoming the cluster head. To select the heads of the clusters, a predetermined number of nodes with the highest chance value in the alpha wolf position vector are selected as the heads of the cluster. Then every ninety members of the nearest cluster head are considered, and the relays of the cluster heads are also selected according to the presented method.

Assumption 1: A suitable value of  $r_0$  to minimize energy consumption is the value of  $\frac{1}{\sqrt[3]{2}} + 1 \approx 1.793$ .

Proof: According to the scenario depicted in Fig. 2, the amount of energy consumed by the cluster head is obtained from the following equation:

$$E_{dual-hop}^{CH} = E_{TX}\left(L, \frac{D}{r_0}\right) \quad (7)$$

which corresponds to the energy required to send a packet of length  $L$  bits to the distance  $r_0 D$ . The amount of energy consumed by the relay is also obtained from Eq. (8), which represents the transmission of two packets, each with a length of  $L$ , from the relay to the base station. As a result, the total energy consumption is calculated by Eq. (9).

$$E_{dual-hop}^{relay} = 2 \times E_{TX}\left(L, \left(D - \frac{D}{r_0}\right)\right) \quad (8)$$

$$E_{dual-hop}^{total} = E_{TX}\left(L, \frac{D}{r_0}\right) + 2 \times E_{TX}\left(L, \left(D - \frac{D}{r_0}\right)\right) \quad (9)$$

In order to achieve the lowest amount of energy consumption, Eq. (9) should be minimized. Assuming that the extra-cluster connections follow the fading multipath model, by expanding the above relation using Eq. (1), we reach Eq. (10), which can be written as Eq. (11). Here because  $L$ ,  $E_{mp}$  and  $E_{elec}$  are constant values, it can be said that to minimize the above expression, it is enough to minimize the expression 12. In addition, since  $D$  is also a constant and non-zero value, the function  $h1$  is minimized when the function  $h2$  is minimized.

$$E_{dual-hop}^{total} = L \times \left( E_{mp} \times \left( \left( \frac{D}{r_0} \right)^4 + 2 \times \left( D - \frac{D}{r_0} \right)^4 \right) + E_{elec} \right) \quad (10)$$

$$E_{dual-hop}^{total} = L \times \left( E_{mp} \times \left( \left( \frac{D}{r_0} \right)^4 + 2 \times \left( \frac{D^4(r_0-1)^4}{r_0^4} \right) \right) + E_{elec} \right) \quad (11)$$

$$h_1 = \frac{D^4}{r_0^4} + 2 \times \left( \frac{D^4(r_0-1)^4}{r_0^4} \right) \quad (12)$$

Assumption 2: The best value for  $r_0$  to create a balance between the energy consumption of the cluster head and the corresponding relay is approximately equal to 1.84.

Proof: In accordance with the preceding proof, to create a balance between the energy consumption of the cluster head and the relay, their absolute magnitude difference should be minimized according to Eq. (13).

$$\text{minimize } g = \left| E_{dual-hop}^{CH} - E_{dual-hop}^{relay} \right| \quad (13)$$

By expanding the above relation using Eq. (1), we reach Eq. (14). Because  $D$ ,  $L$ ,  $E_{mp}$  and  $E_{elec}$  are constant values, the  $g$  function is minimized at a point where the  $g_0$  function given in Eq. (14) becomes zero.

$$g_0(r_0) = \frac{1 - 2 \times (r_0 - 1)^4}{r_0^4} \quad (14)$$

The roots of the above function are the best values for  $r_0$  to balance the energy consumption of the cluster head and relay. A suitable root for this function is 1.8. As a result, choosing  $r_0=1.8$  will lead to the equal energy consumption of cluster head and relay. As a result, to simultaneously achieve both goals of optimality and balance, the value selected for  $r_0$  is equal to the average of these two values, i.e., 1.8.

Assumption 3: The complexity of the control packets of the presented algorithm equals  $O(N)$ , where  $N$  is the number of nodes within the network.

Proof: During each cycle,  $N$  Node-MSG packets are transmitted to the base station. In addition, every node issues a Join-MSG message to its CH. Each CH also sends one CH-ADV message, one Relay-ADV or Rejoin-MSG message, and two packets. If we assume that the number of CHs is 5% of the total number of nodes, the total number of control packets is equal to  $2N + 2 \times \left( \frac{N}{20} \right) = \frac{21}{10} N$ , which is related to  $O(N)$ .

#### IV. SIMULATION RESULTS

The proposed method is simulated and implemented using CPU core i5 and 4GByte RAM. A Matlab simulator has been used to obtain the results. The method was tested under various conditions, such as varying the number of nodes, to ensure accurate results. The results were then compared with those obtained from other methods to prove the proposed method's performance. Table I summarizes the key parameters and variables used in the proposed method's simulation.

The energy expended in delivering the sensed data to the base station is one of the most important parameters of analyzing routing methods in the IoT environment. By properly assessing the energy expenditure, it is possible to optimize the routing methods and improve the overall performance of the IoT system. This measurement can compare different routing methods and select the most energy efficient one. Moreover, it can be used to identify areas of high energy consumption, which can be addressed to further optimize the IoT system. According to Fig. 4 to 6, our method is more energy-efficient than previous methods. Fig. 4 compares our method's average residual energy with R-LEACH when the number of rounds is increased. According to this figure, our algorithm significantly increases the number of alive nodes compared to the comparative algorithm. Fig. 5 and 6 illustrate the comparison between the energy consumption of our method and RDDI. The results show that

our algorithm can reduce energy consumption while ensuring that more nodes remain alive. This is because it can identify clusters that consume less energy, thus reducing the entire network's energy consumption. Additionally, by optimizing the selection of cluster heads, our algorithm can reduce the amount of energy wasted due to redundant communications. The packet delivery rate can be described as the ratio of traffic correctly delivered to the base station as a percentage of all traffic carried within the network. As shown in Fig. 7, our algorithm achieves a higher percentage of packets delivered than the comparative algorithm. The packet delivery ratio decreases as the number of nodes increases and the density increases. Data collisions will result as network density increases, leading to a higher rate of data transmission failures and packet loss.

TABLE I. SIMULATION VARIABLES

Variable	Value
Network dimensions	(100 × 100)
Number of nodes	50-300
Packet size	800 bits
Node distribution	Random
Initial node energy	Different based on the scenario
Iterations	100-500
Efs	10 pj/bit/m2
Eelec	50 nj/bit
Eamp	0.0013 pj/bit/m4

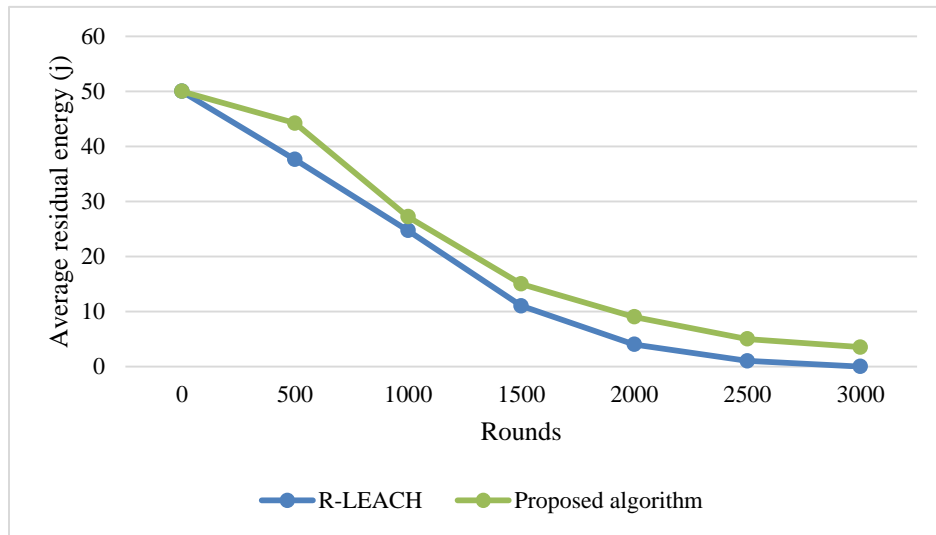

Fig. 4. Average residual energy comparison.

Fig. 5. Energy comparison for 20 clusters.

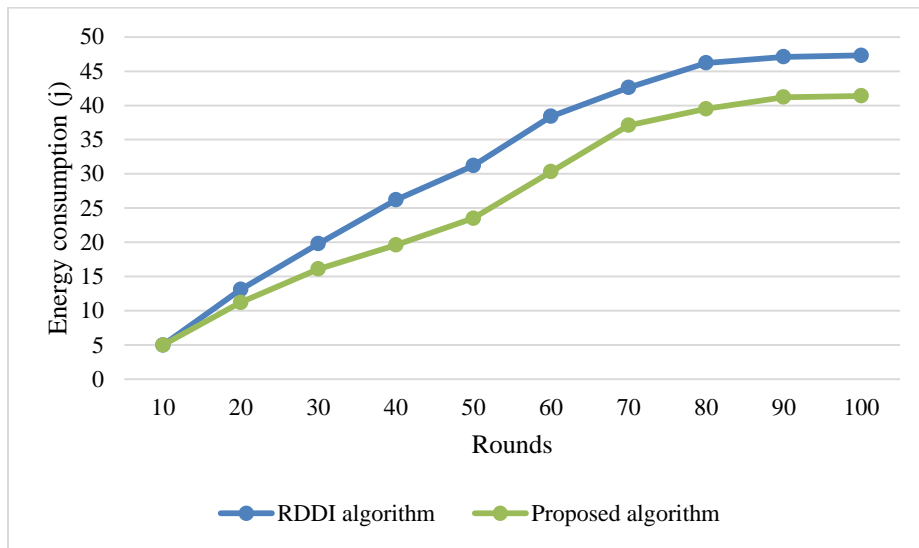

Fig. 6. Energy comparison for 50 clusters.

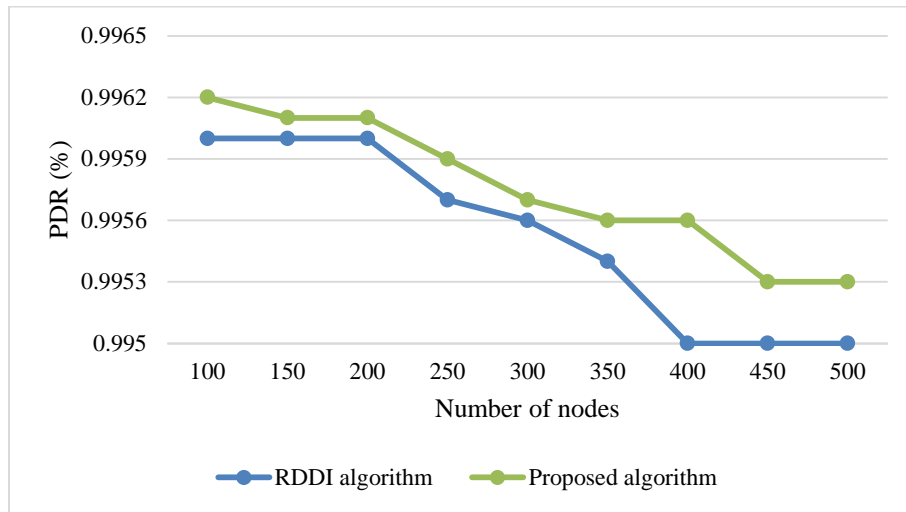

Fig. 7. Packet delivery ratio for 20 clusters.

Fig. 8. End-to-end delay for 20 clusters.

As the name suggests, end-to-end delay refers to the time a packet travels from the source node to the destination node within a network. This delay encompasses various factors, including the propagation delay, which represents the time required for a signal to traverse a specific transmission medium. Additionally, the processing and queuing delay must be considered, as it accounts for the time network nodes take to handle and process the data before placing it into the appropriate queues for further transmission. By evaluating these delay components, a comprehensive understanding of the overall transfer time can be gained. Fig. 8 serves as concrete evidence of the superiority of our proposed method in terms of end-to-end delay compared to the RDDI method. The comparison showcased in the figure highlights the effectiveness of our approach in minimizing the total transfer time. Our method efficiently manages the propagation, processing, and queuing delays, resulting in a significantly improved end-to-end delay performance.

## V. CONCLUSION

Data transmission from sensor nodes poses a major issue for IoT-enabled networks. This paper proposed a novel clustering strategy based on the GWO algorithm. The protocol comprises two stages, namely initialization and stabilization. During the first stage, the base station collects location and energy information about nodes and then determines the cluster heads using this information and the GWO algorithm. Data collected by the cluster heads are sent to the base station during the steady state phase. To conserve energy, the proposed method executes the setup phase only when the current cluster heads are nearing death. This process eliminates the need to send and receive control packets during the setup phase, reducing energy consumption. According to the results, our method outperforms previous ones regarding the end-to-end delay by up to 34%, energy consumption by up to 14%, and packet delivery rate by up to 10%.

**Abstract**—The rising number of automobiles has led to an increased demand for a reliable license plate identification system that can perform effectively in diverse conditions. This applies to local authorities, public organizations, and private companies in Morocco, as well as worldwide. To meet this need, a strong License Plate Recognition (LPR) system is required, taking into account local plate specifications and fonts used by plate manufacturers. This paper presents an intelligent LPR system based on the YOLOv5 framework, trained on a customized dataset encompassing multiple fonts and circumstances such as illumination, climate, and lighting. The system incorporates an intelligent region segmentation level that adapts to the plate's type, improving recognition accuracy and addressing separator issues. Remarkably, the model achieves an impressive precision rate of 99.16% on problematic plates with specific illumination, separators, and degradations. This research represents a significant advancement in the field of license plate recognition, providing a reliable solution for accurate identification and paving the way for broader applications in Morocco and beyond.

**Keywords**—License plate recognition; YOLOv5; intelligent region segmentation; customized dataset; Moroccan license plate issues; fonts-based data

## I. INTRODUCTION

Over the past few decades, the global vehicle population has grown significantly, with estimates placing the number of vehicles in use at around 1.36 billion by late 2016, a number that has likely increased even further in the years since. However, obtaining an exact number is difficult due to the responsibility of each country's administration to keep track of and identify vehicles within its borders. The rapid growth of the global vehicle fleet is driven by a combination of demographic changes, shifts in lifestyles, and advancements in the automotive industry. To accommodate this growth, many countries have developed their vehicle registration systems, assigning unique license plates to each vehicle, including cars, trucks, and motorcycles, using a combination of numbers, letters, or a combination of both. Some countries also associate the license plate with the vehicle owner, providing an alphanumeric identifier for easy identification.

In order to efficiently track vehicles and monitor their activities, automatic number plate recognition (ANPR) systems were developed. ANPR utilizes optical character recognition (OCR) technology to analyze pre-captured images of license

plates, taken by specific cameras, extract the plate numbers, and thus identify vehicles and owners [1]. This eliminates the need for manual plate identification, which was previously done by human agents but was prone to errors. ANPR is widely used by law enforcement agencies for enforcement purposes, as well as by highway agencies for road pricing [2] and automated parking systems for charging purposes [3].

With the advancement of computer science and technology, as well as the improvement of databases, Automatic Number Plate Recognition (ANPR) has become a key aspect of traffic management systems in smart cities [4, 5, 6]. ANPR is seen as a valuable tool for collecting traffic data and improving road efficiency and safety, which are the primary goals of Intelligent Transportation Systems (ITS) [7]. The ANPR process involves several techniques and automated algorithms, which are typically composed of four steps: capturing an image of the vehicle, detecting the license plate, separating the characters on the plate, and finally recognizing the characters.

## II. LITERATURE REVIEW

### A. License Plate Recognition System

The development of license plate recognition systems began at the end of the 20th century. One of the early contributions, by authors in [8], proposed an algorithm that used gray-scale morphological operations to detect the license plate region from an image, with no restrictions on the input. The Car License Plate Recognition System (CLPR-system) proposed by G. Nijhuis et al. in 1995 [9] aimed to identify vehicles by their license plate contents for speed-limit enforcement purposes. This system combined neural and fuzzy techniques to achieve an acceptable recognition rate and a low error rate. Another early contribution was made by S. Draghici [10] who constructed an artificial vision system that used a neural network to analyze images, locate the registration plate, and recognize the registration number. This system showed successful plate position and segmentation of 99%, successful character recognition of 98%, and successful recognition of complete registration plates of 80%. In 2005, J. Matas and K. Zimmermann [11] submitted a study of a new class of locally threshold separable detectors that utilized external regions adaptable by machine learning techniques. This improved license plate detection. With the advent of Convolutional Neural Networks, Q. Wang [12] used a small but powerful network to classify characters on plates extracted by the Single

Shot MultiBox Detector (SSD) [13]. Several extensions of these neural networks have been proposed.

### B. YOLO-based Approaches

In [14], an ALPR system for Chinese license plates was proposed utilizing two CNNs based on the YOLO2 framework. The system was compared to YOLOv2 and YOLOv3 and implemented on PYNQ, resulting in a detection precision of 99.35% and a recognition precision above 97.89% with a speed of 12.19 ms. In [15], a robust and efficient ALPR system based on the state-of-the-art YOLO object detector was presented. The system was fine-tuned and trained for each ALPR stage, and achieved a recognition rate of 93.53% with 47 frames per second (FPS) on 2,000 frames extracted from 101 vehicle videos. The system was tested on a large, public, and realistic dataset, UFPRALPR, and the recognition rate exceeded 78% with 35 FPS. In [16], a sliding window technique was suggested as a means of identifying Taiwan's license plates, resulting in a license plate detection accuracy of around 98.22% and a license plate recognition accuracy of 78%, with each image taking 800 ms to process. Also, a new Automatic License Plate Recognition (ALPR) system based on YOLOv2 was presented by S. M. Silva and C. R. Jung [17], with a focus on capturing license plates in uncontrolled scenarios where views might be distorted. The authors introduced a unique Convolutional Neural Network (CNN) capable of identifying and correcting multiple distorted license plates within a single image. The final outcome was obtained via an Optical Character Recognition (OCR) approach. Another real-time system for recognizing Jordanian license plates using YOLOv3 was proposed by S. Alghyaline [18]. The system was tested on genuine videos obtained from YouTube and achieved an accuracy of 87% in recognition. A similar YOLO framework was implemented by A. Tourani et al. [19] to detect and recognize Iranian license plates. After testing over 5000 images, the system obtained an accuracy of 95.05%.

### C. License Plate Recognition in Morocco

Authors of [20] presented a two-step Moroccan license plate recognition system where a hypothesis is first generated step and then verified. They performed the Connected Component Analysis technique (CCAT) to detect the rectangles that are considered the generated license plate candidates. Then, edge detection is applied inside the generated candidates and the close curves method is performed to ensure the candidate is a license plate and to segment the character. The experiment results so far are satisfying and promising (96,37% accuracy when tested on three videos from Moroccan road. F. Taki and A. El Belrhiti El Alaoui submitted a three-phase method [21]. First, license plate localization under different environmental conditions is based on a combination of edge extraction and morphological operations. Second, the segmentation part exploits the features of Moroccan license plates. Third, the optical character recognition phase is based on the Tesseract framework, considered by the authors as the most accurate open-source OCR. The proposed method is able to recognize several plates in the same image under different acquisition constraints in real-time. No accuracy rate is given. In addition, authors in [22] presented a new robust method to detect and localize Moroccan license plates from images. The proposed approach is based on the edge features and

characteristics of license plate characters. To verify the robustness of the model, various images, including Moroccan's VLP taken from different distances and under different angles were used. The experimental results showed almost 95% precision rate obtained for a recall rate value equal to 81%. In addition, the standard measure of quality was equal to 87.44 %. One of the last YOLO-contribution models for the Moroccan plate context is A. Alahyane, M. El Fakir, S. Benjelloun, and I. Chairi's [23]. Indeed, they constructed a dataset for the Moroccan license plate OCR application. Almost 705 unique and different images manually collected and labeled. This dataset is free to use and suitable for CNN models like Yolov3. Also, contribution [24] proposed a one-stage modified tiny-Yolov3 for real-time Moroccan license plate recognition improved with transfer learning techniques. The latter method achieves an excellent trade-off between speed and accuracy, as well as the system executes the detection /recognition process in a single phase with 98.45% accuracy and 59.5 Frames Per Second (FPS).

In this article, we address the challenges of license plate recognition in Morocco, considering the growing fleet, local plate specifications, and plate detection issues. Section III discusses the license plate recognition scenario in Morocco, emphasizing the need for a robust system that considers local plate specifications and the challenges posed by different plate types. Section IV presents our proposed solution based on the YOLOv5 framework, highlighting its efficient and accurate license plate recognition capabilities. Section V focuses on the experimental setup and results, including the customized dataset used for training and the achieved outcomes. Section VI concludes the paper. This enumeration provides a concise overview of the different sections covered in this article, offering a comprehensive understanding of our intelligent Moroccan license plate recognition system.

## III. LICENSE PLATE RECOGNITION IN MOROCCO

### A. Growing Fleet

In Morocco, as elsewhere in the world, the fleet has jumped and is expected to even more. Table I summarizes the growth observed in vehicle numbers registered in Morocco.

TABLE I. MOROCCAN FLEET GROWTH FROM 2016 TO 2019

Vehicle type	2016	2017	2018	2019
Passenger vehicles	2 670 614	2 808 782	2 950 056	3 090 063
Commercial vehicles	1 065 338	1 117 559	1 170 177	1 225 878
Motorcycles	55 517	130 257	191 611	236 415
<b>Total</b>	<b>3 791 469</b>	<b>4 056 598</b>	<b>4 311 844</b>	<b>4 552 356</b>
<b>Evolution</b>	<b>5,61%</b>	<b>6,99%</b>	<b>6,29%</b>	<b>5,58%</b>

Along with that significant amount of vehicles, Morocco receives each year more than 400 000 additional vehicles. In fact, the African country is experiencing strong growth in tourism activities due to its important diaspora (up to 3 million Moroccans resident overseas), its location in the Northwest of Africa, its historical monuments, its gastronomic cooking, and the hospitality of its people. Enough reasons to make the country the most attractive destination on the continent with more than 11 million air passengers and motorists. In the summer of 2019, the last tourist season before the border

closure imposed by Covid-19 control measures, 600.000 vehicles were registered in the northern regions of the kingdom, shipping almost 2.9 million MROs, an important fleet that increases the number of vehicles in use in Morocco.

**B. Local Plate Specifications**

The most used Plate in Morocco is the Horizontal White Plate (HWP), shown in Fig. 1 and composed of three sections:

- The First section includes the specific number of the prefecture or province to which the vehicle is attached.
- The Second section represents the registration series, which is characterized by one or two letters of the Arabic alphabet. After the exhaustion of the group of registration series starting with the letter A up to the letter S, the second group of registration series will be made up of a combination of the fixed letter A and the first letter of the order.
- The Third section indicates the order of registration ranging from one to five digits (1 to 99999) at most.

Fig. 1. Moroccan horizontal plate composition (HWP).

Some vehicles can accept two horizontal lines plate, as shown in Fig. 2. This arrangement of two horizontal lines is shown on the first line, the first and the second part, separated by a vertical line. On the second line are placed the digits of the third part, separated from the first line by a horizontal line.

Authorities in Morocco have a specific plate, specific in colour and regions but written with the same fonts. These plates, presented in Table II, are composed of two major parts, one at the right composed of an Arabic character that indicates the concerned authority. This part can contain one, two or three characters, and sometimes it can contain the word “Morocco” written in Arabic. The second part, the one at the left, is a generic number specific to the vehicle. In the presented model, these plates are called DP like “Dark Plates”.

Fig. 2. Moroccan two lines plate (VWP).

In addition, official vehicles of ministers, parliamentarians, and municipal elected officials have specific registration numbers made up of two numbers in black on a white background. The left part represents the registration of the vehicle, while the right part is made up of two digits relating to

the function of the person to whom it is allocated (96: Official cars of senior officials e.g. Walis, governors, general secretaries, etc. 97: Official carriages of the royal court, 98: Official cars of Parliament and 99: Ministers' official cars). Because of their limited number and their specificity, these plates are not taken into consideration in our model.

TABLE II. LOCAL AUTHORITY PLATES (DP)

SIGNE	ARABIC	AUTHORITY	PLATE STYLE
ش	الشرطة	POLICE	1 2 3 4 5 6 ش
ج	الجماعات المحلية	LOCAL AUTHORITY	1 2 3 4 5 6 ج
وم	الوقاية المدنية	CIVIL PROTECTION	1 2 3 4 5 6 وم
ق س	القوات المساعدة	AUXILIARY FORCES	1 2 3 4 5 6 ق س
ق م م	القوات المسلحة الملكية	ROYALE ARMED FORCES	1 2 3 4 5 6 ق م م
المغرب	سيارات الدولة المدنية	NATIONAL AUTHORITY	1 2 3 4 5 6 المغرب

Diplomatic, consular agents, representatives, experts, and officials of international or regional organizations in Morocco have a specific plate divided into two parts as shown in Fig. 3. Also, the same plate is reserved for staff of the "international cooperation" registration series for vehicles belonging to employees benefiting from temporary importation and having their main residence outside Morocco. These plates are reserved for those whose activity falls within the framework of international cooperation in Morocco.

Fig. 3. Diplomatic or consular plate (YP).

Another kind of plates to consider is WW and W18 presented in Fig. 4. In fact, the first concerns the declaration of provisional entry into service of a motor vehicle. The second is attributed to vehicles purchased or sold by an automobile dealer holding. These plates are exclusively delivered by importers, manufacturers or traders of new motor vehicles to buyers in Morocco.

WWP and W18P plates concern almost 256 000 Moroccan new vehicles during at least their first 30 days of use, according to vehicle registration of 2022.

Fig. 4. WWP and W18P plates.

C. Plate Detection Issues

Moroccan LP presents, inter alia, the issues proposed in Fig. 5. These issues are rather morphological, related to both the form of the LP and the character used (separators, Arabic characters, shadows, dirt, degradations, etc.), or technical and concern the device used to capture the LPs (angle, illumination, etc.).

a) *Multiple fonts*: local legislators allow vehicle owners free to choose the font of their LPs. The fonts presented in Table III are mainly observed.

TABLE III. FONTS IN USE IN MOROCCAN PLATES

FONT	LABEL	CHARACTERS	SAMPLE
Clarendon Regular Extra	CRE	0123456789	14167     68
Hight Security Registration Plate	HSRP	0123456789	7556     54
FE-Schrift	FE-S	0123456789	20138     42
Ingeborg Heavy Italic font	IHF	0123456789	4578     26
Metalform Gothic JNL font	MGJF	0123456789	48847     20
Morton of (400)	MOTF	0123456789	88225     20
Moroccan Rekika Font	MRF	0123456789	73215     8

b) *Separators*: Moroccan plate constructors use different types of separators. Even if the most common separator is the vertical line, some constructors use hyphens to separate the three parts of the plate while others prefer to use slashes, and others, looking for distinction, avoid using separators. This difference between separators chosen or not changes the configuration of plates and remains an issue for plate recognition systems.

c) *Distance between Characters*: Because of the huge number of plate constructors in Morocco, their plates are not homogeneous and the distance between characters is not fixed in all plates edited. In fact, the distance between characters is not the same and constitutes a considerable issue to ALPR.

d) *Additions*: Even if local authorities have engaged in a massive campaign against additional features in vehicle LPs, some owners still, voluntarily or involuntarily add drawings, logos, stickers, or cameras to plates.

e) *Arabic characters*: Some of the Arabic letters used in Moroccan license plates are written as fragments. For example Arabic character "B" has a point out of its body. Also, short marks are placed above particular characters or may appear as isolated characters (case of Arabic character "A"). Thus, during the character segmentation step, these kinds of characters cannot be correctly segmented because dots or marks are omitted [21].

f) *Illumination*: The presence of objects' shadows can cause various challenges because of the illumination change in the shadow region to be removed to avoid any false positive detections. To accomplish this task, we implement a filtering method, namely median filtering for the removal of certain types of noise.

g) *Camera noise*: Among these issues, the sensor used can alter the taken image. We talk here about camera vibration that can cause blur along with noise caused by rain and climate conditions. This technical degradation can occur due to vehicle position and speed that make it difficult to clear images or video sequences.

h) *Degradations*: Vehicle owners still display their plates when they are damaged, either when they have scratches of painting failures:

- *Scratches*: on metallic plates similar to lines or even new features that can be assimilated to characters if they have the appropriate dimensions;
- *Character's painting failure*: with misleading interpretation or omission of the character altered.

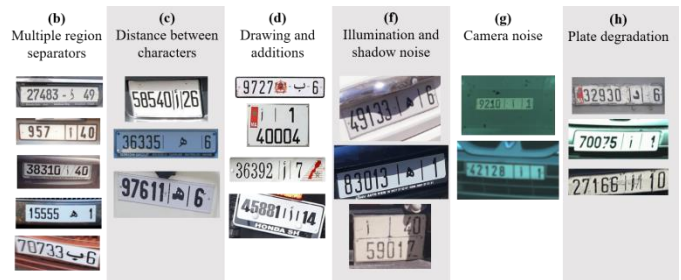

Fig. 5. Common Moroccan plates detection issues.

IV. PROPOSED SOLUTION

A. YOLOv5

YOLO is a real-time object detection algorithm that transforms the detection process into a regression problem. It generates the bounding box (BB) coordinates and class probabilities directly, without extracting the region of interest. YOLO improves detection speed compared to faster R-CNN[25]. YOLOv5, the latest version introduced by Ultralytics in 2020, surpasses all previous versions in both speed and accuracy. YOLOv5 is written in Python, which makes it easier to install and integrate with IoT devices, unlike previous versions written in C. It also has a new PyTorch training and deployment framework that improves object detection results. During training, YOLOv5 uses a data loader with online data augmentation, including scaling, color space modifications, and mosaic augmentation (combining four pictures into four random-ratio tiles).

The YOLOv5 algorithm offers four models - YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x - by adjusting the width and depth of the backbone network using the depth\_multiple and width\_multiple parameters. YOLOv5s is the simplest and fastest among them, with the least number of parameters. The network topology of YOLOv5s consists of various modules such as focus, Convolution, Batch Normalization and Leaky-ReLU (CBL), Center and Scale Prediction: CSP1\_x, CSP2\_x, and Spatial Pyramid Pooling (SPP) [26].

The input image is processed by the focus block, which primarily comprises four parallel slice layers. The CBL block includes a convolutional layer, batch normalization layer, and hard-swish function. The CSP1\_x block contains CBL blocks and x residual connection units, while the CSP2\_x block is

composed solely of CBL blocks. The SPP block consists of three max-pooling layers. The YOLOv5s model is made up of three main components: the backbone, the feature improvement section, and the head, each serving a unique purpose [27] as depicted in Fig. 6.

1) *Backbone*: The backbone is a convolutional neural network that collects and compresses visual features at various levels of detail. It starts by using the focus structure to periodically extract pixels from high-resolution images and reconstruct them into low-resolution. To improve the receptive field of each point and minimize information loss, the four edges of the image are stacked, and the information in the width and height dimensions is condensed into the C channel space. This is done to reduce the number of calculations and speed up the process. The CSP1\_x and CSP2\_x modules are then designed based on the CSPNet concept [28]. The module splits the main layer's feature mapping into two parts before combining them using a cross-stage hierarchical structure, reducing calculation time and increasing accuracy. The SPP network is used in the final section of the backbone network to separate contextual features and increase the receptive field.

2) *Neck*: The neck network in YOLOv5 uses a Path Aggregation Network (PANet) [29] to improve the fusion of extracted features. It consists of several layers that combine the features of the image before passing them on for prediction. The network employs a Feature Pyramid Network (FPN) structure to transmit strong semantic features from the top down, and a feature pyramid structure created by the PANet module to transmit strong positional features from the bottom up. This approach is designed to combine features from different layers.

3) *Head*: In YOLOv5: the head uses features from the neck to make box and class predictions. The head structure in YOLOv5 is similar to that of YOLOv3, with three branches. Its purpose is to make dense predictions, which consist of a vector containing the predicted bounding box coordinates (center, height, and width), a prediction confidence score, and class probabilities. The improvement in YOLOv5 is the use of complete intersection over union (CIoU) loss [30] as the bounding box region loss.

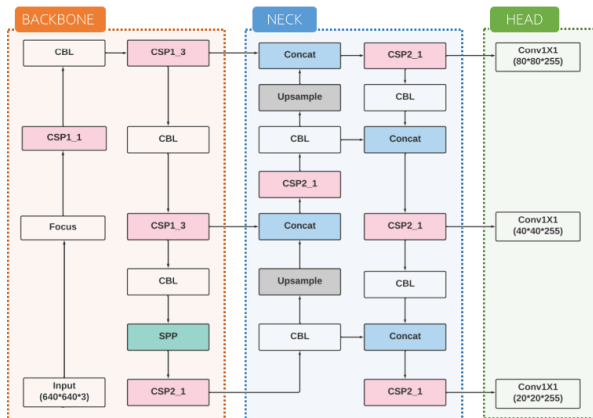

Fig. 6. Network topology of YOLOv5s [25].

## B. Model

Considering the above, the proposed Moroccan Automatic License Plate Recognition System (MALPR) as depicted in Fig. 7, addresses the recognition of all types of license plates used in Morocco, including both local and foreign vehicles, and is designed to meet the specifications of the country while mitigating as many challenges as possible. The MALPR system is divided into two major components [31]. The first component is an SDK-based system embedded with IoT devices such as GPS, GSM, and camera, along with a neural network framework for image analysis. The second component is an API server-side system where further processing such as character segmentation and recognition is performed.

Fig. 7. Proposed solution overview.

The proposed architecture involves capturing a real-time video from a camera and converting it into a specific number of frames per second, based on the deployment location of the device. For instance, if the system is used for detecting parking activity, a low frame rate of one or two frames per second would suffice. However, in areas with higher traffic density, such as highways, a higher frame rate would be necessary to enhance the accuracy of the detection.

Initially, the device performs an analysis of the video and processes the frames to improve their quality and increase the accuracy of predictions through techniques such as compression, gray-scale conversion, etc. [30, 31]. Subsequently, the captured vehicle is classified using the YOLOv5 neural network, a framework that has proven its effectiveness [14-18] in object detection, vehicle classification, and plate localization within the frame. The better the vehicle classification, the more accurately the plate can be located within the image. YOLO can easily locate the plate with a simple configuration. Once the plate is detected, it is cropped and sent as a binary large object (BLOB). On the server side, the software development kit (SDK) completes the process by performing region segmentation, character detection, and gathering recognized characters to construct the final output. The current architecture extends beyond the steps outlined above.

1) *Initial setting*: The user sets initial parameters such as frame rate according to the area where the device is used which

defines the corresponding frames rate [15]. In the presented solution frames are tested with three rates (parking: 1f/s, road: 5f/s, and highway: 10f/s). In addition, night vision parameters are programmed to a specific time of the day. The schedule of night vision switching is implemented using the recurrent rule. The similarity rate of redundancy is set at the beginning, the information needed to select the relevant output from repeated frames of the same vehicle. The user can also choose the codec to be used in the transmission of potentially detected plates.

2) *Video analysis*: The Video Analysis stage involves the examination of the video captured by the camera using a pre-trained weight of YOLO. At this stage, whenever the model detects a vehicle (such as a car, truck, bus, trailer, or motorcycle) within a minimum range, the system crops the vehicle and forwards it to the processing step. The weight was initially trained on the COCO dataset [32] and has demonstrated strong performance in object detection across 80 object categories.

3) *Image processing*: The Image Processing stage involves a suite of quality-enhancement techniques aimed at improving the quality of the captured vehicle frames and enhancing the accuracy of predictions. At the start of the workflow, these techniques (including binarization, contrast maximization, Gaussian blur filtering, and adaptive thresholding) eliminate small components and noises to elevate the required quality for subsequent operations [33], while also reducing computational overhead. This stage may also be carried out following the Plate Detection step through the use of a high-quality second camera, which uses the coordinates from the Plate Detection stage to only capture the detected plate. The applied processing techniques include image binarization [33,34], thresholding [35] and histogram equalization.

4) *Plate detection*: The Plate Detection stage relies on a weight derived from the constructed dataset to determine the location of the plate on the detected vehicle. The weight enables the model to identify the type of plate, including HWP, VWP, DP, YP, or WWP. This stage can be expanded to encompass additional types of plates by incorporating the relevant weight-embedded device. The output of this stage consists of the coordinates of the predicted plate as presented in equation (1).

$$y = (pc, bx, by, bh, bw, c) \quad (1)$$

With  $bw$  and  $bh$  are the width and height of the rectangle,  $c$  stands for the class found and  $bx$  and  $by$  are the coordinate of the center of the box.  $pc$  corresponds to the confidence of the prediction:

$$pc = Pr(\text{Object}) * IoU \quad (2)$$

With  $IoU$  corresponds to the area of overlap between the predicted BB and the ground-truth BB [36] which corresponds to the labeled BB from the testing set that specify where is the object.

5) *Plate cropping*: simple stage, shown in Fig. 8, in which the image is cropped and saved. This stage prepares the result

of the embedded processing to be streamed to the server for further steps. With the use of YOLOv5, this stage consists of cropping the BB got from the above-mentioned grid. The cropped areas can admit color processing to be sent to the region segmentation stage depending on the type of the plate predicted.

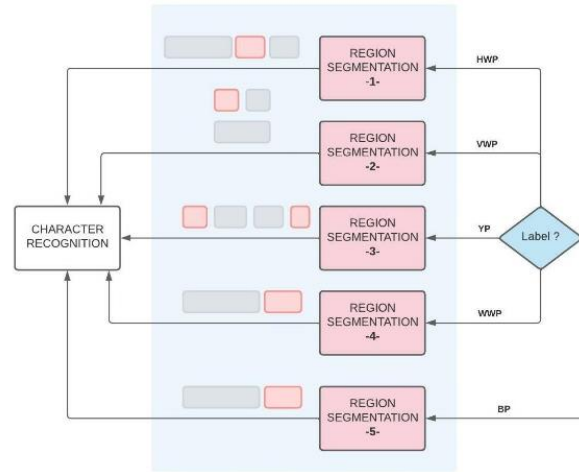

Fig. 8. Region segmentation overview.

6) *Region segmentation*: The proposed system boasts a noteworthy contribution in its region segmentation aspect. It categorizes the license plate into its major digit regions before extracting each character. This stage is crucial in ensuring that every part of the plate is analyzed individually and no section is overlooked. During the training phase, the regions are designed to be as large as possible to accommodate all possible fonts in the test phase. Careful consideration is given to avoid overlapping regions, as this is essential in the subsequent step of separating the digits for analysis. Unlike other Moroccan license plate recognition systems, this model does not consider separators, such as the long line of the Arabic letter "A" and sees no alphabet as separate parts.

7) *Color inversion*: this approach features a straightforward stage of color reversal, where plates with dark backgrounds undergo inversion and are promptly forwarded to region segmentation 5. Instead of compiling a separate dataset made up exclusively of dark plates, segmentation, and training, this process relies on the digit data that has already been acquired.

8) *Character recognition*: The character recognition stage is an optimized process that extracts characters and numbers from separated regions. During this stage, the system only accepts alphabetic letters or words as output in the red regions depicted in Fig. 8. Conversely, in other regions, the system focuses solely on numeric digits and does not permit any alphabetical characters.

9) *Result gathering*: Stage, where characters recognized, are assembled to form the final output.

10) *Exploitation*: Stage reserved for further processing like checking whether the vehicle is stolen or offending road traffic rules, etc.

## V. EXPERIMENT AND RESULTS

### A. Dataset

A significant amount of high-quality data is necessary for machine learning solutions. Although attempts have been made to address the problem of License Plate detection, recognizing license plates in uncontrolled and unrestricted environments is still a challenge. In fact, most proposed methods have low accuracy when attempting to detect license plates that are rotated, in uneven lighting, in snowy conditions, or in a dimly lit environment. Nearly all researchers have trained and tested their detectors on extremely small datasets, which only contain a limited number of unique images or minor variations in angles, restricting their effectiveness to specific scenarios.

To test the presented solution, a specific Dataset is built based on the type of plates (HWP, VWP, YP, WWP, DP) and the font in use in them (CRE, HSRP, FE-S, IHIF, MGJF, MOTF, and MRF). This Dataset, presented in Fig. 9, is composed of 8952 images of distinct vehicles on Moroccan roads under different circumstances (place, weather, time, rotation, backgrounds, illumination, and car type). These images are sorted according to the type of plate and the font utilized. Each annotated plate is cropped and then segmented (HWP-N, HWP-P, HWP-L, etc.). This constitutes segmentation dataset to be annotated and trained aside.

Also, specific folders are built to test the present model on problematic plates: plates with degradations (PDEG), plates with different illumination (PDI), plates with specific separators (PSS), and plates with additions (PADD).

Fig. 9. Dataset composition (fonts and plate types).

### B. Training

The dataset used to test the present model is labeled using LabelImg [37]. This tool analyzes the image annotation process for training artificial intelligence models in modern image recognition systems. This tool creates a classes.txt file and saved annotations with the following structure, with the first character corresponding to the order of the class in class.txt. The next four values are the coordinates of the BB annotated.

Multiple datasets are trained using NVIDIA GeForce RTX 3070 (total memory 8G) build on AMD Ryzen 9 3900XT 12-Core Processor computer with 16384 MB RAM and Windows 10 Pro N 64-bit (10.0, Build 19045). The model was built with Python-3.9.13, torch-1.9.1+cu111 CUDA:0.

The model presented typically provides four cases to classify the results, represented by T and F indicating true or false predictions respectively. The letters P and N indicate whether the instance is expected to belong to a positive or negative class. The model's effectiveness can be evaluated by analyzing the ratio of these prediction outcomes, which are composed of different combinations of these categories. To assess the accuracy of the model, the following metrics are used.

$$\text{Accuracy (A)} = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (3)$$

$$\text{Precision (P)} = \frac{TP}{TP+FP} \times 100\% \quad (4)$$

$$\text{Recall (R)} = \frac{TP}{TP+FN} \times 100\% \quad (5)$$

$$F_1 = 2 \times \frac{P \times R}{P+R} \quad (6)$$

$$mAP = \frac{1}{N(T)} \sum_{r \in T} AP_r \quad (7)$$

True positive (TP) corresponds to a test result that correctly indicates the presence of the characteristic, true negative (TN) stands for results that correctly indicates the absence of the region or the character, false positive (FP) is the result which wrongly indicates that a particular region or character is present and false negative (FN) represents test result which wrongly indicates that a particular condition or attribute is absent. Fig. 10 displays three different types of loss: classification loss, objectness loss, and box loss.

The box loss measures how accurately the algorithm can determine an object's center and how completely the estimated BB encloses an object. The probability that an object exists in a suggested zone of interest is basically measured by objectness. If the objectivity is high, an item is probably present in the image window. How successfully the algorithm can determine the proper class of a given object is shown by the classification loss. Before remaining stable after approximately 50 epochs, the model quickly increased in terms of precision, recall, and mean average precision. The validation box, objectness, and classification losses similarly shown a sharp drop up until about epoch 50. To choose the best weights, we utilized early stopping.

Fig. 10. Plots of box loss, objectness loss, classification loss, precision, recall and mean average precision (mAP) over training and validation epochs.

C. Result and Discussion

After performing precision of 97.492%, a recall of 98.259% and mAP 50% up to 97.768% in training, the model performed excellent rates on problematic dataset. In fact, as shown in Fig. 11, all PADD images were detected and correctly predicted and the model showed very good results when tested on PDEG, PDI and PSS datasets. The average speed of all detection stages (vehicle detection, plate type, plate segmentation, and plate characters) is up to 135.3ms when run under experimentation configuration. Fig. 12 and 13 show results displayed of the model stages A, B, C and D.

Fig. 11. Model precision on problematic datasets.

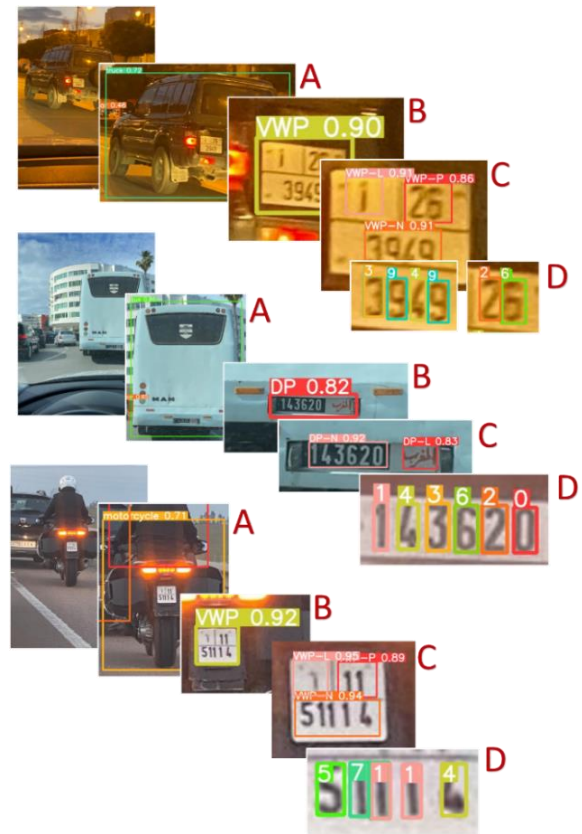

Fig. 13. Model's result on VWP and DP.

By adopting the presented architecture, the model has overwhelmed the above mentioned issues. The present model ensures the following results:

- The recognition of only characters inside regions and the remedy for the separators issue;
- No separators are recognized as characters, especially the Arabic letter "A";
- The mode performs under different conditions of illumination, camera noise, and no matter the distance between character is;
- No additional features are recognized and only essential parts of the plate are depicted;
- The specification of the intended result wanted from the region segmentation result. No letters are recognized as a number (case of "1" and Arabic letter "A" , "W" and the similar number "9", etc.)
- Optimization of the result of the recognition of Arabic similar characters and resolution of recognition of alphabet having separated parts (dots).
- The optimization of training dataset based on digits, different shadows and illumination specification, etc.
- Possibility of the adding of new plates (foreign plates) by adding of new categories in plate detection (HWP, VWP, YP, WWP, DP, FRP, GERP, etc.).

Fig. 12. Model's result on HWP, YP and WWP.

## VI. CONCLUSION

From what has been tackled above, since there are now more cars on the road than ever before, there is a greater demand for a reliable and versatile license plate recognition system. Like everywhere else, local governments, government agencies, and private businesses in Morocco require a robust License Plate Recognition (LPR) system that takes into account local plate specifications (HWP, VWP, DP, YP, and WWP) and typefaces used by plate manufacturers. This study presents a YOLOv5 framework-based intelligent LPR system that was trained on a multiple font-oriented datasets (CRE, HSRP, FE-S, etc.) and environmental factors (illumination, climate, light, etc.). This model contains an intelligent region segmentation stage that is dependent on the plate's type. This segmentation improves significantly recognition precision, and resolves the old separator issue. Results demonstrate that the trained model is capable of identifying automobiles, license plates of every type and font, as well as digits and plate portions with precisions of: 99.165% when test on issued plates.

## VII. FUTURE WORKS

In future research, it is important to explore various avenues to enhance the intelligent Moroccan license plate recognition system. These include extending its capabilities to recognize license plates in multiple languages, accommodating the diverse population and foreign vehicles in Morocco. Also, addressing privacy and security concerns should be a priority, ensuring the secure handling of captured license plate data. Additionally, continuous dataset updates are necessary to keep the system up to date with evolving license plate designs and new plate types. By considering these future works, the intelligent license plate recognition system can be further advanced to enhance its accuracy, versatility, and practicality for various applications in Morocco's context.

## VIII. DATA AVAILABILITY STATEMENT

The data used in this study was collected manually by the authors and sorted by type of plate: WWP, VWP, YP, and DP. After further analyzing the collected pictures, the data was sorted into four folders: PDEG, PDI, PSS, and PADD. A part of this datasets used in the analysis will be available upon request.

## IX. CONFLICT OF INTEREST

The authors of this manuscript declare that they have no financial or personal relationships with other people or organizations that could inappropriately influence their work. The authors confirm that this article is original, has not already been published in any other journal, and is not currently under consideration by any other journal. The authors also confirm that all the data presented in this manuscript are original and authentic.

**Abstract**—Personal Activity Recognition (PAR) is an indispensable research area as it is widely used in applications such as security, healthcare, gaming, surveillance and remote patient monitoring. With sensors introduced in smart phones, data collection for PAR made easy. However, PAR is non-trivial and difficult task due to bulk of data to be processed, complexity and sensor placement positions. Deep learning is found to be scalable and efficient in processing such data. However, the main problem with existing solutions is that, they could recognize up to 6 or 8 actions only. Besides, they suffer from accurate recognition of other actions and also deal with complexity and different placement positions of smart phone. To address this problem, in this paper, we proposed a framework named Robust Deep Personal Action Recognition Framework (RDPARF) which is based on enhanced Convolutional Neural Network (CNN) model which is trained to recognize 12 actions. RDPARF is realized with our proposed algorithm known as Enhanced CNN for Robust Personal Activity Recognition (ECNN-RPAR). This algorithm has provision for early stopping checkpoint to optimize resource consumption and faster convergence. Experiments are made with MHealth benchmark dataset collected from UCI repository. Our empirical results revealed that ECNN-RPAR could recognize 12 actions under more complex and different placement positions of smart phone besides outperforming the state of the art exhibiting highest accuracy with 96.25%.

**Keywords**—Human activity recognition; deep learning; CNN; MHealth dataset; artificial intelligence

## I. INTRODUCTION

Human action recognition (HAR) has become an important research area. Particularly, smart phones came with sensors that are useful to know the activities of humans. At the same time wearable devices are available for monitoring human health or actions. Smart phones became handy to collect data pertaining to human actions. However, based on the position of sensor or smart phone on human body, the data contains details of specific human action that can be discovered automatically using machine learning (ML) and deep learning (DL) techniques [1]. As the position or placement of wearable device or sensor plays crucial role, it is important to consider different positions and corresponding action recognition possibilities. It is observed that learning based approaches in the form of ML and DL techniques have

potential to learn from large volumes of historical data and gain knowledge pertaining to activity recognition [4].

Extensive review of literature has revealed that the existing methods could recognize different number of human activities. Table 1 shows the details of different methods and how many actions they can recognize. In the same fashion, there are different devices that are used for the research on HAR as presented in Table 2. Literature has shown many existing approaches and their ability to recognize different human activities. In [5] a multi-model approach is designed to deal with automatic recognition of human activities. They used different methods for classification besides providing their merits, challenges, and future possibilities. Nandy et al. [7] uses smart phones and wearable devices to obtain data suitable for human activity recognition. In [8] an ultrasonic sensor grid is used in smart phone environment to collect data about human behaviour. In [11], there is an effort to monitor humans automatically besides knowing their actions in an adaptive fashion. In [12], there is exploration of different methods used for automatic recognition of human activities. In [14] adversarial learning is explored in order to improve training quality that leads to higher level of accuracy in human action recognition. From the literature, it is found that the main problem with existing solutions is that, they could recognize up to 6 or 8 actions only. Besides, they suffer from accurate recognition of other actions and deal with complexity and different placement positions of smart phone. Our contributions in this paper are as follows.

1) We proposed a framework named Robust Deep Personal Action Recognition Framework (RDPARF) which is based on enhanced Convolutional Neural Network (CNN) model which is trained to recognize 12 actions.

2) An algorithm known as Enhanced CNN for Robust Personal Activity Recognition (ECNN-RPAR) is proposed to realize RDPARF.

3) An application is built to evaluate RDPARF and its underlying algorithm for performance in detecting more human actions.

The remainder of the paper is structured as follows. Section 2 reviews prior works on automatic human action recognition based on ML and DL techniques. Section 3

presents the proposed framework, procedures, and proposed algorithm. Section 4 presents result of experiments. Section 5 draws conclusions and bestows scope for future possibilities.

## II. RELATED WORK

This section reviews related works pertaining to human activity recognition using sensors associated with devices like smart phones. Chen et al. [1] explored various ML models that make use of data collected from smart phone sensors to recognize human activities. They used a cycle detection algorithm to know the trends on the user behaviour. They discussed about different positions from which sensors are operated and the impact of the positions in human activity recognition. Nweke et al. [2] explored on the importance of data fusion and usage of multiple ML techniques for human activity recognition. Their work includes number of models and approaches that are existing for this kind of research. Gani et al. [3] explored different sensor placement positions targeting specific human actions. They proposed a ML based methodology for detection of various human actions. Thakur and Biswas [4] investigated on ML and DL models that are suitable for human activity recognition based on the data collected by smart phones. In [5] a multi-model approach is designed to deal with automatic recognition of human activities. They used different methods for classification besides providing their merits, challenges and future possibilities.

Suto et al. [6] studied different ML models that are suitable for human activity recognition. Their study has significance in terms of their approaches that work for offline and also online based human activity recognition. They found that sensor data changes based on its position and the position of sensor has to do with which kind of action it supports for recognition. Nandy et al. [7] uses smart phones and wearable devices to obtain data suitable for human activity recognition. From the data, they explored feature importance in order to leverage learning based phenomena in activity recognition. In [8] an ultrasonic sensor grid is used in smart hone environment to collect data about human behaviour. Their approach was found to be non-intrusive in recognizing human activities. Cornacchia et al. [9] reviews different existing studies on human activity recognition that are based on the data collected from wearable sensors. They investigated it with simple sensors and also hybrid sensors. Zdravevski et al. [10] considered Ambient Assisted Living (AAL) environment with feature engineering towards improving accuracy in activity recognition.

In [11], there is an effort to monitor humans automatically besides knowing their actions in an adaptive fashion. Based on the smart phone collected data, their research reveals the utility of automatic human action recognition in healthcare domain. In [12], there is exploration of different methods used for automatic recognition of human activities.

They also explored different approaches for federated learning to improve intelligence required for recognition. In [13] a novel approach is proposed considering swarm optimization algorithm and hybrid diversity enhancement. Besides it follows a selective ensemble approach towards improving detection accuracy further. In [14] adversarial learning is explored in order to improve training quality that leads to higher level of accuracy in human action recognition. A bidirectional LSTM method is explored in [15] for detection of human actions.

A boosting approach is exploited in [16] for to know well-being of humans based on their actions. Sensors of smart phone are used in [17] to obtain data pertaining to human behaviour for analysis and authentication purposes. Feature selection enhancement is the main research focus in [18] for leveraging detection performance.

Machine learning and opportunistic sensing based approach are explored in [19] and [20] respectively for monitoring humans about their actions. Other important researches found in the literature include feature extraction and deep learning [21], classification of sports and daily activities using ML models [22], deep learning for knowing human physical actions [23], monitoring of player activities in presence of mobility [24] and passive mobile sensing for continuous authentication [25].

As presented in Table 1, different prior works are summarized in terms of the activities, position of sensors and the techniques used for activity recognition.

As presented in Table 2, it is observed that different kinds of devices and sensors are used for finding human activities and behaviour associated with physical and mental health of humans. From the literature, it is found that the main problem with existing solutions is that, they could recognize up to 6 or 8 actions only. Besides, they suffer from accurate recognition of other actions and also deal with complexity and different placement positions of smart phone. This paper proposes a framework with underlying algorithm for addressing those issues.

TABLE I. SHOWS SUMMARY OF TECHNIQUES FOUND IN LITERATURE ALONG WITH ACTIVITIES AND SENSOR POSITIONS

### III. PROPOSED WORK

We proposed a deep learning based framework for automatic recognition of personal activities based on the smart phone sensor data. Several researchers have contributed earlier towards personal activity recognition as explored in [26], [27] and [28] to mention few. However, the number of activities recognized is limited to 3 to 8. However, in real world, smart phone sensors could be positioned and it is possible to recognise more activities. Towards this end, in our research, we could experiment with more complex activities due to

different placement positions. Our system recognizes 12 actions such as “standing still, sitting and relaxing, laying down, walking, climbing stairs, waists bends forward, frontal elevation of arms, knees bending, cycling, jogging, running and jump front & back”.

#### A. Our Framework

Our framework is illustrated in Fig. 1. The given M-Health dataset that contains smart phone sensors generated data under complex and different placement positions is used by the framework to explore possibilities of recognising 12 actions.

The dataset is subjected to pre-processing feature extraction. Then an enhanced CNN classifier is trained on the chosen features. The training of deep learning model has resulted in a knowledge model known as personal activity recognition system which is saved to persistent storage for reuse. This model is a multi-class classifier as we intend to recognize 12 personal activities. The pre-processing splits data into training and test set in order to have experiments without over fitting. We also defined an Early Stopping strategy based on validation loss value. If there is no change in validation loss after given patience value, this point is considered to be early stopping condition. This strategy has proved to be good as it could avoid over fitting issues. The saved trained model is reused with test data to perform personal activity recognition.

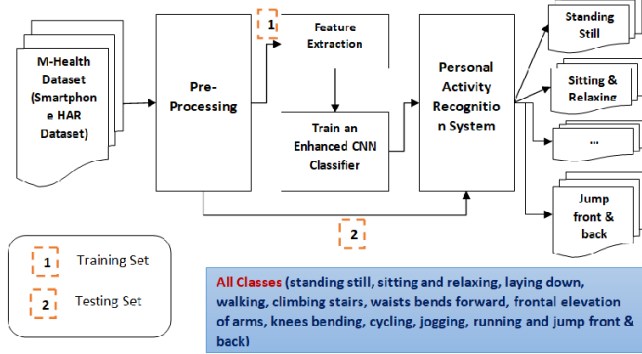

Fig. 1. Proposed framework known as robust deep personal action recognition.

Framework (RDPARF) for personal activity recognition considering more complex and different placement positions of smart phone

We enhanced CNN model to meet our requirement in this research. Layers are configured in such a way that they tend to produce best results with multi-class classification. CNN model is enhanced as one size does not fit all. In other words, the CNN used to solve one problem cannot be directly used for another problem.

### B. Enhanced CNN Model

We configured an enhanced CNN model in such a way that it is best suited for multi-class classification of personal activities. The dataset used for empirical study has sensor positions that are diversified to realize more human actions. The model performs convolutional operations to acquire features from the given data. It has carefully chosen hyperparameters set to improve prediction performance.

In Table 3 the sensor data input vector is denoted as  $x_i^0 = [x_1, \dots, x_N]$  where N refers to the per window values. The outcome of the first convolutional layer is observed and it can be expressed as in Eq. 1. Table 1 shows all the notions used in the proposed model.

$$c_i^{1,j} = \sigma(b_j^1 + \sum_{m=1}^M w_m^{1,j} x_{i+m-1}^{0,j}), \quad (1)$$

Where layer index is denoted by  $l$ , activation function is denoted by  $\sigma$ , the bias term for given feature map is denoted as  $b_j$ , filter size is denoted by M and weight for given feature

map is denoted by  $w_m^j$ . In the same fashion, the outcome of  $l^{th}$  convolutional layer is expressed as in Eq. 2.

$$c_i^{l,j} = \sigma(b_j^l + \sum_{m=1}^M w_m^{l,j} x_{i+m-1}^{l-1,j}). \quad (2)$$

Here  $c_i^{l,j}$  is used to obtain summary of nearby outputs through pooling layer which is meant for optimizing feature maps. We used max pooling as it is characterized by using resulting max value as expressed in Eq. 3.

$$p_i^{l,j} = \max_{r \in R} (c_{i \times T + r}^{l,j}), \quad (3)$$

where pooling size is denoted by R and stride by T. In the enhanced CNN architecture many convolutional and pooling layers are stacked to ensure a hierarchical feature extractor. The extracted features can have ability to discriminate among the personal activities. They have capability to discriminate simple to complex activities. In order to recognize personal activities fully connected layer and softmax layer are combined. This combination forms a top-most layer. The features obtained from convolutional layers and pooling layers are transformed into feature vectors denoted as  $p^l = [p_1, \dots, p_2]$  where number of units is denoted as  $l$  in the ultimate pooling layer. The outcome of these layers is given as input to fully connected layer as expressed in Eq. 4.

$$h_i^j = \sum_j w_{ji}^{l-1} (\sigma(p_i^{l-1}) + b_i^{l-1}) \quad (4)$$

TABLE III. SHOWS DIFFERENT KINDS OF SENSORS USED IN THE PRIOR STUDIES TOWARDS FINDING HUMAN ACTIVITIES LINKED TO DIFFERENT APPLICATIONS

Reference	Device Type	Details
[50]	Sensors in wearable devices	Focused on the importance of wearable biosensors in healthcare industry.
[51]	Sensors in smartphone	Study designed to know physical activity and weight loss possibilities.
[52]	Sensors in smartphone	Study meant for to find long-term diseases and sensor usage in healthcare.
[53]	Sensors in smartphone	Study uses sensors to know mental disorders of humans
[54]	Sensors in smartphone	Investigation into bipolar disorders using iOS and Android smart phones
[55]	Sensors in smartphone	Explores human behavior linked to healthcare analytics
[56]	Sensors in smartphone and wearable devices	Studies on the mental health of humans
[57]	Sensors in smartphone	Explores mental health of humans using ML techniques
[58]	Sensors in smartphone	Explores human activity recognition, categorization and feature engineering.
[59]	Wireless Sensors	Studies the possibilities in remote healthcare and latest methods in the process.

Where activation function denoted as  $\sigma$  and it is same as that of previous layers. The bias terms is denoted as  $b_i^{l-1}$  and the  $w_{ji}^{l-1}$  denotes weights associated with  $i^{th}$  and  $j^{th}$  nodes in the  $l-1$  layer. The softmax layer, which is expressed as Eq. 5, is the final layer in the deep network for performance classification.

$$(c|p)=\operatorname{argmax}_{c \in C} \frac{\exp(p^{L-1}w^L + b^L)}{\sum_{k=1}^{N_C} \exp(p^{L-1}w_k)}, \quad (5)$$

Where the activity class is denoted as  $c$ ,  $p$  is the index of last layer while the number of activity classes is denoted as  $N_C$ . Equations from 1 through 4 perform forward propagation that result in getting error values of the network. SGD is used in training to minimize error cost and also update weights. Sensor data is used in the training process in the form of mini batches. In the fully connected layer back propagation is performed which is expressed as in Eq. 6.

$$\frac{\partial E}{\partial w_{ij}^l} = y_i^l \frac{\partial E}{\partial x_j^{l+1}}, \quad (6)$$

where the cost function is denoted by  $E$ , weight from  $u_i^l$  and  $u_i^{l+1}$  in the  $l+1$  layer is denoted by  $w_{ij}^l$ . Computation of  $y_i^l$  is done as expressed in Eq. 7.

$$y_i^l = (x_i^l) + b_i^l \quad (7)$$

Weights are adjusted using backpropagation in convolutional layers. This process is expressed as in Eq. 8.

$$\frac{\partial E}{\partial w_{ab}} = \sum_{i=0}^{N-M-1} \frac{\partial E}{\partial x_{ij}^{l-1}} y_{(i+a)}^{l-1}, \quad (8)$$

where map function is denoted as  $y_{(i+a)}^{l-1}$  which is equal to  $\sigma(x_{(i+a)}^{l-1}) + b^{l-1}$ . The results of  $\frac{\partial E}{\partial y_{ij}^l} \sigma'(x_{ij}^l)$  are equal to that of  $\frac{\partial E}{\partial x_{ij}^l}$ . The process of back and forward propagations are continued until stopping condition is met.

### C. Regularization

When it comes to weights in the network, it is possible that large weights can lead to weight vector to have local minimum due to small amendments to gradient descent in the optimization process. Thus it makes it difficult in exploring weight space. Therefore, it is required to have regularization mechanism to deal with large weights. It is achieved by adding penalizing term to every set of weights as given in Eq. 9.

$$E = E_0 + \lambda \sum_w w^2, \quad (9)$$

where  $\lambda \sum_w w^2$  is the penalizing term and  $E_0$  is the cost function prior to regularization. As the cost function is updated, the learning rule is updated and it is expressed as in Eq. 10.

$$w_i = (1 - \eta\lambda)w_i - \eta \left( \frac{\partial E_0}{\partial w_i} \right) \quad (10)$$

where the weight decay factor is denoted by  $1 - \eta\lambda$ . Gradient descent can be momentum based to have velocity to parameters that are under optimization. It is done such that only velocity is changed but not the position associated with the weight space. For each weight variable in  $v = [v_1, \dots, v_K]$ , there is corresponding velocity variable. The update of gradient descent rule is then expressed as in Eq. 11 and Eq. 12.

$$v \rightarrow v' = \mu v - \eta \nabla E, \quad (11)$$

$$w \rightarrow w' = w + v' \quad (12)$$

where the momentum coefficient is denoted as  $\mu$ .

We used dropout appropriately to get rid of overfitting problem. It is achieved by doing so instead of amending cost function. The overfitting problem is solved by temporary deletion of nodes without changing input and output neurons. It makes the training process more efficient. This process also makes neurons not to be influenced by other neurons while learning features. For each given training sample, dropout is followed by consideration of an include probability which is done independent of nodes. In the proposed enhanced CNN model dropout is used in fully connected layer of the network.

### D. Hyperparameter Tuning

In the proposed enhanced CNN architecture, there are large number of possibilities of hyper parameter combinations. We followed a greedy tuning process in order to assess the effect of hyper-parameter tuning on the network. The tuning is experimented in terms of pooling size, filter size, number of feature maps and even number of layers in the network. In our empirical study we explored with network layers 1 to 4, feature maps from 10 through 200 with interval of 10, pooling size considered from 1x2 through 1x15 and filter size is considered from 1x3 through 1x15. In all our experiments one softmax layer is used. Finally, best performing hyper-parameters are used.

### E. Proposed Framework

We proposed an algorithm known as Enhanced CNN for Robust Personal Activity Recognition (ECNN-RPAR). It is designed and implemented to realize our PAR framework named Robust Deep Personal Action Recognition Framework (RDPARF).

#### Algorithm 1: Enhanced CNN for Robust Personal Activity Recognition

<p><b>Algorithm:</b> Enhanced CNN for Robust Personal Activity Recognition (ECNN-RPAR)</p> <p><b>Inputs</b></p> <p>MHealth dataset <math>D</math> (reflects more complex and different placement positions of smart phone)</p> <p>Batch size <math>n</math></p> <p>Number of epochs <math>m</math></p> <p><b>Output</b></p> <p>Multi-class classification results of PAR <math>R</math> (12 classes)</p> <p>Performance evaluation results <math>P</math></p> <ol style="list-style-type: none"> <li>1. Begin</li> <li>2. <math>D' \leftarrow \text{DataPreparation}(D)</math></li> <li>3. <math>(T1, T2) \leftarrow \text{SplitData}(D')</math></li> <li>4. Initialize CNN model</li> <li>5. Add max pooling layer</li> <li>6. Add convolutional layer</li> <li>7. Add batch normalization layer</li> <li>8. Add convolutional layer</li> </ol>
--

9. Add batch normalization layer
10. Add linear layer
11. Add batch normalization layer
12. Add linear layer
13. Add softmax layer
14. Tuning hyper-parameters
15. Compile the model  $M$
16. For each epoch  $e$  in  $m$
17. For each batch  $b$  in  $n$
18. IF early stopping criterion is FALSE Then
19. Update  $M$  using  $TI$
20. Else
21. Break
22. End For
23. End For
24.  $(R,P) \leftarrow \text{ModelTesting}(M, T2)$
25. Display  $R$
26. Display  $P$
27. End

$D$ : Dataset	$D'$ : Pro-processed dataset
$m$ : Number of epochs	$n$ : Batch size
$R$ : Classification results	$TI$ : Training set
$T2$ : Test set	$M$ : Proposed model
$e$ : each epoch	$b$ : each batch
$P$ : Performance statistics	

As presented in Algorithm 1, it takes MHealth dataset  $D$ , number of epochs  $m$ , number of batches  $n$  as input and generates personal activity recognition results  $R$  along with performance statistics. It has data preparation phase to improve given dataset with the help of linear interpolation, scaling and segmentation. Then it splits data into 80% training set and 20% test set. Then it initializes our enhanced CNN model. Afterwards, it configures all the layers as per the proposed model. Hyper-parameter tuning is carried out. Then there is an iterative process based on given number of epochs and batch size to train the model using  $TI$ . The model training process gets terminated if it satisfies early stopping criterion. This is considered because it is important to stop training before it overfits. Once the model is trained, it gains knowledge from the training process. This will result in a knowledge model that is saved to persistent storage for further reuse. This saved model is loaded in the testing phase and every instance of test set  $T2$  is subjected to prediction of personal activities. Finally, the algorithm returns personal activity recognition results  $R$  and performance statistics  $P$ .

#### IV. EXPERIMENTAL RESULTS

Experiments are made with the proposed enhanced CNN which is used in the framework and underlying algorithm

named ECNN-RPAR. The enhanced CNN is designed and implemented to cover all PAR classes under more complex and different placement positions of smart phone. Number of epochs used in the empirical study is 200 but it is subjected to early stopping criterion. Dropout is set to 0.5, batch size is 400, window size for data splitting is 50 and step value is set to 25. Total number of classes (including normal/no action class) is 13, size of max pool is 2 and stride of max pool is set to 2. Dataset for our empirical study is collected from [60] which reflects more complex and different placement positions of smart phone. The experimental results are provided in terms of confusion matrix as presented in Fig. 2.

Fig. 2. Confusion matrix reflecting prediction performance of the proposed model for 12 classes.

As the statistics are provided through confusion matrix for all 12 classes, performance of the proposed algorithm ECNN-RPAR is ascertained. With 200 epochs used in experiments, the training loss and validation loss [65] are observed in presence of early stopping criteria.

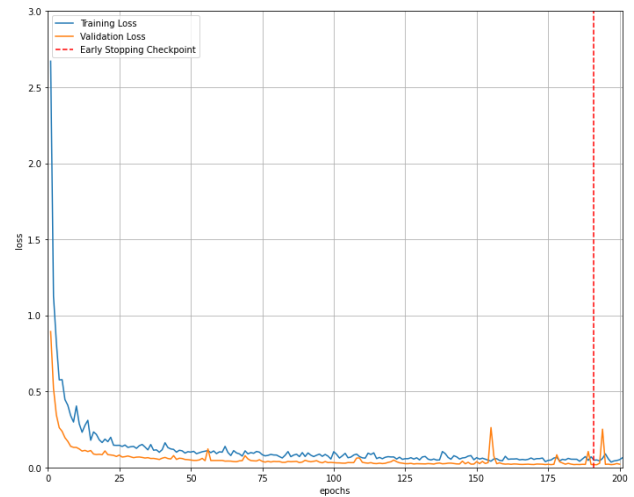

Fig. 3. Loss dynamics and early stopping criterion check point.

As presented in Fig. 3, visualization of the performance of ECNN-RPAR [63,64] is provided against number of epochs. Number of epochs used in experiments is 200 but it is subjected to early stopping criterion.

As the number of epochs is increased, it is observed that the training and validation loss is reduced gradually. Reduced loss indicates improved performance.

As presented in Table 4, the personal action recognition [61] performance of the proposed algorithm ECNN-RPAR is provided.

TABLE IV. PERFORMANCE OF THE PROPOSED MODEL

PAR Model	Performance (%)			
	Precision	Recall	F-1 Score	Accuracy
Proposed (ECNN-RPAR)	89.12	85.32	87.17	96.25

Fig. 4. Personal action recognition performance of proposed ECNN-RPAR algorithm.

As presented in Fig. 4, the action recognition performance of the proposed ECNN-RPAR algorithm is provided. It could achieve detection of 12 classes with 89.12% precision, 85.32% recall, 87.17% F1-score and 96.25% accuracy.

TABLE V. PERFORMANCE OF PROPOSED ECNN-RPAR ALGORITHM COMPARED WITH EXISTING MODELS

PAR Models	Performance (%)			
	Precision	Recall	F-1 Score	Accuracy
ANN	75.48	69.34	72.27	79.36
Baseline CNN	78.45	75.78	77.09	81.58
LSTM	80.25	73.23	76.57	85.73
Proposed (ECNN-RPAR)	89.12	85.32	87.17	96.25

As presented in Table 5, the personal action recognition performance of the proposed ECNN-RPAR algorithm is compared against the state of the art.

Performance of proposed ECNN-RPAR [62] algorithm is compared against ANN model, baseline CNN and LSTM. ANN showed least performance among all models. Its precision is 75.48%, recall 69.34%, F1-score 72.27% and accuracy 79.36%. Baseline CNN model showed performance better than that of ANN. CNN achieved 78.45% precision, 75.78% recall, 77.09% F1-score and 81.58% accuracy. LSTM showed better performance over CNN with 80.25% precision, 73.23% recall, 76.57% F1-score and 85.73% accuracy. The proposed ECNN-RPAR algorithm showed highest performance with 89.12% precision, 85.32% recall, 87.17% F1-score and 96.25% accuracy. It is observed from the results that the existing methods showed comparatively poor performance in accurately predicting 12 personal actions.

Fig. 5. Performance Of Proposed ECNN-RPAR Algorithm Compared With Existing Models.

## V. CONCLUSION AND FUTURE WORK

We proposed a framework named Robust Deep Personal Action Recognition Framework (RDPARF) which is based on enhanced Convolutional Neural Network (CNN) model which is trained to recognize 12 actions. The given M-Health dataset that contains smartphone sensors generated data under complex and different placement positions is used by the framework to explore possibilities of recognising more actions. The dataset is subjected to pre-processing feature extraction. Then an enhanced CNN classifier is trained on the chosen features. The training of deep learning model has resulted in a knowledge model known as personal activity recognition system which is saved to persistent storage for reuse. RDPARF is realized with our proposed algorithm known as Enhanced CNN for Robust Personal Activity Recognition (ECNN-RPAR). This algorithm has provision for early stopping checkpoint to optimize resource consumption and faster convergence. Experiments are made with MHealth benchmark dataset collected from UCI repository. Our empirical results revealed that ECNN-RPAR could recognize 12 actions under more complex and different placement positions of smart phone besides outperforming the state of the art exhibiting highest accuracy with 96.25%. However, we have directions for future scope of our work. First, it is interesting to explore pre-trained deep models with transfer learning towards performance improvement. Second, usage of hybrid deep learning models with our framework could leverage performance. Third, usage of Generative Adversarial Network (GAN) along with deep models for generator and discriminator is another direction for future work.

Department of Computer Systems Engineering-Faculty of Engineering, University of Zawia, Zawia, Libya<sup>1</sup>

**Abstract**—Given the increased popularity of the internet, the exchange of sensitive information leads to concerns about privacy and security. Techniques such as steganography and cryptography have been employed to protect sensitive information. Steganography is one of the promising tools for securely exchanging sensitive information through an unsecured medium. It is a powerful tool for protecting a user's data, wherein the user can hide messages inside other media, such as images, videos, and audios (cover media). Image steganography is the science of concealing secret information inside an image using various techniques. The nature of the embedding process makes the hidden information undetectable to human eyes. The challenges faced by image steganography techniques include achieving high embedding capacity, good imperceptibility, and high security. These criteria are inter-related since enhancing one factor undermines one or more others. This paper provides an overview of existing research related to various techniques and security in image steganography. First, basic information in this domain is presented. Next, various kinds of security techniques used in steganography are explained, such as randomization, encryption, and region-based techniques. This paper covers research published from 2017 to 2022. This review is not exhaustive and aims to explore state-of-the-art techniques applied to enhance security, crucial issues in the domain, and future directions to assist new and current researchers.

**Keywords**—Image steganography; data hiding; steganographic security; randomization; encryption

## I. INTRODUCTION

With the evolution of the internet and social networking as well as a rapid increase in communication facilities, a huge amount of information is being exchanged every moment. Security and privacy of exchanged data should be guaranteed, especially against malicious threats. Cryptography and steganography are techniques that are being used to achieve high security [1]. Cryptography is the process of converting raw information or plaintext to unreadable form called ciphertext, using an encryption algorithm with a key. The algorithm and the key utilized by the sender are, in most cases, used by the receiver for the decryption purpose. Hence, the original data is unreadable, and confidentiality is maintained. However, the availability of the ciphertext raises suspicions and draws the attention of opponents. On the other hand, steganography seems to be more appropriate and has recently received much attention, since it does not give rise to any signs detectable by the human eyes [2]. Steganography is the science of hiding relatively smaller information in a larger multimedia cover. Cover media could take the form of text [3], image [4], audio [5], or video [6]. Image steganography is the process of

concealing secret data within an image that appears normal to the human eye.

Several reviews on image steganography have been published in recent years. Study [7] reviews and compares various deep learning methods in the domain of image steganography. It categorizes these methods into three types: traditional, Convolutional Neural Network based, and General Adversarial Network based methods. It also discusses the datasets, experiments, and metrics used in the field. However, traditional steganographic methods are not discussed in this article. The authors of research [8] provide a comprehensive overview and evaluation of some of the latest steganographic methods. This article addresses the challenges of recent deep learning-based steganographic methods. It also discusses how to measure the performance of a steganographic technique using various criteria. Although it evaluates the security of the techniques vis-à-vis varied advanced attacks and tools, randomization-related security concepts, such as the chaotic map function, have not been mentioned or discussed.

The research [9] presents a review and a critical assessment of recently proposed steganography methods. It describes various schemes, along with their technical terms, main logics, as well as strengths and weaknesses in terms of important measures. This critical assessment is based on the type of cover object used, the algorithmic domain, and important properties used as evaluative measures for the steganographic system. However, this article might be outdated, because many of contributions have been published since then.

This research article provides an extensive and comprehensive review of the security principles used in spatial-domain image steganography. It presents and discusses various steganographic techniques according to the security concepts adopted by them, such as randomization, encryption, and adaptive embedding. Further, it provides an overview of image steganography, its goals, and traditional steganography methods along with their features, pros and cons, and performance evaluation metrics. It also provides analysis, discussion, and suggestions based on its study of image steganography security principles.

The remainder of this paper is organized as follows: Section II presents an overview of image steganography. Section III demonstrates the basic goals of image steganography. In Section IV, the search process is defined, followed by detailing of security techniques in image steganography in Section V. Section VI contains observations,

discussion, and recommendations. Finally, Section VII concludes the paper.

## II. AN OVERVIEW OF IMAGE STEGANOGRAPHY

The word steganography is of Greek origin and is constructed from two words: “steganos” and “graphie”. “Stegano” means covered and “graphie” means writing. Steganography is not a new art; it was used in ancient times to send secret messages by hiding them in certain ways. Fig. 1 summarizes the two ideas used to secure secret information [10].

Generally, cryptography is divided into symmetric and asymmetric keys, based on whether it provides authentication or confidentiality. Likewise, steganography techniques can be classified into spatial and frequency domain techniques. In the spatial domain, the secret information is directly embedded in image pixels; hence, pixel values are modified. On the other hand, in the frequency or transform domain, the image pixels are transformed into another domain, and the secret information is embedded by modifying the coefficient values. Image steganography is the process of embedding secret information within a cover image, wherein the embedded information is not visible to the human eye. The output image, which contains the secret information, is called a “stego image” [11]. Fig. 2 depicts a general steganographic system, wherein the sender optionally compresses or/and encrypts the secret information and then a certain steganographic algorithm is utilized to embed the information and produce a stego image. At the receiver’s end, the same sequence is followed in reverse to obtain the embedded information.

### A. Traditional Steganography Methods

As mentioned above, steganography techniques are classified into spatial domain and frequency domain techniques. In spatial domain techniques, pixel values are modified directly to incorporate the secret information. These techniques are famous for attaining high capacity, but they are not immune to statistical attacks and image manipulations [12]. Examples of spatial domain methods include Least Significant Bit (LSB) Replacement and its successors, Pixel Value Differencing (PVD), Pixel Indicator Techniques (PIT), and Exploiting Modification Direction (EMD) techniques, among others. In the transform or frequency domain techniques, the image pixels are first transformed into the frequency domain. Subsequently, the secret information is hidden by modifying the coefficient values. Finally, the inverse transform is applied to obtain the stego image. These techniques resist statistical attacks but achieve low capacity. The most well-known transform domain methods are the Discrete Cosine Transform (DCT), Discrete Fourier Transform (DFT), Discrete Contourlet Transform (CT), and Discrete Wavelet Transform (DWT) [12],[13].

Fig. 1. Data security classes [7].

Fig. 2. General image steganographic system.

LSB Replacement (or simply LSB) is a well-known spatial domain technique, widely utilized due to its simplicity and potential to achieve high capacity. In this method, the secret information is embedded within the least significant bit of the cover image pixels, in order to minimize distortion. The resultant stego image is indistinguishable from the original image. Further, to increase payload capacity, more than one LSB of a pixel may be used to hide information; however, this might degrade the visual quality of the stego image [14]. It is worth mentioning that several enhancements of the original LSB have already been introduced. LSB Matching (LSBM) is an enhanced version of the LSB method [15]. Here, if the embedded bit does not match the cover pixel’s LSB, then +1 or -1 values are added randomly to that pixel, so as to avoid the asymmetry artefacts that are usually introduced by the standard LSB technique and can be detected by steganalysis techniques [16]. To improve upon the previous methods, the LSB Matching Revisited (LSBMR) method was introduced by [17]. It embeds secret information within the LSB, with minimum changes to the carrier image. It hides two secret bits into two pixels simultaneously, wherein the first bit is embedded directly, while the second secret bit value is produced based on the relationship between those two bits. The objective is to make the detection of the secret information more difficult, compared to standard techniques [14], [17].

Another approach towards embedding secret information in the cover image consists of hiding bits in the edge area where pixels’ intensity values change abruptly. Such techniques are referred to as Edges Based Embedding (EBE) Steganography, which allows the hiding of large payloads in those particular edge pixels. Several research studies have been published in this context, such as [16],[18],[19],[20]. PVD is another method of hiding binary data, wherein the cover image is considered to be in the form of non-overlapped blocks of two pixels each. The difference between the two pixels is calculated and quantized into several regions that determine the number of bits of the payload [21]. In the Cyclic Steganographic Technique (CST), the embedding process is cycled through color channels of consecutive pixels [22]. The color channel selected for the current pixel is not the same color channel used in the previous pixel, or the next pixel. For example, if the LSB of the red channel is selected for the current pixel, then the green channel is selected for the next pixel, and the blue channel is preserved for three consecutive pixels. The concept of randomization along with CST is proposed in [23] wherein secret information is randomly hidden in the pixels’ LSB.

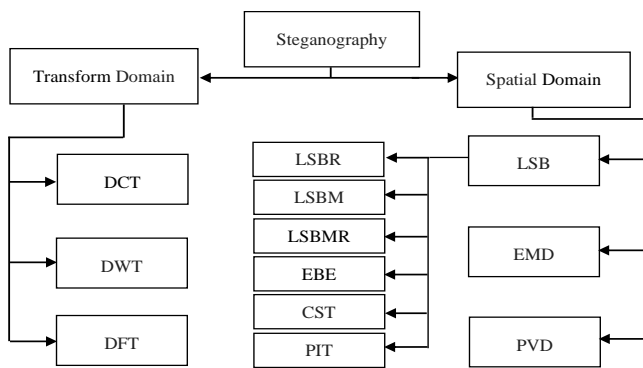

Fig. 3. Traditional steganographic techniques.

PIT is another variation of LSB techniques and is used to enhance the security and robustness of classical systems. In this method, one of the color channels of the pixel is selected as an indicator for the other two channels that are used for the embedding process [12]. An improvement is introduced in [24] takes into consideration the length of the secret message and uses two LSBs of a particular channel to indicate the presence of data in other channels. Another variation is introduced in [25]; it uses three LSBs of one of the pixel's channels as an indicator. EMD is another technique used to enhance security. In this method, the cover image is partitioned into blocks of  $n$  pixels. These  $n$  pixels of the cover image involve secret digits in a  $2n+1$ -ary notational system. One pixel is eventually altered by  $\pm 1$ . For a group of  $n$ , there are  $2n+1$  possible digits to be secretly hidden, since there are  $2n$  possible pixels' modifications and one case with no changes [26]. Article [27] presents a scheme to improve the EMD method called improved EMD (IEMD). This scheme uses an 8-ary notation system, wherein the secret digit is embedded into a group of two pixels. Fig. 3 summarizes the steganographic techniques explained above.

### III. BASIC GOALS OF IMAGE STEGANOGRAPHY

Several considerations must be taken into account while designing a steganography algorithm: capacity, imperceptibility, and security. The ultimate goal is to attain high capacity, better imperceptibility, and high security. However, these considerations are conversely related, and a trade-off needs to be made among the criteria mentioned above. More details are given in the following section [13],[28],[29].

#### A. Capacity

It refers to the amount of data in bits that can be embedded in the cover image. The objective is to hide as many bits as possible in the cover image, without affecting image imperceptibility and security. Embedding rate or Bits Per Pixel (BPP) is another widely-used term, which refers to the total amount of information relative to the total number of the cover image pixels.

#### B. Imperceptibility

When the secret information has been hidden, the resultant stego image should not create any signs that might be suspected by human eyes. Hence, the aim is to make the level of deterioration as low as possible. High imperceptibility

means low capacity and vice versa. Hence, these two concepts need to be balanced.

#### C. Security

Security is the main key to secure information sent over an unsecured network such as the internet. It refers to the ability to withstand the detectability of hidden secret information in the cover image as well as the capability of extracting it. Accordingly, the steganographic algorithm should resist the attacker's attempts to detect and extract the secret information.

As stated before, the aim is to achieve a high embedding rate, high imperceptibility, and high security. However, this is a challenging task since these metrics compete against each other. In other words, focusing on one of them will sacrifice one or more other metrics. For example, embedding high payloads will definitely lead to low imperceptibility and the possibility of low security.

## IV. SEARCH PROCESS

### A. Materials and Methods

This review study examines the existing methods and techniques of image steganography security researched between 2017 and 2022. Only studies that involved spatial image steganography are considered. This section includes subsections on data sources, search processes, data selection, and data extraction.

### B. Data Sources

The search and downloading phase has been implemented intermittently over the period from November 2021 to February 2022. The primary sources for the research have been selected from the following libraries:

- Institute of Electrical and Electronics Engineers Xplore Digital Library (<https://ieeexplore.ieee.org/Xplore/home.jsp>).
- Science Direct (<https://www.sciencedirect.com/>).
- Springer Link (<https://link.springer.com/>).
- Google Scholar (<https://scholar.google.com/>)
- Association for Computing Machinery (ACM) Digital Library (<https://dl.acm.org/>).

In addition, some other resources have been considered as well, such as the International Journal of Advanced Computer Science and Applications (IJACSA).

### C. Search Process

The search has focused on image steganography security and various keyword patterns have been used in this process. Boolean operators have helped refine the data on keywords for each research publication. Symbols and Boolean operators such as "OR" and "AND" have been used to look for the following keywords:

- ((digital image steganography) OR (security in image steganography) AND (randomization OR chaotic) AND (spatial domain)).

- ((chaotic map) AND (image steganography) AND security)) OR (randomization AND (image steganography)) AND (spatial domain).
- (((edge detection) OR (region based)) AND ((LSB image steganography) OR (LSB image steganography))) AND (spatial domain).
- (cryptography AND (image steganography)) OR (encryption AND (image steganography)) AND (spatial domain).

#### D. Data Selection

We have applied three filtering steps to select the relevant studies from the search results based on our keywords. The first step involves specifying the criteria for selecting the studies. Next, in the second step, the titles and abstracts of the studies are reviewed according to the research question in the second step. The third step involves reading the full texts of the selected studies and extracting the data. The following criteria have been mostly used for data selection:

- Has the paper been published in the last five years or so?
- Does the research article mention or discuss any of the security concepts in the image steganography field?
- Has the research article been included in any of the reference data sources?

#### E. Data Extraction

We have examined each preliminary study to identify if it was related to the security of image steganography. We have found about 220 papers upon concluding the search in February 2022. We have selected the relevant ones based on the criteria mentioned earlier. Finally, 100 related studies have been identified.

### V. SECURITY TECHNIQUES IN IMAGE STEGANOGRAPHY

One of the most challenging steganography aspects is the security attribute. Here, security refers to the process of making the hidden secret information undetectable or the embedded size and locations unguessable. Much research has been conducted in this domain, which employs different approaches to improve steganographic security. Fig. 4 depicts a summary of the findings related to securing image steganography, and Fig. 5 classifies research articles accordingly.

Encryption is a concept widely utilized to achieve security; it encrypts the secret information before embedding it. Also, the entire image may be encrypted as an intermediate step in an algorithm. Traditional encryption algorithms such as Rivest, Shamir, and Adleman (RSA), Advanced Encryption Standard AES, and Triple Data Encryption Standard (3DES) are utilized to achieve this goal. User-defined techniques are employed as well. Randomization is another approach towards attaining security, which embeds secret information in a randomized way by scattering it over the original image. As part of this concept, chaotic function, pseudorandom number generator, user-defined keys, and other techniques can be exploited. In addition, randomization can be used alone or combined with encryption techniques to add an extra layer of security. Chaotic

functions are famous for their random behaviour, wherein the outputs are unpredictable for certain input parameter values. The output is then exploited in the process of pixel location selection. Another technique to hide secret information and enhance security is transforming the cover image into another bit plane, embedding, and then retransforming the cover image to the original form. The region-based concept also improves the overall security, since it breaks the adjacent pixel correlations. In addition, some other techniques using different approaches are implemented. In the following section, more details about the above-mentioned categories have been presented.

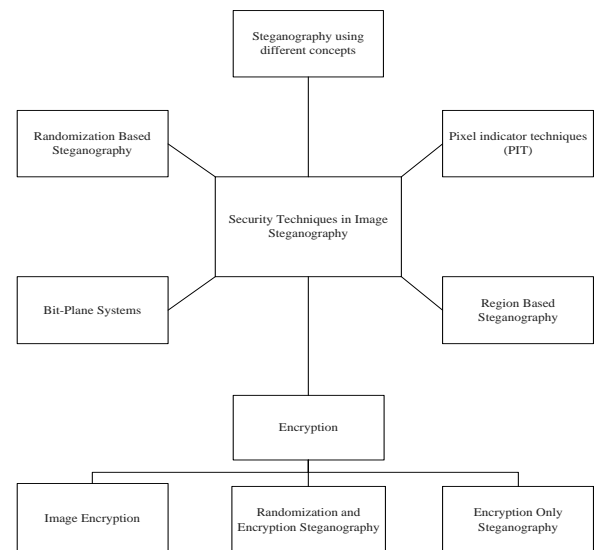

Fig. 4. Summary of findings.

Fig. 5. Classification of the existing methods based on security technique.

#### A. Randomization based Techniques

These techniques rely merely on randomization to achieve security. In [30], random pixel positions are picked using Linear Congruential Generator (LCG). Eight bits from the secret message are embedded using the LSB technique with a sequence of 3-3-2, which means embedding three bits in the red channel, three bits in the green channel, and two bits in the blue channel. Authors in [31] suggest hiding three binary images within a grayscale image. Binary pixel values are rearranged using the mean of three random series and are hidden in a grayscale image employing the concept of Ultra Unique Numbers (UUN). Random numbers are used for pixel selection by generating multiple series in [32]. Similarly, [33]

uses Pseudo-Random Number Generator (PRNG) to choose a pixel for the embedding process. Three PRNGs are generated with the help of the Skew Tent Map (SKTM) in [34]. They are employed to scramble secret messages before insertion, choose an embedding color channel, and select a pixel location with a particular Red-Green-Blue (RGB) channel.

Authors in [35] proposed an improved 1D chaotic system model for choosing an embedding pixel location. The chaotic system utilizes a chaotic Logistic Map (LM) and a sine map function. A secret message is embedded at random positions using the Beta Chaotic Map (CM) in [36]. The algorithm in [37] selects random bits for embedding based on the use of PRNG. The key seed value and number of embedded bits are user-defined. Randomization of pixels is done via random chain codes of the key determined by the user in [38]. These chains contain a random sequence of bytes based on the hexadecimal representation of the bytes in the current key block. This sequence is used to embed the bits of secret message within the LSB of the pixels in the sub cover image. The authors of [39] suggest using two secret keys to randomize one bit of secret message; K1 chooses a channel, whereas K2 places the secret bit within a pixel. The Knight's Tour (KT) algorithm using the LSB technique is suggested by [40]. Here, the cover image is considered to be the surface of a chessboard, wherein the knight travels once to each square. In [41], the secret message is embedded in un-patterned fashion based on the outcomes of quadratic equations. In addition, combinations of RGB channels and image partitions are produced, wherein the Hungarian algorithm is employed to choose the least noisy combination, that is, the partitions of the cover image and the secret message.

In [42], standard deviation is utilized to select a richly-textured block of pixels to hold the secret message. Next, four Most Significant Bits (MSBs) of three diagonal pixels in the

treated block are selected using SKTM to generate three correcting bits [Hamming code H (7,4)]. Two of these bits are XORed with the two secret bits and embedded in the neighboring pixels. In [43], the embedding position is located by a key generated utilizing a chaotic LM. Next, these located positions are further optimized by using two approaches. In the first approach, Arnold's Cat Map (ACM) is applied to add more randomness by shuffling the pixels. In the second approach, LM parameters are adjusted using the Genetic and Bat algorithms to find the best key value for the LM, leading to minimal changes. In the scheme proposed in [44], two chaotic maps are considered for pixel selection purposes: 1-D (Tent map) and 2-D (Baker's map). The embedding is done within the red channel. To minimize distortions, pixels on the edges are avoided, while the embedding process employs one bit or two bits of LSB. In the method proposed in [45], the cover image is scrambled using Power Modulus Scrambling (PMS) with the aid of the Brownian motion concept. Lighter pixels or pixels with less intensity exhibit more randomness than the heavier, darker pixels. The embedding process is carried out considering certain conditional factors. Finally, the reverse Brownian-based scrambling is applied to generate the stego image.

A keyed PRNG is used to scramble pixels, in order to achieve random permutation, in [46]. The permutation order is first based on an 8x8 Sudoku puzzle. Next, the embedding is done using LSB Matching, wherein two bits are embedded in the red channel, one bit in the green channel, and three bits in the blue channel. The Cross-coupled chaotic system (using two chaotic LM) is utilized in [47] to generate a DNA sequence, which is then added to the secret message's DNA sequence using the ASCII format. The result is then embedded using the typical LSB method. Table I summarizes the references related to randomization-based methods.

## B. Encryption

In the following sections, steganographic techniques will be presented based on cryptography only or combined with randomization. In addition, some image encryption techniques will be presented, which can be utilized to encrypt the secret image and be used during the steganographic process.

1) *Encryption based steganography*: The technique in [48] proposes to encrypt the secret message using an XOR operation with a user-defined key. Next, a 4-bit shifting operation is applied to the encrypted text message in order to form the secret message to be hidden. The secret data is eventually embedded within the cover image using the standard LSB method. As per the technique suggested in [49], the letters of the secret message are initially transposed as an encryption process. Next, the secret message bit is XORed with the MSB of the image pixel based on a particular key hidden in the LSB of the cover image. In the method presented by [50], data hiding is performed using the typical LSB concept. The secret message is encrypted using the AES encryption algorithm with a 128-bit key in Cipher-Block Chaining (CBC) mode. Next, the order of pixel selection for embedding is obtained by utilizing a combination of the image attributes such as type and image resolution. The secret message in [51] is encrypted using XOR operation through a key generated via a circular bit shift operation having varying block sizes. Next, the encrypted message is embedded in RGB channels using the LSB algorithm in various ways for each channel. This process uses a 2-3-4 paradigm, wherein the insertion is done sequentially for the red channel, using raster scan pattern from right-left for the green channel, and using top-bottom raster scan for the blue channel.

The input RGB image in [52] is scrambled using a hyper-chaotic map to produce a permuted encrypted version of the cover image. The encrypted image is converted to YCBCR color space, and the luminance channel (Y) is then divided into  $8 \times 8$  non-overlapping blocks to apply DCT and quantization on each block. Finally, Huffman coding is applied to the secret message and embedded in the left MSB. In the technique suggested by [53], the secret message is encrypted using a symmetric key cipher. The encrypted message is XORed with selected bits from the cover image for obtaining a higher-order pixel to add more confusion to the stego image. A block-wise inversion technique is applied to minimize changes during embedding by inserting them to an LSB or inverting them. The stego key consists of a symmetric encryption key and the encoding key, which contains parameter settings such as the number of blocks, starting block, start pixel offset, and block selection rule. In [54], the author introduces a secure steganography scheme, which encrypts the secret information using the permutations concept. Two chaotic map functions are utilized to obtain a sequence that is XORed with secret bits. The cover image is JPEG compressed, and DCT coefficients are modified and adaptively selected to hide the secret bits using a histogram modification-based data hiding scheme. In [55], the cover image is flipped by  $180^\circ$ . Next, the blue channel is divided into four sub-blocks, each of which is shuffled. The

difference between the red pixels and the secret message is calculated and encrypted using a Multi-Level Encryption Algorithm (MLEA), which includes XOR, permutation, and shifting operations. The LSB embedding is done within the blue shuffled pixels. Subsequently, the sub-images are reshuffled and eventually combined using the red and green channels and re-flipped. Table II summarizes the encryption-based method in image steganography.

2) *Randomization and encryption based steganographic techniques*: The study [56] presents a scheme to improve the security of LSB steganography. In this method, the secret message is encrypted using a One-Time Pad (OTP) encryption. Subsequently, randomization is achieved by columnar transposition and RGB color plane scattering technique. Also, the technique in [13] uses OTP to encrypt the secret message, but it employs PRNG to select a pixel location for LSB embedding. In [57], the AES algorithm is applied to encrypt the secret message, which is then embedded using the LSB technique at a location randomly determined by the LCG method. The AES algorithm is also used in [58] to encrypt the secret message before dividing it into blocks. The cover image is segmented using a technique called a Non-Uniform Block Adaptive Segmentation on Image (NUBASI) algorithm. Finally, PRNG is used to randomly choose a message block to be embedded into an image segment. In fact, there are 32 predefined pattern orders of segments that can be selected at random. In [59], the secret message is encrypted and compressed by employing Vigenère Cipher and Huffman Coding, respectively. Next, the image is segmented into blocks in order to apply the KT algorithm to make groups of blocks. An arbitrary function is employed to select which blocks and groups can be used to conceal a specific pixel in the group randomly. Authors of [60] suggest encoding the secret message using bitwise XOR operations between adjacent pixels. Next, a local user selection is applied to find a particular position among the four least significant bits to hide a secret bit. The technique presented in [61] is based on Modified Least Significant Bit (MDLSB) to embed data in the cover image. It uses two layers of randomization: segment selection and pixel selection based on a user key. Further, a lossless compression algorithm, the DEFLATE algorithm, is applied to overcome the issue of embedding size in the subsequent layer. In addition, the AES encryption algorithm is utilized to encrypt the secret message in the next layer. The Artificial Bee Colony (ABC) algorithm is employed to reduce the noise caused by embedded information.

A randomized key based technique is proposed in [62]. First, the cover image is compressed, and then a secret key with the same length as the secret message is generated. Next, the secret message bits are XORed using the generated key. The resultant bits are embedded in the locations specified by the key. Finally, the image is encrypted using the 3DES algorithm. Authors in [63] proposed a secure digital image steganography scheme. In this approach, the secret message is initially compressed using the Run Length Encoding (RLE) algorithm, which is then encrypted using the Bernoulli map and the inverting bit map technique. During the embedding stage, the embedding location is selected by using KT algorithm and Henon Map (HM) function. The cover image is

divided into 8x8 blocks in order to apply the KT for selecting a block. HM function is employed to choose a pixel location among the 64 pixels in a particular block. The selected pixel is decomposed through Fibonacci, so as to embed the secret bit using a New Stego Key Adaptive LSB (NSKA-LSB), which maintains good imperceptibility.

In the technique proposed by [64], the location and the order of the image pixels are randomly chosen for embedding using a chaotic PRNG. The Pseudo-Random Number (PRN) is generated by exploiting the Duffing map and Circle map functions. In addition, the secret message is encrypted by XORing it with PRN before initiating the embedding process. In [65], the authors present a secure method that starts with encryption of the secret message using the RSA algorithm in

combination with the Diffie-Hellman (DH) key exchange algorithm. Next, the encrypted message is compressed using RLE. Finally, via the Direct Sequence Spread Spectrum (DSSS) technique, PRN is used to select random pixels and to embed the secret message through 1-bit LSB and 2-bit LSB. The research [66] suggests a new method to enhance steganographic security. In this technique, the secret message written in Turkish text is encoded and compressed using the Huffman coding. The secret message is encrypted using the XOR operation and an OTP key with an equal-length payload. The key is generated using the super Mandelbrot sets and with the help of the LM. Subsequently, the LSB plane is analyzed morphologically to avoid low entropy pixel locations. Finally, LSB hiding is applied with the help of the chaotic LM in order to randomly choose a pixel location.

In the scheme proposed by [67], the Bernoulli chaotic map function is utilized in three stages. It begins with encryption of the secret message by XORing it using a random sequence generated by the chaotic function. Then, one of the RGB channels is selected randomly using the random sequence. In addition, the secret message bits are randomly embedded in the rows and columns of the cover image. Embedding is done in the fourth least significant bit of the pixel. In [68], the secret data is transformed into binary form and then its CRC-32 checksum is generated. The data and its CRC are Gzip-compressed, followed by the AES encryption that is eventually appended to the header information. The last phase consists of information insertion using the Fisher-Yates Shuffle algorithm. This insertion enables selection of a pixel location for the embedding process, wherein all LSB channels are employed.

A method is suggested in [69] which starts by finding the best place to hide secret data using the LSB technique. Then, the secret information is encrypted using the 3DES algorithm; here, the RSA algorithm is used for the secret key exchange. The last stage is randomization, which is realized using a built-in randomization function based on the modulo Operation (mod) function with a secret seed. The secret seed is exchanged using the RSA. In the three-layered security suggested by [70], a small size fragile watermark is appended to the secret information to make it tamper-proof. The data is scrambled before the embedding process and partitioned into three vectors of varying length. The largest vector is embedded in the lowest order bit plane to minimize distortion that may arise after embedding. Before insertion, the host image is encrypted using the scrambling notion based on a Pseudo-Random Address Vector generated for image encryption, which is called PAVE. The concept of Pseudo Noise (PN) sequence generator is employed to generate the PAVE. The encrypted image is then partitioned. The embedding location is selected randomly by generating a random vector called Pseudo-Random Address Vector for Data Hiding (PAVH). Once the embedding is accomplished, the host image is decrypted to obtain the final stego image.

In [71], the first step towards achieving security comprises encryption of the secret image using RSA, which produces a 16-bit pixel cipher. The resultant cipher is rearranged to obtain a binary image, which is subsequently scrambled using a randomization concept relying on 2-D ACM transformation. The secret image is then embedded within the cover image using an inverted 2-bit LSB steganography wherein two bits are embedded. Bit inversion is based on the 3rd and 4th bits that are utilized as quantifiers. In [72], a chaotic LM and a support image are combined to generate a random binary sequence that is XORed with the secret message to get an encrypted version of the message. LSB embedding is done at positions determined randomly through random sequencing. The support image is pre-processed and utilized during the embedding stages to help resist steganalysis. In the method proposed by [73], the sequential color cycle is combined with pattern-based image steganography. The data to be hidden is encrypted using the AES algorithm. The cover image is divided into blocks and sub-blocks. Finally, a sub-block is chosen based on a predefined bow-tie shape pattern. The

embedding operation is accomplished sequentially for the LSB of the RGB channels.

An algorithm to enhance security using randomization and multiple encryptions of secret images is presented in [74]. This technique embeds three secret binary images inside an RGB cover image. First, the three-color planes are separated. The red channel matrix is further separated into even and odd matrices. Next, the bits of the first secret image are embedded in the LSB of the odd matrix and the second LSB of the even matrix containing red pixels. Further, the bits of the second and third secret images are encrypted by XORing them with the first secret image. Finally, the two encrypted images are inserted in the LSB of the green and the blue channels, respectively. A pixel locator sequence-based technique was suggested by [75] to enhance LSB steganography security. This scheme starts by enciphering the secret information using the AES algorithm. The encrypted information is randomly embedded within the LSB bits of the image pixels with the help of a pixel locator sequence. Modern Fisher-Yates shuffle is utilized to generate the random sequence. The pixel locator sequence is also encrypted and appended to the image to form the final version of the stego image.

To secure communication, [76] incorporates randomization in combination with encryption. Confidential data is first encrypted using the Blowfish algorithm. Next, the LCG algorithm is used to generate random numbers that are in turn used to select pixels for LSB embedding. The number of bits to be inserted varies depending upon the pixel's intensity. Chaos based steganography is presented in [77]. In the first step, the secret information is encrypted using the AES algorithm. Following this, chaotic LM and ACM are employed to generate random values. These values are used to choose the positions of pixels on the cover image within which the secret bits are embedded. The first and second bit planes are used to uniformly distribute bits of the message. Three variations of random values can be constructed using the two aforementioned chaotic maps. Table III summarizes the references related to randomization and encryption-based steganography methods.

*Image encryption:* Various image encryption techniques are explained in this section. In [78], image encryption based on the confusion process is followed. The RGB image is transformed into a square grayscale image in the first step. Next, ACM is applied to scramble image rows and columns, followed by the HM algorithm for further scrambling to obtain the final cipher image. Authors of [79] suggest enciphering digital images by incorporating the confusion and diffusion concepts. First, the 256x256 RGB image is divided into four quadrants. Each of these quadrants is subsequently divided into four sub-quadrants that are rotated 90° anti-clockwise to form 64 sub-blocks in total. Then, modified zigzag transformation is applied to each channel to break the association with the adjacent pixels. Up to this step, confusion is fulfilled. An Enhanced Logistic Map (ELM) is used to generate intermediate encryption keys that pick specific pixel values to guarantee diffusion. The final key 'K' is generated based on the chosen values from the image and external user key, which are then XORed with RGB channels produced earlier after the zigzag step.

In [80], a color image of H×W size is decomposed into three images consisting of its RGB components at the bit-level. These images are then vertically combined to create one bit-level image (3H rows x 8W columns). Based on Chaotic SKTM, permutation is carried out at a bit level of the image. The initial values of the chaotic function are concluded based on a 128-bit key value, which is constructed from a combination of external user key and information extracted from the plain image. Eventually, the function is iterated 3Hx8W times, and the results are recorded and inverted to be used for permuting the image bits accordingly. A lightweight encryption scheme is presented in [81]. The raw image is converted to a 1D array and permuted using a random sequence produced by the LM. This sequence is transformed into a DNA sequence. Also, the LM is used to generate another random sequence that is likewise used to obtain another DNA sequence. The two sequences are added using DNA computation rules. In the final step, each pixel is XORed with its preceding pixel. In [82], the authors propose a compression and encryption method based on hyper-chaotic function, 2D compressed sensing, and DNA encoding. The aim of using a hyper-chaotic function instead of the 1D chaotic function is to increase the system key space, thereby improving system complexity and security. The cover gray image is compressed using the 2D compressed sensing technique. Fractional-order Chen hyper-chaotic system is employed to control DNA encoding and operation. The initial values of the Fractional-Order hyper-chaotic system are generated using the hash value of the original image. The DNA encoded image is enciphered using Arnold transformation to produce the encrypted image.

In [83] authors propose an encryption scheme that uses intertwining and ELMs. The primary point is to de-associate neighboring pixels by shuffling them. Next, the image is partitioned into blocks, and permutation-substitution operations are performed using an intertwining LM and ELM along with the cosine-based transformation. In addition, the image is rotated 90° anticlockwise. Finally, random order substitution is achieved by utilizing the random sequence generated using a

chaotic function. A novel high speed image encryption scheme based on 1-D cosine fractional chaotic map and image encryption scheme (DCF-IES) is proposed in [84], which is based on a new real 1-Dimensional Cosine Fractional (1-DCF) chaotic map. To increase encryption speed, permutation operation is excluded from the architecture design. Despite the absence of the permutation process, a substitution process with a high sensitivity to a plain image guarantees a high level of security. The chaotic function is first utilized to generate two sequences that act as system keys, wherein the keys are used to accomplish substitution. The process is achieved by performing an XOR operation as also addition and MOD functions between the key and raw pixels. This operation is iterated twice over image row values to ensure strong encryption. The output cipher is sensitive to minor changes in the value of the input pixels.

In [85], image scrambling-based encryption is presented. Scrambling is carried out based on a random sequence, which is generated using a formula of two inputs that act as a secret key. Then, the pixels' locations are rearranged utilizing the generated sequence. Permutation based encryption is suggested in [86]. In this method, the Linear Feedback Shift Register (LFSR) produces a PRN that is employed to generate two shuffled images. Permutation of the image rows creates the first one, while permutation of image columns forms the second image. Both images are XORed in the final step to create the encrypted image. The Chaotic Gravitational Search (CGS) concept for encryption is introduced in [87]. In this system, a binary gravitational search algorithm selects a random PRNG, thus starting an encryption key among three algorithms: Mersenne Twister (MT), SIMD-Oriented Fast Mersenne Twister (SFMT), and Combined Multiple Recursive (MRG) algorithms. Then, the Chaotic Gravitational Search Algorithm (CGSA) produces the initial value for the selected generator. The generated keystream is used to encrypt images by applying permutation alone or in combination with the substitution process.

Authors in [88] suggest transposition and substitution encryption-based techniques that utilize two pseudorandom generators: an altered version of the Sophie Germain Prime Generator (ASGPG) and Lehmer Random Number Generator (LRNG), which generate a group of random numbers. The first group is used to assign new values to image pixels by XORing the random numbers with image pixels: a substitution condition. The second group attains the transposition by swapping the positions of pixels. In [89], improved Baker map and LM are used to achieve image encryption. A two-dimensional Baker chaotic map is employed to control the chaotic LM parameters as well as the state variable. It is used to increase the randomness and unpredictability levels. Two random sequences are produced by the chaotic LM. The sequences are then exploited to perform image encryption by first shuffling the pixels, followed by substitution. Likewise, in [90] chaos-based encryption is proposed, which follows the permutation and substitution methodology to encrypt the original image. Clifford's chaotic system and LM are iterated for a particular value followed by a quantization process. Next, positions are shuffled, and grayscale substitution is performed as a final stage. Parameters of the Clifford system map or the attractor, act as encryption keys.

In [91], the authors propose a Hyper-Chaos (HC) based image encryption algorithm. They make use of a 5-D multi-wing hyper-chaotic system to resist cryptanalysis. It generates a chaotic sequence that is used first for pixel-level permutation and then for bit-level permutation. Up to this point, confusion is fulfilled. To achieve diffusion, the chaotic sequence generated earlier is XORed with the confusion step output. It is worth mentioning that the function's parameters are deduced from the plain image properties. In [92] presents a unified image encryption algorithm. This technique utilizes Substitution-Box (S-Box) to realize the diffusion concept.

Hence, a keyed-piecewise linear chaotic map creates a key stream sequence. This key is employed for diffusion operations that are based on a specific formula between this key value and image pixels. However, the intermediate encrypted image is 180° rotated and then scrambled before making the second diffusion. In this technique, the decryption process is identical to the encryption process. Table IV summarizes the related references for the image encryption methods.

### C. Region based Steganography

In the following paragraphs, some techniques will be presented, wherein steganography is carried out in certain areas of the cover image to primarily enhance security. Some techniques exploit only image edges, while others use edges and smooth areas. Image edges and boundaries are the areas in which the intensity value changes sharply within a short distance, while the smooth area is the area with low-intensity variations. In [18], edge pixels are detected and selected for embedding using the Canny edge detector. Huffman code is applied to the secret bits in the primary step for data compression. Then, the edge pixels are randomized, and the number of pixels intended for embedding is determined by coherent bit length L. Next, 2k correction is applied to achieve better imperceptibility. Edge detection incorporated with morphological dilation as part of the steganographic technique is suggested in [20]. In this method, the secret message is embedded in the image sharp regions, which are detected by the Canny edge operator and optimized by the morphological dilation operator. The Canny operator is applied to a modified version of the original image channels obtained by adding the 4 MSBs of RGB channels. Subsequently, a 3x3 dilation operator is utilized to identify reference pixels. The bits are inserted within the remaining LSB bits using the hybrid XOR technique, such that least possible alterations of edge pixels are guaranteed. This meets the high security demands.

TABLE IV. SUMMARY OF ENCRYPTIONS TECHNIQUES OF IMAGE ENCRYPTION TECHNIQUES

Ref	Encryption Concept
[78]	Confusion based encryption using Arnold Cat map and HM algorithm
[79]	Encryption is achieved by rotation, modified zigzag transformation, and enhanced LM output with XOR operation. It is a confusion and diffusion encryption.

[90]	Transposition and substitution encryption using an improved baker map and LM
[91]	Permutation - substitution encryption utilizing Clifford chaotic system and LM
[92]	Permutation - substitution encryption using a 5-D multi-wing hyper-chaotic system
[92]	Substitution - permutation encryption by employing a keyed-piecewise linear chaotic map

In [93], the secret data is hidden in the edges of the image using the LSB technique. The Canny edge detection algorithm is employed to identify image edges. The secret message is converted into a binary sequence and encrypted using the OTP encryption method. The encryption process is achieved by modulus addition of the secret bits with the corresponding OTP bits. Laplacian of Gaussian (LoG) detector is used in [94] alongside a chaotic function. The secret information is first encrypted by XORing it with a PRN generated by a chaotic LM. Then, the edges of the green and blue planes are identified using the LoG edge operator. Finally, 2-LSB of the green and blue edge planes are used for the embedding process. In [19], the author suggests using a hybrid edge detector and encryption to secure the steganographic technique. The Vernam cipher is applied to the secret message using a pseudo-random generated key that is generated using a nonlinear feedback shift register, Geffe Generator. This method uses a hybrid edge detector which combines the Sobel operator with Kirch operators. The LSB technique is used to hide secret message bits; here, three bits are embedded in the edge pixels while two bits are embedded in non-edge pixels.

In [95], an Adaptive Multi Bit-Planes image steganography using Block Data-Hiding (MPBDH) is proposed. First, the secret message is encrypted using the AES algorithm. Then, complex regions are chosen for embedding, based on a complexity threshold estimation and the number of bit planes. If the whole message cannot be embedded within the selected pixels, then parameter readjustment is used to compulsorily ensure that all bits are embedded. LSB and Hamming code-based algorithm is suggested in [96]. The cover image is

divided into blocks, and then edge detection is performed after zeroing all LSBs of the red channel pixels. The embedding is done based on the pixel's location. If the pixel is a non-edge pixel, standard LSB embedding is used for the RGB channels. Otherwise, LSB is performed for the three channels and the other two LSBs of the RG channels are used to embed the Hamming code. In [97], the complexity is based on the pixel variation among the central pixel and all neighboring pixels. The cover image is divided into small overlapping blocks (3x3). Then, a multidirectional high pass filter bank is used to find eight residual responses, which are then utilized to calculate the corresponding complexity using a proposed Complex Block Prior (CBP) criterion. The blocks are also sorted from high to low complexity, and the blocks with the same complexity level are grouped together. Finally, a single bit or multiple bits are embedded adaptively within the central pixel.

The Block-Wise Edge Adaptive Steganography Scheme (BEASS) method is suggested in [98]. It utilizes the edges obtained by using a fuzzy edge detector as well as the surrounding pixels to embed secret message bits. The cover image is divided into 64x64 blocks, and their corresponding standard deviation is calculated to estimate their local complexity. The blocks are sorted according to their standard deviation, and then the blocks are further divided into 3x3 blocks. Three message bits are hidden in edge pixels using the minimal mean squared error (MSE) that helps determine the embedding capacity of neighboring non-edge pixels within the block. Table V summarizes the related references about the region-based image steganography methods.

#### D. Bit-Plane System

The following LSB steganography techniques use the concept of virtual bit-plane. Higher plane systems are exploited instead of using an 8-bit plane to hide secret data. In these systems, the Zeckendorf criterion needs to be satisfied in order to embed the secret information that can be extracted later. "Every positive integer can be represented uniquely as the sum of one or more non-consecutive distinct Fibonacci numbers" [99]. Hence, the number representation is considered valid if no consecutive ones appear in the sequence.

In the scheme presented in [99], secret data is embedded in different bit-planes rather than using the regular binary bit planes. It is based on the Lucas Number system that uses 11 numbers for representations. Hence, the Lucas sequence is utilized for image bit plane representations, which uses 11 bits instead of 8 bits for representing the pixel's intensity. Embedding is achieved in the second bit-plane, which yields deterioration by  $\pm 1$  in the stego image. Blue and green channels of the RGB color image are used for data embedding, while red is used as an indicator. As mentioned, embedding should comply with the extended Zeckendorf theorem for handling redundant representation. In [100], the method represents the cover image using the Fibonacci sequence. The cover image in this situation is represented in 12-bit planes. The secret message to be embedded is encrypted using a symmetric cipher with the help of a chaotic LM to generate the encryption key. Then, the generated key is XORed with secret bits and embedded in the second LSB.

Authors in [101] suggest improving the Fibonacci data hiding technique by utilizing Catalan numbers. A certain set of Fibonacci numbers and a certain set of Catalan numbers are combined to create a new number set that complies with

Zeckendorf's theorem. As a result, 15 virtual bit-planes are obtained, which is three more than the number of bit-planes produced by the Fibonacci method. Authors in [102] propose two embedding techniques by utilizing two different number systems. The first embedding scheme is based on a prime decomposition of pixel value into 15 virtual bit-planes. In contrast, the second is based on natural number decomposition, which yields 23 virtual bit-planes. In these techniques, the secret message can be embedded in higher bit-planes without introducing noticeable distortion. In [103], a new method based on a specific representation is used to decompose pixel intensity values into 16 virtual bit-planes. This scheme necessitates that the sum of all bit-planes must be less than the highest pixel intensity value, which in this case is  $2^8-1$ . For the embedding process, a cover pixel is randomly selected using PRNG, then decomposed, and a particular virtual-bit plane is chosen. To represent numbers that have multiple representations, the one with high lexicographically representation is selected. In addition, if a pixel value post embedding cannot be represented in the system, it is excluded, as the embedded information cannot be extracted. The author in [104] proposes a steganographic technique based on a new pixel value decomposition. This scheme uses a set of decomposition weights that decompose the cover image into 10 bit-planes. The first five LSBs' weights increase slightly while growing exponentially for the rest. The secret message bits are embedded in one or more LSB positions. Embedding is only done for modified pixels with a valid representation in the system. Moreover, in several cases, numbers have more than one representation in the system. Hence, the one with the lowest lexicographical representation is a valid number. Table VI summarizes the references related to bit-plane based methods.

### E. Pixel Indicator Techniques

In indicator-based data embedding schemes, the channels are divided into indicator and data channels. The indicator channel determines the data channel for data hiding, based on certain sequences for better security. In [16], the two least significant bits of one channel are used as an indicator of the presence of secret data in the other two data channels. The indicator channel is chosen based a sequence created from R, G, and B, that is, RGB, RBG, GBR, GRB, BRG, and BGR. The length of the secret message is used as an indicator selection criterion to enhance security. In addition, hiding data in channels considers the pixel's intensity.

In [1], the 7<sup>th</sup> bit of a pixel and the 7<sup>th</sup> bit of the pixel value +1 are concluded. A comparison between those values and two bits from the secret message is conducted to seek a matching. In the case of a mismatch, the difference is calculated and then added to the pixel value. At this point, the embedding process is completed for this pixel. Eventually, the embedding process alters the pixel value by +2 or -2. The aim of designing this algorithm is to implement robust and secure steganography. In [25], a variant version of PIT is presented. This technique uses indicator channel criteria to determine the data channel order, based on the combinations of the MSB in the RGB channel. The first step is to obtain the message length, which is then

stored in the first 8 bytes of the first row. Then, embedding is started from the first 8 bytes of the second row, and the indicator channel selection criteria is utilized to determine the order of the data channel. The selection criteria are based on the message length and the type of the parity bit used to create a shuffled order of RGB channels. Also, the number of bits to be embedded in each channel is specified.

The study [105] suggests a PIT based technique to achieve high capacity. Here, the binary secret message is divided into four parts and the cover image. The two LSB of the first eight bytes of the red channel of the image are used to store the message length. The order of the cover image parts is stored in the two least significant bits of the four first pixels in the blue channel. Next, each pixel is evaluated for the ability to embed using the red channel's three MSBs. The three bits represent the RGB ability: the presence of zero means no embedding has taken place in that channel. Then, the number of zeros in the four MSBs of the candidate channel is counted to determine the number of secret bits to be hidden. The method proposed in [106] utilizes the red channels as an indicator to hide the secret message in the fifth and sixth bits of either the green or the blue channels of the cover image. The count of ones in the red channel determines which channel is currently in use. If the count is even, the green channel is used to embed the secret data; otherwise, the blue is used. A similar technique is found

in [107] in which the green channel is used as an indicator. If the count of the number of ones in the green channel is even, the red channel is used. Otherwise, the blue one is used. Utilizing two bits for embedding process of each pixel leads to reasonable payload capacity but enhances its security. Table VII summarizes the references related to PIT based techniques.

*F. Steganographic Techniques Based on Combination of Different Concepts*

In this section, several techniques are seen to apply different concepts to achieve secure steganography. In the scheme proposed in [108], Huffman coding is applied to the secret message to reduce its size. Then, based on the location (x, y) of the current pixel, either a bitwise XNOR operation or Fibonacci algorithm is applied to embed the secret message. If x is less than y, the XNOR operation is employed to embed the secret bits in the green or blue channels, and the red channel is used as an indicator. If y is greater than x, the Fibonacci algorithm is applied to embed secret bits in the second LSB of the Fibonacci virtual green bit plane. Otherwise, the pixel is skipped. In [109] the author suggests a steganography technique based on control bit and chaotic bit stream. A chaotic LM is used to generate a chaotic bit stream. Then, this stream is XORed with the LSB of the cover image pixels to create a control bit matching with the corresponding secret message bit. Therefore, the embedding process may change the LSB value or be kept intact based on specific criteria. A technique based on Adaptive Directional Pixel Value Differencing (ADPVD) is suggested in [110]. The aim is to enhance embedding capacity

and security. The method starts by evaluating the PVD embedding capacity by traversing three directions: the horizontal, vertical, and diagonal directional edges. That is accomplished after partitioning the original image into two-pixel non-overlapping blocks. The highest capacity rate is calculated for each color channel, and then the appropriate direction is selected.

In [111], the authors suggest a steganography technique based on variant expansion and modulus function. The purpose is to improve embedding capacity as well as the security of the stego image. The cover image is divided into non-overlapping blocks of two pixels. The proposed method considers multiple directions for each color channel and adaptively selects the appropriate embedding direction that achieves the highest embedding capacity. Instead of only considering positive differences, this method selects positive and negative difference values to hide secret data. In [112], the authors present a steganographic method for an RGB image based on the PVD technique. As in most PVD based techniques, the cover image is partitioned into sequential non-overlapping blocks of two pixels. Then, two-color channels combinations are created: red and green color components for the first combination, and green and blue color components for the second. Next, the secret data is embedded in each block using the PVD technique and then examined and readjusted to obtain the modified three-color combination. This operation utilizes a particular threshold to control the embedding capacity of each block in order to minimize distortion.

A steganographic method based on an LM function combined with LSB and PVD to improve security is suggested in [21]. A random key is generated using a chaotic LM that is employed to pick two pixels randomly at a time. In addition, the key value is utilized along with the MOD function to operate either with 3-LSB substitution or PVD, to embed the secret information. In [113], the author claims a novel steganographic approach known as Clustering Modification Directions (CMDs). In this scheme, instead of focusing only on the embedding location clusters of the texture area, clustering of the direction modifications is considered as well. The purpose is to obscure statistical features to resist steganalysis.  $\pm 1$  LSB embedding approach is considered in this situation. The cover image is segmented into several sub-images as well as the secret message. After embedding the first message portion, the costs of the adjacent segments are updated to cluster the embedding direction. Each time embedding occurs, the costs are updated. A variable-length group of bits substitution based scheme is presented in [114]. In this scheme, embedding for a Group of Bits' Substitution (GBS) is done by replacing a group of bits in a pixel with another group of bits of the same message length. The scheme is designed to work in two variations: 1-bit GBS and 2-bit GBS, which hide 1-bit and 2-bits, respectively. The choice is based on certain predefined conditions. Image imperceptibility and security are improved since most of the pixel values remain unchanged.

The authors in [115] suggest LSB based steganography with Optical Character Recognition (OCR). The concept is based on using a secret message in the form of characters within an image. Character-level features are extracted from the secret image and then embedded into a cover image using the standard LSB. The OCR model has been developed and trained to extract character features. The security perspective of this technique is that, even if the attacker extracts the embedded bits, he still needs to know the OCR model in order to recover the original message. In [116], the authors propose a new method by combining the Right-Most Digit Replacement (RMDR) with an Adaptive Least Significant Bit (ALSB). The cover image is divided into lower texture and higher texture regions. Accordingly, either RMDR or ALSB is chosen to embed the secret message based on RMD rather than bits. RMDR is employed to embed secret bits in the lower texture regions, whereas ALSB is used in high texture regions.

In [117], the RGB cover image is cropped into a predefined number of crops with certain secret coordinates. This number is used to divide the secret text message accordingly. Each part of the message is then embedded using standard LSB into a certain cropped part using a secret sequence. Embedding is

achieved using the 3-3-2 sequence. Finally, stego crops are assembled to create the stego image. The coordinates of cropped parts are considered as the key and agreed upon between the two parties. The approach presented in [118] uses two images: a reference image and a cover image. The reference image is divided into N blocks, wherein every block is assigned a unique code. The secret message is also divided into N-bits blocks that are encoded using the block codes obtained earlier. If there is no match between the secret block and the block codes, some LSBs of the reference image need to be altered. Information such as the starting block and traversing direction is incorporated into a secret key, which is then encrypted using the RSA algorithm. Finally, the encoded bit sequence is embedded into the cover image using any LSB technique.

Utilizing bit plane indexes, authors in [119] suggest a secure steganography technique. In this scheme, the secret message is embedded in multiple image bit planes to enhance security without sacrificing capacity payload. It is based on manipulating bit planes indexes. Only the two LSB bits are employed for this purpose. The cover image is initially preprocessed such that the first two bits are not be equal. If the first LSB bit equals the first secret bit, the index is recorded. If they mismatch, the second LSB plane is recorded. In the next turn, the recorded index is in reverse order, for example, if it previously recorded zero, it is one the next time and alteration to LSB is done accordingly. Hence, the final index stream fluctuates between zero and one. In [120], a different perspective is developed to achieve image steganography. Instead of modifying separate image pixels, which causes random noise in the image, this technique changes the image's color palette. All pixels of the same color are transformed into the same color. Therefore, this method achieves a higher user perception. Utilizing quad-trees, authors in [29] present a steganographic method in luminance ( $L^*$  channel) and chrominance ( $a^*$  and  $b^*$  channels) ( $L^*a^*b^*$ ) color space. This approach utilizes a quad-tree segmentation process to partition the spatial domain of the cover image into high correlation and low correlation adaptive size blocks. Embedding is done in the high frequency regions of the DCT of the highly correlated cover image blocks. To improve stego quality,  $L^*a^*b^*$  color space is utilized. A high quality stego image is guaranteed along with better security, since the embedding takes place only in the high frequency regions that produce minimum image degradation. The performance of this method is affected by the correlation of the image, wherein a highly correlated image is preferred. Table VIII summarizes the related references.

## VI. OBSERVATIONS, DISCUSSION, AND RECOMMENDATIONS

### A. Observations

- Chaotic based randomness: even though chaotic based LSB steganography achieves higher security, the payload capacity attained is low, and there exists low robustness against statistical and geometric attacks.
- Secret message encryption-based approach: this concept provides higher security, but the complexity is high, especially while using substitution-permutation encryption.
- Image encryption: using standard encryption techniques, multilevel encryption techniques, and chaotic based techniques provides good security. However, the overall system overhead is high.
- Virtual multi-bit plane-based steganography: this paradigm achieves better payload capacity and higher security as the possibility of randomness is greater. Nonetheless, the secret data can deteriorate if there is a slight stego image change by attackers. It is particularly vulnerable to non-statistical steganalysis (geometrical attacks) such as rotation, scaling, and cropping.
- Region based steganography: these techniques achieve good robustness and security, but the embedding capacity in general is low.

### B. Discussion

Hiding secret information inside a cover image without introducing suspicious artefacts is the main objective of image steganography. In addition, high security, good imperceptibility, and high embedding rate are desirable and challengeable goals. Researchers have been working on enhancing the performance of steganographic algorithms in terms of achieving high security, high imperceptibility, and high payload capacity. Yet, the optimum goal has not been reached since the challenging criteria oppositely affect each

other. When the main consideration is security, the technique should hide the presence of embedded data inside the cover image from the attacker's attention. In addition, it should obscurely hide the data so that attackers cannot identify the original secret message even if they detect its presence. Several concepts have recently been utilized to achieve high security in image steganography.

For securing steganographic techniques, the concept employed most widely is encryption, which has been used to add a layer of security. Encryption can be attained utilizing standard encryption techniques such as AES, 3DES, and RSA along with secret keys to enhance the overall system security. On the other hand, user-defined encryption algorithms are also utilized via the concepts of permutation only, substitution only, or both. The level of security can also be boosted much by embedding the secret data in non-sequential order, that is, by using random sequences to scatter the secret bits all over the cover image. Existing chaotic functions are famous for producing random numbers that can be exploited to create random sequences. Further, some researchers rely on varied concepts to generate such randomness. Pixel channels indicator is another paradigm that has been used to indicate the presence or absence of secret information and identifies the color channel being used.

The visual aspects of an image are also utilized to achieve a level of security, since the image is composed of smooth regions and non-smooth regions also known as low frequency and high frequency regions. Embedding data in a smooth area can raise distortion levels; this breaches the confidentiality of secret data. On the other hand, exploiting the non-smooth regions and edges as embedding locations does not leave evidence of the existence of secret data. Employment of number systems to create virtual bit planes is another means of hiding the secret information without creating noticeable distortion as well as of hiding pixels' relations. Such attributes overcome the security limitations of the standard spatial domain techniques. Frequency domain steganography is another approach that has been followed to guarantee the

security of steganography by choosing appropriate locations to embed secret data. This technique avoids manipulating pixels directly and instead uses transform procedures, thereby leading to good imperceptibility. However, the embedding capacity is limited and the computational cost is higher.

### C. Recommendations

The recommendations of this study are as follows:

- Combining edge-based steganography with randomness-based concepts to achieve higher security approaches that resist statistical steganalysis;
- Utilizing the existing encryption methods to add an extra layer of security;
- Applying the adaptiveness concept by combining multiple hiding techniques based on some image attributes or user-defined criteria (techniques such as quad tree search are useful to segregate the cover image into various segments with different attributes);
- Instead of utilizing the entire image to embed the secret data, hiding data in particular regions known as the Region of Interest (ROI), which resists statistical attacks by breaking the statistics relations of adjacent pixels;
- Employing the optimization concept to enhance the security of chaotic based steganography (machine learning techniques are an appropriate method to achieve such a goal);
- Drawing more attention to images in the YCBCR color system, since it has received less attention in this context; and
- Considering 3D for embedding secret data, as very few attempts have been made in this domain.

## VII. CONCLUSION

Image steganography is used to hide secret information inside a cover image. It is frequently used to guarantee confidentiality while sending information over an untrusted network. A comprehensive review of image steganography in the spatial domain was carried out utilizing recent research mainly through IEEE Explore, ScienceDirect, Springer Link, and other databases. Most methods utilize LSB based steganography in the spatial domain and its variants due to its simplicity and effectiveness. In addition, PVD, EMD, PIT have been employed as well. In this work, a review of image steganography in the spatial domain in general and, more precisely, of the security aspect, led to its classification into multiple categories. These categories are as follows: randomization based, encryption based, randomization and encryption based steganographic techniques, image encryption, region-based steganography, multiple bit-planes based, pixel indicator techniques, and other steganographic techniques based on combinations of different concepts. At the end of this review, some discussion of the gaps and the future scope of the above-mentioned concepts has been included. In addition, future recommendations for new and current researchers interested in this field are provided.

**Abstract**—The low-voltage metering box is a critical piece of equipment in the power supply system. The automated inspection of metering boxes is important in their production, transportation, installation, operation and maintenance. In this work, an automated type identification and size measurement method for low-voltage metering boxes based on RGB-D images is proposed. The critical components, including the door shell and window, connection terminal block, and metering compartment in the cabinet, are segmented first using the Mask-RCNN network. Then the proposed Sub-Region Closer-Neighbor algorithm is used to estimate the number of connection terminal blocks. Combined with the number of metering compartments, the type of metering box is classified. To refine the borders of the metering box components, an edge correction algorithm based on the Depth Difference (Dep-D) Constraint is presented. Finally, the automated size measurement is implemented based on the proposed Equal-Region Averaging algorithm. The experimental results show that the accuracies of the automated type identification and size measurement of the low-voltage metering box reach more than 92%.

**Keywords**—Low-voltage metering box; RGB-D image processing; automated size detection; automated type detection; inspection automation

## I. INTRODUCTION

The low-voltage metering box is an important piece of electrical equipment in power systems. It is responsible for measuring and monitoring the electrical energy consumption of end-users, which are ordinary residents, factories or enterprises [1-2]. It plays a pivotal role in ensuring that the power supply in a building is well regulated and efficiently distributed.

The automated inspection of low-voltage metering boxes is important in their production, transportation, installation, operation and maintenance [3-4]. The type identification and structural size inspection are of significance for the safety and the long-term use of the low-voltage metering boxes [5-6]. The type and size inspection refers to the process of examining the structure, physical shape and size of critical components in a metering box [7-8]. The structure and size of these components should be consistent with the relevant standards and regulations to ensure the proper functioning of the metering boxes. The conforming structure and size are prerequisites for a reasonable, safe and reliable layout of components of the metering boxes. The inappropriate type and size may lead to

equipment damage or electrocution accidents, which can reduce the service life of the metering boxes. The type and structural size inspection is essential to ensure the safe and accurate operation of the low-voltage metering boxes and improve the reliability of electrical systems.

The inspection is typically carried out by a qualified technician in accordance with established procedures and guidelines. The technician should check the exterior and interior of the low-voltage metering box, including the appearance, key components, markings, and size measurement, which is labor-intensive and time-consuming. The automated inspection is urgent for a low-voltage metering box [9-12]. To a certain extent, it can improve the management efficiency and extend its service life.

Machine vision and other computer technologies make the automation inspection of metering boxes possible. Wang et al. [13] designed an intelligent detection management system for the low-voltage metering cabinets to optimize the inspection process and improve the detection efficiency. Shen et al. [14] analyzed the failure mechanism of the metering boxes to further improve their production process. Xu et al. [15] and Weng et al. [16] introduced image-based intelligent monitoring for the low-voltage metering cabinets to guard against theft and facility damage. However, there has been little research about the automatic type identification and size measurement of the low-voltage metering boxes.

To improve the efficiency of industrial production, there have been some studies on the size measurement of workpieces based on image processing and recognition technology. Three common approaches for size measurement are the monocular vision method, the binocular vision method and the structured light method, which are described as follows. (1) The monocular vision method is a commonly used method that uses a single camera to capture a workpiece image and combined with prior knowledge to compute the actual size of the workpiece [17]. Li et al. [18] proposed an axial dimension detection method for a corrugated compensator based on the image recognition. Chen et al. [19] introduced the Canny edge detection and contour feature extraction algorithm to identify the outer diameter and wall thickness of pipes. Cheng et al. [20] applied the camera calibration to measure the key size of injection-molded products. Yu et al. [21] took the actual height as a reference to calculate the sizes of key parts of the

human body. (2) The binocular vision method uses two images which are acquired from different angles, and the three-dimensional spatial location information of the object can be obtained based on the parallax principle. Xue et al. [22] used the Kinect sensors to identify the size and orientation of square box objects, which can be used in mobile robots handling. Liu et al. [23] achieved an on-site size measurement of large forgings based on binocular stereo-vision and forging scene geometry constraints. (3) The principle of the structured light method for size measurement is optical triangulation [24]. The surface of the object modulates the structured light, and the modulated light is captured by a charge-coupled device (CCD), which forms a two-dimensional distorted image [24]. The 3D coordinates and contour information of the designated point could be obtained based on the distorted image and the location of the modulated light bars.

The automated measurement of the workpiece size based on machine vision generally consists of two steps. The first step is to extract an edge or edge feature points of the workpiece via image processing. Then the two-dimensional coordinates are mapped into 3D space by modeling or calculation to obtain the actual size of the workpiece. Different workpieces have different shapes and physical characteristics. Thus, the size measurement method should be designed based on the characteristics of the captured images. The workpiece size measurement approaches mentioned above almost all focused on the measurement of a single small part. It is not applicable for the external and internal size measurement of the low-voltage metering box.

The low-voltage metering boxes with direct connections are classified into four types: single-phase single-meter metering boxes, single-phase multi-meter metering boxes, three-phase single-meter metering boxes, and three-phase multi-meter metering boxes [25]. The phase of a metering box is determined by the number of connection terminal blocks. For a single-phase metering box, the number of connection terminal blocks is four while it is eight for a three-phase metering box. The meter of a metering box is determined by the number of the metering compartments. The accurate automated type identification of the metering boxes remains a difficult problem, due to the illumination, occlusion, and other problems. In particular, the baffle plate in front of the connection terminal blocks significantly affected the detection accuracy.

In this work, an automated type identification and size measurement method for low-voltage metering boxes based on RGB-D (red, green, blue, and depth) images is proposed. The critical components, including the door shell and window, metering compartment, and connection terminal block in the cabinet, are segmented first using the Mask-RCNN network. Then the proposed Sub-Region Closer-Neighbor algorithm is used to estimate the number of connection terminal blocks. Combined with the number of metering compartments, the type of the metering box is classified. To refine the border of the metering box components, the edge correction algorithm based on the Depth Difference (Dep-D) Constraint is presented. Finally, the automated size measurement is implemented based on the proposed Equal-Region Averaging algorithm.

The main contributions of this work are summarized as follows:

- The automated type identification and size measurement method for the low-voltage metering boxes is proposed, based on RGB-D image processing techniques.
- The Sub-Region Closer-Neighbour algorithm for the number estimation of connection terminal blocks is proposed. Based on the calculated number of connection terminal blocks and metering compartment, the type of a metering box is identified.
- For the automatically segmented contour of critical components, the edge correction algorithm is proposed based on the proposed Depth Difference (Dep-D) Constraint in the depth channel. Then, the automated size measurement is implemented based on the proposed Equal-Region Averaging algorithm.

The rest of this paper is organized as follows. Section II introduces the proposed automated type identification and size measurement algorithm for low-voltage metering boxes. Section III describes the dataset and the experimental results. Finally, the conclusions are presented in Section IV.

## II. PROPOSED AUTOMATED TYPE IDENTIFICATION AND SIZE MEASUREMENT ALGORITHM FOR LOW-VOLTAGE METERING BOXES

The low-voltage metering box is a critical component of numerous electrical systems, functioning to guarantee the secure and effective distribution of electrical power [26]. Specifically, this device is utilized to measure and monitor electrical energy consumption within residential, commercial, or industrial settings.

A low-voltage metering box includes two parts: the door shell and the metering cabinet. In the door shell, there are door windows. In the metering cabinet, there are incoming compartment, metering compartment, outgoing compartment, mounting plate, watt-hour meter plug, plug interference fit, plug clearance fit, connection terminal block, and wire. Specially, the sizes of three critical components are essential in the inspection of the low-voltage metering box, which are door shell, door window and metering compartment. The structure of a low-voltage metering box is illustrated in Fig. 1.

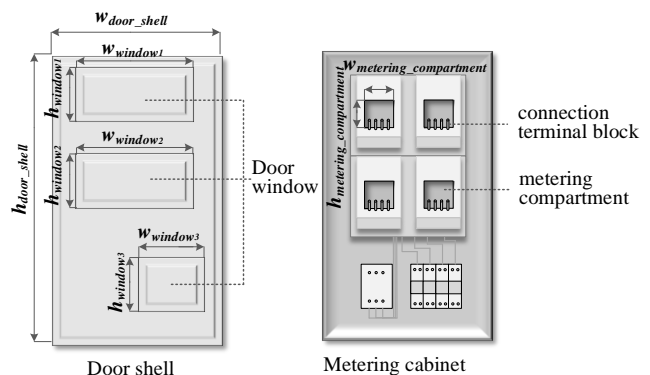

Fig. 1. Structure of a low-voltage metering box.

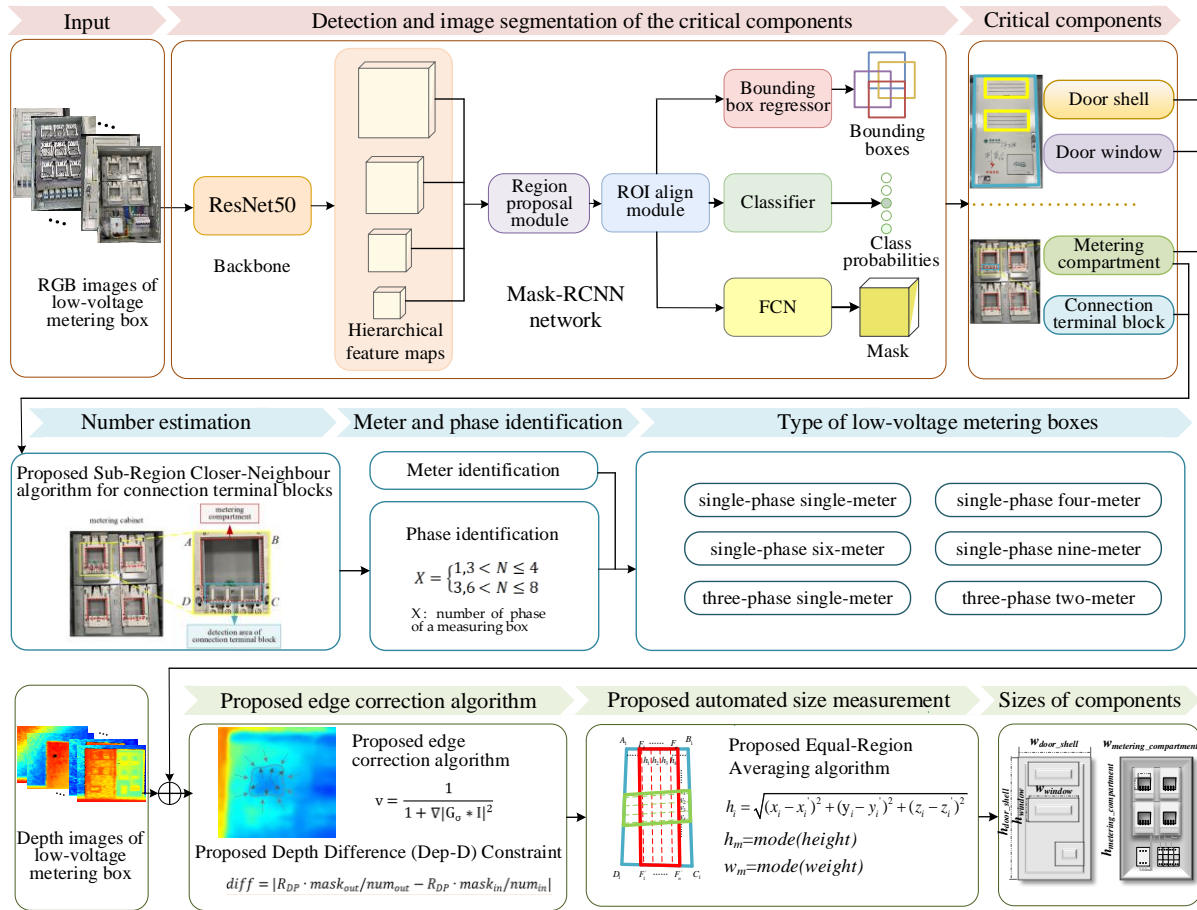

Fig. 2. Flow chart of automated type identification and size measurement for low-voltage metering boxes based on RGB-D images.

The appearance and structure inspection are important in the production, transportation, installation, operation and maintenance of low-voltage metering boxes. The automated inspection could enhance the efficiency of industries, and save labor forces.

In this work, a system for the automated type identification and size measurement of the low-voltage metering boxes is proposed. The overall process flowchart of the system algorithm is shown in Fig. 2.

The critical components of low-voltage metering boxes are detected and segmented by using Mask-RCNN network [27]. The numbers of metering compartments and connection terminal blocks are detected automatically based on the proposed methods. Then according to the phase and number of meters, the type of low-voltage metering boxes is identified. For the segmented contour of the door shell, door window, and metering compartment, the edge correction algorithm is presented to refine the border of the components in the depth images. The Equal-Region Averaging algorithm is proposed to measure the size of these components in the metering boxes.

#### A. Detection and Image Segmentation of the Critical Components

The automated detection and segmentation of the critical components of the metering boxes in the RGB images is the foundation for the automated type identification and size

measurement. By combining the detection results and segmented masks, the numbers of metering compartments and connection terminal blocks in the cabinet can be calculated, which are key for the classification of various types of low-voltage metering boxes.

The size inspection of the critical components is the basis for the production, transportation, installation, and maintenance of the metering boxes. All the parts must comply with the requirements in the design drawings and the relative specifications and standards. By combining the detection and segmentation results with the depth information, the sizes of the critical components can be calculated.

Mask-RCNN is a powerful object detection and instance segmentation network. It extends the multi-task network structure based on Faster R-CNN, which, in addition to learning bounding boxes and class labels in a multi-task fashion, adds a third branch for predicting object masks. This method combines the advantages of both object detection and semantic segmentation, achieving accurate and detailed object location and precise segmentation in complex scenes. The Mask-RCNN architecture consists of a backbone convolutional neural network, a region proposal network used to generate object region proposals, and a network branch for predicting object masks. The architecture of the Mask-RCNN network is illustrated in Fig. 3.

Fig. 3. The architecture of the Mask-RCNN network.

The backbone network is utilized for hierarchical feature extraction from images, while the region proposal network is employed for object detection and generation of candidate regions. The extraction of candidate regions is essentially bounding box regression. For an external bounding box  $G$  of the target, its four vertex coordinates are denoted by  $(G_x, G_y, G_w, G_h)$ . For the proposed initial rectangular region  $P$ , its four vertices are represented by  $(P_x, P_y, P_w, P_h)$ . Obtaining the target bounding box means finding a mapping  $f$  based on the given  $(P_x, P_y, P_w, P_h)$ . Given a set of parameters  $W$  learned through a network for the given input feature vector  $X$ , it can be mapped to the target feature vector  $Y$ , i.e.,  $Y \approx WX$ , that is:

$$f(P_x, P_y, P_w, P_h) = (\hat{G}_x, \hat{G}_y, \hat{G}_w, \hat{G}_h) \quad (1)$$

$$(\hat{G}_x, \hat{G}_y, \hat{G}_w, \hat{G}_h) \approx (G_x, G_y, G_w, G_h) \quad (2)$$

where the  $(\hat{G}_x, \hat{G}_y, \hat{G}_w, \hat{G}_h)$  is derived by the translations and scale transformations depicted in (5) and (6).

The goal of bounding box regression learning is to solve the four transformations  $t = (t_x, t_y, t_w, t_h)$ , where  $(t_x, t_y)$  represents the translation transformation and  $(t_w, t_h)$  represents the scale scaling. The formulas are shown in (3) and (4).

$$t_x = P_w d_x(P), t_y = P_h d_y(P) \quad (3)$$

$$t_w = \exp d_w(P), t_h = \exp d_h(P) \quad (4)$$

$$\begin{aligned} \hat{G}_x &= t_x + P_x \\ \hat{G}_y &= t_y + P_y \end{aligned} \quad (5)$$

$$\begin{aligned} \hat{G}_w &= P_w t_w \\ \hat{G}_h &= P_h t_h \end{aligned} \quad (6)$$

Based on the above formulas, it can be concluded that the objective function for bounding box regression is:

$$d_*(P) = w_*^T \delta(P) \quad (7)$$

where  $*$  =  $(x, y, w, h)$  and  $\delta(P)$  is the input target parameter,  $w_*$  is the parameter to be determined, and  $d_*(P)$  is the predicted value. By introducing the loss function

$$loss = \sum_{i=1}^N (t_*^i - w_*^T \delta(P^i))^2 \quad (8)$$

the optimization objective of the function is:

$$w_* = \arg \min_{w_*} (t_*^i - w_*^T \delta(P^i))^2 + \lambda \|w_*\|^2 \quad (9)$$

By following the aforementioned bounding box regression process, the desired target bounding boxes are obtained. Mask-RCNN has high detection and segmentation accuracies and generalization abilities, making it suitable for object detection and instance segmentation tasks in complex scenes.

### B. Automated Type Identification Algorithm for the Low-voltage Metering Boxes

The type of low-voltage metering boxes can be determined by the number of connection terminal blocks and metering compartments. In this section, the number of connection terminal blocks is estimated by using the proposed Sub-Region Closer-Neighbor algorithm. Then, the number of metering compartments is added, and the type of a metering box can be determined.

1) *Proposed Sub-Region Closer-Neighbor algorithm for the number estimation of connection terminal blocks:* The single-phase metering box is typically connected to a live line and a neutral line in order to measure the amount of electricity flowing into a building or property. For each meter in the metering cabinet, there are two connection terminal blocks for the incoming and outgoing of live lines, and another two connection terminal blocks for the incoming and outgoing of neutral lines. Therefore, there are four connection terminal blocks in a single-phase low-voltage metering box.

Three-phase meter boxes are connected by two live wires and one neutral wire [28]. Inside a three-phase metering box, a single electric meter requires six terminal connection blocks for the live wires to enter and exit and two terminal connection

blocks for the neutral wire to enter and exit, so the number of terminal connection blocks for a single electric meter inside a three-phase metering box is eight.

Due to the complex structure of the metering boxes, as well as the influence of lighting and shooting angle, there are differences in brightness and shading of the connection terminal blocks on the image. This leads to errors in the automated segmentation algorithm. Moreover, the occlusion of wire or baffle plate in front of the connection terminal blocks will result in incomplete or miss segmentation.

In this paper, a quantity estimation algorithm for connection terminal blocks is proposed, to determine whether the metering box is single-phase or three-phase. The connection terminal blocks are located below the metering compartment, as shown in Fig. 4. Fig. 4 shows the inner surface of a low-voltage measuring box, the red dashed box shows the metering compartment region segmented based on the Mask-RCNN network. The four corners of each metering compartment are labeled as A, B, C and D. The connection terminal block region is defined as a quadrilateral I, with a length of  $\max(L_{AB}, L_{CD})$  and a width of  $\max(\frac{1}{2}L_{BC}, \frac{1}{2}L_{AD})$ , which is symmetric with respect to the corner C and corner D connection line.

In the defined detection region, if there are connection terminal blocks inside, the number of connected domains is calculated, and set to N.

With the number of phase of a low-voltage measuring box denoted as X, the phase discrimination of the low-voltage metering box is shown as follows:

$$X = \begin{cases} 1, 3 & 3 < N \leq 4 \\ 3, 6 & 6 < N \leq 8 \end{cases} \quad (10)$$

When the average number of connection terminal blocks in a metering box is close to four, this low-voltage metering box is a single-phase metering box; when the average number of low-voltage metering box is close to eight, the low-voltage measuring box is a three-phase metering box.

Fig. 4. Schematic diagram of connection terminal block detection region.

Under an occlusive situation, the connection terminal blocks might be incompletely segmented. However, the proposed number estimation algorithm could still detect the

number of the connection terminal blocks, and determine the phase of the metering box.

2) *Number estimation of metering compartment*: Based on the segmented results of the metering compartments, the number of metering compartments is estimated by counting the number of metering compartment regions. The metering compartment might be incompletely segmented. Under this situation, the count in the region is still taken. The number of metering compartments is set as  $M, M=1, 2, \dots, k$ .

### C. Edge Correction Algorithm Based on the Depth Difference (Dep-D) Constraint

Due to the influences of factors such as the shooting angle, illumination and shooting time of the depth camera, there may be errors in the edge of  $R_0$ . To correct the edge of  $R_0$  and reduce the impact on the accuracy of subsequent size measurement, an edge correction algorithm based on the depth difference constraint is proposed. The algorithm pseudocode is as follows:

<b>Algorithm 1</b> Edge correction algorithm based on the Dep-D Constraint	
<b>Input:</b>	
1.	$I(x, y)$ : The depth image $R_{DP}$ .
2.	$E_0(x, y)$ : The edge of $R_0$ .
<b>Output:</b>	
3.	$E_{out}(x, y)$ : The corrected edge of $R_0$ .
4.	$C_i(x, y) \leftarrow E_0(x, y)$ // The initial contour
5.	<b>repeat</b>
6.	$C_i.normal \leftarrow \text{normalize}(C_i(x, y))$ // The direction of contour movement
7.	$v \leftarrow 1/(1 + \nabla G_\sigma * I ^2)$ // The speed of contour movement
8.	$C_i(x, y) \leftarrow \text{movement}(C_i, C_i.normal, v)$ // Move the contour in the specified direction and speed
9.	$mask_{out}, mask_{in}, num_{out}, num_{in} \leftarrow \text{template}(C_i)$ // Establish templates based on the shape and size of $C_i$
10.	$diff_i \leftarrow  I \cdot mask_{out}/num_{out} - I \cdot mask_{in}/num_{in} $ // The constraint condition
11.	$diff.append(diff_i)$ // Store the results of each loop into an array
12.	<b>until</b> $diff_i = \max(diff)$

1) *Steps of the proposed edge correction algorithm*: The steps of the proposed edge correction algorithm are as follows:

Step 1: Set the edge of  $R_0$  ( $E_0$ ) as the initial contour.

Step 2: Move each point on the contour to make it closer to the true edge. To improve the correction speed, the direction of contour movement is the normal direction of the contour curve where the contour is located. The speed of contour movement is controlled by the depth gradient corresponding to the point, which is calculated as follows:

$$v = \frac{1}{1 + \nabla|G_\sigma * I|^2} \quad (11)$$

where  $v$  is the calculated speed of contour movement,  $G_\sigma$  represents the Gaussian kernel, which smooths the image, and  $I$  denotes the depth image  $R_{DP}$ . If the gradient is small, it indicates that the point is far from the real edge, and the motion speed is increased; otherwise, the motion speed is decreased.

Step 3: After all points in the contour are changed, the constraint condition for the contour is calculated. Steps 2 and step 3 are repeated until the constraint conditions are met.

2) *Constraint condition based on the proposed outer and inner templates*: In this work, two structure templates are proposed to build the constraint condition. The two structure templates are illustrated in Fig. 5.
