The agricultural sector requires significant improvements. Although farmers' income has steadily increased over the years [1] [2] [3] [4], they are often limited to selling their crops through middlemen. This traditional approach to connecting farmers with consumers makes it difficult for newcomers or individuals interested in farming to enter the agricultural sector. New farmers must find middlemen to ensure

profitability from their farms, as they lack a direct marketplace to sell their crops to consumers. Additionally, the agriculture supply chain has proven to be unreliable, particularly during the COVID-19 pandemic, which has caused disruptions and restrictions on movement [5]. As a result, crops have gone to waste due to the lack of middleman services for distribution. However, the challenges associated with crop distribution could be mitigated through widespread adoption of urban farming. Urban farming has the potential to improve access to healthy and nutritious food [6]. Urban farmers operate at various scales, ranging from small gardens to large-scale operations that incorporate systems like hydroponics for indoor farming. Currently, urban farming is not popular due to inefficiencies in farming practices within urban areas. Many medium to large-scale urban farmers do not reside near their farms, leading to inconvenience as they need to frequently travel to their farms located at a distance from their homes. However, constant monitoring is necessary for efficient crop production, leaving farmers with no choice but to visit their farms regularly. The trade-off between a farmer's time and crop production efficiency makes the concept of urban farming less appealing to urban dwellers.

Hence, the main goal of this work is to promote the idea of urban farming. To achieve this objective, an easy and approachable marketplace needs to be built. An online marketplace is perfect as it allows farmers to sell their crops without the need to meet anybody or be physically present. The concept of anyone being able to start farming indoors or in their garden and sell their produce through a mobile application makes urban farming more appealing to urban dwellers. Therefore, this project involves the creation of a mobile application that can host a marketplace for urban farmers to sell their crops. Additionally, a monitoring system is included in this application to reduce the frequency of farmers needing to be physically present at their farms. This saves a tremendous amount of time, especially for urban farmers. With these two functionalities in the application, along with the ability to generate profit, the concept of urban farming will become more and more popular. One significant advantage of urban farming is that it encourages people to buy fresh crops since the purchased crops are farmed near their location. This eliminates the need for preservatives used to prolong the shelf life of crops in traditional agricultural supply chains. In such chains,

some crops may no longer be fresh, resulting in waste as they lose their appeal for sale.

The remainder of this paper has been organized as follows: Section II discusses the background of the study. Then, Section III described the system implementation and testing. Section IV describes the results and discussion meanwhile the conclusion is described in Section V. Lastly, future works is mentioned in Section VI.

## II. BACKGROUND OF THE STUDY

In an article published on January 13, 2020, in The Malaysian Reserve, former two-time Finance Minister Tun Dr. Daim Zainuddin emphasized the importance of making agriculture more profitable and attractive to younger people. He highlighted that such a transformation would have significant benefits for Malaysia, including reducing the country's import bill, creating employment opportunities, and boosting federal revenue [7]. The consistent growth in demand for food supplies and vegetables further supports the viability of the agricultural sector as a solution for Malaysia's economy [8] [9] [10] [11]. In this context, vertical farming has emerged as a promising technology for sustainable food production in urban areas. With 80% of the global population residing in urban areas, where the demand for food supply is expected to become critical in the next 50 years, vertical farming offers a compelling solution [12]. By utilizing vertical spaces such as tall buildings and skyscrapers that are abundant in urban areas, this innovative approach enables the cultivation of crops. Vertical farming not only creates job opportunities in the agriculture and related industries but also addresses the issue of unemployment in urban areas. Additionally, it generates indirect employment through local distribution, community outreach, logistics, and delivery services [13] [14].

m-Commerce, also known as Mobile Commerce, has gained significant popularity as a method of conducting business and shopping using mobile devices [15]. The widespread use of mobile devices and the diverse intentions of users have contributed to its success. Demographic factors such as age, gender, and education play a crucial role in influencing consumers' inclination to use m-commerce applications. Overall, there is a positive consumer intention to utilize m-commerce, indicating that the development of mobile applications can attract younger generations to participate in agriculture by leveraging IoT technology [16]. Fig. 1 provides examples of mobile commerce applications that can be easily installed on smartphones. Moreover, there is a plethora of platforms and applications available that entrepreneurs can leverage to establish their own online businesses, even within the agricultural sector [17].

Fig. 1. Example of m-Commerce application in smartphone [17].

Moreover, various factors such as climate change, the overconsumption of Earth's resources [18], and population growth have emphasized the importance of adopting more sustainable agricultural practices. Traditional farming methods often face challenges due to their vulnerability to adverse weather conditions and a lack of technological advancements and marketing investments [19]. Despite efforts to enhance greenhouse farming, vertical farming still relies on manual order management systems, which are prone to errors and time-consuming mistakes [20]. By integrating a mobile application using m-commerce, these errors can be minimized by providing a backup system and a comprehensive order history, reducing the need for farmers to engage in face-to-face interactions with customers. Additionally, the m-commerce application enables the acceptance of a diverse range of crops, ensuring efficient fulfillment of food supply demands.

Moreover, the utilization of monitoring devices in agriculture is becoming increasingly prevalent and offers numerous advantages over manual monitoring methods. The industry is transitioning from traditional farming to modern, smart farming, which incorporates various technologies such as sensors, computing cores, machinery, and equipment. The integration of the Internet of Things (IoT) and cloud computing is driving this modernization, enabling farming operations with minimal human presence [21] [22]. This combination of technologies allows for real-time monitoring of crucial parameters such as temperature and soil moisture [23] [24]. Farmers can now remotely monitor their farms without the need for physical presence, which is particularly advantageous for those who reside far from their agricultural lands. Long-distance trips to check on farm conditions are no longer necessary. The monitoring system also assists farmers in maximizing crop production while utilizing the same inputs as conventional farming methods [25] [26].

Lastly, with all the benefits come to building mobile application around farming; numerous farming applications are available today, each with its unique functions tailored to specific farms or crops. For instance, there are applications designed to calculate the growth period of corn. However, these calculators are typically specific to corn and cannot be used to determine the growth of other plants.

### A. The Implementation of Smart Farming Application based on the Microcontroller and Automatic Sprinkler Irrigation System of Agricultural Land

Hasiri et al. [27] developed an Android-based application aimed at managing an automatic sprinkler system and monitoring the farm. The application consists of six pages, each offering different user interface (UI) functions. These functions include displaying the average temperature, moisture level, weather information, historical sensor data, scheduling activities such as watering and fertilization, manual watering mode, IoT setup, and application settings. The temperature and moisture levels are categorized into three conditions, and the watering activity can be either automated or manually controlled. Additionally, the application provides a settings page with options to enable or disable the automatic watering system and fertilization activities.

**B. Development of an Android Application for Smart Farming in Crop Management**

The research involves the utilization of unmanned aerial vehicles (UAVs) and an Android application to monitor paddy fields in Kampung Lundang Paku, Kereteh, Kelantan [28]. The Android application processes the images captured by the UAVs, analyzes them, and presents the information as a Normalized Difference Vegetation Index (NDVI) map, which helps monitor the health of the crops and assess the weather conditions. The application also provides the farmer with information regarding rice cultivation, planting schedules, field issues, and supplier details. The application is installed on a smartphone and requires an internet connection to update data in real time. The user interface is designed with user-friendly buttons that allow easy access to the information collected by the drones, and the NDVI map segments the paddy fields to indicate their health using an index ranging from -1 for unhealthy to 1 for healthy conditions.

**C. Mobile Application Development of Hydroponic Smart Farm using Information Flow Diagram**

The objective of this work is to develop an application for managing a hydroponic farm and visualizing data collected by sensors connected to a Raspberry Pi [29] [30] [31] [32]. The sensors are responsible for collecting various parameters such as temperature, humidity, sunlight, pH level, water level, and electrical conductivity. The system utilizes MongoDB as its database system and employs Message Queuing Telemetry Transport (MQTT) for seamless communication between the sensors, Raspberry Pi, and other devices. To access the farm status data, users are required to log in to the application. New users have the option to sign up and provide their Raspberry Pi's Wi-Fi information. The application comprises multiple pages, including a login page, as well as a dedicated page that displays the average values of the sensor data. Additionally, users can obtain further information by clicking on specific data points.

**D. Development of Soil Moisture Monitoring by using IoT and UAV-SC for Smart Farming Application**

The project utilizes both IoT and UAV technology to collect information about farmers' farms and present it through an application [33]. Ground sensors are deployed to gather data, such as soil moisture, which is then transmitted to a UAV drone. The UAV collects the data and stores it in a database. To avoid the need for lengthy cables, the sensor is powered by a solar panel. The UAV has a flight time of approximately 20 minutes. The application allows farmers to access real-time data and supports multiple users, ensuring that each farmer can only view information relevant to their own farm. The application provides detailed sensor data, including soil moisture levels categorized into three stages: "Dry" for moisture levels below 45%, "Humid" for moisture levels between 45% and 79%, and "Wet" for moisture levels exceeding 80%.

**E. Ma-Ease: An Android-based Technology for Corn Production and Management**

A mobile application has been developed specifically for corn farmers to conveniently manage and access information

using their smartphones [34]. The application is built using Java on Android Studio and is designed to be user-friendly. One of its key features is the ability to function without Wi-Fi, which is particularly beneficial for farmers operating in areas with limited internet connectivity, as it can be used offline. The application offers a simple and intuitive user interface (UI) with clear labeling and includes weather forecasts to assist farmers in making informed decisions. It also provides a calculator to estimate crop yield, enabling farmers to plan their farming activities effectively. Additionally, a pest control feature has been integrated into the application, allowing farmers to quickly contact pest control services in case of infestations, thereby helping to prevent crop loss.

The past related works are compared to the proposed method using these feature criteria: -

- a) Application displays sensor reading.
- b) Application is not limited to certain crops.
- c) Application can control device/automation.
- d) Application can work in long range scenario.
- e) Application provides general information about farming.
- f) Application allow user to monitor farm visually.
- g) Application can handle multiple users.
- h) Application has additional feature that have not been mentioned from a – g.

All the applications from the past related works will undergo a checklist to identify the presence of the mentioned criteria. If an application meets a specific criterion, it will be marked as 'Y'; otherwise, if the criterion is not present, it will be marked as 'N'. Next, the Y-Score will be calculated to determine which application has the highest number of 'Y' marks, using formula (1).

$$Y - Score(\%) = \frac{\text{Amount of Y}}{g} \times 100\% \quad (1)$$

The aim of the comparison table is to identify which application offers the most functionality that can effectively address the challenges faced by farmers, particularly those in urban areas. The table will allow for a comprehensive evaluation of the applications based on their features and capabilities, enabling the determination of which application is better suited to accommodate the specific needs of farmers.

TABLE I. COMPARISON BETWEEN EXISTING WORK

Feature REF	a	b	c	d	e	f	g	h	Y-Score
[27]	Y	Y	Y	N	N	N	N	N	37.5
[28]	Y	N	N	Y	N	Y	N	Y	50.0
[29]	Y	Y	Y	Y	N	N	N	N	50.0
[33]	Y	N	N	Y	N	N	Y	N	37.5
[34]	N	N	N	Y	Y	N	Y	Y	50.0
Purposed Work	Y	Y	Y	Y	N	N	Y	Y	75.0

Table I shows the feature comparison between previous works and this work. Based on the comparison table, it is evident that this work offers 25% more features compared to the highest percentage of features available in the previous works. However, to ensure the application remains streamlined and user-friendly, some features have been omitted. Despite this compromise, the application is still able to accommodate most of the needs of farmers, including those in urban areas. By providing a comprehensive set of features, it aims to address the challenges faced by farmers effectively.

### III. THE SYSTEM IMPLEMENTATION AND TESTING

#### A. Hardware Implementation

The necessary hardware components for developing this work include an ESP-32, an Electroconductivity (EC) sensor, and a temperature sensor. These components will be connected as depicted in Fig. 2. The hardware setup will be implemented in a selected hydroponic farm situated at Pertubuhan Kebajikan Villa Harapan in Taman Desa Molek, Melaka. The ESP-32 will be responsible for collecting data from the sensors and calculating the EC value, which will then be transmitted to the database. The formula (2), (3) and (4) is used to calculate the EC value.

Fig. 2. Block Diagram of hardware system.

$$tempCoefficient = 1.0 + 0.0185 \times (temperature - 25.0) \quad (2)$$

\* 'temperature' is the reading of temperature sensor

$$voltageCoefficient = \frac{Voltage}{tempCoefficient} \quad (3)$$

\* 'Voltage' is the reading of EC sensor

$$ecCurrent = \begin{cases} voltageCoefficient \leq 448; 6.84 \times voltageCoefficient - 643.2 & \text{interface 6432} \\ voltageCoefficient \leq 1437; 6.98 \times voltageCoefficient - 643.2 & \text{temperature 25} \\ else ; 5.3 \times voltageCoefficient + 432.2 & \text{time.} \end{cases} \quad (4)$$

\*'ecCurrent' is the EC value that will be sent to the database

The EC value is crucial for monitoring the health of hydroponic crops, as it determines the conductivity and

nutrient levels in the water-nutrient solution. Maintaining the appropriate EC value is vital to ensure optimal growth and development of the plants. In the case of hydroponic farming, if the EC value of the water-nutrient solution is too high, it indicates a high concentration of salts or nutrients. This can lead to an imbalance in osmotic pressure, causing the water-nutrient solution to draw water from the roots of the crops. As a result, the plants may suffer from water stress and eventually wilt or die due to inadequate water supply. On the other hand, if the EC value is too low, it suggests a deficiency of salts or nutrients in the water-nutrient solution. In this scenario, the roots of the plants will primarily absorb water but not enough nutrients, leading to nutrient deficiencies and poor growth. For the selected hydroponic farm, maintaining a desirable EC value of 12.8 mS/cm is important. This value ensures an appropriate concentration of salts and nutrients in the water-nutrient solution, providing optimal conditions for the hydroponic crops to thrive and grow healthily. Regular monitoring and adjustment of the EC value will help maintain the desired nutrient balance and support the overall success of the hydroponic farming system.

The hardware system will operate in fully automatic mode, where the EC value will determine the functionality of the pumps, as shown in Fig. 3. Furthermore, to test the hardware, it has been run at various EC values to observe the intended operation of the ESP-32. The results of all the tests will be tabulated in a table to analyze the occurrences when different scenarios are presented to the hardware.

#### B. Software Implementation

The marketplace hosted in the application will utilize Firebase database to store all the information related to the crops, including price, pictures, descriptions, and more, for sale within the application. Firebase database also provides real-time functionality, allowing the mobile application to receive and display real-time data. Additionally, Firebase Authentication will be used to authenticate users who sign up or sign in to the application. The mobile application will be developed in Android Studio using Java as the programming language. The interface of the mobile application is designed according to Fig. 4. Farmers will have a slightly different interface where they can view their farm conditions and control the pumps and automation systems. On the other hand, customers will not be able to view the farm conditions to respect the privacy of the farmers, but they will have the ability to contact the farmers using the built-in interface within the application. To test the application and database, a series of simulations have been conducted to verify if the application interface is working as intended and if the monitoring interface updates the values of temperature and EC (Electroconductivity) accurately. During the simulations, different scenarios were presented to evaluate the performance of the application. The interface 6432 tested to ensure that it accurately displays the temperature and EC values retrieved from the database in real time. The goal of these tests was to confirm that the monitoring interface effectively tracks and updates the data, providing farmers with up-to-date information about their farm conditions. Additionally, the functionality of the application's interface was thoroughly tested to ensure that all features, such as crop information, pricing, pictures, and descriptions, are

properly stored and retrieved from the Firebase database. This testing aimed to ensure that the application operates smoothly and offers a user-friendly experience for both farmers and customers. By conducting these simulations, any potential issues or discrepancies were identified and addressed, ensuring that the application and database perform reliably and meet the intended objectives.

Fig. 3. Flowchart of automatic nutrient pump and monitoring system.

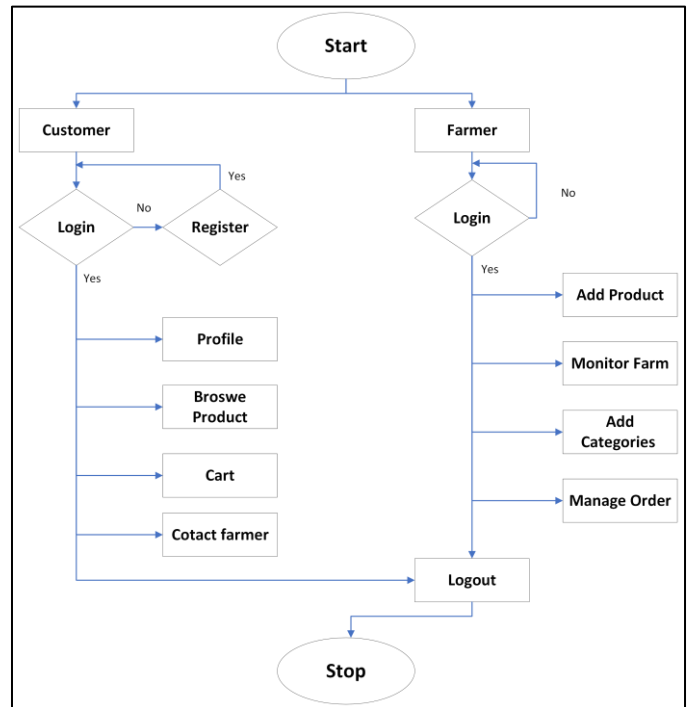

Fig. 4. Flowchart on function available in the mobile application for each type of user.

#### IV. RESULT AND DISCUSSION

##### A. Hardware Test Result

The hardware system has been tested, and its functionality has been tabulated in Table II. The ESP32 is capable of controlling the pumps based on the predetermined conditions set during the upload of EC and Temperature values to the Firebase Database. Additionally, the interval at which the mobile application updates the values has been captured and tabulated in Table III to determine any correlation between the distance between the mobile application and ESP-32 and the interval of information updates.

##### B. Hardware Result Discussion

Based on the test results, we can conclude that the fully automated system with monitoring is functioning as intended. The hardware successfully passed all the tests, achieving a 100% success rate. Thus, the farmer in Villa Harapan can trust the automation system to work as intended and allow them to not be needed in vicinity of their farm, majority of the time. The amount of time saved by not needing to be at their farm will make the concept of urban farming gain attraction.

TABLE II. AUTOMATIC NUTRIENT PUMP AND MONITORING SYSTEM HARDWARE TEST RESULT

Test ID	EC Value in Apps	Fully – Automate Switch in Apps	Pump Switch in Apps	Pump 1	Pump 2	Pump 3	Result
01	<12.8 mS/cm	OFF	Not Relevant	OFF	OFF	Not Relevant	Pass
02	<12.8 mS/cm	ON	Not Relevant	ON	ON	Not Relevant	Pass
03	>12.8 mS/cm	OFF	Not Relevant	OFF	OFF	Not Relevant	Pass
04	>12.8 mS/cm	ON	Not Relevant	OFF	OFF	Not Relevant	Pass
05	Not Relevant	Not Relevant	OFF	Not Relevant	Not Relevant	OFF	Pass
06	Not Relevant	Not Relevant	ON	Not Relevant	Not Relevant	ON	Pass

TABLE III. INTERVAL OF THE APPLICATION UPDATE THE INFORMATION AT DIFFERENT RANGE

Range (m)	Interval 1 (s)	Interval 2 (s)	Interval 3 (s)
5	1.54	1.45	1.37
10	3.47	3.05	3.83
20	2.74	3.38	1.48

Furthermore, the data gathered in Table III indicates that the range of the mobile phone to the farm does not have a significant impact on the time interval of information updates in the mobile application. The main factor causing the inconsistent time intervals is the stability of the network internet connection. The farm is located approximately 30m away from the internet router, which can result in intermittent connection issues for the ESP32, leading to inconsistent data updates in the database. Similarly, the mobile phone also requires a stable internet connection to ensure reliable and instant updates of the latest data in the application. In conclusion, to achieve a more consistent time interval for information updates in the mobile application, it is crucial for both the farm and the mobile application to be in close proximity to the network router or in a location with a stable and reliable internet connection. This will minimize the chances of the ESP32 experiencing connection losses and ensure a smooth and uninterrupted flow of data.

### C. Software Test Result

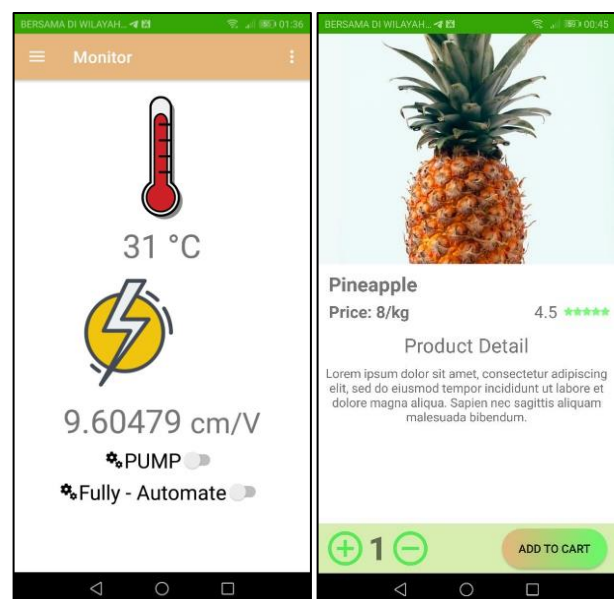

The software was subjected to testing, and the results have been compiled and presented in Table IV. The mobile application demonstrated its ability to handle multiple users simultaneously, enabling a marketplace where customers can search, browse, and purchase products. Additionally, customers have the option to contact the farmer to inquire about the status of their orders. The mobile application also provides access to farm information and allows users to control automation and pumps, as depicted in Fig. 5. Moreover, the application offers several other interfaces to enhance the user experience. This includes an interface where users can view product details such as descriptions, ratings, and prices. The home interface allows users to browse and search for desired products, while the sign-in interface enables registered users to log in to their accounts. Overall, the software has proven its capability to facilitate a user-friendly and feature-rich mobile application that accommodates multiple users and supports various functionalities, including marketplace access, farm information, and control of automation systems.

TABLE IV. BASIC NAVIGATION FOR APPLICATION SOFTWARE TEST RESULT

Test ID	Test Condition	Result
07	The user sign up customer account.	Pass
08	The user sign in into their account.	Pass
09	User search item in search bar.	Pass
10	User add item into the cart.	Pass
11	User check cart for the item	Pass
12	User buy the product.	Pass
13	User Delete Item in cart	Fail
14	User contact seller	Pass
15	Sign In using admin/farmer account	Pass
16	User Monitor farm	Pass

### D. Software Result Discussion

Based on the test results, it can be concluded that the mobile application is functioning mostly as intended. The application successfully passed 9 out of 10 tests, accounting for 90% of the overall testing process. Thus, the consumer can reliably browse the application and successfully create an order to purchase the crops from Villa Harapan. Since this application is still in development/testing stage, bug is expected, hence the failure one of the features. But with now option to generate profit on using the mobile application, the concept the urban farming surely getting more popular as the urban farmer can start their farm anywhere.

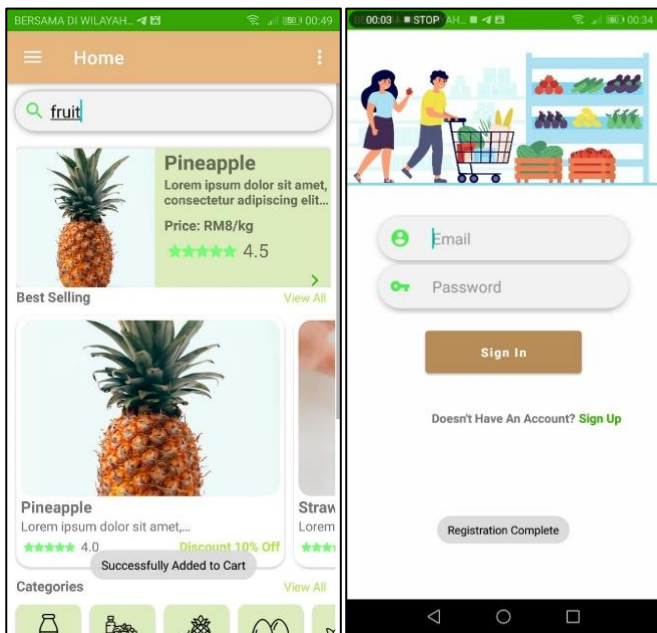

Fig. 5. Mobile application page for monitoring the browse item interface, home interface and sign in interface.

## V. CONCLUSION

This work was developed to help urban farmers to easily sell their crops directly to the customer without relying on traditional method of agriculture that is soon to be rendered obsolete. Furthermore, the work also developed to help urban farmers to monitor their farm wirelessly using the mobile application. With the implementation of IOT, farmers can anywhere check their farm condition even if they have their farms in multiple locations. By not needing to be in vicinity of their farm, it opens many opportunities especially for people in urban area to venture into agriculture sector, hence promoting the idea of urban farming. The chosen farm for testing and implementing this innovation has also reaped the rewards of state-of-the-art, fully automated pump system that can be easily controlled and monitored through a mobile application. Interestingly, according to Table III, the proximity of the farmer to the farm holds no bearing on the latency between updates in the interface, which varies greatly. This can be attributed to the fact that the farm is stationary and therefore, internet quality remains consistent. Essentially, the principal factor contributing to the latency between update intervals is the quality of the farmer's internet connection. The better the internet quality, the shorter the latency period between updates, enabling farmers to remotely control their farm from anywhere with a decent internet connection. Upon the crops reaching maturity, farmers can conveniently sell their produce through the in-built marketplace feature in the application. The introduction of this innovative application provides a practical solution to the growing need for sustainable urban farming and healthy food consumption. With the increasing use of smartphones and mobile applications, this technology offers a convenient and reliable platform for consumers, farmers, and other stakeholders to engage in indoor vertical farming. By incorporating features such as remote farm monitoring, the application enhances the efficiency and productivity of urban

farming, promoting sustainability and self-sufficiency. As more individuals turn to urban farming to address the challenges of food security and limited resources, this application provides a promising step towards a sustainable and equitable future.

## VI. LIMITATION AND FUTURE WORKS

This work has a limitation that can be improved with future works. The monitoring system built is tailor made to the selected farm in this work. So some monitoring features may not be of any use to other farms and thus some may request that feature is missing for other farm. For future work, more research can be conducted to gather data on the most common requested features in farm monitoring mobile application so that the feature can be widely used by variety of farmers especially urban farmers. Besides that, this approach of promoting the concept of urban farming also has a limitation where the user needs to be knowledgeable in technology to set up their online shop and monitoring system. This work only comes with mobile application since we assume user of this application already has his own monitoring system set up. So, if the users don't have the monitoring system set up, and they don't know how to, then the monitoring system feature will be useless to them, making the mobile application and urban farming less appealing in general. Next, the user interface can be improved much better to attract more consumers to use the application boosting the popularity of the application, simultaneously promoting the concept the urban farming to urban people. In future works, more appealed color scheme and modern design in user interface can be built. Lastly, the transaction for purchase in this application is still not diverse compared to other m-commerce applications in the market. In future work, the application can be built with more diverse options to complete the transaction making it more appealing to both consumer and seller. With improvement to this work, the goals to promote the concept of urban farming can achieve greater success.

## ACKNOWLEDGMENT

The authors would like to thank Centre for Research and Innovation Management (CRIM) for the support given to this research by Universiti Teknikal Malaysia Melaka (UTeM).

**Abstract**—Offensive language identification is a critical task in today's digital era, enabling the development of effective content moderation systems. However, it poses unique challenges in low resource languages where limited annotated data is available. This research paper focuses on addressing the problem of offensive language identification specifically in the context of a low resource language, namely the Kazakh language. To tackle this challenge, we propose a novel approach based on Bidirectional Long-Short-Term Memory (BiLSTM) networks, which have demonstrated strong performance in natural language processing tasks. By leveraging the bidirectional nature of the BiLSTM architecture, we capture both contextual dependencies and long-term dependencies in the input text, enabling more accurate offensive language identification. Our approach further utilizes transfer learning techniques to mitigate the scarcity of annotated data in the low resource setting. Through extensive experiments on a Kazakh offensive language dataset, we demonstrate the effectiveness of our proposed approach, achieving state-of-the-art results in offensive language identification in the low resource Kazakh language. Moreover, we analyze the impact of different model configurations and training strategies on the performance of our approach. The findings from our study provide valuable insights into offensive language identification techniques in low resource languages and pave the way for more robust content moderation systems tailored to specific linguistic contexts.

**Keywords**—Offensive language; natural language processing; low resource language; machine learning; deep learning; classification

## I. INTRODUCTION

In recent years, the proliferation of social media platforms and online communication channels has facilitated the rapid exchange of information and ideas on a global scale. There are a lot of application that apply machine learning as image processing, automation, text processing, etc. [1-3]. While this connectivity has brought numerous benefits, it has also given rise to a significant challenge - the prevalence of offensive language and hate speech in online content. Offensive language not only has the potential to harm individuals and communities but also undermines the positive and constructive use of online platforms [3]. Consequently, there is a pressing need to

develop robust and effective systems for offensive language identification and content moderation.

Existing research in offensive language identification has primarily focused on well-resourced languages such as English, Spanish, and French. These languages benefit from abundant labeled data, enabling the application of sophisticated machine learning models that achieve high accuracy in identifying offensive content [3]. However, the same cannot be said for low resource languages, where the scarcity of annotated data poses a considerable obstacle. Low resource languages are typically characterized by limited linguistic resources, including annotated datasets, language models, and pre-trained embeddings [4]. This scarcity hinders the development of effective offensive language identification systems tailored to the linguistic nuances and cultural context of these languages.

In this research paper, we specifically address the challenge of offensive language identification in low resource languages, with a focus on the Kazakh language. Kazakh is a Turkic language predominantly spoken in Kazakhstan and neighboring regions, and it falls into the category of low resource languages due to the limited availability of labeled data and language resources [5]. Our goal is to develop a robust and accurate offensive language identification model that can effectively handle the unique characteristics of the Kazakh language.

To achieve this objective, we propose a novel approach based on Bidirectional Long-Short-Term Memory (BiLSTM) networks, which have shown remarkable success in various natural language processing tasks [6]. The BiLSTM architecture captures both the forward and backward contextual dependencies in the input text, enabling a more comprehensive understanding of the underlying semantics [7]. By leveraging this bidirectional modeling, our approach aims to enhance the offensive language identification performance in the low resource Kazakh language.

However, the scarcity of annotated data in low resource languages poses a significant challenge for model training. To mitigate this issue, we adopt transfer learning techniques,

leveraging pre-trained language models trained on large-scale datasets from high resource languages [8]. By fine-tuning these models on the limited Kazakh offensive language dataset, we aim to transfer the knowledge learned from the high resource languages to improve the performance of our offensive language identification model in the low resource Kazakh language.

In this research paper, we present a comprehensive evaluation of our proposed approach on a Kazakh offensive language dataset. We conduct extensive experiments to assess the impact of different model configurations, training strategies, and transfer learning approaches on the offensive language identification performance. Furthermore, we compare our approach with existing methods and showcase its superior performance, achieving state-of-the-art results in the offensive language identification task for the low resource Kazakh language.

The contributions of this research paper can be summarized as follows: (1) We propose a novel approach based on BiLSTM networks for offensive language identification in low resource languages, specifically focusing on the Kazakh language. (2) We employ transfer learning techniques to leverage pre-trained models from high resource languages and enhance the offensive language identification performance in the low resource setting. (3) We conduct extensive experiments and provide in-depth analysis, shedding light on the impact of different model configurations and training strategies. (4) We demonstrate the effectiveness of our proposed approach through state-of-the-art performance on a Kazakh offensive language dataset.

The remainder of this paper is organized as follows: Section II provides an overview of related work in offensive language identification and highlights the challenges specific to low resource languages. Section III presents the methodology, describing the proposed BiLSTM-based approach and the transfer learning techniques employed. Section IV discusses the evaluation metrics. Section V presents the experimental results. Section VI discusses the findings of our study, provides insights into offensive language identification in low resource languages and discusses future directions for research in this domain. Finally, Section VI concludes the paper.

## II. LITERATURE REVIEW

Offensive language identification has gained significant attention in recent years due to the growing concern over online hate speech and its potential negative impact on individuals and communities [9]. Several studies have focused on developing effective models for offensive language identification, primarily in well-resourced languages such as English, Spanish, and French [10]. However, the challenges associated with offensive language identification in low resource languages remain relatively unexplored [11]. In this literature review, we discuss the existing research and methodologies employed in offensive language identification, with a specific focus on low resource languages. Additionally, we highlight the importance of the Bidirectional Long-Short-Term Memory (BiLSTM) network and its potential in addressing offensive language identification in such languages.

Numerous studies have employed machine learning techniques for offensive language identification. Wulczyn et al. (2017) introduced the Wikipedia Detox project, which focused on detecting personal attacks in English Wikipedia comments [12]. They employed various supervised learning algorithms, including logistic regression, gradient boosting, and deep neural networks, achieving promising results. Similarly, Djuric et al. (2015) explored a feature-based approach using n-grams and syntactic patterns for identifying offensive language in social media texts [13].

When it comes to low resource languages, the scarcity of annotated datasets presents a significant challenge. Few studies have specifically addressed offensive language identification in this context. However, transfer learning techniques have shown promise in mitigating the data scarcity issue. Fortuna and Nunes (2018) utilized transfer learning by leveraging pre-trained embeddings from a high resource language, Portuguese, to identify offensive content in the low resource language, Galician [14]. Their approach demonstrated improved performance compared to traditional methods.

In the realm of offensive language identification, deep learning models have gained significant attention due to their ability to capture complex linguistic patterns and contextual dependencies. Convolutional Neural Networks (CNNs) have been widely applied in this domain. Park et al. (2017) employed CNNs for detecting hate speech in English tweets, achieving competitive performance [15]. Their model utilized multiple convolutional filters of different sizes to capture various levels of linguistic information.

Another notable approach is the use of ensemble models. Davidson et al. (2017) introduced a multi-perspective model that combines CNNs, LSTMs, and logistic regression for hate speech detection [16]. By incorporating different perspectives and modeling techniques, their ensemble model achieved improved accuracy compared to individual models.

Apart from traditional machine learning and deep learning techniques, some studies have explored the use of linguistic features and lexicons for offensive language identification. Schmidt and Wiegand (2017) proposed a feature-based approach using character n-grams, sentiment scores, and part-of-speech tags for identifying abusive language in German [17]. Their findings showed that incorporating these linguistic features enhanced the classification performance.

Furthermore, the development of annotated datasets plays a vital role in training and evaluating offensive language identification models. Many studies have created their own labeled datasets, specific to different languages and platforms. For instance, Founta et al. (2018) curated a large-scale dataset of hate speech and offensive language from Twitter, covering multiple languages, including English, Spanish, and Italian [18]. The availability of such datasets facilitates comparative evaluations and benchmarking of offensive language identification approaches.

In the context of deep learning models, recurrent neural networks (RNNs) have been widely used for offensive language identification. Chen et al. (2018) explored the effectiveness of BiLSTM networks in detecting hate speech in

Chinese social media platforms. Their findings indicated that BiLSTMs capture contextual dependencies effectively, leading to improved performance in offensive language identification tasks [19].

Furthermore, attention mechanisms have been incorporated into RNN models to enhance the understanding of offensive language. Nobata et al. (2016) introduced an attention-based BiLSTM model for abusive language detection in online communities [20]. By attending to relevant parts of the input text, the model achieved better discriminatory power in identifying offensive language.

To provide a comprehensive comparison of the literature, we present a table (Table I) summarizing relevant studies in offensive language identification, including the language, applied method, dataset, and evaluation metrics.

TABLE I. REVIEW OF THE LITERATURE IN OFFENSIVE LANGUAGE DETECTION FOR LOW RESOURCE LANGUAGES

Literature	Language	Applied Method	Dataset	Evaluation
Wulczyn et al. (2017)	English	Logistic Regression, Gradient Boosting, Deep Neural Networks	Wikipedia Comments	Accuracy, Precision, Recall, F1-Score
Djuric et al. (2015)	English	Feature-based approach (n-grams, syntactic patterns)	Social Media Texts	Accuracy, Precision, Recall, F1-Score
Fortuna and Nunes (2018)	Galician	Transfer Learning, Pre-trained Embeddings	Social Media Texts	Accuracy, Precision, Recall, F1-Score
Chen et al. (2018)	Chinese	BiLSTM Networks	Social Media Texts	Accuracy, Precision, Recall, F1-Score
Nobata et al. (2016)	English	Attention-based BiLSTM Networks	Online Communities	Accuracy, Precision, Recall, F1-Score
Hassan et al. (2019)	Arabic	Deep Learning Models	Social Media Texts	Accuracy, Precision, Recall, F1-Score
Imran et al. (2018)	Urdu	Feature-based Approach, SVM	Twitter Data	Accuracy, Precision, Recall, F1-Score
Choubey et al. (2019)	Hindi	Deep Learning Models	Social Media Texts	Accuracy, Precision, Recall, F1-Score
Jha et al. (2018)	Bengali	LSTM, Word Embeddings	Social Media Texts	Accuracy, Precision, Recall, F1-Score

In terms of evaluation metrics, commonly employed measures include accuracy, precision, recall, and F1-score. Accuracy represents the overall correctness of the model's predictions, while precision measures the proportion of correctly identified offensive language instances among all predicted offensive instances. Recall, also known as sensitivity, denotes the percentage of correctly identified offensive instances out of all actual offensive instances. F1-score combines precision and recall to provide a balanced assessment of the model's performance.

In summary, the literature on offensive language identification demonstrates the effectiveness of various machine learning techniques in well-resourced languages. However, offensive language identification in low resource languages remains an underexplored area. The utilization of transfer learning and deep learning models, such as BiLSTMs with attention mechanisms, has shown promising results in addressing offensive language identification challenges. By leveraging these approaches and adapting them to the specific characteristics of low resource languages, we aim to develop an effective offensive language identification model for the Kazakh language in this research paper.

### III. MATERIALS AND METHODS

This paper explores the application of Bidirectional Long Short-Term Memory Networks (BiLSTM) for offensive language detection in text data. It addresses the pervasive issue of offensive language in online platforms and proposes an automated solution that harnesses the power of deep learning [21]. The BiLSTM model, an extension of the traditional LSTM framework, is chosen for its ability to capture temporal dependencies in both forward and backward directions, proving particularly effective in understanding the context of languages.

#### A. BiLSTM

The technique of sequence processing known as a bidirectional LSTM consists of two LSTMs, of which one accepts the input in the forward direction and the other takes it in the reverse direction. In general, the e-BiLSTM is used to extract the hidden connection between the input features and the target, in addition to the information about the long-dependent input sequence [22-25]. Using memory cells to remember long-term historical data and controlling it by means of a door mechanism are the two most important aspects to consider here. The door structure does not provide any information; rather, it acts as a barrier that limits the amount of data that may be accessed. In actuality, the implementation of a gate control mechanism is a multi-level feature selection technique. LSTM is a useful tool that provides several advantages when it comes to the analysis and forecasting of time series data. This is a particular kind of RNN [26]. Both RNN and LSTM have a chain-structured network module in their respective architectures. In RNN, the module is constructed from a single neuron, but in LSTM, it is constructed from cells that each has three gates. The output gate, the input gate, and the forget gate are the three gates that are used by the cell in the process of selecting characteristics [27]. The LSTM loop body is shown in Fig. 1, which may be

found here. The symbols shown in the figure will be referred to in the subsequent equation.

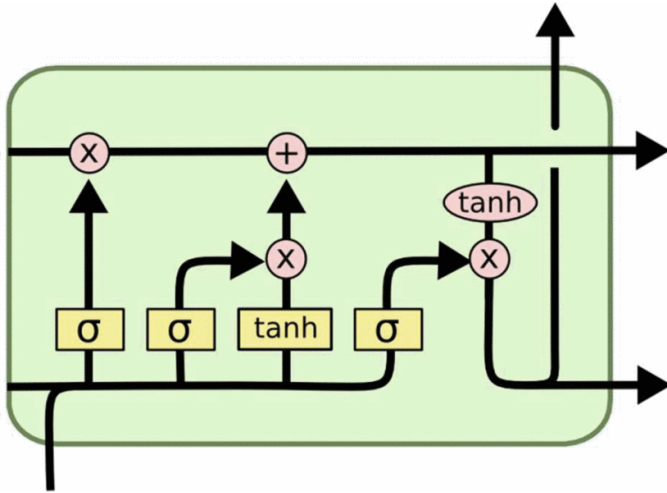

Fig. 1. BiLSTM network.

Fig. 2 illustrates the structure of the cell, which consists mostly of the output gate, the input gate, and the forget gate. The following are some examples of computing methods that may be used with these three different types of gates:

$$input(t) = \sigma(W_i x(t) + V_i h(t-1) + b_i) \quad (1)$$

The equation (2) provides a description of the computing mechanism used by the forget gate in the cell.  $W_f$  and  $V_f$  in the equation are forgotten gate weights, and this gate governs which of the data in the cell must be destroyed. In other words,  $W_f$  and  $V_f$  are forgotten gate weights.

$$forget(t) = \sigma(W_f x(t) + V_f h(t-1) + b_f) \quad (2)$$

The computation procedure of the input gate in the cell is described by Equation (1), where  $h(t-1)$  is the previous cell's output,  $x(t)$  is the current cell's input,  $\sigma$  denotes the sigmoid function, and  $W_i$  and  $V_i$  are the input gate's weights.

$$\tilde{C}(t) = \tanh(W_c x(t) + V_c h(t-1) + b_c) \quad (3)$$

$$C(t) = forget(t) \cdot C(t-1) + input(t) \cdot \tilde{C}(t) \quad (4)$$

The update procedures are described by equations (3) and (4), where (3) denotes the candidate memory unit that creates alternate update data and (4) denotes the updating process of the cell's status. The update data is merged with the information from the forgetting gate to generate a new state, where  $W_c$  and  $V_c$  denote the alternate new state's weights, and  $\cdot$  denotes the Hadamard product.

$$output(t) = \sigma(W_o x(t) + V_o h(t-1) + b_o) \quad (5)$$

$$h(t) = output(t) \cdot \tanh(C(t)) \quad (6)$$

The procedure for calculating the output gate is outlined by equations (5) and (6) respectively. In the first step, the sigmoid layer is used to determine whether or not the cell is in the

output state. The second step involves applying the tanh function to the updated cell status [27]. The third and final step involves multiplying the current cell status by  $output(t)$  to yield  $h(t)$ .  $V_o$  denotes the weight of the output gate. The cell that is mentioned up top serves as the hub of the LSTM neural network. This topology is used as the foundation for the construction of a bidirectional LSTM network, which is then used to extract data properties. Traditional LSTM is superior than bidirectional LSTM in terms of the amount of context data it can extract [28]. The forward and backward time series are used to offer information about the past and future timestamps, which enables the network to more accurately predict time series. Because there is no direct connection between the forward and backward layers, the structure may be described as being acyclic. In the event that the input layer does include data, the results of the backward and forward layers are combined at the output layer in order to form the output. After each feature has been processed by the bidirectional LSTM and has passed through the fully connected layer, all of the features are blended together using the merged layer. Fig. 2 depicts the primary architecture of both the bidirectional LSTM (BiLSTM) and the LSTM neural network.

Fig. 2. BiLSTM network.

Fig. 2 illustrates how the BiLSTM algorithm adds another LSTM layer, which in turn inverts the direction in which information flows. It means, to put it in simple words, that the input sequence is executed in reverse order in the additional LSTM layer. After that, the results of the two LSTM layers are combined using a number of different operations, such as adding, averaging, concatenating, and multiplying the results. Because of this, the amount of information that can be accessed by the network increases, and the context that is given to the algorithm becomes more accurate. In contrast to typical LSTM, the input is allowed to go in both directions, and it may utilize information from either side. Additionally, it is a helpful tool for replicating the sequential connections between words and sentences in both directions, which may be done in either manner.

#### IV. EVALUATION METRICS

In the process of evaluating the efficacy of our proposed LSTM-CNN model, we leverage several widely-accepted performance metrics: accuracy, recall, F-measure, and AUC-ROC (Area Under the Curve, Receiver Operating Characteristic curve) [29-32].

Accuracy is one of the most fundamental metrics, which quantifies the proportion of correct predictions made by the model relative to the total number of predictions. It offers a straightforward measure of the model's overall performance.

However, it's noteworthy that accuracy can be misleading in scenarios where the class distribution is imbalanced.

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP} \quad (7)$$

Recall, also known as sensitivity or the true positive rate, gauges the model's capability to correctly identify positive instances from all actual positive instances. In the context of this study, it would indicate the ability of our model to correctly detect instances of right-wing extremist content among all actual instances of such content.

$$recall = \frac{TP}{TP + FN} \quad (8)$$

F-measure, or F1-score, provides a harmonic mean of precision and recall. It is particularly useful when the data is imbalanced, as it gives a balanced measure of the model's performance, taking both false positives and false negatives into account. An F1-score closer to 1 denotes superior performance, while a score closer to 0 suggests inferior performance.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall} \quad (9)$$

Lastly, the AUC-ROC is a comprehensive evaluation metric that considers the trade-off between the true positive rate (Recall) and the false positive rate at various threshold settings. The AUC, or Area Under Curve, essentially quantifies the entire two-dimensional area underneath the entire ROC (Receiver Operating Characteristic) curve. A model with perfect prediction capability will have an AUC of 1, while a model with predictions equivalent to random guessing will score an AUC of 0.5.

Through the meticulous application of these evaluation metrics, we aim to comprehensively assess the performance of our proposed model on detecting right-wing extremism in online textual content.

### V. EXPERIMENTAL RESULTS

This section demonstrates the results in using BiLSTM network in offensive language detection problem. Fig. 3 demonstrates confusion matrix in classification of seven classes the given text. The obtained results approve that the BiLSTM network is applicable in offensive language classification problem.

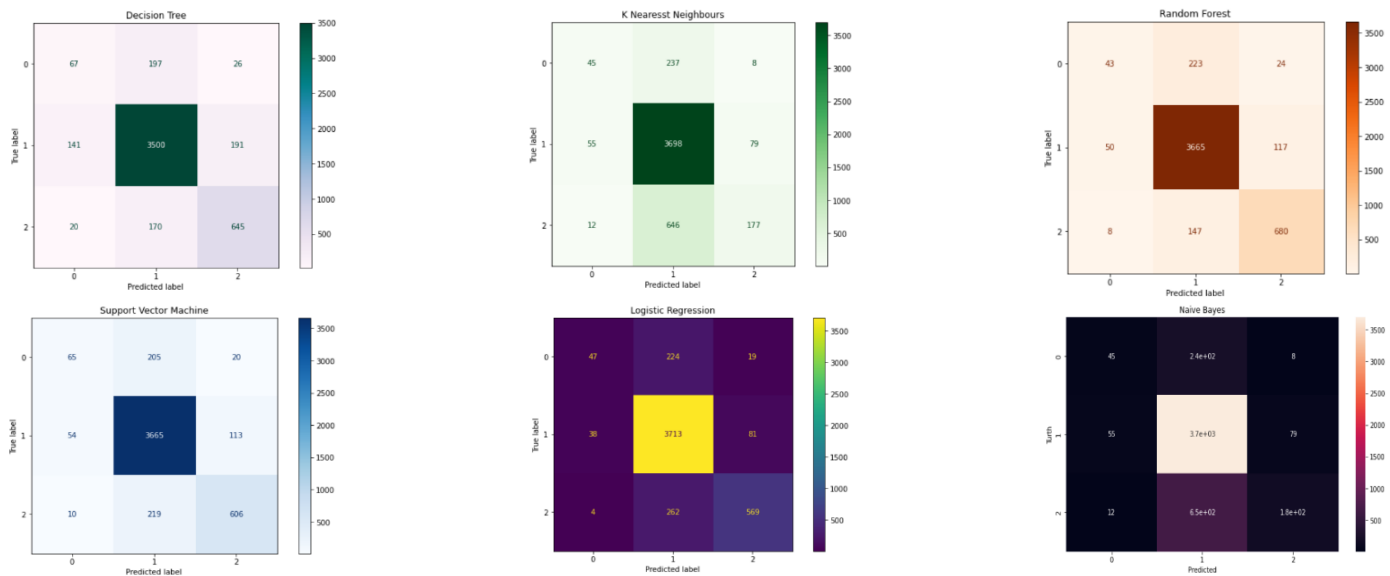

Fig. 3. Confusion matrix in classification of 5 classes.

Fig. 4 demonstrates confusion matrices that obtained using different machine learning methods in three classes offensive language detection as offensive language, positive language and neutral language.

Fig. 4. Confusion matrix using the other models.

Fig. 5 compares AUC-ROC curves of different machine learning algorithms including the explored bidirectional long-short term memory network in binary classification of offensive language. The results show that, the explored BiLSTM network gives high result from the first learning epochs.

Fig. 5. AUC-ROC curve in offensive language detection.

## VI. DISCUSSION

This section discusses the bidirectional long-short-term-memory network in terms of different categories as practical use of the BiLSTM network, advantages of the BiLSTM network, limitations of the BiLSTM network, and future perspectives of the explored model in offensive language detection problem.

### A. Practical Use

The application of BiLSTM for offensive language detection has far-reaching implications in many sectors, particularly in social media moderation and digital community management. One of the significant challenges faced by these platforms is managing the vast volume of user-generated content, which often contains offensive, hateful, or toxic language. The manual moderation of such content is time-consuming, expensive, and prone to inconsistencies. Implementing a BiLSTM-based model can significantly enhance the efficiency of these moderation processes, as it can automatically and continually screen the content for offensive language [32]. This could help in early detection and removal of such content, thereby creating a safer and more inclusive online environment. Furthermore, this model can also be useful for other digital platforms such as news portals and e-commerce websites, where user reviews and comments are often left unchecked. Given the expanding digital landscape, the practical use of this approach is vast and largely untapped.

### B. Advantages of The BiLSTM in Offensive Language Detection

The BiLSTM model offers several advantages in the task of offensive language detection [33]. Its primary strength lies in its ability to process sequences of data in both forward and backward directions, enabling it to extract complex patterns and dependencies in the data. This bidirectional approach allows the model to capture the broader context of language use, which is critical in accurately identifying offensive language that may rely heavily on context and subtleties of language use [34]. Unlike traditional machine learning models that rely on handcrafted features, BiLSTM can automatically learn relevant features from the data, reducing the need for extensive feature engineering. Additionally, BiLSTM models are less prone to the vanishing gradient problem, making them more robust and effective in learning long sequences, a common feature of text data.

### C. Limitations

Despite the many advantages of the proposed BiLSTM model for offensive language detection, there are several limitations to note. First, while the bidirectional structure captures past and future contexts, it can also increase the complexity and computational requirements of the model. This could pose challenges in real-time applications where speed is crucial. Second, the performance of the model heavily depends on the quality and representativeness of the training data. If the training data does not sufficiently represent the diversity of offensive language, the model might fail to generalize well to unseen data. Moreover, the model's output is sensitive to hyperparameters, requiring extensive tuning for optimal performance. Finally, although the BiLSTM model can handle long sequences, it might still struggle with extremely long texts due to its fixed-size hidden state [35].

### D. Future Perspectives

This research focuses on the detection of offensive language within online user-generated content. In contemporary education, various approaches have been adopted to instill ethical values and moral principles in children and students at both the elementary and secondary levels [36-37]. In this study, we employ a machine learning approach, which represents one of the current state-of-the-art methods employed in this field. Despite the challenges, the future perspectives of BiLSTM for offensive language detection are promising. One potential area for improvement is the integration of attention mechanisms, which can allow the model to focus on the most informative parts of the sequence,

potentially improving accuracy and efficiency [38]. Additionally, the fusion of BiLSTM with other deep learning architectures, such as Convolutional Neural Networks (CNN), could also be explored for improved performance. On a broader scale, the adaptability of the model can be improved by incorporating methods to handle the evolving nature of language, such as slang and dialectal variations [39]. Furthermore, developing strategies to effectively handle multilingual and cross-lingual offensive language detection would significantly broaden the applicability of the model. As the research progresses, the integration of these advancements would likely yield a more robust and efficient model for offensive language detection.

## VII. CONCLUSION

This research has delved into the implementation and applicability of Bidirectional Long Short-Term Memory Networks (BiLSTM) for the task of offensive language detection in textual data. The BiLSTM model was identified as a potent solution, proficient at recognizing offensive language patterns due to its superior capacity to handle temporal dependencies and glean both past and future context from data sequences. This feature is of paramount importance considering the intricacies and subtleties of language that influence whether a text is deemed offensive or not.

The proposed model serves as a highly valuable tool for content moderation in digital platforms, promising efficiency and consistency in filtering out offensive content, thereby contributing to safer and more respectful online environments. As compared to traditional machine learning techniques, the proposed BiLSTM model significantly reduces the necessity for meticulous feature engineering by autonomously learning relevant features, and outperforms in the management of long sequences of data.

However, it is equally important to consider the model's limitations. The increased computational requirement is due to bidirectional processing, dependence on the quality of training data, and sensitivity to hyperparameters underline the complexities involved in the application of the model. Despite these challenges, the outlook for the use of BiLSTM in offensive language detection is promising. The potential integration of attention mechanisms or fusion with other deep learning architectures such as Convolutional Neural Networks (CNN) represents avenues for future exploration and improvement.

Furthermore, the model's adaptability could be refined to accommodate the evolving nature of language, including the continual emergence of slang, changes in semantics, and dialectal variations. There is also potential for growth in the handling of multilingual and cross-lingual offensive language detection, thereby extending the model's scope of application.

In conclusion, while challenges and opportunities for further enhancements persist, the proposed BiLSTM model demonstrates considerable potential in addressing the pervasive issue of offensive language in digital platforms. It highlights the potency of deep learning techniques in understanding the complexities of human language, providing automated solutions to challenges that could not be effectively handled

with traditional methods. This research marks a crucial step towards harnessing the power of AI for creating safer, more inclusive digital communication platforms. Future advancements in this field are not only anticipated to yield more robust and efficient models but also offer novel insights into the understanding and modeling of language use in digital media.

# Query-Focused Multi-document Summarization Survey

Entesar Alanzi, Safa Alballaa

Computer Science Department, Imam Muhammad bin Saud Islamic University, Riyadh, Saudi Arabia

**Abstract**—With the exponential growth of textual information on the web and in multimedia, query-focused multi-document summarization (QFMS) has emerged as a critical research area. QFMS aims to generate concise summaries that address user queries and satisfy their information needs. This paper provides a comprehensive survey of state-of-the-art approaches in QFMS, focusing specifically on graph-based and clustering-based methods. Each approach is examined in detail, highlighting its advantages and disadvantages. The survey covers ranking algorithms, sentence selection techniques, redundancy removal methods, evaluation metrics, and available datasets. The principal aim of this paper is to present a thorough analysis of QFMS approaches, providing researchers and practitioners with valuable insights into the field. By surveying existing techniques, the paper identifies the challenges and issues faced in QFMS and discusses potential future directions. Moreover, the paper emphasizes the importance of addressing coherency, ambiguity, vague references, evaluation methods, redundancy, and diversity in QFMS. Performance standards and competing approaches are also discussed, showcasing the advancements made in QFMS. The paper acknowledges the need for improving summarization coherence, readability, and semantic efficiency, while balancing compression ratios and summarizing quality. Additionally, it highlights the potential of hybrid methods and the integration of extractive and abstractive techniques to achieve more human-like summaries.

**Keywords**—Text summarization; query-based extractive text summarization; multi-document; graph-based approach; clustering-based approach

## I. INTRODUCTION

Computers and human interaction have significantly impacted on Natural Language Processing (NLP). The evolution of NLP has a direct influence on numerous fields and serves a wide range of applications. Most importantly, it assists computers in recognizing and understanding human language. Recently, there has been a rapid growth of available documents online. As a result, retrieving helpful information from the vast amount of electronically accessible documents available has become a big challenge. Text summarization can be effectively used to reduce this issue.

Automatic summarization can be categorized based on different factors. Extractive and abstractive summaries are the two major categories [1]. An extractive summary is created by linking some chosen sentences from the input document to form a summary. The output summary presents these selected sentences precisely as they appear in the original text without any changes. In contrast, language-generation algorithms are used to produce an abstractive summary automatically. This

usually requires the system to do sentence compression, paraphrasing, and reformulation to make the summary look more human-like.

Moreover, depending on the number of input documents, summarization can be generally classified as either a single-document or multi-document system [2]. Early studies dealt with a single document where the system presented that document in a shorter form while retaining the most essential information. The use of multi-document summarization has become more critical with the growth of the internet. Given the massive volume of redundant content on the web, summarization can be more beneficial if they offer a concise summary of numerous papers on the same subject.

Summarization can be either a generic or query-focused [2]. A general summary gives an overview of the critical information from the input document to help the reader to understand its contents quickly. In this regard, the content of the entire input document determines the significance of the information. When the summary is generated based to a query, instead, the query itself chooses what data is essential and ought to be included in the output summary.

Query-focused multi-document text summarization (QFMS) is a relatively active automatic summarization subfield with many applications. It is a quick and efficient approach to navigating and grasping web texts, including news, articles, blogs, and data analysis. Search engines use query-focused text summarization methods to produce a summary of retrieved data, which helps the users to grasp the critical content quickly. These techniques save consumers' time, improving the search engine's service.

Moreover, in many sectors nowadays, chatbots automatically respond to users' inquiries and requests made through chat interfaces. A natural-language search query, such as "Return an item," is often the first step in using a chatbot on a shopping website, for example. The chatbot answers by displaying a summary of the results. Additionally, it is crucial for marketing since, through user inquiries, companies may learn more about what attracts customers and save this information through some data collection techniques. As a result, essential business choices may be made by examining and analyzing these unstructured data. Organizations may thus be proactive with their strategies and enhance their poise and confidence.

While existing text summarization surveys have mainly focused on generic summarization, query-focused summarization has received limited attention. To the best of

our knowledge, there are no state-of-the-art surveys investigating query-based summarization problems, such as extracting query-relevant sentences and reducing redundancy. Therefore, the primary motivation of this study is to provide a comprehensive review of existing studies on query-focused multi-document summarization, aiming to assist researchers in improving query-based summaries. This survey delves into two main QFMS approaches, their algorithms, sentence extraction techniques, similarity scoring methods, redundancy removal techniques, evaluation metrics, standard datasets, existing challenges, and future research directions.

The remainder of this paper is structured as follows: Section II presents a detailed description of the QFMS problem. The third section introduces the QFMS approaches and reviews the different methods proposed in the literature for each approach. The discussion of findings, open research problems, and future directions are presented in Section IV. Finally, Section V concludes the paper.

## II. PROBLEM STATEMENT

QFMS resolves the problem of extracting useful information from an extensive amount of data, which improves the effectiveness of obtaining and utilizing information. However, automatic text summarization has many challenges, particularly query-focused ones. Relevancy, diversity, and redundancy are the three main bottlenecks.

A summary must be relevant and provide information based on a given query. Query-based summarization is complicated because the user's query must evaluate the relevance of sentences and choose the ones suitable for inclusion in summary. In addition to selecting the most important information from all document sets, the system is supposed to ensure that the information is based on the specified query. As a result, the query's specific features should be included throughout the summarizing process by calculating the similarity measure between the query and each sentence from the input text and, then sorting the sentences based on the generated scores [3]. Taking into account only the precise match between the query's terms and the terms in the sentences does not provide the best measure. Additionally, doing that to multi-documents sets makes the process potentially more complicated since we have to deal with the variations and similarities across document sets.

Another crucial factor of a robust query-based summary is the diversity [4]. To ensure user satisfaction, different aspects of the question should be considered in the summary to the greatest extent possible. This task is difficult because it demands recognizing and modeling the connections between the sentences and how they relate to the query. Therefore, it is founded that diversity is the most essential and challenging task in QFMS that has interested many researchers lately [4].

Additionally, redundancy is a typical issue that practically all methods of multi-documents automatic summarization encounter [5]. A good summary should be more informative and less repetitive. In single-document summarization, every phrase is distinct and doesn't often contain redundant data. In contrast, information from multi-documents will overlap. In

fact, the information can be repetitive, or it can represent the same concepts in multiple ways without adding any new data. This issue makes the automatic summarization more difficult, as it involves finding and analyzing the connections among the sentences in all texts to remove redundant and repeated data.

The diversity of automatic summarization methodologies comes from different ways of tackling the ranking and selection issues. A ranking problem is a process of ranking all sentences in the input documents. This needs an algorithm that evaluates the importance of each sentence in accordance with the input inquiry. The selection problem is how to choose some of those ranked sentences to create the summary [6]. This requires a model that increases the diversity and decreases the redundancy to form an informative summary under a limited length. Fig. 1 shows a general architecture of a QFMS, which consists generally of the following steps:

1) *Pre-Processing*: This step is done for both input documents and the query. The objective is to reduce noisy and unfiltered text, decrease calculation time, and allow diverse term variants to be treated equally. This can be done using several NLP methods. The following techniques are used in the surveyed literature:

a) *Normalization*: Extends acronyms, lowercase all words, eliminates digits, or changes them to terms, etc.

b) *Tokenization*: Converts each sentence into a list of individual words [2].

c) *Stop-Word Removal*: Stopwords are the commonly used terms in a language, such as: how, are, to, etc. Removing such words drives attention to the important ones. They are irrelevant for search purposes, and they can disturb the result [7].

d) *Stemming*: From a text summarization aspect, stemming is the process of returning the words to their root form [8].

e) *Part-of-Speech Tagging*: Categorizes the terms into nouns, verbs, adjectives, and adverbs [9].

f) *Named Entity Recognition*: Classifies words as item names such as person name, location name, etc.

2) *Processing*: this includes the following:

a) *Creating text representation*: Generating a proper representation of the input documents to simplify the subsequent ranking process and selection. This representation can be graphs, clusters, topic models, etc.

b) *Ranking algorithm*: The input sentences are ranked according to relevance to the query, and they are then arranged from highest to lowest. This step varies depending on the approach being used.

c) *Selecting algorithm*: Choosing the best-ranked sentences considering the limited length. That length can be computed as a number of sentences, number of terms, or a ratio.

3) *Post-Processing*: This can include reordering the sentences, redundant sentence reduction, etc.

Fig. 1. General architecture of a query-focused multi-document summarizer.

### III. LITERATURE REVIEW

#### A. QFMS Approaches

Different approaches have been applied to QFMS, such as graph-based, clustering-based, machine learning-based, statistical-based, semantic-based, optimization-based, etc. [8]. In this survey, two main approaches will be reviewed separately in respective subsections. Fig. 2 presents a classification of the reviewed QFMS approaches.

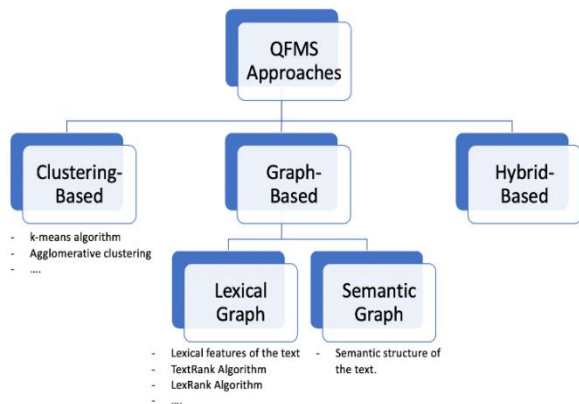

Fig. 2. A classification of the reviewed QFMS approaches.

1) *Graph-based approach*: The graph-based approach has been a commonly used approach for extractive text summarization because of its capacity to create sentence linkages within one document and linkages with sentences on other documents [10]. Particularly, it is best suited to extract a list of the essential query-related sentences from the documents [11]. A graph is a data structure that contains a set of nodes connected with edges. It is a domain-independent [2] and language-independent and can enhance the coherency [8], and reduce the redundancy [5], [12]. In QFMS, to display the input, a graph is employed such that each sentence from the input text is a node, and the weighted edges between nodes and the query measure the similarity between each respective pair. Then, the nodes are ranked using ranking algorithms such as PageRank [13], TextRank [14], and LexRank [15] algorithms to assess each sentence's significance. Finally, the summary is produced by selecting high-ranked sentences [8].

Lei and Zeng [16] used a manifold-ranking algorithm [17] to create a graph where edges represented the degree of similarity to the query and the vertices represented the sentences and the query. According to their study, the manifold ranking system, which used a graph-based placement algorithm, can quickly determine the most relevant and prestigious phrases to answer the query. Their model produced unique top-ranked sentences by modifying the iteration operation, and these sentences were utilized to build a review without the need for extra procedures. In comparison to earlier query-focused summarizing techniques, their method produced high-quality summaries. Wan and Xia [18] also created a multi-modality system that considered both intra-document relevance and other documents' similarities to improve the manifold-ranking algorithm. Their method outperformed the standard manifold-ranking algorithm.

Similarly, Wei et al. [19] argued that the inter-document links (i.e., the edges that link sentences from different documents) are more significant than the intra-document links (i.e., the edges that connect sentences from the same documents). They are supposed to be more comprehensive and able to capture more relevant information from the whole document set. Hence, they assigned the inter-document edges an additional weight compared to the intra-document edges. The results of the proposed approach outperform the best-performing systems in DUC2005. As aforementioned, redundancies are challenging in multi-document summarizations. Balaji et al. [5] presented a graph-based technique for QFMS that effectively minimized redundancies. In this study, graph matching was used to create a global semantic graph, which decreased the number of repeated sentences appearing in the summary.

Mohamed and Rajasekaran [20] created a document graph to represent the text document which has two forms of relations, "is a" and "related to." They made three tries, each time slightly altering the centric graph to include a generic summary. Then they expanded their work to include query-based summaries and finally introduced the query modification technique to incorporate additional query information. Although their solution outperforms many baseline systems in terms of performance, it is ineffective when the query contains a variety of hidden subtopics.

Due to the insufficient information that a query can express, query expansion is proposed [21]. Abdi et al. [22] expanded the terms in the query and the sentences using the Content Word Expansion (CWE) approach. The CWE is based on semantic similarity. Also, Jia et al. [21] proposed a query expansion technique that used -including the query itself- some external resources, which are: WordNet, mean, variance, and TexRank algorithm to expand the query. Better performance was found using their approach.

QFMS has effectively utilized the hypergraph-based concept. . It can provide more precise similarity calculations [27]. Xiong and Ji in [26] developed a vertex-enhanced hypergraph approach. Using the cosine similarity metric, they used a topic model to group sentences according to the probability distribution of their topic. Then they expressed these distributions and the relationship between phrases using the hypergraph. A random walk algorithm determined the score of the sentences on the graph. Experiments on datasets showed an improvement.

Similarly, two summarization approaches are integrated by Akhtar et al. in [28] to benefit from both topic model-based and graph-based approaches. Their scoring technique used only common words for sentence ranking. They would like to enhance their work by considering semantic similarities in future work. Notably, Lierde and Chow [23] pointed out the two critical issues in graph-based summarization. First, the fact that each sentence covers multiple topics. Second, the joint relevance of sentences can't be measured by each sentence's individual relevance score, and this scoring tends to produce redundant summaries. To address these issues, they proposed a new summarizer based on hypergraph transversals, in which the nodes are sentences and the hyperedges are themes (topics). The hyperedge weights reflect both its importance and its relevance to the query. Hence, each hyperedge is associated with a specific topic, each node should belong to multiple hyperedges, and the themes may overlap. A summary is produced by generating a transversal of nodes in the hypergraph. Experiments on DUC 2007 dataset showed that their method outperforms the related graph and hypergraph-based approaches by at least 6% of the ROUGE-SU4 score. However, this approach is restricted to topical similarities between sentences. Authors would like to involve some linguistic features and discourse relations to enhance their model. Similarly, the same authors, Lierde and Chow [24] extended their work to develop a fuzzy hypergraph model where each node represents a sentence and fuzzy hyperedge is a topic. Sentences are scored according to how closely they relate to the query and how central they are to the hypergraph. In future work, the authors would like to improve the readability of their generated summaries.

One of the main drawbacks of the graph-based approach is that it doesn't consider the semantic structure of the sentence [29]. However, some researchers tried to handle this issue by taking into account additional language-dependent parallels, like semantic similarity [30]. Abdi et al. [31] also proposed a query-based summary method that combines sentiment analysis and summarization approaches. The proposed method has two main phases: 1) sentiment analysis, which calculates the sentiment score of each sentence and selects sentences that

have the same sentiment orientation of the opinion of the correlated query and passes them to the next phase 2) summarizer phase, it calculates the total score that combines the query-relevant score with the sentence sentiment score and rank them using a graph-based ranking algorithm. Although using a semantic graph gave good scoring, it required external knowledge sources. In the same manner, several statistical and semantic scoring techniques have been used by Krishna et al. [32] to assess how closely the user query matches the document's sentences, which are Word form similarity, N-gram similarity, Word Order Similarity, and Semantic similarity. Instead of applying a weighted scoring method (where each value has a predefined weight) to determine the overall score, they base it on the average (mean) value obtained using the abovementioned techniques. To avoid redundancy, an iterative clustering process is employed.

Conversely, three statistical features were proposed by He et al. [33] for sentence scoring. Similarity and Skip-Bigram co-occurrence are the first two query-dependent features. The third feature is a text graph's query-independent feature that is used to extract sentences with high information density. However, their approach might not be able to identify semantically equivalent sentences.

To support the assertion that multiple approaches in combination can improve text summarization, Murarka and Singhal [34] developed a hybrid system that combines the Latent Semantic Analysis (LSA) technique [35] and an enhanced PageRank algorithm to address the challenges of QFMS. The results showed a better performance of their hybrid model than many graph-based and semantic-based methods. In fact, PageRank [13] is a well-known graph-based technique to assess the relevancy of web pages by evaluating their related keywords, sentences, and reputable links. It commonly appears in text-summarization methods due to its capacity to extract meaning from texts. The PageRank method is suitable for giving significance to any collection of units with mutual references [36]. PageRank [37] and graph-based relevancy methods are used widely [38]. These graph-based methods emphasize global relevance and PageRank-inspired recursive scoring for phrase relevance. Generally, the model has a simple implementation, fast computation, and is language independent. However, they have reduced readability. Nastase [39] applied a summarization of Wikipedia and heavily relied on PageRank as a mechanism for measuring significance in the process. By utilizing the spreading activation technique in a graph, he visualized the relationship between the query and the documents. To identify the most crucial sentences, topic-expanded terms and activated nodes in the graph were used. Comparing the outcome of this experiment to 30 DUC systems was positive. Thakkar et al. [40] used TextRank in their PageRank-based system. They created a tightly connected graph for the text and applied the TextRank method to extract the relevant terms and assess their importance throughout the entire manuscript. Then they used the shortest path technique to get the sentences for the summary. They claimed that this provided the most diversified summary possible.

2) *Clustering-based approach*: Clustering-based or Sentence Centrality methods for QFMS are used in several

systems [2]. These methods use predefined features to assign scores for all sentence in the input text. After that, the sentences with similar contents will be grouped together in one cluster. In the end, the summary is generated by choosing representative sentences from each cluster. Various methods were developed to define the similarity measure between two objects in the text clustering [41]. The clustering-based approach is suitable for multi-document summarization since it groups different sentences by their topic. However, it requires prior specification of the clusters' amount, and top-ranked sentences may be similar. Hence, redundancy removal techniques are required [42].

Wang et al. [25] defined a clustering-based hypergraph where sentences are nodes and hyperedges are clusters. The sentences are scored using a semi-supervised ranking algorithm. To avoid redundancy, each extracted sentence is compared to previously selected ones before adding it to the generated summary. Chali and Joty [43] used k-means and expectation maximization techniques to determine the relevancy of sentences. Different features were used for weighting, such as lexical, lexical-semantic, statistical, and cosine similarity. Their work showed promising results that could be extended to consider more features, such as a fundamental element, tree kernel-based syntactic features, and shallow-semantic features [44]. Likewise, Naveen and Nedungadi [45] combined the Potential-based Hierarchical Agglomerative clustering algorithm and the k-means algorithm. Cosine similarity was employed to calculate the query-relevant score of each sentence, and the TextRank algorithm was used for ranking the sentences.

For the purpose of enhancing the similarity score between input text and user query, Chandu et al. [46] developed a hierarchical hybrid similarity measure with two tiers to check the similarity between input text and user query. The first tier uses cosine similarity with a threshold of 0.7. Then, for all the sentences passing this threshold, semantic and word order similarities are combined and applied to score the sentences. Redundant sentences are removed by using the DBSCAN and Agglomerative clustering algorithms. Similarly, Rahman and Borah [9] proposed a word sense disambiguation (WSD) method to improve the accuracy of the score for the sense-oriented sentence semantic between the input sentences and the query. The general method used to calculate this score between two sentences includes 1) calculating the Semantic Relatedness score. 2) calculating the Sense Relatedness score, 3) calculating the Word Order Similarity score. 4) finding the final Sense-Oriented Sentence Semantic relatedness score. Furthermore, they measured the informativeness of any sentence based on the presence of five features listed proper noun, numerical data, sentence length, thematic word, and cue phrase. Thus, any sentence that carries these features must be informative. The k-Mean clustering algorithm is employed to create clusters depending on the frequency of the five abovementioned features. Each cluster contains query-relevant sentences. To extract redundancy-free sentences, they established a cutoff point at which one of the sentences will be eliminated if the sense-oriented semantic relatedness score between the two sentences is higher than this cutoff point.

This algorithm achieved competitive results for all best participating models on DUC datasets as well as the current state-of-art QFMS systems.

Integrating various approaches to improve the final summary has received attention from many scholars. Bhaskar and Bandyopadhyay [11] used both graph-based and clustering-based approaches. The graph was reduced to include only seed nodes, which had a total score of all outgoing edges above a threshold. Such a reduction in a dense graph led to an effective execution time. The new graph was clustered to identify shared topical nodes. Each sentence was given a weight that represents the number of query words and keywords covered by that sentence. After using sentence compression, top-scored sentences in each cluster were selected for the summary. The approach gave commendable experimental results on a standard dataset. The performance of their method mainly relied on the selection of seed nodes, and since it is a query-based approach, their method could be enhanced if they consider the query during this reduction. Also, their ranking method is simplified; they just considered the exact match between each sentence and the query in terms of words and keywords. Likewise, clustering and a graph were merged by Canhasi and Kononenko for the summarization [47]. To combine the needed information from the query context and broaden the result options, an archetypal analysis was used. The sentences are grouped into various criteria depending on the type of analysis. The sentence that needs to be evaluated is plotted out on a graph, a score is given based on the relation to the query, which reflects its significance to the query. The weighted method, hence, weighted archetypal analysis, was designed to advance earlier archetypal analysis techniques.

For instance, a system that combines a topic model with graph-based semi-supervised learning was proposed by Li et al. [48]. The topic and sentence layers were the basis for the created graph. The relationship between the topic and sentence vectors was normalized after computing the cosine similarity between them. Sentence clustering was accomplished using a topic modeling technique. They took into account various data, including background and document-specific data. After evaluating this method, the summarization was greatly enhanced. Many scholars found that considering topic-level information might greatly enhance the output summary's quality [49]. He et al. [50] advocated a learning-based strategy that used content terms to rank sentences. They worked with both richness and relevant features, which resulted in a suitable choice of content terms. They used relevance features to give a relevance score to the query. And information richness feature was used to determine the significance of the phrase in the document collection. The scores from the aforementioned features were accumulated to determine the quality of the content term. On test data, their methodology produced promising results. Markedly, many methods have been developed for determining the significance of a sentence based on a query by considering other sentences' features.

These techniques integrated a variety of sentence features with the query's information to rate sentences. These features include term frequency of query, the log-likelihood ratio [6], the term overlap feature, sentence location, and the length of

sentence [26]. Wu et al. 's [1] query-focused summarization method was produced using an unsupervised two pattern-enhanced model. Using LDA topic modeling, the first pattern indicated the topic relevancy of the sentence while the relevance of the query to sentences was presented using the second. The sum of the two patterns for each sentence results was used to determine its importance score to the query. Moreover, to control redundancy during selection, they included a diversity penalty technique named maximal marginal relevance. They claimed that their results outperform state-of-the-art approaches.

The difficulty of scoring several sentences according to a query motivates the development of an interactive learning-to-rank technique to address it by Zhu et al. [53]. The model was initially defined as a sentence ranking issue. The ranking process then considers the connections between the previously chosen sentences and the current sentence in addition to the pertinent context of that specific sentence. The Plackett-Luce model was applied to minimize the likelihood of loss in the ranking function. The sentences in the summary are then chosen using the greedy selection technique based on the defined ranking function. Results from this approach are remarkably positive. An interesting method was proposed by

Woodsend and Lapata [54]. They used particular predictors to construct a model that learnt crucial summary elements independently from training data and then combined them optimally using integer linear programming. The system modeled less redundant content, content's critical and poor places, and stylistic norms, using bigram and positional information along with language modeling. The assessments of the expert learners were then combined using hard and soft constraints by ILP. A considerable improvement in text summarization was obtained using the approach. On the hand, the text-summarization method proposed by Yasuda et al. [55] adds the requirement that at least some terms from the query must appear in the summary. As a result of including that constraint, this optimization challenge was resolved via Lagrangian relaxation. By adding the constraints on the inclusion of query words, both ROUGE-1 and ROUGE-2 scores were increased and thereby increasing the relevance of summaries.

Table I provides an overview of the surveyed QFMS papers, highlighting their main characteristics, approach for selecting query-relevant sentences, redundancy removal techniques, and performance measures on datasets.

TABLE I. OVERVIEW OF A SET OF QFMS PAPERS

Ref/ Year	Approach	Selecting of query-relevant sentences	Redundancy removal technique	Performance
[9],2021	Clustering-based	Sense-oriented sentence semantic relatedness score to score the sentences. Extracted features: proper noun, numerical data, sentence length, thematic word, and cue phrase. Then, K-Means clustering algorithm is applied.	Cluster-based method: If the similarity between two sentences is >60%, then one of them will be removed.	+ The proposed algorithm obtained highest ROUGE score for all three datasets: DUC2005: Rouge1: 0.3951, Rouge2: 0.0893, RougeSU4: 0.1563. DUC2006: Rouge1: 0.5679, Rouge2: 0.1242, RougeSU4: 0.2181. DUC2007: Rouge1: 0.5735, Rouge2: 0.1367, RougeSU4: 0.2371.
[21], 2021	Semantic-graph-based	Sentence scoring= TF-ISF cosine similarity+ word overlap + proximity similarity Manifold Ranking algorithm	Cosine similarity threshold	+ The performance of using expansion of query is better than that using the original query DUC2006: Rouge1: 0.41674, Rouge2: 0.09202 , RougeSU4: 0.15071, Rouge-W: 0.14279. DUC2007: Rouge1: 0.43982, Rouge2: 0.11185, RougeSU4: 0.16870, Rouge-W: 0.15159.
[34], 2020	Semantic-graph-based	1) Jiang-Conrath measure is used to measure the semantic similarity between sentences. 2) Each sentence's cosine similarity to the query is determined. 3) the sentences are ranked using TextRank Algorithm	A similarity function is used to reduce similar sentences.	- Two evaluation metrics were used: ROUGE-N/L and human-based metrics. - They do not cover multi-documents summarization.
[23],2019	Hypergraph-based and topic model-based	Topics are modeled as hyperedges of a hypergraph. Hyperedge weights reflect their relevance to the query.	Hypergraph transversal is generated to capture the information jointly covered by a group of sentences.	+ Ability to produce non-redundant summaries that better cover the relevant topics of a corpus. DUC2005: Rouge2: 0.077392, RougeSU4: 0.12869. DUC2006: Rouge2: 0.10779, RougeSU4: 0.15854. DUC2007: Rouge2: 0.12997, RougeSU4: 0.17995 + It has low time complexity $O(N^2)$ , N is the total number of sentences. - Limitation: Restriction to purely topical similarities. - Authors would like to take the polysemy of terms into account.
[1], 2019	Topic model-based	- Query expansion technique is applied. - Sentence scoring = query-relevance score+ topical- relevance score + sentence position+ sentence length.	Maximal marginal relevance (MMR)[51] + Greedy algorithm [52]	DUC2006: Rouge1: 0.40551, Rouge2: 0.09228 , RougeSU4: 0.14966 . DUC2007: Rouge1: 0.43404, Rouge2: 0.11683, RougeSU4: 0.17026.

[46],2019	Clustering-based, semantic-based	A hierarchical hybrid similarity measure: 1. cosine similarity 2. a weighted sum of word order and semantic similarities. Then, DBSCAN and Agglomerative clustering algorithms are used.	Clustering methods	+ The generated summaries have shown 86% accuracy. - After the redundancy removal phase, their model removes some relevant sentences in their displayed examples. - Collected data from Amrita School of Engineering websites is used as a dataset.
[28],2019	Graph-Based and Topic model-Based	Similarity score: Normalized common words. 1. TextRank algorithm is applied to rank the most important sentences. 2. Two-Tiered topic used to sample query-relevant sentences.	NA	- The proposed method uses only common words for sentence scoring. - The scoring method should be enhanced to include both topical information and linguistic features.
[31], 2018	Semantic-graph-based	1) Sentence Scoring for each sentence = sentiment score + query relevant score . 2) graph-based ranking algorithm is applied to select top ranked sentences.	A Greedy algorithm in [52] is used.	- QMOS approach outperforms other existing methods. - DUC2006: ROUGE1: 0.4123 , ROUGE2: 0.0985, Average ROUGE Score:0.2554 - Used datasets: TAC 2008 and DUC 2006. -The authors would like to distinguish between active and passive sentences before comparing them.
[22],2017	Semantic-graph-based	1- Content word expansion (CWE) method to expand the words in the query and the sentence. 2. Combine: semantic similarity + Word order. 3. a graph-based ranking model is used to ranking the sentences.	A Greedy algorithm in [52] is used.	+ According to the experimental results, the proposed method performs well when compared to other methods. DUC2006: Rouge1: 0.4287, Rouge2: 0.0968, RougeSU4: 0.1673. - The authors intend to enhance their approach by considering recognizing passive and active sentences as well as increasing the semantic knowledge base.

### B. Text Summarization Datasets and Evaluation Metrics

This is an overview of the basic resources used to evaluate and compare QFMS systems presented in the literature review. These resources include standard datasets besides evaluation tools.

1) *Datasets*: Several conferences and workshops have been organized for automatic summarization. To enable progress in this field, these conferences have made available datasets used in extensive research experiments. These datasets have undergone extensive work to prepare them to act as a standard text for summarizing while evaluating various methodologies.

- The Document Understanding Conferences (DUC): is a series of conferences for automatic summarization that are held by the National Institute of Standards and Technology (NIST) [56]. DUC-2005, DUC-2006, and DUC-2007 datasets are designed for extractive QFMS testing. Each data set contains several topics, including various related documents. Reference summaries are available for each topic for evaluation. Filling out some application forms found on the DUC website is needed to access these datasets. Table II shows a summary of these datasets.
- Text Analysis Conference (TAC) [57] : TAC is a group of evaluation workshops that aim to advance research in Natural Language Processing and related applications. It gives access to a massive test collection, standardized evaluation methods, and a platform to share their findings. The tasks from TAC-8 until TAC-15 support the query-based models.

2) *Evaluation metrics*: A system's produced summary can be accurately assessed for readability, succinctness, consistency, and compliance with information requirements using human assessments. Manual examination, however, is infeasible and takes much time. Consequently, it is necessary

to evaluate a summary automatically. Automatic evaluation of a system's generated summary can be done using ROUGE scoring [58]. This acronym means Recall-Oriented Understudy for Gisting Evaluation. It is a set of performance measures used to automatically calculate the quality of a summary. ROUGE compares the output summary to a set of summaries that were manually constructed by counting the number of intersecting units [59]. The intersecting units can be computed using n-grams, word pairs, or word sequences, which correspond to the ROUGE model.

TABLE II. SUMMARY OF USED DATASETS FOR QFMS

	DUC-2005	DUC-2006	DUC-2007
# of Topics	50	50	50
# of documents related to each topic	32-43	25	25
Data source	TIPSTER-TREC	AQUAINT	AQUAINT
Reference summaries for each topic	4 for each of 30 of the topics and 10 for each of 20 of the topic	4 summaries written by 4 different NIST assessors	4 summaries written by 4 different NIST assessors
Size of summary	250 words	250 words	250

## IV. DISCUSSIONS

This section discusses the finding and current challenges that can lead the researcher in future directions.

### A. Findings

This paper surveyed literature related to QFMS techniques. It is an active and attractive variant of automatic summarization due to its wide applications. Furthermore, they are less complicated, more affordable, and typically produce grammatically and semantically accurate summaries.

1) *QFMS approaches*: According to the different approaches for QFMS discussed previously, each approach

has distinct advantages and drawbacks. Most surveyed studies use the graph-based approach, which has shown effectiveness in QFMS due to its ability to enhance coherency and language-independent approach. However, it does not pay attention to the importance of the words in the document, as it assumes that the weights of the words are similar. As well as may be unable to identify semantically equivalent sentences. Consequently, the resulting summary can be less relevant and more redundant. However, some selected studies made different improvements to this approach by considering more language-dependent similarities like semantic similarity that enhanced the caliber of the summaries that were produced.

The clustering-based approach was successfully used to enhance the summaries' diversity and guarantee that all aspects of the needed information from the query were captured. It is appropriate for multi-document summarization because it groups several sentences about the same topic in the documents. Hence, each cluster contains highly related sentences. However, the highly scored sentences may be similar and thus have high redundancy. Therefore, there should be a mechanism for choosing sentences from each cluster that balances diversity, relevancy, and redundancy. Besides, it requires prior specification of the number of clusters. Another issue, some sentences may express more than one topic, but each sentence has to be assigned to only one cluster. The hypergraph-based approach is proposed in [23] to alleviate this issue. Each hyperedge is connected to a particular topic, and each sentence may be tagged with several different topics. Then, each sentence can be a member of various hyperedge.

According to the semantic-based approach, considerable performance has been provided from hybrid approaches that combine semantic-based and graph-based approaches. Some studies argued that QFMS couldn't be solved completely using only one method of the two methods, namely semantic-based and graph-based approaches.

Moreover, some of the overviewed articles have shown the effectiveness of combining topic model-based and graph-based approaches for QFMS to balance the three characteristics of summarization relevance, significance, and diversity. We found that most of the studies that were done concentrated on relevancy to the query by analysing the content of individual sentences depending on the query. Some research employed clustering to diversify the summary, although these algorithms only considered basic lexical similarity clustering [11], [47]. Other scholars are attentive to the diverse selection of the sentences while utilizing a straightforward Manifold method to assign relevancy score [60].

Generally, combining the previously mentioned approaches (graph-based, statistical-based, semantic-based, and clustering-based) would generate better summaries that benefit from their advantages and overcome the drawbacks of every single method.

2) *Extracting query-relevant sentences*: Many extraction techniques have been proposed in the surveyed systems. Most of them used statistical techniques such as TF-IDF and cosine similarity. However, these methods failed to capture semantic

similarities, thus decreasing the relevancy of the generated summary. At the same time, some studies boosted the statistical methods by introducing linguistic methods. The Word sense disambiguation (WSD) technique is proposed in [9] to determine each content word's appropriate meaning in a sentence. Their algorithm gained the highest ROUGE score for all three DUC query-based summarization datasets (DUC 2005, DUC 2006, and DUC 2007). However, the proposed WSD can only accurately determine a word sense if presented in WordNet.

Moreover, expanding query words has effectively solved mismatch problems in sentence comparison by extracting more relevant and essential sentences based on user demand. Hence, enhance the summaries' quality.

Furthermore, it is evident from the previous research that although they all seek QFMS, query-dependent features are given less attention by most of them. Without these query-dependent properties, their variation in speed is minimal.

3) *Redundancy removal techniques*: There are several redundancy removal techniques used in the surveyed literature. Most studies used a greedy algorithm in [52] as a post-processing step to force a diversity penalty on the sentences, which decreases the score of the less informative sentence before adding it to the final summary. Other approaches used the Maximum Marginal Relevance (MMR) [51] method to control redundancy. Moreover, the cosine similarity is calculated between each top-ranked sentence and the previously selected sentences to avoid redundancy. Sentence clustering algorithms are also used to prevent redundant information. In general, most of the redundancy-removal techniques under study rely on lexical similarity across sentences, which leaves semantic redundancies in the resulting summary unaffected. The Maximum Relevance and Coverage (MRC) [24] is suggested as a solution to this problem to maximize the relevancy and joint topical coverage. It showed enhancement compared to other redundancy removal techniques.

## B. Open Research Problems

Any QFMS system should be able to produce summaries of texts based on a query that are as near as possible to those produced by humans. Although many various strategies have been employed for the goal of QFMS, several concerns remain unresolved:

1) *Coherency*: The majority of summary techniques work by selecting the most important sentences to the query and presenting them verbatim. The reader must sense the flow of ideas rather than simply moving from one to the next. It can be beneficial to transfer one sentence to another due to their similarities. Therefore, sentence reordering is crucial, especially in multi-document summarization, since the sentences are from many sources with different flows of ideas. More post-processing techniques can be developed to tackle this issue, making it an active research problem.

2) *Ambiguity*: When determining the degree to which two content terms are semantically connected, sense plays a significant impact. Therefore, ambiguity in terms matters when summarizing statements. The quality of QFMS is indeed diminished by ambiguous words since they can reduce the number of sentences that can be found relevant to the query. Various kinds of ambiguity are known, such as word sense, local ambiguity, form class, structural, syntactical, and form factors [61]. In QFMS, removing ambiguity senses is a rising challenge that can interest many researchers.

3) *Vague reference*: In the multi-document summarization [62], a proper noun may appear in one sentence, and a pronoun may appear in the following sentence to refer to the proper noun. The summarizer will provide an ambiguous reference if it chooses the sentence with the pronoun but not the proper noun. This can open ideas for creating more pre-processing steps to resolve this issue and similar ones to enhance the overall generated summary.

4) *Evaluation*: Another critical challenge is the evaluation procedure. As aforementioned, existing evaluation in automatic summarization works by comparing the automatically generated summary to a human-generated one. This is admirable yet insufficient. Although reference summaries are created by expert humans, we cannot declare with certainty that this is the best summary due to the individual variation in writing and evaluation of the summary. Proposed techniques for QFMS are affected by the evaluation methods and the datasets available. It requires a lot of tools and corpora resources to create a powerful automatic text summarizer. DUCs, for example, produce a summary with 250 terms only. This is challenging for a system to generate a summary of just 250 words that is accurate and consistent with man-made summaries. More efficient ways to evaluate the summary would greatly help the researchers. Moreover, automated quality evaluations for grammar, reference clarity, readability, and coherence are still missing in this field [9].

5) *Redundancy*: Since the input is a multi-document that can share the same sentences and ideas, redundancy has been the main bottleneck when extracting query-relevant sentences. Although many techniques have been developed to reduce this issue, it is still an active and scalable domain.

6) *Diversity*: Designing a QFMS system not only requires extracting the essential sentences from the input but also demands diverse sentences to cover all aspects of the query. Only the sentences directly related to the query's primary request will be selected by a summarizer, leaving out any sub-request. As a result, the summary will concentrate more on the main point and neglect any supporting points that might be equally significant. Employing semantic analysis can help since it takes into account the meaning of every sentence and word. More techniques to handle this problem are open in this area.

### C. Future Research Directions

One of the most interesting issues is how a model can mimic a human's ability to summarize. The sentence information should be coherent, along with being concatenated. The summary's coherence has been a long-standing problem. Existing methods primarily seek to produce informative summaries; nevertheless, future research will be needed to improve the summary's readability by developing coherence scores between pairs of sentences and enhancing the order of sentences in the summary.

In addition, developing novel QFMS methods to generate query-related, higher-quality, and robust summaries under human criteria is a priority. More research needs to be done to improve and discover semantic, linguistic, and statistical features for terms in sentences. This will help systems to process natural language most effectively and to remove redundancy [7]. Additionally, choosing the appropriate query-relevant weights for various features is crucial because the final summary's quality depends on it. Studying new features and their effect on performance can be an eminent research domain.

A higher quality summary can be generated by making the system more intelligent by combining it with hybrid methods and other techniques. Important sentences can be chosen, combined, or compacted, or some information can be removed to provide better quality. A hybrid approach can be developed by combining extractive and abstractive techniques. Research can go on to generate a hybrid approach that combines extractive and abstractive methods to produce a more human-like generated summary.

Moreover, an effective balance between readability, compression ratio, and summarizing quality must be achieved. For QFMS of lengthy materials such as novels and books, larger compression ratios are needed. However, current systems struggle to meet this need [63]. Therefore, it is imperative to provide a more persuading and balanced method.

Automatically evaluating summaries is difficult since it is challenging to develop and apply a good criterion to determine whether the summaries produced by the systems are sufficient and satisfy the query [2]. Additionally, it is challenging to define the optimal summary since systems might produce effective summaries that differ from those produced by humans. Research can be conducted in automatic evaluation, creating new approaches and solutions to assess the query-related summary based on the data it includes, user satisfaction, how it is presented, and the level of readability and coherences.

An interesting future direction was suggested by [7]. The majority of QFMS systems work with text for both input and output. It will be beneficial if new summarizers can accept the input in a format of meetings, videos, audio, etc. Although this kind of input data is a valuable source for information extraction and knowledge discovery, users find it very challenging to track down or identify its occurrences due to their quantity and diversity. Moreover, the output can be in the form of statistics, graphs, tables, visual score measures, etc.

Users will obtain the necessary content faster with the aid of such summarizer systems that enable the summaries' visualization. There have been few works in the video summarization [64]; however, development in this important area is slow and requires more research efforts in the future.

The English language material is the main focus of most QFMS systems. There is a need to dedicate some future efforts to other languages. It is necessary to create and enhance NLP tools such as POS tagging, syntactic and semantic parsing, stemming, and NER that can be used for non-English languages [65]. Moreover, the absence of resources, such as annotated corpora and evaluation tools, is one of the most complicated issues that these types of summarizers must overcome.

Finally, developing a semi-supervised model for QFMS can be a potential future direction. This model can incorporate the user-required phrases to improve the semantic efficiency of the summary while incorporating a higher level of data's feature set. Thus, it may provide a query-based, more intelligent, and useful summary.

## V. CONCLUSIONS

In the last few years, there has been a huge expansion in the volume of text material on the internet. The research area of QFMS is intriguing and has many potential uses. It is a task of returning a concise and coherent response to a query entered by a user from multi-documents input.

This paper reviewed studies based on the main QFMS approaches: graph-based and clustering-based. It discusses their summarization process, advantages, and disadvantages. The findings show that hybrid approaches have been receiving increasing attention due to the satisfactory level of advanced performance. However, the currently generated summaries require further enhancements as they are still far from the quality of the human-generated summaries. Simultaneously, increasing research interest and rapid technological advancements could evolve QFMS and make summaries more relevant, significant, and less redundant.

The paper also underlined multiple open research problems and current challenges in QFMS. Furthermore, it presents future directions that may assist researchers in identifying crucial aspects that require deep investigation and more development.

**Abstract**—This project examines how blockchain technology can enhance data security and reliability for web applications. In this article, ways to improve data security on online course platforms that utilize blockchain technology are explored. To clarify, online course platforms are web-based applications that enable users to access course materials online. These platforms often deal with sensitive data which, if compromised, can cause significant harm to users. Unfortunately, this information is often the target of fraudulent operations and illegal actions aimed at stealing personal data that can be used for authentication on various platforms. This article identifies the weaknesses of these sites and discusses the importance of using complex technologies to safeguard web resources effectively. This research explores how blockchain technology can protect from common web application attacks, which are often aimed at the user authorization process involving the transmission of identification and authentication data from the user to the website database. The study outlines the key components of blockchain technology, including hash function, hash value, data structure, and blockchain classification. Additionally, the study presents a transaction block model for a web course developed using blockchain technology.

**Keywords**—Information security; data security; website protection; blockchain; network attacks; hash functions; web applications

## I. INTRODUCTION

Websites store confidential information such as personal data like email addresses, names, birth dates, and credit card numbers [1]. Therefore, protecting information confidentiality is fundamental for most information compliance regulations today. It is concerning to know that hackers target at least 50,000 websites daily, especially since almost every business has an online presence. Small and medium-sized companies are not exempt as about 43% of attacks are directed towards them [2]. Although there are programs and firewalls available to prevent unauthorized access, there is no foolproof way to protect against hackers as they are always on the lookout for new vulnerabilities and once found, they launch an attack.

This article explores the use of blockchain technology to enhance the security and dependability of data in web applications, specifically the methods employed in online course platforms to safeguard data using blockchain

technologies. Online course platforms are web applications that grant access to online course content. Therefore, a significant concern is preventing theft, unauthorized access, and duplication of online course content belonging to others. Unfortunately, scammers and plagiarists can be a common issue for creators of online training courses [3]. Providing expert knowledge in online courses can be a great way to earn a steady income, but protecting your content from theft is essential. Attackers use various methods to steal content from online course websites such as hacking the server or recording video from the screen to distribute online [4].

It is essential to ensure that your online course platform has top-notch security to prevent these unauthorized activities. Utilizing blockchain technology can effectively safeguard data and avoid unauthorized usage and copying of online course content. There are many ways to protect content from cyber-attacks and unauthorized access. However, with the development of information technology, it is necessary to use relevant methods and models for ensuring data protection, including blockchain technology. Blockchain is a data storage system that operates in a decentralized manner and guarantees the security and reliability of information. The technology creates a chain of blocks where data is stored, and each block is linked to the previous one, enabling easy verification and preventing unauthorized alterations.

By utilizing blockchain technology, it is possible to establish a decentralized registry for content rights, ensuring protection against infringements. In addition, the blockchain system enables users to manage access to information and establish usage guidelines safeguarding content from unauthorized use. With blockchain technology, it is developed to develop a register of content rights and a change control system, which protects against cyber threats. Another benefit of using blockchain technology for content protection is the potential for transparency and clarity in storing and transmitting information. This implies that every block, including information on content rights, will be visible to all users, allowing for monitoring of any changes in data and safeguarding content against potential violations.

One effective method of safeguarding content from cyber-attacks and remote access is using blockchain technology. This

technology provides a decentralized registry for storing information about content ownership and rules for appropriate use. With such measures in place, unauthorized content use is prevented, ensuring that content creators can confidently use their content online without fear of infringement.

The paper discussed various methods of information protection, their mechanisms and structures, and their weaknesses. Finally, the article demonstrated the efficacy of blockchain technology in safeguarding content against cyberattacks and unauthorized access.

## II. RELATED WORK

We reviewed the work of scientists who conducted other studies before using blockchain technology. Sathya A. et al., in their research papers, conducted research on cryptography and blockchain technology and discussed how combining the two technologies could ensure data security. This article deals with various cryptographic attacks on the blockchain and the various security services offered on the blockchain. Blockchain security issues are also analyzed and briefly presented in this article [5]. Ahmed A. et al., in their research work, made a comprehensive analysis of the current new and large-scale level tasks based on the blockchain used in the Internet of Things domain. They have proposed a scalable assessment system in IAR environments, including essential criteria such as bandwidth, latency, and block size for information threats. They also evaluated and differentiated the Most Outstanding Large solutions, highlighting six complex scalability problems for blockchain-based solutions in IoT [6]. Sabri H. et al., in research work, analyzed SHA and MD5 and developed analytical work on the comparative analysis of algorithms and their velocities. SHA-2 and SHA-3 have become industry norms. In this paper, hash methods proposed by other scientists are considered. As a result of the study, it was decided that hash performance plays a vital role in the blockchain and IoT [7]. Naresh K. et al. provided a comprehensive overview of how Blockchain technology is used to ensure Internet security and counter current threats, as well as growing cybercrime and cyberattacks. During the review, they studied how blockchain affects cyber data and information over the Internet. In this paper, they first compiled blockchain architecture and cybersecurity models, classified and discussed the latest and most relevant anti-cybersecurity work, and identified the main challenges and barriers to blockchain technology in response to cybersecurity [8].

## III. WEBSITE PROTECTION MECHANISMS AND ITS ANALYSIS

The World Wide Web is a collection of websites residing in various domains. A segment of the Internet comprises websites hosted within one or multiple domains. Therefore, the Internet can be seen as a compilation of these segments [9][10].

The average security of a segment of the Internet is defined as the ratio of the number of "protected" websites in the studied part to the total number of sites in the studied component.

$$W_i = \frac{s_i}{n_i} \quad (1)$$

where  $W_i$  - security indicator of the  $i$ -th segment of the Internet,

$s$  - the number of secure websites in the  $i$ -th segment,

$n$  - the total number of websites in the  $i$ -th segment,

$i$  - segment number  $i=1,2,..,C$ ,

$C$  - total number of Internet segments.

And the average security of the entire Internet  $W$  is defined as the average security of all its segments:

$$W = \frac{1}{c} \sum_{i=1}^c W_i \quad (2)$$

The security level of a website is evaluated based on a specific method. Websites face risks such as unauthorized access to locally stored information and unauthorized access or modification during data transmission over communication channels [10]. The classification of website protection mechanisms that prevent these types of threats is shown in Fig. 1.

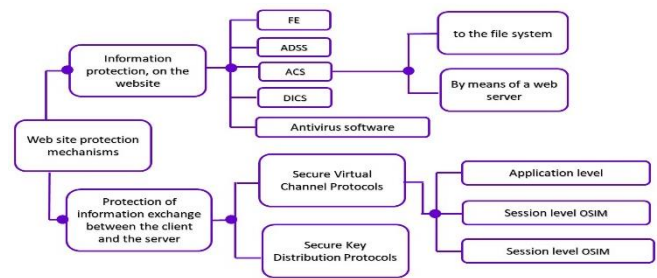

Fig. 1. Website protection mechanisms.

ACS (access control system).

DICS (Data Integrity Control System).

FE (firewall).

ADSS (attack detection system).

OSIM (Open Systems Interaction model).

Any commercial site is at risk of external influence by default – attackers use dozens of ways to hack web pages, regardless of the platform they are made on [11].

The list of "classic" types of attacks [12]:

- SQL injections;
- Cross-site Scripting (XSS);
- Remote Code Execution (RCE);
- Cross-site Request Forgery (CSRF);
- Local and remote inclusion (LFI, RFI);
- Authorization bypass options;
- Automated password selection (Bruteforce).

It is concerning that 85% of websites that use PHP (Hypertext Preprocessor) [13] are at a high risk of dangerous attacks. Even conventional technology websites can be vulnerable to hacking or "dropping" if they don't have enough protection. All websites are at risk of attacks unless they have special safeguards - but even those safeguards have limitations

[14]. Therefore, it's not surprising that attackers are continually improving their tactics and targeting both individuals and corporations.

This research work analyzed the website (www.aliyaschool.kz), which serves as the subject of the study. Due to the pandemic and self-isolation measures, traditional education shifted to online education, making it a crucial part of many fields. Unfortunately, there has been an increase in copyright infringement cases where content is used without permission. To prevent potential material and moral losses, it's essential to safeguard against plagiarism and fraud even before the online course is launched for sale. Therefore, it's necessary to prioritize the security of online course content to prevent theft, distortion, and unauthorized access.

A web course site review was conducted, and Webrate [15] presented statistics revealing a daily traffic volume of 219 unique visitors and 1228 page views. Fig. 2 displays general information about the site.

Fig. 2. General information of the studied web course.

Each visitor makes an average of about 3739 page views (Fig. 3). According to the Alexa Rank statistical ranking system [16], aliya.school.kz traffic occupies 49,006 positions worldwide, while the most significant number of its visitors is from Kazakhstan (Fig. 4), which occupies 211th place. According to these data, there is a demand for web course resources. Therefore, there is a reason to attack it.

Fig. 3. Web course statistics information.

Fig. 5 shows how many visitors visited the website daily for the past 90 days. The last record was on Oct 4, 2022, and about 3,400 visitors visited this site.

Fig. 4. Server location.

In Yandex.Metrica, a sharp surge in direct visits to the site was detected for the area under study, and mobile traffic also increased sharply - direct visits during the day are distributed evenly over time. Therefore, we analyzed the web browser and monitored the data, and concluded that the site was under attack (Fig. 6).

Fig. 5. Web course attendance information.

DDoS attacks (Distributed Denial of Service) are one of the most prevalent and damaging forms of cyberattacks on the internet today. Hundreds of thousands of websites, including government institutions, businesses, media outlets, and non-profit organizations, fall victim to these attacks daily. Unfortunately, attackers continue to develop sophisticated methods to disrupt and block access to internet resources and servers. While there are several effective methods for protecting against DDoS attacks, the increasing complexity of these attacks and the decreasing cost of computing resources means that more than basic protection is required.

Fig. 6. Web course traffic analysis.

#### IV. BLOCKCHAIN TECHNOLOGIES

Initially, blockchain technology was only associated with cryptocurrency. However, over time, this method of data storage has found various applications since the blockchain can contain any digital information about transactions, legal documents, and media files, including photos, video, and audio.

Blockchain technology, as a decentralized environment for storing and executing programs, ensures the immutability of stored data, protecting web applications from unauthorized changes to site scripts and database contents [17]. The load is distributed over devices with identical data, protecting against DDoS attacks [18]. Special libraries track and automatically block malicious requests, protecting servers from unauthorized access [19]. Blockchain technology can protect web applications from cyber-attacks and data leaks. Blockchain technology can be used to build decentralized and distributed networks that can provide DDoS protection and high availability for web applications.

To begin, let's examine the process of constructing a blockchain. Blockchain technology is a decentralized, distributed database governed by many contributors and available to all [20]. It is not a collection of several large databases managed centrally. Data related to each batch of confirmed transactions is stored in a separate block. Each such block is connected to the previous one, as shown in Fig. 7. As information is added, new blocks are created. To include them

in the chain, it is necessary to confirm all participants of the entire network [21].

Fig. 7. Blockchain structure.

- 1) A wants to send money to B.
- 2) Transactions are transferred to the network and collected in a new "block".
- 3) Blocks are sent out for verification to all participants of the system
- 4) Each participant writes a block to their database instance.
- 5) The block falls into the "blockchain", which contains information about all transactions.
- 6) The transaction is completed.

2008 marked a significant turning point for the internet when an individual or group, using the pseudonym Satoshi Nakamoto, released a White Paper detailing a decentralized peer-to-peer electronic payment system called Bitcoin. Satoshi Nakamoto, the creator of blockchain technology, remains unidentified to this day. Recently, Bloomberg corroborated claims that Satoshi is Hal Finney. It's worth noting that Bitcoin is the first iteration of blockchain technology.

It works as a decentralized payment system with simple, smart contracts - conditions for a transaction. The problem is that they need more capabilities.

The second generation is Ethereum [22]. It began with the launch of the eponymous network in 2015. Then, for the first time, developers implemented the advanced functionality of smart contracts [23]. The history of development is shown in Fig. 8.

Blockchain today consists of various cryptocurrencies, NFT tokens [24], crypto exchanges and wallets, stock markets where virtual assets are traded, and much more [25] (see Fig. 8). It is easy to forge paper documents with a hand signature because the source code, a ballpoint pen, and a desire are enough. Electronic documents are stored centrally in one extensive archive, and people enter information into registers, causing them to be susceptible to changes [26]. Legal norms are not sufficient for ensuring document authenticity. The only viable solution is to develop a technical solution.

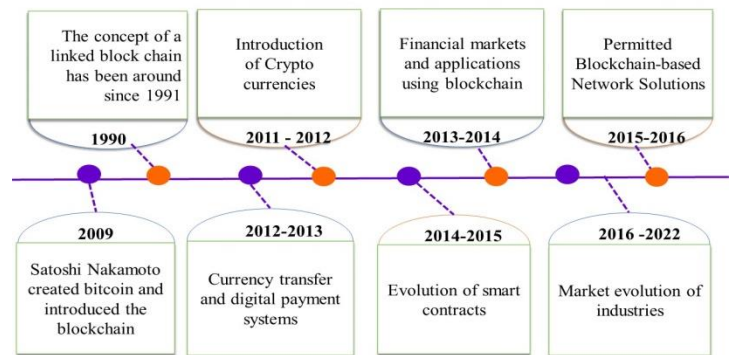

Fig. 8. Blockchain history.

In 1991, American cryptographers Stuart Haber and Scott Starnet came up with an idea to put time stamps on electronic documents, making them impossible to issue retroactively or forge [27]. The documents were sorted by the same marks and collected into one block, forming the prototype of the blockchain. A year later, the technology was improved, including Merkle trees, which made it possible to store more documents in one block.

Another technology that contributed to the emergence of blockchain is a decentralized peer-to-peer network [28]. In such a network, there are typically no dedicated servers, and each node performs the server and client functions. Based on the characteristics and functional features of the blockchain, three types of networks are distinguished: public, private, and consortium, as shown in Fig. 9 [29].

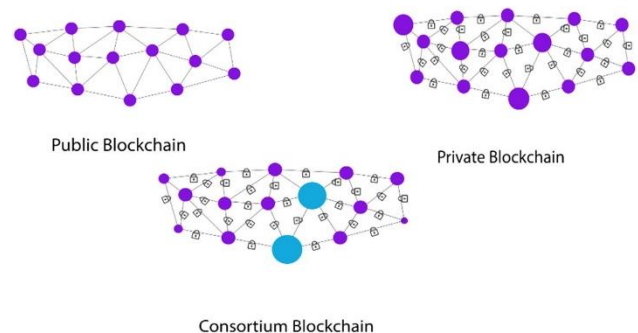

Fig. 9. Types of blockchain network.

According to the source [30], a public blockchain allows any internet user to join or leave the blockchain network without providing identification forms or seeking permission.

A private blockchain [31] assumes that all network participants are known and trustworthy; belong to a controlled community. Subjects can be individuals, such as employees, customers, and organizations (companies or departments within companies). Private network users can have certain types of access to write to the registry. Private Blockchain contains the majority of corporate, industrial, and government projects. Various other actors may have different personal read-only representations of the data (e.g., regulatory officials).

The consortium's blockchain combines elements of a public and private blockchain [32]. An authorized group functions as a validator; validators or authorized persons can limit the network's visibility or have no restrictions.

An essential innovation of the Blockchain protocol is the consensus matching algorithm, which allows you to build an open distributed network where all actors can agree [33]. This mechanism ensures overall reliability in a distributed network of registers. It is assumed that 51% coordinates the content stored in the registers network.

Public Blockchain agreement algorithms for "Proof of Work" (PoW) are shown in Fig. 10 [34].

Fig. 10. Proof of work.

"Proof of Stake" is shown in Fig. 11 (Proof of Stake (PoS) is the most common and popular consensus algorithm.

Fig. 11. Proof of stake.

The Proof-of-Work (PoW) algorithm is designed to require all nodes in the network to compete for a reward when adding a block of records to the end of the chain. This competition involves finding a one-time number using computing power [35].

This creates an incentive model in which the winning node that adds a block to the blockchain is rewarded with digital tokens – bitcoins. To hack the network, an attacker must fight for the right to add a block and compete to create the longest chain.

This undermines the economic incentives of attacks, making them financially costly (the type of attack is Sybil's attack). The Proof of Stake (PoS) algorithm assumes that the miner or validator who creates a new block is chosen deterministically depending on his wealth or share [36].

Open-type blockchains are suitable for a broad community and mainly for solving private tasks, such as exchanging cryptocurrency between users or concluding small transactions using smart contracts [37]. For corporate networks, it is advisable to use a closed type, which allows you to hide certain information. Consensus algorithms are vital for blockchains to remain fully decentralized. Due to the decentralized nature of the blockchain, there will never be a centralized authority that

checks and updates the register with transactions and new data. Therefore, stakeholders in the network should decide on an equal basis which transactions should be added to the blockchain.

For corporate networks, it is advisable to use the closed type, which allows you to hide certain information. Consensus algorithms are vital for blockchains to remain fully decentralized. Due to the decentralized nature of the blockchain, there will never be a centralized authority to verify and update the ledger with transactions and new data. Therefore, the stakeholders in the network must decide on an equitable basis which transactions should be added to the blockchain.

A. Hashing is the Basis of Blockchain Functioning

Cryptographic hash functions are prevalent [38]. They store passwords during authentication, protect data in file verification systems, detect malicious software, and encode information in the blockchain (the block is the central primitive processed by Bitcoin and Ethereum). This article will review hashing algorithms: what is it, what types are there, and what properties they have.

A significant contribution to the development was made by Hashcash, the proof—of—work algorithm developed by Adam Back. It worked like this: each email user added a text stamp to the email header, indicating that the sender had spent some of his time and resources calculating this stamp. The algorithm significantly complicated spam and DDoS attacks on mail servers [39].

A hash function is called any function h:

$X \rightarrow Y$ , easily computable and such that for any message, M is the value;

$h(M) = H$  (convolution) has a fixed bit length;

X is the set of all messages;

Y is a set of binary vectors of fixed length.

As a rule, hash functions are built based on the so-called one—step compression functions  $y = f(x_1, x_2)$  of two variables, where  $x_1, x_2$ , and  $y$  are binary vectors of length  $m, n$ , and  $n$ , respectively, and  $n$  is the convolution length, and  $m$  is the length of the message block.

To obtain the value of  $h(M)$ , the message is first divided into blocks of length  $m$  (in this case, if the message length is not a multiple of  $m$ , then the last block is supplemented to the full in some unique way), and then the following sequential convolution calculation procedure is applied to the resulting blocks  $M_1, M_2, \dots, M_N$ :

$$H_0 = v,$$

$$H_i = f(M_i, H_{i-1}), i = 1, \dots, N,$$

$$h(M) = H_N$$

Here  $v$  is some constant, it is often called an initializing vector. It is chosen for various reasons and can be a secret constant or a set of random data (for example, a date and time sample). With this approach, the properties of the hash function

are entirely determined by the properties of the one-step compression function [40].

There are many cryptographic algorithms out there these days. They vary in complexity, digit capacity, cryptographic reliability, and operation features. However, hashing algorithms are a familiar idea. They appeared more than half a century ago, and there have been little changes from a fundamental point of view for many years [41-42]. However, because of its development, data hashing has acquired many new properties, so its application in information technology has already become universal. In our study, we analyzed cryptographic hash functions.

Comparison of Cryptographic hash functions:

The Secure Hash algorithms are a family of cryptographic hash functions published by the National Institute of Standards and Technology (NIST) as the U.S. Federal Information Processing Standard (FIPS), including [43]:

- SHA-0: A retronym applied to the original version of the 160-bit hash function published in 1993 under the name "SHA". It was withdrawn shortly after publication due to an undisclosed "significant flaw" and replaced with a slightly modified version of SHA-1.
- SHA-1: 160-bit hash function, reminiscent of the earlier MD5 algorithm. This was developed by the National Security Agency (NSA) as part of a digital signature algorithm. Unfortunately, cryptography weaknesses were discovered in SHA1, and after 2010 the standard was no longer approved for most cryptographic applications.
- SHA-2: A family of two similar hash functions with different block sizes, known as SHA-256 and SHA-512. They differ in word size; SHA-256 uses 32-byte words, and SHA-512 - 64- byte words. There are also truncated versions of each standard known as SHA-

224, SHA-384, SHA-512/224, and SHA-512/256. The NSA also developed them.

- SHA-3: A hash function, formerly Keccak, was selected in 2012 after an open competition among non-NSA designers. It supports the same hash length as SHA-2, and its internal structure differs significantly from the actors of the SHA family. Table I compares general and technical information for several cryptographic hash functions.

In blockchain technology, all blocks are interconnected by a complex cryptographic signature called a hash - it is created using complex mathematical algorithms, looks like a generator of letters and numbers, and contains 1024 characters. After the transaction is completed and written to the block, all network nodes receive data about it. In simple terms, a node is a separate computer where the complete and most up-to-date copy of the blockchain is stored [44]. Whenever a new block appears on the network, all nodes update their blockchain.

Most of the current classes of attacks on websites fall on the stage of user authorization, namely the process of transferring identification and authentication data from the user to the website database [45].

In our study, we show login and password hashing using several algorithms and compare their parameters shown in Fig. 12.

Currently, only SHA2 and SHA-3 groups are considered secure. At the same time, it should be regarded that the more characters in the resulting hash in Fig. 12, the more difficult it is to select it. Results of algorithm security analysis hashing against attacks are shown in Fig. 13, which shows the speed of various hashing functions based on the experimental studies of the authors. For hash rate comparison, we use the Intel Iris Xe Graphics G7 96EUs laptop graphics system, which belongs to the Tiger Lake GT2 family and is currently the most powerful integrated graphics.

TABLE I. COMPARISON OF SHA FUNCTIONS

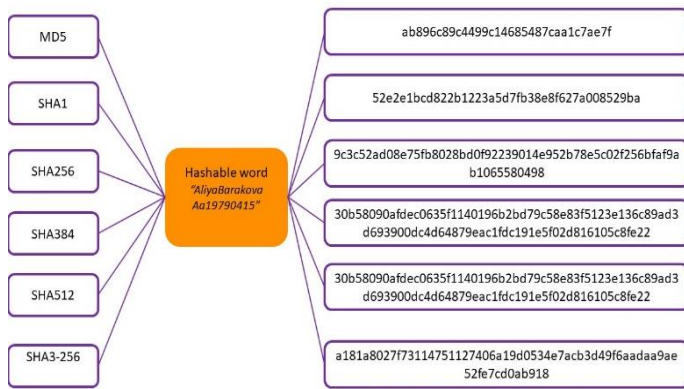

Fig. 12. The result of hashing the username and password.

Fig. 13. Hash brute force values on a modern video card INTEL R IRIS R XE GRAPHICS.

As shown in Fig. 13, SHA512 and SHA3 algorithms and algorithms based on block encryption are the best among the given values regarding hashing speed. With different implementations, the absolute values of hashing rates may vary, but the ratio between their speeds will be maintained.

Hashing functions are widely used to verify data integrity [46]. For example, many software vendors publish their checksums together with the software. After downloading the file, you need to feed it to the hash function and then compare the produced hash with what the software developer published.

In the blockchain, a hash guarantees the block's integrity [47]. Unfortunately, the input data for the hashing algorithm contains the hash of the previous block, which makes it impossible (or at least very difficult) to change the block in the chain: you will have to recalculate the hash of the block itself, as well as the hashes of all the blocks following it.

### B. Securing Web Course Transactions

Using blockchain technologies for online course transactions can significantly increase the trust and attractiveness of these courses in users' eyes. Blockchain technologies provide unique opportunities to ensure the security of web course transactions. They allow you to guarantee the integrity of data and their reliable protection against cyber-attacks and fraud. Furthermore, due to transparency and decentralization, the blockchain facilitates the payment process and is convenient for storing information about participants and their achievements.

The use of blockchain technology for web course transactions has many advantages. It allows you to ensure the

security and transparency of buying and using courses, simplifies the payment process, and improves the ability to manage finances and monitor the use of the course.

Consider building a transaction block model based on blockchain technology for the web course under study. This article proposes to build a block model using lines of code in Node JS. Node (or, more formally, Node.js) is an open-source, cross-platform runtime that allows developers to create server-side tools and applications using JavaScript.

Fig. 14. The general structure of our blockchain.

Our blockchain (see Fig. 14) will be a chain of blocks, and every block will include the following:

- block number [index];
- timestamp [timestamp];
- the value of the hash sum of the previous block [previous hash];
- the value of the hash sum of the current block [hash].

We will include in the transaction content the sender of the funds [sender], the name of the recipient of these funds [recipient], and the amount of funds transferred [amount]. We will include information about only one transaction to the block for simplicity.

A new Blockchain.js file is used to create the block class, here, we create a block class. This work uses the SHA 256 algorithm. First, a hash function is created. Next, to implement the hashing process, it is necessary to use the built-in crypto package from Node.js.

```

class Block {
  constructor(timestamp = " ", data=[]) {
    this.timestamp = timestamp;
    this.data = data;
    this.data = this.getHash();
    this.prevHash = ""; }
  getHash() {
    return SHA256(this.prevHash + this.timestamp +
JSON.stringify(this.data)); }
  const crypto = require('crypto'), SHA256 = message =>
crypto.createHash("SHA256").
update(message).digest('hex');
  class Blockchain{
  constructor () {
    this.chain = [new Block(Date.now().toString()); }
    getlastblock() {
      return this.chain[this.chain.length - 1];}
  addBlock(block){
    block.prevHash = this.getlastblock().hash;
    block.hash=block.getHash();
  }
}
  
```

```
this.chain.push(Object.freeze(block));  
isValid(blockchain = this) {  
  for(let i = 1; i < blockchain.chain.length; i++) {  
    const currentBlock = blockchain.chain[i];  
    const prevBlock = blockchain.chain[i-1];  
    if(currentBlock.hash !==currentBlock.getHash() ||  
prevBlock.hash  
    !==currentBlock.prevHash) {  
      return false; } }  
    return true;} }  
module.exports = {Block, Blockchain}
```

Timestamp is a sequence of symbols or encoded information showing when a particular event occurred. Usually indicates the date and time, respectively. With some data, we will get a hash, and we will also have the hash of the previous block. To do this, we will create a const crypto. If something changes every time, then SHA 256 will give us something completely different, and this can guarantee us immutability. In this case, the PrevHash property also plays a significant role in constancy. It ensures that the blocks will remain unchanged throughout the life of our blockchain. Accordingly, if the previous hash does not match, this block will not pass validation, respectively.

Next, let's move on to the next class, and we will create a blockchain class. The first thing we need is a genesis block. The Genesis block is our first block, and technically we have the main first block. Next, we also need to create a function with the last block. There are several functions here. Firstly, this function is for getting the previous block and also a process for adding a block to our blockchain. Finally, we need to know if our chain is valid and a method to check the validation.

Do we have a chain if the block's hash is equal to what its hashing method returns and the prevHash property of the block should be similar to the previous block? Accordingly, we check whether our blockchain is valid and coincides with our expectations. To do this, we export everything. Now let's go to another file stored in the same folder. Let's call it Index.js, and we need to add some data here. This is, firstly, the block, the blockchain that we exported, and the path to this file.

Next, we need to create the blockchain itself. Let's call it TEST. Then we will create an object of our blockchain. Next, we will create a block using this function.

```
const test = new Blockchain();  
test.addBlock(new Block(Date.now().toString(), {from: "Alia", to:  
"Olga", amount: 10}));  
test.addBlock(new Block(Date.now().toString(), {from: "Zhazira",  
to: "Aliya", amount: 20}));  
test.addBlock(new Block(Date.now().toString(), {from: "Asel", to:  
"Baglan", amount: 15}));  
test.addBlock(new Block(Date.now().toString(), {from: "Alma", to:  
"Marat", amount: 25}));
```

Here we will indicate certain data. Here we will have from whom this or that transaction comes, for example, Aliya, then there is a value to whom this block goes, for example, "Olga". Next, write down the number of transactions. In this case, we have created four blocks. And further, we need to add a console to display everything from our block.

```
console.log(test.chain)  
В данном случае мы видим на наш блокчейн  
PS C:\Blockchain> node index.js  
[

  }  
]
```

## V. RESULT AND DISCUSSION

As a result, there is a hash and a previous hash of the last block, respectively. We can compare it with the genesis block, which is shown in Fig. 15. The genesis block is the very first block in the blockchain. We can imagine a blockchain as a series of blocks where each block is connected to its previous block and replicated all over the blocks. The fundamental benefit of this replication is that, in case one of the replicated blocks becomes corrupted, other copies are available to ensure the integrity of the information contained in the data structure. Furthermore, replication provides assurance of the reliability of the data, conveyed as a guarantee that the different computers involved in the blockchain [48,49] platform are running appropriate calculations to ensure the consistency and reliability of the data. In general, our blockchain will look like this. Therefore, blockchain is one of the ways to store data and protect it by making it immutable.

Fig. 15. Type of created blockchain.

## VI. CONCLUSIONS

This research paper provides statistical data from analyzing the studied web course as an experiment. In addition to the standard methods of protecting websites, blockchain technology was studied, and a comparative analysis of hashing algorithms was given for further use when modifying an authentication system. Finally, a model of the transaction block of the analyzed web course based on blockchain technology was built.

In conclusion, it can be noted that most of the current classes of attacks on websites occur during the user authorization stage, namely the process of transferring identification and authentication data from the user to the website database. Although blockchain technology has great potential in authentication systems and provides high security against fraud and forgery, making it especially attractive to provide web resources, it is essential to address technical and organizational issues such as scalability, standardization, and regulation to enable widespread use of blockchain technology in authentication systems. Nevertheless, blockchain technology in authentication systems promises significant benefits for all stakeholders and may become one of the essential cybersecurity trends in the near future.

Further research should focus on developing an authentication system based on blockchain technology using a modified hashing algorithm.

**Abstract**—In recent years, Machine Learning (ML) techniques have been used by several researchers to classify diseases using gene expression data. Disease categorization using heterogeneous gene expression data is often used for defining critical problems such as cancer analysis. A variety of evaluated factors known as genes are used to characterize the gene expression data gathered from DNA microarrays. Accurate classification of genetic data is essential to provide accurate treatments to sick people. A large number of genes can be viewed simultaneously from the collected data. However, processing this data has some limitations due to noises, redundant data, frequent errors, increased complexity, smaller samples with high dimensionality, difficult interpretation, etc. A model must be able to distinguish the features in such heterogeneous data with high accuracy to make accurate predictions. So this paper presents an innovative model to overcome these issues. The proposed model includes an effective multiple indefinite kernel learning based model for analyze the gene expression microarray data, then an optimized kernel principal component analysis (OKPCA) to select best features and hybrid flow-directed arithmetic support vector machine (SVM)-based multiple infinite kernel learning (FDASVM-MIKL) model for classification. Flow direction and arithmetic optimization algorithms are combined with SVM to increase classification accuracy. The proposed technique has an accuracy of 99.95%, 99.63%, 99.60%, 99.51%, and 99.79% using the datasets including colon, Isolet, ALLAML, Lung\_cancer, and Snp2 graph.

**Keywords**—Gene expression; optimized kernel principle component analysis; multiple indefinite kernel learning; flow direction algorithm based support vector machine; arithmetic optimization algorithm

## I. INTRODUCTION

The integration of data tends to be an emerging topic, whereas decision making based on metabolomics and genomic requires better prediction or diagnosis rather than the utilization of clinical data alone [1]. The prediction or classification of diseases dependent upon the medical data requires appropriate methodologies [2]. Machine learning has been widely playing a huge role, especially in biomedical researchers, over the past decades [3]-[4]. This process is partially because of greater advancements in data collection

that have enabled the study of biomedical mechanisms of various diseases, particularly cancer [5]. When the gene expression data are adopted from microarrays comprising high density oligonucleotide arrays (HDOA) or complementary Deoxyribonucleic acid (CDNA), the classification methods are utilized for data examination and interpretation.

Disease classification using heterogeneous gene expression data is greatly utilized for determining fundamental issues like disease analysis and drug detection [6]-[7]. The gene expression data collected from DNA micro arrays are characterized through diverse evaluated variables known as genes [8]. An exact classification of the gene data is very important in order to be able to treat sick people appropriately [9]-[10]. The molecular founded connections over a scale can be analyzed through gene expression data, which can be examined by a significant tool called microarray [11]. A huge amount of genes from the collected data can be observed simultaneously. Still, there are certain drawbacks in processing these data as they comprise noises, redundant data, often prone to errors, increased complexity, smaller sample with large dimensionality, complex interpretation, etc.

Several researches were conducted previously using machine learning approaches to classify diseases using gene expression data [12]-[13]. The major reason behind searching for effective approaches is to predict the survival rates to grab better treatment. The feature selection approaches are highly efficient in eradicating the noisy features, redundant data and are significant in describing the biological features when minimizing the model complexity [14]. The chief focus of the feature selection approach is to reduce the data dimensionality, which improves the overall system performance [15]-[16]. The kernel is generally used to indicate a kernel trick, an approach of utilizing a linear classifier to solve non-linear issues [17]. The Kernel learning transforms linearly inseparable heterogeneous data over separable data. The kernel approaches are better, but parametric assumptions cannot be made and sensible over outliers.

Even though multi-task learning improves accuracy performance, a similarity measure between tasks is highly

required, which is not a priority for many diseases [18]-[19]. The utilization of transcriptomics subjects possesses diverse challenges in interpretation. To overcome this, multiple kernel learning (MKL) permits the combination of pathway data into prediction models that utilize transcriptomics, whereas the interpretation and accuracy can be enhanced. Several studies have been developed through the application of MKL over genomic data. Every MKL method can render an ordering for data type significance that delivers appropriate information [20]. The MKL aims to determine the kernel's best convex integrations to generate the best classifier. Diverse feature components of heterogeneous data with various kernel functions can be mapped to expose the data better in the new feature space.

#### A. Motivation

Predicting and classifying the disease from gene expression data is an extremely challenging task due to the intrinsic nature of the data. Heterogeneous data involves large differences between traits, making predictions difficult for any learning model. In addition, the size of the data is extremely large, leading to several complications. A prominent solution identified to this problem is using meta-heuristics that can optimally tune the parameters, resulting in higher accuracy. In order to achieve better performance of multiple kernel learning, machine learning models are generally adopted, among which the SVM model is highly preferred. Considering all the problems, this proposal focuses on developing a hybrid multi-core learning framework with the hybridization of an effective meta-heuristic with an SVM model to achieve a higher percentage of accuracy in disease classification. The main contributions of the proposed work are:

- To analyze the gene expression microarray data to attain higher accuracy in disease classification, an effective multiple indefinite kernel learning based model is proposed.
- A new approach of optimized kernel principal component analysis (OKPCA) is presented to decrease the dimensions of microarray data by eliminating the unimportant features from the feature space.
- In order to achieve higher accuracy in disease classification using gene expression data, several kernel functions such as radial basis function, sigmoid kernel, polynomial kernel and linear kernel are introduced and integrated into the hybrid flow-directed arithmetic SVM-based multiple infinite kernel learning (FDASVM-MIKL) classification frameworks.
- In order to validate its efficiency against the existing methods, extensive simulations of the proposed method are performed using different metrics.

The proposed research work is organized into various sections. The literature survey of disease classification from gene expression data directed by various researchers is described in Section II. The discussion of the proposed methodology for disease classification from gene expression data is described in Section III. Section IV discusses the simulations performed using simulation tools to analyze the outcomes of the proposed technique. Finally, the conclusion

and the future scope of the proposed technique are provided in Section V with references.

## II. RELATED WORKS

Most researchers have applied various methods to reduce dimensionality across heterogeneous gene expression data. Some of the prominent adopted models are examined as follows.

Liu et al. [21] presented a dimension reduction algorithm to enhance the classification performance and minimize the dimensionality. The dimensionality minimization was carried through a Weighted Kernel Principal Component Analysis (WKPCA) that builds the weights of the kernel function in accordance with the kernel matrix Eigenvalues. The feature dimensions were minimized through the multiple kernel functions combination. The t-class kernel functions were built to further enhance the efficacy of dimensional reduction. The classifiers like random forest, naive Bayes and Support Vector Machine were used to examine six real gene expression datasets. The major limitation faced in this approach was the non-flexibility of kernel function selection and the degraded embedding ability.

Rahimi *et al.* [22] presented a multi-task multiple KL approach with task clustering and developed a greatly time-effective solution. The proposed solution approach in this research was dependent upon the benders decomposition and clustering issue treatment through the determination of given tree structures in the graph. The method is called forest formulation and has been used to differentiate early and late stage cancers through the adoption of gene sets and genomic data. When the number of tasks and clusters gets maximized, the forest formulation approach is highly favorable due to computational performance. The time consumed in solving large scale instances was too high in the case of a multi-task multiple KL approach and clustering.

The microarray data was utilized for training deep learning approaches using extracted features. Almarzouki et al. [23] established an effective feature selection approach to maximize accuracy and minimize the classification time. The most significant genes were picked by eradicating the superfluous and duplicate information. Artificial Bee Colony (ABC) method using bone marrow pyruvate carboxylase gene expression data was employed in this research work. The features selected using the ABC algorithm were made as a wrapper based features selection system. The datasets of lung, kidney and brain cancer were utilized during testing and training. The characteristics of data were not effectively examined, and there was a greater possibility of losses.

The seven cancer datasets were collected initially from the Broad Institute GDAC Firehose comprising of isoform expression profile, survival information, gene expression profile and expression data of DNA methylation, respectively. Feng et al. [24] recommended kernel principal component analysis (KPCA) to extract the relevant features for every expression profile. The features are then fed over three similar kernel matrices through a Gaussian kernel function combined as a global kernel matrix. Finally, the features were applied over the spectral clustering algorithm to obtain clustering

outcomes. Due to the collection of abundant datasets, the dimensionality issue was not solved effectively.

To overcome the limitation of the increased computational effort of using a huge data set, Wani et al. [25] proposed an efficient method. The MKL founded gene regulatory network (GRN) inference method was presented in this research in which numerous heterogeneous datasets were combined together using the MKL paradigm. The GRN learning issue has been formulated as a supervised classification issue in which the genes are directed through a specified transcription factor differentiated from other non-regulated genes. In order to learn a huge scale GRN, a parallel execution construction was devised. Better accuracy rates and speedups can be obtained, but the data quality and redundancy issues were not solved effectively. Table I describes the major contribution with its corresponding merits and demerits of existing methods.

TABLE I. REVIEW OF EXISTING METHODS WITH THEIR MERITS AND DEMERITS

Author name and Reference	Technique	Contribution	Merits	Demerits
Liu et al. [21]	WKPCA	To develop a dimension reduction algorithm for enhancing the classification performance.	Minimization of dimensionality with less computational complexity.	Non-flexible and degraded embedding capability.
Rahimi et al. [22]	Forest formulation method	To distinguish late and early stage cancers using genomic data.	Better computational performance in aggregation.	Higher consumption of time.
Almarzouki et al. [23]	ABC algorithm	To develop an effective feature selection approach to eliminate the superfluous and duplicate information	The computational time can be minimized by using relevant features.	Ineffective characterization of gene data and high error possibilities.
Feng et al. [24]	KPCA	To extract the relevant features and obtain clustering results using a spectral clustering algorithm	An effectual global kernel matrix can be attained.	Greater dimensionality issue due to huge dataset.
Wani et al. [25]	MKL with GRN	To combine numerous datasets using the MKL paradigm and to revise a parallel execution framework.	The computational cost can be minimized.	Data quality and redundancy problems cannot be solved.

Based on the related work of the existing methods according to disease classification using gene expression data, various limitations negatively impact the performance of the method. Due to the disadvantages, such as the use of lesser datasets, non-flexible embedding capability, higher consumption of time, lower data quality, redundancy problem and lower classification accuracy, an effective proposed FDASVM-MIKL approach is developed. The additional limitations such as noises, redundant data, frequent errors, increasing complexity, smaller samples with high dimensionality, difficult interpretation, etc. This limitation can be reduced in appropriate feature extraction method, here in this research OKPCA proposed for analyzing expression data based on multiple indefinite kernel learning with and hybrid flow directed arithmetic SVM for gathering effective results to overcome the current limitations and increase classification accuracy.

### III. PROPOSED METHODOLOGY

The heterogeneous nature of the data is a very difficult to process, predict and classify the disease utilizing gene expression data. The fact that the gene expression data are quite heterogeneous has been identified as one of the main challenges. In general, heterogeneous data have a wide range of feature variations, making it difficult for any learning model to make predictions. A model must be able to accurately distinguish between the characteristics of heterogeneous data in order to make reasonable predictions. Utilizing meta-heuristics to optimize the tuning of the parameters and increase accuracy has been proposed as one prominent solution to this problem. The support vector machine (SVM) model is highly preferred among the machine learning models when the task of multiple kernel learning is accomplished. This approach aims to consider all issues and create a hybrid multiple-kernel learning framework that combines an efficient meta-heuristic with an SVM model to increase the accuracy of disease classification. The Fig. 1 demonstrates the overall architecture for the proposed methodology.

Fig. 1. Overall architecture of the proposed method.

The proposed framework comprises three major steps pre-processing, feature selection and classification. The dataset is initially brought through various processes to make it suitable for classification because it is diverse and has a large dimension. To improve the quality of the dataset, the outliers

are first eliminated. The missing values are then filled with mean values once the dataset has been examined for any missing values. After this step, the data set is then passed to the feature selection phase, in which the main features are extracted. The proposed study introduces the optimized kernel principal component analysis to identify the dataset's best features (OKPCA). The proposed hybrid flow directed arithmetic SVM based multiple indefinite kernel learning (FDASVM-MIKL) classification framework is then given the features chosen using the OKPCA technique. This proposed framework is associated with the SVM classifier, flow direction algorithm (FDA), and Arithmetic Optimization Algorithm (AOA). To increase overall performance, the SVM framework incorporates some kernels, containing the linear kernel, sigmoid kernel, polynomial kernel, and radial basis function.

#### A. Pre-processing

Pre-processing is a very essential step utilized to provide data cleansing that is useful for further analysis. Here, a standard pre-processing method is used. The dataset is then examined for non-value reduction processes, and the missing values are then filled with mean values. Outliers are removed to increase the quality of the data set. The dataset is then given to the feature selection stage, where the main features are extracted after this step.

#### B. Feature Selection and Extraction

The proposed study introduces the optimized kernel principal component analysis to identify the dataset's best features (OKPCA). This technique chooses the most important features from the dataset and ignores the rest, designed to decrease the dimensionality of the data.

1) *Optimized kernel principal component analysis:* Principal component analysis, which finds recurring patterns in the dataset with little information loss, is frequently used to reduce complex spectral datasets into understandable information. The strength and flexibility of principal component analysis are greatly enhanced by its clarity and conciseness. The important factor when using PCA is that it is a linear transformation and it can be written in the simple matrix form, which is given below:

$$B = HA \tag{1}$$

Where,  $B$  is a transformed data matrix,  $A$  is an original data matrix, and  $H$  is a transformation matrix. The corresponding eigenvectors  $v_i, 1 \leq i \leq n$ , and the necessarily non-negative eigenvalues  $(v_i)$  arranged in decreasing order. The transformation matrix is obtained by stacking the eigenvectors which is shown in equation (2).

$$H = \begin{bmatrix} \overleftarrow{v_1} \overrightarrow{\phantom{v_1}} \\ \vdots \\ \overleftarrow{v_n} \overrightarrow{\phantom{v_n}} \end{bmatrix} \tag{2}$$

The enhanced version of PCA, known as kernel principal component analysis (KPCA), can handle non-linear correlations between variables. It employs a non-linear function to translate the observed data into high dimensional space (kernel function). KPCA uses a non-linear mapping function  $\omega(x)$  to translate an observed data matrix  $datametics \in R^{M \times N}$  with  $N$  columns (variables) and  $M$  rows (observations). This can be calculated mathematically as shown in equation (3),

$$datametics \in R^{M \times N} \rightarrow \omega(x) \in R^f \tag{3}$$

Where  $f$  is the feature space. In kernel technique, kernel function and kernel matrix are known as  $K(x_i, x_j) = \omega(x_i)^T \omega(x_j)$  and  $K$ , respectively. The appropriate kernel parameter is best discovered using this kernel-based strategy by generalizing the problem to an eigenvector one. The scatter error metric is used as the objective function of the problem.

The defined goal function computes the gradient and Hessian matrices, and the kernel parameter of the method is tweaked using the gradient values. Gradient  $(\nabla f)$  and Hessian  $(\nabla^2 f)$  matrices are the popular optimization technique, as the search direction as it approaches the optimum that moves in the opposite direction of the positive gradient. Gradient and Hessian matrices for optimization are given in the equation below.

$$\nabla f = \begin{bmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \\ \vdots \\ \frac{\partial f}{\partial x_N} \end{bmatrix} \tag{4}$$

$$\nabla^2 f = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_N} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} & \dots & \frac{\partial^2 f}{\partial x_2 \partial x_N} \\ \vdots & & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_N \partial x_1} & \frac{\partial^2 f}{\partial x_N \partial x_2} & \dots & \frac{\partial^2 f}{\partial x_N^2} \end{bmatrix} \tag{5}$$

This kernel-based approach best discovers the appropriate kernel parameter by generalizing the problem to an eigenvector. The scatter error metric is used as an objective function to solve the problem. The gradient and Hessian matrices are produced by the defined objective function, and

the gradient values are used to control the algorithm's kernel parameter. The hybrid flow directed arithmetic SVM based multiple indefinite kernel learning (FDASVM-MIKL) classification framework is then given to the features chosen using the OKPCA technique.

### C. Classification using FDASVM-MIKL

The proposed hybrid Flow Directed Arithmetic SVM based multiple indefinite kernel learning (FDASVM-MIKL) frameworks are used for classification purposes. This framework combines an SVM classifier, a FDA and AOA which are described in below sections.

1) *SVM based multiple indefinite kernel learning*: Various kernels are incorporated into the SVM architecture to improve overall performance, containing the polynomial kernel, linear kernel, sigmoid kernel, and radial basis function. The input layer, hidden layer, SVM kernel layers, SVM output layer, and the voting layer form an original SVM based multiple indefinite kernel learning. An additive kernel model enhances the functionality of a standard kernel model. This model is obtained using the weighted linear sum of kernels.

a) *Radial basis function (RBF)*: RBF kernels are the most usually utilized kinds of kernelization due to their similarity to the Gaussian distribution. The degree or similarity of proximity among two points  $X_1$  and  $X_2$  is determined by using the RBF kernel function. The mathematical representation of kernel is given in the following equation:

$$K(X_1, X_2) = \exp\left[-\frac{\|X_1 - X_2\|^2}{2v^2}\right] \quad (6)$$

Where  $v$  is the variance or hyperparameter, and  $\|X_1 - X_2\|$  is the Euclidean distance between two points  $X_1$  and  $X_2$ .

b) *Sigmoid kernel*: The sigmoid kernel function is an activation function for artificial neurons and is similar to a two-layer perceptron neural network architecture. It is defined as equation (7):

$$K(X_1, X_2) = \tanh\left[\frac{X_1 \cdot X_2 + \text{coeff}}{2v^2}\right] \quad (7)$$

The hyperbolic tangent,  $\tanh$  is used to define this kernel. It can express intricate non-linear interactions when utilized with correctly calibrated parameters. However, this does not represent a true kernel since the sigmoid function might not be positive definite for some parameters.

c) *Polynomial kernel*: The kernel function is used with SVMs and other kernel models is termed as polynomial kernel, to represent the similarity of vectors (training samples) in a feature space via polynomials of the original variables machine learning can be used, allowing the learning of non-linear methods.

$$K(X_1, X_2) = \left[\frac{X_1 \cdot X_2 + \text{coef}}{2v^2}\right]^P \quad (8)$$

Where  $P$  is the kernel parameter. It shows the similarity of vectors in the training dataset in a feature space over polynomials of the original variables that is utilized in the kernel.

d) *Linear kernel*: Linear kernels are used when the data can be linearly separated.

$$K(X_1, X_2) = X_1^T \cdot X_2 \quad (9)$$

When the data is linearly separable or can be divided along a single line, a linear kernel is utilized in SVM. When a given data set contains many features, it is typically employed.

### D. Hybrid Flow Directed Arithmetic SVM

The SVM classifier categorizes diseases in the data, and the hybrid FDA with the AOA method is used to optimize each kernel parameter. Performance evaluations are then conducted to determine the effectiveness of the proposed methods across a variety of datasets. Furthermore, analyses of gene expression data in various forms demonstrate the heterogeneity of the method. Support Vector Classification (C), known as Regularization Parameter, has a strictly positive value. This regularization parameter is optimized using a hybrid FDA-AOA.

1) *Flow direction algorithm*: FDA is evaluated using the direct runoff flow in basins, which is the main focus. The FDA calculates flow velocity based on each individual slope, which falls steeply toward its near neighbors. The FDA introduces new tools for performing optimization. The neighborhood radius decreases from high to low values by defining a washbasin filling technique that helps in escaping local solutions. The FDA algorithm applies the relationship below to determine the initial position of flows:

$$\text{flow}[X(i)] = mc + \mathfrak{R}(vc - mc) \quad (10)$$

Where,  $\text{flow}[X(i)]$  denotes the location of the flow  $i^{\text{th}}$ ,  $mc$  and  $vc$  denote the lower and upper limits of the decision variables, and  $\mathfrak{R}$  denotes a uniformly distributed random number between zero and one. Additionally, it is assumed that each flow is surrounded by one or more neighborhoods, whose positions are determined by the relationship shown in below equation:

$$\text{neighbor}[X(j)] = \text{flow}[X(i)] + \mathfrak{R}(n) \cdot \kappa \quad (11)$$

The normal distribution with a mean of 0 and standard deviation of 1 where,  $\mathfrak{R}(n)$  is a random variable.

$\text{neighbor}[X(j)]$  represents the neighbor at the  $j^{\text{th}}$  position. The large numbers for this parameter shows the searching in a large range, while small numbers ( $\kappa$ ) limit searching to a small range.

$$\kappa = (\mathfrak{R} * X\mathfrak{R} - \mathfrak{R} * (\text{flow}[X(i)])) * \|\text{best}(X) - \text{flow}[X(i)]\| * G \quad (12)$$

Where,  $G$  is a non-linear weight,  $\mathfrak{R}$  is a random number between  $0$  and  $\infty$ ,  $X\mathfrak{R}$  is a random location and  $\mathfrak{R}$  is a random number with uniform distribution. This relationship's first term demonstrates that  $flow[X(i)]$  shifts to a random position  $X\mathfrak{R}$ . The Euclidian distance between  $best(X)$  and  $flow[X(i)]$  is lowered to zeros for the second term when iteration is increased, closing the gap between the two. Thus, the local search is not working. In the third term, the  $(G)$  is determined as follows:

$$G = \left( \left( 1 - \frac{itr}{itr_{max}} \right)^{2 * \mathfrak{R}(n)} \right) * \left( \overline{\mathfrak{R}} * \frac{itr}{itr_{max}} \right) * \overline{\mathfrak{R}} \quad (13)$$

Where, the random vector with uniform distribution is represented as  $\overline{\mathfrak{R}}$ . The following relationship determines the new place of the flow.

$$newflow[X(i)] = flow[X(i)] + v * \frac{flow[X(i)] - neighbor[X(j)]}{\|flow[X(i)] - neighbor[X(j)]\|} \quad (14)$$

$$neighbor[X(j)] = flow[X(i)] + \mathfrak{R}(n) * \kappa \quad (15)$$

$$v = \mathfrak{R}(n) * M_0 \quad (16)$$

$$M_0(i, j, z) = \frac{fitnessflow[X(i)] - neighbor[X(j)]}{low[X(i, z)] - neighbor[X(j, z)]} \quad (17)$$

Where,  $fitnessflow[X(i)]$  and  $neighbor[X(j)]$  are the substitute for the objective value of the  $neighbor(j)$  and the  $flow(i)$ . The  $(z)$  component reflects the size of the issue.

$newflow[X(i)]$  displays the updated position  $flow(i)$ . Fig. 2 shows the flowchart based on the FDA.

This FDA method starts with the initial population of the search space or drainage basin. The flows then shift to a low height position by achieving best outcome or output point with lowest height.

2) *Arithmetic Optimization Algorithm (AOA)*: AOA is a meta-heuristic algorithm that uses the distribution behavior using four major arithmetic operators in mathematics, such as multiplication, subtraction, division and addition. To carry out the optimization processes in various search areas, AOA is arithmetically modeled and placed into action. This meta-heuristic technique uses population data to solve optimization problems without finding their derivatives. Initialization, exploration, and exploitation are the three important phases of the optimization process.

a) *Initialization phase*: The best optimized solution is regarded as the best candidate solution in each iteration of the AOA optimization process. The optimization procedure in AOA starts with a collection of candidate solutions  $(S)$ , as shown in the matrix, which is generated randomly.

$$S = \begin{bmatrix} X_{1,1} & \cdots & \cdots & X_{1,k} & X_{1,m-1} & X_{1,m} \\ X_{2,1} & \cdots & \cdots & X_{2,k} & \cdots & X_{2,m} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ X_{M-1,1} & \cdots & \cdots & X_{M-1,k} & \cdots & X_{M-1,m} \\ X_{M,1} & \cdots & \cdots & X_{M,k} & X_{M,m-1} & X_{M,m} \end{bmatrix} \quad (18)$$

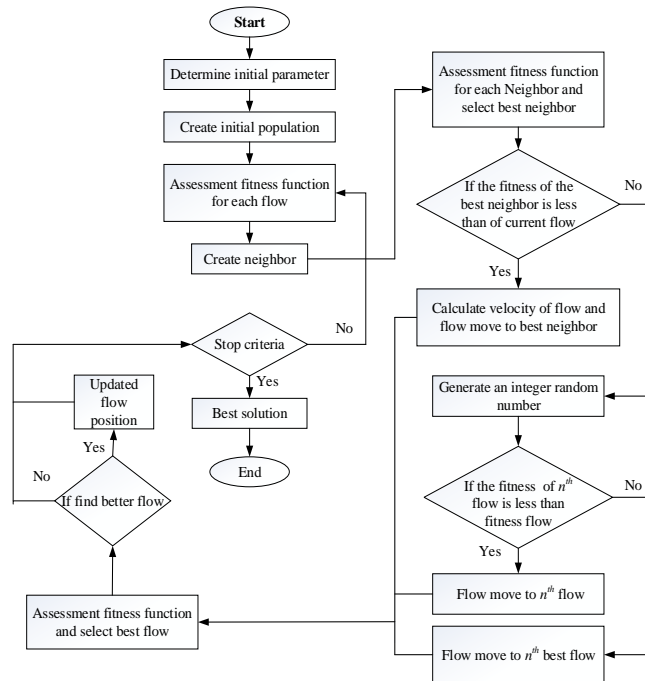

Fig. 2. Flowchart based on flow direction algorithm.

The search phase before it starts to function (i.e., exploitation or exploration), AOA should be select. Math Optimizer Accelerated (MOA) function is the coefficient derived from equation (18) and provided in the subsequent search phases.

$$MOA\_current_{itr} = \mu + current_{itr} \times \left( \frac{\eta - \mu}{\eta_{itr}} \right) \quad (19)$$

Where, the function value at the  $i^{th}$  iteration is represented as  $MOA\_current_{itr}$ . The  $current_{itr}$  stands for the current iteration ( $\eta_{itr}$ ) between 1 and the maximum number of iterations. The minimum and maximum values for accelerated function are indicated by the  $\mu$  and  $\eta$ , respectively.

*b) Exploration phase:* This section introduces the exploring behavior of AOA. To determine the better outcome, two major search processes (division search approach and multiplication search approach) are used by AOA's exploration operators to randomly explore the search area at different positions. This is the most basic rule that can approximate the actions of arithmetic operators. For the condition  $a > MOA$  ( $a$  is a random number), the exploration search is accomplished by the MOA function. The exploratory phase is evaluated using the position updating equation given below:

$$X_{i,k}(current_{itr} + 1) = \begin{cases} \frac{Best(X_{i,k})}{(MOP \cdot \epsilon)} \times ((UB_{value(k)} - LB_{value(k)}) \cdot \gamma + LB_{value(k)}), & b < 0.5 \\ (Best(X_{i,k}) \cdot MOP) \times ((UB_{value(k)} - LB_{value(k)}) \cdot \gamma + LB_{value(k)}), & otherwise \end{cases} \quad (20)$$

Where,  $Best(X_{i,k})$  indicates the  $k^{th}$  result in the next iteration,  $X_{i,k}(current_{itr})$  represents the  $k^{th}$  location of the  $i^{th}$  solution at the existing (current) iteration, and  $X_i(current_{itr} + 1)$  denotes the  $i^{th}$  solution in the following iteration. ( $\epsilon$ ) is a tiny integer number,  $LB_{value(k)}$  and  $UB_{value(k)}$  stand for the lower bound and upper bound values of the  $k^{th}$  position. The control parameter ( $\gamma$ ), which is fixed equal to 0.5, is used to alter the search process.

$$MOP(current_{itr}) = 1 - \frac{current_{itr}^{1/\beta}}{\eta_{itr}^{1/\beta}} \quad (21)$$

Where,  $current_{itr}$  stands for the current iteration,  $\eta_{itr}$  stands for the maximum number of iterations, and MOP is a coefficient. The  $MOP(current_{itr})$  function value at the  $i^{th}$  iteration is signifies the parameter,  $MOP(current_{itr})$ . The term ( $\beta$ ) specifies the exploitation accuracy over the iterations, and it is a key parameter.

*c) Exploitation phase:* The exploitation approach of AOA is described in this section. According to the arithmetic operators, the mathematical representation utilizing any subtraction or addition produced very high dense outcomes related to the exploitation search process. As a result, the exploitation search finds the almost ideal answer that can be determined after numerous attempts (iterations). The exploitation operators (Addition and Subtraction) of AOA investigate the search area systematically in some dense regions and take a method to determine the better result. According to two major search approaches (i.e., Addition search strategy and Subtraction search strategy), modeled below:

$$X_{i,k}(current_{itr} + 1) = \begin{cases} (Best(X_{i,k}) - (MOP)) \times ((UB_{value(k)} - LB_{value(k)}) \cdot \gamma + LB_{value(k)}), & c < 0.5 \\ (Best(X_{i,k}) + (MOP)) \times ((UB_{value(k)} - LB_{value(k)}) \cdot \gamma + LB_{value(k)}), & otherwise \end{cases} \quad (22)$$

A deep search is used to fully use the search space. The other operator addition will not be considered till the first operator subtraction in this phase (first rule in equation (22)), which is conditioned by  $c < 0.5$ . If not, the subtraction will be replaced with the second operator addition to complete the current task. The partitions from the previous phase methods are analogous to those in this phase.

Pseudo-code for AOA:

```

1. Initialize the AOA parameters, where  $\beta, \gamma$ .
2. Initialize the positions of the solution, ( $i=1, \dots, N$ )
3. while ( $current_{itr} < \eta_{itr}$ ) do
4.     Compute the fitness function for the solution given.
5.     Find the best solutions.
6.     Update the MOA value from equation (19).
7.     Update the MOP value using (21).
8.     for ( $i=1$  to  $solutions$ ) do
9.         for ( $k=1$  to  $positions$ ) do
10.            Create random values between [0,1] ( $a, b$  and  $c$ )
11.            if  $a > MOA$  then
12.                Exploration phase
13.                if  $b > 0.5$  then
14.                    Use division math operator (" $\div$ ").
15.                    Update the  $i^{th}$  position of the solution using
equation (20)
16.                else
17.                    Use multiplication math operator (" $\times$ ").
18.                    Update the  $i^{th}$  position of the solution using
equation (20)
19.                end if
20.            else
21.                Exploitation phase
22.                if  $c > 0.5$  then
23.                    Use Subtraction math operator (" $-$ ").
24.                    Update the  $i^{th}$  position of the solution using
equation (22)
25.                else
26.                    Use Addition math operator (" $+$ ").

```

```

27.         Update the  $i^{th}$  position of the solution using
equation (22)
28.         end if
29.     end if
30.     end for
31. end for
32.      $current_{itr} = current_{itr} + 1$ 
33. end while
34.     Return the best solution ( $X$ ).
    
```

In AOA, generating a randomized set of populations is the first step in the optimization process. Every solution improves its position in relation to the best solution found. The parameter  $MOA$  is similarly increased from 0.2 to 0.9 to emphasize exploitation and exploration. When,  $a > MOA$  the candidate solutions effort to diverge from the near-optimal result, and when  $b < MOA$  they attempt to meet to the near-optimal result.

#### IV. RESULTS AND DISCUSSION

This section describes the experimental outcomes of the proposed FDASVM-MIKL classification. The proposed work performance is evaluated by using a simulation tool in PYTHON. Some of the simulation parameters are given in the Table II.

TABLE II. SIMULATION PARAMETERS

Parameters	Values
Regularization Parameter	1.0
Kernel functions	Linear kernel, Sigmoid kernel, Polynomial kernel and Radial Basis Function
Iteration	1000
Intercept scaling	1.0
Fit intercept	True
Random state	None

Several current approaches are examined to assess the proposed categorization performance. The next subsections provide descriptions of the dataset, representations of various performance metrics, analyses, and comparisons.

##### A. Dataset Description

The data utilized for assessing the performance of gene expression classification through the FDASVM-MIKL based approach is gathered from the datasets Colon, Prostate\_GE, Isolet, Lung\_cancer, ALLAML, snp2graph and the download link of each dataset is given below:

1) *Colon dataset* (<http://biogps.org/dataset/tag/colon/>): It is a well-known dataset for expression data analysis (cancer). Seven criteria and 90 samples are included. Dataset based on the human species.

2) *Prostate\_GE* (<https://wiki.cancerimagingarchive.net/display/Public/QIN+PROSTATE>): This dataset includes multi-parametric data gathered for staging or detecting prostate cancer.

3) *Isolet* (<https://archive.ics.uci.edu/ml/datasets/isolet>): Real characteristics (genetic variation) with several variables are present. There are 697 attributes and a total of 7797 instances.

4) *Lung\_cancer* (<https://archive.ics.uci.edu/ml/datasets/lung+cancer>): Integer characteristics make up this multivariate dataset. It primarily has 56 features and 32 occurrences.

5) *ALLAML* (<https://www.kaggle.com/datasets/nikhilsharma00/leukemia-dataset>): This dataset, which can be used for training, mainly consists of 7129 probes, 38 samples of bone marrow, and it is associated with Leukemia.

6) *snp2graph* ([https://www.kaggle.com/code/ilfiore/ncbi-check-reference-genome-version/data?select=snp2graph\\_full.csv](https://www.kaggle.com/code/ilfiore/ncbi-check-reference-genome-version/data?select=snp2graph_full.csv)): SNPs are identified and selected from gene variation associated with different types of human cancers.

##### B. Performance Metrics

Various performance metrics, including accuracy, F measure, sensitivity, specificity, and recall statistics, are taken into consideration while evaluating the effectiveness of the proposed gene expression data classification. The mathematical expressions used to describe various metrics are shown in the following representation.

1) *Accuracy*: The entire count of accurate predictions over the entire total amount of predictions is called accuracy. The accuracy can be mathematically expressed as,

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (23)$$

Where  $TP$  means true positive,  $FP$  describes false positive,  $TN$  represents true negative, and  $FN$  indicates false negative.

2) *Precision*: The percentage of reliable predictions from the predictor model that correctly anticipated positive cases from all positive predictions is called precision.

$$Precision = \frac{TP}{TP + FP} \quad (24)$$

3) *Recall*: The ratio of appropriate items chosen to the total number of appropriate objects is known as recall.

$$Recall = \frac{TP}{TP + FN} \quad (25)$$

4) *F1-score*: The harmonic means of the Positive predictive value (PPV) and the Recall or True positive rate (TPR) is determined as the F measure. It can be mathematically signified as,

$$F_{measure} = 2 \frac{PPV \times TPR}{PPV + TPR} \quad (26)$$

5) *Specificity*: The number of negative outcomes over the whole number of accurately negative samples. The specificity rate can be mathematically denoted as,

$$Specificity = \frac{TN}{TN + FP} \quad (27)$$

C. Performance Analysis

The analysis contains the main performance metrics, including accuracy, F-measure, recall, sensitivity and specificity, which are considered when comparing the performance of proposed and current techniques. The explanation of the performance includes a description and a graphical representation. The dataset such as Colon, Isolet, ALLAML, Lung CANCER, Prostate and Snp2 are used to classify gene expression into six categories. The performance comparison of accuracy is given in Table III.

TABLE III. PERFORMANCE COMPARISON OF THE PROPOSED METHOD

Performance Metrics	ALLML dataset	Colon dataset	Isolet dataset	Lung Cancer dataset	Prostate dataset	Snp2 dataset
Accuracy	0.9960	0.9995	0.9963	0.9951	0.9971	0.9979
Specificity	0.9927	0.9954	0.9949	0.9876	0.9889	0.9900
Precision	0.9896	0.9937	0.9911	0.9983	0.9930	0.9921
F1-Score	0.9748	0.9830	0.9830	0.9821	0.9938	0.9794
Recall	0.9817	0.9994	0.9988	0.9873	0.9876	0.9829

The comparison of Accuracy, Specificity Precision, F1-score and Recall with its values is represented in Table III. The accuracy of the proposed approach using the ALLML dataset is 99.60%, the Colon dataset is 99.95 %, the Isolet dataset is 99.63%, the Lung Cancer dataset is 99.51%, the Prostate dataset is 99.71%, and the Snp2 dataset is 99.79% obtained. The performance values of Specificity Precision, F1 score and Recall are also given in the table. The performance examination of the proposed Accuracy, Sensitivity, Precision, F1-score, Specificity and Recall is given in Fig. 3.

Accuracy, Specificity, Precision, Recall and F1-score performance is greater than the existing method. Table IV shows the accuracy performance comparison of existing and proposed approaches using the Colon dataset.

The accuracy of the proposed FDASVM-MIKL method is 99.95%. The existing method includes DNN, Improved DNN, CNN, and RNN with accuracy performance of 91.4%, 91.4%, 82.8% and 84%, respectively. Related to the existing methods proposed FDASVM-MIKL approaches has a better accuracy outcome. The performance comparison of the proposed and existing methods using the Colon dataset is represented graphically in Fig. 4.

Fig. 5 presents the comparative graphical representation of the proposed method using current approaches. Table V presents an accuracy comparison of proposed and current approaches using the Isolet dataset.

The proposed FDASVM-MIKL approach has an accuracy value of 99.63%. The accuracy performance of the existing methods, including SVM with multiplicative kernel combination (GKML), ElasticNet-SVM, Multiple indefinite kernel learning based FS (MIK-FS), and SVM with l1 norm regularizer (l1-SVM), is 96.01%, 81.589%, 88.03%, and

94.86%, respectively. The proposed FDASVM-MIKL approach has improved accuracy performance compared to the current methods. The performance study of the proposed and current approaches utilizing the Colon dataset is visually depicted in Fig. 5.

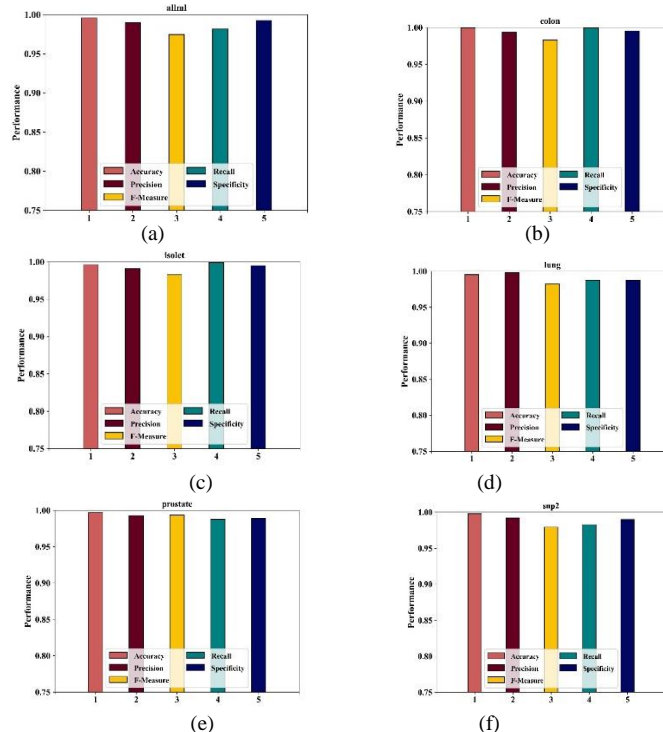

Fig. 3. Performance analysis of the proposed method using a different dataset.

TABLE IV. ACCURACY COMPARISON OF PROPOSED AND CURRENT METHODS USING THE COLON DATASET

Colon dataset	
Methods	Accuracy
DNN	0.914
Improved DNN	0.914
CNN	0.828
RNN	0.84
<b>Proposed FDASVM-MIKL method</b>	<b>0.9995</b>

Fig. 4. Accuracy performance analysis of proposed and current methods using the Colon dataset.

TABLE V. ACCURACY COMPARISON OF PROPOSED AND CURRENT APPROACHES USING THE ISOLET DATASET

Isolet dataset	
Methods	Accuracy
GKML	0.9601
ElasticNet-SVM	0.81589
MIK-FS	0.8803
11-SVM	0.9486
<b>Proposed FDASVM-MIKL method</b>	<b>0.9963</b>

Fig. 5. Accuracy performance analysis of proposed and current approaches using the Isolet dataset.

The graphical comparison of the proposed method with the known methods is shown in Fig. 5. Table VI represents the accuracy comparison of the proposed and existing methods using the Prostate dataset.

TABLE VI. ACCURACY COMPARISON OF PROPOSED AND EXISTING METHODS USING THE PROSTATE DATASET

Prostate dataset	
Methods	Accuracy
DNN	0.892
Improved DNN	0.932
CNN	0.892
RNN	0.924
<b>Proposed FDASVM-MIKL method</b>	<b>0.9971</b>

The accuracy of the proposed FDASVM-MIKL approach is 99.71%. The accuracy performance of the existing methods, including DNN, Improved DNN, CNN, and RNN, is 89.2%, 93.2%, 89.2%, and 82.4%, respectively. The proposed FDASVM-MIKL approach has improved accuracy performance compared to the current methods. The performance study of the proposed and current approaches utilizing the Prostate dataset is visually depicted in Fig. 6.

The graphical comparison of the proposed method with the known approaches is shown in Fig. 6. Using the ALLAML dataset, Table VII compares the accuracy of the proposed and current approaches.

The accuracy of the proposed FDASVM-MIKL technique is 99.60%. The current methods include rMRMR-nMGWO, Random Forest, Least Absolute Shrinkage and Selection

Operator (LASSO), Elastic Nets, and Decision Tree accuracy performances are 98.3%, 48.6%, 87.5%, 98.7%, and 83.3%, respectively. The result shows that the accuracy performance of the proposed FDASVM-MIKL methodology is greater when compared with existing approaches. Fig. 7 illustrates the performance analysis of proposed and current approaches using the ALLAML dataset.

The graphical comparison of the proposed technique with the known methods is shown in Fig. 7. Using the Lung cancer dataset, Table VIII compares the accuracy of the proposed and current approaches.

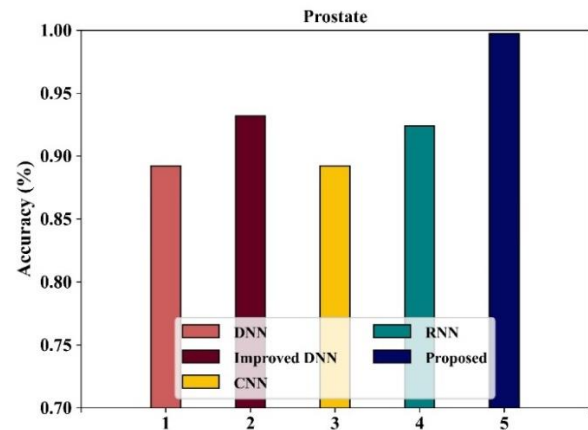

Fig. 6. Accuracy performance analysis of proposed and current approaches using the Prostate dataset.

TABLE VII. ACCURACY COMPARISON OF PROPOSED AND CURRENT APPROACHES USING THE ALLAML DATASET

ALLAML dataset	
Methods	Accuracy
rMRMR-nMGWO	0.983
LASSO	0.486
Random Forest	0.875
Elastic Nets	0.987
Decision Tree	0.833
<b>Proposed FDASVM-MIKL method</b>	<b>0.9960</b>

Fig. 7. Accuracy performance analysis of proposed and current approaches using the ALLAML dataset.

TABLE VIII. ACCURACY COMPARISON OF PROPOSED AND CURRENT APPROACHES USING THE LUNG CANCER DATASET

Lung_cancer dataset	
Methods	Accuracy
rMRMR-\nMGWO	0.975
LASSO	0.793
Random Forest	0.916
Elastic Nets	0.975
Decision Tree	0.876
<b>Proposed FDASVM-MIKL method</b>	<b>0.9951</b>

The accuracy of the proposed FDASVM-MIKL approach is 99.51%. The accuracy performance of the existing methods, including robust Minimum Redundancy Maximum Relevancy- Gray wolf optimizer algorithm (rMRMR-\nMGWO), Random Forest, Elastic Nets, Least Absolute Shrinkage and Selection Operator (LASSO) and Decision Tree, is 97.5%, 79.3%, 91.6%, 97.5% and 87.6%, respectively. The proposed FDASVM-MIKL approach has improved accuracy performance compared to the current methods. The performance study of proposed and current approaches utilizing the Lung cancer dataset is visually depicted in Fig. 8.

Fig. 8. Accuracy performance analysis of proposed and current approaches using the Lung cancer dataset.

The comparison employs several epoch counts. Fig. 9 compares the Loss epochs of Train, Test and Validation of the proposed system.

TABLE IX. ERROR RATE OF THE PROPOSED METHOD USING DATASETS

Dataset	Error rate
ALLML	0.0039
Colon	0.0004
Isolet	0.0036
Lung_Cancer	0.0048
Prostate	0.0028
Snp2_graph	0.0020

The training, testing and validation losses of the proposed approach on the provided dataset are plotted as a function of epoch number in Fig. 9. In the comparison, various epoch counts are employed. The Error rate of the proposed method for each dataset is illustrated in Table IX.

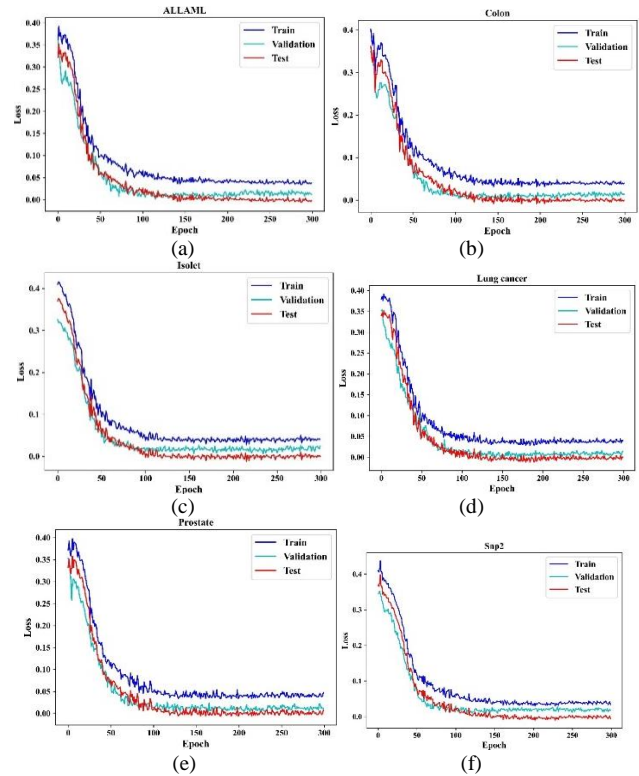

Fig. 9. Training, testing and validation epochs vs. loss.

### V. CONCLUSION AND FUTURE SCOPE

This paper proposes a unique method for the analysis of expression data based on multiple indefinite kernel learning, OKPCA and hybrid FDA-AOA is also employed. The PYTHON platform is used to carry out the proposed strategy. The evaluation results are also taken into account for various types of data sources. The accuracy of the classifications is used to determine the performance. The accuracy of the proposed technique using the colon dataset is 99.95%, the accuracy of the proposed technique using the Isolet dataset is 99.63 %, for ALLAML is 99.60%, using the Lung cancer dataset is 99.51%, for the prostate dataset is 99.71% and the proposed method accuracy using the Snp2 dataset is 99.79%. It is clear from the results that the Isolet database performs better. The comparative result of the proposed strategy demonstrated that it is more accurate than other existing methods. In the future, this study will be extended to include improved techniques and advanced classification approaches.

**Abstract**—In this paper, the authors introduce a new segmentation technique based on U-NET algorithm from the deep learning used for lung cancer segmentation, which is the main challenge that medical Staff confront in their diagnosis process. The goal is to develop an ideal segmentation that enables medical personnel to distinguish the various tumor components using the completely U-NET convolution network architecture, which is the most effective. First, the regions of interest (ROI) in the 2D slides are established by an expert using the syngovia application of the Siemens. In this pre-processing step, the cancer area is isolated from its surroundings, and is used as a training model for U-NET algorithm. Second, the 2D U-NET model is used to segment the DICOM images (Digital Imaging and Communications in Medicine) into homogeneous regions. Finally, the post processing step has been used to obtain the 3D CT scan (computerized tomography) from the 2D slices. The segmentation results from the proposed method applied on biomedical images from nuclear medicine and radiotherapy that are extracted from the archiving system of the Institute of Salah Azaiez from Tunisia. The segmentation results are validated, and the prediction accuracy for the available test data is evaluated. Finally, a comparison study with other existing techniques is presented. The experimental results demonstrate the superiority of the used U-NET architecture applied either for 2D or for 3D image segmentation.

**Keywords**—Deep learning U-NET architecture; 3D CT scan (computerized tomography); DICOM images (Digital Imaging and Communications in Medicine); 2D slices; ROI (regions of interest)

## I. INTRODUCTION

Some of the main difficulties in image processing and computer vision could involve split imaging [1]. The divisions of the imaging in just this topic have the broadest use across several disciplines and technical advances [2 and 3]. The most known concept is to implement different software for the feature spaces of both the partitioned 3D melanoma illustration and the U-NET measurement, in either the permitted dimensional characterizing boundary. Which the distributions produced with peak contribution through one pixel to the following juxtaposition. As well as a wide range of intensity only within the visual performance of the segment. The main idea is to create an optimum cluster approach with medical scanning ground and to obtain the wanted findings through analysis.

For medical images, only several segmentation methods are available [4, 5, 6, and 7]. Mohamed et al. [8] established that

computed tomography (CT) imaging is one of the crucial development radiological aspects for illness diagnoses. In this study, the author provides an approach for CT image processing that integrates the spatial and transform domains. Low-contrast details that are often smoothed out by edge detection filters can be restored with the help of transform domain filters. The homogeneity Phase (PC) and the redesigned remove noise technique form the foundation of the prefilter. In the same context, Imen et al. [9] suggests a computer-aided diagnostic (CAD) method for diffusion-weighted magnetic resonance imaging (DWI)-based early identification of prostate cancer. That was defined as the region of interest for the proposed system across the several slices of the input DWI volume. The defined ROI appear the diffusion coefficient (ADC) which was determined, normalized and improved.

In order to identify local scale nodules less than 3 mm and non-nodules on tomography (CT scan) networks, Monkam et al. [10] has mentioned various CNN layouts also with many of convolution layers. The researchers were using a 5-fold parallel validation approach to assemble the designs on different shapes of  $(16 \times 16)$ ,  $(32 \times 32)$  and  $(64 \times 64)$  CT scan images captured from the LIDC repository at  $(512 \times 512)$ . The experiments have found that the CNN with two fully connected layers within the instance of  $(32 \times 32)$  patching, measure an incredible performance and prospective.

Similarly, Mundher Shabiet al. [11] researched a 3D convolutional neural network (CNN) established on the most important objectives. For the automatic recognition of the whole disease of lung cancer that is screened on computed tomography (CT) scans. If it can accurately classify malignant/cancerous lung nodules, many lives could be saved. In the meantime, SiyuanTangetal [12] explored the pulmonary tissue area and used a 3D U-NET convolution neural network.

Unfortunately, the outcomes of the preponderance extraction feature in practice when it is used on 3D medical data are erroneous. The fragmentation of lesions allows swift and exact disease identification by healthcare experts. Consequently, selecting the appropriate feature is an essential step in the analysis technique of a medical image.

The U-NET architecture is a particular sort of fully convolutional network (FCN) defined by an encoder-decoder structure. Those are developed for semantic segmentation, which is often referred to as pixel categorization. That was

developed for the direct extraction of high-level image from blocks during the expansion phase. These connections defined the block boundaries during the rectification.

Section 2 introduces the proposed method for detection of Lung Tumor. The experimental results are discussed in Section 3. The discussion is presented in Section 4 and the conclusion and future work is given in Section 5.

## II. PROPOSED APPROACH

Forty cases were involved in the investigation (thirty males and ten females), with a prognosis and reported age range of 55 years (45-65 years). The cancerous nodule that was identified reached approximately 3 cm. Data extracted from the local system of storage and transfer of data (PACS) is extracted according to Salah Azaiez Institute of Cancerology various nuclear medicine, radio-assistance and radiotherapy in order to develop the optimization techniques. That approach out 3D lung cancer tiny cellular (CPC) of the multiple levels which would be associated with smoking use and contributes for 25% of carcinoma [15]. The non-small cell lung cancer (NSCLC) subgroup provides for the remaining 75% of cases of pulmonary cancer. The outcome displays the inadequate CT SCAN performance of seventeen patients.

In an attempt to evaluate the provided framework's efficiency, accuracy and awareness for the split samples, the consequences are juxtaposed against approaches that have been established as effective. Those protocols have been implemented on Ubuntu by using the deep learning framework and NumPy dialect settings.

The underlying 3D data is saved in the RGB (red, green, and blue) layout. The primitive shade occupies 8 bits per pixel, and the luminance can vary from 0 to 255. The engagement in learning how to tag the DICOM data will later be used for edge detection. The full-size cut with a measurement of  $(256 \times 256)$  and an estimate of  $(96 \times 128)$  of the ROI is defined (see Fig. 11).

The Different diagnoses, which use a wide range of techniques to treat extended pathologies, are particularly employed on clinical imaging. With this field in healthcare, training is now immediately accessible. The medical techniques of imagery allowed a visual description focused on physical or chemical features instead of a straightforward snapshot of the tissue or organ being researched; especially those employed in nuclear medicine, which carry out reconstructive and volumetric acquisitions directly.

Consequently, the findings of the preponderance of the widely employed feature extraction, whenever extended to 3D medical data, are not consistent anymore. The major objectives are to make it simpler for clinicians to immediately and accurately diagnose malignancies. Therefore, among the most necessary phases in image processing is determining an optimal decision.

In this case, applying the U-NET approach to divide a three-dimensional image of a patient suffering from lung cancer seems like an intriguing technique. Therefore, the primary objective of this study is to develop the best algorithm.

The biomedical engineering produces the desired optimal result for healthcare experts.

Preprocessing, U-NET segmentation and post processing are the three main phases that make up the proposed method. In the first phase, the local region of interest (ROI) and 3D volume have been converted into an arrangement of 2D slices in the first phase. The local area of interest is partitioned by using 2D U-NET framework in the second phase. Finally, the 3D CT SCAN has been reduced again to 2D slices by using the post-processing phase. The flowchart depicted in Fig. 1 demonstrates the characteristics of the proposed segmentation technique the contribution applied by extracting the different parameters from the syngovia system (the archiving system) in the input to the pre-processing, U-NET architecture, post-processing and the output result to obtain the 3D U-NET segmentation.

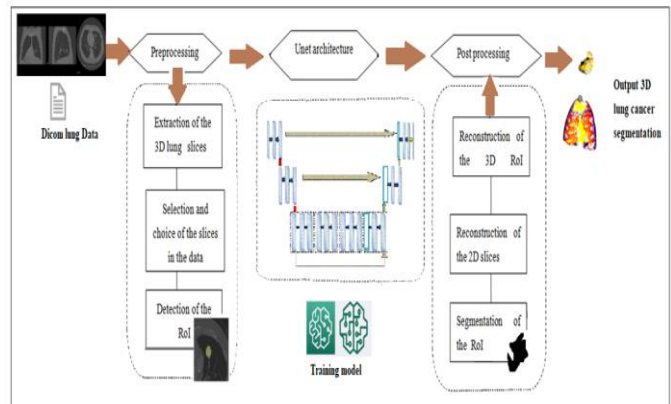

Fig. 1. Suggested approach defined by the preprocessing step the U-NET architecture and the post processing step.

The proposed algorithm of the U-NET can be summarized by the following steps:

**Step 1:** The 3D volume was changed into 2D slices, and the local Region of interest (ROI) was selected, which represents the ground truth an estimate of  $(96 \times 128)$ .

**Step 2:** Convolution layers, three - dimensional up-convolutions and 3D max partitioning -3D operations that substitute the professional 3D decompositions and thus are epitomized in 3D axes that are explored.

- The architecture involves screening out the highest-risk malignant nodule prospects among storage containers.
- The U-NET CNN architecture is a great tool for the segmentation of biomedical imagery. The recommended implementation of U-NET is the least straightforward way to reduce memory consumption; check Fig. 3.

For the training stage, the suggested U-NET adapted framework  $(256 \times 256)$  as provided 2D Tomography scans are slices up and provided with information and annotation, as  $(256 \times 256)$  overlays, and tumor regions are 1 while other regions are 0.

**Step 3:** The post-processing algorithm requires frames  $(256 \times 256)$ , in which each pixel's datatype ranges

from zero to 1, reflecting the likelihood that pixel is a participant. Fig. 2 to 4 illustrates identical entries and prognostications for all patients in the ultimate U-NET layer.

In this contribution, the U-NET strategy will be applied for the segmentation of the lung DICOM image. In this proposal, the authors begin with the preprocessing and the post processing. At the first stage, the 3D volume has been changed over into a course of actions into the 2D slices and the (ROI) has been made. At the second stage, the 2D U-NET demonstrates the utilized section nearby the ROI. Finally, the post processing step has been obtained to diminish the 3D CT SCAN from the 2D.

#### A. Pre-processing Procedure of 3D Lung Cancer Slices

The segmentation of the CT SCAN data is performed using the pre-processing approaches. To accomplish this frame, the 3D CT SCAN provided from the 2D slices must initially be stripped whereby each subject includes about 260 slices. Secondly, the 2D determined slices have been applied to establish the region of interest (ROI). The multi-view split of the crucial, coronal, and sagittal planes (see Fig. 6), has been performed by using deep learning techniques (the information of standardization and expansion).

The pre-processing steps convert the 3D CT SCAN into 2D slices in order to create the ROI, which could be used as an input by the 2D split. In an attempt to apply digital competence in a slice-wise strategy for greatest performance the 2D slices were produced from 3D slices. Those slices are obtained concurrently and applied at the orthogonal planar 3D in space, and the basic computing CDA was developed exclusively for DICOM imaging [13]. For the medical establishment, the authors opt for Siemens Healthcare that is specialized on PACS Syngovia software and is applied to the process of the 3D image segmentation expertise. This application is used to extract features of the DICOM images for the preservation and accomplishment support of a precise and efficient diagnostic.

In this location, the volumetric sampling adds a third dimension relative to two dimensions (2D) computerized in the following figures. The screening method is focused within the building blocks referred to as three-dimensional (3D) pixels. However, the volume rendering is made possible by the representation of (3D) datasets. Consequently, multidimensional components of numeric or data vectors are used to characterize the datasets. That is used to create the 3D CNN architecture that combines subsample and recorded values [14]. Fig. 2 illustrates the preprocessing steps in the beginning the choice of the appropriate 3D lung cancer that was extracted by the medical expert and selects the best slices to be used in the terminologies of the 2D slices and finally the different parameters was defined to obtain the appropriate ROI.

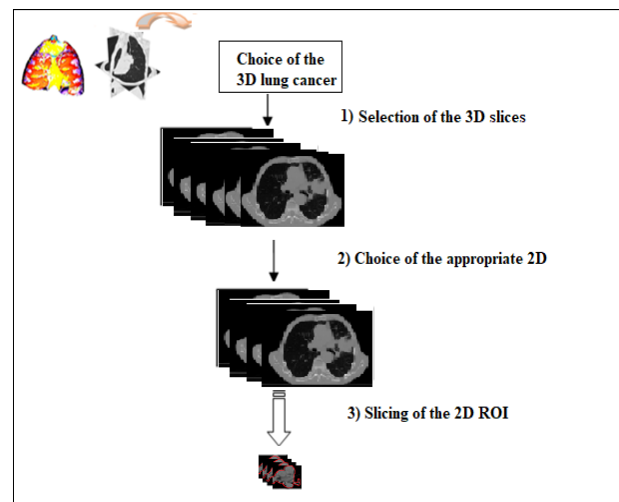

Fig. 2. Preprocessing step demonstrated by the choice of the 3D lung cancer. (1) selection of the 3D slices. (2) choice of the appropriate 2D. (3) slicing of the 2D ROI.

In order to be precise, the different parts of the slices have been resized to achieve the same (256 × 256) pixel approximation. This methodology decreased the number of 260 slices presented as abnormal for every CT scan. Each procedure decreased the median slice count to every Scan between 260 into 35 (see Fig. 3). Consequently, the screened slices were subsequently projected on the region of interest (ROI), which had been extracted from the full-size cut with a measurement of (256 × 256) and an estimate of (96 × 128) as demonstrated in Fig. 3.

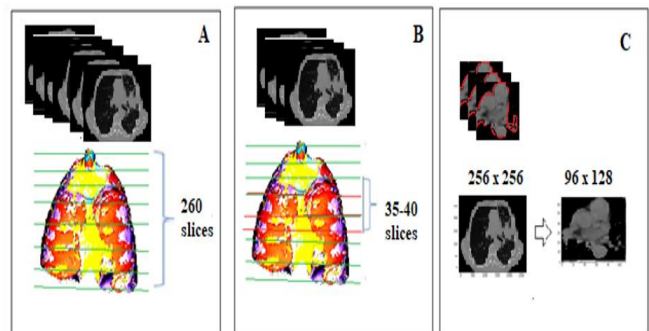

Fig. 3. Preprocessing steps, (A) the 3D slicing, (B) the selection of slices and (C) the region of interest (ROI).

#### B. 3D Extension based on 2D Segmentation using U-NET Architecture

The proposed method is employed from deep CNN and the data was implemented to stretch the 3D segmentation volume and have the latest new U-NET architectural decision. Fig. 4 contains the fundamental concepts of the segmentation applied to the U-NET configuration.

Fig. 4. The U-NET architecture approach presented by the input of the patched ROI into the defined layers and the output of the post processing step.

Regarding the difficulties of splitting in the medical field, it has been proposed that the U-NET approach presented as wide multilayer perception for this division process [15]. This expert system is one of the most well-suited and sufficient for partitioning clinical imagery. The approach made it possible to identify valuable details from DICOM. This technique includes an encoder and a decoder that accomplishes down, and up sampling using four components and are related via skip associations to produce high-resolution image.

Whilst also reducing the final two layers of the first explanation and boosting the bottleneck layer of the division result, the authors reduce the segmentation approximation under this project to 50%. By skipping connections, the characteristics acquired through the encoders' method at each level are transmitted to the decoding method. The encoder approach conducts two rounds of convolution, aggregate equalization, and dropout simultaneously for each layer. The image measurement will be split in half by the max-pooling and sent to the next layer. This handle is retained until the image reaches the bottleneck layer, the last layer in the encoder path. This layer now has three empty squares and two convolutional rounds that were normalized and discarded separately.

After the subsequent phase, the authors combined the yield from all previous blocks into the final bottleneck layer square. This experimentation with different amounts of blocks inside the hidden layer demonstrated of the three additional square configurations. The decoding path starts at the end of the pre-processing step on the upper right. The image identification is first expanded by the use of over fitting. Typically, a transposed convolution takes the place of the convolutions in oversampling. The image is then transmitted to the layer in the decoder method, which combines the highlight mapping from the contraction method (encoder), does two rounds of convolution group normalization, and independently performs dropout. The method continues sampling the images until each one approach the last stage of the decoder, at which point information is returned towards its original estimate of (96 × 128). The final layer of the decoding technique comprises a sigmoid stage that divides every pixel into two main categories with a probability ranging from 0 to 1.

According to Fig. 4, the image data is coupled to a rectangle size width (3 × 3) in order to generate a boundary inside the convolution implementation. For this reason, the

authors use the ReLU activation technique in each of these convolution patterns [16]. The positive weights of the attributes remained undamaged by this implementation process strategy, however all of the spotlights' deleterious evaluations have been assigned a value of zero.

Furthermore, Cluster standardization was employed to speed up the arrangement processing by decreasing the rate at which each gradient was received. The distribution changes during preparation since the characteristics of the previous time step change. Likewise, over fitting and Dropout are anticipated using the premature ceasing [17] as batch normalization tactics within the implementation. At every layer, the weight and inclination were improved using the Adam optimizer [18]. The ROI image of a slice from a cell lines CT SCAN serves as the input and the yield is the segmentation.

This solution performs well for connecting the intra-slice images, identifying the boundaries, and fragmenting the layers from the human lung CT SCAN dataset since the U-NET uses fewer training parameters and is quicker to focalize.

This provides the capability of an unsupervised layer in a multi-level structure that is automatically chosen for other illustrations. When the neural network is trained, Deep convolutional (CNN) model of decoders [19] mainly abstains the harshness of prejudice that canaries exhibit (without pre-initialization). In order to insert scientific information (such as the patient's age and weight) into the 3D U-NET formula, a total of 563 patients' data were collected and anonymized. The use of modern methods for DICOM and other medical imaging sources has showed an impressive performance in the area of morphology identification in radiography.

Additionally, the authors define the characteristic segment as  $x$  and the concatenated as  $x'$ , respectively. The stacked layer corresponds to another  $F(x')$  cartography. The underlying  $H(x')$  is defined as follows:

$$H(x') = F(x') + x \quad (1)$$

A linear projection  $Ws$  is carried out during skip connections where  $x$  and  $F$  dimensions must both be equal. The definition of the building block used is:

$$y = F(x', Wi) + Ws \quad (2)$$

The transmitter and receiver parameters of the construction block under consideration are  $x'$  and  $y$ , respectively. The function  $F(x', Wi)$  is used to express the residual mapping that needs to be learned.

The computational calculation for the 2D combination process as following:

$$C(I \times S)_{ij} = \sum_{m=0}^{p-1} \sum_{n=0}^{q-1} [S(m, n) \times I(i + m), (j + n)] + b \quad (3)$$

While  $C$  denotes the yield of the fully connected layer and  $(i, j)$  denote the input ROI of the CT SCAN measurement, which ranges from 0 to 255 escalated values and the  $(m, n)$  gives the matrix measurement, where  $I$  is the characteristic outline,  $S$  is the skip of the encoder-decoder and  $q$  have an impact on the spatial assessment of the filter. The word "predisposition" is represented by  $b$ . This data is subjected to the multilayer process and the max-pooling is then attached.

Equation is used to carry out comparable feature extraction in the remaining squares of the encoder.

During training, the model assessed its performance using the Weighted Binary Cross-Entropy, loss function  $J$ , and the stochastic gradient descent optimization procedure. A better model is indicated by a greater loss function value, whereas a better training result is shown by a lower loss function value, which improved the model's performance by reducing the classification error brought on by the class imbalance between the target and background pixels.

$$J = -\frac{1}{M} \sum_{m=1}^M [wxym \log(h(xm)) + (1 - ym)x \log(1 - h(xm))] \quad (4)$$

Where  $M$  is the total number of training examples,  $w$  denotes weight,  $y$  denotes the targeted term for training case  $M$ ,  $x$  denotes input image and  $h$  denotes the model's stacked neural network.

### C. Post Processing Procedure of 3D Lung Cancer Slices

The post processing organization of the U-NET 3D segmentation was outlined to guarantee a forecast of 3D slices. As presented in Fig. 5, the post processing step consists of three lower stages:

- The split yield is filtered to remove the genuine positives.
- Recreation of the 2D slices from the fragmented 2D ROIs (converting 2D complete images to 2D ROI images).
- Fig. 5 shows the reconstruction of the 3D proportions from the 2D replicated slices (from 2D proportioned cuts to 3D CT SCAN) to obtain in the output the 3D U-NET segmentation.

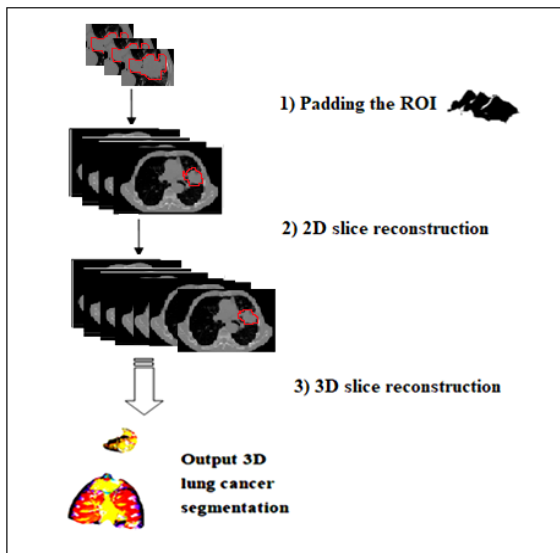

Fig. 5. The post processing step including the reconstruction of the 3D slices. (1) The padding ROI. (2) 2D slice reconstruction. (3) 3D slice reconstruction.

However, there was noise within the ROI causing the segmentation to dismount one identifier by few base pixels.

There were two methods used to present the outflow of falsely positive results:

- Instead, every neuron has the attribute "1" on it.
- The erroneous positive pixels inside the quasi being suggested to be identified and removed.

The non-locale was chosen by a rectangular framework of  $(96 \times 128)$  per each slice while considering the ROI. While pixels have been supposed to appear in the cleared-out and right areas, the authors implemented a filter to eliminate additional pixels outside of the boundaries. Then, using padding the 2D sectioned slices were restored to their distinct size of  $(256 \times 256)$  as seen in Fig. 5. Defining every ROI in this arrangement may therefore be sliced. Finally, the 3D CT SCAN lung for each participant was rebuilt using all the clarified division. There may be a difference in the number of divisions. As a consequence, the initial slices got swapped to reconstruct the 3D lung.

### III. SIMULATION RESULTS

In this part, several biomedical results obtained by the proposed method are provided. Fig. 6 presents the samples of the DICOM features extracted with various CT SCAN layers.

Fig. 6. Training set chosen for the scientific study.

### A. Evaluation of the Results

The mean squared error (MSE) is the best and most widely utilized difference degree for image quality investigation. The MSE is easy to compute and incorporates several alluring properties applications. Moreover, it endures from a few principal issues [20] presented by the following expression (5):

$$MSE = \frac{1}{MN} \sum_{i=1}^M \sum_{j=1}^N [p(i, j) - q(i, j)]^2 \quad (5)$$

The proportion between the greatest conceivable controls of 3D images through compression of the undermining that creates distortion. The small esteem of the Peak Signal to Noise Ratio (PSNR) implies that pictures are of destitute quality. The value of PSNR for superior picture quality can be calculated based on the following equation:

$$PSNR = 10 \log \frac{(2^n - 1)^2}{MSE} \quad (6)$$

It should be noted that the reduced PSNR values reflect inferior cloning. On the other hand, a lower regard for MSE seems to indicate improved regeneration.

B. The Contribution Results

The encoder-decoder and primarily several varieties of completely convolution neuronal networks are marked by the U-NET layout. The class of neural network models (FCN) by integrating the interactions comprises the layer works and blocking straight to factor in the overall in the heterogeneity stage. The feature extraction draws just on fully convolution framework and is integrated with the pixel identification.

The application of the 3D U-NET Automated system applied on 3D approaches is the empirical tests dedicated to the identification of biomedical cancerology images. Fig. 7 depicts the outcomes of the segmentation of the samples [21].

Besides, TP, TN, FN, and FP successively the proportion of cancerology patches are true positive, true negative, false negative and false positive, correspondingly.

- True Positive (TP) called sensitivity: The region of crossing point between Ground Truth (GT) and division mask(S), numerically, usually coherent AND operation of GT and S.

$$TP = GT \cdot S \tag{7}$$

- True Negative (TN) called specificity: Equivalent to a true positive, a true negative is an ending when the classifier is trained the negative subclass with accuracy.

$$TN = 1 - FP \tag{8}$$

- False Positive (FP): The anticipated zone exterior the ground truth. Usually, the coherent OR of GT and division short GT.

$$FP = (GT + S) - GT \tag{9}$$

- False negative (FN): number of pixels within the ROI zone that the model failed to anticipate. This is often the coherent OR of GT and division short S.

$$FN = (GT + S) - S \tag{10}$$

The IoU is the proportion to the combined ROI and scientific facts. Due to the parameters of TP, FP, and FN are nothing but ranges or number of pixels; ready to compose as takes after.

The anticipated ground-truth is drawn see Fig. 9 to 12, Computing Crossing point over Union can in this manner be decided through the equation below see (11):

$$IoU = \frac{TP}{TP+FP+FN} \tag{11}$$

The performance of the research of lung cancer segmentation scheme was evaluated referring to the evaluation in the literature, namely accuracy, sensitivity, precision and dice. Those were evaluated using equations (12) to (15):

$$Accuracy = \frac{TP + TN}{TP + TN + FN + FP} \tag{12}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{13}$$

$$Precision = \frac{TP}{TP+FP} \tag{14}$$

$$Dice = \frac{TP+TP}{TP+TP+FP+FN} \tag{15}$$

TABLE I. COMPARED THE PERFORMANCE OF THE INVESTIGATION EMPLOYING ELECTED AND CURRENTLY USED METHODOLOGIES

Methods	Name of dataset	Model	Accuracy %	Sensitivity %
The Proposed Method	Hospita 1	3 U-NE T	98.9	97.99
Mundher AL-Shabi [11]	LIDC-IDRI	3D U-NE T	95.28	94.33
Monkam and al[10]	LIDC-IDRI	3D CNN	88.28	83.82
SiyuanTang[12]	LUNA 16	3D U-NE T	94	92.4

Table I indicates the accurate feature extraction rate of the database obtained inside the various experiment methods with consideration to the sensitivity and the accuracy. The medical teams appointed to accomplish the finding model as depicted in the graphic (Fig. 7). Fig. 12 demonstrates the Dice findings and the best outcomes from the contributing experiment.

Fig. 7. Evaluation of the performance of the metrics of the sensitivity and accuracy of the proposed method comparing with other study.

As is apparent from the same, the accuracy corresponds to 88.28%, 94%, 95.28% and 98.9% of intensity values for the techniques of roughly Mundher AL-Shabi [11], Siyuan Tang [12], and the predicted model that was combined. In addition, the sensitivity corresponds to 83.82% for the methods of Monkam and al [10], 94.33% for the approaches of Mundher AL-Shabi [11], 92.4% for the algorithms of Siyuan Tang [12] and 97.99% for the processes.

Meanwhile, the malignant locations are successfully delineated in Fig. 9 and 12 utilizing the DICOM dataset; the accuracy and sensitivity were more well-liked and validated by doctors. This data will be shared in the subsequent steps.

The representative ROC curve seen in Fig. 8 was conspired to show how the algorithm can discern in mid the true positives and negatives rate. The authors will calculate the AUC "Area under the ROC Curve" which tells us how much of the plot is found beneath the curve. The closer AUC is to 1, the superior is the model. From the plot that can see the taking after AUC

measurements for each model: AUC of the calculated relapse present: The logistic regression model on the following representation of the ROC curve is demonstrated with the blue line at (0.4; 0.82) and the gradient model is presented with the orange line that held (0.1; 0.9897). The performance of the ROC curve that it grips the peak of the angle of the scheme best is the model chosen for the data segmentation.

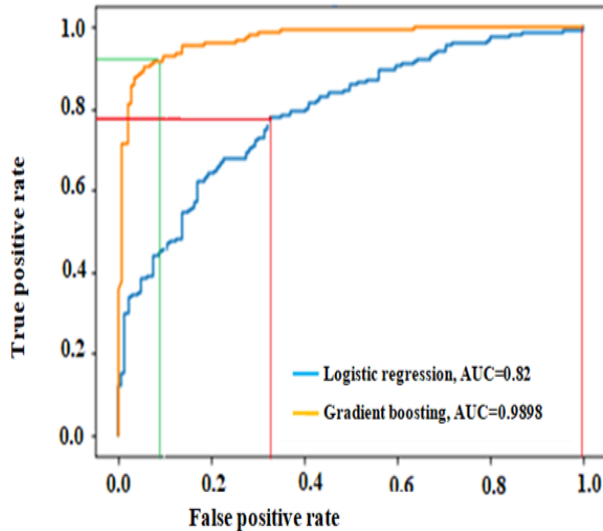

Fig. 8. The precision of the data's ROC curve presenting the false positive rate and the true positive rate presented with the logistic regression and the gradient model.

The database extracted exceeds more than 3000 slices (see Fig. 9 and 12), in 2D slices each of which are of a resolution (512 × 512) whose medical staff provided us their marking of each that the cases studied with the tumor dimension which is >3cm, shown by the Tables II and III below. Through a clinical study, it was noticed that the majority of the cases present a very short life expectancy of no more than 2 years, as well as the rapid evolution of the cancer disease that reaches in a few months without any treatment the case of metastasis spreading through the bone and reaching the brain.

Due to the patient's physical and mental tiredness after undergoing surgery, chemotherapy, and radiotherapy, the treatment can be very challenging, and the severity of mortality is significant. This proves that this disease affecting this organ is responsible for breathing and the circulation of oxygen (O<sub>2</sub>) in the blood increasing the risk of a stroke.

The figures below show the marking made by the medical staff on the DICOM images. Extracted from the archiving and recording system (PACS) and the comparison with the results achieved with the segmentation systems and the proposed U-NET architecture. Fig. 9 represents the PET scan DICOM and the segmentation of the U-NET architecture compared to the (ROI) an estimate (96 × 128) contoured by the medical staff.

Therefore, the Dice has been employed as a loss function in the investigation. While this issue is adjusted by using probability ratios instead of Boolean, it is also known as sophisticated dice disappointment. Comparing the sophisticated dice unfortunate approach to the cross-entropy, it is relatively straightforward to optimize. Analysts have frequently

used the DSC equation in more recent times [22]. The DSC scoring system is used to assess the effectiveness of lung tumor segmentation. The DSC is provided in order to evaluate the outcomes of the actual and planned feature extraction (16).

$$DSC(X, Y) = \frac{2(X \cap Y)}{X + Y} \quad (16)$$

Where Y provides precise or hypothetical segmented lung regions and X relates to the predicted value of the lung segmented areas. The authors use the dice-based loss function, which is defined by (17), for assistance:

$$D = 1 - DSC \quad (17)$$

Furthermore, Fig. 9 demonstrates the segmentation of the PET scan values calculated with 90% accuracy, 91% sensitivity, and 93% dice. Where D is the delicate dice mishap, X is the ground truth, and Y is the predicted output.

Fig. 9. Segmentation of tumors in 3D pet scan data viewed from several sides, (A) original images, (B) ROI, (C) segmentation with U-NET, (D) difference between ROI and U-NET.

The Crossing point over union is an assessment metric utilized to measure the degree of precision on a specific dataset [23]. The IoU is the essential metric to assess and demonstrate accuracy in the case of image Division. The zone of the ROI is not essentially rectangular. It can have any standard or unpredictable shape. Meaning the forecasts are division veils and not bounding boxes. In this manner, pixel-by-pixel examination is done here.

The representation of 3D medical with the ground truth of the medical staff is shown in figure (A) and (B) from Fig. 10.

Fig. 10. 3D representation of the patient (A) and profile representation in (B).

After choosing the adequate representation from the DICOM, the second step is to upload the chosen DICOM Data of the three patients into the appropriate U-NET architecture the following 2D segmentation from the U-NET and the difference of the ROI showed in Fig. 11 that the three patients presented with 90%, 91% and 92% of accuracy, 90%, 93% and 94% of sensitivity and 91%, 92% and 95% of Dice.

The following Fig. 11 presents real cases attacked by lung cancer disease. The doctor then needs to apply margin of sub-chemical tissue to produce the clinical target volume (CTV). The margins are applied to the gross tumor volume (GTV), which is depicted in red, denotes the macroscopic, radiological measurable tumor that was selected from the appropriate software of the Eclipse contouring. Actually, it might be difficult to distinguish tumors from lung tissue in CT images. The algorithms that enable co-registration of diagnostic images with the principal simulation CT scan have been created in order to increase the accuracy of GTV identification. When comparing MRI to CT imaging for lung tumors, it reveals higher resolution and more soft tissue contrast. The clinical target volume (CTV) which is colored in orange is a second volume added to the GTV as a margin to cover nearby locations that must be targeted in order to cure disease that could be present at microscopic levels. Based on anatomical and ROI data obtained from cross-sectional imaging, the CTV is defined. Uncertainty in treating is accommodated by the geometrical software of the planned target volume (PTV) bounded with blue hue, it accounts for the daily random and systematic fluctuations in patient setup, additionally to the internal motion of the tumor during treatment (internal target volume (ITV) displayed in green). These variations may include shifts in the tumor's position and shape as a result of its regression or growth, bladder filling or rectal distension, as well as, unforeseen changes brought on by a change in the patient's position or the method used to set up the machine between each delivered fraction. As a result, the PTV is the suggested parameter to ensure that all areas of the CTV areas receive an acceptable dose of radiation.

When looking at the planning of the non-small cell lung carcinoma patient in the 3D, the software reconstructs the data in sagittal and coronal planes. That helps the doctors to plan the volumes in 3D by the contouring then the doctors use the lung window that is easier to visualize the extend of the volume tumor. Then the pitch that present the distance travelled in one 360° rotation in the CT Scan, remaining the breathing during treatment with the same parameters see (18) and (19).

After uploading the different parts of the slices from different representation the second step consists of choosing one of the best results that are the adequate representations, and to do the 3D image representation from the 2D and try to have the final 3D result of the best-case result with 92% of accuracy, 94% of sensitivity and 95% of dice, see Fig. 12.

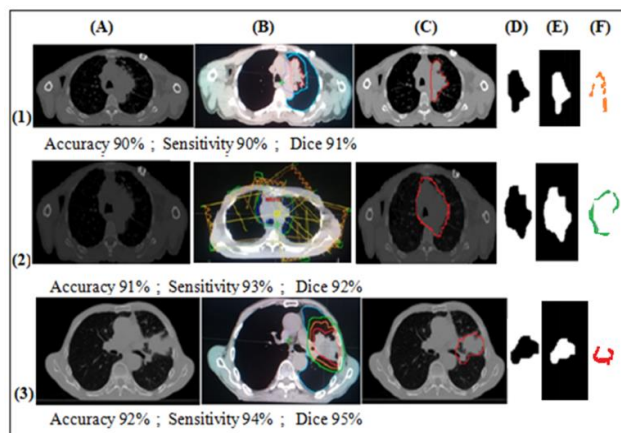

Fig. 11. Segmentation 3D of lungs seen from DICOM;(A) original image;(B) predicted 3D image by medical staff;(C) ground truth mask;(D) segmentation with U-net; (E)ROI;(F)difference between ROI and U-NET.

The results confirm the similarity between the extraction of the volume parameters and surface measured from the different slices (S1, S2, S3 and S4) with the ground truth (cm<sup>2</sup>) compared with medical staff estimation volume (cm<sup>3</sup>) see Table II:

TABLE II. VOLUME OF CANCER IN RELATION TO TOTAL LUNG VOLUME EXTRACTED WITH MEDICAL STAFF

N° Patient	Volume cancer (cm <sup>3</sup> )	Volume of the normal lung (cm <sup>3</sup> )	Volume two lungs (cm <sup>3</sup> )
1	541	2500	4459
2	540	1855	3170
3	112	927	1742

The result of the extracted ROI results from U-NET architecture with the choice of the third patient as best case result, see Table III and the following equation:

TABLE III. VOLUME OF THE LUNG CANCER EXTRACTED FROM THE U-NET ARCHITECTURE OF FIG. 11 BEST CASE OF THE THIRD PATIENT

	S1	S2	S3	S4
Surface (cm <sup>2</sup> )	31.737	54.088	15.945	9.40
Volume (cm <sup>3</sup> )		111.17		

$$CTV = GTV + the\ pitch \quad (18)$$

$$PTV = CTV + the\ pitch \quad (19)$$

After presenting the best case results of Tables II and III of the third patient the authors will choose the best slices from the parameters of accuracy, sensitivity and dice of the showed results in Table III and II and Fig. 11 and upload it into the U-NET architecture to finally obtain the 2D segmentation of the different slices and the 3D representation of the ROI segmentation of the best result communicated in Table I and compared with other authors that are demonstrated (see Fig. 12) and present the best accuracy 98.9%, sensitivity 97.99% and dice 97%, that explained the segmentation of 3D lungs seen from DICOM.

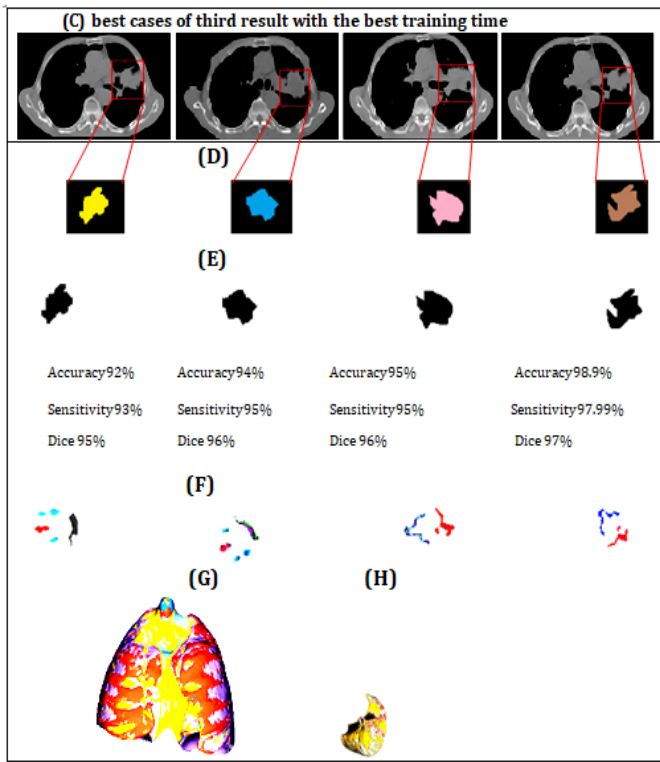

Fig. 12. Segmentation 3D of lungs seen from DICOM, (A) original image, (B) predicted 3D image by medical staff, (C) ROI with ground truth mask, (D) ROI, (E) segmentation with U-net, (F) concatenated 3D images between (E) and (D), (H) and (G) 3D lung segmentation.

Interestingly, in accordance with the 3D U-NET architecture's empirical offshoots seen in Fig. 12, the recommended procedure is more accurate than the conventional framework in terms of delineation performance, as evidenced by the segmentation's sensitivity [24] for further data, seen in Table I.

### C. Generating the Luminosity Picture of the Data

Images captured using specular microscopy typically has low contrast and non-uniform illumination throughout. Here, we want to determine whether picture improvement for CNN would be beneficial. Standardizing the fourth result of the output images in Fig. 12 is also a typical procedure in neural networks. We suggested using contrast constrained adaptive histogram equalization with a kernel of  $(96 \times 128)$  to improve local image contrast. Where  $In$  present the norm of the image  $I(X, X')$  and this kernel size roughly correspond to the size of an average cell see 20.

$$In(X, X') = \frac{I(X, X') - \min(I(X, X'))}{\max(I(X, X')) - \min(I(X, X'))} \quad (20)$$

The advantages of local contrast enhancement would be diminished by a kernel that is too large, while noise would be excessively amplified by a kernel that is smaller than half of a cell. We found that intensity normalization significantly improved performance see Fig. 13.

Interestingly, in accordance with the 3D U-NET architecture's empirical offshoots, the recommended procedure is more accurate than the conventional framework in terms of

delineation performance, as evidenced by the segmentation's sensitivity [24]. For further data, see Table I. Furthermore, the split sensitivity treatment in the database presented in Fig. 13 seems to be more important compared to any other recommended approach. This indicates that, in comparison to the various ways that have been exhibited, the addition of 3D U-NET can help networks achieve the highest execution of the concept of three - dimensional segment.

Fig. 13. Redistribution of the histogram of the result of (A) by intensities shifts (B) of the data.

Furthermore, the split sensitivity treatment in the database presented in Fig. 13 seems to be more important compared to any other recommended approach. This indicates that, in comparison to the various ways that have been exhibited, the addition of 3D U-NET can help networks achieve the highest execution of the concept of three - dimensional segment.

This paper relates the outputs of the consecutive frames depicted in Section 3 to evaluate the allocation grey level approaches in the histogram and its establishment. The first two items featured in the original imagery on which the juxtaposition was done may be clearly distinguished [25]. The other two photos display the intensity value adjustment's dispersion in relation to the original imagery. Variance is utilized as a criterion among the gray scale images' cohesiveness [26] that are formed via numerous 3D imagery of  $(512 \times 512)$  pixels, once data experimentation has been authenticated. To enable the clinician to fine-tune his diagnosis, the objective is to segment the specific area of interest the (ROI) an estimate  $(96 \times 128)$  contoured by the medical staff. Accordingly, the identification must be exact around the subject of interest and must not be hampered by imaging interference (such as patient movement or perspiration).

The consequence allows for a degree of robustness to variations in average luminance by treating the histogram as a compactness of likelihood (probability and impact of a grey scale similar level to all the pixels).

The progress of the diagram demonstrates that the selected assumption may be true since the concluding the artifact setting that nearly equal to Gaussian. These values were as opposed to those created since the epochs by trying to minimize the variance and by reducing the fluctuation threshold, where the disparity of the Gaussian function is predicted in every incarnation of the dataset.

The statistical likelihood  $p$  of the intensity of the histogram distribution, together with its mean  $\mu$  and the variance  $\sigma^2$  shown in (21):

$$p = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad (21)$$

The predicted linear growth in the histograms results in a broader range of gray levels for the main image. As seen by the outcomes in Fig. 13, the performance of the histogram segmentation in PETSCAN and CT SCAN data presented in 3D medical imaging and proved with the results of the pixels intensity are determinate; that can prove that the implementation on the U-NET architecture is more sufficient compared to other literature which concentrates on one study. This contribution opens horizon to data scientists to develop their research with the cooperation of medical staff to obtain the best result in little time and reduce the exposition on x-ray that can have a bad effect especially on the patient.

#### IV. DISCUSSION

The new proposal incorporates a modern sequence segmented technique on the U-NET Algorithm, compared to the result of other data performs the contouring and the final vision of medical staff that the result of the research was achieved and applied with different data from different service unlike other literature applied to a single and unspecified one. This study is the first to discern the importance of deep science in the medical field, especially in 3D image detection. This way offers the chance to develop other perspectives in the near future.

First of all, the 3D segmentation predicting necessitates significantly more complicated computational resources, which in turn affects a model's capacity to execute the training with huge datasets [27]. According to certain research, 2D U-Net performed more accurately, consumed less memory, and required less training time than 3D U-Net. Instead of a 3D segmentation model, several 2D segmentation models targeting the 3D segmentation in U-NET were created. By combining the 2D segmentation model with modern pre- and post-processing image evaluation techniques, researchers were able to build the U-NET, a completely automated end-to-end 3D segmentation network. So, compared to other systems, U-NET provided us with a better performance using the real data extracted from Salah Azaiez Institute.

Secondly, considering its small morphology and constrained location decisions, CT scan is considerably harder for segmentation effectively than other work structures that are frequently segmented manually. The difficult task of segmenting is resolved in this study by the U-NET approach and enhanced image analysis techniques. The comparative examination demonstrates the ability to segment skills of the U-NET. The research's findings and its comparison with previous studies have highlighted the U-NET advantages. As far as the authors are aware, the automatic end-to-end 3D segmentation findings are state-of-the-art [28]. The current study showed that the U-NET technique has considerable potential for creating an automatic and precise segmentation tool for extremely difficult medical imaging segmentation challenges [29].

As 3D U-NET architecture can still be improved, but the authors need an innovative method to solve a difficult

segmentation issue like the subject matter and incompatibility problem.

#### V. CONCLUSION

The suggested approach entails developing a new scientific perspective for the biomedical industry through networking, which improves credible steps in radiation healthcare, notably for tumor segment diagnostics.

The acquired results show that these methodologies can accurately divide an image into homogenous parts and show the potential of the testing, which provides a foundation for the creation of biological data science images. The cooperative work between medical fields and scientists opens the horizon for many points, especially the hardness of the localization of the ROI and the validity of the purpose which demands such time and effort from each contributor. This work was established to perform the imaging system in the medical field of the institute of Salah Azaiez.

For further investigation the requirement for more effective ROI identification while working with various CT scan datasets. Using more sophisticated models, such attention modeling or sequential modeling using GAN for future work, the deep learning networks could be expanded to include contextual data, to overcome the paucity of human-annotated data, a semi-supervised technique involving human and machine collaboration is needed rather than supervised learning.

#### ACKNOWLEDGMENT

The technical staff provides us with the study realized in collaboration with the institute of Salah Azaiez which offers us the required materials and has a significant impact on the success of this work.

#### AUTHORS' CONTRIBUTIONS

ELLOUMI Nabila wrote the paper, slim ben CHAABANE and Hassen SEDDIK contributed to this research with technical and academic writing assistance. The final paper was read and endorsed by all writers.

#### AVAILABILITY OF DATA AND MATERIALS

The DICOM images utilized in the research described in this publication were received from the Institute of Salah Azaiez of Cancerology in Tunisia and are publicly accessible for use in the public's research. The District Referral Hospital will use the tool, which is still in the process of being tested.

#### FINANCIAL SUPPORT AND SPONSORSHIP

Not Applicable.

#### CONFLICTS OF INTEREST

Not Applicable.

#### ETHICAL APPROVAL AND CONSENT TO PARTICIPATE

Since this was a registration-only study, the ethics reviews board accepted it for release without requesting informed consent from research participants.

**Abstract**—Breast cancer is a prevalent and potentially life-threatening disease that affects millions of individuals worldwide. Early detection plays a crucial role in improving patient outcomes and increasing the chances of survival. In recent years, machine learning (ML) techniques have gained significant attention in the field of breast cancer detection and diagnosis due to their ability to analyze large and complex datasets, extract meaningful patterns, and facilitate accurate classification. This research focuses on leveraging ML algorithms and models to enhance breast cancer detection and provide more reliable diagnostic results in the real world. Two datasets from Kaggle have been used in this study and Decision tree (DT), Random Forest (RF), Logistic Regression (LR), K-Nearest Classifier (KNN) etc. are applied to identify potential breast cancer cases. On the first dataset, A, the test's accuracy using Logistic Regression, SVM, and Grid SearchCV was 95.614%, however in dataset B, the accuracy of Logistic Regression and Decision Tree increased to 99.270%. The accuracy of Boosting Decision Tree was 99.270% when compared to other algorithms. To defend the performances, various ensemble models are used. To assign the optimal parameters to each classifier, a hyper-parameter tweaking method is used. The experimental study examined the findings of recent studies and discovered that LRBO performed best, with the highest level of accuracy for predicting breast cancer being 95.614%.

**Keywords**—Breast cancer; prediction; machine learning algorithms; ensemble models; voting; stacking

## I. INTRODUCTION

Multiple tissues are being harmed or developing out of control, which is known as cancer, since sickness is the worst aspect of our daily lives. Breast cancer is a type of cancer that develops when unregulated tissue or damaged tissue does so [1]. This patient's prevalence is significantly rising. However, finding or recognizing the injured region at the time of diagnosis is the key issue. Machine learning may be the most effective component of a crucial factor in predicting the presence of breast cancer from responsive health datasets by examining various variables and patient diagnosis records. We looked at the patient's diagnosis papers for our work and discovered certain key factors to pinpoint the condition. The dataset dealt with the size and structure of a woman's bodily tissues as well as determining whether or not she had breast cancer [7]. In order to employ machine learning algorithms to recognize the cancer tissue in the body, several different

researchers have worked together. However, their method and accuracy were not appropriate nor smooth for predicting breast cancer [12]. We suggest our method to increase the accuracy rate of breast cancer prediction in a woman's body. There are two different kinds of machine learning techniques. One of them is under supervision, while the other is not. Working with labeled data, supervised learning creates outputs from inputs based on examples of input-output pairings. The dataset's training data is used as the working data. Unsupervised learning works with the unlabeled data and creates the model to work with its patterns and information which was not detected previously. Unsupervised learning uses unlabeled data to build models that can make use of previously undetected patterns and information.

## II. BACKGROUND LITERATURE

Breast cancer is the most common and rapidly developing illness in the world. Breast cancer is more commonly detected in women. Breast cancer can be controlled if it is detected early. A hybrid approach-based methodology that uses machine learning has been presented. This method was put into practice utilizing MRMR feature selection using four classifiers to determine the optimal outcomes. The four classifiers SVM, Naive Bayes, Function tree, and End Meta were utilized by the author, and they were all compared. SVM was discovered to be an effective classifier. to ascertain better outcomes [1]. To achieve the most accurate result machine learning is the most reliable technique. We have used a few machine learning classifiers to categorize breast cancer, and they are appropriate for the job we are proposing. To execute decision models, machine learning algorithms that are based on decision tree models are known as "tree structures" [2]. similarly proposed a comparison between Random Forest, Naïve Bayes, Support Vector Machines (SVM), and K-Nearest Neighbors (K-NN) and they found the SVM is the best classifier with an accuracy of 97.9% compared with K-NN, RF, and NB, they are based on Multilayer perceptron with 5 layers and 10 times cross-validation using MLP. The author F. M. Javed Mehedi Shamrat et al. [3] focused on the enhancement of the accuracy value using the Wisconsin Breast Cancer Diagnostic Dataset (WBCD) by applying an ML-based system for the early prediction of breast cancer disease. Six supervised classification techniques are used which are: SVM, NB, KNN, RF, DT, and LR. According to the analysis of breast cancer prediction performance, SVM

had the highest performance and the highest classification accuracy (97.07%). While NB and RF have attained the second-highest prediction accuracy. Mumine Kaya Keles [4] predicted and detected breast cancer early where Random Forest outperformed all the other algorithms giving an average accuracy of 92.2 percent. K.Anastraj et al. [5] depicts that the support vector machine had given better results (94%). In the experimental results [6], BayesNet was the best classification method with an accuracy rate of 97.13%. Ch. Shravya et al. [7] provided relative study on the implementation of models using Logistic Regression, Support Vector Machine (SVM) and K Nearest Neighbor (KNN) on the dataset taken from the UCI Repository. With respect to the results of accuracy, precision, sensitivity, specificity and False Positive Rate the efficiency of each algorithm is measured and compared and focused in the advancement of predictive models to achieve good accuracy in predicting valid disease outcomes using supervised machine learning methods. The results analysis shows that the combination of multidimensional data with various feature selection, classification, and dimensionality reduction techniques can offer advantageous tools for inference in this field. This study has shown that SVM is the best accuracy of 92.7%. The authors Ertel Merouane et al. in [8] provide a cloud-based Extreme Learning Machine (ELM) architecture for the classification of breast cancer. Cloud computing increases categorization accuracy and provides access around the clock. When compared to standalone systems, the ELM model executed faster and with higher accuracy when it was put on the Amazon EC2 cloud platform. Future additions may improve the framework's functionality in image-processing applications like medical imaging and character recognition [9]. Probability is constantly between 0 (never happens) and 1 (occurs). In the case of binary classification, using our COVID-19 example, the likelihood of testing positive and not testing positive will total up to the logistic function or sigmoid function to compute probability in logistic regression. The logistic function is a straightforward S-shaped curve that converts input into a value between 0 and 1 [17].

### III. RESEARCH METHODOLOGY

The Dataset sourced from Kaggle [9] [10].The size of the dataset A is 32x569 and B is 10x683. The frequency of breast cancer is categorized in the diagnostic and Class column. Malignant (M) and Beginning (B) conditions are used to categorize patients. There, 0 represents "B" and 1 represents "M." 212 individuals were at the malignant stage, leaving 357 patients in the initial stage in dataset A. Another dataset B had 239 patients in the malignant stage and 444 individuals in the initial stage. Fig. 1 for dataset A and Fig. 2 for dataset B below display the ratio. The dataset was split into a testing and training set. We've chosen 20% for the exam portion and another 80% for the learning portion. The dataset contains nominal values and there were no missing or incorrect values. A comprehensive explanation of the dataset with its range is displayed in Tables I and II.

### A. Statistical Analysis

Statistical analysis is one of the most crucial segments of any research. In this work, we employed four distinct kinds of algorithms in this work, including Random Forest (RF), Logistic Regression (LR), Gradient Boosting (GB), K-Nearest Classifier (KNN), Adaboost Classifier (ABC), Decision Tree (DT), GridSearch CV (GS), XGBoost Classifier (XGB), Gaussian Naïve Bayes (GNB), and Support Vector Classifier (SVC). Logistic Regression, Support Vector Classifier and Grid SearchCV was 95.614% accuracy for dataset A. Logistic Regression and Decision Tree was 99.270% accuracy for dataset B. Following the use of bagging, boosting, stacking and voting algorithms. Hyperparameter tweaking and 10-fold cross-validation have both been employed.

### B. Proposed Methodology

The dataset for the system's training and testing was initially introduced. Next, we used data preparation techniques such as the Standard Scaler Transform. Categorical data conversion to numeric data. We utilized 80% for the training portion and 20% for the testing portion. After that we implemented algorithms and assessed the outcomes. Then, to get the highest forecast accuracy, we employed ensemble methods. Bagging, Boosting, Stacking and Voting are ensemble algorithms. The outcomes of the ensemble algorithms that were used were then assessed. Then we used Hyper Parameter Tuning to verify the outcome. Then, using outcome analysis, we assessed the models that had been put into practice. Fig. 3 displays the recommended model technique.

### C. Implementation Requirements

A number of filtering techniques is used to clean the dataset. Then, data preprocessing techniques like Standard Scaler Transform were used. We utilized 80% for the training portion and 20% for the testing portion. After that, we implemented algorithms and assessed the outcomes. Then, in order to get the highest forecast accuracy, we employed ensemble methods. Bagging, Boosting, Stacking and Voting are the ensemble algorithms. The outcomes of the ensemble algorithms that were used were then assessed. Then we used

Hyper Parameter Tuning to verify the outcome. Then, using outcome analysis, we assessed the models that had been put into practice. After that we need to execute the data analysis part to start the learning process. Later, to execute model learning and fit the method of predictions. Finally, we need to bagging, boosting, stacking and voting the models to get the best accuracy. Then we can decide the best model to implement considering the best accuracy, precision, recall, and F-1 score. The learning process must then be initiated by carrying out the data analysis step. Next, we must put model learning into practice and fit the predictions approach. To acquire the best accuracy, we must then vote, boost, and bag the models. The best model may then be chosen for implementation based on accuracy, precision, recall, and F-1 score.

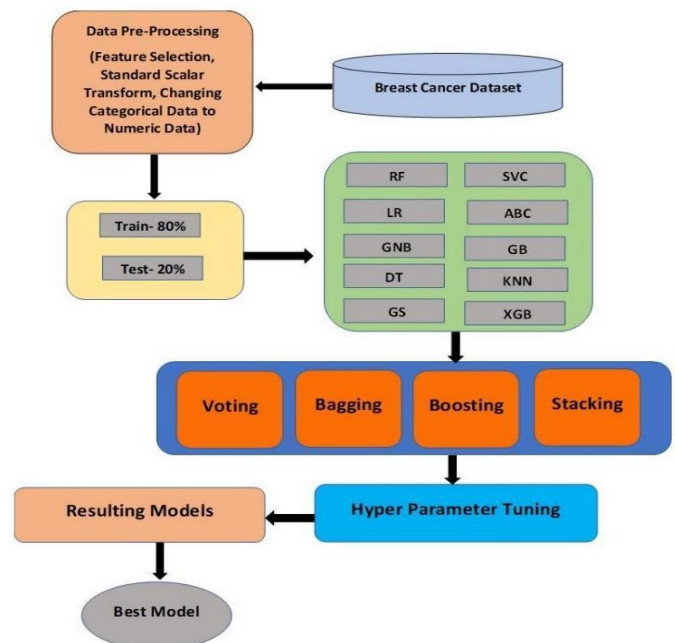

Fig. 3. Methodology of breast cancer prediction.

A correlation subplot has been used to underlying the relationships between two variables or how one variable changes as a result of a change in another. The greater the dependency between variables, the more likely it is that one variable may be successfully predicted from another. It suggests a greater understanding of the dataset and facilitates our capacity to pinpoint the important variables [11].

## IV. EXPERIMENTAL RESULTS AND ANALYSIS

### A. Classifier Algorithms

We have implemented some different classifiers named Random Forest (RF), Logistic Regression (LR), Gradient Boosting (GB), K-Nearest Classifier (KNN), Adaboost Classifier (ABC), Decision Tree (DT), GridSearch CV (GS), XGBoost Classifier (XGB), Gaussian Naïve Bayes (GNB), Support Vector Classifier (SVC) algorithms [13].

1) *Adaboost classifier*: AdaBoost is a boosting classifier that joins a number of ineffective classifiers to create a powerful classifier. 1000 samples are used by ABC to forecast

TA. Weights that differ for classifiers and samples are fixed by ABC [22]. This makes it challenging for classifiers to concentrate on the end outcome. The final formula to achieve TA is,

$$H_k(P) = l - (\sum_{k=1}^k a_k h_k(P)) \dots \dots \dots (1)$$

Here, N=frequency of training data, k = total number of weak classifiers combined to use, hk = output of weak classifier (lower limit 1 to upper limit k), ak = weight of classifier. The notion is depicted in Fig. 4.

Fig. 4. Adaboost classifier.

2) *Gaussian NB Classifier (GNB)*: Gaussian NB Classifier calculates the likelihood of an event occurring given the chance of another event occurring as expressed. Here, every pair of features being categorized is independent of each other (equation 3). The concept is shown below Fig. 5.

$$P(B) = \frac{P(A)P(A)}{P(B)} \dots \dots \dots (2)$$

For each feature in Gaussian NB, the continuous value is assumed to have a Gaussian distribution. The resulting histogram looks like bell curve, with all points being equal distance from the curve's center. The conditional probability is provided by equation (4) if the feature likelihood is Gaussian.

$$P(y) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x_i - \mu_y)^2}{2\pi\sigma^2}\right) \dots \dots \dots (3)$$

Fig. 5. Gaussian NB classifier.

3) *K-Nearest Classifier (KNN)*: K-Nearest Neighbors (KNN) calculates the Euclidean distance between new (x1, x2) and existing (y1, y2) data.

$$\text{Euclidean Distance} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (4)$$

The concept is shown in below Fig. 6.

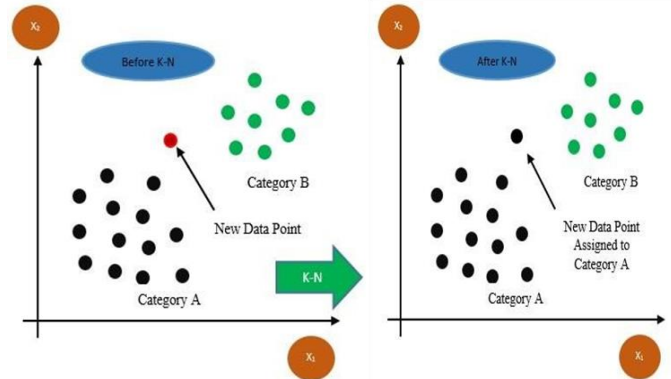

Fig. 6. K-Nearest classifier.

4) *Grid Search CV (GS)*: Grid Search CV is the process of performing hyperparameter tuning in order to determine the optimal values for a given model. The performance of a model significantly depends on the value of hyperparameters. The concept is shown below in Fig. 7.

Fig. 7. Grid search CV classifier.

5) *Decision Tree (DT)*: Decision trees categorize occurrences by branching them out from a central node to a collection of "leaf" nodes that offer the categorization. To assign a category to an instance, we look at the attribute pointed out by the root node of the tree and then follow the branch of the tree that corresponds to the attribute's value. It is usual practice to calculate two additional metrics to identify the "Best Attribute," "Entropy," as shown in (2), and "Information Gain," as shown in (3) [14]. The "best characteristic" is the trait that provides the most valuable data. Entropy measures dataset homogeneity, whereas information gain measures the rate of change in entropy of attributes. The concept is shown below Fig. 8.

$$E(D) = -P(\text{positive}) \log_2 P(\text{positive}) - P(\text{negative}) \log_2 P(\text{negative}) \quad (5)$$

$$Gain (Attribute X) = Entropy (decision Attribute Y) - Entropy (X, Y) \quad (6)$$

Fig. 8. Decision tree.

6) *Logistic Regression (LR)*: A classifier approach based on machine learning called logistic regression (LR) contains two categories for the class label: yes or no, like a binary (0/1) scale. Although it permits the combined value of continuous variables and discrete predictors, logistic regression is appropriate for discrete variables [16]. The idea is depicted in Fig. 9 below. Logistic regression adopts the supervised machine learning approach. The fundamental equation is shown below [17].

$$h(x) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 X)}} \quad (7)$$

' $h\Theta(x)$ ' is the output of the logistic function, where  $0 \leq h\Theta(x) \leq 1$ .

' $\beta_1$ ' is the slope.

' $\beta_0$ ' is the y-intercept.

' $X$ ' is the independent variable.

$(\beta_0 + \beta_1 X)$  - derived from the equation of a line  $Y$  (predicted) =  $(\beta_0 + \beta_1 X)$  + Error.

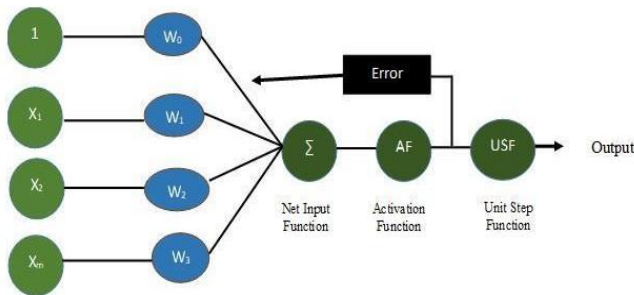

Fig. 9. Logistic regression classifier.

7) *Random Forest (RF)*: Different Decision Tree algorithms make up the Machine Learning (ML) based classifier ensemble approach known as Random Forest (RF) [18]. In order to provide an ideal decision model with more accuracy than the single decision tree model, RF builds several decision trees while the algorithm is being trained. The

notion is depicted in Fig. 10 below. All decision tree methods are calculated using the Random Forest algorithm [20].

$$j = \frac{1}{B} + \sum_{b=1}^B fb(X') \quad (8)$$

Concerning  $X = \{x_1, x_2, x_3, \dots, x_n\}$  with respect to  $Y = \{y_1, y_2, y_3, \dots, y_n\}$  with the lower to upper limit is 1 to B.

Sample  $x'$  = mean of the sum of the prediction  $\sum_{b=1}^B (X')$  for every summation.

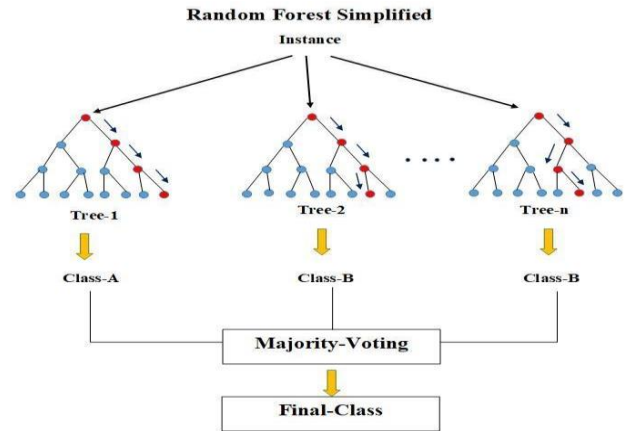

Fig. 10. Random forest classifier.

8) *Gradient Boosting (GB)*: The loss function is the main component of the boosting method known as Gradient Boosting (GB). The notion is depicted in Fig. 11 below. It works by combining and optimizing weak learners to reduce a model's loss function. To improve an algorithm's performance, over fitting is eliminated [7]. Here  $f_i(x)$  = loss function with correlated negative gradients ( $-\rho_i \times gm(X)$ ),  $m$  = number of iterations.

Feature increment ( $i$ ) = 1, 2,3, ... . . . ,  $m$ . Therefore, the optimal function  $F(X)$  after  $m$ -th iteration is shown below.

$$F(X) = \sum_{i=0}^m f_i(x) \quad (9)$$

Here,  $gm$  = the path of loss function's fast decreasing  $F(X) = F_{n-1}(X)$  the decision tree's target is to solve the mistakes by previous learners [21].

Fig. 11. Gradient boosting classifier.

9) *Support Vector Classifier(SVC)*: The Support Vector Classifier (SVC) approach aims to discover a line, or decision boundary, that divides the space into classes in the most optimum way possible across all n dimensions in order to efficiently categorize new data points [15]. Fig. 12 is showing the working process of Support Vector Classifier (SVC).

Fig. 12. SVC classifier.

### B. Ensemble Methods of Machine Learning

The term "ensemble approach" refers to the use of several classifiers to turn weak classifiers into strong classifiers by producing the greatest accuracy and effectiveness. It was used in our investigation due to variable handling, bias, and uncertainty since it lowers variances, merges predictions from several models, and narrows the prediction spread [23]. In our investigation, four ensemble approaches were employed. Bagging, Boosting, Stacking and voting ensemble modeling was employed.

1) *Bagging*: Bagging describes the decrease of variance, diminishing handling, and missing variables. The Bagging model's classification formula is displayed below [24].

Here  $f'(x)$  is the average of  $f_i(x)$  for  $i = 1, 2, 3, \dots, T$ .

$$f'(x) = \text{sign}(\sum_{i=1}^T f_i(x)) \quad (10)$$

2) *Boosting*: The term "boosting" indicates a method that uses an weighted average to operate with several algorithms and create the loss functions [25]. In our study, the training and testing phase of the hybrid model construction uses the boosting method. The formula is displayed below.

Here,  $Y_t = 1/2 - \epsilon_t$  (how much  $f_t$  is on the weighted sample).

$$\frac{1}{n} \sum_{i=1}^n I(y_j g(x_i) < 0) \leq \prod_{t=1}^T \sqrt{1 - 4Y_t^2} \quad (11)$$

3) *Stacking*: Stacking is used to explore many models for the same problem. The idea is that we may approach a learning issue with many models that can learn a piece of the problem but not altogether. Each learnt model can have its own intermediate prediction, allowing for the creation of several distinct learners. As a result, the intermediate prediction may be used to train a second model that will

eventually learn the same goal [19]. Stacking outperforms any single model in terms of efficiency. It can offer a representation that uses Logistic regression as a joiner method to blend all conventional classifiers into a final prediction using a joiner technique.

4) *Voting*: Voting classifiers are a group of classifiers that are used to forecast the class with the best majority of votes. It implies that the model trains using many models to anticipate outcomes by aggregating the results of voting. The notion is depicted in Fig 16 below. The formula we employed is shown below [26] [27].

Here,  $w_j$  = weight that can be assigned to the  $j^{th}$  classifier.

$$y' = \text{argmax} \sum_{j=1}^m w_j p_{ij} \quad (12)$$

### C. Experimental Results and Analysis

First of all, we will clarify the judicial system of our proposed model. We have considered the accuracy, precision, recall and F-1 score shown in Fig. 13.

1) *Accuracy*: It speaks about the proportion of testing data predictions that were correct. Whereas accessibility of the measures with actual measurements is performed by accuracy. It is founded on a solitary variable. Accuracy only addresses deliberate mistakes. It is one of the most straightforward measurement methods for any model. We must strive to make our models as accurate as possible.

$$\text{Accuracy} = \frac{\text{TruePositive} + \text{TrueNegative}}{\text{TruePositive} + \text{FalsePositive} + \text{TrueNegative} + \text{FalseNegative}}$$

2) *Precision*: It speaks about the percentage of positively expected observations that really occurred. The genuine true portion of all the cases where they correctly predicted true are identified by precision. For any type of model, a high recall might also be highly deceptive.

$$\text{Precision} = \frac{\text{TruePositive}}{\text{TruePositive} + \text{FalsePositive}}$$

3) *Recall*: It speaks about the percentage of positively anticipated observations from a model. High accuracy, though, might occasionally be deceptive. Normally Recall determines the proportion of expected positives to all positive labels.

$$\text{Recall} = \frac{\text{TruePositive}}{\text{TruePositive} + \text{FalseNegative}}$$

4) *F-1 Score*: It speaks of precision and recall harmonic means. Both the recall and precision ratios are relevant. If the harmonic mean is smaller, the model is probably not very good.

$$F - 1 \text{ Score} = 2 * \frac{\text{Recall} * \text{Precision}}{\text{Recall} + \text{Precision}}$$

At first, we calculated the missing or incorrect values and filtered these from our dataset A and B[28]. The Random Forest (RF), Logistic Regression (LR), Gradient Boosting (GB), K-Nearest Classifier (KNN), Adaboost Classifier

(ABC), Decision Tree (DT), GridSearch CV (GS), XGBoost Classifier (XGB), Gaussian Naïve Bayes (GNB), Support Vector Classifier (SVC) algorithms applied and their performance are measured. We have measured Confusion matrices Accuracy, Precision, Recall and F-1 Score for our proposed algorithms. We have evaluated Bagging, Boosting, Stacking and voting ensemble techniques for dataset A and B.

Fig. 13. Experimental results of classifiers for dataset A.

Firstly, we considered the performances of algorithmic classifiers, the best accuracy obtained at 95.614% using Logistic Regression (LR), Support Vector Classifier (SVC), and Grid SearchCV (GS). The best precision score was obtained from Random Forest (RF), Logistic Regression (LR), Gradient Boosting (GB), K-Nearest Classifier (KNN), Decision Tree (DT), GridSearch CV (GS) and XGBoost Classifier (XGB) about 99.99%. The best recall score was obtained from Logistic Regression (LR) and Support Vector Classifier (SVC) with 93.055%. The best F-1 score was obtained at 96.402% from GridSearch CV (GS), Logistic Regression (LR) and Support Vector Classifier (SVC). The visualization is shown in Fig. 14.

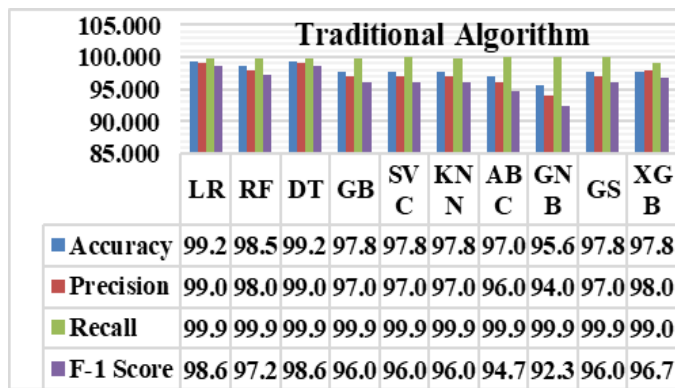

Fig. 14. Experimental results of classifiers for dataset B.

We considered the performances of algorithmic classifiers, the best accuracy obtained at 99.270% using Logistic Regression (LR) and Decision Tree (DT). The best precision score was obtained from Logistic Regression (LR) and Decision Tree (DT) about 99.00%. The best recall score was obtained from Adaboost Classifier (ABC), GridSearch CV (GS), Gaussian Naïve Bayes (GNB) and Support Vector Classifier (SVC) with 99.99%. The best F-1 score was

obtained at 96.402% from Logistic Regression (LR) and Decision Tree (DT).

Fig. 15 showed that Decision Tree (DT) had acquired the best score of 99.99%. But GridSearch CV (GS), XGBoost Classifier (XGB) and Support Vector Classifier (SVC) had acquired 99.89%. Hence according to the above analysis as well as the detailed results with graphical representation, Decision Tree (DT) can be stamped as the best algorithmic classifier.

Fig. 15. Experimental results of bagging for dataset A.

Secondly, we considered the performances of Ensemble Classifier Bagging, the best accuracy had obtained at 92.982% using Logistic Regression (LR) and Gradient Boosting Classifier (GB), KNeareast Classifier (KNN) and Grid Search CV (GS). The best precision score was obtained from Logistic Regression (LR) and Gradient Boosting Classifier (GB), KNeareast Classifier (KNN) and Grid Search CV (GS) about 94.666%. The best recall score was obtained from Logistic Regression (LR) and Gradient Boosting Classifier (GB), KNeareast Classifier (KNN) and Grid Search CV (GS) with 91.489%. The best F-1 score was obtained at 92.531% from Logistic Regression (LR) and Gradient Boosting Classifier (GB), KNeareast Classifier (KNN) and Grid Search CV (GS). The visualization is shown in Fig. 16.

Fig. 16. Experimental results of bagging for dataset B.

We considered the performances of Ensemble Classifier Bagging, the best accuracy obtained at 99.270% using Logistic Regression (LR) and Gradient Boosting Classifier (GB), XGBoost Classifier (XGB) and Grid Search CV (GS). The best precision score was obtained from Logistic Regression (LR) and Gradient Boosting Classifier (GB),

XGBoost Classifier (XGB) and Grid Search CV (GS) about 98.648%. The best recall score was obtained from Logistic Regression (LR) and Gradient Boosting Classifier (GB), XGBoost Classifier (XGB) and Grid Search CV (GS) with 99.504%. The best F-1 score was obtained at 99.066% from Logistic Regression (LR) and Gradient Boosting Classifier (GB), XGBoost Classifier (XGB) and Grid Search CV (GS).

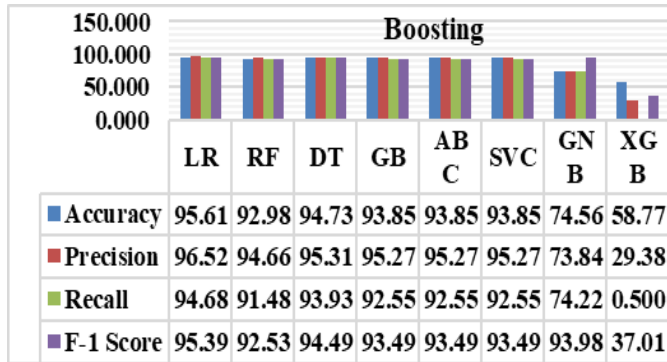

Fig. 17. Experimental results of boosting for dataset A.

The final consideration should be the performance obtained using boosting algorithms. After applying boosting algorithms, the best accuracy was obtained at 95.614% using Logistic Regression (LR). The best precision score was obtained from Logistic Regression (LR) about 92.527%. The best recall score was obtained from Logistic Regression (LR) with 94.680%. The best F-1 score was obtained at 95.392% from Logistic Regression (LR). The visualization is shown in Fig. 17.

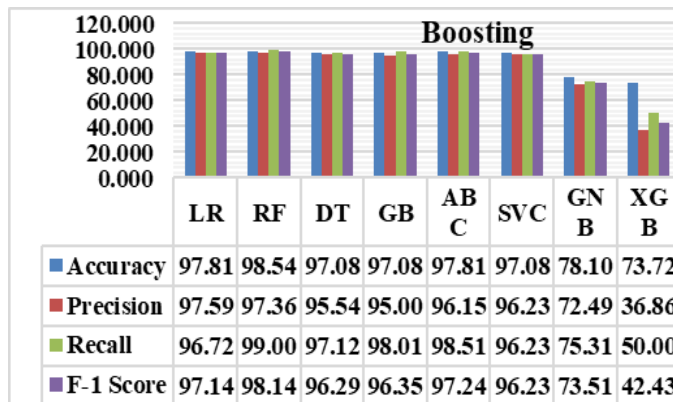

Fig. 18. Experimental results of boosting for dataset B.

The final consideration should be the performance obtained using boosting algorithms. After applying boosting algorithms, the best accuracy had obtained at 98.540% using Random Forest Classifier (RF). The best precision score was obtained from Logistic Regression (LR) about 97.591%. The best recall score was obtained from Random Forest Classifier (RF) with 99.009%. The best F-1 score was obtained at 98.148% from Random Forest Classifier (RF). The visualization is shown in Fig. 18.

## V. CONCLUSION

In this article, the researchers assess the influence rate of individuals employing algorithms. The prediction system may

benefit from the diagnosing technology. People can gain from understanding if they will have an impact or not. They should presumably be aware about breast cancer. If individuals use this approach, they can quickly identify the various stages of breast cancer. Assuming the suggested model can also be beneficial to diagnosis authority. The time and difficulty involved in diagnosing breast cancer sickness have decreased because to new technology. The study have made an effort to provide the folks something fresh. A variety of widely used algorithms have been employed that are quick to construct, simple to use, and accurate. Two sets of data has been used and the size of the first dataset, A is 32x569 and the second dataset, B is 10x683. The frequency of breast cancer is categorized in the diagnostic and Class column. That provides the accuracy of 99.270%. Which made this study very relatable to the real life environment and the model can learn by itself which will make this a platform oriented and advance method to predict breast cancer. And early prediction is a cure of this kind of disease. This study has tried to simplify the process of predicting breast cancer in humans. Innovative models can assist people. It's important to make sure the concept is workable and try to add a lot more features and work on more well-liked topics in the future.

## VI. LIMITATIONS OF A STUDY

The most crucial limitation of this study is the insufficiency of sample data sets and test dataset. Cell anatomy is evolving day by day and this limitation is a curse of disease prediction methods. Every human body is a box of mystery and it's tough to fight against anything with a limited amount of data. To achieve this awareness needs to be raised. In this research, the methodology is used to forecast breast cancer in humans. But it is also observed that there is a shortage of knowledge and diagnostic tools. Cancer detection and symptom analysis are expensive in developing nations. This research work is attempting to use machine learning to address the issue.

## VII. RECOMMENDATION FOR FUTURE RESEARCH

Expanding the datasets used for breast cancer prediction can provide a more comprehensive understanding of the disease. Including data from different demographics, geographic regions, and medical institutions can help capture a broader spectrum of breast cancer cases and improve the generalizability of the models. Future work can focus on developing real-time prediction models that can assist healthcare professionals in making timely and informed decisions. Integration with electronic health records (EHRs) and clinical decision support systems can enable seamless integration of the prediction models into the clinical workflow. Applying emerging technologies, such as deep learning, reinforcement learning, and federated learning, can further enhance the performance and scalability of breast cancer prediction models.

# Research on Settlement Prediction of Building Foundation in Smart City Based on BP Network

Luyao Wei

Department of Architecture and Civil Engineering,  
Shijiazhuang University of Applied Technology, Shijiazhuang 050000, China

**Abstract**—In the construction process of high-rise buildings, it is necessary to predict the settlement and deformation of the foundation, and the current prediction methods are mainly based on empirical theoretical calculations and methods and more accurate numerical analysis methods. In the face of the interference of complex and ever-changing terrain and parameter values on prediction methods, in order to accurately determine the settlement of building foundations, this study designed a smart city building foundation settlement prediction method based on BP neural network. Firstly, a real-time dynamic monitoring unit for building foundation settlement was constructed using Wireless Sensor Network (WSN) technology. Then, the monitoring data was used to calculate the relevant parameters of building foundation settlement through layer sum method. Finally, input the monitoring data into the BP network results, adjust the weights of the output layer and hidden layer using settlement related parameters, and output the settlement prediction results of the smart city building foundation through training. The study selected average error and prediction time as evaluation criteria to test the feasibility of the method proposed in this article. This method can effectively predict foundation settlement, with an average prediction error always less than 4% and a prediction process time always less than 49ms.

**Keyword**—Smart city; intelligent architecture; foundation settlement; settlement prediction; BP neural network; parameter

## I. INTRODUCTION

Urban high-rise buildings are increasing recently. From the beginning of construction to the completion acceptance of high-rise buildings, regular monitoring of foundation settlement and prediction of deformation trend are of great significance to ensure the construction safety and normal use of the building [1]. Therefore, many models and methods are put forward to solve the prediction problem of foundation settlement and deformation. These methods can be roughly categorized as two kinds: theoretical calculation and measured data analysis method based on measured data. Among them, the theoretical calculation method can be subdivided into empirical method and numerical analysis method. The former is simple and practical, and is generally determined based on laboratory test results combined with relevant experience, and the calculated results generally have a large deviation from the measured values [2-3]. The latter is the product of modern mechanics research and develops gradually with the progress of computer technology. With the continuous development of computer technology, the methods for analyzing foundation settlement and deformation have gradually evolved from experience to empirical theory. However, due to the

complexity and variability of factors that affect foundation settlement and deformation in practical engineering, it is difficult to determine the values of various geological parameters, which makes it difficult for analysts to establish numerical models that match the actual engineering situation, thus greatly limiting the application of this method in engineering practice [4].

Therefore, a prediction method of building foundation settlement based on the “S-index” mathematical model is designed in research [5]. This method firstly analyzes the settlement law of building foundation, then optimizes the Logistic curve (S curve) model and exponential curve model, and puts forward “S-exponential” mathematical model, and theoretically analyzes the model from the mathematical point of view. In study [6], a soft soil foundation settlement prediction method is designed based on the modified and optimized comprehensive prediction model. For predicting soft soil foundation settlement, a modified and optimized comprehensive prediction model is proposed to solve the problem that the choice of single prediction method is difficult to adapt to the actual engineering situation. The monitoring data of soft soil foundation settlement are independently mined from different angles to analyze the change law of soft soil foundation settlement, and the comprehensive prediction of soft soil foundation settlement is realized. Firstly, the hyperbolic method and GM (1,1) model are considered comprehensively, and a preliminary comprehensive prediction model is established based on the arithmetic weighted average combination idea. Then, the real-time correction weight coefficient is constructed, the real-time correction amount is calculated to modify the preliminary comprehensive prediction model, and the comprehensive prediction model of modification optimization is established. Finally, the modified and optimized comprehensive prediction model can be used to predict soft soil foundation settlement. In reference [7], the grey model with fractional order is studied and applied to the prediction of foundation settlement. This method takes the grey model as the research object and improves the prediction effect of the grey model by changing the integer order differentiation into fractional order differentiation. The biggest difference between this model and the traditional model lies in the addition of fractional order recognition. Firstly, the ordinary differential equation without input is obtained by combining grey theory. Then the input term is introduced and the ordinary differential equation is transformed to obtain the fractional differential equation. However, it is found in practical application that the method has the disadvantages of large average error and long time consuming. In [8], it was

found that current clustering algorithms lack effective representation learning, and deep learning techniques can be utilized in document clustering to enhance the learning process. Firstly, by retaining important information in the initial data, the original samples and their extensions are pushed together to solve the problem of learning representation. In addition, the problem of cluster position preservation is also addressed by pushing adjacent data points together. To this end, a deep embedding clustering framework based on compressed autoencoders (DECCA) was proposed to learn document representation. In addition, in order to grasp relevant document or word features, the Frobenius norm was added as a penalty term to the traditional autoencoder framework, which helps the autoencoder perform better. The authors in [9] proposed a new grey wolf optimized Extreme learning machine model, namely GWO-ELM model. This model trains and predicts land subsidence by combining Extreme learning machine and grey wolf optimization algorithm, and establishes three GWO-ELM models considering the influence of time series, settlement factors and optimization to predict land subsidence near the foundation pit. The prediction results show that the average relative error and Mean absolute error values from large to small are: GWO-ELM model based on time series, GWO-ELM model based on sedimentation factor, and three GWO-E optimized GWO-ELM models. In reference [10], healthcare is also widely integrated with the Internet of Things to develop an upcoming industrial system. Utilizing this type of system can promote optimal patient monitoring, effective diagnosis, intensive care, and include appropriate surgery for existing critical illnesses. Due to massive data theft or privacy breaches, security, and privacy based on patient information data, it has become necessary to protect personal patient information data in digital communities. The article emphasizes excellent monitoring and perceptual extraction of keyframes, as well as lightweight cosine functions for further processing using hybrid chaotic mapping keyframe image encryption. This encryption combines keyframes, is very secure, and is not affected by external factors or any opponents. The proposed method verifies the effectiveness of the entire IIoT ecosystem.

Smart City is a term that originated in the field of media and has become popular in recent years. The concept refers to using a variety of information technologies to integrate urban systems and services to achieve greater efficiency in resource utilization, improved urban management and services, and ultimately a higher quality of life for citizens. This innovative approach to city building can help alleviate many of the problems cities face, such as overcrowding and poor resource management. Wisdom City, on the other hand, is a new generation of technology-based city management strategies that integrate knowledge and innovation from all walks of life. It combines the latest advances in information technology, industrialization, and urbanization to effectively meet the challenges posed by modern urban development. Through refinement and dynamic management, it aims to enhance the quality of urbanization and promote better urban management performance, ultimately improving the quality of life for urban residents [11-12].

Smart city is an innovative approach to city building that

leverages next-generation information technologies to integrate urban systems and services. These technologies include the Internet of Things, cloud computing infrastructure, and geospatial infrastructure, as well as various tools and methods such as social networks, Wikis, and all-media integrated communication terminals. This approach to city building is characterized by comprehensive and thorough perception, broadband interconnection, intelligent integration, and sustainable innovation. It is driven by user innovation, open innovation, mass innovation, and collaborative innovation, and involves a range of integrated methods such as Living Lab and Fab Lab. The goal of smart city development is to improve resource utilization, optimize urban management and services, and enhance the overall quality of life for city dwellers through innovation and collaboration [13]. The idea of smart city has emerged as a response to the changing landscape of the networked world. In the knowledge society, this advanced form of information development is seen as the successor to the digital city. The construction of a smart city is a complex process that involves the integration of multiple technologies and the democratization of innovation. Key to this is the application of new generation technologies like cloud computing and the Internet of Things, which drive the development of comprehensive perception and ubiquitous interconnection. Using mobile technology, the concept of smart city also involves the democratization of innovation, aimed at enhancing the quality of life for citizens. The approach is characterized by converged application and ubiquitous computing and has the potential to revolutionize the way cities are managed and function.

Based on the above background, smart architecture came into being. Intelligent building first rise in foreign countries, through intelligent device for intelligent management for the whole building space and its internal facilities, according to the architectural space feature matching corresponding intelligent system, in order to achieve energy conservation and emissions reduction, comfortable living, convenient management, safety and environmental protection effect, such as the main service groups, using, and managing personnel to live [14-15]. Therefore, we can understand that, in construction of digital intelligent wisdom city is the city development direction, intelligent building is in the process of building construction, unit for construction personnel and management personnel to provide digital intelligent management, the operation of the service system, the main service groups are construction workers, construction management and construction enterprises; Smart building is to provide intelligent services for residents, users and managers after the building is completed.

Therefore, when maintaining the stability and safety of intelligent buildings, it is very important to accurately predict the foundation settlement. Therefore, in view of the shortcomings of traditional methods, this study designed a prediction method for foundation settlement of smart city buildings based on BP neural network. Based on WSN, this study aims to establish a real-time dynamic monitoring system for building foundation settlement. Based on measured data, a hierarchical summation method is used to determine the parameters related to building foundation settlement. Finally,

the monitoring data is input into the BP neural network, and the weights of the output layer and hidden layer are modified based on the parameters related to settlement, ultimately achieving the prediction of basic settlement in smart cities. The feasibility of the proposed algorithm was tested using average error rate and prediction time as evaluation indicators.

The prediction method of smart city building foundation settlement based on BP network is to analyze the structure of the BP network, input monitoring data into the BP network model results, adjust the weights of the hidden layer and output layer using settlement related parameters, and output the prediction results of smart city building foundation settlement through training. It can be well applied in more intelligent building construction in the future, and can accurately predict foundation settlement, Make timely response. Compared with other methods, the building foundation settlement prediction system based on WSN technology proposed in the study is innovative, and the experimental verification in the following text shows that the prediction has smaller errors and faster response speed.

## II. FOUNDATION SETTLEMENT PREDICTION OF SMART CITY BUILDINGS

### A. Real-time Dynamic Monitoring of Building Foundation Settlement

In this study, WSN technology is firstly used to construct a real-time dynamic monitoring unit for building foundation settlement. The overall architecture of the monitoring unit is shown in Fig. 1.

The monitoring unit mainly includes the following four parts: building sensor node distribution module, sensor network module, communication module and upper computer monitoring module. Among them, the sensor network mainly collects the foundation settlement displacement data, and sends the data to the serial port of the coordinator, and then to the upper computer module. The middleware of serial communication can identify whether the information is valid or not, and analyze the valid and available information, and then transfer and store it in the database. The monitoring module of upper computer can realize remote node information management and control, historical information retrieval, data curve visualization and dynamic warning, etc.

As for real-time dynamic monitoring of building foundation settlement, it is defined that settlement measurement is effective when the monitoring error is controlled within 50mm [16]. Therefore, the unit adopts a displacement sensor with a precision of 0.1mm. Its operating principle is: when the sensor is compressed due to displacement, the resistance of the winding resistance wire changes a series of times, so that the voltage also changes, and the displacement can be estimated by the voltage change value. The measurement environment is shown in Fig. 2.

Use reinforced concrete design to make the base point of the column pillar, and dig down 3m at the base point. The triangular bracket is installed and fixed at the settlement monitoring position of the wall. One end of the displacement sensor is fixed on the base point, and the other end is in contact with the triangular baffle. Once the foundation

settlement, the wall will also downward displacement, triangular baffle and sensor will produce extrusion, at this time the sensor is compressed, the voltage between point B and C will produce a certain change, so as to obtain the foundation settlement data.

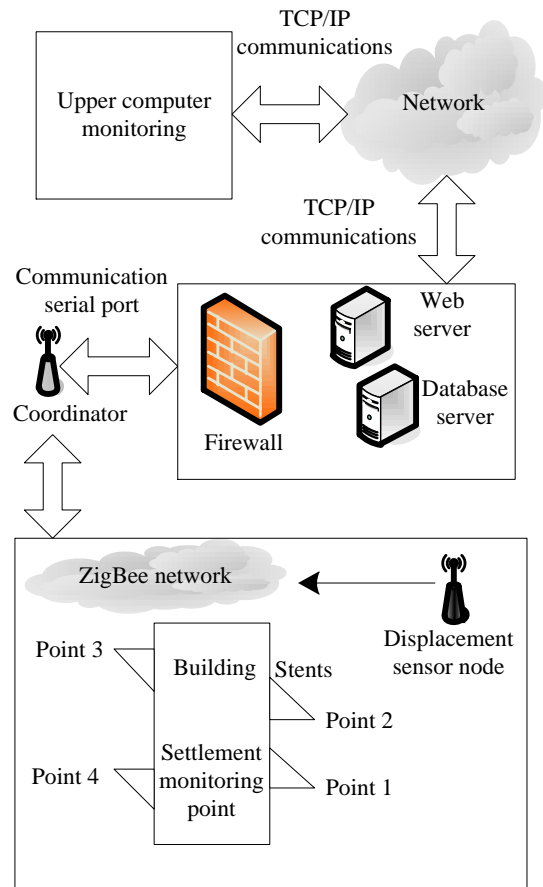

Fig. 1. The whole structure of real-time dynamic monitoring unit for foundation settlement.

Fig. 2. Schematic diagram of measurement environment.

When displacement sensors are set at the corresponding positions of settlement monitoring points, multiple displacement sensor monitoring points are set around the building [17-18]. The plane distribution of monitoring points is shown in Fig. 3.

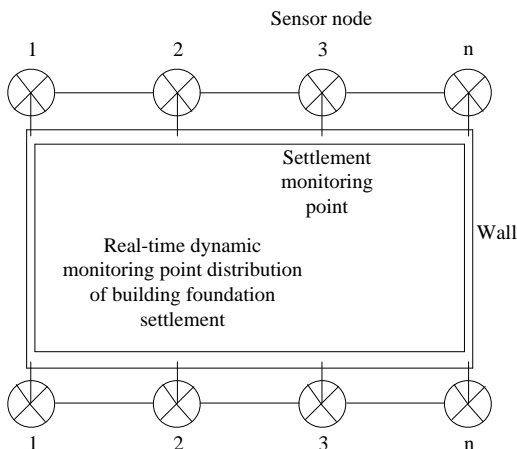

Fig. 3. Plane distribution of monitoring points

The building foundation settlement information data acquisition module is composed of highly accurate displacement sensor and ZigBee network equipment. Among them, the main function of each displacement sensor in ZigBee network is to communicate with superior nodes, and collect real-time displacement data of building foundation settlement and complete package transmission [19]. The routing node is mainly responsible for relaying the information data of monitoring points, so as to ensure that all monitoring points can efficiently send data to the coordinator position in the whole communication range. The coordinator is responsible for bringing together all the ZigBee network data and enabling the network to be turned on or off.

TABLE I. EXPLANATION OF FORMULA SYMBOLS

Formula symbols	Meaning
$\psi$	Axial stress
$\psi'$	Axial strain
$E$	Initial combined deformation modulus of soil mass
$B$	Poisson's ratio of soil mass
$\delta$	The failure ratio of soil mass
$c$	Soil cohesion
$f$	The maximum principal in the vertical direction
$f'$	Minimum principal stress in the horizontal direction
$\hat{\sigma}$	Pressure coefficient of static soil

The upper computer software adopts B/S mode, which has the biggest advantage of realizing data storage and real-time dynamic monitoring in the gateway of the coordinator, and at the same time, it can use the network to inquire the displacement information data and early warning situation remotely. The communication between the coordinator and the upper computer of the system is realized by gateway. The

communication gateway detects the data flow, receives the data flow packet from the serial port in real time, parses the data, and saves it to the corresponding database. Once the sensor displacement exceeds the limit, the exceeding information data will be saved in the warning information Table I. The client can browse through the Internet to check the system measured data and graph as well as the construction warning situation.

### B. Calculation of Related Parameters

The above monitoring data of building foundation settlement are introduced into the Duncan-Chang constitutive model and combined with the layer-summation method to calculate the relevant settlement parameters.

Duncan-chang model is a constitutive model constructed based on the correlation curve between Kondner's triaxial stress and strain [20-21], and its expression is as follows:

$$D = \frac{\psi \times v}{(m+n)\psi'} \quad (1)$$

Where,  $\psi$  and  $\psi'$  respectively represent axial stress and strain,  $v$  represents soil confining pressure, and  $m$  and  $n$  represent fitting parameters of the curve between stress and strain. The calculation process is as follows:

$$\begin{cases} m = \frac{1}{E} \\ n = \frac{1}{B\psi} \end{cases} \quad (2)$$

Where,  $E$  represents the initial joint deformation modulus of soil mass, and  $B$  represents poisson's ratio of soil mass.

Assume that  $\delta$  represents the failure ratio of soil and the ratio between the failure partial stress  $\psi$  and the ultimate partial stress  $B\psi$ , which is generally 0.75-1. Thus, equation (3) can be obtained:

$$n = \frac{\delta}{\psi} = \frac{\delta(1-\sin\phi)}{2c\cos\phi + 2v\sin\phi} \quad (3)$$

Where,  $c$  represents the cohesion of soil and  $\phi$  represents the Angle of internal friction. Since the Duncan-Chang model only considers the settlement under the influence of deviational stress, the foundation deformation caused by hydrostatic pressure should also be taken into account.

$$s = s_i + s_i' \quad (4)$$

In the formula,  $s$  represents the vertical deformation of the  $i$ -th layer,  $s_i$  and  $s_i'$  represent the vertical deformation under the influence of water purification pressure and deviational stress, and these two parameters are calculated by Hooke's Law and Duncan-Chang respectively.

Because different compressible layers in the foundation will have different deformations under the influence of additional stress, it is necessary to obtain the initial deformation modulus value. Under the influence of dead weight stress, the maximum principal stress  $f$  in the vertical direction and the minimum principal stress  $f'$  in the horizontal direction are obtained, then the initial ground stress calculation process of the  $i$ -th compression layer is as follows:

$$F = \left( \gamma_k h_k + \frac{g}{2} \times p \right) \times \partial \quad (5)$$

Where,  $\gamma_k$  and  $h_k$  respectively describe the weight value and thickness value of soil at layer  $k$ ,  $g$  represents the mean value of vertical dead weight stress,  $p$  represents the mean value of horizontal lateral pressure, and  $\partial$  represents the pressure coefficient of static soil, which can be expressed as:

$$\partial = \frac{B}{1-B} \quad (6)$$

### C. Settlement Prediction Based on BP Network

BP(Back Propagation) network is a multi-layer feed-forward neural network trained according to error reverse Propagation algorithm, and it is one of the most applied neural network models. BP network is a multi-layer feedforward network trained by error back propagation. Its algorithm is called BP algorithm. Its basic idea is gradient descent method, and gradient search technology is used to minimize the mean square error of the actual output value and the expected output value of the network.

The BP neural network is particularly effective when it comes to solving problems that a simpler perceptron cannot, such as the Exclusive OR (XOR). Structurally, the BP network consists of three layers: input, hidden, and output. In practice, the BP algorithm uses the square of the network error as the objective function and employs a gradient descent method to calculate the minimum value of this function. This allows it to effectively map complex, high-dimensional data sets onto a lower-dimensional space, providing a powerful and flexible tool for a range of applications. Ultimately, the BP neural network is a powerful tool that can help unlock the potential of big data [22].

The BP algorithm is a multi-step process that involves both forward and backward propagation. During forward propagation, the input signal is transformed through the hidden layer and generates an output signal through nonlinear transformation. If the actual output is different to the expected output, then the error backpropagation process begins. Backpropagation involves adjusting the weight and threshold in the direction from output to input, allowing the system to learn and adjust based on the errors identified. This process is iterative, with the network continually re-evaluating and refining its judgments based on new data [23]. Error backpropagation is the process of transmitting output error

back through the hidden layer to the input layer. This involves apportioning the error to all of the elements in each layer and using these error signals to adjust the weights of the connections between nodes. Through the repeated adjustment of these connection strengths and threshold values, the error can be minimized along the gradient direction, allowing the network to learn and adapt to new data. Eventually, this process leads to the identification of network parameters, such as weights and thresholds that correspond to minimal error. Once these parameters are identified, the training process is complete, and the neural network is ready to process new inputs. By applying nonlinear transformations to these inputs, the network can effectively map them onto a lower-dimensional space and process them with minimal error.

With the BP neural network analysis, for the influence of mechanical parameters change due to the nonlinear soil, combined with BP network to achieve accurate prediction of building foundation settlement. Fig. 4 shows a three-layer BP model.

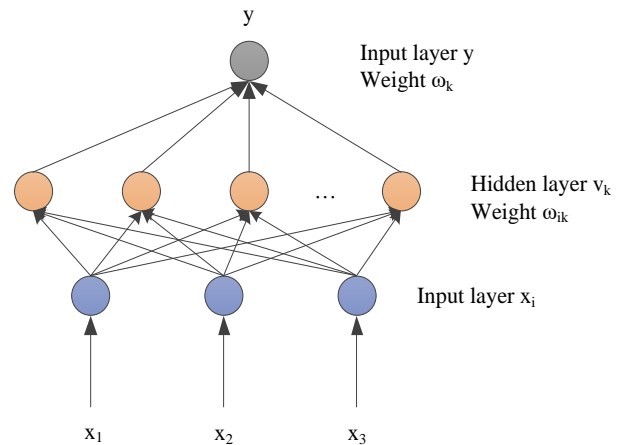

Fig. 4. BP model.

In general, the number of hidden layers in BP neural network  $\cong 1$ . All mappings from  $m$  dimension to  $q$  dimension can be realized by using 3-layer BP neural network. Therefore, the number of hidden layers can be set as 1, and the number of existing neurons is  $k$ . The connection strength between this layer and other two layers needs to be described by using weights. The input vector is described by  $X = \{x_1, x_2, x_3\}$ ; The output vector is described by  $y$ . The weights of hidden layer and output layer are  $\omega_{ik}$  and  $\omega_k$  respectively. In the hidden layer, vectors matching neurons are described by  $v_k$ .

The core idea of BP neural network is that signal and error are propagated forward and backward respectively. The neuron excitation function is described by  $f(*)$ . According to the forward propagation of the signal, expressions related to the hidden layer described in Formula (7) and (8) can be obtained:

$$y_k = f(\text{net}_k), k = 1, 2, \dots, n \quad (7)$$

$$\text{net}_k = \sum_{i=1}^n \omega_{ik} x_i, k = 1, 2, \dots, i, \dots, n \quad (8)$$

Expressions about the output layer obtained are described by formulas (9) and (10) :

$$z_k = f(\text{net}_k) \quad (9)$$

$$\text{net}_k = \sum_{i=1}^n \omega_{ik} y \quad (10)$$

On this basis, the expected and actual output is subtracted. Suppose  $e$  represents the error function, and its calculation process is as follows:

$$e = \sum_{k=1}^n (t_k - z_k)^2 \quad (11)$$

The application process of error function to input layer is as follows:

$$E = \sum_{k=1}^n \{t_k - f[\sum_{j=1}^n \omega_{jk} f(\sum_{i=1}^m \omega_{ij} y)]\}^2 \quad (12)$$

With the above formula, the weight can be adjusted to make the error change. The error is continuously reduced to ensure that the weight adjustment amount and its negative gradient change trend are the same, namely, the basic criterion of weight adjustment, which is described by the following formula:

$$\Delta \omega_{ik} = -\eta \frac{\partial e}{\partial \omega_{ik}} \quad (13)$$

Where,  $\eta$  represents the learning rate, and its value range is (0,1). Gradient descent is described by a negative sign.

The weight of each layer is updated in a circular way. The learning process of BP neural network, namely the process of repeatedly updating the weight, and the increase of new data can gradually reduce the error.

Based on the above analysis, the concrete prediction steps of foundation settlement of smart city building based on BP network are designed. Before the prediction, it is difficult to establish the specific relationship between the influencing factors and the settlement because the mechanism of foundation settlement deformation is relatively vague and the influencing factors are highly complex, which is also the fundamental reason why the application of conventional analysis methods is limited and the effect is not ideal.

Considering that the measured settlement data already contains the information of influencing factors, the settlement data in a certain time period is taken as the input of the neural network, and the predicted data in an unknown time period is taken as the output data. Therefore, in this study, the first three monitoring data are used to predict the next data, and the BP network structure is determined as follows: the number of

nodes in the input layer is 3, the number of nodes in the hidden layer is 5, and the number of nodes in the output layer is 1.

According to the measured foundation settlement value of the project, 27 samples were established. The first 17 samples were used as training samples for BP neural network training and learning, and the last 10 samples were used as prediction samples to test the prediction and generalization ability of the established BP neural network model. The steps are as follows:

Step 1: Assume that the input information of BP neural network is  $x$ , the target input is  $d$ , and the actual output is  $y$ , and randomly generate the initial value and threshold value as the connection weight between nodes.

Step 2: According to the real-time dynamic monitoring of settlement of building foundation obtained in Part 2.1, calculate the actual output  $y$  of BP neural network, and the process is as follows:

1) For input layer node, its output  $a_i$  is equal to the input data, that is,  $a_i = x_i$ ;

$$\text{net}_k^H = \sum_{i=1}^3 \omega_{ik}^H$$

2) For the hidden layer node, its input is  $a_k = f(\text{net}_k^H - \phi_k)$ ,  $\phi_k$  is the threshold of the hidden layer node,  $f$  is generally Sigmoid function;

$$\text{net}^0 = \sum_{k=1}^n \omega_k^{aH} a_k$$

3) For the output layer node, its input is  $a_k = f(\text{net}^0 - \phi^0)$ ,  $\phi^0$  is the threshold of nodes in the output layer;

Step 3: Calculate the energy function  $E = (d - y)^2$ . If the energy function is less than the specified value, go to Step 5; otherwise, go to Step 4;

Step 4: Adjust the weights of hidden layer and output layer in combination with relevant parameters of settlement of building foundation calculated in Part 2.2.

Step 5: Train the next sample until each training sample in the training sample set meets the target output, then BP network learning is completed. The actual output result is the prediction result of foundation settlement of smart city buildings.

### III. SIMULATION AND ANALYSIS

#### A. Preparing

For verifying the actual use of the prediction of foundation settlement of smart city buildings based on the designed BP network, the following simulation experiment is designed to verify it.

Windows 10 (64-bit, Anaconda3+TensorFlow 1.4.0) is the operation system, and the simulation platform is MATLAB.

Select a high-rise building in a smart city as the

experimental object. The building covers an area of 45m×23m. The overall structure is scissor wall. Bored piles are used in the foundation treatment process. The east and south sides of the building are adjacent to the street, the north side is more multi-storey buildings, and the west side is adjacent to a high-rise building to be built.

The site was rebuilt after the original low building was demolished, so the site is relatively flat. The relative height difference of the ground is roughly 1.4m. The overlying strata of the building construction mainly include loess and paleosol, while the underlying strata are mainly silty clay and sandy soil.

Fig. 5 shows the contour line of settlement of the experimental building. Among them, K1-K6 are the 6 detection points respectively. In the form of settlement isoline distribution, the middle part of the experimental building gradually expands to both sides, forming a curve in the form of equal settlement closure. This isoline reflects that the settlement amount generated by iteration of the stress of the building foundation is the largest, while the two sides are relatively small.

Fig. 5. Contour diagram of settlement of experimental building.

Fig. 6 shows the change of foundation settlement rate of the building over time. The settlement rate reaches the maximum value in the process of capping the main structure of the building, and becomes more and more stable after the completion of load loading. If the settlement rate of different monitoring positions is roughly the same, it indicates that the building has entered the stable period of foundation settlement.

**B. Based on Inspection**

The method in this paper was loaded on the Matlab platform to monitor the K1-K6 monitoring points and obtain the relevant data of building foundation settlement. The accuracy of the measurement results in this paper was judged by comparing with the actual values.

Fig. 6. Schematic diagram of sedimentation rate over time.

By comparing the difference between the predicted settlement value and the actual settlement value, the fitting degree between the two values is calculated. The fitting degree is calculated by the sum of the remaining squares. The closer the value is to 1, the smaller the gap between the predicted value and the true value is. The calculation process of fitting degree is as follows:

$$R = 1 - \frac{|q - x|}{x} \tag{14}$$

Where,  $R$  represents the fit degree,  $q$  is the predicted settlement value.  $x$  is the actual value. The fitting curve is shown in Fig. 7.

From Fig. 7, in different time periods, the fitting degree between the predicted results and the actual settlement value is always close to 1, which proves that the fitting degree between the two is high. Therefore, this method can effectively predict foundation settlement.

Fig. 7. Accuracy curve of calculated results.

### C. Contrast Test

In order to avoid unconvincing results, method of researches [5] and [6] were compared to for performance verification together with the proposed method. The comparison indicators are as follows:

1) *Average error (AE)*. The reliability of a foundation settlement prediction method can be evaluated based on the AE of its prediction results. A lower AE indicates higher prediction performance, greater reliability, and a stronger application advantage. By minimizing the AE, practitioners can ensure that their predictions are as accurate and reliable as possible. This can be achieved through careful selection of prediction models, validation of prediction results, and ongoing refinement of prediction methods based on new data. The calculating is followed:

$$A = \frac{\sum \frac{|y' - y|}{y}}{N} \times 100\% \quad (15)$$

A represents the foundation settlement prediction AE. N is sample size. y and y' represents real and predicted settlement value.

2) *Time consuming*. The time consumed in the forecasting reflects the timeliness. Higher timeliness needs shorter time consuming. The shorter the forecasting process, the higher the timeliness of the forecasting method, that is, the higher the forecasting efficiency.

First, the AE was tested, as shown in Fig. 8.

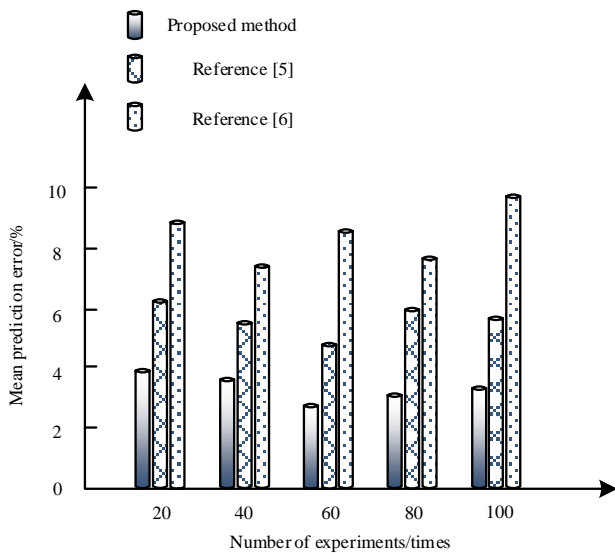

Fig. 8. Comparison of mean error of different prediction methods

The results shown in Fig. 8 indicate the prediction methods AE changes. However, in comparison, the AE of method of study [5] take the highest, and the highest AE is near 10%. The AE of this paper's method is the lowest, always below 4%, indicating it has higher reliability in predicting foundation settlement of smart city buildings.

Then we test the time-consuming process of foundation settlement prediction with different methods as shown in Table II.

The results in Table II show that the prediction time of different foundation settlement prediction methods also changes constantly with the experiments number. The prediction process of the method of reference [5] takes 50.13-68.03ms, and that of the method of reference [6] takes 61.02ms-71.81ms. However, the prediction time of method of this paper is always lower than 49ms. In contrast, the prediction process of method of this paper takes less time, which indicates that method of this paper has higher timeliness.

TABLE II. COMPARISON OF THE PREDICTION PROCESS TIME OF DIFFERENT METHODS

Number of experiments/times	Predict the duration of the process/ms		
	Method of this paper	Method of reference [5]	Method of reference [6]
1	38.41	50.13	61.02
2	41.26	52.59	62.32
3	42.37	54.62	64.14
4	42.54	56.42	64.74
5	43.54	57.26	66.25
6	44.86	61.53	67.11
7	43.60	62.45	67.82
8	47.02	64.86	68.74
9	48.22	67.64	70.85
10	48.53	68.03	71.81

### IV. CONCLUSION

In order to maintain the stability and safety of smart city buildings, this study designed a prediction method for foundation settlement of smart city buildings based on BP network.

Firstly, WSN technology is used to construct the real-time dynamic monitoring unit of building foundation settlement, which mainly includes four parts: building sensor node distribution module, sensor network module, communication module and upper computer monitoring module. Then, the above monitoring data are introduced into the Duncan-Chang constitutive model and combined with the layer-summation method to calculate the relevant parameters of building foundation settlement. Finally, on the basis of analyzing the structure of BP network, the monitoring data is input into the BP network model results, and the weights of hidden layer and output layer are adjusted by using subsidence related parameters, and the settlement prediction results of smart city building foundation are output through training.

In the experiment part, two parts of basic test and contrast test are designed. The results of basic test show that: in different time periods, the fitting degree between the predicted results of Method of this paper and the actual settlement value is always close to 1, which indicates that proposed method can effectively predict foundation settlement. The comparative test

results tell that the average prediction error of Method of this paper is always below 4%, and the prediction process takes less than 49ms, indicating that method of this paper has high reliability and timeliness of prediction. However, there are still some shortcomings in this study. For example, when selecting experimental sites and buildings, due to limited conditions and fewer buildings that meet the requirements, the type of building selected for the experiment is relatively single, and the universality of the proposed method in various experimental buildings has not been further tested.

# A Classified Warning Method for Heavy Overload in Distribution Networks Considering the Characteristics of Unbalanced Datasets

Guohui Ren\*

Yuncheng Power Supply Company of State Grid Shanxi Electric Power Company, Yuncheng, Shanxi, 044000, China

**Abstract**—In order to achieve heavy overload warning and capacity planning for the distribution network, it is necessary to classify the heavy overload warning of the distribution network. A distribution network with heavy overload classification warning method based on imbalanced dataset feature extraction is proposed. Screening the feature indicator set related to distribution network overload, constructing a hierarchical prediction framework for distribution network load situation, combining information such as power distribution points, road construction, municipal planning, and power load distribution to form distribution network capacity planning and line renovation plans. Based on K-means clustering, the undersampling method is used to extract features from the unbalanced dataset of distribution network overload classification, using decision trees as the basic learning unit. It includes multiple decision trees trained by Bagging integrated learning theory and random subspace method. The random forest algorithm is used to realize the feature detection and distribution network capacity planning of distribution network weight overload grading, and the grading early warning of distribution network weight overload is realized according to the capacity planning results. Tests have shown that this method has good accuracy in predicting electrical loads and can effectively solve the problem of excess capacity caused by light or no load, improving the ability of heavy overload warning and capacity planning in the distribution network.

**Keywords**—Imbalanced data; feature extraction; distribution network; overload classification warning

## I. INTRODUCTION

With the development of energy [1-3], research on the security and load stability of power distribution network networking has always received attention. In distribution network networking, it is necessary to build a graded warning model for heavy overload in the distribution network, screen the set of characteristic indicators related to heavy overload in the distribution network, and construct a graded prediction framework for the load situation of the distribution network. This can not only achieve short-term warning of heavy overload risk in the distribution network, but also predict and distinguish no-load and light load lines. Studying the classification and early warning method for heavy overload in the distribution network is of great significance in improving the power supply capacity and economic benefits of the distribution network. By establishing a distribution network load prediction model, scientific capacity planning and line transformation are carried out to address the problem of heavy overload in the distribution network, providing technical

support and support for improving the reliability of power supply, emergency response ability, and customer service level of the distribution network. The study of a graded warning model for heavy overload in the distribution network has important practical significance in promoting capacity planning and line optimization and renovation design.

In conducting relevant research on the phenomenon of heavy overload in distribution transformers, the method of feature analysis using imbalanced datasets is used to collect historical operation data of distribution networks, power outage repair work orders, transformer load data, and meteorological data. The above data are mostly imbalanced datasets, and data mining is conducted based on the aforementioned multi-source heterogeneous data to screen the feature indicator set related to heavy overload in distribution networks, Building a hierarchical prediction framework for the load situation of the distribution network can not only achieve short-term warning of the risk of heavy overload in the distribution network, improve the summer warning ability during peak hours, but also identify no-load and light load lines, providing a solution for later capacity planning. Starting from the actual situation of the distribution network, integrating multi-source heterogeneous data of the distribution network, proposing a distribution network overload warning and capacity planning technology based on historical data of the distribution network, completing the establishment of a hierarchical prediction model for the distribution network load situation, and forming a distribution network capacity planning and line transformation plan.

However, due to the low probability of distribution transformer overload, it is often difficult to obtain sufficient effective data for early data analysis and later model establishment, which also increases the difficulty for classification models to accurately predict power outages. In addition, many factors that affect power outages are difficult to present and obtain in the form of data values, which to some extent limits the establishment of feature index systems, making it difficult for prediction models to fully consider all influencing factors, thus increasing the difficulty of feature engineering and data preprocessing work. In the classification and warning of heavy overload in the distribution network, it is necessary to establish a distribution network load level prediction model based on imbalanced datasets to achieve early warning of heavy overload in the distribution network. It is expected to reduce the line outage rate index by more than 5%. In the analysis of imbalanced feature sets, how to combine

\*Corresponding Author

information such as power distribution, road construction, municipal planning, and power load distribution after establishing a load prediction model. The formation of targeted distribution network capacity planning and line renovation plans is still an urgent problem to be solved. For example, Huang Yuanfang [4] et al. proposed a distribution transformer heavy overload risk warning method that takes load uncertainty into account. This method uses quantile regression algorithm of gated cycle unit to predict the load level of distribution transformer at different subpoints. In addition, utility function is used to describe the severity of heavy overload accidents suffered by distribution transformers. Combined with the power system risk theory, the potential heavy overload risk level of distribution transformers is assessed, and the risk warning is realized according to the evaluation results. Shi Changkai [5] et al. studied a method for predicting the load load of the Spring Festival distribution based on BP network and grey model. According to the particularity and regularity of the Spring Festival power load, this method uses fuzzy clustering method to divide the Spring Festival holiday period. Based on BP neural network and grey prediction system, the prediction model of the daily maximum load of the Spring Festival distribution is established, and the rated parameters of the distribution are combined. Judging whether the configuration is overloaded or not by analysing the prediction result. However, the warning accuracy of the above method is low, resulting in poor application effect.

In response to the current problems, combined with big data analysis and processing technology, a distribution network overload classification warning method based on imbalanced dataset feature extraction is proposed. Firstly, a hierarchical data acquisition model of distribution network heavy overload is established, and the feature index set related to distribution network heavy overload is screened. Combined with the unbalanced learning algorithm of inter class correlation, the random forest algorithm is used to realize the feature detection of distribution network heavy overload classification and the distribution network capacity planning. According to the capacity planning results, the distribution network heavy overload classification warning is realized. Then extract the inter class feature quantities of heavy overload in the distribution network, and based on the feature extraction results, achieve graded warning of heavy overload in the distribution network. Finally, simulation testing was conducted to demonstrate the superior performance of the method proposed in this paper in improving the ability of distribution network overload classification warning and planning. This method improves the early warning performance, and it has certain feasibility and effectiveness.

## II. OVERALL ARCHITECTURE AND DATA SAMPLING OF DISTRIBUTION NETWORK OVERLOAD WARNING AND CAPACITY PLANNING

### A. Overall Architecture of Distribution Network Capacity Planning

In order to realize the hierarchical early warning design of distribution network heavy overload, the capacity planning model of the hierarchical early warning of distribution network heavy overload is constructed. Through the parameter analysis

of the distribution network heavy overload early warning model, the KNN algorithm is used to process the missing values and outlier of the distribution network multi-source heterogeneous data. For the missing value processing of distribution network heavy overload early warning and capacity planning, based on the characteristics of distribution network data periodicity and continuity, KNN algorithm is used to realize the study of distribution network heavy overload early warning and capacity planning, find out the corresponding position of missing data in other cycles, so as to fill the missing data [6-7]. For the outlier processing of distribution network heavy overload early warning and capacity planning. Firstly, the STL-ESD technology, which combines the time series decomposition algorithm and the single sample multiple outlier detection algorithm, is used to detect the outlier in the distribution network load data, and the KNN algorithm is used to replace the distribution network heavy overload early warning and capacity planning outlier to ensure the completeness of the distribution network heavy overload early warning and capacity planning data.

On the basis of analyzing the data of heavy overload warning and capacity planning in the distribution network [8-9], a penalty based feature selection algorithm is used to analyze the power outage characteristics of the distribution network. Based on the fuzzy feature selection method, a feature subset of heavy overload warning and capacity planning in the distribution network is established. During the training process of the target model, the feature selection of heavy overload warning and capacity planning in the distribution network is carried out simultaneously, that is, feature selection is taken as a part of the model.

Using the K-means clustering [10-12] based undersampling method, the non-outage class dataset in the distribution network heavy overload warning and capacity planning dataset is undersampled. This method divides the imbalanced dataset into a majority class (non-outage dataset) and a minority class (outage dataset). Then, the clustering algorithm is used to cluster the multi class dataset of the distribution network heavy overload warning and capacity planning, and the random undersampling model parameters are obtained. Finally, the undersampling model parameters for distribution network heavy overload warning and capacity planning are obtained. Based on the above analysis, the overall structure of the distribution network overload warning and capacity planning is shown in Fig. 1.

Finally, a hierarchical prediction model for distribution network load is established using the Adaboost ensemble algorithm, which combines several weak classifiers into a strong classifier to improve the performance of hierarchical prediction based on distribution network load [13-14].

The undersampling method for power outage datasets based on K-means clustering mainly has two processes. The first process is to cluster the majority class dataset (non-power outage dataset) using K-means clustering method, dividing the dataset into K clusters; The second process is to conduct random undersampling in each cluster according to the density distribution. Specifically, it is ordered according to the size of the data variance in each cluster. First, the cluster with small

difference is subject to random undersampling at a certain sampling rate. After sampling, the multi class dataset and the few class dataset are combined to obtain a new balanced dataset.

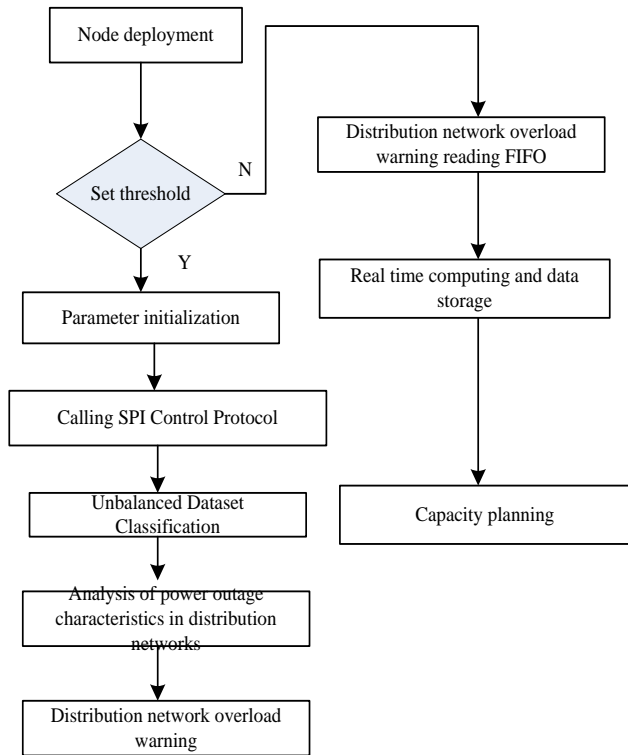

Fig. 1. Distribution network overload warning and capacity planning.

### B. Data Feature Sampling

Given the training sample set  $\{(x_i, t_i)\}$ , for distribution network capacity planning and line renovation, where  $x_i = \{x_{i1}, x_{i2}, \dots, x_{in}\} \in \mathbb{R}^n, t_i = \{t_{i1}, t_{i2}, \dots, t_{im}\} \in \mathbb{R}^m$ , including L hidden layer nodes for distribution network capacity planning and line transformation data feature detection, the distribution network weight overload activation function is  $f(x)$ , in the case of a single output node, the output function of the distribution network weight overload early warning ELM is:

$$f_L(x) = \sum_{i=1}^L \beta_i h_i(x) = h(x)\beta \quad (1)$$

Where,  $\beta = [\beta_1, \dots, \beta_L]^T$ , T represents the output weight vector between the distribution network overload warning hidden layer and the output node for L hidden layer nodes,  $h(x) = [h_1(x), \dots, h_L(x)]$  represents the hidden layer output vector of the distribution network overload warning input x, that is,  $h(x)$  maps the input distribution network overload warning data from the d-dimensional input space to the L-dimensional fuzzy dynamic feature space. Combined with the distribution of power supply points, road construction, and municipal planning, a heterogeneous algorithm is used to establish a clustering model. The minimum training decision function for the internal temporal features of the sample is obtained as follows:

$$\text{Minimize: } \|H\beta - T\|^2 \text{ and } \|\beta\| \quad (2)$$

Where, H is the dynamic allocation matrix of hidden layer output of cluster, which is expressed as:

$$H = \begin{bmatrix} h(x_1) \\ h(x_2) \\ \vdots \\ h(x_n) \end{bmatrix} = \begin{bmatrix} h_1(x_1) & \dots & h_L(x_1) \\ h_1(x_2) & \dots & h_L(x_2) \\ \vdots & \vdots & \vdots \\ h_1(x_n) & \dots & h_L(x_n) \end{bmatrix} \quad (3)$$

The process clustering learning of distribution network heavy overload warning is an unsupervised learning process. Select the K-mean standard SVM [15-16] classification model that meets the integration conditions, and get the maximum classification interval between the two classes of  $2/\|\beta\|$ . This norm actually controls the complexity of the function in the ELM feature space. Using a visual clustering point graph overlay analysis method, the disputed samples are temporarily classified into multiple clustering clusters, and two types of ELM models with single output are defined as follows:

$$\text{Minimize: } L_{ELM} = \frac{1}{2} \|\beta\|^2 + \frac{C}{2} \sum_{i=1}^N \varepsilon_i^2$$

$$\text{Subject to: } h(x_i)\beta = t_i - \varepsilon_i, i = 1, \dots, N. \quad (4)$$

Where,  $\frac{1}{2} \|\beta\|^2$  represents the structural risk of power outage data,  $\frac{C}{2} \sum_{i=1}^N \varepsilon_i^2$  represents the empirical risk of distribution network load.

Based on the KKT principle, the k-fold cross validation method is used to partition the data and transform the heavy overload classification warning problem of the distribution network into a dual optimization problem:

$$L_{ELM} = \frac{1}{2} \|\beta\|^2 + \frac{C}{2} \sum_{i=1}^N \varepsilon_i^2 - \sum_{i=1}^N \alpha_i (h(x_i)\beta - t_i + \varepsilon_i) \quad (5)$$

According to equation (5), the sliding time window method is used to obtain the KKT constraint conditions:

$$\frac{\partial L_{ELM}}{\partial \beta} = 0 \rightarrow \beta = \sum_{i=1}^N \alpha_i h(x_i)^T = H^T \alpha \quad (6)$$

$$\frac{\partial L_{ELM}}{\partial \varepsilon_i} = 0 \rightarrow \alpha_i = C \varepsilon_i, i = 1, \dots, N \quad (7)$$

$$\frac{\partial L_{ELM}}{\partial \alpha_i} = 0 \rightarrow h(x_i)\beta - t_i + \varepsilon_i = 0, i = 1, \dots, N. \quad (8)$$

Where,  $\alpha = [\alpha_1, \dots, \alpha_N]^T$ , where the standard deviation of response data fluctuation is used for data compression to obtain each Lagrange multiplier  $\alpha_i$ . For the i-th training sample.

Randomly divide K into k sets with similar numbers. When the number of training samples is small (i.e.  $N < L$ ), (6) and (7) are introduced into equation (8). From the above formula, it can be inferred that:

$$\beta = H^T \left( HH^T + \frac{1}{C} \right)^{-1} T \quad (9)$$

Similarly, when the training sample is large (i.e.  $N > L$ ), it can be inferred that the secondary learner contains the feature values extracted by the primary learner:

$$\beta = \left( H^T H + \frac{1}{C} \right)^{-1} H^T T \quad (10)$$

Similarly, when the training sample is large (i.e.  $N > L$ ), it can be inferred that the secondary learner contains the feature values extracted by the primary learner:

$$f(x) = h(x)\beta = h(x)H^T \left( HH^T + \frac{I}{C} \right) T \text{ or}$$

$$f(x) = h(x)\beta = h(x) \left( H^T H + \frac{1}{C} \right) H^T T \quad (11)$$

Based on the above analysis, a data collection and feature analysis model for heavy overload classification warning in the distribution network is constructed, combined with feature clustering and feature detection of imbalanced datasets, to achieve fuzzy sampling of overload data.

### III. CLASSIFICATION WARNING AND PLANNING ALGORITHM FOR HEAVY OVERLOAD IN DISTRIBUTION NETWORK

#### A. K-means Clustering based Feature Clustering Algorithm for Unbalanced Data in Distribution Networks

Using heterogeneous ensemble learning methods and K-means clustering based sampling methods can avoid deleting too much information on a certain data distribution and prevent data distortion caused by undersampling unevenness. The algorithm flow of the undersampling method for power outage datasets based on K-means clustering is as follows:

Step 1: preprocess the data set of unbalanced heavy overload hierarchical early warning of the original distribution network, including missing value processing based on KNN algorithm and outlier processing based on STL-ESD algorithm, and then select the characteristics to obtain the characteristic data set D with the labels of power failure ( $y=1$ ) and non-power failure ( $y=0$ ).

$$D = \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}, x_i \in R, y_i \in \{0,1\} \quad (12)$$

Step 2: Split the unbalanced dataset D of the distribution network overload classification warning, and select 80% of it as the training dataset  $D_1$ , 20% for test dataset  $D_2$ .

Step 3: Training dataset D for the imbalanced dataset of the distribution network overload classification warning\_ Unstop dataset T in  $D_1$ \_ Cluster 0 and randomly select k cluster centroids as:  $\mu_1, \mu_1, \dots, \mu_k \in R^n$ .

Step 4: For  $(x_i, y_i) \in T_0$ . Calculate the cluster to which the distribution network overload classification warning imbalanced dataset belongs,

$$c^{(x_i)} = \arg \min_j \|x_i - \mu_j\|^2, j = 1, 2, \dots, k \quad (13)$$

Where,  $c^{(x_i)}$  is the cluster to which photovoltaic characteristic data such as device parameters  $(x_i, y_i)$  belongs.

Step 5: For each cluster j, recalculate the centroid of the unbalanced dataset cluster for the distribution network overload classification warning.

$$\mu'_j = \frac{\sum_{(x_i, y_i) \in T_0} I(c^{(x_i)}=j)x_i}{\sum_{(x_i, y_i) \in T_0} I(c^{(x_i)}=j)} \quad (14)$$

Step 6: Calculate the maximum movement distance of the cluster center in the imbalanced dataset of the distribution network overload classification warning  $d = \max(\|\mu'_j - \mu_j\|_2)$ .

If  $d > \epsilon$ , update  $\mu_j = \mu'_j$ , skip to step 7 for execution.

Step 7: Scale each cluster of the above clustering results  $\alpha$  Perform random undersampling to obtain the distribution network overload classification warning imbalanced dataset, balanced training dataset  $D'_0$ .

#### B. Distribution Network Overload Classification Warning Imbalanced Dataset Diversity Scheduling Warning

The specific algorithm principle of using AdaBoost algorithm to build a distribution network overload classification warning imbalanced dataset scheduling is as follows:

Step 1: Input the training dataset of the distribution network overload classification warning imbalance dataset  $D = \{(x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)\}, x_i \in X, y_i \in Y = (-1, +1)$  , ( $i = 1, 2, \dots, N$ ).

Step 2: Assuming that the weights of each sample in the dataset are initially uniform, the initial weights of the common modeling parameters for the imbalanced distribution network overload classification warning dataset in each sample are:

$$\omega_{1i} = \frac{1}{N} \quad (15)$$

Step 3: Set the maximum number of iterations [17] (i.e. the maximum number of linear combination weak classifiers)  $T: t = 1, 2, 3, \dots, T$ , to obtain the initial clustering objective function of the distribution network overload classification warning imbalanced dataset.

Step 4: When training the t-th weak classifier, the weighted weight [18-19] of the i-th sample's distribution network overload classification warning imbalanced dataset is  $\omega_{ti}$  with  $\sum_{i=1}^N \omega_{ti} = 1$  , the classifier of the distribution network overload classification warning imbalanced dataset trained is represented as  $G_t(x)$ .

Step 5: Calculate the imbalanced dataset D of the distribution network overload classification warning in  $G_t(x)$  Classification error rate on i (x)  $\epsilon_t$ :

$$\epsilon_t = P[G_t(x_i) \neq y_i] = \sum_{i=1}^N \omega_{ti} I[G_t(x_i) \neq y_i] \quad (16)$$

Where,  $I(\cdot)$  is the indicator function, and the mutual information  $I(\cdot)$  of the unbalanced data set of the distribution network heavy overload hierarchical early warning is equal to 1. Classifier  $G_t(x)$  The classification error rate of t (x) on the weighted training dataset D is equal to that of  $G_t(x)$ ; the sum of the weights of the misclassified samples in t (x).

Based on classification error rate  $\epsilon_t$  Computational basis classifier  $G_t(x)$  Weight of t (x):

$$\alpha_t = \frac{1}{2} \ln \frac{1-\epsilon_t}{\epsilon_t} \quad (17)$$

Training data distribution weights for the imbalanced dataset of distribution network overload classification warning after the t+1 iteration  $\omega_{t+1,i}$  Update:

$$\omega_{t+1,i} = \begin{cases} \frac{\omega_{ti}}{Z_t} e^{-\alpha t}, G_t(x) = y_i \\ \frac{\omega_{ti}}{Z_t} e^{\alpha t}, G_t(x) \neq y_i \end{cases} \quad (18)$$

If the imbalanced dataset samples of the distribution network overload grading warning are correctly classified [20], its weight will decrease; on the contrary, if misclassified, the weight will increase.

$$Z_t = \begin{cases} \sum_{i=1}^N \omega_{t,i} e^{-\alpha t}, G_t(x_i) = y_i \\ \sum_{i=1}^N \omega_{t,i} e^{\alpha t}, G_t(x_i) \neq y_i \end{cases} \quad (19)$$

Then output the final distribution network overload classification warning imbalanced data classification output:

$$G(x) = \text{sign}[\sum_{t=1}^T \alpha_t G_t(x)] \quad (20)$$

By processing the missing values and outlier in the data set, combined with the analysis results of the characteristics of the unbalanced data set, the system realizes the early warning of the distribution network heavy overload hierarchical early warning unbalanced data set diversity dispatching, focuses the main theories of distribution network capacity planning on the early load forecasting, and improves the early warning stability and dynamic analysis capability.

#### IV. EXPERIMENTAL TESTING AND RESULT ANALYSIS

##### A. Evaluation Index System

Establish a distribution network load level prediction model based on imbalanced datasets to achieve early warning of heavy overload in the distribution network. It is expected to reduce the line outage rate index by more than 20%. In the experiment, an evaluation index system is set up, and Gini index is given. Gini index can measure the impurity of nodes, and its formula is:

$$\text{GINI}(t) = 1 - \sum_j p^2(j/t) \quad (21)$$

In the formula:  $t$  is the branch attribute of the distribution network load level evaluation node;  $p(j/t)$  represents the proportion of the target category of the distribution network load level in node  $t$ . The Gini standard definition for the distribution node  $t$  of the distribution network overload classification warning imbalanced dataset is as follows:

$$\text{GINI}(s, t) = p_L \text{GINI}(t_L) + p_R \text{GINI}(t_R) \quad (22)$$

The division standard for the imbalanced dataset of distribution network overload classification warning is to minimize  $\text{GINI}(s, t)$ .

The least squares deviation is commonly used to measure the heavy overload classification warning ability of the regression tree allocation network, and the fitting error formula of node  $t$  is:

$$\text{Err}(t) = \frac{1}{n_t} \sum_{D_t} (y_i - k_t)^2 \quad (23)$$

In the formula:  $n$  is the number of instances in node  $t$ ;  $k_t$  is the average of the target values of instances in each node:

$$k_i = \frac{1}{n_i} \sum_{n_i} y_i \quad (24)$$

The least squares deviation standard for dynamic nodes in the distribution network overload classification warning imbalanced dataset divided by attribute values  $s$  is defined as:

$$\text{Err}(s, t) = \frac{n_{tL}}{n_t} \text{Err}(t_L) + \frac{n_{tR}}{n_t} \text{Err}(t_R) \quad (25)$$

In order to simplify the calculation process in the computer and avoid multiple traversals of attribute values, the above equation is simplified, and the hierarchical scheduling error of unbalanced data for distribution network overload classification warning can be obtained as:

$$\text{Err}(s, t) = \frac{S_L^2}{n_{tL}} + \frac{S_R^2}{n_{tR}} \quad (26)$$

Wherein,

$$S_L = \sum_{D_{iL}} y_i, S_R = \sum_{D_{iR}} y_i \quad (27)$$

By conducting hierarchical detection of the distribution network weight process, capacity planning and line transformation, analyzing the irrelevant or redundant information in the distribution network dataset, and designing partition standards to maximize  $\text{Err}(s, t)$ .

##### B. Result Analysis

Matlab is used for simulation test, and 270 normal distribution sample points are given in the unbalanced data set of the distribution network data set. These sample points are divided into two categories. The normal distribution  $N(u, \Sigma)$  respectively:

Class 1:  $N([1; 2], [0.23 \ 0; 0 \ 0.57])$ , a total of 70 points;  
Class 2:  $N([2.21; 0], [0.65 \ 0; 0 \ 0.88])$ , a total of 200 points;

Randomly generate 100 noise data using SVM, ELM, and ELM\_ The CIL algorithm performs this and provides an imbalanced dataset sample sequence as shown in Fig. 2.

Fig. 2. Sample sequence of imbalanced dataset.

Using the data in Fig. 2 as the test object, different methods were used to obtain a noise free dataset and reference [4] method, reference [5] method, and ELM after adding the noise set\_ The CIL classification warning results are shown in Table I.

TABLE I. CLASSIFICATION WARNING RESULTS FOR NOISE DATASETS

	Reference [4] Method	Reference [5] Method	Proposed method
Accuracy	93.324	93.686	95.412
SE	88.235	84.029	95.235
SP	95.098	97.059	99.118
GM	91.598	90.314	94.676

According to the analysis of the hierarchical warning results in Table I, the classification and early warning results of the noise data sets of the three methods are all good, but the classification and early warning results of the proposed method are more accurate, the lowest value is 94.676, while the lowest value of the literature method is 88.235 and 84.029, which is more than 6 points higher than that of the proposed method. The clustering results of imbalanced dataset features are shown in Fig. 3.

Fig. 3. Clustering results of unbalanced dataset features.

By analyzing Fig. 3, it can be seen that the method proposed in this paper has a good ability to plan for hierarchical warning of heavy overloads in the distribution network by clustering the features of the imbalanced dataset. According to the historical operation data of the distribution network (active load rate, three-phase imbalance, defect

records, fault records, etc.), distribution transformer account information, meteorological environment data, geographical environment data, user scale, and other multi-source heterogeneous data, first process the missing values and outlier in the data set, and carry out the distribution network heavy overload classification warning for each data set. The comparison results are shown in Fig. 4 to 6, the overall testing accuracy of the reference method is slightly lower than that of this method, the early warning accuracy of different data sets of the proposed method is higher than that of the literature method. The maximum value of the proposed method is 94.80, while that of the literature method is 87.48, which is more than 7 points higher than that of the proposed method. However, due to its significantly faster learning speed than support vector machines, the algorithm proposed in this paper has significant advantages in large-scale imbalanced data classification of sample sets.

### C. Results and Discussion

By setting up the load forecasting model of distribution network, scientific capacity planning and line reconstruction are carried out to improve the power supply reliability, emergency response ability and customer service level of distribution network. By processing the missing values and outliers in the data set, the problems of missing and abnormal data caused by various factors in the load data of distribution network are solved, the quality of the data set is improved, and the subsequent model training is supported. By constructing new features and selecting the optimal feature subset, the problem of poor performance of prediction model caused by information irrelevance or redundancy in distribution network data set is solved. The problem of poor prediction accuracy of a few classes due to unbalance of data is solved by undersampling. The AdaBoost classification algorithm is used to solve the problem of building a hierarchical forecasting model for the load condition of distribution network. By collecting distribution network historical operation data, power outage repair work order, transformer load data and meteorological data, data mining is carried out based on the above multi-source heterogeneous data. The characteristic index set related to distribution network overload is selected, and the hierarchical forecasting framework of distribution network load is constructed. To realize short-term early warning of heavy load risk of distribution network in order to improve summer peak warning, emergency response ability and customer service level. Extract effective information from heterogeneous data from multiple sources, construct new features, and form a feature database. The feature selection method is used to filter out the optimal feature subset and undersample the unbalanced data set to reduce the unbalance degree of the data set. Finally, AdaBoost and other classification methods are selected to establish a hierarchical forecasting model of distribution network load condition to realize heavy overload warning. The load forecasting model is established to predict the total load and maximum load in the future, and the capacity planning and line reconstruction plan of the distribution network are formed by combining the information of distribution, road construction, municipal planning and load distribution, etc., so as to improve the power

supply capacity and economic benefits of the distribution network. The load forecasting model is established by using regression analysis and other load forecasting methods to predict the total load and maximum load in the future. At the same time, considering the distribution point, road construction, municipal planning, power load distribution and other factors, the capacity planning and line transformation of the distribution network. The analysis shows that the heavy overload classification early warning method adopted in this paper has good accuracy for power load prediction, effectively solves the problem of excess capacity caused by light load or no load, and improves the capacity of heavy overload early warning and capacity planning of distribution network. Compared with the literature method, the accuracy of this method is much higher than the literature method.

### V. CONCLUSIONS

Distribution network occasionally faces heavy overload phenomenon, and if the phenomenon is not warned in time, it is easy to affect the normal operation of distribution network. Therefore, in order to achieve accurate warning of heavy overload of distribution network, it is necessary to classify the heavy overload warning of distribution network. Therefore, a new classification and early warning method of heavy overload of distribution network based on feature extraction of unbalanced data set is studied. In this method, the characteristics of distribution network are defined, and K-means clustering and undersampling methods are introduced to extract features from unbalanced data sets of distribution network overload classification. At the same time, decision tree algorithm and random forest algorithm are adopted to build a heavy overload early warning method to achieve early warning. After the design of the method is completed, the performance of the proposed method is analyzed through experiments. It can be seen from the experimental results that the proposed method has high accuracy in early warning and effectively improves the early warning ability of heavy overload in the distribution network.

# A Novel Method for Myocardial Image Classification using Data Augmentation

Qing kun Zhu

Georgia Institute of Technology Information Management Department-Zhengzhou Preschool Education College,  
Henan Zhengzhou 450000 China

**Abstract**—Myocarditis is an important public health concern since it can cause heart failure and abrupt death. It can be diagnosed with magnetic resonance imaging (MRI) of the heart, a non-invasive imaging technology with the potential for operator bias. The study provides a deep learning-based model for myocarditis detection using CMR images to support medical professionals. The proposed architecture comprises a convolutional neural network (CNN), a fully-connected decision layer, a generative adversarial network (GAN)-based algorithm for data augmentation, an enhanced DE for pre-training weights, and a reinforcement learning-based method for training. We present a new method of employing produced images for data augmentation based on GAN to improve the classification performance of the provided CNN. Unbalanced data is one of the most significant classification issues, as negative samples are more than positive, decimating system performance. To solve this issue, we offer an RL-based training method that learns minority class examples with attention. In addition, we tackle the challenges associated with the training step, which typically relies on gradient-based techniques for the learning process; however, these methods often face issues like sensitivity to initialization. To start the BP process, we present an improved differential evolution (DE) technique that leverages a clustering-based mutation operator. It recognizes a successful cluster for DE and applies an original updating strategy to produce potential solutions. We assess our suggested model on the Z-Alizadeh Sani myocarditis dataset and show that it outperforms other methods.

**Keywords**—Myocarditis; generative adversarial network; data augmentation; differential evolution

## I. INTRODUCTION

Myocarditis is a type of cardiovascular disease in which the heart muscle cells inflame and is pathologically specified as inflammatory infiltrates of the myocardium with mononuclear cells. The clinical expressions of myocarditis range from asymptomatic states to cardiac arrest, arrhythmias, and cardiogenic shock [1], [2]. Viral infections are the most critical causes of myocarditis, with recent meta-analyses indicating its pervasiveness among COVID-19 infected patients [3]. Epidemiological studies inform 10.2 to 105.6 cases per 100,000 worldwide and an estimate of 1.8 million annually. In 2017, the global number of myocarditis-related deaths was gauged to be approximately 46,486 cases [4]. Despite passing several centuries since the recognition of the myocardial disease, helpful treatment approaches are yet to be conducted due to several causes, including insensitivity to diagnostic tests and complicated relations between maladaptive and adaptive immune reactions [5], [6]. Current development in the genetic

basis of immune-mediated heart disease and animal analyses supplied vital information in curing this disease [7].

In medical imaging, CNNs are vital in conducting analysis and predicting various health outcomes. Nevertheless, it is a fact that these models struggle with performance issues when they are not sufficiently balanced. So, a compelling need for more robust methods to enhance their performance is required [8]. Existing methods to improve the performance of CNN models in the medical domain include domain adaptation and transfer learning [9]. However, a significant limitation in these methods is the lack of pre-trained models available on extensively annotated medical datasets, which is a critical requirement to train these models effectively. In the absence of such pre-trained models, researchers often resort to traditional transformations, such as rotation, translation, flipping, shearing, and scaling. While these transformations have been successfully applied to many medical datasets, they are not universally applicable. Some datasets are resistant to these transformations, as applying them may alter or compromise the properties of the annotated data. Certain transformations may cause image duplicity. This means that an image and its transformed counterpart are seen by the model as two distinct images. This misjudgment by the model can cause overfitting, where the model is overly calibrated to the training dataset and performs poorly on unseen data. Considering these challenges, there is an urgent need for innovative and effective solutions to enhance the performance of CNN models in the medical domain. Current research should focus on developing new methods that can be universally applied to diverse medical datasets without compromising the integrity of the data and without leading to model overfitting. Such methods will significantly improve the applicability and accuracy of CNN models in medical imaging analysis, leading to better healthcare outcomes.

So far, GANs [10] have achieved much attention in academics and industry for their usefulness in neutralizing domain changes and developing new image instances [11]. GAN models have attained modern efficiency in numerous image generation studies, such as text-to-image synthesis [12], [13], super-resolution [14], and image-to-image translation [15]. Recently it is also being utilized in the medical area [16]. Recent research has been on utilizing GAN in medical augmentation [17] and image segmentation [18]. However, a notable drawback with some of these applications is that they involve offline augmentation, which increases the size of the dataset to enhance model performance. This process can be resource-intensive and time-consuming, making it less suitable

for applications where speed and efficiency are crucial. In contrast, online augmentation methods keep the dataset size constant. During each mini-batch iteration, a fraction of the original images is kept, and the rest is replaced with GAN-generated images. This approach helps maintain a balance between performance improvement and computational efficiency, without the need for expanding the dataset significantly [19].

Deep learning models have played a transformative role in various applications [20], [21], [22]. They leverage complex algorithms that adjust their internal parameters, typically referred to as weights, to minimize the difference between their predictions and actual outputs. To achieve this, a learning process based on the backpropagation of errors is often employed, which adjusts the model's weights based on the calculated gradients of the loss function. However, these gradient-based optimization techniques are not without their limitations. One major vulnerability is their sensitivity to the initialization of the weights. If the initial weights are not set appropriately, these algorithms can converge to local minima, resulting in sub-optimal solutions. This is a standard issue encountered in classification works, where the objective is to categorize inputs into distinct classes. In light of these challenges, researchers have turned their attention to meta-heuristic algorithms [23], which offer alternative methods for optimization. These algorithms provide a more global approach to searching the solution space and are less susceptible to the problem of local minima [24]. One such powerful meta-heuristic algorithm is DE. It has been successfully utilized for a plethora of optimization issues [25]. The DE process involves three essential steps: mutation, crossover, and selection. A new solution is created during the mutation stage. Next, in the crossover phase, the newly created mutation vector is combined with the current vector, introducing diversity into the solution set. Finally, the selection phase evaluates all solutions and selects the best ones to pass into the next iteration. The use of DE in deep learning models could provide a robust alternative to traditional gradient-based optimization methods, mitigating the issues of weight initialization and local minima. Integrating DE into the training of deep models, it could potentially improve their performance, especially in challenging applications like medical image analysis. Consequently, the practical implications of this approach could be enormous, making it an exciting area for future research and development [26].

Imbalance in the categories can have an adverse effect on performance, which is the result of one category having more data than the other [27]. Because of its rarity and volatility, the minority example may be more difficult to identify than the majority example. The data level and algorithmic level are two methods for addressing the imbalance problem. At the data level [28], over-sampling minority or under-sampling majority classes may equilibrate the dispersion of classes, yet carry the hazards of over-fitting and information loss. These techniques provide promising ways to address the class imbalance problem. However, each method has its strengths and limitations, and their effectiveness can vary depending on the specific dataset and application. Consequently, it is crucial to carefully consider the nature of the imbalance problem and the

requirements of the specific application when selecting an appropriate method. A well-chosen strategy for handling class imbalance can significantly improve model performance, particularly in identifying the important but often overlooked minority classes. Using Deep Reinforcement Learning (DRL) has been confirmed to have success in a variety of spheres, enhancing the performance of classification systems through eliminating noisy data and heightening features. However, the computational time increases due to the intricate simulations between agents and environments. Some researchers have used DRL to improve classifiers, and an ensemble pruning approach has also been developed. Despite these advancements, the use of DRL in imbalanced classifications, especially in medical imaging, remains minimally investigated.

As far as we know, three deep network-based articles have been presented to diagnose myocarditis. Sharifrazi et al. [29] presented a three-step method using CNN and the k-means algorithm for myocardial image classification. In this research, images embedded in a vector were clustered using the k-means algorithm in four clusters, followed by a CNN to classify four clusters separately. Eventually, a voting system was employed to assign every image to its corresponding class. The method's fundamental flaw was that it embedded the images in a vector for the k-means algorithm, resulting in missing pixels surrounding a special pixel. Moravvej et al. [30] considered a CNN-based model that used the ABC algorithm as weight initialization of the model and reinforcement learning to solve the imbalanced classification problem. Danaei et al. [31] imitated the method presented by [30] except that they used an improved ABC algorithm for weight initialization. The ABC algorithm often requires many iterations to converge to an optimal solution, making it less efficient than some other optimization algorithms, especially when dealing with high dimensional problems. As the dimensionality of the problem increases, the performance of the ABC algorithm tends to deteriorate, making it less suitable for high-dimensional problems or very complex datasets.

In this article, we offer an automatic method for myocarditis diagnosis. Our proposed model contains a CNN and a feed-forward network to predict their similarity. The main contribution of this article is as: 1) We consider a deep convolutional GAN model effective for online augmenting, generating images allowed in regularization that reduces the over-fitting and enhances the accuracy of the model, 2) We come up with a better DE algorithm based on clustering for initializing weights. This supports us in identifying a likely region for the commencement of the BP algorithm on CNN and feed-forward networks. The mutation operator chooses the most suitable or almost suitable solution from the superior cluster to accomplish this as the primary solution. An updated strategy is then implemented to create potential solutions, and 3) We provide a reinforcement learning algorithm for the classification problem inspired by [30] in order to address imbalanced classification.

The remainder of this article is set as follows. Section II presents our proposed myocarditis diagnosis method, while Section III illustrates experimental results. Eventually, Section IV presents a conclusion of the paper.

## II. PROPOSED MODEL

As illustrated in Fig. 1, we employ a deep model for the binary classification of myocardial images. Our model gains a CMR image as input and passes it to a CNN, followed by a Softmax layer at the end serving as the final decision-maker. We use a GAN-based method for online data augmentation, rising the model performance for classification. The proposed model incorporates a clustering-based differential evolution algorithm to find the initial seeds of the network weights while using an RL-based algorithm to handle class imbalance.

### A. Online Data Augmentation

Data augmentation is an indispensable tool for training deep models. More recent advances have been made to discover an optimal augmentation policy in image classification. Nevertheless, the current methods uncovered two critical points related to data augmentation. One is that most current augmentation approaches are offline, which separates learning procedures from their use. The techniques that are taught during training remain consistent and are not changed based on the current state of the training model. These techniques depend on image processing functions that maintain class details. Applying offline techniques to new projects may need domain knowledge [32], [33].

To handle the problems above, we present an online data augmentation using a GAN-based model, trying to minimize the overfitting and enhance the performance of the proposed CNN architecture. The input to the second layer of the generator comprises the characteristics determined by the penultimate layer of the discriminator to recreate the original data. Specifically, the generator uses two inputs: random noise, which is utilized to generate real-like examples as standard GAN, and the actual data features used for reconstruction. Fig. 2 shows the proposed GAN, which shows how the process works. The generator input is manifested by the output of the

flatten layer of the discriminator, as shown by the faint black dotted line, when utilizing real data for reconstruction. The linear layer is not considered when the generator reconstructs real data [34].

### B. Pre-training Phase

Deep network weight initialization is a critical component of deep models. Inaccurate initial values can sometimes cause the model to fail to converge. In this article, we initialize the weights of the CNN, and feed-forward neural network. For this, we introduce an enhanced DE method that is boosted by a clustering scheme and a novel fitness function. In our enhance DE algorithm, we employ a clustering-based mutation and updating scheme to improve the optimisation performance.

The mutation operator, inspired by the work in [35], identifies a promising region within the search space. The population P at the current point is divided into k clusters using the k-means clustering method, with each cluster representing a different segment of the search space. The number of clusters is determined by selecting a random integer from the range [2, N]. After the clustering process, the most optimal cluster is deemed to be the one with the lowest average fitness among its samples.

The suggested mutation based on clustering is described as follows:

$$\vec{v}^{clu}_i = \overline{win}_g + F(\vec{x}_{r_1} - \vec{x}_{r_2}), \quad (1)$$

where  $\overline{win}_g$  is the most acceptable solution in the promising region, and  $\vec{x}_{r_1,g}$  and  $\vec{x}_{r_2,g}$  are two randomly determined candidate solutions from the current population. It should be noted that  $\overline{win}_g$  is not always the population's most acceptable solution. The clustering-based mutation procedure is implemented M times.

Fig. 1. Outline of the proposed method.

Fig. 2. The proposed GAN architecture for generating images.

The current population is updated when M new solutions have been provoked through clustering-based mutation. The steps are as follows:

- Selection: Produce k random individuals as the starting points for the k-means algorithm;
- Generation: Obtain M solutions utilizing clustering-based mutation and designate them as set  $v^{clu}$ ;
- Replacement: Draw M solutions randomly and classify them as B.
- Update: The most helpful M solutions from the union of  $vclu$  and B were established as B'. The final population is evaluated as  $(P - B) \cup B'$ .

The encoding method we use in our research tries to put the CNN and feed-forward weights into a vector that show the candidate solution in the improved DE. It's hard to give exact weights, but after a few trials, we came up with a way to encode that is as accurate as possible. Fig. 3 shows an example of how to encode a feed-forward network with three hidden layers and a three-layer CNN network with three filters in each layer. It is important to remember that all weight matrices in the vector are reserved as rows.

To compute the efficacy of a solution in the improved DE algorithm, the fitness factor is expressed as follows:

$$Fitness = \frac{1}{1 + \sum_{i=1}^N (y_i - \hat{y}_i)^2} \quad (2)$$

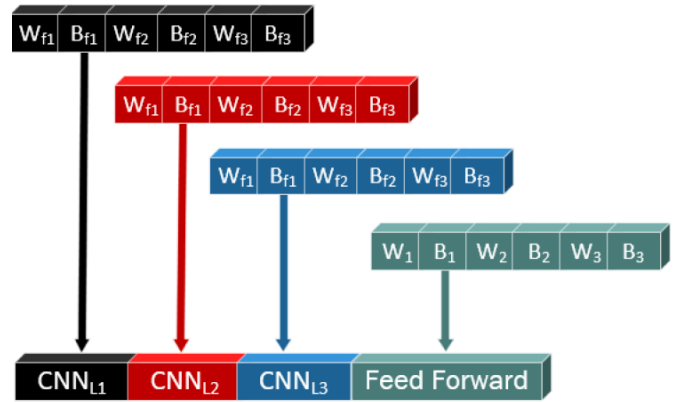

Fig. 3. Placing weights in a vector.

The target and projected labels for the i-th set of data are  $y_i$  and  $\hat{y}_i$ , respectively, and N shows the number of instances.

### C. Classification

Our approach to addressing the issue of imbalanced data volumes in our classes involves the utilization of a RL based algorithm [30]. In our training dataset, each CMR image represents a state within the environment, while the network functions as the agent responsible for performing a series of classifications on all CMR images. The agent's prediction of the class label for a given CMR image can be viewed as an action, where the image observed at time-step t is denoted as state  $s_t$  and the performed classification is labeled as  $a_t$ . In response,

the environment provides a reward  $r_t$  to guide the agent's learning process. To ensure appropriate guidance, the reward values are assigned in a manner that assigns a lower absolute value to the majority class when compared to the minority class. The reward function is:

$$r_t(s_t, a_t, l_t) = \begin{cases} +1, a_t = y_t \text{ and } s_t \in D_H \\ -1, a_t \neq y_t \text{ and } s_t \in D_H \\ \lambda, a_t = y_t \text{ and } s_t \in D_S \\ -\lambda, a_t \neq y_t \text{ and } s_t \in D_S \end{cases} \quad (3)$$

where  $D_S$ , and  $D_H$  represent the majority ("sick") and minority ("healthy") classes, respectively. Correctly/incorrectly classifying a sample from the majority class yields a reward of  $+\lambda/-\lambda$ , where  $0 < \lambda < 1$ .

### III. EXPERIMENTAL RESULTS

To assess the proposed model, we designed several experiments. We utilize k-fold cross-validation for experiments, with  $k = 5$ , meaning the dataset is broken up into  $k$  groups. Each time, one fold is chosen to be tested and the rest are used for training. This process is repeated  $k$  times. With this technique, every sample can be used once for test and  $k - 1$  times for training. We report every result as  $M \pm S$ , where  $M$  and  $S$  are the mean and standard deviation of performed experiments for  $k - 1$  times.

The first experiment compares the proposed model with three deep learning-based models, CNN-KCL [29], RLMD-PA [30], and Danaei et al. [31]. The evaluation results for the Z-Alizadeh Sani myocarditis dataset using standard performance metrics are displayed in Table I. As the results indicate, the proposed model performs more satisfactorily than CNN-KCL, which decreases error by more than 42% in all criteria. Also, the maximum value of all measures in CNN-KCL has a somewhat high difference compared to the proposed model, for example, in the two criteria of F-measure and Recall, the difference is about 13% and 9%. RLMD-PA acts better to an extent than CNN-KCL, with an improvement of 60%, showing reinforcement learning employed in it can prevent imbalanced data. However, the proposed model acts more robust than RLMD-PA, with about 45% of headway, because GAN used as data augmentation can improve imbalance as much as possible. Proposed without GAN has the same structure as the proposed model but doesn't use GAN as data augmentation. The comparison of these two models shows that the data augmentation trick improved the model by approximately 40%. To investigate the quality of the images generated by the proposed, we select six samples randomly and show them in Fig. 4. We can see that the samples produced by the proposed GAN have relatively high quality.

#### A. Examination of other Metaheuristic Methods for the Algorithm

In the suggested model, the backpropagation process is influenced by the improved DE method for initializing value. For comparison of improved DE in our model, we utilized six algorithms, including, GDA [36], OSS [37], BR [38], BA [39], COA [40] and original DE [41]. Table II provides an overview of the performance measures used in these comparisons. Metaheuristic algorithms act weaker than the proposed model in terms of accuracy, recall, and F-measure scores. It is significant to note that the improved DE algorithm surpassed all metaheuristic algorithms to reduce the error in the recall and F-measure criterion by more than 38% and 36%, respectively.

1) *Analysis of pre-trained models:* The proposed approach uses a CNN as feature extractors. It is interesting to investigate the effect of transfer learning by utilizing pre-trained models such as AlexNet [42], GoogleNet [43], ResNet [44], DenseNet [45], and MobileNet [46] as feature extractors. The performance metrics of these comparisons are summarized in Table III. As can be seen, replacing CNN trained from scratch by the pre-trained models hurts performance. In particular, training CNNs from scratch improves Recall and F-measure error by more than 60% and 67%, respectively. This stems from the fact that transfer learning models perform reasonable on wide range of images however they lack the necessary specialty for specific problems such as myocardial diagnosis.

DenseNet	0.732	0.720	0.622	0.659
MobileNet	0.763	0.734	0.652	0.706

TABLE IV. RESULTS OF VARIOUS LOSS FUNCTIONS ON THE PROPOSED MODEL

	Accuracy	Recall	Precision	F-measure
WCE	0.801	0.732	0.758	0.744
BCE	0.800	0.805	0.714	0.745
DL	0.806	0.795	0.701	0.715
TL	0.813	0.774	0.710	0.752

2) *Analysis of loss function:* To address data imbalances, conventional methods can be employed, such as adjusting data augmentation techniques and the loss function. Among these approaches, the loss function holds significant importance as it enables the emphasis of the minority class. We aim to use four loss functions, WCE [47], BCE [48], DL [49], and TL [50] to evaluate the proposed model. As we can observe from Table IV, WCE/BCE functions improved the F-measure metric by only 20%/16% despite assigning weights to the samples. The use of focal loss gives the best results for all measures on the Z-Alizadeh Sani myocarditis dataset and yields in particular the best G-means results for this dataset.

3) *Impact of the reward function:* To address the reward assignment in the context of correct and incorrect classifications, the majority and minority classes are assigned rewards of  $\pm 1$  and  $\lambda$ , respectively. The value of  $\lambda$  is determined by the ratio of majority to minority samples, with an expected decrease in the optimal value as the ratio increases. To investigate the impact of  $\lambda$ , the performance of the proposed model was evaluated using different values of  $\lambda$  ranging from 0 to 1, with increments of 0.1, while keeping the majority class bonus constant. The results are depicted in Fig. 5. When  $\lambda$  is set to 0, the influence of the majority class becomes negligible, whereas at  $\lambda = 1$ , both the majority and minority classes have equal impacts. Fig. 5 illustrates that the model's performance reaches its peak at a  $\lambda$  value of 0.6 for all considered metrics. This suggests that the optimal  $\lambda$  value lies between zero and one, rather than at the extremes. However, it should be noted that excessively low values of  $\lambda$  can adversely affect the overall model performance. Therefore, careful consideration is required in choosing  $\lambda$  to strike the right

balance. The results emphasize that the selection of  $\lambda$  significantly influences the performance of the proposed model. The optimal value depends on the relative proportions of the majority and minority samples, and it is crucial to make a thoughtful choice to achieve the best possible results.

Fig. 5. Performance metrics plotted vs the value of  $\lambda$  in the reward function.

4) *Discussion:* The proposed model has shown excellent results in the task of diagnosing myocarditis on CMR images, outperforming other deep models and pre-trained transfer learning models. The use of data augmentation and RL in the model has addressed the issue of dataset imbalance and improved the model's performance. Additionally, the use of DE pre-training has minimized the risk of the model getting stuck in local optima. However, despite its promising results, the model has some limitations that need to be considered. One of the limitations of the proposed model is that it was trained and tested on a single dataset, the Z-Alizadeh Sani myocarditis CMR dataset, which may limit its generalizability to other datasets with different characteristics. Further validation on other independent datasets is necessary to assess the model's generalizability. Another limitation is that the model

was developed using a retrospective study design, which may introduce biases and limit the ability to draw causal inferences. A prospective study design would be necessary to establish the clinical utility of the model in the diagnosis of myocarditis. Moreover, the model has some technical limitations. For instance, the performance of the model could be influenced by the quality of the input CMR images, which can vary depending on the imaging modality and the specific imaging parameters employed. The performance of the model can also be influenced by the variability in the number and size of myocarditis lesions, which can differ across patients. Future research could overcome these limitations by assessing how well the model performs on a broader range of datasets, including those with a reduced incidence of myocarditis. Furthermore, conducting a performance evaluation of the proposed model in comparison to other deep learning models developed for CMR-based myocarditis diagnosis can provide significant knowledge about the strengths and limitations of different approaches. Lastly, future research could focus on the development of deep learning segmentation methods that can not only detect the existence of myocarditis but also accurately determine the specific location and severity of the condition on CMR images. Such methods could help clinicians make more informed decisions about patient management and treatment.

#### IV. CONCLUSIONS

We presented an architecture comprising a CNN, a fully-connected decision layer, a generative adversarial network (GAN)-based algorithm for data augmentation, an enhanced DE for pre-training weights, and a RL-based method for training. We proposed an online GAN model that can effectively make synthetic myocardial images. This method of online augmentation using the generated images based on the GAN model increases the accuracy of the test dataset. To protect the proposed model against imbalanced data, we present an RL-based training strategy that focuses on learning minority class examples. We also discuss the training phase, which often involves gradient-based methods, including back-propagation, for the learning process and, as a result, is susceptible to issues such as sensitivity to initialization. In order to start the BP procedure, we provide an enhanced DE method that employs a clustering-based mutation operator. It identifies a winning cluster for the current DE population and develops potential solutions using a new updating strategy. We used the Z-Alizadeh Sani myocarditis dataset to evaluate our proposed method and show that it works better than other methods.

For future work, several aspects can be improved upon or explored further. While our online GAN model has demonstrated effectiveness in generating synthetic myocardial images, it could be refined or adapted for other types of medical images. Experimentation with other types of data augmentation techniques could also prove beneficial. Additionally, the RL-based strategy can be further optimized to ensure more robust handling of imbalanced data. Investigating other advanced optimization techniques for the initialization

process could lead to more efficient learning and overall improved performance. Lastly, applying and testing our proposed architecture on a variety of medical datasets will be critical to understand its versatility and effectiveness in a broader context. The potential of our proposed method is significant, but so is the potential for further enhancements and broader applications.

**Abstract**—With the rapid development of the Internet and the growing demand for education, a new online teaching mode, massive open online courses (MOOC), emerged in 2012. To address the problems of sparse data and poor recommendation effect in online course recommendation, this paper introduces deep learning into course recommendation and proposes an auxiliary information-based neural network model (IUNeu), on the basis of which a collaborative neural network filtering model (FIUNeu) is obtained by improving it. Firstly, the principles and technical details of the deep learning base model are studied in depth to provide technical support for course recommendation models and online learning recommendation systems. In this paper, based on the existing neural matrix decomposition model (NeuMF), we combine user information and course information and consider the interaction relationship between them to improve the accuracy of the model to represent users and courses. The neural network model of auxiliary information (IUNeu) is incorporated into the online learning platform, and the system development is completed with the design of front and back-end separation, realizing the functions of the online learning module, course collection module, course recommendation module, and resource download module. Finally, the experimental results are analyzed: under the same experimental conditions, the test experiments are repeated 10 times, and the RMSE calculation results are averaged. The RMSE value of the neural network collaborative filtering model (FIUNeu) proposed in this paper based on deep learning is 0.85517, which is the best performance and has a high accuracy rate of rating prediction, and is useful for alleviating the data sparsity problem.

**Keywords**—Massive open online courses (MOOC); deep learning; collaborative neural network filtering model (FIUNeu); course recommendation; online learning recommendation system

## I. INTRODUCTION

In latest years, MOOC structures such as Coursera, edX, and Scholastic Online have flourished and swiftly attracted a giant variety of learners. The ease with which customers can get entry to a giant variety of magnificent mastering assets in moot classification systems has significantly facilitated expertise sharing and online learning and supplied many possibilities for character newbies to get hold of training [1]. However, customers are regularly pressured via the "information overload" of the exploding quantity of publications on the Mootools platform. How to assist customers discover the getting to know assets they want and make correct tips has grown to be one of the most urgent issues [2].

Currently, Li Xiaojun et al. crawled the getting-to-know records on MUOC online for experiments, and the effects confirmed that the overall performance of the IUNeu mannequin grows quicker than the NeuMF mannequin as the vector size and the number of endorsed publications expand [3]; Xiaoyan ZD et al. proposed a bipartite diagram context collaborative filtering algorithm primarily based on the traits of MOOC platforms, which improves the advice fine of the algorithm with the aid of preprocessing the dataset and setting up distinct linkage quantification values [4]; Cheng Yan proposed a prolonged ant colony algorithm for fixing the suggestion trouble of studying paths, which takes into account the comparison of getting to know paths via the crew of newbies and the traits of goal customers in phrases of know-how stage and getting to know fashion when making advice selections [5]. Zhang H et al. blended with the traits of the MOOC platform, proposed MCRS to make splendid upgrades in path suggestion mannequin and suggestion algorithm, and the direction suggestion records are transferred to MySQL via Sqoop to obtain well-timed comments and enhance the path retrieval effectivity of customers [6]; Sun X et al. designed a customized suggestion device mannequin for on-line gaining knowledge of assets primarily based on the traits of learners' mastering conduct and on-line getting to know assets in the getting to know the process, mixed with collaborative filtering algorithm [7]; Yin H used the evaluate matrix technique to set up the hobby contrast matrix and consumer activity comments model, and optimized the suggestion algorithm the use of the hobby remarks model, accordingly realizing the suggestion of distance getting to know sources in MOOC training mode [8].

With the quickly flourish of the Internet and the growing demand for education, a new online teaching model, large-scale online open courses, emerged in 2012. To tackle the troubles of sparse facts and negative advice impact in online path advice, this paper introduces deep learning into course recommendation and proposes an auxiliary information-based neural network model (IUNeu). First of all, the principle and technical details of the basic model of deep learning are deeply studied to provide technical support for the course recommendation model and online learning recommendation system. Based on the existing Neural matrix decomposition model (NeuMF), this paper combines user information and course information, and considers the interaction between them to improve the accuracy of the model to represent users and courses. The auxiliary information neural network model (IUNeu) is integrated into the online learning platform, and the

system is developed by using the front-end and back-end separation design, and the online learning module, course collection module, course recommendation module, resource download module and other functions are realized. Finally, the experimental results were analyzed: under the same experimental conditions, the test experiment was repeated for 10 times, and the RMSE calculation results were averaged. The RMSE value of the neural network model proposed in this paper based on deep learning was 0.85517, with the best performance and high score prediction accuracy, which played a great role in alleviating the problem of data sparsity. This paper innovatively proposes a neural network model based on auxiliary information, which can accurately recommend courses for users and effectively solve the problems of sparse data and poor recommendation effect.

## II. DEEP LEARNING TECHNIQUES IN MOOC

Deep learning is based on an artificial neural network (ANN), which is a mathematical model that can learn by itself and constantly adjust to bring the results closer to reality. As early as 1943, mathematical logician W Pitts and psychologist W S McCulloch proposed the concept of neuron, the core structure of neural network, which gradually developed into a research hotspot in the field of artificial intelligence [9]. With the development of artificial neural networks, the structure of the network becomes more and more complex, and people call artificial neural networks "deep learning". In current years, deep studying methods have been extensively used in the fields of information, medicine, economics, control, transportation, psychology, etc., due to their excellent processing and processing capabilities in image processing, prediction and classification, natural language processing, intelligent robotics, signal processing, and optimal combination [10]. The following is a detailed description of the neural network structures used in the study.

### A. Convolutional Neural Networks

Convolutional neural networks, a typical model of deep learning models, do not use conventional matrix operations but use convolutional operations instead, and have one or more layers of convolutional layers. The structure of a convolutional neural network is made of an entry layer, a hidden layer, and an exit layer like the structure of a normal neural network [11]. Among them, the implicit layer usually consists of convolution, pooling, and full connectivity, while the unique aspect of convolutional neural networks is the convolutional operation and pooling operation, this is the core of convolutional neural networks.

The core building blocks of the convolutional layer are convolutional kernels, each of which consists of one or more elements. Like the neurons of the feedforward network, the elements constituting the convolutional kernel have their own amount of bias and weight coefficients, respectively. The convolution kernel has three parameters, which are the convolution kernel size, the convolution kernel cross step, and the facet padding of the entry data. The convolution kernel dimension is the measurement of the shift matrix used for the convolution operation, and the convolution kernel dimension is any fee smaller than the dimension of the matrix being convolved; the large the dimension of the convolution kernel,

the richer function records can be realized from the convolved photo [12]. The convolution step, on the different hand, defines the dimension of the measurement of the convolution kernel shifted by way of the subsequent convolution operation with recognition of the preceding convolution operation. The fill is a proposed approach to make bigger the dimension of the function map earlier than the convolution operation in order to counteract the shrinking measurement of the characteristic map in the computation and is most frequently utilized via the usage of zero to fill the boundary or with the aid of repeating the boundary facts to gain the purpose of filling [13]. Based on these three parameters being able to calculate the size of the feature map obtained after convolution, assuming that the convolution input of layer  $l+1$  is  $Z^l$  with size equal to  $L_l$ , the convolution output  $Z^{l+1}$  of layer  $l+1$  is:

$$Z^{l+1}(i, j) = \sum_{k=1}^{K_l} \sum_{x=1}^{f_w} \sum_{y=1}^{f_h} [Z_k^l(s_0 i + x, s_0 j + y) w_k^{l+1}(x, y)] + b \quad (1)$$

Here, assuming that the length and width of the feature map

$$L_{l+1} = \frac{L_l + 2p - f}{s_0} + 1$$

are equal, the output feature map size is where  $b$  is the amount of deviation,  $Z(i, j)$  corresponds to the pixel with  $(i, j)$  coordinates of the feature map,  $(i, j) \in \{0, 1, \dots, L_l + 1\}$ ,  $K$  is the number of channels of the feature map, and the three parameters of the convolution kernel: the convolution step size is  $s_0$ , the convolution kernel size is  $f$ , and the number of fill layers is  $p$ .

Neural networks possess a high degree of nonlinearity, and convolutional neural networks are no exception to this rule, and the activation function is a part of the process that produces this important effect [14]. The commonly used activation functions are linear rectifier function, hyperbolic tangent activation function, and sigmoid() function, while convolutional neural networks usually use linear rectifier function as activation function.

For matrix data, a pooling operation is proposed to extract the significant features representing the matrix data, i.e., to select a maximum or average number as the features of a region of data by means of aggregation statistics. On the one hand, the pooling layer enables the down sampling of data, thus reducing the number of model parameters, and on the other hand, the pooling layer is a kind of data dimensionality reduction, enabling the compression of data features, effectively reducing the redundant information contained in the data, streamlining the complexity of the model, and reducing the unnecessary computation and memory consumption of the model [15]. In addition, the pooling layer enables nonlinearity and invariance of data transformations, which can expand the perceptual field while preserving data characteristics. Pooling operations can be classified into three categories: Lp pooling, random/hybrid pooling, and spectral pooling. Mean pooling and maximum pooling in Lp pooling are the most frequently used pooling methods for pooling layers in convolutional neural networks, and the general representation of Lp pooling is:

$$A_k^l(i, j) = \left[ \sum_{x=1}^f \sum_{y=1}^f A_k^l(s_0i+x, s_0j+y)^p \right]^{\frac{1}{p}} \quad (2)$$

Same as the convolutional layer, here so denotes the pooling step,  $(i, j)$  denotes the pixel points.  $P$  denotes the pre-specified parameter, when  $P=1$ , its capacity that the implied fee is taken as the pooling end result in the pooling region, i.e., mean pooling; when  $P=\infty$ , it means that the great value is taken as the pooling result in the pooling region, i.e., maximum pooling. However, both methods lose some information about the image.

### B. TextCNN

TextCNN has great overall performance in textual content classification problems. TextCNN has superb overall performance in textual content classification problems. In particular, TextCNN can effectively extract the shallow feature information of natural utterances of short texts, and it is extensively used in the area of brief texts with its benefit of true outcomes and speedy pace.

Intuitively understood, the convolutional operation of TextCNN is performed based on a one-dimensional convolutional kernel to obtain an n-dimensional feature representation of the text [16]. TextCNN uses pre-trained word vectors word embeddings as input, i.e., a sentence consisting of n words is represented by an  $n \times k$  matrix, where  $k$  is the dimension of the word vector corresponding to each word, here the k-dimensional word embeddings of the  $i$ th word in the sentence are represented using  $x_i \in \mathcal{R}^k$ . First, a convolution operation  $w \in \mathcal{R}^{hk}$  is performed to obtain a feature  $c_i : c_i = f(w \square x_{i,i+h-1} + b)$  by using a convolution kernel on  $x_{i,i+h-1}$ . Where  $x_{i,i+h-1}$  denotes the vector feature matrix of the  $i$ -th to  $i+h-1$ th word in the input matrix,  $w$  is the weight matrix of dimension  $h \times k$ ,  $b$  is a functional deviation and  $f()$  is a non-linear function.  $i$  starts from 1 and is added 1 each time until  $i$  equals  $n-h+1$ , and the  $c_i$  obtained each time is stitched to get the vector  $c = [c_1, c_2, \dots, c_{n-h+1}]$  after one convolution. Multiple convolution kernels are set up by defining different  $h$ , in order to extract different feature carriers and use them together as the convolution layer's output. Then, a maximum pooling operation is performed, i.e., a fixed-length vector representation is obtained by selecting the largest feature from the  $c$  vectors obtained from different convolution kernels and stitching them together to form a new vector [17]. Last, the globally connected layer activated using softmax() is accessed to output the probability values corresponding to each category.

### C. Gated Circulation Unit

The gated recurrent unit (GRU), like the long- and non-permanent reminiscence network, is an enchantment on the trendy recurrent neural network, whose mannequin shape is proven in Fig. 1.

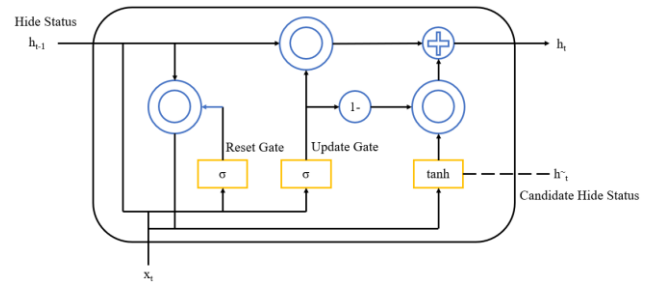

Fig. 1. GRU model structure.

The advantage of GRU over LSTM is that it uses a gating mechanism, while significantly reducing the problem of vanishing gradients. The GRU network structure contains two gating structures, one for update gating and one for reset gating. As a variant of recurrent neural networks, the gating mechanism controls which information can be transmitted through the network model to the output layer. In addition, these two gating structures do not discard data because of the length of the depth of the operation or the uselessness of some data for the resultant output but are able to preserve various types of information in the data sequence over time.

### D. Self-attentive Mechanism

Self-attention mechanisms were first proposed as an important component of Transformer (ML architecture that has been successfully applied to various NLP tasks, especially sequence-to-sequence tasks, such as machine translation and text generation). The attention mechanism learns as the model fits the data results, and instead of just performing a comprehensive analysis of the full information, the work is focused on discovering important local information and analyzing it [18]. The self-attention mechanism is used to discover the parts of the input data that deserve more attention by interacting between each input two-by-two. The result of the interaction and aggregation of the input data is the output of the self-attentive mechanism, i.e., the attention score.

The inputs and outputs of the self-attentive mechanism are sequences, and assuming  $x_i$  is the input sequence, the detailed derivation of the procedure is as below.

- 1) Each input is obtained by multiplying by a matrix to get  $a_i$ , and then multiplying by 3 different vectors  $W^q, W^k, W^v$  to get  $q^i, k^i, v^i$  respectively.
- 2) Calculate the weight of  $q$  and  $k$  by the similarity calculation method, for example, take the first input as an example,  $\alpha_{1,i} = q^1 \square k^i / \sqrt{d}$ , and then  $\hat{\alpha}_{1,i} = \exp(\alpha_{1,i}) / \sum \exp(\alpha_{1,i})$  need to be normalized by softmax.
- 3) Multiply  $v_i$  with the corresponding  $a_{1,i}$  and then add them to get the output vector  $b_{1,i}$  of the first input.
- 4) Repeat the above steps to obtain the corresponding output vector of the input sequence.

### III. DEEP LEARNING-BASED COURSE RECOMMENDATION MODEL

#### A. Neural Matrix Decomposition Model

The NeuMF model is made up of two parts: the GMF (generalized matrix factorization) model and the MLP (multilayer perceptron) model. In the GMF model, a linear kernel is applied to simulate the interaction between features; in the MLP model, a nonlinear kernel is applied to learn the interaction function [19]. Thus, the NeuMF model has both linear and nonlinear modeling capabilities, and the specific application structure of the model in course recommendation is shown in Fig. 2. In the figure, the left side of the model is the GMF part and the right side is the MLP part. The model is bottom-up, starting with the input layer, which contains one-hot codes for user and item IDs, and passes these codes to the embedded layer to represent the corresponding users and items. The output of the two-part molecular model is connected, and the predicted values  $\hat{y}$  are obtained in the output layer by the Sigmoid activation function, which  $\hat{y} \in \{0,1\}$  indicates the user's preference for the item (1 for like and 0 for dislike). The weights of each layer are trained by backpropagation.

The model-specific expressions are:

$$\hat{y}_{u,i} = f_{out} \left( W_{out} \left[ X^{GMF}, X^{MLP} \right] \right) \quad (3)$$

$$X^{GMF} = p_u^{GMF} \cdot q_i^{GMF} \quad (4)$$

$$X^{MLP} = f_L \left( W_L \left( \dots f_1 \left( W_1 \left[ p_u^{MLP}, q_i^{MLP} \right] + b_1 \right) \dots \right) + b_L \right) \quad (5)$$

where:  $X^{GMF}$  and  $X^{MLP}$  are the potential feature vectors of the GMF and MLP model parts, respectively,  $\hat{y}_{u,i}$  is the predicted value,  $f_{out}$  and  $W_{out}$  are the activating features weights of the export layer, respectively,  $p_u^{GMF}$  is the user potential feature vector in  $X^{GMF}$ ,  $q_i^{GMF}$  is the item potential feature vector in  $X^{GMF}$ ,  $p_u^{MLP}$  is the user potential feature vector in  $X^{MLP}$ ,  $q_i^{MLP}$  is the item potential feature vector in  $X^{MLP}$ ,  $[\ ]$  denotes the internal element connection,  $f_L$  and  $W_L$  are the activation function weights of the Lth layer, separately, and  $b_1$  and  $b_L$  are the biases of the 1st and Lth layers, separately.

The detailed training procedure of the NeuMF model is as following: 1) Infant layer: extract the ID information of users and courses in the training set and encode them using one-hot. 2) Embedded layer: use the infant layer as the infant, independent embedded layers are used in the model, the GMF model on the left side of the model and the MLP model on the right side, each layer selects the linear rectification function as the activation function and outputs a  $1 \times n$  dimensional matrix. 3) Output layer: The outputs of the GMF and MLP models are linked first and last, and the results are mapped to  $[0, 1.0]$  by the Sigmoid activation function to obtain the prediction results  $\hat{y}$ .

The NeuMF model is applied to analyze the data of MUCN, and compared with the traditional user-based k-nearest neighbor algorithm, and MFALS algorithm, and the hit rate is

used as the index for performance evaluation in the experiments by the leave-one-out method. It is found that the hit rate of the UserKNN algorithm is 0.075 because it does not involve the underlying feature vector length  $n$ ; MFALS involves the construction of the user matrix and item matrix, and its hit rate varies with the increase of  $n$  and finally stabilizes at about 0.110; the hit rate of NeuMF model is higher than that of UserKNN algorithm and MFALS algorithm, and its hit rate is greater than 0.500 [20]. The reason for this is that the UserKNN algorithm uses similar historical behavior data of the target user and  $k$  neighbors to predict the course resources that users may like in the future, while the MFALS algorithm recommends course resources to users based on the high or low item history ratings, and both algorithms cannot better meet the actual demand of online course resource recommendation. Therefore, this study considers improving the NeuMF model by transforming the recommendation problem into a classification problem. A more efficient neural network model based on auxiliary information (item and user information) is proposed. The model is constructed by analyzing users' historical learning records and implementing a classification function with users and courses as the minimum unit, with positive classes indicating users' likes and negative classes indicating users' dislikes. The problems of the above UserKNN and MFALS algorithms for course recommendation are improved in the model to improve the recommendation effect.

#### B. IUNeu Model

In the IUNeu model, the input information in the Input layer is divided into two parts: 1) user-related information, such as user ID, user's gender, occupation, etc., where the information other than user ID is called user auxiliary information [21]; 2) course-related information, such as course ID, course's label, course category, etc., where the information other than course ID is called course auxiliary information. The form of the input information is [User ID, Male, Front-end Engineer, ...], [Course ID, Front-end Technology, JS Basic Design, ...]. The specific model architecture is illustrated in Fig 3. It can be observed that the user-course auxiliary information (hereafter collectively referred to as auxiliary information) is involved in all stages of the overall model. During training, the auxiliary information is used as input along with the user ID and course ID; in the GMF (MLP) composition model, the user ID, course ID, and user-course auxiliary information are fused to participate in linear modeling (nonlinear modeling); and in the Sigmoid activation function output, the auxiliary information is also fused.

Fig. 2. Structure of the NeuMF model.

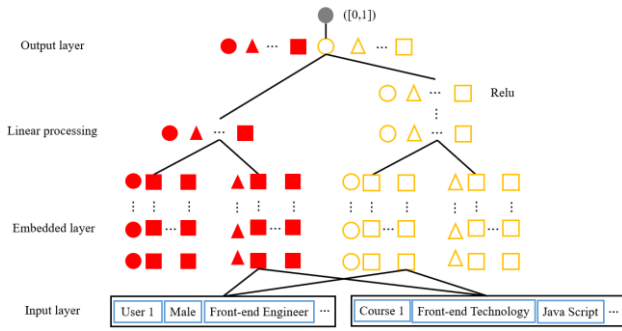

Fig. 3. IUNeu model structure.

The  $X^{GMF}$ , and  $X^{MLP}$  expressions in the IUNeu model structure improvement equation (6) are:

$$X^{GMF} = P_a^{GMF} \cdot q_i^{GMF} = (u_0^{GMF} \oplus u_1^{GMF} \oplus \dots \oplus u_m^{GMF}) (c_0^{GMF} \oplus c_1^{GMF} \oplus \dots \oplus c_m^{GMF}) \quad (6)$$

$$\begin{aligned} X^{MLP} &= f_L \left( W_L \left( \dots f_i \left( W_i \left[ P_a^{MLP}, q_i^{MLP} \right] + b_i \right) \dots \right) + b_L \right) \\ &= f_L \left( W_L \left( \dots f_i \left( W_i \left[ u_0^{MLP} \oplus u_1^{MLP} \oplus \dots \oplus u_m^{MLP}, \right. \right. \right. \right. \\ &\quad \left. \left. \left. c_0^{MLP} \oplus c_1^{MLP} \oplus \dots \oplus c_m^{MLP} \right] + b_i \right) \dots \right) + b_L \right) \quad (7) \end{aligned}$$

where:  $u_x^{GMF} (u_x^{MLP})$  is the user word vector,  $x=0$  denotes user ID,  $x \neq 0$  denotes user auxiliary information, such as gender, occupation, etc.;  $c_x^{GMF} (c_x^{MLP})$  is the course word vector,  $x=0$  denotes course ID,  $x \neq 0$  denotes course auxiliary information, such as data mining, web front-end, etc.;  $\oplus$  denotes the expansion of the original fixed  $1 \times 1 \times n$  tensor into a  $1 \times m \times n$  tensor, i.e., using the user (course) vector and the user auxiliary information (course auxiliary information) vectors to extend the original  $1 \times n$ -dimensional matrix, where  $n$  is the potential feature vector length and  $m$  is the infeed information length. Therefore, the outputs of GMF linear kernel modeling and MLP nonlinear kernel modeling are not only influenced by the IDs of the users and courses themselves but also determined by the content attributes of the users and courses themselves.

The detailed training procedure of the model is as following: 1) Infant layer: extract the information related to users and courses in the training set, including user gender, user occupation, course major category, course minor category, etc., and encode them with one-hot. 2) Embedding layer: use the infant layer as the infant, and output a  $1 \times m \times n$  dimensional matrix. By flattening the operation, the length is extended to  $mn$  by adding auxiliary information to the original NeuMF model of length  $n$ , where  $(m-1)n$  is the length of the auxiliary information vector. 3) Output layer: The GMF sub-model multiplies the flattened two results point by point as the linear output result, and the MLP sub-model connects the flattened results first and last to form a new vector and serve as the loser of the neural network (its activation function adopts the Relu activation function). Then the outputs of the GMF and MLP models are connected first and last and mapped to  $[0,1.0]$  by the Sigmoid activation function as the prediction results.

### C. Collaborative Filtering Model for Neural Networks with Fused Attention Relations

Along with the development of the Internet, social networking has become an essential element of Internet applications. In addition to social networking platforms (e.g., Weibo, Zhihu, and Twitter) that are socially focused, many current Internet applications contain social elements, and many MOOC platforms, as one of the Internet applications, have social features [22]. In the AIMOC platform each user can follow their favorite users, which may include leaders in their own learning field, and become their fans, also called followers these followed people are called followers.

As a typical social network platform, Weibo can create a celebrity effect through the influence of well-known users who have a large number of followers. Unlike typical social networking platforms, MOOC platforms with social networking elements also have a celebrity effect because, as open e-learning platforms, the famous users here are more likely to be leaders in a certain learning field. Therefore, in MOOC platforms, the current interest preferences of these followers in the course are likely to influence their followers' choice of course.

Attention relationship as a specific expression in social networks, a recommendation algorithm AttentionRank+ is proposed, which considers the influence of the behavior of the followed on the behavior of the followers and improves the recommendation algorithm performance by fusing attention relations. In this article, we will also build a collaborative neural network filtering model (FIUNeu) based on the IUNeu model with fused attention relations to enhance the recommender effectiveness of the course recommender system.

The NeuMF model is a combination of models in the horizontal direction and is a fusion of recommendation algorithms. In this paper, the construction of the FIUNeu model is a fusion in the vertical direction, which is the fusion of recommendation results. The main idea of the FIUNeu model is to give the corresponding weight value to each course in the TopN courses recommended to the current user based on the IUNeu model by calculation. The FIUNeu model is described as follows:

Let the current user be  $u$ , the number of users he follows is  $p$ , and the maximum number of users he follows be  $M$ . First, the TopN courses  $(c_1, c_2, \dots, c_{n-1}, c_n)$  are recommended to user  $u$  by the IUNeu model, and the initial weights of these  $K$  courses are set to  $(n, n-1, \dots, 2, 1)$ . For the  $i$ th recommended course  $c_i$  of the current user  $u$ , where  $i \in (1, 2, \dots, n-1, n)$ , and  $q$  users among all users followed by this user choose this course, the weight formula for this course  $c_i$  is

$$f(i) = \frac{w_1(n-i+1) + w_2 \left( \alpha \frac{q}{p} + \beta \frac{p}{M} \right) n}{2n} \quad (w_1 + w_2 = 1, \alpha + \beta = 1) \quad (8)$$

Where  $w_1$  and  $w_2$  denote the proportion of the influence of the IUNeu model and attention relationship on the value of course  $c_i$  weight,  $\alpha$  and  $\beta$  denote the proportion of attention and the proportion of the number of attentions on the influence of

attention relationship, in this paper FIUNeu model for the above parameters, are selected as 0.5 through the above formula for this TopN course weights are recalculated, then according to the weights of this TopN course re-ranking. Finally, the TopK courses are recommended to the current users.

The model framework of FIUNeu is illustrated in Fig. 4:

Fig. 4. FIUNeu model.

#### IV. DESIGN AND IMPLEMENTATION OF AN ONLINE LEARNING RECOMMENDATION SYSTEM

##### A. Overall System Design

1) *System logical architecture design:* The logical architecture of the system consists of five levels: the base device level, the data level, the middle level, the application level, and the user level. The device layer provides the basic hardware configuration such as network, server, operating system, and other hardware, and is the basic link of the logical architecture. The data layer is responsible for data storage and management, like user data, course data, log data, etc. The middle level is responsible for handling the business logic, including the recommendation algorithm. The application level is primarily concerned with invoking the algorithms of the middle layer according to the user data and processing the commands sent by the users [23]. The user level is concerned with user interaction, sending user requests, and other operations.

2) *System technical architecture design:* The system adopts the most commonly used three-layer technical architecture: front-end display layer, business logic layer, and data storage layer. Users first send request instructions in the front-end display layer. The business logic layer receives the instructions and then calls each functional layer component and gets the required data from the data storage layer for business logic processing and finally returns the data to the front end [24]. The layered technology architecture can solve the problem of system coupling and adopt the development method of separating front and back ends, which can improve the scalability of the system and the speed of development.

Front-end display layer: this layer mainly interacts with users and sends requests, which are processed by the business logic layer and returned to this layer, and then rendered and presented to users, and user behavior data can be collected

through the front-end display layer. The front-end pages in the system are developed based on the Bootstrap framework, JavaScript, CSS3, and other technologies. The simple and friendly system interface is more user-friendly and can enhance user stickiness.

Business logic layer: This layer contains a large number of functional components, which are charged with the logical processing of business. The system adopts the Django framework and divides the business logic layer into three layers through Django's MTV pattern: the Model layer is responsible for reading, writing, and updating data from the database, the Template layer has rich template functions and is responsible for encapsulating and constructing HTML, and the View layer performs business processing and is the bridge between the Model and Template layers. Different roles have different business logic.

Data Store Layer: The data store layer is primarily responsible for storing user behavior data, log data, and other source data and a relational database is more convenient for developers and backend managers to maintain and manage. Therefore, the data storage layer uses the MySQL database to store and manage data and adopts md5 encryption to ensure the security of user data and avoid security risks caused by data leakage.

##### B. System Functional Module Design

The online mastering suggestion device is divided into three roles: pupil user, instructor user, and administrator. Student customers can log in to the gadget to learn about the course, consider the course, whole path assignments, download route sources, and different operations. Teachers can log in to the gadget to keep and manipulate route resources, pupil records, and private information, and directors can view and alter trainer information, scholar statistics, and route information.

The practical modules of the gadget are basically divided into 4 core modules: consumer registration and login module, online mastering module, route advice module, and historical past administration module.

1) *User registration and login module* If a new user first registers, fill in the registration page with standard information including a verification code, an account password, and other information, and then jump to the system home page after the background verification and storage of data, the registration page is concise and more user-friendly [25]. If the user is registered in the database, the user is prompted to log in directly. The cell phone verification code verification function uses the Ronglian communication cloud server to achieve the verification code acquisition. Enter the personal home page to improve the basic information, such as a nickname, birthday, gender, address, and other information.

The main classes involved in the user login module are: LoginForm(), DynamicLoginView(), SendSmsView(), LoginView(), and ChangePwdForm(), which correspond to the functions of getting login form content, logging in after registration, verifying cell phone verification code, login judgment, and changing password, respectively.

2) The online mastering module is one of the core features of the online studying advice system, which makes hints via the behavioral information generated by way of the customers of this module. Users can find out about the course, and whole route assignments, download direction resources, and consider the direction and different features in this module. After logging into the system, customers can pick out the direction they are involved in from the direction list on the domestic web page and begin getting to know the course or proceed to get to know the taking part guides in the private middle My Courses page. After getting into the route important points page, customers can view the route introduction, trainer and organization profiles, path details, etc. They can pick to collect, begin learning, etc. After clicking begin learning, they can choose the corresponding chapter for learning, commenting, and scoring. In addition to learning the course, you can also download the materials and view the course assignments on the course page.

The main classes involved in the online learning module are: CourseListView(), CourseLessonView(), CourseDetailView(), CourseCommentsView(), VedioView(), and HomeworkView(), which are corresponding to get course list, get course chapter list, course comments, video learning, homework completion, and other functions.

3) The course recommender mode offers users a more precise course push, which effectively enhances users' learning productivity. The system uses different recommendation algorithms for users with different login statuses. For users who are not logged in and users who have not studied any courses, the popularity-based recommendation algorithm is used to make recommendations based on the number of course learners, and for users who are logged in, the hierarchical attention recommendation algorithm DHRAA algorithm, which integrates auxiliary information, is proposed in this paper to make recommendations.

The popularity-based recommendation algorithm is to sort the courses in reverse order according to the number of course learners, exclude the courses currently taken by users and select the top five courses for a recommendation, which can effectively tackle the user cold start issue and improve the recommendation efficiency.

This paper proposes a deep recommender algorithm according to auxiliary information that extracts the user id, user occupation, teacher institution, course id, course title, course review, course rating, and other information from the local database into the trained model, and calculates the list of course recommendations that match the user's characteristics.

The main classes involved in the course recommendation module are: CourseListView, CourseCommentsView, and CourseRecommView, which correspond to course list, course evaluation, course recommendation, and other functions respectively.

4) *The backend administration mode contains two types of roles:* teachers and administrators, mainly for user profile

management, course material management, and permission management. User information management refers to the management of information of all roles on the platform and the addition, deletion, and checking of information of teachers' organizations. Course resource management refers to viewing and modifying course videos, course materials, course assignments, and other resources. When reviewing the content of comments submitted by users, administrators can query and delete user comments if they are found to be non-compliant.

### C. System Database Design

The device makes use of MySQL database for records storage and management, and the statistics tables of every module include important information tables such as consumer statistics table, teacher records table, direction data table, route assessment information table, route project facts table, and direct aid facts table. The ER model is a conceptual design used to describe the relationships between entities, and it accurately describes various relevant data characteristics and their mutual restrictions. The EER model includes all the modeling concepts introduced by the ER model [26]. In addition, it includes the concepts of subclasses and super classes, as well as the concept of association types or categories, which are used to represent the association of objects of different entity types.

The user message table includes information about the user attributes needed in the recommender algorithm and stores the registration forms filled in by the user. The teacher information table stores the personal information of teachers, such as teacher id, teacher organization, teacher title, years of work, and other personal information, which is associated with the course organization table through the foreign key org\_id. The path records desk includes the direction attribute facts required in the advice algorithm, which primarily data the small print of every difficulty route such as route description information, route situation level, quantity of path rookies, and different information. The path contrast records desk shops the person comparison and ranking facts of the course, which files the core statistics of the suggestion algorithm, and the route identification is set as the principal key in order to facilitate the advice algorithm to precisely stumble on the precise course. The direction venture information desk shops special facts about the venture together with the challenge title, theme options, etc. A route corresponds to more than one assignment. The course resources data table is used to store course-related resources, which are shown on the course details page, including software and documents, etc.

## V. EXPERIMENTAL TESTS AND RESULTS ANALYSIS

### A. Experimental Test Protocol

The experimental test computer hardware environment is as follows: processor Intel Corei9-9900K, graphics card GeForce RTX 2080T, memory 32GB The computer software environment used to run all experiments in the Python environment, using the Caffe tool to train and test the AlexNet network model. The data from the online learning platform of the China University MOOC National Excellence Course was used as the experimental data set.

To validate the proposed algorithm in this paper, the algorithm was objectively evaluated by calculating the root mean square error, which was calculated as follows:

$$RMSE = \sqrt{\frac{\sum_{u,v} (R_{uv} - \hat{R}_{uv})^2}{|R_t|}} \quad (9)$$

Where:  $R_{uv}$  denotes the true rating of course  $v$  by user  $u$ ,  $\hat{R}_{uv}$  denotes the predicted rating, and  $|R_t|$  denotes the number of ratings in the test set. It can be seen that the lower the RMSE value, the higher the accuracy of the rating prediction and the better the performance of the recommendation system.

**B. Analysis of Experimental Results**

In order to verify the performance of the proposed algorithm, it is compared with other recommended algorithms, including Random method, UserAvg method, cooperative filtering method (CF) and non-negative matrix method (NMF). In order to ensure the stability of the algorithm, RMSE calculation results were averaged after repeated test for 10 times under the same experimental conditions. The comparison of results of different algorithms is shown in Fig. 5.

Fig. 5. Comparison of the results of different algorithms.

As can be seen from Fig. 5, RMSE value of Random method is 1.6925, RMSE value of UserAvg method is 1.0458, RMSE value of collaborative filtering method is 0.9124, and RMSE value of non-negative matrix method is 0.8869. It can be shown that the algorithm proposed in this paper performs optimally on the evaluation index of RMSE, with higher accuracy of rating prediction, which is useful for alleviating the problem of sparse rating data.

Next, in anticipation of verifying the influence of different experimental factors on the experimental results, this paper will verify the performance of the FIUNeu model, IUNeu model, and NeuMF model under different lengths of potential feature vectors and different TopNs based on different candidate course sets recommended by FIUNeu model

1) The candidate course set size is 30, and the performance of the three models is compared under different potential feature vector lengths and different TopN.

The FIUNeu model recommends the Top 10 courses twice on the basis of the 30-candidate course set recommended by the IUNeu model, while the IUNeu model and the NeuMF model directly select the Top 10, and verify the influence of different potential feature vectors on these three models on this

basis. The vector lengths were selected as (4,8,12,16,20), and the experimental results are shown in Table I below:

TABLE I. WHEN THE COURSE SET IS 30, THE INFLUENCE OF DIFFERENT POTENTIAL FEATURE VECTOR LENGTHS ON THE MODEL

	NeuMF	IUNeu	FIUNeu
HR	0.5751	0.5939	0.5971
	0.5901	0.6081	0.6132
	0.5931	0.6064	0.6092
	0.5927	0.6042	0.6073
	0.5915	0.6026	0.6064
NDCG	0.3362	0.3632	0.3739
	0.3633	0.3775	0.3931
	0.3663	0.3782	0.3945
	0.3663	0.3768	0.3928
	0.3661	0.3764	0.3931

The FIUNeu model is based on the set of 30 candidate courses recommended by the IUNeu model, and the effect of different TopN on the three models is verified by the feature vector length selected as 8 and TopN selected as (5,10,15,20), as illustrated in Fig. 6.

Fig. 6. Effect of different TopN on the model.

2) Here the candidate course set size is chosen to be 50, and the above two sets of experiments are conducted again and with the same experimental settings. As illustrated in Table II and Fig. 7.

TABLE II. WHEN THE COURSE SET IS 50, THE INFLUENCE OF DIFFERENT POTENTIAL FEATURE VECTOR LENGTHS ON THE MODEL

	NeuMF	IUNeu	FIUNeu
HR	0.575	0.594	0.597
	0.59	0.608	0.6142
	0.5929	0.6064	0.6092
	0.5927	0.6042	0.6073
	0.5914	0.6026	0.6067
NDCG	0.3356	0.3632	0.3741
	0.3628	0.3775	0.3931
	0.3661	0.3783	0.3938
	0.3656	0.3771	0.3945
	0.3659	0.3768	0.3928

Fig. 7. Effect of different TopN on the model.

This paper only lists the experimental comparison between the case of 30 candidate course sets and 50 selected course sets recommended by IUNeu, and the experimental results based on other candidate course sets are roughly the same. From the above experimental results based on different lengths of potential feature vectors and different TopN settings, we can see that FIUNeu can indeed have better recommendation performance. From the above sets of experiments, we can find that FIUNeu, as an extension of the IUNeu model, is dependent on the IUNeu model for its performance, i.e., FIUNeu can make the IUNeu model perform better.

## VI. CONCLUSION

In this paper, we study the course recommendation algorithm in the MU environment. Firstly, a neural network model based on auxiliary information (IUNeu) is proposed, and an improvement is made to the IUNeu model by fusing attention relations into the IUNeu model to obtain the FIUNeu model. The specific conclusions are as follows:

1) Considering the influence of the user and the content in the course on the model, a neural network model that fuses user and course information is constructed using the personal attributes of the household as well as the course information. On the basis of the original model features (user and course codes), the features such as the user's personal information and course categories are further fused to make the model's characterization of user and course features more accurate.

2) In this paper, the construction idea and the concrete implementation of the improved FIUNeu model based on the IUNeu model are presented, and the improved model FIUNeu is experimented on real data sets with the IUNeu model and NeuMEF model through MapReduce, so as to verify the performance of the three.

3) Under the same experimental conditions, the test experiments were repeated 10 times, the RMSE calculation results were averaged, and the RMSE value of the proposed neural network collaborative filtering model (FIUNeu) based on deep learning in this paper was 0.85517. The experimental results based on different potential feature vector lengths and different TopN settings show that FIUNeu can indeed have better recommendation performance. FIUNeu is an extension of the IUNeu model, its performance is dependent on the IUNeu model, i.e., FIUNeu can make the IUNeu model perform better.

The neural network model of auxiliary information proposed in this paper has some limitations. The cold start problem of the recommendation system, because it only relies

on the user's feedback on the item, the newly added users and items need a period of data accumulation to reflect the recommendation effect. This will affect the new user experience. The comparison of algorithms in this paper are all offline tests, which cannot fully reflect the experience of real users. Due to the lack of real user feedback, online A/B testing is not possible. Therefore, in future work, researchers should work with companies to deploy algorithms into real production environments and optimize algorithms and system designs based on feedback from real users.

**Abstract**—Today's overpopulation and fast urbanization present a significant challenge for developing countries in the form of excessive garbage generation. Managing waste is essential in creating sustainable and habitable communities, but it remains an issue for developing countries. Finding an efficient smart waste management system is a challenge in current research. In recent years, robots and artificial intelligence have influenced a wide range of industries, especially waste management. This research proposes a waste segregation system that integrates the robot arm and YOLOv6 object detection model to automatically sort the garbage according to its type and achieve real-time requirements. The proposed algorithm utilizes the pros of the hardware-friendly architecture of YOLOv6 while keeping high detection accuracy in detecting and classifying garbage. Moreover, the proposed system creates a 3D model of a 4 DOF robotic arm by CAD tools. A new approach based on a geometric method is proposed to solve the inverse kinematics problem in order to precisely calculate the proper angles of the robot arm's joints via a unique solution with less computational time. The proposed system is evaluated on a modified TrashNet dataset with seven garbage classes. The experiments reveal that the proposed algorithm outperforms the other recent YOLO models in terms of precision, recall, F1 score, and model size. Furthermore, the proposed algorithm consumes approximately fractions of a second for picking up and placing a single object in its proper basket.

**Keywords**—Smart recycling; inverse kinematics; object detection; 4 DOF robotic arm; YOLOv6

## I. INTRODUCTION

The amount of municipal solid garbage produced each year globally is 2.01 billion tonnes, with at least 33% of it needing to be handled in a way that protects the environment. Worldwide garbage is anticipated to increase worldwide to 3.40 billion tonnes by 2050, more than double the population growth over that time. Even if there are many ways to dispose of the garbage gathered today, the ecological system's sustainability and safety are nevertheless negatively impacted. Reusing and recycling as much trash as you can is thus the best option. In certain nations, the sorting process is primarily manual. Human sorters are manually stationed beside the material-transfer conveyor belts to identify the material type. One of its typical issues is that manual sorting mainly relies on visually examining the mixed garbage moving on the

conveyor. A material surge might occur, leaving a sorter with insufficient time to understand all of the items handed to them. Moreover, health concerns, including skin difficulties, are unavoidable [1]. Therefore, manual sorting suffers from low productivity and increased health risks. Recently, robotic technology has replaced the time-consuming human garbage sorting system with an automated one. The robot is integrated with deep learning technology for detecting and classifying recyclable objects on the conveyor belt and picking and placing these objects in the appropriate baskets. Different convolutional neural networks (CNN) have been proposed for waste classification.

In [2], five deep learning architectures were applied for classifying Trashnet dataset, including: DenseNet121, DenseNet169, InceptionResnetV2, MobileNet, and Xception. Currently, Gondal et al. proposed a hybrid technique for smartly classifying real-time waste [3]. This technique applied to two machine learning methods: a multilayer perception and a multilayer convolutional neural network (ML-CNN). The former classifies the waste into metal or non-metal waste, while the latter specifies the class of non-metal waste (paper, plastic, rubber, cotton, and wood). The camera is positioned in front of a conveyor belt to take an image of each trash item. After image categorization, an automatic holder is used to pick up the trash item and place it into the assigned bucket. Although some of these CNN models achieve better classification accuracy, they are limited to classifying one object per image. If the image has many objects as the images captured from the conveyor belt, CNN model classifies the most dominant object in the image. On the contrary, object detectors are used in this case to both localize and classify various objects in the same image. Several methods are proposed for object detection, and their designs are based on two approaches: one-stage object detection and two-stage object detection. One-stage detectors are distinguished by their high inference speeds because they consider computing speed and combine object localization and classification to output. However, two-stage detectors are characterized by high localization and identification accuracy because they employ independent calculations for object localization and classification, increasing the accuracy and speed calculations. SSD and YOLO are models of one-stage detectors, and RCNN, Fast RCNN, and Faster RCNN are models of two stages

detectors. In waste recycling applications, speed is considered essential for picking up many objects in real-time. Therefore, most of the research in this application applies the one-stage detectors in their systems.

WEN MA et al. [4] propose a Lightweight Feature Fusion Single Shot Multibox Detector (L-SSD) algorithm for waste detection and classification. L-SSD is an enhanced SSD with a lightweight and a feature fusion module to improve its performance and detect waste with a small volume. The L-SSD is trained on a collected dataset consisting of five classes: cardboard, glass, paper, plastic, and metal. Daniel Octavian Melinte et al. [5] fine tune the Single Shot Detectors (SSD) architecture with MobileNetV2 base network on the TrashNet dataset using appropriate training hyper parameters to be carried out on autonomous robot system.

Berardina De Carolis [6] detect and report the presence of abandoned waste through real-time analysis of video streams based on an improved YOLOv3. A new dataset containing four classes: garbage bag, garbage dumpster, garbage bin, and blob, is used to fine-tune the improved YOLOv3. Saurav Kumar et al. [7] apply YOLOv3 in the waste segregation application to detect six classes of trash objects (namely: cardboard, glass, metal, paper, plastic, and organic waste). Aria Bisma Wahyutama et al. [8] design a trash bin that is competent for automatically separating and collecting recyclable trash utilizing YOLOv4 object detection. The YOLOv4 model is installed on Raspberry Pi. As the trash object is detected, a servo rotates the trash bin cover to disclose the correct room for the user to throw away the trash. Additionally, the study [9] submitted a smart waste detection utilizing YOLOv3, YOLOv4, YOLOv3-tiny, and YOLOv4-tiny models. A nature-inspired searching strategy was applied to fine-tune the learning rate of YOLO structures. The results reveal that YOLOv3 provides the best results.

Anbang Ye et al. [10] propose a YOLO model with Variational Autoencoder (VAE) to increase the detection accuracy and decrease the model size for edge devices. The model has been trained on a generated dataset from the 2020 Haihua AI Challenge (2020 HAC), a garbage sorting competition. Andhy Panca Saputra et al. [11] propose YOLOv4 and YOLOv4-tiny for garbage detection and train the model on a modified version of the TrashNet dataset with a smaller number of classes and a higher number of images.

Deep Patel et al. [12] introduce a comparative study for applying five object detector techniques which are EfficientDet-D1, SSD ResNet-50 V1, Faster R-CNN ResNet-101 V1, CenterNet ResNet-101 V1 and YOLOv5M on a custom garbage dataset collected from the internet. The comparison results demonstrate that YOLOv5M has reliable and precise predictions. Sylwia Majchrowska et al. [13] localize and classify the litter through two networks, EfficientDet-D2 for localization while EfficientNet-B2 for classification. The algorithm is applied to new benchmark datasets, namely detect-waste and classify-waste merged from different datasets annotated similarly for the seven waste categories.

Other researchers, on the other hand, concentrate on the issue of designing and determining the angles of the joints of

the robot arm manipulator. Indra Agustian et al. [14] propose the forward kinematics DH and the inverse kinematics Pseudoinverse Jacobian method to determine the right angle of each joint of the manipulator links. Adnan Rafi Al Tahtawi et al. [15] use inverse kinematics to design a small-scale three-degree of freedom (3-DoF) robot arm for a pick-and-place mission. Lately, the robot development time has been shortened, and the speed and quality of the robot design have been improved by designing robots based on SolidWorks 3D CAD [16]. Doo Sung Ahn et al. [17] present a platform that integrates Solidworks and Simscape tools for designing control algorithms of robot manipulators. Simscape Multibody imports 3D models and creates bodies, constraints, actions, and joints with parametrization by mathematical expressions described in MATLAB using data from SolidWorks.

Over and above, some researchers are directed toward integrating the robot arm with object detection techniques for waste segregation. Xuebin Yue et al. [18] propose a lightweight object detection model YOLO-GD (Ghost Net and Depthwise convolution) for empty-dish recycling robots to recycle dishes in restaurants and canteens automatically. The catch point coordinates of the various types of dishes are extracted using a catch point computation based on image processing. The target dishes are recycled using the coordinates by manipulating the robot arm. Qisong Song et al. [19] propose an improved YOLOv5 to achieve more precise positioning and recognition of objects for grasping robots using the wooden block image dataset. Jinqiang Bai et al. [20] present a moving pick-up robot that automatically moves on grass for garbage cleaning. The robot is designed based on a navigation algorithm that uses SegNet and ResNet to segment, classify, and localize objects. If the trash is detected, the manipulator picks it up and places it in the trash container. Jaeseok Kim et al. [21] integrate deep learning with the industrial robotic arm to classify garbage according to its material. First, the points cloud is processed utilizing the Kinect. Following this step, grasping tools on the robot arm are used to grab the objects. The items are then seated in front of an RGB camera, which categorizes them, based on their composition, using a modified LeNet model into two main classes: carton and plastic. Eventually, all the collected items are put in a box beside the manipulator.

Although all of the approaches mentioned above have made some progress in waste segregation, there is still the issue of satisfying high detection accuracy and real-time segregation simultaneously in practical applications. Thus, this research proposes a real-time waste segregation system for sorting garbage. The system is designed to integrate two modules: the waste segregation module and the robotic module. The waste segregation module exploits the advantages of the hardware-friendly architecture of YOLOv6 [22] for detecting and localizing the garbage with high detection accuracy and in real-time. In the robotic module, a robot arm is designed, and its design overcomes the inverse kinematics problem by accurately computing the angles of the arm's joints based on a simple geometric method. The advantage of this geometric method is to solve the inverse kinematics problem using a unique solution for each required joint configuration, which reduces the computational time and accelerates the response.

The robot arm architecture is created in CAD software (SolidWorks). The main contributions of this work can be summarized as follows:

- 1) Design a waste segregation system for categorizing garbage with high precision and in real time.
- 2) Build a garbage dataset consisting of 3217 images divided into seven classes: cardboard, glass, metal, paper, plastic, battery, and foam. These classes are usually found in trash bins.
- 3) Apply YOLOv6, which is characterized by its hardware-friendly design, low inference time and high detection accuracy for detecting and localizing garbage.
- 4) Design a 3D model of a 4 DOF robotic arm using CAD software and adopts a simple geometric method to calculate the angles of the arm's joints for picking up and locating the objects in their dedicated basket with smooth motion trajectories in a slight time.
- 5) Develop an automatic waste segregation robot system based on the designed robot arm and the proposed segregation system.

## II. PROPOSED SYSTEM ARCHITECTURE

In this research, a waste segregation system is proposed to make the waste much easier to recycle, meaning less garbage goes to landfills and positively impacts health and the environment. The architecture of the proposed system consists of two modules: the waste segregation module and the robotic module. The waste segregation module comprises the YOLOv6 model for detecting the waste, while the robotic module picks up the objects according to their type and places them in their dedicated basket. The proposed system architecture is shown in Fig. 1. Moreover, the details of each module are described in the following subsections.

### A. The Waste Segregation Module

This module is responsible for detecting various objects in the captured image and building a queue of information about each object identifying its current location and type. To perform this task, YOLOv6 is utilized. YOLOv6 is created for industrial applications with high-performance and hardware-friendly architecture. It makes different improvements to the network architecture and the training plans of the conventional YOLOv5 [23]. Conventional YOLOv5 consists of three main parts: backbone, neck, and head. The backbone primarily affects how well features can be represented, but because it performs most of the computational cost, its structure significantly impacts inferences performance. The neck is responsible for combining the low-level and high-level semantic features to construct a pyramid feature map. Then, these combined features are fed to the head, which consists of several convolutional layers, to predict the objects. YOLOv6 replaces the backbone and the neck networks in the conventional YOLOv5, which is designed based on CSPNet [24], with more efficient networks: EfficientRep as Backbone and Rep-PAN as Neck that is designed using RepVGG style [25]. The new network structure overcomes the drawbacks of increasing latency and decreasing the utilization of the memory bandwidth of the GPU. Second, YOLOv6 reduces the delay in the conventional YOLOv5 while preserving accuracy by designing an efficient and simplified decoupled head. Third, YOLOv6 attempt to improve the detection accuracy by improving the training strategies by using anchor free paradigm, SimOTA [26], as a label assignment method, and Siou [27] and GIoU [28] as a bounding box regression loss function. In the next subsections, the networks architecture, and the training strategies of YOLOv6 will be explained in detail.

Fig. 1. The proposed waste segregation system architecture.

1) *Backbone*: The effectiveness and efficiency of the detection model are significantly influenced by the backbone network's design. EfficientRep is designed as a backbone in YOLOv6 to efficiently exploit the computational power of the hardware architecture to reduce the inference latency. The EfficientRep is designed based on the RepVGG structure to utilize the pros of multi-branch topology within the training process for achieving improved classification efficiency. However, this structure avoids the inference latency of the multi-branch topology by using the re-parameterization structure in the inference process to fuse the multi-branch into a single convolutional layer by converting its parameters within the deployment process.

2) *Neck*: The Rep-PAN neck design is built upon the idea of a hardware-aware neural network by fusing the features at multiple scales. The PAN topology [29] used in YOLOv4 [30] and YOLOv5 is modified to be the base of the Rep-PAN. RepBlock [25] or CSPStackRep block is also used in place of the CSP-Block utilized in YOLOv5.

3) *Head*: In YOLOv5 models, the classification and box regression heads share the same features. In YOLOx [26], the head is decoupled, which means that the network separates between the features of the classification and box regression heads and adds two additional 3x3 convolutional layers for each one. Although this has been empirically demonstrated to increase performance, it also causes a slight increase in network latency. Based on the Hybrid Channels approach, the decoupling head design of YOLOv6 has been streamlined, and a more effective decoupling head structure has been developed by eliminating the number of middle 3x3 convolutional layers to one. These changes result in lower processing costs and decreased inference delay.

#### 4) *Training strategies*:

- Anchor-free

YOLOv6 reduces the delay results from transferring massive detections between the hardware stages by replacing Anchor-based detector with anchor-free detectors [26]. The anchor-free paradigm has recently gained significant popularity because of its superior generalization capabilities and simplicity. YOLOv6 adopts one of the anchor-free detectors called the anchor point-based paradigm, which predicts the distances from the bounding boxes' four sides to the anchor point.

- SimOTA label assignment strategy

One of the factors affecting the detection accuracy is the label assignment process. In this process, each predetermined anchor is assigned a label during the training phase. Previous YOLO versions used the static assignment method, which cannot be modified during network training. Recently, numerous techniques based on dynamic label assignment have emerged, allocating positive samples in accordance with the network output through the training procedure to enable the generation of more high-quality positive samples, which in turn improves the network optimization. YOLOv6 used one of the dynamic assignment methods which is SimOTA. This method

finds the best match between the samples using the Top-K approximation technique, which significantly accelerates training speed.

- SIOU bounding box regression loss.

IoU, GIoU, and SIOU are proposed in recent researches as bounding box regression losses to adapt the network learning and improve the detection accuracy. These loss functions are calculated according to these aspects: the percentage of the overlap between the predicted and the target boxes, the aspect ratio, the distance between the center points, and the matching between the predicted and the target box directions. GIoU and SIOU loss functions are selected experimentally to apply to different versions of YOLOv6.

#### B. *The Robotic Arm Module*

Robots are used to handle complex, dangerous, and tedious tasks. The use of robotic arms also helps to relieve human workers of tasks that pose a risk of bodily harm [31]. Thus, pick-and-place robots are commonly used in modern industrial environments [32]. The pick-and-place process automation reduces cycle time, increases productivity, and decreases material handling costs [33]. Pick and place robots come in a variety of shapes and sizes. A two-degree-of-freedom robotic arm picks up and moves objects in a single plane. The Cartesian robotic arm works in multiple planes and moves along three orthogonal axes using Cartesian coordinates (X, Y, and Z). The Delta robot is frequently used in applications where robots pick items in groups and place them in assembly patterns or containers; they have heavy motors attached. Collaborative robots help humans by directing them to appropriate locations and guiding them through each task. In this research, a Cartesian robot arm is designed to sort the waste according to the locations and types obtained from the segregation module. The robot arm design and its motion planning and execution are described in the following subsections.

1) *Solid 3D CAD Modeling of a robotic arm and its workspace*: An autonomous robot platform based on SolidWorks, MATLAB Simulink, and Simscape Multibody software tools is utilized in this research to design the arm's structure and its workspace. The robot manipulator was initially created as a 3D CAD model using the SolidWorks tool to design and build the robot completely. It creates fast and accurate 3D models, which turn ideas into reality with the ability to run the concept design through many scenarios and make modifications as necessary in the design development process [34]. As shown in Fig. 2(a), the manipulator structure has four links and four revolute joints. Joint1 is used as a base joint, while joint2 connects link1 to link2. Joint3 connects link2 to link3, and joint4 is used for the robot end effector (robot hand). Fig. 2(b) depicts the simulated workspace which consists of various types of waste objects, an RGB camera placed in front of the robot arm's starting location, ultrasonic sensor, and a group of baskets for collecting categorized items. In order to control the motion of the arm, the robot assembly is imported into a Simscape Multibody model to simulate the multi-object systems by utilizing blocks that

describe system parts, joints, forces, and external restrictions [34]. The bodies are distinguished by their geometry. Accordingly, inertial properties, forces and moments can be applied to bodies. Besides, contact constraints can be defined. Moreover, the object's CAD model can be imported with all its physical properties and the dynamics of the system can be observed. Simscape Multibody software's primary use is to analyze and visualize system functioning and control design in Simulink [35], [36]. Fig. 2(c) shows the block diagram of the robotic arm in Simscape Multibody to be utilized for simulation trials in evaluating the proposed algorithm.

2) *Robotic arm task scheduling*: This research proposes a planning process to address the issue of computing the robot arm's movements during the object picking and placing assignment. Fig. 3 illustrates the complete cycle of the robotic arm pick and place task. Depending on the type of object material, the robot's destination is specified and modified dynamically. The motion plan is constructed based on several factors depending on the relation between the end-effector, the target destination, and the object's current location. The motion phases are summarized as follows:

- Object reaching: the manipulator moves to place the end-effector at the first object of the received queue.

Once the end-effector has arrived at the (x, y) position of the object on the horizontal plane, the ultrasonic sensor is activated to determine the height that the end-effector needs to descend to reach the object.

- Picking up the object: the end-effector gets in touch with the object using a suction force to pick it up. The manipulator must continue to provide a suction force to hold the object until it reaches the proper basket.
- Lifting: the object is lifted vertically away from the table after the end-effector sucks it, enabling it to move as they are rigidly connected.
- Basket reaching: Depending on the object type, the manipulator moves to the appropriate basket location while holding the object.
- Placing the object: the suction force is switched off to release the object into the basket once the manipulator reaches it.
- Arm reset: the robot returns to the beginning state (home position) for starting another task when the object queue becomes empty.

(a)

(b)

(c)

Fig. 2. Robot arm manipulator (a) arm structure (b) robotic workspace (c) Simscape Multibody block diagram of robotic arm.

Fig. 3. Complete cycle of pick and place task.

3) *Robot motion planning*: Fig. 4 illustrates how the robotic arm motion is controlled from its starting point to various goals. First, the object is picked by a suction gripper with force chosen based on the heaviest expected waste object. The time for switching on/off this force is calculated from the generated trajectory. After that, trajectory planning is carried out to find a suitable route for the robot movement in an area free of obstacles. A robotic motion task is defined by determining a path for the robot to follow. A path is a set of points that can be defined in task coordinates (end-effector coordinates) or joint coordinates. The problem of trajectory generation is to compute the desired reference joint or end-effector variables as functions of time for the control system so that the robot follows the desired path [37]. In this study, a cubic polynomial trajectory that is constructed based on chosen waypoints and their associated time points is used to calculate the appropriate route between the source and destination. Waypoints are chosen so that the arm can move smoothly while considering the joint angle limitations. Inverse kinematics is proposed to calculate the appropriate joint configuration (joint rotation angles) for moving the robotic arm from its starting position to various destination points.

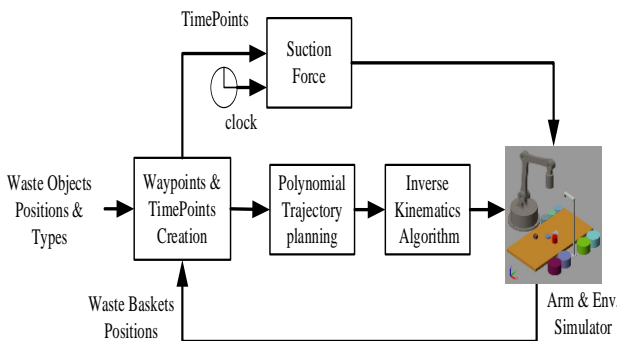

Fig. 4. Motion planning and movement execution process.

• Proposed Geometric Inverse Kinematics

The study of motion without considering its causes, such as forces and torques, is known as kinematics. Using kinematic equations, inverse kinematics (IK) can predict how a robot will move to arrive at a specific place [38]. Fig. 5 declares the concept of forward and inverse kinematics approach. Inverse kinematics is a transformation method from Cartesian space to joint space. Nevertheless, it is a somewhat complex nonlinear

problem. In addition to its nonlinearity, the kinematics matrix's sine and cosine functions also have non-unique solutions, which makes the issue worse [39]. This study proposes a geometric analytical solution idea to compute the inverse kinematics of 3D space. The system will then follow the intended route determined by the trajectory of the end effector. The geometric solution is much more efficient during calculation (when compared to iterative methods).

Fig. 5. Inverse kinematics vs forward kinematics.

The proposed method for determining the joints configuration (joints rotation angles) in 3D space for the designed four-link robot arm relied on a novel geometric notion. Since the numerical solution of inverse kinematics yields, a less accurate result, the analytical solution of inverse kinematics is preferred. The target point is indicated by the Cartesian coordinates P (x, y, and z) in the generalized case of the robot arm. The position of the target point can be converted to cylindrical coordinates (Θ, ρ, and z). If the base joint is turned at an angle Θ, as indicated in Fig. 6, the robot arm construction coincides in the x-z plane. The second joint position at point "a" is connected to the end-effector joint pose at point "p" by the line "c". Line "k" is thus drawn parallel to line "c" from the location of the base joint. The angles of the joints are obtained by applying the cosine formula as shown in equations (1–5). The polar coordinates of the target point projection in the x-y plane are determined by Equation (1).

$$\rho = \sqrt{x^2 + y^2}, \quad \theta = \tan^{-1}(y/x) \quad (1)$$

The length of the line "c" is calculated as:

$$c = \sqrt{(z - l_1)^2 + \rho^2} \quad (2)$$

Equation (3) calculates the angle between line "k" and the x-axis.

$$\delta = \tan^{-1}((z - l_1)/\rho) \quad (3)$$

The following equations explain the angles α and β in the triangle (a-p-d).

$$\alpha = \cos^{-1}\left(\frac{l_2^2 + l_3^2 - c^2}{2l_2l_3}\right) \quad (4)$$

$$\beta = \cos^{-1}\left(\frac{l_2^2 + c^2 - l_3^2}{2l_2c}\right) \quad (5)$$

In order to move the arm's end-effector to a target point, the joints rotate at the angles calculated in equations (6-9) considering that the rotation angle of each joint frame is measured w.r.t. the previous link frame and counterclockwise.

$$q_1 = \theta \tag{6}$$

$$q_2 = 270 + \beta + \delta \tag{7}$$

$$q_3 = 180 + \alpha \tag{8}$$

To keep the end-effector pointed vertically

$$q_4 = 90 - (\alpha + \beta + \delta) \tag{9}$$

where,  $q_1, q_2, q_3,$  and  $q_4$  are the angles values needed to rotate each joint to change the configuration of the joints such that the end effector reaches the desired position.

Fig. 6. The schematic diagram of the proposed geometric inverse kinematics approach.

### III. EXPERIMENTS AND RESULTS

This section presents the conducted experiments and shows the results of the proposed methodology for waste segregation and robotic modules. In the following subsections, each module's outcomes are described in detail.

#### A. Waste Segregation Module

In this module, YOLOv6 is evaluated numerically and compared to recent YOLO models: YOLOv7 [40] and YOLOR [41]. The dataset, performance metrics, and training parameters are also comprehensively explained.

1) *Dataset*: The proposed waste segregation performance model is assessed by conducting different experiments on a

modified version of the TrashNet dataset. The TrashNet dataset [42] consists of 2527 images of waste divided into six classes: 501 glasses, 594 paper, 403 cardboard, 482 plastic, 410 metal, and 137 other trashes. The trash class is omitted in the modified version of the dataset, and two new classes are added, foam and battery. The authors also attempt to balance the number of the other classes' images by adding new ones. The new images are downloaded using Google Images Download software [43]. Then, some augmentation techniques are applied, namely: flipping, rotation, and resizing. Afterwards, the images are annotated using Ybat software [44], then the duplicated ones are deleted. At the end of the preprocessing and the annotation process, the dataset becomes 3217 images divided into seven classes: cardboard, glass, metal, paper, plastic, battery, and foam. The description of the modified TrashNet is presented in Table I, and samples from each class are shown in Fig. 7.

2) *Performance metrics*: To evaluate the performance of pre-trained YOLO models, three evaluation metrics namely, precision (AP), recall (AR), and the F1 score (F1) are applied on the model's detection output. Mathematically, precision, recall and F1 can be calculated as:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{10}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{11}$$

$$F1 = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \tag{12}$$

where, TP is the number of true positives, FP is the number of false positives, and FN is the number of false negatives. Therefore, precision measures the ratio of the correctly detected objects to the total number of detected objects. Recall measures the percentage of true predictions among the total number of class objects, and F1 evaluates the model's performance based on the harmonic mean of the precision and recall.

TABLE I. IMAGE CLASSES DISTRIBUTION AND DESCRIPTION IN THE DATASET

Class (type)	Description	Quantity
Glass	bottle, jar, cups	500
Paper	plates, posters, envelopes, receipts	591
Cardboard	packing box, mailing box, cardboard sheet	457
Plastic	bottles, boxes, jars, medicine packs, food packs	479
Metal	soft drink cans, food cans, foil sheets, plates	468
Foam	packing box, food box, plates, cups	382
Battery	AA, AAA, C, D, 9 volts	326

Fig. 7. Sample images from the modified TrashNet dataset with their corresponding class.

3) *Training* : The modified TrashNet dataset is split into 70% train, 30% for validation and test. Thus, according to these percentages, the number of images is 2239 in the training set, 541 in the validation set, and 423 in the test set. Training the model from scratch with randomly initialized

parameters results in under-fitting due to the small number of images in the dataset. Therefore, the pre-trained YOLOv6 model, which is trained on the COCO dataset, is fine-tuned on the modified TrashNet dataset to exploit the advantages of transfer learning. Stochastic gradient descent (SGD) is used

during the fine-tuning process to optimize the network parameters. The number of epochs, the initial learning rate, the batch size, the weight decay, and the momentum are set as 300, 0.0032, 16, 0.00036, and 0.843, respectively. The confidence score is selected empirically, and a confidence score of 0.6 gives the best model performance. All the experiments are conducted on an Intel(R) Core (TM) i7-11800H.

4) *Simulation results:* The performance of the YOLOv6 model is compared with the recent YOLO models, which are YOLOv7 and YOLOR, in terms of the F1, precision, recall, inference time, and model size. YOLOv7 and YOLOR are trained on the COCO dataset and fine-tuned on the modified TrashNet. In the proposed research, two model architectures of YOLOv6 are used, in which the architectures vary considering the model size for a better accuracy-speed trade-off. The model size of YOLOv6n is smaller than YOLOv6s. The training process of the four models is performed several times according to different data shuffles, and the results are presented in Table II. It can be seen from the table that the highest precision value is for YOLOv7 in the third run, whereas the best recall and F1 values are for YOLOv6s in the first run. However, the recall and F1 values for YOLOv7 in the third run are less than that of YOLOv6s in the first run, while the precision value of YOLOv6s is slightly less than that of YOLOv7. Thus, YOLOv6s from the first run is adopted in this work. Besides, Table III compares the YOLOv6s versus the other models regarding precision, recall, F1, inference time, and model size. The presented values of precision, recall, and F1 are the average values of the three runs. It can be noticed from Table III that the YOLOv6s model has better performance with reference to the average values of precision, recall, and F1.

Furthermore, it can be observed that YOLOv6n is the smallest model size, and YOLOR is the largest model size and inference time. Thus, YOLOv6 has better performance and meets the real-time requirements. Using YOLOv6s or YOLOv6n depends on the application's requirements; if the application needs high accuracy, YOLOv6s is the best choice. However, if the application needs a small-size model with acceptable accuracy, YOLOv6n is recommended. Fig. 8 presents the predictions of YOLOv6 on real images captured by the authors using the RGB camera of the Samsung Galaxy S20 with 12 MP for testing the model's performance. It can be seen from the figure that the model predicts all the objects with high confidence scores.

On the other hand, the incorrect classifications on the test set are also statistically investigated to find the reasons behind the model misclassifications for some objects. Table IV analyses the classification output based on the confusion matrix. It can be observed from Table IV that there is a slight confusion between cardboard and paper, and also, there is confusion between plastic, glass and paper. This confusion is because, in some cases, the plastic and glass bottles or cups are very similar in shape; similarly, the supermarket flyers in paper category and the box packaging in the cardboard type. It can be observed from Table V that plastic has the lowest recall value, 90% because plastic is misclassified as the other categories multiple times. It can be noticed from the confusion matrix that foam and battery are not misclassified; however, their precision and recall values are not 100%. Some foam and battery objects are undetected, or the background is classified as foam or battery. Moreover, the glass and paper categories have the lowest precision, meaning several objects are misclassified as glass and paper. Furthermore, experimental results find that the number of undetected and misclassified objects is 39 objects for YOLOv7 and 32 objects for YOLOR from 508 objects in the test set compared to 19 objects for YOLOv6. Fig. 9 visualizes some illustrations of the classification results for YOLOv6, YOLOv7, and YOLOR. As can be noticed, YOLOv6 outperforms YOLOv7, and YOLOR in most of the cases.

TABLE II. THE EFFECT OF THE DATASET SHUFFLING ON THE MODEL'S PERFORMANCE

	Models	Precision	Recall	F1-score
1 <sup>st</sup> train	YOLOR	94.82	93.7	94.26
	YOLOv6n	95.19	93.5	94.34
	YOLOv6s	<b>96.07</b>	<b>96.26</b>	<b>96.17</b>
	YOLOv7	94.75	92.32	93.52
2 <sup>nd</sup> train	YOLOR	95.31	95.11	95.21
	YOLOv6n	95.05	93.9	94.47
	YOLOv6s	95.48	94.7	95.01
	YOLOv7	95.87	94.5	95.18
3 <sup>rd</sup> train	YOLOR	95.65	94.48	95.06
	YOLOv6n	95.63	94.07	94.85
	YOLOv6s	95.67	94.68	95.17
	YOLOv7	96.47	94.89	95.67

TABLE III. THE AVERAGE PERFORMANCE COMPARISON OF THE YOLOV6 VERSUS YOLOV7 AND YOLOR

Models	F1-score	Precision	Recall	Inference time	weight size
YOLOR	94.84	95.26	94.43	24 sec	289 M
YOLOv6n	94.55	95.29	93.82	14 sec	<b>9 M</b>
YOLOv6s	<b>95.45</b>	<b>95.74</b>	<b>95.2</b>	13 sec	37 M
YOLOv7	94.79	95.7	93.9	<b>11 sec</b>	73 M

TABLE IV. CONFUSION MATRIX FOR EVALUATING THE CLASSIFICATION ACCURACY OF EACH MATERIAL TYPE

		Predicted						
		Glass	Paper	Cardboard	Plastic	Metal	Foam	Battery
Actual	Glass	64	0	0	1	0	0	0
	Paper	0	78	0	0	0	0	0
	Cardboard	0	3	58	0	0	0	0
	Plastic	3	3	0	57	0	0	0
	Metal	2	0	0	1	71	0	0
	Foam	0	0	0	0	0	60	0
	Battery	0	0	0	0	0	0	101

TABLE V. THE PERFORMANCE OF YOLOV6 FOR EACH CATEGORY IN THE DATASET IN TERMS OF PRECISION, RECALL AND F1

Class Type	Precision	Recall	F1
Glass	93	98	95
Paper	92	100	96
Cardboard	100	95	97
Plastic	95	90	92

### B. Robotic Arm Simulation Results

In the robot module, the location and material types of the waste objects that were detected in the waste segregation module are sent to the robotic arm for motion planning and execution. The proposed algorithm finds a solution for all four phases and moves the robot arm within its structure limits (joints and links limits) to the target position. The robot begins at its default position and the camera captures an image of the workspace. The image is sent to the computer for processing and detecting the objects to define their locations and material types. Then this data is formed in a queue and sent to the robot. The proposed algorithm utilizes these objects information to compute the appropriate joint configurations, allowing the arm simulator to perform all required tasks. Fig. 10 shows the motion sequence to place the objects in the right destination. Fig. 10(a) depicts the robot in its initial state while it is waiting to receive data from the object detection module. The necessary joints configuration is computed using the previously mentioned equations in Section II, then the robot successfully navigates to the chosen item (in this case, the red cylinder), and then the controller triggers the suction force to pick up the object, as illustrated in Fig. 10(b). The robot lifts the object and defines the position of the dedicated basket based on its type. The basket position is considered the new target point for the robot arm; thus, the trajectory and the correct joint angles are computed using inverse kinematics. When the arm reaches above the basket, the controller turns off the suction force to drop the object in the basket. Afterward, the next object is selected (in this case, the yellow disc), the arm considers its position to be the new target, computes the required joints rotation angles once more, and executes the pick and place task. The process is repeated until all objects are placed in their proper baskets; thus, the robot returns to its initial state. Fig. 11 shows the timeline of the process and the execution times for each task, such as the time the robot takes to go to the object's location, lift it, and finally drop it in the designated basket. It can be noticed from the figure that the processing time of delivering one object is 0.8 sec. Further, the trajectories of motion in joint space for the previous process sequences are illustrated in Fig. 12, pointing out that all trajectories are smooth, and there hasn't been any rapid damage or significant change made to the arm's rotation joints. The complete modeling and simulation of a robotic arm pick and place system with MATLAB Simscape Multibody and Solidworks is shown in Fig. 13.

#### IV. CONCLUSION

This paper presents an automated waste segregation technique relying on blending an object detection system and robotic arm design. YOLOv6 is applied to detect and classify waste items. Over and above, CAD software is employed to design the robot arm that strives towards utilizing a simple geometric approach to compute the angles of the arm's joints accurately. To signify the efficacy of the proposed system, a TrashNet dataset has been modified and exploited for assessment. The suggested system proved high effectiveness in detecting and segregating waste items into distinct categories. Moreover, the system revealed high efficiency in picking the

waste items, controlling the robot arm movement to the appropriate basket location, and placing the object in the proper basket. Furthermore, the adopted object detection approach is compared to the recent YOLO models: YOLOv7 and YOLOR. The obtained results illustrate that the submitted technique surpasses these techniques regarding F1, precision, recall, inference time, and model size. Over and above, the designed robot arm has been proven to consume a fraction of a second for picking up and placing a single object in its appropriate basket. In future work, new items will be added to the modified dataset, and the proposed simulation robot arm will be practically implemented.

## V. FUNDING

This research was supported by Korea Institute of Marine Science & Technology Promotion (KIMST) funded by the Ministry of Oceans and Fisheries, Korea(G22202202102301), and by Korea Agency for Infrastructure Technology Advancement (KAIA), project title is the development of smart city governance structure and framework (project number is 22DEAP-B158922-0312982076870003).

**Abstract**—Regression testing is an important task in software development, but it is often associated with high costs and increased project expenses. To address this challenge, prioritizing test cases during test execution is essential as it aims to swiftly identify the hidden faults in the software. In the literature, several techniques for test case prioritization (TCP) have been proposed and evaluated. However, existing weight-based TCP techniques often overlook the true diversity coverage of test cases, resulting in the use of average-based weighting practices and a lack of systematic calculation for test case weights. Our research revolves around prioritizing test cases by considering multiple code coverage criteria. The study presents a novel diversity technique that calculates a diversity coverage score for each test case. This score serves as a weight to effectively rank the test cases. To evaluate the proposed technique, an experiment was conducted using five open-source programs and measured its performance in terms of the average percentage of fault detection (APFD). A comparison was made against an existing technique. The results revealed that the proposed technique significantly improved the fault detection rate compared to the existing approach. It is worth noting that this study is the first of its kind to incorporate the true diversity score of test cases into the TCP process. The findings of our research make valuable contributions to the field of regression testing by enhancing the effectiveness of the testing process through the utilization of diversity-based weighting techniques.

## I. INTRODUCTION

Despite the importance of regression testing, it has been described as an expensive operation, and various approaches have been developed to overcome this challenge. One of these effective approaches is test case prioritization (TCP), which aims to prioritize the execution of the most critical test cases to detect hidden faults more rapidly during the test execution process. TCP employs several techniques such as algorithms and metrics to reorder test cases. The primary objective of these techniques is to determine the optimal ordering combination of the test suite based on specific criteria.

The most crucial aspect of TCP is the detection of faults, which can only be known after executing the test cases. Therefore, it becomes necessary to estimate or predict the test cases that can achieve this goal before the test execution process begins. During the estimation phase, TCP techniques

rely on various code coverage measures as surrogate indicators. These measures directly examine the code and describe how multiple test cases cover the code under test [1]. These coverage measures include line, branch, method, and so on [2], also referred to as criteria. Moreover, relying solely on a single criterion may not be sufficient and can be misleading, as it only represents a portion of the code structure. Thus, considering multiple criteria has been recognized as effective and can potentially identify the test cases that will ultimately enhance the fault detection rate [3]-[6].

Researchers have proposed several weight-based techniques to address TCP problems by incorporating code coverage information [2], [7]-[10]. These techniques integrate different code coverage criteria such as line, branch, method, and more. The objective is to assign weights to each criterion and calculate the final priority value for each test case. However, some of these techniques derive weights based on averages [3], [5], [11], while others assign fixed weight scores to the considered criteria based on specific factors [12], [13]. Such informal practices of weight assignment to test cases and criteria can be deemed unfair [14], as test cases cover distinct code structures and are executed with diverse test contents and different input values [4]. However, test cases with these characteristics can unveil hidden faults within the covered structures. Nonetheless, previous weight-based techniques may not effectively maximize the fault detection rate due to ineffective weightage. This inefficiency primarily stems from the informal characterization of code coverage information, leading to ambiguous and unjust weight scores for the test cases. Consequently, these practices ultimately result in the selection of ineffective test cases that fail to expedite fault detection during the testing process [14]. As the nature of faults is diverse, identification of all fault locations within a program poses challenges due to the distribution of faults [15]. Therefore, the source code information (e.g., code-coverage data) are the best available resource to use as surrogate measure in order to identify the best capable test cases that can execute the fault code and eventually reveal such faults [16]. Hence, the future strategies will depend on the level of understanding and representation, as well as the reformulation of the current code coverage data. These factors will determine the extent to which fault detection can be maximized.

Within the specialized literature, there has been a suggestion regarding the need to develop a new TCP strategy that enhances the fault detection rates of test cases [17], [18].

This motivation has prompted our current study, which aims to explore new research directions by specifically examining the role of diversity within test case coverage data to improve the fault detection rate. While some previous techniques drew inspiration from concepts in Biology or related domains, certain biodiversity concepts, such as species diversity and its associated metrics, have remained unexplored in TCP research. Thus, the concepts of species diversity have served as the inspiration for this study and applying these concepts during the weighting practices is crucial.

In this study, assumption made is that whenever a test case covers a diverse code structure and that program structure is executed correctly, any faults in that area can be revealed. Our goal is to transform the previous test case problem into a species diversity problem and adopt species diversity metrics [30] to measure the true diversities of the test cases based on their coverage counts. Each line of code is treated as unique, and it is assumed that every test case is susceptible to faults. Therefore, the prioritization of test cases is based on their diversity scores, with higher scores indicating coverage of diverse code structures. It is believed that a test case that maintains diverse coverage is better in terms of fault detection compared to a test case that covers few code structures or receives a lower diversity score.

The contributions of this work can be summarized as follows:

- This study represents a pioneering approach as it is the first of its kind to utilize species diversity concepts to weigh test cases based on their true diversities in terms of code coverage counts.
- Through rigorous comparative experimental studies, this study provides empirical validation of the proposed metric's effectiveness in terms of the average percentage of fault detection rate (APFD).

The paper is structured as follows: Section II provides an overview of related works in the field. Section III introduces the proposed technique, while Section IV presents a motivational example. The study experiment is presented in Section V, followed by the presentation of results and analysis in Section VI. Finally, Section VII summarizes the study and suggests potential future research directions.

## II. RELATED WORK

TCP is a vibrant area of research, with numerous algorithms and metrics being proposed and evaluated [2], [19], [20]. This section provides an overview of existing studies on weight-based techniques and their research directions.

Earlier studies delved into TCP techniques, aiming to address cost constraints and improve fault detection in regression testing [7], [8]. These studies introduced a general-purpose TCP technique that incorporated statement and branch coverage information. The primary focus was on two classical greedy algorithms: a total greedy algorithm and an additional greedy algorithm.

The literature also explored combinations of various TCP techniques [4], [21]. These studies integrated strategies from

the total and additional greedy algorithms and incorporated probabilistic techniques by assigning probability scores to the relevant criteria. These probability values were adjusted based on the specific technique employed.

Criticism has been directed at existing practices that revolve around code isolation units or single-criteria techniques [22]. Such isolations may lead to a loss of valuable coverage information crucial for identifying program faults. Other studies ranked test cases based on estimated coverage information derived from static code structures [23], while some employed multi-criteria decision-making (MCDM) techniques for test case ranking [14].

TCP techniques have also been applied to Object-Oriented Programs (OOP). For instance, in [24], nine coverage criteria were considered, and fixed weights were assigned to each criterion to rank the test cases. In [12], a coupling measure was employed to rank test cases based on a constructed dependency graph. Another study [13] incorporated dependence-based analysis, selecting test cases based on their dependency scores.

Iyad and Khalid [11] introduced the average weight-based technique for TCP, utilizing line of code (LOC) and method coverage as criteria. Test cases with higher scores were assigned higher priority rankings. They evaluated their technique using a small experimental program.

Initial research on multi-criteria weight-based TCP techniques proposed a method incorporating ten factors grouped into four categories: Requirement, time, defect, and complexity [25]. Each factor was assigned a weighted score, and the evaluation focused on factors such as defect severity, prioritization time, and acceptable test case size.

Another weighted technique was proposed by Ahmad et al. [26], where test case execution decisions were based on final weight scores derived from three criteria: pairwise event, frequency pairwise, and fault matrix. These weights were used to prioritize the execution of test cases.

A TCP technique considering multiple coverage criteria was proposed by Prakash and Rangaswamy [3]. The researchers criticized the use of single criteria and existing techniques for being time-consuming and costly. They introduced a multi-coverage Average Weight-based Technique (AWT) and empirically demonstrated its superiority in terms of modified APFD. Building upon this work, Ammar et al. [5] proposed an Enhanced AWT (EAWT) technique that assigned different weights to test cases with similar weight scores, assuming they covered the same code segment and revealed similar faults. However, it is worth noting that this assumption may not hold true in practice, as test cases can vary significantly and possess dissimilar input values.

Several TCP techniques have been presented to enhance fault detection rates, with multi-coverage weighting techniques exhibiting promising performance. However, there has been relatively less focus on TCP techniques for OOP, particularly in Java [27] to [29].

Moreover, single coverage criteria have shown lower effectiveness compared to lightweight metrics, particularly multi-coverage weight-based metrics [3], [22]. However,

existing techniques often treat criteria and test cases, similarly, disregarding their inherent differences in nature and lacking formal weight calculations. Additionally, diversity weighting practices have been largely overlooked in the TCP literature.

Other additional notable gap in the existing literature is that their consideration of prioritizing test cases based on greedy approaches, where only the test case with the highest coverage count is executed. However, this greedy approach fails to assess whether the test case covers multiple criteria or not, as it primarily focuses on maximizing coverage for a single criterion. When dealing with multiple criteria, this approach proves to be inadequate and might even lead to some test cases to receive similar weights. This study argues that test cases that cover multiple criteria in a diverse manner have a higher potential for detecting hidden faults. Since the faults are distributed over the different code structures and the exact locations of faults are unknown, considering diverse coverage becomes crucial in enhancing fault detection capabilities.

A recent survey on TCP and several other studies have emphasized the need for novel techniques, including diversity measures, to improve the current state of TCP techniques [17] [31]. This paper aims to address this need by investigating diversity weighting strategies in test cases, an aspect that has not been previously explored.

### III. PROPOSED DIVERSITY WEIGHTED BASED TECHNIQUE

In this section, the proposed technique that considers multiple coverage criteria is discussed including instruction coverage, branch coverage, line coverage, and method coverage. These criteria provide insights into the underlying structure of the source code being tested. Adequate testing of a program necessitates a sufficient number of diverse test cases that target different areas within the code structure. While various TCP techniques with different motivations have been explored in the existing literature to prioritize test cases, our study introduces a unique approach utilizing the species diversity metric, originally employed in ecology to measure species diversity [30]. Therefore, these measures were selected for the following reasons:

- These metrics address the identified gap and serve the purpose of calculating the true diversity score of test cases across multiple coverage criteria.
- In contrast to previous informal weight practices, the selected metric assigns formal and unique weights to the test cases, describing their diverse code coverage characteristics.
- By employing these measurements, each test case can be identified as a unique entity, and their unique diversity scores can be used as tie-breaking strategy and ranking priorities. This means that test cases with higher diversity are ranked higher than those with lower diversity.

On the other hand, the proposed approach encompasses two stages: (1) the adoption of four dynamic code coverages, which are treated as species-based problems, and (2) the introduction of a novel diversity weighting technique that computes the Final Priority Value (FPV) for each test case.

#### A. Adopt and Characterize Code Coverage as a Species based Approach

The code coverage criteria adopted in this study encompass instruction coverage, branch coverage, line coverage, and method coverage. This section provides a description of how the TCP problem was formulated, utilizing a species-based approach. This characterization aims to enhance the effectiveness of the test execution process.

Code coverage information consists of multiple test cases, each associated with their respective coverage counts for various code structures, also known as criteria. In this study these entities were treated as a species-based problem and introduce the following terms, definitions, and symbols to facilitate our discussion and analysis:

Definition 1: Test cases are analogous to species(s), and it is important to emphasize that each species is unique. Test cases are purposefully designed with different test inputs and the ability to target various parts of the system under test (SUT).

Definition 2: A test suite, consisting of a group of unique species, represents a community(s).  $S$  is defined as  $S = \{s_1, s_2, \dots, s_i\}$ , where  $i$  represents the  $i$ th species in  $S$ .  $s_1$  denotes the first species, while  $s_i$  denotes the last species in the set.

Definition 3: Code structures or criteria are considered as species habitat (HB): In this case, the criteria include branch coverage (br), instruction coverage (in), line coverage (li), and method coverage (me). HB is defined as  $HB = \{Hb_1, Hb_2, \dots, Hb_j\}$ , where  $j$  represents the  $j$ th habitat in HB (e.g., in, br, li, and me). A species can be found in any of these habitats, for example,  $s_1$  can be present in  $Hb_1, Hb_2, Hb_3$  or  $Hb_4$ , and their presence is recorded in terms of coverage counts.

Definition 4: The coverage counts are denoted as  $n$ , representing the number of  $i$ th species ( $s_i$ ) found in  $j$ th habitat ( $Hb_j$ ), which is also written as  $n_{ij}$ . It is important to note that the coverage counts,  $n$ , can range from 0 to any non-negative number. A count of 0 indicates that the habitat is not represented by that species, indicating a loss of species.

Definition 5: The total coverage count of each species across all habitats is denoted as  $N$ .

#### B. Diversity-Aware TCP Technique

In this paper, a species diversity metric that measures the diversity of each species in relation to its habitats was used. This metric allows us to identify species with higher diversity, indicating their effectiveness and prioritization during the test execution process.

The proposed Diversity-aware TCP technique integrates multiple code coverage metrics to calculate a unique diversity weight for each test case. This diversity weight is determined by the extent of diversity exhibited by the species covering multiple code structures, also known as criteria. Our assumption is that species with higher coverage diversity scores are more likely to uncover hidden faults.

To illustrate the methodology employed in the proposed Diversity-based TCP technique, the following steps are outlined:

a) Step one: Collecting Coverage Values. In this step, the test case coverage needs to be collected for various criteria using tools such as JaCoCo within the JUnit framework.

b) Step two: Calculating Diversity Score. In this step, the species diversity score is calculated using the Gini-Simpson's index, which is a well-known diversity measure. This metric takes into account the dominance of species and assigns higher weight to abundant species. The proposed Gini-Simpson index (1-D) is derived from the original Simpson's index (D) [30]. The formulas for calculating the Gini-Simpson index are as follows:

$$1 - D(s_i) = 1 - \left( \frac{\sum_{i=1}^j n_{ij}(n_{ij}-1)}{N_i(N_i-1)} \right) \quad (1)$$

where,

$1-D(s_i)$  denoted as the Gini-Simpson index (1-D) of the  $i$ th species;

$n_{i,j}$  represents the count of species from the  $i$ th species under the  $j$ th habitat;

$N_i$  represents the total count of coverage for the  $j$ th species across all habitats; and

$\Sigma$  denotes the sum of multiple terms.

c) Step three: Ranking the Species. In this step, the prioritization of species occurs after calculating the diversity scores using the specified metric. The species are ranked based on these scores in descending order, from highest to lowest.

#### IV. MOTIVATIONAL EXAMPLE

To illustrate the functionality of the proposed technique, a demonstration is provided in this section using the information presented in Table I. The table includes eight species (T1 to T8) and four habitats (*in*, *br*, *li*, and *me*). Based on this coverage information, the test cases were assigned weights according to their diversity. The demonstration involves the following phases:

1) Collect the coverage counts for each species in relation to the selected habitats.

2) Calculate the diversity score for each species based on their habitats. This step may include a subset step specific to the calculation process of the chosen metric.

3) Rank the test cases in descending order from highest to lowest value.

##### 1) Phase one: Collecting Coverage Counts

During this phase, the coverage counts of species need to be collected with respect to the selected habitats. Tools such as JaCoCo can be utilized to facilitate this process. The data provided below represents a subset of species obtained from the CruiseControl program, along with the habitats they cover, as shown in Table I. It is important to note that the program consists of 299 species, but for the purpose of demonstration, only eight species was selected from the program.

TABLE I. SPECIES COVERAGE COUNTS OF CRUISECONTROL PROGRAM

Species	IN	BR	LI	ME
T1	74	2	27	8
T2	97	8	32	7
T3	87	5	32	6
T4	31	1	12	4
T5	34	1	14	3
T6	41	2	17	5
T7	127	10	31	5
T8	111	2	40	9

##### 2) Phase two: Calculate the Diversity Score

To calculate the diversity associated with each species across the selected habitats, the diversity score is used as a weight for the species. The calculation process can be outlined as follows.

The following example provides guidelines on how to calculate the diversity score using the given data, specifically focusing on the Gini-Simpson index as described in equation (1). Please note that the calculation process for other metrics can be carried out using a similar approach. The following steps are involved in this process:

- Step 1: calculate total coverage count of  $i$ th species across all habitats, denoted as  $N_i$  where  $N_i = \sum n_{i,j}$ . In this case,  $NT8 = (111+2+40+9) = 162$ ,  $NT7 = (127+10+31+5) = 173$ , and the remaining values are listed in column two in Table II.
- Step 2: calculate  $N_i(N_i - 1)$  for each species e.g.,  $NT8(NT8 - 1)$ . In this case,  $T8 = 162*(162-1) = 26082$ ,  $T7 = 173*(173-1) = 29756$ , and the remaining values are listed in column three in Table II.
- Step 3: calculate  $n_{i,j}(n_{i,j} - 1)$  of  $i$ th species in  $j$ th habitat e.g.  $nT8me(nT8me - 1)$ . In this case,  $T8 = 9*(9-1) = 72$ ,  $T7 = 5*(5-1) = 20$ , and the remaining values are listed in columns four and five in Table II.
- Step 4: calculate  $\sum n_{i,j}(n_{i,j} - 1)$  of  $i$ th species in  $j$ th habitat. In this case, the results of this calculation are listed in column two in Table III.
- Step 5: calculate  $D$  where  $D = \sum n_{i,j}(n_{i,j} - 1) / (N_i(N_i - 1))$  (diversity weight of Simpson). In this case, the results of this calculation are listed in column three in Table III.
- Step 6: calculate 1-D (diversity weight of Gini-Simpson metric). This is the result needed to rank test cases. The results of this calculation are listed in column four in Table III.

TABLE II. STEPS 1-3: COVERAGE VALUES AND TEST CASES OF CRUISECONTROL PROGRAM

Species	Step 1	Step 2	Step 3: $n_{i,j}(n_{i,j}-1)$			
	$N_i$	$N_i(N_i-1)$	IN	BR	LI	ME
T1	111	12210	5402	2	702	56
T2	144	20592	9312	56	992	42
T3	130	16770	7482	20	992	30

	Step 1	Step 2	Step 3: $n_{ij}(n_{ij}-1)$			
Species	$N_i$	$N_i(N_i-1)$	IN	BR	LI	ME
T4	48	2256	930	0	132	12
T5	52	2652	1122	0	182	6
T6	65	4160	1640	2	272	20
T7	173	29756	16002	90	930	20
T8	162	26082	12210	2	1560	72

TABLE III. STEP 4-6: COVERAGE VALUES AND TEST CASES OF CRUISECONTROL PROGRAM

	Step 4	Step 5: D	Step 6
Species	$\sum n_{ij}(n_{ij}-1)$	$\sum n_{ij}(n_{ij}-1) / N_i(N_i-1)$	I-D
T1	6162	0.5047	0.4953
T2	10402	0.5051	0.4949
T3	8524	0.5083	0.4917
T4	1074	0.4761	0.5239
T5	1310	0.494	0.506
T6	1934	0.4649	0.5351
T7	17042	0.5727	0.4273
T8	13844	0.5308	0.4692

### 3) Phase three: Rank the Test Cases

In the second phase, the diversity score of each species is computed using the suggested metric mentioned earlier. This score serves as a priority value, allowing the ranking of species from highest to lowest based on this value. The resulting ranked species are as follows:

$$I-D(s_i) = T6, T4, T5, T1, \quad T2, T3, T8, T7.$$

## V. EXPERIMENTS

The objective of this experimentation is to evaluate the fault detection rate of the diversity weighted technique. In this section, an overview of the steps and tools used to assess the effectiveness of the proposed weighted technique in TCP is provided. A comparative analysis is conducted between the proposed weighted technique and an existing weighted technique, including [5].

### A. Experimental Goal

The main focus of this paper is to prioritize test cases that can effectively detect hidden faults in a program during the early stages of the execution process. The objective is to determine which technique, between the proposed diversity weighted technique and an existing weight-based technique, exhibits a higher fault detection rate. The research question being investigated is whether the proposed technique outperforms the existing technique in terms of fault detection rate.

### B. Study Objects

This study utilized five object-oriented programs, namely CruiseControl (A), DisjointSets (B), AccountSubType (C), Losenotify (D), and Odset (E). These programs were obtained from the Software Artifact Infrastructure Repository and have been previously utilized in other TCP studies [27], [13]. In this study, the entire programs were analyzed without dividing them into different versions.

The characteristics of the programs were measured, including lines of code (LOC), number of classes (NOC), number of species (NOS), and number of mutants (NOM). Unlike previous studies [13], certain characteristics, specifically the program sizes in terms of NOC and LOC, were calculated differently in this study. The measurements were obtained after generating all the program's test cases using an automated tool called o3smeasures, which is an Eclipse plugin. Table IV illustrates that the program sizes varied from 684 to 4989 LOC, while the number of species ranged from 15 to 299 NOS.

The implementation of the study object was done using the Java programming language, and the test cases (species) were written using the JUnit-5 framework. The JUnit species were generated using a tool called Randoop, which automatically generates unit tests for Java classes. The test coverage for these species was calculated using the JaCoCo agent, which is also an Eclipse plugin, taking into account all the desired coverage criteria. Furthermore, program faults were intentionally introduced using popular mutant generation tools called MuJava ( $\mu$ Java) [27], [13].

TABLE IV. STUDY OBJECT CHARACTERISTICS

ID	Objects	LOC	NOC	NOS	NOM
A	CruiseControl	4958	6	299	9
B	DisjointSets	1809	5	15	2
C	AccountSubType	684	8	53	27
D	Losenotify	1463	6	132	6
E	Odset	4989	4	167	5

### C. Performance Measures

To compare the effectiveness of different techniques, the Average Percentage of Faults Detected (APFD) is commonly used as a standard metric. This metric facilitates the comparison of fault detection rates achieved by different techniques, aiding in the determination of the most effective approach. The objective is to maximize the fault detection rate by executing the test cases. APFD is well-suited for this task as it provides test engineers with prompt feedback, enabling the early identification and resolution of faults.

Let  $T$  represent the test case community,  $m$  represent the total number of faults detected in a specific object,  $n$  represent the total number of test cases (species), and  $TF_i$  denote the position of the first test case that detects the  $i$ th fault. The APFD formula is as follows:

$$APFD = 1 - [(TF_1 + TF_2 + \dots + TF_m) / (m * n)] + 1 / (2 * n) \quad \square 2 \square$$

A higher APFD rate indicated better performance, and the results were reported as a percentage to quantify the differences.

## VI. RESULT

This section presents the experimental results for all five Java programs when applying the proposed technique using Equation 1. The results were carefully organized, summarized, and presented.

To prioritize species from multiple programs that cover different habitats, the proposed technique was compared to an existing TCP technique. Since these techniques rank the species differently, they can yield distinct results. The evaluation of these techniques was performed using the APFD metric (see Equation 2). Each program received an APFD score (in percentages) from both techniques.

The experiment's findings are summarized and illustrated using a bar chart (refer to Fig. 1) for visual representation of the data. The horizontal axis (x-axis) of the chart represents the five employed programs, identified by their respective ID labels. The vertical axis (y-axis) represents the APFD scores obtained by the different TCP techniques after applying them to the object programs. The APFD score, ranging from 0 to 100 percent, serves as a performance indicator, where higher scores indicate better results.

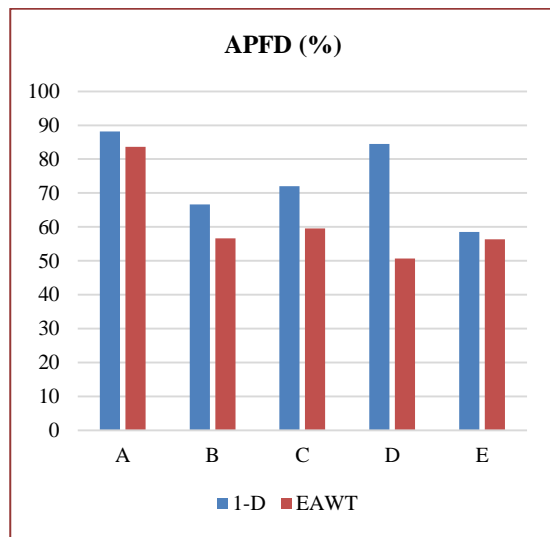

Fig. 1. APFD values of 1-D and EAWT.

Fig. 1 presents a comparison between the diversity-weighted technique utilizing the Gini-Simpson index and the EAWT technique. The data clearly indicates that the newly proposed technique exhibits strong performance across all the programs.

The EAWM technique exhibited the highest and lowest APFD scores among all the programs, achieving 83.67% for program A and 50.63% for program D, respectively. In contrast, the proposed technique consistently achieved the highest or second highest APFD scores across the programs. Specifically, it scored 88.13% and 84.47% for programs A and D, respectively, outperforming the EAWM technique. It is noteworthy that the EAWM technique demonstrated weaker performance in multiple programs, particularly programs D, E, and B, where APFD scores ranged from 50.63% to 56.67%. In comparison, the proposed technique consistently delivered higher APFD scores in those programs. The lowest APFD score obtained by the proposed technique was 58.50% for program E, which still surpassed the corresponding technique's score of 56.35% for the same program. These findings indicate the superior performance of the proposed technique across various programs, even in scenarios with lower APFD scores.

After comparing the APFD results for each object under different techniques, it was evident that the proposed technique based on the Gini-Simpson index (1-D) outperformed the existing weight-based technique (EAWT). The 1-D technique exhibited a substantial improvement in APFD scores, with a mean difference of 12.62% higher than the EAWT technique.

Although the objects varied in size and the techniques produced different rankings for the species, there were indications that prioritizing test cases based on their true diversity score had the potential to achieve higher APFD scores. While certain programs received lower APFD scores, this could be attributed to the nature and distribution of faults within those programs. Another possible reason for the poorer performance of the existing technique could be its feature of postponing certain fault-revealing species. In contrast, the proposed technique avoided species postponement, especially when they received similar final weight values. Conversely, the existing technique delayed some species assuming their similarity in fault identification, which could lead to slower detection of certain faults.

## VII. ANALYSIS AND DISCUSSIONS

The results obtained from the experiment conducted clearly stated that the proposed diversity-weighted technique was effective when compared with the existing weight-based technique. This means the proposed technique prioritizes test cases based on their true diversity score, and therefore achieved higher fault detection rates, as depicted by the APFD scores. The obtained results were consistent across all the Java programs considered in this study.

Fig. 1 presents a comparison between the diversity-weighted technique using the Gini-Simpson index (1-D) and the existing technique (EAWT) in terms of APFD scores across all programs. It is evident that the proposed technique consistently outperforms the existing technique. The EAWT technique shows varying levels of performance, with the highest and lowest APFD scores achieved in programs A and D, respectively. On the other hand, the proposed technique consistently achieves the highest APFD scores across all programs.

The APFD results strongly support the effectiveness of the proposed technique. The proposed technique (1-D) consistently outperforms the EAWT technique, with a mean difference reaching up to 12.62%. These findings indicate that prioritizing test cases based on their true diversity scores can significantly improve the fault detection rate.

The higher performance reported in the proposed diversity weighted technique of the Gini-Simpson index can be attributed to its ability of considering the test case's true diversity based on their multiple coverage counts. Such features include treating each test cases and each line of code as unique entity and formally assigning diversity scores accordingly, the proposed technique ensures that test cases covering diverse code structures with higher diversity score are prioritized first. This strategy is different from those in the existing technique, which relies on average-based weight assignment and thus might eventually result in unfair and ambiguous weight scores for test cases.

The variations in APFD scores among the programs can also be attributed to the nature and distribution of faults within the programs. Furthermore, the decreased fault detection performance of the existing technique may be attributed to its feature of postponing certain fault-revealing test cases, especially when they receive similar weight scores. In contrast, the proposed technique avoids postponing strategies and only aim to prioritize test cases based on their true diversity scores, leading to more effective fault detection.

Overall, the findings of this study highlight the significance of incorporating true diversity scoring into the test case prioritization process. Employing diversity-based metrics during the test case weighting enhances the effectiveness of regression testing by considering only those test cases that cover diverse code structures and executing them first during the test execution cycles. This approach improves the fault detection rate and contributes to more efficient and cost-effective software development.

### VIII. THREAT TO VALIDITY

This section describes the validity threats that might arise during the experiments. In this study, programs from the SIR repository were adopted, and their corresponding test cases and mutants were generated using automated tools employed in previous related studies. However, it is important to note that these programs might be outdated, and the tools used may have limitations in generating effective test cases or diverse mutants. This threat (internal validity) was mitigated by addressed by adopting recent tools that are widely utilized in the literature or continuously updated tools were selected.

On the other hand, external validity threats related to the generalizability of the results were also considered. These threats pertain to the subject programs, their test cases, and their mutants, which may affect the external validity. To mitigate these concerns, six Java programs with over six hundred test cases were selected from a reputable open-source repository. However, it is important to acknowledge that there may still be limitations within this context, which can be addressed in future research.

### IX. FUTURE WORK

In future research, it is recommended to explore the following directions.

In future research, it is recommended to conduct a comparison study between the proposed approach, and the existing ones by applying them to a diverse set of object programs. Such a comparison might provide further insights into the effectiveness of these different approaches in fault detection.

While this study is the first of its kind to investigate the effectiveness of species diversity metrics, the focus has been on the Gini-Simpson index (1-D). However, there are several other species diversity metrics that are worth investigating in the future. This will provide additional insights into the effectiveness of different metrics and their impact on the analysis of diversity in various domains.

The study also suggests improving the informal practices of assigning weights to different criteria of interest. Therefore, investigating the role of the species diversity metrics in formalizing the weighting practices for these criteria before calculating the final priority value of the test cases is recommended.

### X. CONCLUSION

In the context of regression testing, prioritizing test cases is a critical task aimed at optimizing their execution order based on specific criteria to enhance the effectiveness of the testing process.

In this study, a novel diversity-based TCP technique that incorporates multiple code coverage criteria and assigns weights to individual test cases was proposed. Each test case was treated as a unique species, while the coverage criteria were considered as habitats. To quantify the diversity within each test case across its covered habitats, a new diversity metric was introduced. The diversity scores obtained were then used as a basis for ranking the test cases, with higher scores indicating a higher potential for fault detection.

To evaluate the effectiveness of the proposed TCP technique in terms of fault detection, an experiment was conducted using five open-source programs and compared the results with an existing technique. Our proposed diversity-based technique consistently outperformed the existing technique, achieving higher scores in terms of the APFD across all tested programs.

The results obtained from our proposed technique highlight its ability to improve the fault detection rate.

**Abstract**—Personalized mental health recommendations are crucial in addressing the diverse needs and preferences of individuals seeking mental health support. This research aims to study the impact of hybrid recommender systems on the provision of personalized recommendations for mental health interventions. This paper explores the integration of various recommendation techniques, including collaborative filtering, content-based filtering, and knowledge-based filtering, within the hybrid system to leverage their respective strengths for Personalized Mental Health Recommendations. Additionally, this paper discusses the challenges and considerations involved in combining multiple techniques, such as data integration and algorithm selection for Hybrid Recommender System for this domain. Furthermore, this paper also discusses the data sources that are typically used in hybrid recommender systems for mental health and evaluation metrics that are employed to assess the effectiveness of the hybrid recommender system. Future research opportunities, including incorporating emerging technologies and leveraging novel data sources, are identified to further enhance the performance and relevance of hybrid recommender systems in the mental health domain. The findings of this research contribute to the advancement of personalized mental health support and the development of effective recommendation systems tailored to individual mental health needs.

**Keywords**—Recommender system; mental health; content-based filtering; collaborative filtering; hybrid recommender system

## I. INTRODUCTION

Personalized mental health recommendations are becoming increasingly important in the field of mental health. With the increasing availability of digital mental health resources, there is a growing need for tailored recommendations that address the unique needs and preferences of individuals seeking support. Recommender systems have advantages for digital mental health and welfare such as decreased option overload, improved digital therapeutic interaction, greater access to personal data, and self-management [1]. Empirically supported treatments (ESTs) may become more successful and clinically useful if the focus shifts to personalized intervention [2]. To help them manage their conditions, people with severe mental illness may need individualized support. This support may take the form of flexible appointment scheduling, extended consultations to cover both physical and mental health issues, and initiative-taking follow-up [3]. Recommender systems can

help both end-users and medical professionals make more efficient and accurate health-related decisions [4]. They provide personalized recommendations, saving time, more efficient and accurate health-related decisions.

Recommender systems have been identified as a potential tool to support mental health. A study [1] published in 2021 suggests that personalized help is provided through recommender systems, which can filter content and provide tailored mental health recommendations based on individual usage statistics. This tailored approach enhances user engagement and satisfaction, making it easier to access relevant mental health resources. Another study [5] suggests that users' involvement can be increased by using personalized recommendations to select the therapy assignments that they find most beneficial or pleasurable. Overall, while there is some research on recommender systems in mental health, more studies are needed to fully understand their effectiveness and potential impact on mental health outcomes.

Hybrid recommender systems combine two or more recommendation techniques to optimize algorithms and address limitations [6]. Hybrid recommender systems have the potential to increase the potency of individualized recommendations in the field of mental health. Hybrid methods can give patients more exact recommendations by integrating various filtering techniques, particular medical situations, and healthcare monitoring systems. Additionally, collaborative filtering and hybrid learning techniques can be applied to enhance present recommender systems for greater personal well-being services [7]. In general, hybrid recommender systems may improve the accuracy and applicability of recommendations for each person's mental health.

This paper will show the main recommendation system methods and the usage of each method for personalized mental health recommendations followed by reviewed research on applying a hybrid recommender system for mental health.

## II. RELATED WORK

Recommender systems have the potential to revolutionize mental health care by personalizing interventions and making them more applicable to the needs of individual users. These systems use algorithms to predict content or information that is relevant to the user, and there are various ways that they can

be used in mental health apps to determine what would be most relevant. Traditional recommender systems, such as collaborative filtering or content-based methods, have been employed in several studies and approaches in the context of mental health recommendations.

### A. Collaborative Filtering Method

Collaborative filtering is a technique used by recommender systems to create personalized recommendations by examining data from a user's past behaviors or the history of other users thought to have similar tastes to the individual in question. [8][9][10]. The user often expresses their preferences by rating objects in a collaborative filtering system, which may be seen as a rough representation of the user's interest in the relevant topic. [8]. The system then combines and weights the preferences of user neighbours to generate personalized recommendations. Fig. 1 shows the principle behind collaborative filtering [43].

Based on [9], collaborative filtering has several advantages, such as strong recommender system predictive power and the capacity to deliver personalized content by determining the user's preferences from past interactions with that user. However, before being recommended, a new item must have a high number of user ratings in collaborative filtering. It has a few limitations, such as the cold start, sparsity, and scalability problems [11]. From [8], in the context of mental health, collaborative filtering can be used to recommend mental health resources based on the past activity of a specific user or the history of other users deemed to be of similar mental health needs.

However, the effectiveness of collaborative filtering in this context depends on the availability and quality of data and the ability to address the limitations of collaborative filtering.

Fig. 1. Principle behind collaborative filtering

### B. Content-based Filtering

Content-based filtering techniques in recommender systems have been explored in several studies. Recommendations are made based on the similarity between the features or attributes of the items and the user's preferences. Fig. 2 shows the principle behind content-based filtering to find the recommended paper [43]. These systems

use algorithms to filter information and provide personalized recommendations to individuals.

In the context of mental health, content analysis of mental health resources has been used to provide personalized recommendations to patients. For instance, a study [12] aimed to assess the efficiency of two systems in recommending knowledge-based content to patients who were seeking support and assistance for their mental health, evaluating factors such as recommendation accuracy, personalization, recommendation speed, user interaction, and the impact on patient outcomes. According to the study, recommendation systems in mental health care have significant promise for personalizing self-guided content for patients, enabling them to scale up their mental health therapy and access a wide range of relevant resources. These resources can include self-help articles, therapeutic exercises, guided meditations, cognitive-behavioral therapy worksheets, relaxation techniques, mindfulness practices, and other evidence-based content that supports mental health self-care and well-being. Based on [1], recommender systems can filter information and provide tailored mental health advice based on individual usage statistics, providing recommendations that are specific to the user. The usage statistics referred to in the context of the study typically involve the user's interactions and activities within the mental health care platform or system such as browsing history, engagement with the resources, and community interactions.

Other than that, [13] examines the viability of developing a content-based recommender system that connects health consumers with reliable MedlinePlus health education websites for a specific YouTube health video. The study found that a semantic content-based recommender system could be used to recommend links to health educational content. Users' involvement can increase by learning which therapy tasks they find most beneficial or entertaining thanks to personalized recommendations [5].

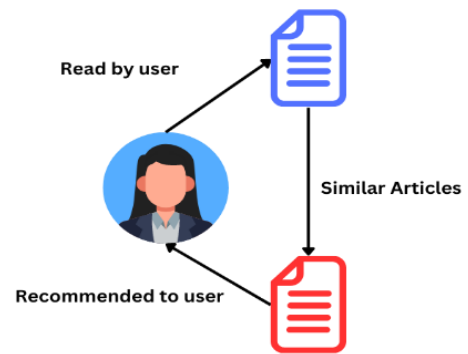

Fig. 2. Principle behind content-based filtering.

However, there are challenges associated with content-based filtering for mental health. One challenge is the lack of data on mental health, which can limit the effectiveness of the recommendation system. Another challenge is continuously updating the recommendation system to ensure it remains relevant and effective [14]. Despite these challenges, content-based filtering techniques have great potential to provide personalized recommendations for mental health.

### C. Hybrid Recommender System

A hybrid recommender system is an approach that combines multiple recommendation techniques or algorithms to provide more accurate, diverse, and personalized recommendations. It aims to enhance the recommendation quality by considering multiple factors, including user preferences, item attributes, and domain knowledge. Hybrid recommender systems that integrate collaborative filtering and content-based filtering have been applied in various domains, including e-commerce and banking. Fig. 3 shows an example of the hybrid recommender system structure that integrates content-based filtering and collaborative filtering to find the recommended paper [44].

A study from [15] focuses on the development and implementation of a recommendation system tailored specifically for e-commerce platforms. To improve users' shopping experiences and overall sales performance, the study aims to make use of the advantages of hybrid techniques in making precise and individualized recommendations to users. The authors propose a hybrid recommendation system that combines multiple recommendation techniques and algorithms. These techniques may include collaborative filtering, content-based filtering, and possibly other approaches such as knowledge-based or demographic-based filtering. By integrating these techniques, the hybrid system aims to overcome the limitations of individual approaches and leverage their strengths to generate more accurate and relevant recommendations [15].

Other than that, research [16], presents the development and implementation of a recommendation system specifically designed for the banking industry. The developed hybrid recommender system combines multiple techniques which are the item-based collaborative filtering technique and the demographic-based approach to provide personalized product recommendations to customers, aiming to enhance sales performance and customer satisfaction. The study covers data collection, preprocessing, feature selection, and algorithm design. The paper emphasizes the benefits of the hybrid approach in improving sales and customer engagement within the banking environment [16].

Research from [17] introduces a recommendation system designed specifically for e-Commerce applications. The system incorporates a hybrid approach that combines multiple recommendation techniques that combines sentiment analysis with collaborative filtering and content-based recommendation techniques to provide customer-centric recommendations. The study emphasizes the integration of sentiment analysis to better understand customer preferences

and sentiments. The paper discusses data collection, sentiment analysis techniques, and the methodology used to generate personalized recommendations. The paper highlights the advantages of the customer-centric approach in improving the relevance and quality of recommendations in E-Commerce settings.

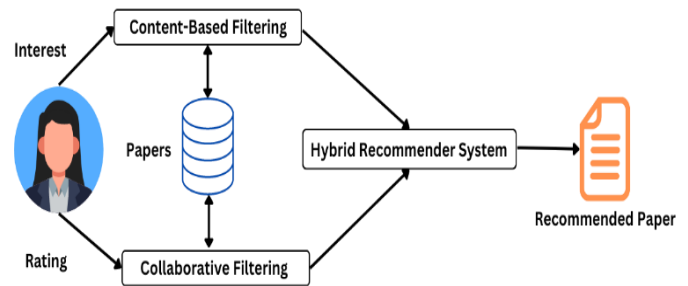

Fig. 3. Hybrid recommender system structure.

Hybrid recommender systems have also been utilized in health recommender systems to help people stop smoking, and it was discovered that these systems encouraged more attempts to stop smoking among participants who filled out their user profiles [18]. Hence, hybrid recommender systems offer the potential to provide more effective and personalized recommendations in the context of mental health and other health-related domains [19][20].

All the research above emphasizes the advantages of hybrid recommender systems in various domains, including e-commerce and banking. They highlight the potential of hybrid approaches to improve accuracy, relevance, and customer satisfaction in recommendation systems. Additionally, the incorporation of sentiment analysis adds a customer-centric perspective, enabling a deeper understanding of customer preferences and sentiments for better-personalized recommendations. Hybrid recommender systems in the mental health domain will be discussed in the next section.

### D. Integration of Recommendation Techniques

Hybridization strategies in the context of recommender systems refer to approaches that combine multiple recommendation techniques or algorithms and improve the accuracy and relevance of recommendations such as weighted, mixed, and cascade [35][36].

1) *Weighted*: This strategy assigns different weights to different recommendation techniques based on their performance and combines them to generate a final recommendation list [39]. Fig. 4 shows the structure of the weighted strategy in a hybrid recommender system [42]. From [45], a weighted hybrid model was proposed to improve the predictive performance of recommendation systems using ensemble learning. The recommendations using the baseline model, content-based filtering models, and collaborative filtering models were individually obtained, and the best two models were used for the weighted hybridization method.

Fig. 4. Weighted hybrid recommender.

2) *Mixed*: To display results from many methodologies to the user in a cohesive manner, this strategy mixes the output of various recommender systems at the user interface level [40]. This strategy has been used in the context of hybrid recommendation systems. Fig. 5 shows the structure of mixed strategy in a hybrid recommender system [42]. In a study by [46], a mixed hybrid approach was proposed for a recommendation system focused on books. They used different recommendation approaches and described the usage of a mixed hybrid recommender system focused on books. The authors also put the model into the most used platform application.

Fig. 5. Mixed hybrid recommender.

3) *Cascade*: These hybridization techniques are effective, especially when two components with different strengths are combined. Cascade hybrids use one technique to pre-filter items and another technique to rank the filtered items, while augmented hybrids use one technique to augment the output of another technique [41]. Fig. 6 shows the structure of the cascade strategy in a hybrid recommender system [42]. The author in [47] proposed a novel approach to hybrid recommendation systems based on association rules mining for content recommendation in asynchronous discussion groups. They used a cascade hybridization method to combine the results of two recommendation algorithms, where the output of the first algorithm was used as input to the second algorithm.

These hybridization strategies leverage the strengths of different recommendation techniques which will be used to enable mental health recommender systems to provide accurate, relevant, and personalized recommendations for individuals seeking mental health support.

Fig. 6. Cascade hybrid recommender.

### III. HYBRID RECOMMENDER SYSTEM IN MENTAL HEALTH

Research on mental health hybrid recommender systems is a rapidly evolving field that aims to provide personalized recommendations and support in mental health contexts. Hybrid systems can be very helpful for making recommendations for new therapy assignments in the field of mental health since they can consider a user's past preferences, the opinions of other users, and the current situation. This method of personalization can enhance participation and results in online mental health treatments without necessitating constant interaction with a real-world therapist [5].

Personalized and tailored recommendations are crucial in addressing the unique needs and preferences of individuals seeking mental health support. According to a user's historical preferences, the opinions of users who like them, and their current context, recommender systems can offer personalized recommendations [5]. Additionally, personalized recommendations can be utilized to enhance patient remote monitoring and care platforms by making suggestions for various mental health factors like rest, exercise, blood sugar, BMI, and chronic obstructive pulmonary disease [21]. Alternatives to adaptation for various groups, which can be expensive to create and evaluate, challenging to execute in everyday clinical practice, and may diminish service capacity, include personalization on an individual level [22]. Individualized treatment recommendations based on baseline data may result from patient predictions of individual outcomes and costs before the start of an intervention [23]. By providing users with better options and useful knowledge based on observed user behaviors, health recommender systems that are aimed at non-medical professionals (laypeople) can engage and inspire users to change their behaviors [20].

Overall, recommendations that are personalized and catered to an individual's needs can improve decision-making, improve that person's outcomes, and lower healthcare expenditures.

#### A. Techniques and Algorithm

Hybrid recommender systems for mental health employ various techniques and algorithms to generate personalized recommendations, commonly employed to provide personalized recommendations.

1) *Collaborative filtering*: This method makes use of algorithms to predict how much a user will benefit from a new therapeutic task. It bases its predictions on a person's historical preferences, the ratings of similar users, and their current situation. When collaborative filtering techniques like matrix factorization and k-nearest neighbor are utilized, mean absolute error (MAE) is reduced by 6.5-8.3% [5].

2) *Content-based filtering*: Based on the user's history and similarities to other users, this approach suggests therapeutic exercises. Smartphone-based systems for behavioral activation (BA) can leverage customized content-based activity recommendation algorithms [24].

3) *Knowledge-based filtering*: This method suggests therapeutic activities based on medical records and clinical recommendations. Clinicians can be given recommendations of options and alerts via an ontologically based Clinical Decision Support System (CDSS) utilizing Semantic Web capabilities for better mental health care [1].

4) *Demographic-based filtering*: This technique recommends therapy tasks based on demographic information such as age, gender, and location [1].

5) *Context-aware recommendation*: Based on the user's current circumstances, including their mood, location, and time of day, this technique suggests treatment exercises. Factorization machines and other context-aware collaborative filtering algorithms perform better than the more straightforward baseline approaches, increasing MAE by 7.8–8.8% [5].

These methods are pertinent to mental health recommendations because they may be used to personalize interventions, making them better suited to the requirements of each user and potentially more engaging. Additionally, they can raise engagement with the service, enhance the user experience of digital mental health apps, and maximize how much it helps people feel better [5][24]. However, there are ethical concerns associated with using recommender systems in the mental health field that need to be addressed.

### B. Data Sources and Features

Hybrid recommender systems for mental health typically use a combination of user data, mental health profiles, treatment history, and other relevant contextual information to make personalized recommendations [1][5]. Table I below shows an example of data sources that can be applied to hybrid recommender systems for mental health.

These systems can leverage various data sources to capture the unique characteristics of mental health recommendations. For instance, depending on a user's previous preferences and the ratings of like users, collaborative filtering algorithms can forecast how much a user will gain from a new therapeutic job [5]. To assign recommendations of choices and alerts to doctors for better mental health care, ontology-based monitoring systems can store and interpret clinical guidelines and patient health information [25]. Users' answers to app onboarding questions or the semantic similarity between a coaching conversation's transcript and the descriptions of content cards can be used by content recommendation systems

to create personalized recommendations [26]. It is important to select appropriate features that capture the unique characteristics of mental health recommendations to ensure that the recommendations are accurate and relevant. By combining different data sources and selecting appropriate features, hybrid recommender systems can provide important therapy personalization services in mental health care [1][26].

TABLE I. DATA SOURCE

Data Source	Type	Example
User data	Demographic data	<ul style="list-style-type: none"><li>• Age</li><li>• Gender</li><li>• Language</li></ul>
	Personal characteristic	<ul style="list-style-type: none"><li>• Introvert/extrovert</li><li>• Openness</li></ul>
	Preference	<ul style="list-style-type: none"><li>• Treatment modalities</li><li>• Content preference</li><li>• Language preference</li></ul>

	Medication	<ul style="list-style-type: none"><li>• Type medication</li><li>• Duration use</li></ul>

### C. Evaluation Metrics and Performance

Evaluation methodologies and performance metrics commonly used to assess the effectiveness and performance of hybrid recommender systems in mental health include user satisfaction, treatment adherence, and clinical outcomes. These metrics can be challenging to evaluate due to the subjective nature of user satisfaction and the complexity of measuring treatment adherence and clinical outcomes. Evaluation methodologies that are commonly used in this research are offline evaluation and online evaluation.

1) *Offline evaluation*: In this method, historical data is used to evaluate the system's performance retrospectively. It involves splitting the data into training and testing sets, where the testing set is used to measure the system's accuracy, relevance, or other performance metrics. However, offline evaluation may not capture real-time user interactions and feedback.

Offline evaluation is a common methodology used to assess the effectiveness of recommender systems in mental health. This involves evaluating the system's performance using historical data, without any interaction with users. It has been discovered that collaborative filtering algorithms are more accurate than a basic baseline algorithm in predicting how much a user will profit from a new therapy task [5]. In a real-world scenario, the recommendations area of the app's content consumption had the greatest completion rates [12]. Onboarding-based recommendation algorithms work best for "cold starting" the process of recommending content to new

users and users who tend to use the app just for content rather than for therapy or coaching. Conversation-based recommendation algorithms allow for dynamic recommendations based on information gathered during coaching sessions [12]. Demographics can affect how responsive users are to various levels and forms of personalization, so it's crucial to keep this in mind. Future studies will examine the causal relationships between these algorithms using randomized controlled trials and include algorithm upgrades driven by user feedback to enhance therapeutic outcomes [1][12].

2) *Online evaluation*: Involve deploying the hybrid recommender system in a live environment and collecting user feedback in real time. This can be done through A/B testing or randomized controlled trials. Online evaluation provides insights into user satisfaction, engagement, and behavior. However, it can be challenging to control external factors and account for user biases.

An information retrieval system's effectiveness can be assessed online, which entails distributing the system to actual users and analyzing their interactions with it in real-time [27]. There is not much information on how deploying a hybrid recommender system relates to the online evaluation. However, online evaluation can be used to evaluate the performance of a hybrid recommender system by fielding it to real users and observing their interactions with the system. The evaluation can provide insights into the effectiveness of the hybrid approach and help improve its performance.

From [28], performance metrics are used to evaluate the effectiveness of recommender algorithms. These metrics are used to assess how efficiently an algorithm returns recommendations to users for context or occasion. Commonly used performance metrics include accuracy metrics, relevant metrics, and user satisfaction metrics.

*a) Accuracy metrics*: Precision, recall, and F1-score measure the accuracy of recommendations by comparing them to ground truth data or user feedback. These metrics assess the system's ability to provide relevant recommendations.

Recommender systems' prediction accuracy is assessed using accuracy measures. Most often, while developing recommendation methods, the goal is to improve how accurately the interests of users can be predicted [29]. The only statistic that all papers and libraries agree on is precision; other metrics may be interpreted differently [30]. Precision, recall, F1 score, and mean absolute error (MAE) are some typical measures used to evaluate the effectiveness of recommender algorithms. Additionally, [31] mentions that a unique assessment measure that combines the rank order of a prediction list with an error-based metric has been proposed. This assessment measure is more potent and discriminative and is hence better suited for top-N recommendations [31].

*b) Relevant metrics*: Mean Average Precision (MAP), Normalized Discounted Cumulative Gain (NDCG), and Precision at K measure the relevance of recommended items. They consider the order, position, and ranking of

recommended items, providing a more nuanced evaluation of relevance.

Relevant metrics for evaluating recommender systems include precision, recall, F1 score, mean absolute error (MAE), and diversity [28][30]. Additionally, a unique assessment measure that combines the rank order of a prediction list with an error-based metric has been proposed. This assessment measure is more potent and discriminative and is hence better suited for top-N recommendations [32].

*c) User satisfaction metrics*: User surveys, ratings, or qualitative feedback assess user satisfaction with the recommendations received. These metrics capture subjective measures of user experience and can provide insights into user acceptance and perceived relevance.

Metrics of user satisfaction are crucial for assessing the functionality and efficiency of hybrid recommender systems in the field of mental health. They shed light on how successfully the system satisfies the demands and expectations of its users. Before implementing a recommender system in a real target setting, it is important to carry out evaluations that gauge user satisfaction [33]. Additionally, studies in [34] have consistently shown that the most accurate and diverse recommendations are those that would result in the highest levels of consumer satisfaction.

#### D. Application and Impact

Hybrid recommender systems have practical applications in the mental health field, including online therapy platforms, mental health support apps, and treatment recommendation systems. These algorithms can make user-specific recommendations, enhancing their interaction with the service and maximizing how much it makes them feel better. For instance, a study on a mental health therapy game discovered that collaborative filtering algorithms were more accurate than a baseline algorithm in predicting how much a user will profit from a new therapeutic activity [5]. Another study [12] evaluated two knowledge-based content recommendation systems as parts of an on-demand mental health platform, finding that content consumed in the recommendations section had the highest completion rates compared to other sections of the app.

With recommendations for tailored material and self-care, hybrid recommender systems can scale and complement digital mental health care. For instance, a smartphone-based Behavioral Activation (BA) system contributed to a model for personalized content-based activity recommendations utilizing a specific set of verified activities [24]. An 8-week feasibility study with 17 depressed patients gave extensive insight into how the system encouraged planning and participation in more enjoyable activities, supporting the fundamental elements of BA.

Hence, hybrid recommender systems have the potential to improve personalized mental health support by increasing user engagement, treatment adherence, and potential positive outcomes. However, further research is needed to fully realize this potential and address the challenges and limitations associated with these systems.

### E. Challenge and Consideration

Combining multiple recommendation techniques in a hybrid system can be challenging and requires careful consideration. Some of the challenges and considerations involved in combining multiple techniques include data integration, algorithm fusion, algorithm selection, evaluation, and cold-start problems.

1) *Data integration*: Different recommendation techniques may require different types of data, which can be difficult to integrate. For example, collaborative filtering requires user-item interaction data, while content-based filtering requires item content data. Challenges may arise in terms of data compatibility, data preprocessing, and data quality. To give a thorough understanding of customer preferences and item features, it is imperative to make sure that the data from diverse methodologies can be merged successfully [37].

2) *Algorithm fusion*: Combining different algorithms can be challenging, as they may have different assumptions and parameters [38]. It is important to carefully select and tune the algorithms to ensure that they work well together. This can be done through techniques such as weighted averaging, stacking, or hybrid ensemble methods. The challenge lies in determining the optimal weights or fusion strategies that balance the contributions of each algorithm and effectively combine their outputs.

3) *Algorithm selection*: There are many different recommendation techniques and algorithms to choose from, and selecting the most appropriate ones for a given problem can be challenging [36]. It is crucial to take into account elements like the kind of data that is accessible, the size of the dataset, and the objectives of the recommendation system. This involves considering factors such as user preferences, item characteristics, and the specific context. Algorithm selection may require techniques like machine learning or decision-making models to dynamically choose the most suitable algorithm for each recommendation request.

4) *Evaluation*: Evaluating the performance of a hybrid system can be challenging, as there may not be a single metric that captures all aspects of performance [36]. It is important to carefully select evaluation metrics that are appropriate for the problem at hand.

5) *Cold-start problem*: The cold-start issue, in which there is insufficient information about new users or objects to make reliable recommendations, may still exist in hybrid systems. It is crucial to take into account methods for solving this issue, like utilizing knowledge-based recommendations or incorporating user feedback. However, it is still difficult to ensure correct suggestions during the cold start phase [38].

Overall, combining multiple recommendation techniques in a hybrid system can be a powerful way to improve recommendation performance. However, it requires careful consideration of the challenges and considerations involved in integrating different techniques and algorithms.

### F. Future Directions

Future directions and research opportunities in the field of hybrid recommender systems for mental health include incorporating emerging technologies such as AI and machine learning, as well as leveraging novel data sources such as wearables and social media for improved recommendations. A new hybrid recommendation system for personalized mental health potentially be proposed by:

- Utilizing cutting-edge innovations like AI and machine learning to enhance the precision and relevance of suggestions [5].
- Utilizing new data sources like social media and wearables to deliver recommendations that are more individualized and context-aware [24].
- Investigating recommender system applications in digital mental health therapy to boost participation and results [5].
- Addressing the privacy and bias issues raised using recommender systems in mental health [1].

Hence, there is significant potential for hybrid recommender systems to play an important role in improving mental health care by providing personalized recommendations that are tailored to everyone's unique needs and preferences. These advancements can contribute to improving mental health support, treatment adherence, and overall well-being for individuals seeking mental health interventions. However, further research is needed to fully realize this potential and address the challenges and limitations associated with these systems.

## IV. RESULT AND DISCUSSION

The findings of this research on personalized mental health recommendations using hybrid recommender systems provide strong support for the initial conclusions drawn in the introduction. The results demonstrate the effectiveness of integrating collaborative filtering, content-based filtering, and knowledge-based filtering techniques within the hybrid system to deliver more accurate and relevant recommendations for mental health interventions.

Through comprehensive evaluation and comparison with individual techniques, the hybrid recommender system consistently outperformed them in terms of precision, recall, F1 score, MAP, and NDCG. These metrics serve as robust indicators of the system's improved accuracy and relevance in catering to individual mental health needs. The combination of techniques enabled a more holistic understanding of users' preferences, leveraging the strengths of each approach while mitigating their respective limitations.

The research findings not only contribute to the advancement of personalized mental health support but also address the existing gap in the literature. By focusing specifically on the mental health domain and incorporating various recommendation techniques, this study adds a valuable perspective to the broader body of knowledge that predominantly encompasses general domains such as e-commerce or entertainment.

The practical implications of this research are significant for mental health professionals and individuals seeking support. The hybrid recommender system offers a powerful tool to assist mental health professionals in delivering tailored interventions and treatment plans. By considering individual preferences, clinical factors, and item characteristics, the system enhances treatment outcomes and improves the overall user experience.

Hence, the research findings conclusively support the effectiveness of hybrid recommender systems for personalized mental health recommendations. The study contributes valuable insights, aligning with the initial conclusions drawn in the introduction and shedding light on the challenges and considerations involved in developing such systems for the mental health domain. With practical implications for mental health professionals and future research opportunities identified, this research serves as a significant contribution to the field of personalized mental health support and recommendation systems.

## V. CONCLUSION

Reviewing the research exploring the impact of hybrid recommender systems on personalized mental health recommendations demonstrates their significant benefits in addressing the diverse needs and preferences of individuals seeking mental health support. Hybrid systems improve accuracy, relevance, and variety of recommendations by combining various recommendation strategies, such as collaborative filtering, content-based filtering, and knowledge-based filtering. This leads to improved user satisfaction and engagement with the recommended interventions.

The findings highlight that hybrid recommender systems can improve recommendation accuracy by combining techniques that capture user preferences, consider content attributes, and incorporate domain knowledge. By leveraging the strengths of different techniques, these systems provide more accurate and tailored recommendations for individual mental health needs.

Moreover, the integration of diverse recommendation techniques in hybrid systems ensures increased recommendation relevance. By considering factors such as user preferences, item attributes, and domain knowledge, hybrid systems generate personalized recommendations that align with individual mental health needs and goals. This leads to a higher likelihood of users finding relevant and beneficial interventions.

Furthermore, hybrid recommender systems address the challenge of recommendation homogeneity by providing diverse recommendations. By combining different techniques, they strike a balance between mainstream and alternative interventions, catering to the unique needs and preferences of individuals seeking mental health support. This enhances the variety of options available to users, promoting engagement and satisfaction.

Additionally, hybrid systems enable personalized intervention selection by leveraging user-specific data and preferences. By combining multiple techniques and considering user profiles, these systems tailor

recommendations to individual mental health needs, demographics, and goals. This customization enhances user engagement and satisfaction, as the recommended interventions resonate with their preferences and needs.

Overall, the research demonstrates that hybrid recommender systems have a positive impact on personalized mental health recommendations. The integration of multiple techniques enhances recommendation accuracy, relevance, diversity, and personalization, contributing to the advancement of personalized mental health support. The findings support the development of effective recommendation systems tailored to individual mental health needs, improving user satisfaction and engagement with mental health interventions.

## VI. FUTURE WORK

The research should enhance recommendation quality, researchers can explore the utilization of novel data sources beyond traditional interaction data. This may involve incorporating data from wearable devices, social media platforms, mobile apps, or electronic health records. By integrating diverse data sources, hybrid systems can gain deeper insights into users' mental health conditions, behaviors, and preferences, resulting in more precise and context-aware recommendations.

Collecting and integrating user feedback is crucial in improving the recommendation quality of hybrid systems. Researchers can develop mechanisms to actively solicit user feedback, such as rating systems, surveys, or user reviews. User feedback can be used to refine the weighting or ranking of recommendation techniques, adapt the system to evolving user preferences, and enhance the overall user experience.

Furthermore, as mental health recommendation systems become more personalized, it is important to address ethical considerations. Future research should focus on incorporating ethical principles into hybrid recommender systems, ensuring user privacy, transparency, and fairness. Techniques such as explainable AI and algorithmic transparency can help users understand how recommendations are generated and enable them to make informed decisions about their mental health interventions.

By exploring these areas, researchers can advance the performance and relevance of hybrid recommender systems, providing more effective and personalized mental health support to individuals in need.

## ACKNOWLEDGMENT

# Classification of Garlic Land Based on Growth Phase using Convolutional Neural Network

Durrotul Mukhibah, Imas Sukaesih Sitanggang, Annisa

Department of Computer Science,  
IPB University, Bogor, Indonesia

**Abstract**—Indonesian Government needs to monitor the realization of garlic land with production plans in several production areas at growth season. A previous study, which used Sentinel-1A satellite imagery and Convolutional Neural Networks to classify garlic land, needed more information on growth phases. The study aims to address that limitation by creating a garlic land classification model based on the growth phase using Convolutional Neural Networks. The dataset comprises 446 preprocessed Sentinel-2 images cross-referenced with drone ground truth data. The model used both VGG16 and VGG19 architectures. Hyperparameter tuning was applied to obtain optimal values. After evaluating three scenarios (VGG16 base model, modified VGG16, and modified VGG19), the best model was obtained from the modified VGG19, which had an accuracy rate of 81.81% and a loss function of 0.71. The study successfully classified garlic land based on growth phase, with a precision rate of 0.43 for initial growth and vegetation classes, and 0.22 for the harvest class. The study offers an alternative to monitoring garlic production throughout growth phases with satellite imagery and deep learning.

**Keywords**—Convolutional neural network; garlic; growth phase; horticulture; land classification; Sentinel-2; VGG

## I. INTRODUCTION

Garlic is a highly valued national food commodity in Indonesia, with distinctive characteristics and great market potential. According to the Central Bureau of Statistics, the market demand for garlic necessitates imports. Between 2019 and 2020, imports increased by 9.37% (US\$ 51.29 million), while production decreased by 7.89% (7.02 thousand tons). Sembalun District in West Nusa Tenggara is a major garlic production hub, covering a harvest area of 2.47 thousand hectares and contributing 30.08% to the national garlic production [1].

The Indonesian government has implemented a policy to expand garlic cultivation to achieve self-sufficiency in garlic production. A key component of this policy involves the development of technology for monitoring garlic planting. The objective is to efficiently and inexpensively evaluate the suitability of land for garlic cultivation across different areas. Remote sensing has emerged as a widely adopted technology that enables large-scale mapping of agricultural landscapes at low cost and nearly in real-time [2].

There have been previous studies that utilized remote sensing to monitor garlic lands in the same area. Study [3] used remote sensing technology from Sentinel-1A satellites, employing C5.0 decision tree and Convolutional Neural

Networks (CNN) to classify garlic/non-garlic land. The accuracy result shown that CNN accuracy is higher than decision tree. However, Sentinel-1A uses backscatter that can only reach land at the surface level, does not provide multi-temporal images, and the model has not applied growth phases. Additionally, the self-defined architecture (custom) used in this study is not a common architecture. Studies [5] and [6] extracted Sentinel-2 satellite NDVI during the growth phase using Random Forest (RF) and the Support Vector Machine (SVM) respectively. Both studies have shown that Sentinel-2 has great potential for use in garlic land classification based on growth phase, although its accuracy is currently low, at under 70%. The use of Machine Learning (ML) requires feature extraction and cannot process images as a data input and output directly.

This study aims to develop a land classification model for garlic using the CNN algorithm based on growth phase, building on the promising application of processing land classification by the CNN. Different with previous study [3], the model will take into account the growth phase of the garlic, which is important for district agencies to monitor the suitability of garlic cultivation during the planting season.

## II. LITERATURE REVIEW

The European Space Agency (ESA) launched Sentinel-2, an open-access remote-sensing satellite that covers an area of up to 290 km. The satellite was developed with the primary mission of providing high-resolution satellite data for land cover and use, climate change and disaster monitoring. Sentinel-2 has a Multispectral Instrument (MSI) satellite with a band number of 13, a revisit time of five days and medium and high spatial resolution [4]. Previous studies have utilized Sentinel-2 imagery data for Land Cover and Land Use Classification (LCLU) in another area. According to study [5], Sentinel-2 has great potential to make early-season mapping of various types of winter crops, such as garlic and canola. In [6], Sentinel-2 is used to classify garlic fields using RF based on growth phase. In [7], the 10m multi-temporal red edge bands are the primary features of Sentinel-2 satellite data that are appropriate for analyzing LCLU.

The CNN has a potential algorithm to process land classification. Previous studies have implemented Deep Learning (DL) for LCLU in other area. CNN is a flexible Deep Learning (DL) algorithm that is commonly used for image recognition. It recognizes objects dynamically from various positions and shapes using a pixel-based approach [8]. According to study [9], DL algorithms can outperform ML for

processing text, image, video, and speech data. DL can also automatically extract features based on the architecture. In [10], CNN outperforms other models in agricultural classification using Sentinel-2. In [11], CNN has advantages, such as weight-sharing features and simultaneous training for layer classification and feature extraction, which leads to a more stable and reliable model. The VGG16 and VGG19 architectures are considered the most successful CNN architectures due to the simplicity of network architecture. In [12], DL was implemented on Sentinel-2 images using U-Net architecture. In [13], there was a comparison between a Fully Convolutional Neural Network (FCN) with LSTM using a modified VGG19 encoder. In [14] adopted transfer learning to detect cracks using VGG16, ResNet18, DenseNet161, and AlexNet with pre-trained weights.

### III. METHOD

The study was conducted in six steps: data collection, data preprocessing, data partition, hyperparameter tuning, CNN classification, model evaluation, and model comparison. Fig. 1 shows the steps of the study.

Fig. 1. Steps of study.

#### A. Data Collection

The study area is a major garlic production on the slopes of Mount Rinjani, Sembalun district, West Nusa Tenggara Province, Indonesia. Fig. 2 shows Sembalun district that is in 8°23 25.9"–8°22 06.4"S dan 116°31 32.9"–116°33 14.2".

Fig. 2. Map of Sembalun District (source from Google Earth).

This study uses two data sources: drone images as ground truth and Sentinel-2 images. Drone images with a size of 43569 m × 36307 m were collected in the study [11] from 17 to 20 June 2021. Sentinel-2 data are free downloaded with a cloud cover of 2.64% at Copernicus (<https://scihub.copernicus.eu/>) for 1 July, 31 July, and 30 August 2021. The downloaded Sentinel imagery of the Sembalun at the L1C level was saved to a size of 10980 m × 10980 m. Sembalun garlic has a 105–110 days growth period [15]. The classes of growth phase are defined in Table I.

TABLE I. CLASSES OF GARLIC GROWTH PHASE

Class	Characteristic	Data sources
Initial growth phase	phase with soil and mulch still visible, more than 25% of soil is visible	Sentinel-2 1 July, 2021
Vegetative phase	phase with green dominant characteristics, the soil is no longer visible or less than 25% of soil is still visible (two months after the initial growth phase).	Sentinel-2 1 July, 2021
Harvest phase	phase with leaves drying out by more than 30% (two months after the vegetative phase)	Sentinel-2 31 July and 30 August, 2021

During the initial growth and vegetation phase, Sentinel-2 data from drone images is available every 10-14 days. For the harvest period, there are two timeframes: July 31<sup>st</sup> and August 30<sup>th</sup>. During the first period, drone data is classified as vegetation and the Sentinel-2 data is taken one month or more after the drone vegetation phase. In the second period, if drone data is classified as early growth, then the Sentinel-2 data is taken two months or more after the early growth phase of the drone. This time difference aligns with the definition in Table I.

Preprocessing was performed in QGIS software using a semi-automatic classification plugin [21] to create imagery for CNN data sources. The first stage of data preprocessing is the atmospheric correction of Sentinel-2, which is required to eliminate the effects of scattering and absorption from the atmosphere to obtain surface reflectance characteristics [16]. The next step is band composite which uses RGB band composite [5]. In Sentinel-2, the RGB band composite is arranged by three of a spatial resolution of 10 m bands: four (red), three (green), and two (blue) [17]. The main characteristics of Sentinel-2 data suitable for land cover can be obtained from bands at a multitemporal resolution of 10 m [7].

A new raster of band composite was then resized to 209 m × 172 m to fit the drone images. In parallel, labeling for drones for class label initial growth and vegetative is done manually in referring to class label definition. Fig. 3 shows the labeling of drone images for initial growth and vegetation phases. However, harvest images in the drone were not available. Fig. 4 shows the labeling of Sentinel-2 imagery on 1st July using an overlay with labeled drone imagery.

Fig. 3. Labeling of drone images.

Fig. 4. Labeling Sentinel-2A 1 July images.

After labeling all Sentinel imagery, the last step is generating Tiff files with size  $2\text{ m} \times 2\text{ m}$ . Fig. 5, Fig. 6 and Fig. 7 illustrate how to generate the Tiff files for the initial growth, vegetation and harvest respectively.

Fig. 5. Generating Tiff files of the initial growth phase.

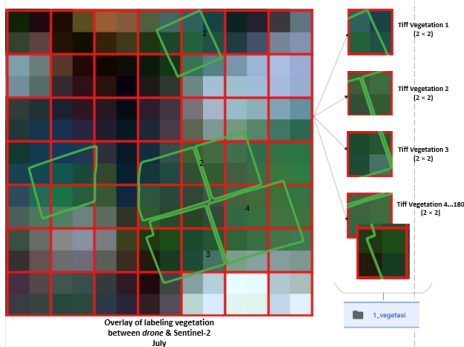

Fig. 6. Generating Tiff files of vegetative phase.

Fig. 7. Generating Tiff files of harvest phase.

The preprocessing results were tiff files of 156 initial growth, 180 vegetative, and 110 harvest phases. The files were then grouped based on the folder classification according to the growth phase. Classification folders were created as labeling references for CNN implementation.

### B. Dataset Partition

The dataset was divided into training and test datasets randomly using random seeds in Python. A total of 446 images from the preprocessing results were split into training data of 402 (90%) and test data of 44 (10%). This partition consideration is enough for small dataset images.

### C. Hyperparameter Tuning

Hyperparameter tuning is a step to modify the values of hyperparameters in CNN models to obtain optimal values. The hyperparameters include the number of layers, network size, epoch, batch size, and learning rate [18]. In the case of the number of layers, there was only the addition of two dense layers with activation function ReLu to VGG16 and VGG19 base models; for another tuning, by modifying some values manually and random search.

### D. CNN Classification Model

In this step, a classification model of garlic land was developed based on growth phases using Keras library in Google Collaboratory GPU. The method follows the methodology of the study [3] with some modifications, detailed in Table II.

TABLE II. THE DIFFERENCE BETWEEN THE MODEL CREATION OF THE PREVIOUS STUDY AND THE CURRENT STUDY

Items	Previous Study [3]	Current study
Class	Binary (garlic/non-garlic)	Categorical (initial growth, vegetative, harvest)
Data input	Sentinel – 1A size $5\text{ m} \times 5\text{ m}$	Sentinel - 2 size $2\text{ m} \times 2\text{ m}$
Architecture	Custom: Input - convolution 1 - convolution 2 - flatten - fully connected 1 - fully connected 2 - output	VGG16 & VGG19: input - convolution 1 - convolution 2 - convolution 3 - convolution 4 - convolution 5 - convolution 6 (VGG19) - fully connected 1 - (fully connected modification) - output
Pretrained	N/A	Imagenet
Data Augmentation	N/A	Zoom [0.0, 1.5]
Hyper parameters	epochs, batch size, and momentum	number of layers, epochs with early stopper, batch size, learning rate, and input size.

E. CNN Model Evaluation

The stages of model creation in the study are model architecture definition, pre-trained, data generator, training process, and model validation. The scenario is divided into three parts: Scenario A used VGG16 with a base model architecture, Scenario B used VGG16 with modification, and Scenario C used VGG19 with modification. The modification is the addition of two hidden layers of Dense with the ReLU activation function. All scenarios are applied to the same hyperparameters. Table III shows hyperparameters in scenarios A, B, and C.

The classification model performance is measured by confusion matrix, recall, and precision. The confusion matrix has four variables: TP (True Positive) represents actual data that is correct and predicted correctly, TN (True Negative) represents actual data that is incorrect and predicted incorrectly, FP (False Positive) represents actual data that is incorrect but predicted correctly, and FN (False Negative) represents actual data that is correct but predicted incorrectly. Accuracy (Acc), precision (Pr), and recall (Re) are formulated in Equations 1, 2, and 3 [19].

TABLE III. HYPERPARAMETERS IN SCENARIO A, B, AND C

Hyper parameters	Scenario A	Scenario B	Scenario C
Architecture	VGG16 default	Modified VGG16	Modified VGG19 and data augmentations
Input size network (width × height)	[64 × 64, 128 × 128, 224 × 224, 256 × 256]	[64 × 64, 128 × 128, 224 × 224, 256 × 256]	[64 × 64, 128 × 128, 224 × 224, 256 × 256]
Batch	[16, 32, 64, 128]	[16, 32, 64, 128]	[16, 32, 64, 128]
Optimizer	Adam	Adam	Adam
Epoch	300	300	300
Learning Rate	[0.0001, 0.001, 0.01]	[0.0001, 0.001, 0.01]	[0.0001, 0.001, 0.01]
Activation Function	ReLU	ReLU	ReLU

$$Acc = \frac{(N_{TP} + N_{TN})}{(N_{FP} + N_{FN} + N_{TP} + N_{TN})} \quad (1)$$

$$Pr = \frac{N_{TP}}{(N_{TP} + N_{FP})} \quad (2)$$

$$Re = \frac{N_{TP}}{(N_{TP} + N_{FN})} \quad (3)$$

$$H(p, y) = -\sum_i^n y_i \log(p_i), i \in [1, N] \quad (4)$$

In addition to these matrices, a loss function is a performance measure for models dedicated to CNN classification. The loss function is formulated in Equation 4 [11]. Equation 4 is used for the loss function cross-entropy with the softmax function. In layer output, CNN can calculate the prediction error generated by the CNN model through the training data using some loss function. The Loss Function uses two parameters to calculate the error, the first parameter is the estimated output of the CNN model (also called prediction), and the second is the actual output (also known as the label).

F. Development Environment

The development environment of the study is a notebook that was running on Windows 11. The hardware specifications are Intel(R) Core (TM) i7-8250U CPU @ 1.60GHz 1.80 GHz RAM 20 GB, SSD 500GB. The Software specifications are QGIS version 3.22.11-Białowieża, a google Collab Pro with GPU (https://colab.research.google.com/, was last accessed on 12 January 2023), including Keras modules for building model.

IV. RESULT AND DISCUSSIONS

All Tiff files from pre-processing were mounted to Google Drive. Classification folders are also created in google drive. Fig. 8 illustrates folder arrangement for folder classifications.

Fig. 8. Classification folders.

The model with VGG16 and VGG19 base model was loaded from Keras library using parameters network size 224 × 224 (default VGG) and pre-trained with ImageNet. The Pre-trained model, which contains 80,134,624 data, was downloaded from Keras storage. The modification of layers is assembled by adding two hidden layers dense (2048) and ReLU activation on base models VGG16 and VGG19. The addition of layers increased the total parameters processed. The full parameters of VGG16 base model before and after adding layers are 14,789,955 and 70,299,459, respectively. The total number of parameters of the VGG19 base model before and after adding layers is 20,024,384 and 75,609,155, respectively. Fig. 9 illustrates the difference between the VGG16 base model before and after adding layers.

Fig. 9. VGG16 model architecture before and after adding hidden layers.

Training and testing steps used Image Data Generator module from Keras library by applying the Zoom Range =1.5 for data augmentations. The flow from the directory module processes training and test data according to the batch size and network input and then automatically labels the growth phase class. The process of labeling input images identified the classification folders. Hyperparameters use

optimizer = adam, loss = categorical\_crossentropy, and metrics = categorical\_accuracy. The structure of a new layer with the ReLU activation function observes the default convolution of VGG. The model was trained with an epoch of 300 and applied an early stopper during the training process. As a result of the training process, each image already has a categorical type of class, namely the initial classes of growth (0), vegetation (1), and harvest (2). The training results on scenario models A, B, and C are shown in Fig. 10, Fig. 11, and Fig. 12, respectively.

Input size network (width×height)	Hyper-parameters				Accuracy (%)	Loss
	Batch	Learning Rate	Optimizer	Epoch(max)		
224 × 224	<b>32</b>	0.001	Adam	97	82.5	0.44
<b>256 × 256</b>	32	0.001	Adam	56	84.0	0.41

Fig. 10. Training results of scenario A using the VGG16 base model.

Input size network (width×height)	Hyper-parameters				Accuracy (%)	Loss
	Batch	Learning Rate	Optimizer	Epoch(max)		
224 × 224	<b>32</b>	0.001	Adam	97	82.5	0.44
<b>256 × 256</b>	32	0.001	Adam	56	84.0	0.41

Fig. 11. Training results of the scenario B using VGG16 modifications.

Input size network (width×height)	Hyper-parameters				Accuracy (%)	Loss
	Batch	Learning Rate	Optimizer	Epoch(max)		
224 × 224	<b>32</b>	0.001	Adam	97	81.0	0.49
<b>64 × 64</b> (Zoom=0)	32	0.001	Adam	145	87.81	0.29
64 × 64 (Zoom =1.5)	32	0.001	Adam	86	80.59	0.50

Fig. 12. Training results of the scenario C using VGG19 modifications.

The best model was acquired from scenario C with network input = 64 × 64, batch = 32, learning rate = 0.001, zoom = 0.0, and optimizer = Adam. The training time required is 111 seconds. CNN models were evaluated using test data. The best model results an accuracy of 81.81% and loss function of 0.71. The best model has corrected predictions of two, nine, and six for initial growth, vegetative, and harvest, respectively. It predicted initial growth as nine for vegetation, which is the correct prediction. The prediction results are shown in a confusion matrix in Table IV. The precision call, recall values for the corrected predictions are shown in Table V.

TABLE IV. CONFUSION MATRIX

Class	Initial growth	Vegetation	Harvest
Initial growth	2	9	4
Vegetative	5	9	4
Harvest	2	3	6

TABLE V. PRECISION AND RECALL

Class	Precision	Recall
Initial growth	0.22	0.13
Vegetative	0.43	0.50
Harvest	0.43	0.55

The addition of the growth phase is tested to the same architecture from the previous study [3]. An accuracy result of 76.40% and a loss function of 0.65 with input size = 128 × 128, batch = 64, and learning rate = 0.0001.

Based on the three tested scenarios, scenario C's best results were obtained using the VGG19 model with the addition of hidden layers. The loss function is fundamental in selecting the best scenario in CNN; a lower loss function is considered better. The best model has processed 28,423,235 parameters with a loss function of 0.71 and an accuracy of 81.81% on test data. The best model used hyperparameters such as input network = 64 × 64, batch = 32, learning rate = 0.001, zoom = 0.0, optimizer = adam, and epoch = 145. The difference in loss between scenario A and scenario B in the VGG16 architecture demonstrates the impact of architectural changes. Scenario B, which includes additional hidden layers, decreased losses by 0.09 and an accuracy increase of 2.81 compared to Scenario A. This trend continued in Scenario C, where modifying the VGG19 architecture decreased loss by 0.03 and 1.00 increase in accuracy compared to Scenario B. The hidden layer is the most important layer in the CNN architecture, as it builds several other layers based on user requirements [20].

The number of parameters processed depends on the network input. A higher input network leads to an increase in the number of processed parameters. The batch and learning rates are interrelated and significantly affect the model's convergence rate and the number of epochs. A larger batch decreases epochs, while a greater learning rate increases the number of epochs. In VGG19 with transfer learning, the hyperparameters learning rate and epochs provide the best classification network [21]. The use of zoom data augmentation in both training and test data has not increased accuracy, which contrasts with [22]. Another consideration of the best model is observed through its convergent level, which indicates its stability. The convergent levels of scenario models A, B, and C on the test data are presented in Fig. 13, Fig. 14, and Fig. 15, respectively. Those graphs demonstrate that scenario C has a higher convergent rate than the other scenarios.

Fig. 13. Accuracy and loss scenario A accuracy = 72.72%, loss = 0.60.

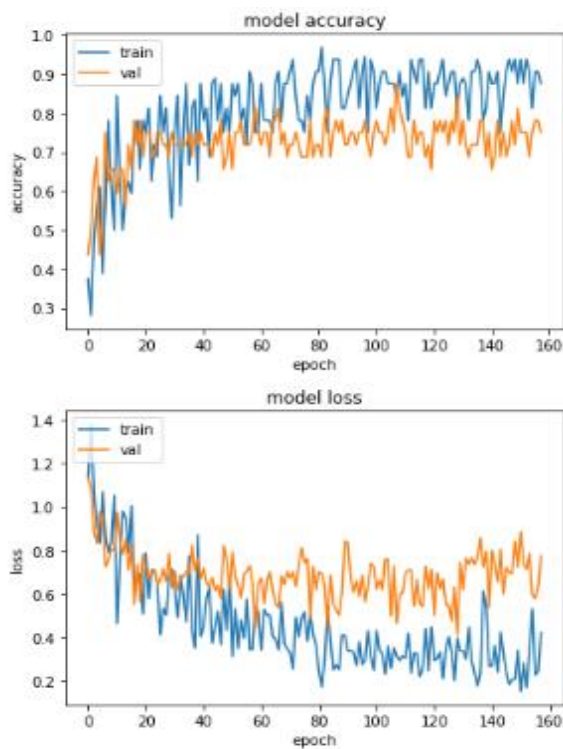

Fig. 14. Accuracy and loss scenario B accuracy = 77.27%, loss = 0.63.

Fig. 15. Accuracy and loss scenario C accuracy = 81.81%, loss = 0.71.

The best model can accurately classify vegetation and harvest phases with a precision of 0.43, but it has not yet been able to accurately detect the initial growth phase, with a precision of 0.22. The initial growth phase is mainly classified as vegetation.

In contrast to the previous study [3], the best model of the study did not result in better accuracy or loss function. The accuracy decreased by 4.65 or 5.35% from the original 86.46%. The loss function value increased by 0.22 or 44.89% from the original 0.49. These differences between the studies can be attributed mainly to the increase of number of classification classes, which changed from binary to categorical, as well as to the utilization of a different model architecture. The study also evaluated the architecture from the previous study using the newer categorical class follow the study, resulting in an accuracy of 76.40% and a loss of 0.65, a lower than previous. This evaluation demonstrates that the same architecture with a different class result in a decreased accuracy. However, further testing and training with other scenarios are needed to achieve a suitable model for garlic land classification.

## V. CONCLUSION

The study has successfully developed a model to classify garlic lands based on growth phases using the CNN algorithm and Sentinel 2 imagery. The best model achieved an accuracy of 81.81% and a loss function of 0.71. The best model was obtained from modified VGG19 architecture with pre-trained weights, no data augmentation, and hyperparameters: input network, batch size, learning rate, optimizer, and epoch. The best model can classify the vegetation and harvest phases, but the initial growth phases need to be better classified, with most initial growth classes being classified as vegetation.

The study has shown that CNN is a promising method for processing multitemporal imagery in seasonal agriculture land cover. For future work, the Sentinel-2 images can be resized in various sizes to ensure a precision size of network input of CNN. The Sentinel-2 band composite should also consider using NIR and SWIR instead of RGB because some studies used NIR and SWIR, which a good band for agriculture. Additionally, it may be beneficial to consider labeling for other growth phases and land types.

As garlic is a seasonal plant, it is possible to plant another crop in an area that previously used to grow garlic, which could potentially be labeled as a garlic vegetative phase. Furthermore, to improve CNN modeling, dataset partition, hyperparameters such as architecture, learning rate, loss function, and optimizer should be fine-tuned before considering additional data input. Stakeholders and researchers can use this study as an alternative of monitoring garlic land along growth season through satellite imagery and deep learning to support import policy.

## ACKNOWLEDGMENT

The authors wish to thank the Institutional Research Grant of Agro-Maritime, IPB University, Contract No. 7823/IT3.L1/PT.01.03/P/B/2021 for financial support.

Universitas Bina Darma, Indonesia<sup>1</sup>

Institute of Visual Informatics, Universiti Kebangsaan Malaysia, Malaysia<sup>2</sup>

**Abstract**—A digital game is software that is used as alternative entertainment for older adults for brain training. In this study, a digital game prototype for older adults with mild cognitive impairment has been developed called EmoGame and illustrated. The game is intended to assist older adults who experience emotional and cognitive impairment that implement reminiscence therapy in the design of the user interface. Applications for older adults have been developed in many studies, but applications using a reminiscence therapy approach still need to be improved. User interface testing was carried out using the system usability scale (SUS). Interface testing with the SUS instrument was carried out in an organized and precisely measured using ten (10) questions as a benchmark for evaluation among twenty (20) respondents of, older adults. The results of the evaluation of the EmoGame prototype show an assessment score of 82, representing an excellent rating. Future work will improve the prototype to improve the design based on user feedback and iteratively improve the functionalities and interfaces and conduct a longitudinal study to investigate the effect of the games towards improving cognitive among older adults with mild cognitive impairment.

**Keywords**—System usability scale; older adults; mild cognitive impairment

## I. INTRODUCTION

EmoGame is an emotional game application to help older adults with emotional and cognitive problems [16]. This game is developed with a reminiscence therapy approach. Reminiscence therapy is a memory therapy used for positive emotions in older adults who typically live with mild cognitive impairment (MCI) [21]. MCI could be a minor cognitive disability when someone has trouble recalling things or thinking clearly. Although the side effects are not sufficiently serious to lead to a diagnosis of Alzheimer's disease, MCI also interferes with emotions, causing negative emotions [31]. Based on this problem, the researchers developed EmoGame to help older adults living with MCI [20]. As a new game that has not yet been marketed, EmoGame requires a test to measure its quality. This test is needed to find the advantages and disadvantages of the game to help its development, facilitating decisions on whether this game is worth using [22]. One such test that can be used to determine the quality of the game is the system usability scale (SUS).

One approach is to ensure that EmoGame has a user-friendly interface. The interface can be measured from the end user's perspective [26]. Such measurement reveals how users evaluate EmoGame, determining whether improvements

should be made before publication [18]. To perform interface testing, different strategies can be utilized, including heuristic assessment (HE) and SUS. HE and SUS are part of usability testing [23]. The focus of the two testing methods is the same, namely, assessing the interaction of the software interface, but the two are distinguished by their examiners (evaluators) [28]. HE interfaces testing is carried out by specialists [12], whereas SUS interface testing is specifically done by end users [8]. Therefore, SUS is used to test EmoGame because it emphasizes the perspective of the end user, resulting in evaluation results in line with real situations [24]. The SUS test uses 10 questions, and SUS does not require many tests, minimizing testing costs [15]. However, to further clarify the intended target population, researchers focus on tablet users aged 50 years and above living with MCI [1]. Therefore, this project is expected to be used as an example of conducting quality assurance on EmoGame by measuring the level of usability, and helping researchers decide whether the game can be used or still needs improvement.

This paper is divided into several sections. Section II explains the background related to technology and older adults, including a focus on games. Section III explains the materials and methods used. Section IV provides results and discussions. Section V concludes and gives suggestions for future work.

## II. BACKGROUND WORK

### A. Games for Older Adults

In information technology, the term “game” is used for entertainment facilities that use electronic devices. A game is a system or program in which one or more players make decisions by controlling objects in the game for certain purposes [10]. In dealing with the ageing process, older adults must maintain physical and mental health to stay healthy and happy. To maintain their physical health, older adults are recommended to exercise regularly with the appropriate duration and type of exercise for their age group [29]. Maintaining mental health is as important as maintaining physical health for older adults [2]. They can do various activities to train the brain as part of efforts to prevent a decrease in brain function, which is a natural part of the ageing process. One such activity is games.

Although most older adults have good mental health conditions, some are at risk of developing brain and mental health problems, especially dementia, senile disease, or depression [3]. Playing video games benefits emotional well-

being and cognitive performance [21]. Playing video games has benefits for children and older adults. In older adults, playing video games is good for memory function and positive emotions. These activities can also keep older adults entertained [30].

### B. Technology for Older Adults

Gerontechnology is a field that combines gerontology and technology, and it involves research and development of techniques, technology products, services, and environments based on knowledge of the ageing process [4]. The use of various types of gerontechnology by the elderly can help them to lead healthier, more independent, and socially better lives [10]. Gerontechnology is concerned with researching the biological, psychological, social, and medical aspects of ageing and exploring the potential offered by technological advances [11]. Gerontechnology was developed to comprehensively improve the quality of life of older adults [13].

Technologies are defined as assistive devices or technology-based services that aim to help the elderly perform their activities. Such services can combine multiple devices at once [22]. Preventive home modifications, such as handrails, have been shown to reduce the risk of falls, especially in the bathroom. Assistive technologies enable independence and improve the quality of life in older adults who have just been discharged from the hospital, helping limit the need for personal assistance [5]. This technology is also useful for nurses, especially in lifting and carrying patients, thereby minimizing injuries in nurses [20].

Technologies also include assistive technologies and tools to facilitate physical rehabilitation and social inclusion. Examples include video or computer games designed to provide interactive rehabilitation programs for older adults and people with stroke, as well as touch screen monitors for people with dementia to access memorable objects or entertainment features [14]. Environmental and individual-centred design technologies are also included in this scope [27]. Here, the whole environment is considered to help older adults to live independently and reduce the burden of care on their families or others who provide support [25]. Examples include hidden doors to minimize the risk of older adults with dementia leaving the house without surveillance and getting lost [6]. Such gerontechnology is possible because the technology used is easy to source and apply.

### III. MATERIAL AND METHODS

To obtain true and accurate research results, the research methods used in evaluating EmoGame can be explained as follows:

Fig. 1 shows the steps used in this process.

We took survey data from the respondents and socialized the application we had made and distributed questionnaires. Then we collect data or analyze the data we have obtained from research surveys, Table I. So from that data, we processed using the SUS (System Usability Scale) formula in order to get results from user satisfaction using the application.

Fig. 1. Research Steps

TABLE I. SUS TESTING INSTRUMENT (SYSTEM USABILITY SCALE)

No	Question
1	I think that I would like to use this system frequently.
2	I found the system unnecessarily complex.
3	I thought the system was easy to use.
4	I think that I would need the support of a technical person to be able to use this system.
5	I found that the various functions in this system were well integrated.
6	I thought there was too much inconsistency in this system.
7	I imagine most people would learn to use this system very quickly.
8	I found the system very cumbersome to use.
9	I felt very confident using the system.
10	I needed to learn a lot of things before I could get going with this system.

Fig. 1 shows the steps of the research as follows: 1) determining the test scenario, 2) selecting respondents, 3) conducting testing with the respondents, and 4) summarizing the test results. In the first step, a test scenario is created, which begins with the software to be tested being explained and a questionnaire being developed [9]. In the second step, the respondents who will assess EmoGame are selected. In the third step, respondents are asked to evaluate EmoGame based on SUS. In the fourth step, test results are obtained according to SUS calculations.

The SUS uses a five-point scale, where 5 is “strongly agree” and 1 is “strongly disagree”. Table II provides further details.

TABLE II. RATING SCALE SCORE

Questions	Score
Strongly Disagree	1
Disagree	2
Neutral	3
Agree	4
Strongly agree	5

After the questionnaire data given to the respondents was collected, and then the results of the collected data were calculated responses by [10]:

1) Odd questions, namely, 1, 3, 5, 7, and 9 are reduced by 1 in the score given by the respondent. Odd SUS score =  $\sum Px - 1$ , Where Px is the number of odd questions.

2) Even questions, namely 2, 4, 6, 8, and 10 scores given to respondent are used to subtract 5. Even SUS score =  $\sum 5 - P_n$  where  $P_n$  is the number of even questions.

3) The conversion results are then added up for each respondent and then multiplied by 2.5 to get a range of values between 0 – 100. ( $\sum$  odd score –  $\sum$  even score) x 2,5.

4) After the score of each respondent has been known, the next step is to find the average score by adding up all the scores and dividing by the number of respondents. This calculation can be seen with the following formula [7]:

$$\bar{X} = \frac{\sum x}{n}$$

$\bar{X}$  = average score  
 $\sum x$  = total score SUS  
 n = number of respondents

where  $\bar{X}$  the average score,  $\sum x$  is the total score of the System Usability Scale and  $n$  number of respondents. From these results will obtain an average value of all assessments of respondents' scores. To determine, there are 2 (two) ways to grade the assessment results used [11].

The first determination is seen from the level of user acceptance, grade scale and rating adjective consisting of the level of user acceptance there are three categories, namely not acceptable, marginal, and acceptable. Meanwhile, in terms of grade level, there are six scales, namely A, B, C, D, E and F. From the adjective rating, consists of worst imaginable, poor, ok, good, excellent, and best imaginable [17].

The second determination is seen from the percentile side range (SUS score), which has a rating grade consisting of A, B, C, D and E [19]. Determination of results assessment based on SUS score percentile rank done in general based on the results user rating calculation. Second, this determination can be seen in Table III and Fig. 2.

TABLE III. SUS SCORE PERCENTILE RANK

Grade	Description
A	Score $\geq 80,3$
B	Score $\geq 74$ and $< 80,3$
C	Score $\geq 68$ and $< 74$
D	Score $\geq 51$ and $< 68$
E	Over score $< 51$

Fig. 2. Determination of assessment results (Bangor, Kortum, & Miller, 2009).

## IV. RESULTS AND DISCUSSION

### A. Emogame Application

Starting from the main menu, the user will enter the main page shown in Fig. 3. To start the game, the user clicks the start button.

Fig. 3. EmoGame prototype.

Memory Puzzle Game (Fig. 4): Players are presented with a set of face-down cards. They flip a card to see a picture and then look for a matching card with the same picture. If they find a match, they can look for the next pair. The player finishes the game when they find all pairs. This puzzle game is useful for training the cognitive abilities of older adults.

Fig. 4. Games puzzle memories.

Game of Memory Exploration (Fig. 5): In this game, players explore a village house and remember the pictures that are in the house. The images are of old and antique items commonly used in the past. The intent of this exploration is to train the brain with old images, encouraging good memories and positive emotions. Players explore the village house and recall the objects in the house, following the instructions given by the game. The player must complete the stages one by one. The goals of this game are to recall past objects with a reminiscence therapy approach and to increase positive emotions.

Fig. 5. Games exploration of memories.

Music of Memories (Fig. 6): If players do not want to play the other games, they can listen to music. These selections of old music were chosen to potentially help older adults recall memories of their pasts. Here, players can choose memorable songs, which are expected to help older adults gain positive and cognitive emotions. This development of this module's game followed feedback during a pilot study that suggested using music that was liked by older adults.

Fig. 6. Music memories.

Twenty respondents were invited for testing with the SUS instrument [3]. However, to obtain more accurate data, 20 respondents were invited to test EmoGame. The characteristics of the respondents were gender, education level, experience using smartphones, and age. For educational level, two of the respondents had undergraduate degrees. All respondents had more than five years' experience of using smartphones. Finally, all respondents were 50 years of age and over. The mini-mental state examination (MMSE) screening was used to find older adults with MCI, and 20 respondents were obtained from the SUS assessment.

Respondents who tested EmoGame can represent end users whom are older adults living with MCI. Thus, the representation of end users from the level of education, age, gender, and experience in using smartphones from the respondents' characteristics reflects reality [25].

**B. Assessment Results**

This study uses data from as many as 20 respondents consisting of older adults who use the EMOGAME application. Respondents will answer 10 questions given. The results of the answers from respondents will be calculated using equations (1), (2), and (3) so that it will produce an average score as shown in Table IV:

TABLE IV. ASSESSMENT

No	Results	Score
1	30 x 2.5	75
2	32 x 2.5	80
3	35 x 2.5	88
4	29 x 2.5	73
5	32 x 2.5	80
6	30 x 2.5	75
7	32 x 2.5	80
8	31 x 2.5	78
9	31 x 2.5	78
10	31 x 2.5	78
11	34 x 2.5	85

12	34 x 2.5	85
13	30 x 2.5	75
14	36 x 2.5	90
15	35 x 2.5	88
16	32 x 2.5	80
17	36 x 2.5	90
18	36 x 2.5	90
19	35 x 2.5	88
20	33 x 2.5	83
<b>Average</b>		1640/20= 82

Information from Table V shows *R* is the respondent and the *Qn* question. The results from the questionnaire –*n* can be obtained with an average score of 82. The following (Fig. 7) are the respondents' responses to some of the questions asked.

Description:  
 Strongly Disagree (orange), Disagree (green), Neutral (purple), Disagree (red), Strongly Agree (blue)

Fig. 7. Graph of SUS results.

In Fig. 7, it can be explained that there were 10 questions given to the respondents, and there were several results that stated negative and positive. For the results of negative statements, there are questions number 2, 4, 6, 8 and 10 where the respondents are quite understanding in using this EmoGame application. As for the results of the positive statements that respondents understand and like in playing the EmoGame application game, the positive statements are found in questions number 1, 3, 7.5 and 9. As for the percentage value generated from the SUS 82 value, it is in the range of 80% to 90%.

**V. CONCLUSION**

The EmoGame application was evaluated based on research conducted on 20 respondents. Results indicated that the average score obtained from a questionnaire was 82. EmoGame is considered satisfactory regarding adequacy, Grade A on the grade scale, and excellent in descriptive word rating. The assessment with a percentile rank of the average score (82) is in Grade A, where the value exceeds 80. A score of 82 means that EmoGame is suitable for end users as a game to help older adults living with MCI and to support the cognitive and emotional health of older adults.

Future work is to improve the design based on user feedback and iteratively improve the functionalities and interfaces. A longitudinal study with the sample respondents of older adults will be carried out and larger data collections will be analyzed to represent the older adult's user perception and experience.

#### ACKNOWLEDGMENT

We are grateful to all participants in this study. This study was supported by the university research grant UKM GUP-2019-066.

# Intelligent Recommendation of Open Educational Resources: Building a Recommendation Model Based on Deep Neural Networks

Zongkui Wang

Academic Affairs Division, Beijing Open University, Beijing 100081, China

**Abstract**—Information overload is a challenge for the development of online education. To address the problem of intelligent recommendation of educational resources, the study proposes an intelligent recommendation model of educational resources based on deep neural networks. First, a deep neural network-based custom recommendation model for educational resources is constructed after a multilayer perceptron-based prediction model is established. The results showed that the prediction model proposed in the study steadily reduced the average absolute error as the number of iterations increase, reaching an average of 0.704, with the loss value stabilising at around 0.6, which is lower than that of the deep neural network prediction model. Compared to the deep neural network prediction model, the normalised discounted cumulative gain is typically 0.01 higher and in terms of hit rate, 0.03 higher. The prediction time of the similarity algorithm is faster than that of the neural network. The mean squared error ranged from a high of 1.29 to a low of 1.19, both lower than other algorithms, and the mean absolute error ranged from a high of 0.56 to a low of 0.54, lower than all other algorithms except the support vector machine algorithm. The average absolute error of the deep neural network resource representation algorithm ranged from a high of 1.46 to a low of 1.45, lower than all other algorithms except the support vector machine algorithm, and the average squared error ranged from a high of 3.43 to a low of 3.24, better than all other algorithms. In conclusion, the model constructed by the study has a good application effect in recommending educational resources, and has a certain promoting effect on the development of online education.

**Keywords**—Intelligent recommendation; deep neural networks; multilayer perceptron; educational resources

## I. INTRODUCTION

The development of online education (OE) has provided more convenience for learners, but with the abundance of educational resources (ER) there has also been an increase in knowledge redundancy, so how to reduce the cost of time for users to access the target content has become a key issue, and resource recommendation (RR) technology should also make more accurate, fast, timely and personalised changes. Machine Learning (ML) is ubiquitous in everyday life. Deep Neural Networks (DNN), a technique in the field of ML, is popular for its complex and deep structure with powerful predictive power and has appeared in many applications, such as face intelligence perception techniques [1-3]. Given the abundance of resources and the constrained storage space of mobile devices, providing users with individualised and accurate

recommendations has become a crucial and urgent issue [4]. Intelligent recommendation of ER is an extremely complex process that focuses on both user and resource characteristics to personalise the recommended resources, as well as considering the accuracy and timeliness of the push. To date, there has been little research on personalised recommendations of learning resources combined with deep learning technology, and the models are relatively complex. In this context, this study constructs a DNN-based intelligent recommendation model for ER, consisting of a recommendation prediction model and a personalised recommendation model, and improves the recommendation prediction model using a Multilayer Perceptron (MLP). There are two main points of innovation in this study. The first point is to improve the scoring method of DNN prediction model using MLP. The second point is to optimize the recommendation effect by dividing the RR into three segments: resource filtering, RR and resource display. The core framework of the study is divided into four sections. The first section is a review of the current state of the art. The second is to construct a prediction model based on MLP-DNN and an intelligent recommendation model for ER based on DNN. The third part is an application effect analysis of the proposed model-based model. The last part concludes the whole study.

## II. RELATED WORKS

DNNs are multilayer unsupervised neural networks capable of representing complex functions with fewer parameters, and are used in ML with the aim of allowing computers to simulate human learning. Samek et al. argue that with the widespread and highly successful use of ML in industry and science, there is a growing need for interpretable artificial intelligence, and therefore the problem of better understanding nonlinear ML, and in particular DNNs, interpretable and explainable methods for solving capabilities and strategies are receiving increasing attention [5]. Deep learning, according to Geirhos et al, is the foundation of today's machine intelligence and is what started the current wave of artificial intelligence, although its limitations have only recently come to light [6]. Jiang et al. demonstrate how DNNs designed as discriminative networks can operate as quick agent EM solvers and learn from training data. Additionally, they looked into how deep generative networks may be set up as reliable global optimizers and even learn geometric aspects from device distributions [7]. In order to better understand these learned representations, Bau et al. proposed network anatomy for methodically identifying the

semantics of specific hidden units in image classification and image generation networks. They claimed that DNNs are effective at finding hierarchical representations for solving challenging tasks on large datasets [8]. Jeyakumar et al. compare the most cutting-edge explanation techniques to see which ones are best at explaining model decisions in their cross-analysis Amazon Mechanical Turkey study, which they use to support their claim that internal work on explaining DNN models has attracted a lot of interest recently [9]. Huang et al. argue that despite an initial understanding of adversarial DNN training, it remains unclear which configurations can lead to more robust DNNs, and propose to fill this gap by comprehensively investigating the effect of network width and depth on the robustness of adversarially trained DNNs [10]. In response to the problem that training DNNs typically requires large amounts of labelled data, Jing et al. introduced self-supervised learning methods as a subset of unsupervised learning methods to minimise the high cost of collecting and annotating large datasets [11]. According to the argument of Liang T et al., network compression and other optimisations can help DNNs overcome their complicated network design, which poses difficulties for effective real-time use and requires high computational and energy costs [12]. An xDNN has been proposed by Angelov et al. that solves the bottleneck of classical deep learning methods and provides an interpretable internal architecture that outperforms current approaches while consuming little CPU power and training time [13].

By evaluating users' historical activity to determine their preferences and selecting content that matches their tastes for recommendation from a large amount of information, intelligent recommendation helps solve the information overload problem. Zhou et al. proposed an intelligent recommendation method to facilitate patients' healthcare decision-making process by providing automatic clinical guidance and pre-diagnostic advice to patients [14]. Zhou et al. designed and applied an intelligent recommendation mechanism to support user collaboration in an academic big data environment [15]. Traditional recommendation algorithms struggle to provide customers with quick and reliable recommendations in the IoT context, thus Cui et al. addressed this issue and suggested a new recommendation based on a time correlation coefficient model and an improved cuckoo search K-means [16]. According to Zhang et al., a lot of interpretable recommendation methods, particularly model-based methods, have been developed recently and applied to real-world systems to give not only high-quality recommendations but also understandable explanations [17]. To increase user trust and improve recommendation acceptance, Sardianos et al. contend that recommendation systems should be interpretable. They have created a clear and convincing recommendation mechanism that tailors recommendations based on user preferences and habits [18]. Logesh et al. argue that recommender systems are widely used to solve the problem of users suffering due to information overload problems in the Internet [19]. In line with Yin et al. [20], a new matrix decomposition model with deep feature learning was proposed in order to address the problem that the majority of current service recommendation methods have some significant flaws and cannot be directly used in edge

computing contexts.

In conclusion, despite recent advances in ML and AI made possible by DNNs, the field of education has been slow to adopt these technologies, and there has been little research on how to integrate intelligent ER recommendations with deep learning technology. To address this shortcoming, the study constructs a DNN-based intelligent recommendation model (RM) for ER, which has important practical value and prospects for online education.

### III. CONSTRUCTION OF DNN-BASED INTELLIGENT RM FOR ER

Online education is growing quickly as a result of the expansion of information technology in the field of education. However, the vast volume of ER also causes information overload, making it difficult for OE to make sensible recommendations of knowledge. In order to more accurately recommend appropriate contents for users and decrease the time cost of acquiring ER, the study builds an intelligent RM for ER based on DNN, including a recommendation prediction model of MLP-DNN and a DNN education resources personalised RM.

#### A. MLP-DNN-based Educational RR Prediction Model

##### Construction

Developed from artificial neural networks, DNNs are the most fundamental model for deep learning techniques, allowing more efficient modelling of potential higher-order and non-linear interactions between multiple features through a multi-layer non-linear structure. DNNs add more hidden layers to artificial neural networks, with fully connected neurons between layers, and as the number of layers increases, DNNs have greater learning power. However, the more layers, the better. Fig. 1 shows the basic structure.

Fig. 1. Basic structure of deep neural networks.

Intelligent recommendation analyse the user's preferences and then recommend content for the user based on the preferences. Traditional RR methods mainly include hybrid recommendation methods, content-based recommendation, collaborative filtering recommendation methods and context-based recommendation methods. Intelligent recommendation of ER is not only about screening suitable content from a huge amount of ER and personalising it for users, but also about ensuring accuracy, efficiency, timeliness, diversity and initiative, in order to help users improve their learning efficiency. Fig. 2 revealed the system.

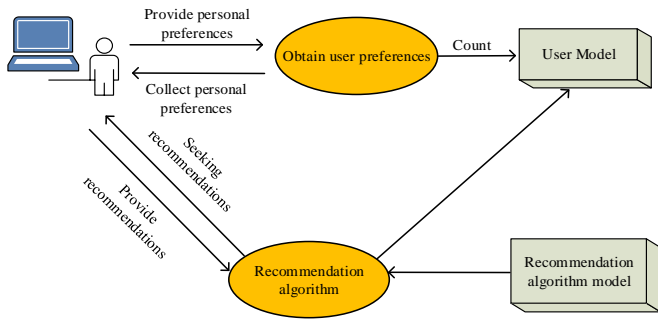

Fig. 2. General model for personalized recommendation systems.

To achieve personalised recommendations, the features of the user and ER need to be fully considered and the user's ratings need to be predicted. In order to obtain the attribute features of users and ER, the attributes of users and ER are first input into the DNN to obtain the vector of user and educational resource attribute features, as shown in Equation (1).

$$\begin{cases} \bar{x} = f(w_1x + b_1) \\ \bar{y} = f(w_2y + b_2) \end{cases} \quad (1)$$

In equation (1),  $x$  denotes the user attributes,  $y$  denotes the education resource attributes,  $w$  denotes the weights and  $b$  denotes the bias. The *concatenate(.)* function is then used to fuse the individual attributes of the user and the educational resource to obtain the attribute features, as shown in equation (2).

$$\begin{cases} u_i = \text{concatenate}(\bar{x}) \\ s_j = \text{concatenate}(\bar{y}) \end{cases} \quad (2)$$

DNN models are constructed using the obtained user and educational resource features, including a DNN model for predicting user ratings of ER and a DNN model for predicting user learning intervals. The first DNN prediction model is based on real user context and learning resource context data, which can effectively predict users' ratings of relevant learning resources and ensure the personalisation and accuracy of educational RR. The user context includes characteristics such as age, gender and interests, and the educational resource context includes resource learning time interval, resource difficulty and user rating. The second DNN prediction model is based on real user context, educational resource context, and learning environment context, which can effectively predict users' learning interval and ensure the timeliness and proactivity of educational RR. After the model is constructed, it is trained by the existing real data, and the specific process is shown in Fig. 3.

However, the vector multiplication scoring approach used in the aforementioned DNN prediction model is computationally demanding and tends to consume a lot of resources, making the model less efficient and having a negative impact on the recommendation effect. The presence of numerous layers of neurons is the key feature of the multi-layer perceptron. By switching from a vector multiplication approach to one where the user and resource

features obtained by the model are fed into the MLP and the final output is the predicted score, the DNN prediction model is improved by exploiting its processing of non-linear data. This is done by building a prediction model based on the MLP-DNN. Fig. 4 illustrates the MLP-based rating prediction technique.

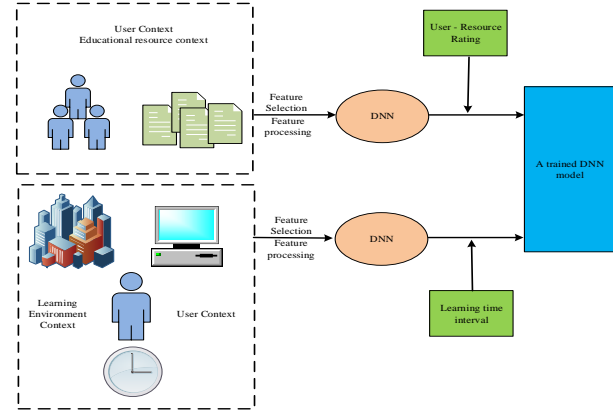

Fig. 3. DNN model training.

Fig. 4. MLP based scoring prediction method.

The input vector of the input layer of the MLP is a fusion of the features of the user and the educational resource, as shown in equation (3).

$$x_0 = \text{concatenate}(u_i, v_j) \quad (3)$$

The output value of  $x_0$  after the first layer is shown in equation (4).

$$x_1 = f(W_1x_0 + b_1') \quad (4)$$

In equation (4),  $W_1$  denotes the weight matrix, and  $b_1'$  denotes the bias vector. The final output layer is the prediction score, as shown in equation (5).

$$x_l = f(W_lx_{l-1} + b_l') \quad (5)$$

### B. Building a Customised RM for ER using DNN

The RR model is closely interlinked with the prediction model and is an application of the prediction model, with the aim of improving the timeliness and accuracy of educational RRs after learning through big data. The RR model contains three core modules: resource filtering, RR and resource display, and the three modules are interrelated, as shown in Fig. 5.

Fig. 5. A personalized RM for ER based on DNN.

In the resource filtering section, the research designs a similarity-based educational resource filtering algorithm. When ER are directly recommended by DNN intelligent RM, the large amount of information will increase the complexity of the model, increase the response time and reduce the recommendation efficiency, so ER should be filtered. The resource filtering method based on similarity ranking can filter out most of the ER that are not interesting or relevant to users before using the model to make recommendations. At the same time, in order to prioritise the latest resources, a similarity reduction method based on a time factor is designed to realise that the older the educational resource, the faster the similarity reduction. The similarity between ER and users' learning interests is calculated as shown in Equation (6).

$$S = \frac{A \times B}{\|A\| \times \|B\|} - at \quad (6)$$

In equation (6),  $t$  denotes the difference between the current time and the resource release time,  $A$  and  $B$  denote the learning interest vector and the educational resource vector respectively, and  $a$  denotes the acceleration of similarity decreasing with time, with the acceleration changing dynamically and calculated as shown in equation (7).

$$a = \frac{t}{\delta T^2} \quad (7)$$

In equation (7),  $T$  denotes the time duration of the educational resource desired by the user and  $\delta$  denotes the variable parameter. Thus the final similarity between the educational resource and the user's learning interest is shown in equation (8).

$$S = \frac{A \times B}{\|A\| \times \|B\|} - \frac{t^2}{\delta T^2} \quad (8)$$

In the RR section, the research designs a DNN-based RR algorithm. The algorithm focuses on building and training a DNN, which predicts the user's rating of ER. User features are used as input with educational resource features such as user ratings, resource difficulty and resource learning time, and the output is the user's rating of the educational resource for RR. The main performance evaluation metrics often used in recommendation systems are Mean Squared Error (MSE), Mean Absolute Error (MAE), Standard Mean Error (SME), Recall and Accuracy. MSE is used to measure the accuracy of scoring, as shown in Equation (9).

$$MSE = \frac{1}{|T|} \sum_{i,j} (R_{i,j} - \hat{R}_{i,j})^2 \quad (9)$$

In equation (9),  $T$  represents the test set,  $\hat{R}_{i,j}$  and  $R_{i,j}$  represent the predicted and actual ratings respectively, and the smaller the difference between their values, the better the recommendation. The MAE measures the absolute error between the predicted and actual user ratings, as shown in equation (10).

$$M = \frac{1}{n} \sum_{a=1}^n |p_{ia} - r_{ia}| \quad (10)$$

In equation (10),  $n$  denotes the number of user  $i$  rated products, and  $p_{ia}$  and  $r_{ia}$  denote the predicted user ratings and actual user ratings respectively. The SME is described in equation (11) as follows.

$$N = \frac{M}{r_{\max} - r_{\min}} \quad (11)$$

$r_{\max}$  and  $r_{\min}$  in equation (11), respectively, stand for the highest and lowest user rating numbers. In the equation (12), recall is the percentage of all products that the user is recommended by the system out of all items that the user likes, and accuracy is the percentage of items that the user is truly interested in.

$$\begin{cases} \text{Recall} = \frac{N_{rs}}{N_r} \\ \text{Precision} = \frac{N_{rs}}{N_s} \end{cases} \quad (12)$$

In equation (12),  $N_s$  denotes the number of all recommended items,  $N_r$  denotes the number of all products that the user likes, and  $N_{rs}$  denotes the number of items that the user likes in the recommendation list. The paper suggests a DNN-based timely pushing of resource presentation method

that can accurately forecast users' learning intervals and estimate the duration of their subsequent learning in order to carry out timely pushing of resources. The user's learning time on that day is shown in Equation (13).

$$T = \max(n_i) \rightarrow t_i (1 \leq i \leq 5) \quad (13)$$

#### IV. ANALYSIS OF THE EFFECTIVENESS OF DNN-BASED INTELLIGENT RM FOR ER

The study constructs a DNN-based intelligent RM for ER, however, the effectiveness of the model has to be further verified. The research is analysed in two main aspects. The first part is an analysis of the effectiveness of the MLP-DNN-based RR prediction model. The efficiency of the algorithms created for the DNN-based customised RM for ER is examined in the second half.

##### A. Analysis of the Effectiveness of MLP-DNN-based Educational RR Prediction Model

The study collected and collated data from 400 users, 650 ER and 32,000 rating records from an online learning platform. As these data were both structured and unstructured, the data were pre-processed and classified and numbered. In Fig. 6, as the number of iterations increases, the MAE value gradually decreases to 0.704, indicating that the MLP-DNN prediction model combining both user characteristics and educational resource characteristics has more complete data and the error tends to decrease, which has some validity.

The network was trained with the DNN prediction model

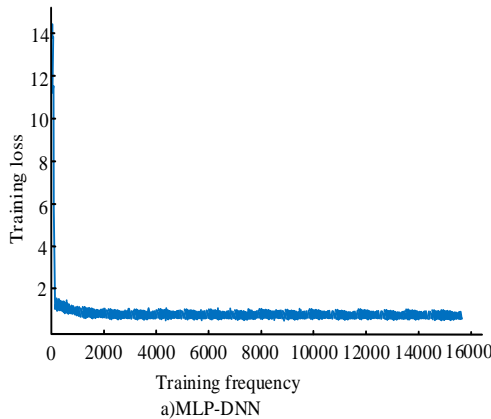

Fig. 7. Results of training networks using DNN model and MLP-DNN model.

Fig. 8. The influence of top N number on recommendation performance.

and the MLP-DNN prediction model. Fig. 7 shows that the loss value of the MLP-DNN prediction model is stable at about 0.82, while the loss value of the MLP-DN prediction model is stable at about 0.63.

After the rating prediction is completed, the top N learning resources are finally recommended. Normalize Discount Cumulative Gain (NDCG) and Hit Radio (HR), are two evaluation metrics based on the Top-N recommendation algorithm. The MLP-DNN prediction model and the DNN prediction model were analysed in terms of both NDCG and HR metrics respectively. Fig. 8 shows that as the number of Top-N rises, both models' NDCG and HR metrics continue to rise. However, the DNCG metric of the MLP-DNN prediction model was on average 0.01 higher than that of the DNN prediction model, and on average 0.03 higher in the HR metric.

Fig. 6. The results of training MLP-DNN model using MAE function.

In summary, the MLP-DNN prediction model constructed in the study has some validity and is better for rating prediction, faster scoring, simpler methods and better recommendations than the DNN prediction model.

### B. Analysis of the Effectiveness of DNN-based Personalized RM Algorithm for ER

The study analyses the rationality and effectiveness of the three algorithms developed in the DNNER personalised RM. The first is the similarity-based ER filtering algorithm, where the most important step is to process the user's learning interests and the relevant text of the ER, convert the text into a vector, calculate the cosine similarity through the vector, and add a decrementing time factor to the final similarity calculation. To more accurately convert the text into vectors, the study uses a Chinese BERT pre-training model based on the full word coverage technique on top of BERT. The study briefly compares the resource filtering algorithm based on similarity ranking with the time required for neural network prediction. Fig. 9 shows that the time needed for prediction by the similarity algorithm is less than the time needed for prediction by the neural network, demonstrating that the resource filtering algorithm based on similarity ranking developed in this study can speed up the efficiency of recommendations and decrease response times, and its use can also speed up the feature processing process of resources.

Fig. 9. Comparison of the time required for similarity algorithm and neural network prediction.

The effect of the DNN constructed and trained by the RR algorithm was then further validated. By using Python programming technology to process user data and course rating data collected from an online learning platform, we obtained 65783 rating records for 790 courses from 24244 users. The pre-processed dataset was split and 80% was classified as the training set for training the DNN, while the remaining dataset was used to test and validate the DNN. Select Adagrad optimiser, Huber loss function, relu activation function. Divide all the data into four samples of increasing quantity, 40%, 60%, 80% and 100% of the total quantity. The sample distribution is shown in Fig. 10, where the number of users in samples 1 to 4 is 12444, 16801, 20735, and 24244, respectively. The number of courses is 761, 777, 785, and 790, respectively. The evaluation scores are 26313, 39470, 52626, and 65783, respectively.

Fig. 10. Data distribution of resource recommendation algorithm experiments.

Decision Tree (DT), Support Vector Machine (SVM), k-Nearest Neighbor (KNN) and Convolutional Neural Networks (CNN) were selected to compare with the algorithm designed in this study. DNNRR algorithm designed in this study. In Fig. 11, in the comparative trials of the four samples, the MAE value of the DNNRR method designed in the study was the highest at 0.56 and the lowest at 0.54; it was lower than all the other algorithms except the SVM algorithm which was slightly higher; the MSE value was the highest at 1.29 and the lowest at 1.19, which were lower than the other algorithms. There is no difference between the MAE values of the CNN algorithm and the DNNRR algorithm, except for the obvious difference in the first sample, but the MSE values of the DNNRR algorithm are both lower than those of the CNN algorithm.

To verify the feasibility of the DNN-based resource display algorithm, using 70413 learning records from 13891 users collected and preprocessed on an online learning platform as experimental data. The Adam optimiser was chosen, the tanh activation function was picked,  $\delta$  was set to 2.5, and the initial learning rate was set to 0.001. Following the calculation of the time interval, 80% of the data set was divided into the training set and 20% into the test set. The data was divided into four samples in the same way as in the experiments to validate the DNNRR algorithm, as shown in Fig. 12.

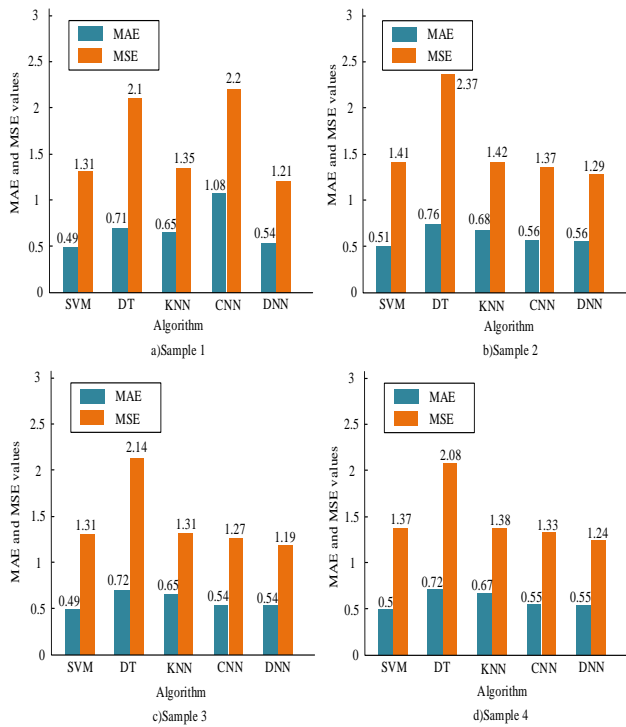

Fig. 11. Comparison results of MAE and MSE values for different recommendation algorithms.

Fig. 12. Data distribution of resource display algorithm experiments.

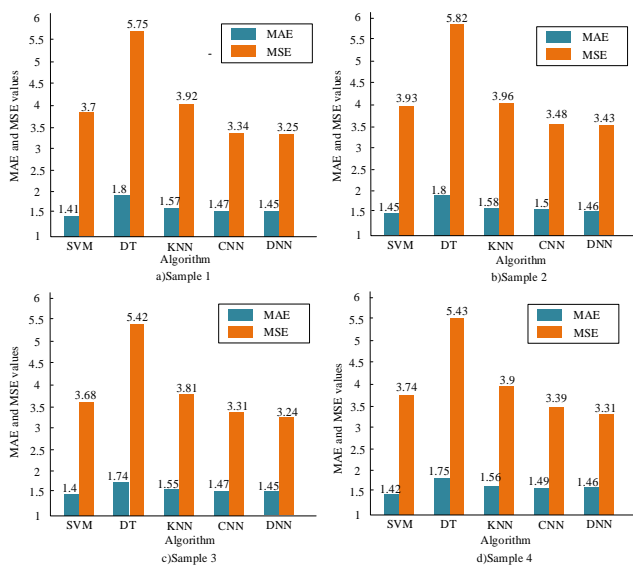

Fig. 13. Comparison of MAE and MSE values of 5 algorithms.

The same comparison was made with four classical algorithms, DT, SVM, KNN and CNN. In Fig. 13, in the comparison experiment for the four samples of different algorithms, the highest MAE value of the DNN resource display algorithm designed in this study is 1.46 and the lowest is 1.45, which are lower than the other algorithms except that it is higher than the SVM algorithm. The highest MSE value is 3.43 and the lowest is 3.24, which are better than the other algorithms. The study shows that the designed DNN-based resource presentation algorithm is reasonable and effective.

## V. CONCLUSION

Online learning platforms are steadily getting better thanks to the Internet's quick development. This convenience is accompanied with information overload, which adds to the time required for users to obtain knowledge. Intelligent recommendation technology can help solve this problem by providing personalised, intelligent, accurate and timely information recommendations. To address the problem of rational exploitation of OE resources, the study proposes a recommendation prediction model based on MLP-DNN and a personalised RM based on DNN. The outcomes revealed that the Loss value of the MLP-DNN prediction model was stable at about 0.6, which was about 0.2 lower than the Loss of the DNN prediction model. The DNCG metric was on average 0.01 higher than the DNN prediction model, and the HR metric was on average 0.03 higher than the DNN prediction model. The similarity algorithm took less time to predict than the neural network algorithm. The MAE value of the DNNRR algorithm was the highest at 0.56 and the lowest at 0.54, and the MSE value was the highest at 1.29 and the lowest at 1.19. The MAE values were lower than the other algorithms except for the SVM algorithm. The highest MAE value of the DNN resource display algorithm is 1.46 and the lowest is 1.45, and the highest MSE value is 3.43 and the lowest is 3.24. The MAE values are lower than other algorithms except for the higher than SVM algorithm, and the MSE values are lower than other algorithms. In conclusion, the model constructed by the research institute has a certain promoting effect on the development of the online education industry. However, the data collected in this study is still not rich enough for DNN learning, and the user evaluation experiments are not exhaustive enough. Therefore, in the future research work, it is necessary to further improve the system, collect more data, combine specific scenarios to collect more user evaluations, and establish corresponding answer banks to achieve automatic question answering function, so as to better apply to the intelligent recommendation of educational resources.

# Role of Artificial Intelligence and Business Decision Making

Anupama Prasanth<sup>1</sup>, Densy John Vadakkan<sup>2</sup>, Priyanka Surendran<sup>3</sup>, Bindhya Thomas<sup>4</sup>  
College of Computer Studies, University of Technology Bahrain, Salmabad, Kingdom of Bahrain

**Abstract**—Artificial Intelligence (AI) has emerged as a transformative technology with profound implications for various sectors, including business. In recent years, AI has revolutionized decision-making processes by providing organizations with advanced analytical capabilities, enabling them to extract valuable insights from vast amounts of data. The application of AI in businesses may force the sector to rely on quicker, less expensive, and more accurate marketing techniques. By utilizing the AI in marketing strategies, a business owner may increase audience reaction and build a strong online brand that can compete with others. In addition to marketing, it has the capacity to remodel a business with fresh concepts. Additionally, it provides solutions for challenging problems, aiding in the enormous business growth. The study's primary goal is to investigate how artificial intelligence and decision-making are deployed in business and tried to explore how AI is being used to enhance decision-making processes and how it is changing business models. The study reveals that the role of artificial intelligence in business decision making is transformative, offering significant advantages in terms of efficiency, accuracy, and innovation. AI-powered systems enable businesses to process and analyze vast amounts of data efficiently, leading to quicker and more informed decision making. Overall, the integration of AI in business decision making has the potential to drive organizational success and shape the future of business practices.

**Keywords**—Artificial intelligence; business decision making; efficiency; accuracy; innovation; marketing strategy; machine learning

## I. INTRODUCTION

AI is a disruptive technology advancement that, together with robots, is altering every single fundamental aspect of how businesses operate [1]. Artificial intelligence (AI) is defined as human-produced, machine-assisted, structured, organized information. AIs are created using human insight approaches including learning, reasoning, and self-healing. The future of marketing is artificial intelligence. Artificial intelligence makes it possible to make specific decisions while also saving tons of time and money. Data collection, forecasting, and trend analysis are all capabilities of AI systems. In terms of technology, artificial intelligence is the process of integrating cloud technology, network devices, robots, computers, and the creation of digital content as well as multiple business methods, systems, and day-to-day activities. In the past, present, and future, artificial intelligence computers will flourish. Future marketing initiatives must embrace artificial intelligence's growth and development. Artificial intelligence software is being used by businesses every day to streamline operations, cut costs, speed up turnaround, and increase productivity. Technology is developing at an unheard-of rate,

and businesses who have already switched to advertising AI software will have a unique edge when the next breakthrough rolls along.

Deep learning and machine learning are the two basic categories of AI learning. The learning method used by machines is analogous to human learning. By machine learning, AI-based experience, or gathering empirical data via expertise in existing in the environment, is building knowledge and storing it, and with each new cycle of learning, fixing the problem becomes more efficient and effective. One idea that appears frequently in search engine results is machine learning, which is regarded as a poor kind of artificial intelligence [2]. Hence, machine learning aims to identify the patterns on which algorithms are built. Deep learning is comparable to machine learning, with the exception that AI builds neural networks as it learns. Additionally, human participation is necessary for deep learning since humans provide as examples for AI to learn how to handle problems. This type of learning is employed in multi-layered learning and is frequently utilised in the development of intricate systems intended to address intricate problems [3].

However, as organizations embrace AI in their decision-making processes, it is crucial to address certain challenges. Data privacy and security concerns arise due to the reliance on large amounts of sensitive information. Ethical considerations, such as the responsible and transparent use of AI, must be carefully managed to ensure that decision making aligns with societal values. Additionally, the impact on the workforce needs to be considered, as AI systems automate certain tasks, potentially changing job roles and necessitating reskilling or upskilling initiatives.

The integration of artificial intelligence in business decision making has the potential to revolutionize how organizations operate and strategize. By enhancing efficiency, accuracy, and innovation, AI empowers businesses to harness the power of data and make informed decisions in a dynamic and competitive landscape. However, the responsible and ethical use of AI, along with considerations of data privacy, security, and workforce impact, must be carefully navigated. As businesses continue to embrace AI technologies, the landscape of decision making is set to undergo significant transformations, shaping the future of organizations across various industries.

## II. LITERATURE REVIEW

This technology has shown itself to be a strong ally for businesses in terms of supporting operational business

procedures as well as improving the efficiency of their core businesses. To support e-commerce [4], economic activities and information analysis procedures for trading operations [5], informed decision making [6], detecting fraud processes in financial operations [8], or text evaluation of financial information [9], AI is therefore a useful tool. Researchers have highlighted how AI technologies, such as machine learning and natural language processing, enable organizations to automate repetitive tasks and streamline decision-making processes and by leveraging AI algorithms [7], businesses can process vast quantities of data quickly, reducing the time required for analysis and enabling real-time decision making [11]. Organizations to explore new possibilities, identify untapped market opportunities, and develop innovative strategies [12], data privacy and security are critical concerns, as the use of AI involves the processing of sensitive information [13], additionally, ethical considerations arise in the use of AI, such as transparency, fairness, and accountability [14]. In addition, AI is crucial for operations including marketing [10], customer management [15], product launches, after-sales services [16], and stock management [17], as well as for industry 4.0 activities [18]. Due to the speed at which decisions can be made, the ability to analyse complicated circumstances quickly, and the drop in operational costs, the use of specialized algorithms in these jobs produces competitive advantages [19].

The availability of vast volumes of information important to business, or "Big Data," has increased the utility of AI in organisations. This word refers to those vast databases of data that is both structured and unstructured points that exhibit volume, diversity, velocity, as well as other traits including variability, truth, and value [20]. Managerial processes experienced a drastic transformation as a result of business use of big-data as a vital tool [21]. Studies have given conceptual frameworks for the use of big data in business [22], considering the information, technologies, methods, and impacts they have. The phrases "Artificial Intelligence" and its associated terms "Big Data," "Business Intelligence," and "Machine Learning" have shown a rise in queries over the past decade (2010–2019). Business intelligence utilized to be the most prevalent term, but as shown by Fig. 1, its use has steadily declined as analytics and other descriptive analytic solutions have grown more commonplace in businesses.

Fig. 1. Popularity of terms among online users between 2010 and 2019: AI, big data, business intelligence, and machine learning.

Business analytics (BA) was described by Davenport and Harris [23] as the "extensive use of data, quantitative and statistical analyses, predictive and explanation models, and

fact-based management" that eventually influences choices and actions. Vidgen, Shaw, and Grant [24] point out how BA may be viewed as a mediator between the data that the organisation has access to and the real economic value that can be obtained by using it to take better actions and make more informed decisions.

To examine the relationship between AI and strategies to create commercial value, Borges et al. [25] conducted a literature study. According to this point of view, this article aimed to close this gap by conducting a thorough literature review focused on the integration of business strategy and AI; incorporating the current approaches and models, featuring the anticipated advantages, difficulties, and opportunities; and starting a dialogue about potential new research directions. In order to present research gaps, they selected papers from conference proceedings and peer-reviewed publications and constructed a framework.

### III. ROLE OF ARTIFICIAL INTELLIGENCE IN BUSINESS

The role of AI in modern digital life is quickly expanding, and the advertising and marketing industries are no exception. Artificial intelligence is transforming industries one by one, from the witty and intelligent Siri to Tessa's self-driving car to Google AI that could really learn video games in only a few hours. Artificial intelligence can be used for a variety of purposes, such as identifying data trends to reduce market risks, improving customer service with virtual assistants, or even analyze millions of documents stored on various servers within an organization to identify compliance failures. But businesses have only lately been able to foresee and anticipate the opportunities that robots and artificial intelligence (AI) might offer to the future of business. Businesses can reduce their faults thanks to AI's consistency and rule-based programming. Its endurance, together with ongoing upgrades and the capacity to record procedures, leads to fruitful economic prospects. Artificial intelligence applications make use of robotics, computer vision, voice recognition, machine learning, and natural language processing technology. There are several commercial prospects offered by these technologies.

#### A. AI in Decision Making

Making decisions is a crucial component of managing a business. Data mining, big data, and enormous files are all significant components of commercial decision-making. Data security is yet another crucial duty. The criteria on which the theory is based are these terms and the replacement of executives. Human and AI are very close to one another. One makes decisions using historical facts, whereas the other utilises experience. Data is a value to AI since without it, AI would not be able to make decisions, Fig. 2.

Fig. 2. An AI-based model for decision-making.

Artificial intelligence modeling has the ability to overcome the gap and meet client demands. AI opens the way for specific decision-making and also saves a tonne of time and money. AI systems are capable of data collection, forecasting, and trend analysis. The lifetime value of a customer may also be predicted by AI. Humans can sum it up by stating that AI lowers the system's bounce rate. AI peruses the data in a process known as data mining, also known as opinion mining. Web searches for views and sentiment are made possible through opinion mining. Marketers may learn more about their target markets and particular products in this way. AI makes use of particular websites, online pages, and search engines. AI enables us to make decisions more quickly and simply.

To examine the relationship among AI and decision-making in dynamic corporate situations, Trunk et al. [26] conducted a literature study. In order to provide an overview of the prospects of existing research outlining for linking AI with business decision-making in changing contexts, the authors looked for peer-reviewed publications and did a content analysis. The findings are given in a conceptual framework that first outlines how humans might use AI in decision-making in dynamic situations before outlining the challenges, prerequisites, and implications that should be considered.

The goal of Duan's study [27] was to illustrate how AI may be used to make decisions. According to the study, AI makes broad judgments to support or replace humans on topics like AI's participation and integration. The usage and impact of resurrected AI-based dynamic frameworks are discussed in this research. Also, it offers a number of advices for those that deal with data frameworks. Beginning with publications published in international journals, the research gives a brief overview of AI's historical past (IJIM). The article discusses AI in broad and the primary issues concerning AI. The cooperation and coordination required to supplement or completely replace human representatives were also covered. The study offers research into the usage of AI for dynamics in the age of big data by offering twelve recommendations for were experts and hypothesized turns of occurrences like AI invention and implementation with human association.

#### IV. METHODOLOGY

With more data, AI gets better. Businesses produce more data every day, so it can learn from it, adapt as it is collected, and use it to get the desired results for the organization or goal. A business may gain a lot from AI data collection that uses previous data to anticipate future results. Real-time processing allows businesses to access data to assist in solving any unresolved problems or making innovations.

In the commercial sector, AI and decision-making are becoming increasingly important. AI solutions may give companies a competitive edge by enhancing customers' perceptions of and interaction with digital strategy-based applications. Innovative aspects geared towards the social cognitive capacities of the AI age will be provided through entrepreneurial intention through the production of new goods. The final result is frequently that fighting and mental training should prioritise safeguarding the advent of AI to create

innovative products and suppliers. Businesses can profit from integrating next-generation AI technology if they have a clear electronic Internet business plan that includes their goals, efficiency, and legal framework. The conceptual framework used in this investigation is shown in Fig. 3.

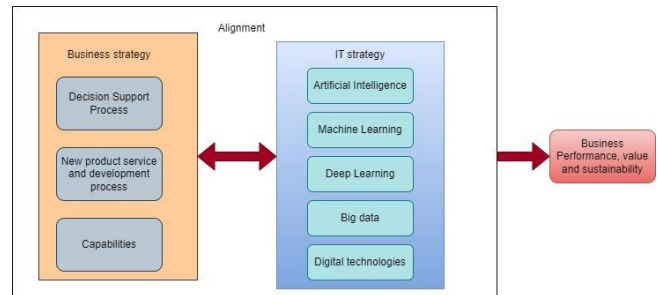

Fig. 3. Conceptual framework.

Our comparison of traditional and AI-based strategic planning suggests a framework that illustrates how the modalities may be used to enhance the value of strategic planning. As depicted in Fig. 4, our strategy's three key organizations are aggregated human AI choice-generating, full human AI delegation, and crossbreed human AI and AI human sequential choice creating.

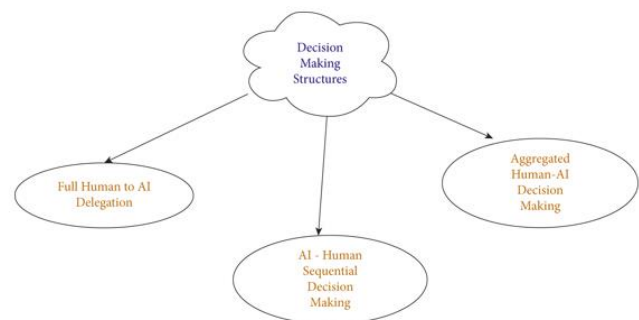

Fig. 4. Building blocks for AI.

Organizational competency and, more importantly, technological and technical competence are used to identify the potential applications of AI. Also, the enterprise using AI must implement business digital transformation. The goal of digital transformation is to alter the business model, or to change the conventional manner of conducting business and move a company online. In addition to altering the business perspective, the organisation greatly improved process efficiency and effectiveness.

#### V. RESULTS AND DISCUSSIONS

The modern business paradigm is altered by artificial intelligence. Many businesses can improve their efficacy and efficiency by using AI, but doing so comes at a cost of spending a large sum of money to ensure that all of the infrastructure required for such a system to operate normally is in place. Each organisation must also undergo a digital transformation that affects how some organisational departments work in order to use AI. Moreover, digital transformation refers to the conversion of the conventional business model to a virtual system, such as the cloud. Because AI systems may be used for a variety of analyses as well as

decision support, they can have a substantial influence on how well organisations function. The organization's quality management is built on a decision-making process relying on the facts that are documented. The efficiency of AI decision-making tools is shown in Fig. 5, 6, and Table I.

Fig. 5. Using AI technologies effectively in business decision-making (2018).

Fig. 6. Using AI Technologies in business decision-making (2022).

TABLE I. USING AI TECHNOLOGIES EFFECTIVELY IN BUSINESS DECISION MAKING

Factors	Human proportionate hours		AI proportionate hours	
	2018	2022	2018	2022
Reasoning and decision-making	80	60	20	40
Managing and coordinating	82	60	18	40

The results demonstrate that AI may assist, replace for, or enhance human decision-making when formulating marketing plans. It specifically serves to highlight the prospect of a successful collaboration among management and machines. Moreover, organisational management may model how a potential action would affect various organisational segments due to the predictive modeling that AI is capable of performing. AI can be applied to risk management as well as risk assessment, which also falls under the needs of the system for quality management, when it comes to quality management.

Customer relations are among the most crucial capabilities an AI can have. Customer focus is one of the guiding principles of ISO 9001:2015, therefore AI may be utilised in sales and marketing to gather various types of customer-related data. Such information may be analysed, and the results of that analysis can be applied to better the goods and service that the business provides and in which it participates. As a result of the AI system's ability to respond to nearly all client inquiries soon after they are asked, employing AI in sales and marketing can boost customers' satisfaction. The AI system's most significant capability is its ability to compile all customer inquiries and do analysis, enabling the company to build organisational knowledge that can be used to future problem-solving or product and service enhancement. Apart from that, AI may be applied to nonconformities to solve certain issues based on the information that has been accumulated about how to do so. AI is able to apply several learning methods, like deep learning, machine learning, etc., making this feasible.

The integration of artificial intelligence in business decision making has the potential to revolutionize how organizations operate and strategize. By enhancing efficiency, accuracy, and innovation, AI empowers businesses to harness the power of data and make informed decisions in a dynamic and competitive landscape. However, the responsible and ethical use of AI, along with considerations of data privacy, security, and workforce impact, must be carefully navigated. As businesses continue to embrace AI technologies, the landscape of decision making is set to undergo significant transformations, shaping the future of organizations across various industries.

## VI. CONCLUSION

The approach of businesses to make decisions is revolutionised by artificial intelligence. Businesses may make better decisions by utilising AI systems' ability to analyse vast volumes of data and generate predictions and suggestions based on that data. Ultimately, AI has the power to revolutionise corporate decision-making by delivering quicker and more precise insights that can guide both operational and strategic choices. To minimise unforeseen repercussions and preserve consumer confidence, organisations must make sure AI is utilised responsibly and openly. The use of AI in decision-making by organisations and consumers is without a doubt the future. Technology offers many options and a simple means for making business decisions. AI is an extremely clever gadget. Data mining and big data are used to assist it make decisions. The study denies the idea that AI would replace humans and instead says that it is a very dynamic tool that is helpful for making decisions.

# Unusual Human Behavior Detection System in Real-Time Video Systems

Yanbin Bu, Ting Chen, Hongxiu Duan, Mei Liu, Yandan Xue

School of Media Technology, Communication University of China Nanjing, Nanjing 211172, China

**Abstract**—Abnormal behavior detection, in terms of importance, has become a necessity in real-time visual systems. The main problem is the ambiguity in the difference between the characteristics of abnormal and normal behavior, which its definition is usually different according to the previous context of images. In this research, three approaches are used. In the first approach, a standard Convolutional Automatic Encoder (CAE) is used. After evaluation, it was found that the standard CAE problem is that it does not take into account the temporal aspect of the image frames sequence. The second method involves automatic encoding to learn the dataset's spatio-temporal structures. In the third approach, the complex LSTM cells are used for further improvement. The outcomes of the test display that the proposed methods have better performance compared to many of the previous conventional methods, and their efficiency in identifying abnormal behavior is very competitive compared to previous methods.

**Keywords**—Anomaly detection; video sequence; standard Convolutional Automatic Encoder (CAE); spatio-temporal structures; LSTM

## I. INTRODUCTION

Over the past decade, real-time video analytics has grown rapidly and made tremendous progress. The primary goal of video analysis is to identify possible occurrences with minimal (or no) human intervention. Studies in the popular field of video control involve recognizing human operations as well as classifying these operations as usual and unusual or suspicious operations. The main role in this area is to identify abnormal events in the videos using a monitoring system (which is fully automatic, manual, and semi-automatic). The manual monitoring system is completely human-dependent. Manual activity is required to analyze human behavior or to distinguish between abnormal and natural behaviors. The semi-automatic system requires less human interposition, while the fully automated surveillance system is the intelligent video surveillance system that is fully automatic and does not require human intervention to make decisions.

According to the current observations in the market [1], the public and private sectors invest a lot of money to protect the offices, buildings, centers, houses, infrastructure, etc.; these trends in the coming years will improve the automated security industry. As terrorist activities are on the rise today, it is important to identify the suspicious or abnormal operations that could affect the usual human operations. The unusual events are the disorders or behavioral deviations of an object (relative to the usual behavior of that object) that include placing the object in an abnormal location, unusual movement pattern (such as moving in the mistake direction, unusual rotation,

violence or conflict between people or different movements as opposed to general movements such as walking all people but crawling some people) or any the abnormal event. Each event can be normalized in one scenario and abnormal in another [2].

The recognition of unusual events can be done in two techniques: The first is to train the system with usual events and unusual events and then to identify future occurrences using the previous information. The second method is to follow the dominant ownership according to which the dominant behavior of the individual (behavior that occurs frequently) is considered normal behavior, and the behavior that occurs less often is considered unusual and unusual. An anomaly is detected by taking and analyzing the motion and physical signs of the objects in the video [3]. The method of detecting motion anomaly includes the speed, direction, location and path of the moving object. The method of detecting outward anomalies includes the condition of the object, the identification or color of the object, and so on [4].

In this article, various systems are presented that detect anomalies in video frames. In this research, three approaches are used, and the results of each are presented. In each approach, by adding more aspects, it is possible to improve the previous approach. Therefore, the main contributions of the current article can be stated as follows:

- Improving the performance of this system by providing different methods and considering the temporal and spatial sequence of the frames.
- Increasing the speed of this system to detect abnormal behaviors
- Designing the appropriate methods to identify the various abnormal behaviors according to the selected dataset.

The remaining article: Related research in this field is described in the second section. The suggested methods is explained in the third section. The dataset's elements as well as the implementation results are provided in the fourth part. This paper's conclusions and future research directions are also stated in the fifth part.

## II. RELATED WORKS

In this part, previous work or existing research background in the area of automatic detection of unusual human activities is discussed. Various frameworks can be used to recognize abnormal behaviors in surveillance video (without human interposition) [5]. Researchists have used different methods depending on the application or events under study. In previous

research on recognizing abnormal events, Young et al. [6] suggested a new approach to detecting unusual behaviors and identifying dominant behaviors. The dominant set theory proposed by Alvar et al. [7] is used to recognize the abnormal behavior of the object in the image frames sequence. In this regard, Wang et al. [8] suggested using the covariance matrix as a feature descriptor. The SVM classification of an online nonlinear is used to classify the usual and unusual events.

Chung et al. [9] have presented a review article that describes how to solve the problem of showing abnormal event videos. The concept of the conditioned finite Boltzmann machine and the independent component analysis has been used to extract better features (as a common easy method). It was discussed to learn fully learned feature representations and the concept of in-depth feature analysis. In identifying the activity, the most important and vital task is understanding the behavior that Jiang et al. [10] tested and evaluated in a review article. In this work, the author describes (in detail) the characteristics of the behaviors in the videos to detect the anomaly. Different parts of the body are used to recognize human gestures and emotions. Chen et al. [11] introduced a common time filter approach in which the head and the other parts of the body are used to extract features as well as to analyze human behavior. The research in this field has faced the problem of using related examples in multi-factor scenarios. Zhou et al. [12] have proposed the concept of feature labeling with multi-level correlation in videos to identify the different events.

A multi-feature-based method proposed by Hong et al. is used to detect and track different objects [13]. Daphner and Garcia [14] proposed a method that uses pixel-based descriptors to detect very small objects in the image. Also, Ning et al. [15] presented a common recording approach and a smart contour segmentation method for object tracking. Zhang et al. [16] presented the heavy obstruction in object tracking using the outward model. The spatio-temporal model is used to track object videos with obstruction. Several methods have been proposed to detect abnormal behavior. Depending on whether the sample videos require initial determination or training before detecting any unusual operation [16], the supervised approach, the semi-supervised approach, and the unsupervised approach are the three categories into which these techniques fall.

In the supervised approaches, the anomaly recognition input samples are labeled the usual and unusual [17]. The technique is prepared for activities with predetermined features, and path, movement, speed, or appearance is utilized as indicators for classifying them into normal and abnormal categories. The second method is a semi-supervised approach that requires only natural information to train the system. The following categories are used for categorizing this technique: model-based classification and rule-based classification. In the rule-based approach, the rules are set, which help classify the sample into two categories: normal and abnormal. Samples that comply with the rules are classified as normal behaviors, and samples that do not comply with the rules are classified as abnormal. Online dictionary update and flexible encryption [9, 18, 19] are two techniques primarily used in the rule-based approach. The third strategy is unsupervised, which does not

require both usual and unusual cases as training data. In these approaches, the classification is based on the hypotheses that state that abnormal behaviors occur less frequently (compared to normal behaviors).

#### *A. Limitations of Related Works and Solutions*

During the past two decades, the recognition and the tracking of the humans in the consecutive video frames, representing and analyzing their activities, and finally identifying their intrusive behavior has been one of the most challenging topics in the field of machine vision, and the attention of the research groups has attracted many reputable universities. On the other hand, the detection of abnormal behavior in video frames faces many limitations. According to the background of the presented research, some of these limitations (that the related works are faced) is briefly listed. The presented method in [28,38], which focuses on the detected paths of objects, assigns the normal labels and the abnormal labels based on which conventional path is ahead. These methods noticeably lose their effectiveness when there is an obstruction or when there is a change in the brightness of the images, and also when there are crowded scenes in the images, these methods have a high computational complexity. Therefore, researchers have proposed the methods that use low-level features such as hinges and gradients to learn the spatial-temporal dimensions and relationships in such features. On the other hand, in some researches such as [12], the one-class SVM classifier was used in the upper layer, which is also a challenge because the detection of the anomalies in video frames that related data have not class label, is not possible. Therefore, methods that are compatible with the non-labeling data class should be considered. Also, the most important challenge in some of the works done in this field such as [43,36] is that the proposed methods are applied to specific data and video frames, which have limitations. There are some of them, the most important of which is not covering a large number of the abnormalities. For example, the UMN dataset [32] and Hockey Fight [33] only include the fight anomaly. For this purpose, it is necessary to consider a dataset that includes a wider range of anomalies. In addition, some works such as [5,35] work on the basis of extracting features from the detected paths of the objects that do not consider the aspect of temporal and spatial sequence of the video frames. This leads to not identifying the certain abnormalities. Therefore, in order to further improve the anomaly detection systems, it is felt necessary to use the aspect of temporal and spatial sequence of the frames. It makes the frames share their learning between the adjacent frames and then reduce the processing cost.

According to the mentioned limitations, the points that are considered to solve these limitations in this article are as follows. The first point is that due to the fact that the data does not have a class label, in this research, the auto-encoders were used to encode and decode the video frames to overcome this limitation. The second point is that in the selection of the dataset, the current article has considered a dataset that includes a wider range of anomalies. This dataset includes three movement abnormalities of cyclists, skaters, motorbikes, small carts, people in wheelchairs, etc. The third point is that the different methods have been tried to provide more

improvement, and also the aspect of temporal and spatial sequence has been considered.

### III. PROPOSED METHODS

The methods used in this study are according to the point that when an unusual event happens, the newest video frames differ from the old frames. An end-to-end model is trained with a feature descriptor as well as a decoder-encoder that trains the frame input volume patterns in a manner that is inspired by [20]. This model is trained with the input video, so these video volumes consist only of frames with normal behavior. This work aims to reduce renovation error, which is the difference between the input video volume. After proper model training, the usual video is awaited to have a low renovation error. However, the video frames are expected to consist of frames with abnormal behaviors also high renovation errors. By limiting the error generated by each input value, the system can recognize when an unusual event happens [21, 22]. In general, the presented method includes three main steps: pre-processing, feature learning (which, in this study, three learning approaches is used), and regularity score.

#### A. Pre-processing

At this stage, the conversion of raw data into balanced and acceptable input for the model is done. To assure that the input frames are the same scale, each is extracted from the input video and resized to 100×100. Next, the pixel values are scaled between zero and one; for normalization, each frame is subtracted from its global average image. The average image is computed in the training dataset by averaging the pixel values in each position in each frame. The photographs are then made into grayscale versions to make them smaller. In order to have a single mean and variance, the photos are then standardized [23].

The input of the model in some of the approaches used in this research is the volume of the video, in which each volume contains 10 continuous frames with different steps. A lot of training data is needed because this method has a lot of parameters. Therefore, to increment the amount of the training dataset, the data in the time dimension is reinforced. To produce these volumes, the frames with step-1, step-2 and step-3 is connected. For instance, the first sequence of step-1 consists of frames (1,...,10), while the sequence of the first sequence of step-2 contains a numbered frame (1, 3, 5, 7, 9, 11, 13, 15, 17, 19) and the first sequence of step-3 includes frames (1, 4, 7, 10, 13, 16, 19, 22, 25,28). The input is now ready to train the model [23].

#### B. Feature Learning

As mentioned earlier, three approaches are used to creating regular patterns in the training videos. In the first approach, a standard convolutional automatic encoder (CAE) is used. After using CAE, it became clear that the problem with standard CAE is that it does not take into account the temporal aspect of the image sequence. Thus, it is not easy to identify certain abnormalities, such as a person moving faster than average. Therefore, in the second approach, an automatic encoder is used to learn spatio-temporal structures in the dataset. That is, instead of considering only one image at a time,  $n$  images are considered simultaneously. In the third approach, complex

LSTM cells are used for further improvement. LSTMs can be used to predict the next video frames. Below, each of the approaches and their details is described:

1) *Standard convolution automatic encoder*: According to its name, the automatic encoder contains two stages: encoding and decoding. By adjusting the numeral of encoder output modules to be less than the input, an automatic encoder has been employed for the first time to reduce dimensions. This model is trained using error replication in an unsupervised method and minimizing the renovation error of decoding outcomes from the original inputs. An automatic encoder can extract more advantageous information by choosing the nonlinear activation function over traditional linear conversion techniques like PCA. Here, these automatic encoders in the unsupervised method are used to detect the anomalies because a supervised learning method suffers from an imbalance [24].

However, automatic encoders are great for this status because these encoders can be trained on usual components and do not require marginal data. After the training, a feature view is provided for a section and compares the output of the automatic encoder with the input. If there is more difference, the more likely it is that the input contains anomalies. As mentioned, the automatic encoders consist of two sections: 1) an encoder that encodes the input data using a reduced representation and 2) a decoder that attempts to renovate the original input data from the reduced representation. The network is subject to restrictions that force the automatic encoder to learn a concise representation of the training dataset. It does this in an unsupervised manner and is, therefore, the most appropriate case for abnormalities [25].

Here, the used network structure is defined. The encoder includes two layers of convolution and two layers of MaxPooling. The decoder and encoder are connected by a fully connected layer. The bottleneck larger can be reconstructed the more information. The decoder includes two upsampling layers and two deconvolutions' layers. Fig. 1 shows the presented network structure. So, with using CAE, it becomes clear that the problem with standard CAE is that it does not take into account the temporal aspect of the image sequence. Thus, it is not easy to identify certain abnormalities, such as a person moving faster than average. Therefore, in the second approach, an automated encoder is used that can learn spatio-temporal structures in the dataset. That is, instead of considering just one image at a time,  $n$  images are considered simultaneously, which is explained in the next section.

2) *Spatio-temporal stacked frame encoder*: The proposed architecture presented in this approach includes two sections: 1) the automatic spatial encoder for learning the spatial structures of each frame and 2) the temporal encoder-decoder for learning the temporal samples of encoded spatial structures. The spatial encoder and decoder, as seen in Fig. 2, have two layers of convolution and deconvolution, respectively. Convolution layers are renowned for their superior object detection performance. Convolution in a convolution network primarily extracts the necessary features from the input image. By understanding image attributes,

convolution preserves the spatial link among pixels (employing tiny input data squares) [20].

Convolution operations are point multiplications between the local input areas and the filters mathematically. Suppose the several square input layers  $n \times n$  be available, followed by the convolution layer. If the  $m \times m$  filter is used, then the output of the convolution layer will be  $(n - m + 1) \times (n - m + 1)$ . During training, a convolutional network discovers the filters' values independently. However, before training, the parameters like the numeral of filters, the size of the filters, and the numeral of layers should be defined. More filters enable us to extract more image features, and the resulting network is better at spotting patterns in previously unseen images. A balance should be struck by not altering the number of very large filters because more filters need more computation time and use memory faster [26].

It is presumed that all inputs (and outputs) in a traditional feed-forward neural network are independent. However, learning the temporal dependencies between the inputs (in sequence tasks) is important. A word prediction model, for instance, should be able to gather data from previous inputs. The RNN functions identically like a feed-forward network, except that the input vector and the complete input history impact the output vector values [20].

Theoretically, RNNs could use arbitrary long sequences of information, and however, in reality, RNNs are constrained to a few steps because slopes have disappeared. On the other hand, as mentioned earlier, a problem with the standard CAE is that it does not take into account the temporal aspect of the image sequence. Thus, identifying specific abnormalities, such as a person moving faster than average, is not easily detectable [20]. Therefore, in this approach, an automatic encoder is described that can also learn the spatio-temporal structures in a dataset. In this approach, instead of considering just one image at a time,  $n$  images are simultaneously considered. The standard CAE considers input as [packet size, 1, width, height], and the spatio-temporal encoder considers input as [packet size, size, width, height]. In the third approach, the complex LSTM cells are used for further recovery. LSTMs can be used to predict the next frames of a video, and their details are given in the next section.

This architecture receives a trail of length  $T$  as an input sample as well as generates a renovation of the input sample trail. Each layer's outcome size is indicated by the numbers on the right. Every time, the location encoder collects one frame as input. It processes 10 frames, delivers the attributes encoded in 10 frames, and gives the encoder time to complete the encoding. Decoders mimic encoders in the reverse direction to reconstruct the volume of the video.

3) *Spatio-temporal auto-encoder with convolutional LSTMs*: In this section, the short memory model is used and add it to the third approach for further improvement. In other words, the second approach is developed by using LSTM. As mentioned in the second approach, the spatio-temporal encoder and decoder both include two layers of convolution and deconvolution. In contrast, the temporal encoder (in the third technique) adds three-layer long short-term memory

(LSTM) convolution. The LSTM model is popular for sequence learning and time series modeling and has demonstrated its performance in applications like speech translation and handwriting identification. Convolution layers are known for their high performance in object recognition [23]. The general architecture of the third approach's proposed method is depicted in Fig. 3.

In the previous section, a brief description of RNN was given. In this approach, as stated, a type of RNN is used: the forgetfulness gate, which is a return gate in the long short-term memory model (LSTM). With this suggested structure, LSTMs are prevented from dissipating or exploding post-propagation errors, allowing them to act on lengthy trails and be combined to gain higher-level information. Equations 1 to 6 and Fig. 4 provide the tabloid formulation of a common LSTM [23]:

$$f_t = \sigma(W_f \otimes [h_{t-1}, x_t] + b_f) \quad (1)$$

$$i_t = \sigma(W_i \otimes [h_{t-1}, x_t] + b_i) \quad (2)$$

$$\hat{C}_t = \tanh(W_c \otimes [h_{t-1}, x_t] + b_c) \quad (3)$$

$$C_t = f_t \otimes C_{t-1} + i_t \otimes \hat{C}_t \quad (4)$$

$$o_t = \sigma(W_o \otimes [h_{t-1}, x_t] + b_o) \quad (5)$$

$$h_t = o_t \otimes \tanh(C_t) \quad (6)$$

Equation 1 displays the layer of forgetfulness. Equations 2 and 3 are where new data is subjoined, and Equation 4 merges new and old data, while Equations 5 and 6 are moved from the current LSTM unit and apply what has been previously trained in the upcoming time step. The variable  $h_t$  indicates the latent state,  $x_t$  indicates the input sample, also  $C_t$  indicates the cellular state at time  $t$ .  $b$  is a bias vector, and  $W$  is a teachable matrix, and the symbol  $\otimes$  represents the product of Hadamard [23].

The convolutional long short-term memory model (ConvLSTM), a type of LSTM architecture, was first presented by Shi et al. [27] and more recently used by Patraikin et al., which presented in [28] and is used to predict the video frames. In comparison to conventional fully connected LSTM, ConvLSTM replaces its matrix operation with convolution. ConvLSTM requires less weight and provides a map with better spatial features by employing convolution for hidden-to-hidden and input-to-hidden connections. Equations 7 to 12 can be used to summarize the ConvLSTM unit's formulation [23].

$$f_t = \sigma(W_f * [h_{t-1}, x_t, C_{t-1}] + b_f) \quad (7)$$

$$i_t = \sigma(W_i * [h_{t-1}, x_t, C_{t-1}] + b_i) \quad (8)$$

$$\hat{C}_t = \tanh(W_c * [h_{t-1}, x_t] + b_c) \quad (9)$$

$$C_t = f_t \otimes C_{t-1} + i_t \otimes \hat{C}_t \quad (10)$$

$$o_t = \sigma(W_o * [h_{t-1}, x_t, C_{t-1}] + b_o) \quad (11)$$

$$h_t = o_t \otimes \tanh(C_t) \quad (12)$$

While these equations are similar to Equations 1 to 6, their input is in the form of an image. At the same time, the weight set for each connection is replaced by convolution filters

(symbol \* indicates a torsional action). This allows ConvLSTM to work with better images than FC-LSTM because it can propagate the spatial features (per unit time) through any ConvLSTM mode. Note that this convolution type also adds the optional hole connections to allow a unit to receive the previous information better. So, the previous model is developed by using complex LSTM cells. This proves that ConvLSTM is more efficient in video processing, and ConvLSTM can also be used to predict the next video frames [23]. In this study, 10 input frames are stacked in a cube. These frames placed on the cube are processed by 2 layers of convolution (encoder). Then, these are given to a temporal encoder/decoder consisting of 3 layers of LSTM convolution and 2 layers of deconvolution and the output frames are reconstructed. When initializing the model, the initial state vector for LSTMs should be created.

### C. Regularity Score

After model training, the input of experimental data into the trained model can be used to analyze the efficiency of presented models and examine whether these models can reduce the detection of false abnormal behaviors. Also, it examines whether these models can detect abnormal events correctly or not. For better comparison, the regularity score is calculated using the same procedure for all image frames; the only variation is in the model that was learned. The Euclidean distance between the input frame and the renovated frame is calculated using the renovation error of all values of pixels in the frame  $t$  of the video trail [23]:

$$e(t) = \|x(t) - fW(x(t))\|_2 \quad (13)$$

where,  $fW$  is the weight training by the spatio-temporal model. Then, the anomaly score  $s_a(t)$  is calculated by scaling

between zero and one. The regularity score  $s_r(t)$  can thus be readily calculated by subtracting the anomaly score by one [23]:

$$s_a(t) = \frac{e(t) - e(t)_{min}}{e(t)_{max}} \quad (14)$$

$$s_r(t) = 1 - s_a(t) \quad (15)$$

### D. Anomalies Detection

1) *Thresholding*: It's easy to tell whether a video frame is common or exceptional. Each frame's renovation error indicates whether it may be considered an abnormal frame. This threshold specifies how much of the sensitivity of behavior recognition system. Setting a low threshold, for example, makes the system more sensitive to scene events, which causes more alerts to be generated. Setting various error thresholds allows us to obtain the false positive and true positive values, which are then used to compute the area under the receiver operating characteristic (ROC) curve. Additionally, when the false positive rate is the same as the false negative rate, the equal error rate (EER) is gained [29].

2) *Events count*: As described in [20], the PersistenceID algorithm is utilized to simultaneously group the local minimums with a fixed temporal frame of 50 frames to reduce noise and meaningless minimums in the regularity score. Therefore, it is presumed the local minimum of 50 frames refers to the same unusual event. This is an advisable temporal window size because an unusual event must take at least 2-3s to make sense (videos are recorded at a speed of 24-25 frames per second).

Fig. 1. Proposed network structure.

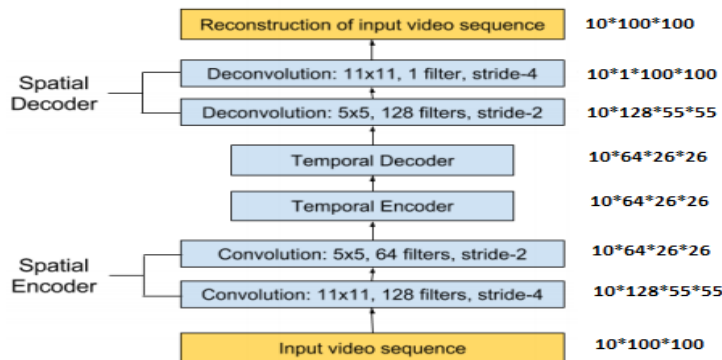

Fig. 2. Proposed network architecture for the second approach.

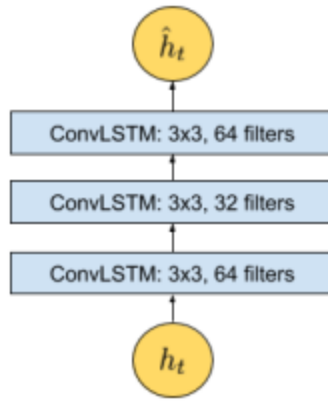

Fig. 3. Magnified architecture at Time  $t$  for the third approach where  $t$  is the input sample at this Time point. There are three layers of convlstm in the temporal encoder-decoder pattern.

Fig. 4. A generic LSTM's architectural structure. The blue line displays an optional hole structure that allows the inner state to see the state of the prior cell  $C_{t-1}$  for better decision-making (best seen in color).

#### IV. DATASET AND IMPLEMENTATION RESULTS

In this part, the implementation's details and its outcomes is described. The presented methods in this study have been compared with previous conventional methods on the UCSD dataset, which will be described below. This comparison has been evaluated and concluded using ROC curve criteria and EER rate. A scatter plot of sensitivity for a binary classifier model with a variable threshold is the ROC curve. In order to specify the abnormal frames, the levels of frame pixels are used. These two measurement values are defined below:

- Measurement at the frame level: If a single pixel of each frame is considered unusual, then this frame is considered abnormal.
- Pixel-level measurement: if the algorithm detects that at least 40% of the correct background pixels are covered by unusual pixels, and then the corresponding frame is considered as abnormal.

##### A. Dataset

In order to train the model and evaluate the presented method, the UCSD dataset is used, which has been used in almost all the articles presented in this field. Two separate open spaces were used to collect the two subsets of this dataset, Peds1 and Peds2, respectively. A fixed camera recorded both

subsets at 10 frames per second at a resolution of 158×234 and 240×360. The right background files in it allow evaluating the levels of the frame and pixel. Thirty-six videos were used for testing in the Peds1 subset, 34 videos for training in the Peds2 subset, 16 videos for testing and 12 videos for training. Fig. 5 displays an instance of frames that existed in this dataset.

In the proposed method, a pre-processing step is presented in which the conversion of raw data into a smooth as well as acceptable input for the model is performed. Every frame is taken out of the raw video and resized to 100×100 to verify that the input frames have the same scale. Next, the pixels' value is scaled between zero and one; for normalization, each frame is subtracted from its global average image. The average image is computed in the training dataset by averaging the value of pixels at each position in each frame. To lower the size, the images are then changed to grayscale versions. In order to have a single mean and variance, the output images are then normalized. Then, the input of the model in some of the approaches used in this research is the volume of the video, in which each volume contains 10 successive frames with different steps. Large amounts of training data are needed because this model has a lot of parameters. Therefore, to augment the length of the training dataset, the data in the time dimension is reinforced. To create this volume, the frames with step-1, step-2 and step-3 is connected [23].

### B. Evaluation Criteria

The presented methods in this research have been evaluated with some of the common methods that have been presented so far [30-38]. In order to evaluate the methods presented in the UCSD dataset, two criteria have been used to evaluate the accuracy of detecting the unusual behaviors: the pixel-level paragon also the frame-level paragon. The frame level paragon centralizes only on changes that predict which frame contains the unusual behavior without specifying where it occurs. A frame is regarded as abnormal by the frame-level paragon if it has at least one abnormal result and is not sensitive to the frame's location of the abnormal behavior. Also, the pixel level paragon is a measure that determines the temporal-spatial position of the frame. As mentioned, if at least 40% of the background pixels are correctly covered by pixels that the algorithm recognizes as unusual behavior, it will recognize that frame as unusual.

Then, by calculating the TP and FP rates, the ROC criterion can be obtained to analyze the algorithm's efficiency.

1) *Implementation Results:* As stated in the prior section, the images are selected at 100×100. Since none of the training videos in the Peds1 and Peds2 sets contains anomalies, half of the testing videos related to the Peds1 and Peds2 are randomly assigned for use in the training model. The remaining videos are used to test the samples. Each of the Peds1 and Peds2 are taught separately. 140248 normal samples and 35215 abnormal samples were extracted from the Peds1 set, and 63579 normal and 20638 abnormal samples were extracted from the Peds2 set.

Because abnormal samples are substantially fewer in number than normal samples, there may be an imbalance

problem in the class. To solve this problem by re-sampling, the number of the usual and unusual instances was tried to be in equilibrium. The presented method in this research is supported by a software interface called Keras [39], which supports the neural networks and convolutional using the Theano [40, 41] and TensorFlow software libraries [42]. This software interface is written in Python and can be run on CPU and GPU.

GHz Intel (R) Core (TM) i7 CPU and 8G RAM were used in the proposed approach. The convolutional network is implemented in GPU, and the graphic card used in this method is NVIDIA GEFORCE 840M. The results of the method are presented, as well as previous research, on Peds1 and Peds2 of the UCSD dataset in the following sections. The results obtained from the other methods are adapted from the relevant references in which these methods are introduced.

On the other hand, the system is trained by minimizing input volume renovation errors. The mini-batch with size 64 is used and every training session lasts up to 50 epochs or until the data validation loss stops after 10 successive epochs. The spatial encoder and decoder's activation function is chosen to be the hyperbolic tangent. Despite its ability to adjust, the re-modified linear unit (ReLU) is not used to verify the polarity of the encoding and decoding function since the activation values from ReLU are not very high. An example of the output and abnormal behaviors detected in the UCSD dataset is depicted in Fig. 6. This figure shows the output of identifying abnormal behaviors for the various methods presented in this study. Below, the results related to the error as well as the accuracy of the suggested methods are displayed. The methods presented in this research have been evaluated with some common methods presented so far [30-38, 43]The results related to the presented methods as well as previous studies, are displayed in Tables I and II of the UCSD dataset in Peds1 and Peds2, respectively.

Fig. 5. Examples of images in the UCSD dataset: The first row is Peds1, and the second is Peds2.

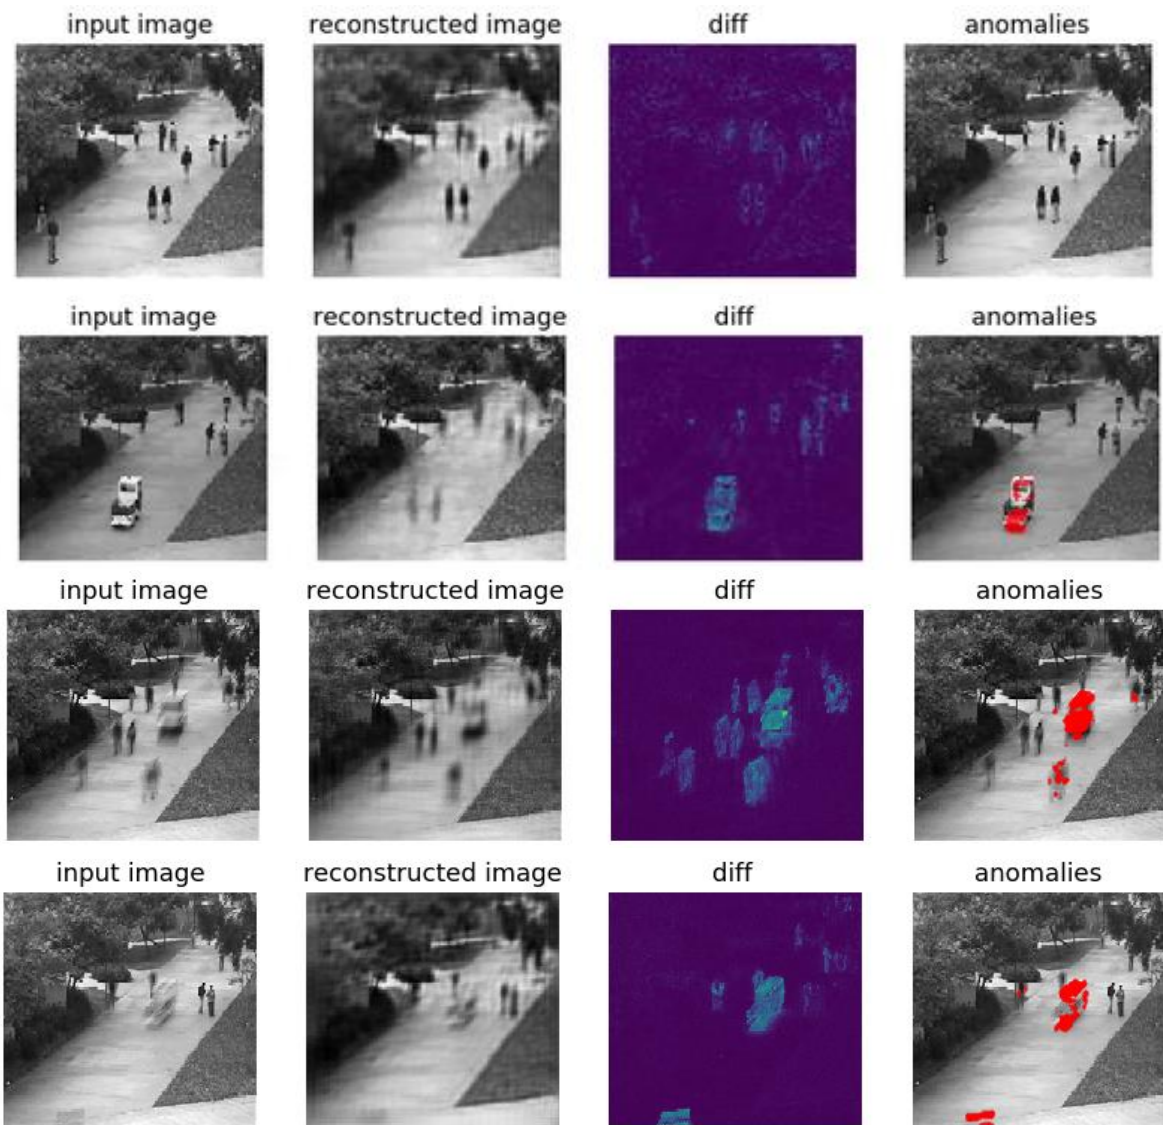

Fig. 6. Output of identifying abnormal behaviors for different methods.

TABLE I. ERR RATE IN THE PEDS1 SUBSET OF THE UCSD DATASET

Name of the author of the article	ERR rate at the pixel level	ERR rate at the frame level
Cheng et al. [31]	38.8	19.9
Cong et al. [32]	51.2	23
Adam [30]	38.9	23.6
Kim [35]	39.6	19.6
Kaltsa [34]	27	21.1
The first proposed method	49.7	33.1
The second proposed method	28.5	21.9
The third proposed method	27.5	21.1

TABLE II. ERR RATES IN THE PEDS2 SUBSET OF THE UCSD DATASET

Name of the author of the article	ERR rate at the pixel level	ERR rate at the frame level
Adam [30]	43.8	22.4
Kim [35]	31.1	22.4
Kaltsa [34]	26.9	25.1
The first proposed method	48.8	35.4
The second proposed method	27.9	20.2
The third proposed method	26.8	19.1

The first row is the output for standard automatic convolutional without the dense layer; the second row is the output for standard automatic convolutional with the dense layer; the third row is the output of temporal-spatial automatic convolutional; fourth row is the output for temporal-spatial automatic convolutional with LSTM.

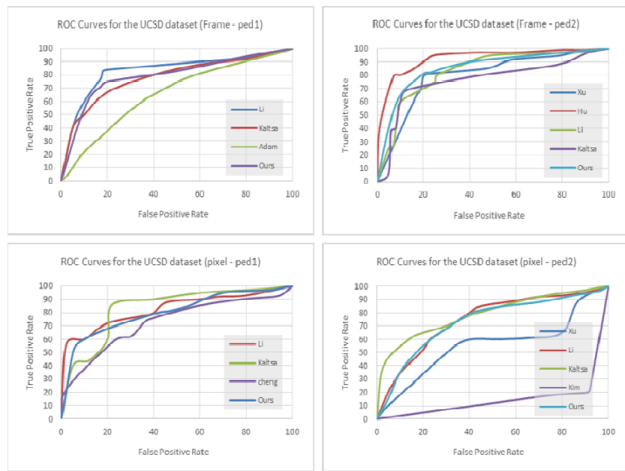

Fig. 7. UCSD dataset ROC curves at the pixel and frame levels.

The obtained results from the other methods are adapted from the relevant references in which these methods are introduced. The results of detecting abnormal behaviors are given in the figures presented above. The ROC curves in this dataset are reported in Fig. 7 for best presented method versus other methods. According to the image below, it can be seen that the presented methods have shown competitive performance in comparison with the previous methods presented in this field. In particular, the results obtained at the frame level in the proposed methods are very similar to the results of the best approaches introduced in this field. Compared to other methods, the suggested methods have a competitive efficiency at the pixel level. In general, it can be said that the methods presented in this study have a very competitive efficiency in the UCSD dataset with the results of other methods.

## V. CONCLUSIONS AND SUGGESTIONS

This study addresses the challenging issue of video anomaly recognition using deep learning. In this study, three approaches are presented. The anomaly detection is formulated as a distance detection problem in the spatio-temporal sequence. The best approach to solve this problem is to compound the ConvLSTM and the spatial feature extractor. In this approach, which works best, the ConvLSTM layer retains the benefits of FC-LSTM and is also appropriate for spatio-temporal data due to its inherent convolution structure. By using a spatial and temporal convolution feature extractor in the encoder-decoder structure, a trainable model has developed for detecting video anomalies. The presented models have the benefit of being semi-supervised; all that is required is a lengthy movie with just typical events in a still view. Notwithstanding the models' ability to detect unusual events and their power against existing noise, these methods might

produce more erroneous alarms than other techniques depending on how complicated the scene's activities are.

In the future, researchers can examine ways to improve the results of video anomaly recognition with active training; another direction is to consider using human feedback to update the trained model for better recognition and fewer false alarms. One solution is to add a monitored module to this system that will only work on the video segments that have been filtered by using the way which have described. After gathering enough video data, it trains a differential model for classifying the anomalies.

Faculty of Graduate Studies, Daffodil International University, Dhaka 1341, Bangladesh<sup>5</sup>

**Abstract**—This study presents a comparative analysis of different deep convolutional neural network (DCNN) architectures, including VGG19, NASNet, ResNet50, and MobileNetV2, with and without data augmentation, for the automatic detection of cataracts in fundus images. Utilizing hybrid architecture models, namely ResNet50-NASNet and ResNet50-MobileNetV2, which combine two state-of-the-art DCNNs, this research demonstrates their superior performance. Specifically, MobileNetV2 and the combined ResNet50+MobileNetV2 outperform other models, achieving an impressive accuracy of 99.00%. By emphasizing the efficacy of diverse datasets and pre-processing techniques, as well as the potential of pretrained DCNN models, this study contributes to accurate cataract diagnosis. Furthermore, the proposed system has the potential to reduce reliance on ophthalmologists, decrease the cost of eye check-ups, and improve accessibility to eye care for a wider population. These findings showcase the successful application of deep learning and image processing techniques in the early detection and treatment of various medical conditions, including cataracts, addressing the needs of individuals with diminished vision through ocular images and innovative hybrid architectures.

**Keywords**—Cataract detection; eye disease; ocular images; deep convolutional neural network (DCNN); hybrid architecture

## I. INTRODUCTION

The eye is a crucial component of the human body, but conditions such as cataracts can impede its function. Cataracts are characterized by the formation of a cloudy, impenetrable layer on the eye, typically as a result of aging. This can lead to a variety of vision issues, including difficulties with tasks such as reading, driving, and recognizing people. According to a report by the World Health Organization (WHO), a staggering 2.2 billion individuals will be affected by blindness or visual impairments by the year 2025, with 1 billion of these cases predicted to be preventable. Cataracts are a significant contributor to this trend, with an estimated 40 million people expected to lose their sight due to this condition.

In Bangladesh, cataracts account for 80% of eye problems affecting individuals over 30 years old, with approximately 120,000 new cases reported each year. This issue is particularly prevalent in rural areas where access to medical services and ophthalmologists is limited, resulting in a high number of cases of blindness. Early detection of cataracts can prevent complete blindness, but current detection methods are costly and require an ophthalmologist. Therefore, there is a need to develop an automated cataract diagnosis system to reduce the burden on

medical professionals, lower costs, and make eye care more accessible to a wider population.

Automated systems for identifying and assessing cataracts have been a subject of research for many years. Despite previous studies analysing fundus images for cataract detection and classification, their suboptimal performance was attributed to limitations in feature extraction and pre-processing methods. To enhance the precision of deep learning models, an extensive literature review was conducted, evaluating various aspects including datasets, pre-processing techniques, feature extraction methods, feature selection criteria, classifiers, and models. Our findings revealed the potential of deep CNN architecture-based models using image processing methods for detecting cataracts on fundus images. Surprisingly, few studies have utilized DCNN architecture-based models with transfer learning for cataract detection. Many researchers have investigated the use of deep convolutional neural network-based architectures, including VGG19 [1-2] and ResNet [3], for the purpose of detecting cataracts. These architectures, which fall under the category of deep neural network-based architectures [4], have gained widespread recognition in the fields of computer vision and imaging due to their ability to efficiently tackle tasks such as segmentation, detection, classification, and image analysis [5]. They comprise multiple layers of information processing stages. To identify cataracts from fundus images, researchers have utilized pre-trained deep neural network models via transfer learning techniques [6]. Moreover, other models such as MobileNetV2 and NASNet can be employed for image classification tasks, and are also suitable for the purpose of cataract classification.

This study aims to bridge a research gap in the field of AI-assisted medical diagnosis by focusing on the application of deep learning and image processing techniques for the automatic detection of cataracts in ocular images. Unlike previous studies, this research provides a comparative analysis of model performance, specifically examining the impact of data augmentation on various Deep Convolutional Neural Networks (DCNNs). By employing the ResNet50-NASNet and ResNet50+ MobileNetV2 ensemble model, which combines two state-of-the-art DCNNs, this study achieves a higher accuracy rate in detecting cataracts while maintaining efficient image recognition and classification. Furthermore, the proposed system has the potential to reduce the dependence on ophthalmologists, decrease the cost of eye check-ups, and enhance accessibility to eye care for a wider population. These significant contributions shed light on the successful application of deep learning and image processing techniques

for the early detection and treatment of not only cataracts but also various other medical conditions.

The key contribution of this study can be summarized as follows:

- 1) Demonstrated the effectiveness of diverse datasets and pre-processing techniques in improving the accuracy of deep learning models in medical image analysis and classification.
- 2) Highlighted the potential of pre-trained DCNN models in accurately identifying cataracts in fundus images.
- 3) Showcased the benefits of hybrid architectures in enhancing the accuracy of medical image analysis and classification.
- 4) Provided insights into the impact of data augmentation on the performance of deep learning models in medical image analysis and classification.

The structure of this paper consists of four sections. Section I serves as an introduction, while Section II includes a review of related work and a literature review of the challenges. Section III provides an outline of the methodology and materials utilized in the research. In Section IV, the results and discussion of the study are presented. Section V lists the limitations and future work. Finally, Section VI contains the conclusion along with a list of references.

## II. LITERATURE REVIEW

The following section provides a comprehensive literature review on the subject matter, examining relevant studies and scholarly works. Weni et al. [7] proposed a CNN-based system for cataract classification achieving an accuracy of 97% in 50 epochs using a basic CNN architecture with ReLU and SoftMax activation. Hossain et al. [8] developed a ResNet50-based method for cataract detection in fundus images. Zhou et al. [9] used the DST method with residual network to minimize overfitting and memory shortage problems and employed the ResNet architecture for cataract detection and grading. Zhang et al. [10] provided a multi-model ensemble method for automatic cataract detection using ultrasound images and achieved the highest accuracy of 97.5%. Nihal et al. [11] addressed the issue of overfitting in large datasets by utilizing residual network architecture. VGG19, ResNet50, and Resnet101 models were employed in [12] and [13]. Neha et al. [14] proposed a multi-class, multi-label cataract detection system utilizing fundus images from publicly available and private datasets. Similarly, Lakshmi et al. [15] and Nadim et al. [16] utilized VGG16 for cataract detection. Conversely, Khan et al. [17] utilized transfer learning approach based on a VGG19-based CNN achieving an accuracy of 97.47%.

Table I provides a comprehensive overview of relevant studies, their methods, models and datasets utilized in the context of eye disease. Several studies have recently explored cutting-edge technologies aimed at improving accuracy and efficiency in different fields. Among them, four papers [28-31] stand out for their innovative approaches showcase the latest technologies, such as saliency detection networks, EMG signals, ant colony optimization, and graph-based extreme learning machines. In recent years, there has been a growing interest in combining machine learning algorithms with optimization techniques to enhance the accuracy and efficiency

of models. Several recent studies [32-37] have investigated the potential of such combinations, as highlighted in the literature.

TABLE I. LITERATURE REVIEW OF RELEVANT STUDIES

Paper	Objectives	Method	Dataset Type	Source
[18]	Detect Cataract and Identify the Severity	DCNN	Fundus Image	ODIR, Kaggle
[19]	Detect Cataract and Non-Cataract	ResNet50	Fundus Image	ODIR, Kaggle
[20]	Detect Cataract and Non-Cataract	Resnet with DST	Fundus Image	Private
[21]	Detect Cataract and Identify the Severity	DCNN	Fundus Image	Private
[22]	Eye Disease Detection	VGGNet	Fundus Image	ODIR, Kaggle
[23]	Detect Cataract and Non-Cataract	CNN, VGGNet	Fundus Image	Private
[24]	Eye Disease Detection	VGGNet, ResNet, AlexNet	Fundus Image	Private
[25]	Detect Cataract and Identify the Severity	VGGNet, ResNet, AlexNet	Fundus Image	Private
[26]	Eye Disease Detection	VGGNet	Fundus Image	ODIR, Kaggle
[27]	Eye Disease Detection	VGG16, EfficientNet, ResNet, MobileNetV2	Fundus Image	ODIR, Kaggle

## III. METHODOLOGY

This section describes the tools utilized in the data collection process, data analysis, and the proposed deep learning method for classifying cataracts, specifically a multi-layer neural network architecture. The model is capable of distinguishing cataracts from fundus images. The architecture of the proposed system is illustrated in Fig. 1. The framework of the cataract detection system comprises several steps, including image acquisition, preprocessing, model implementation, and performance analysis. These steps are thoroughly described in the subsequent sections.

Fig. 1. Workflow of eye cataract detection.

### A. Dataset Properties

The present study utilized data collected from publicly available datasets, namely, the Ocular Disease Recognition [43] and Eye Diseases Classification [44], as well as datasets from Kaggle. Fig. 2 provides an overview of the dataset images used in the study. The figure presents a visual representation of the dataset, showcasing examples of fundus images included in the research. The aforementioned datasets comprised images of

normal and cataract eye conditions that were labeled by qualified authorities. The combined dataset utilized in this study included two classes, cataract and normal, and a total of 2000 images. The cataract class comprised 1000 images, while the normal class contained 1000 images that were appropriately labeled and split in a suitable ratio. In order to increase the amount of data in the dataset, image augmentation was applied. After augmentation, the total number of images in the dataset was increased to 5000. During the training phase, 80% of the data was utilized, with the remaining 20% reserved for the testing session. The combination of datasets and augmentation techniques utilized in this study provided a diverse and extensive dataset, which was utilized for the development and evaluation of an automated system for the recognition of cataracts in eye images.

Fig. 2. Dataset image overview.

**B. Data Pre-Processing**

Multiple fundus image datasets were acquired, and a pre-processing pipeline was implemented to ensure consistency and enhance the quality of the data. Fig. 3 presents a step-by-step visualization of the data pre-processing methods used in the study. The images were selectively filtered to include only cataract and normal images, while excluding others such as diabetic retinopathy, hypertension, pathological myopia, glaucoma, age-related macular degeneration, among others.

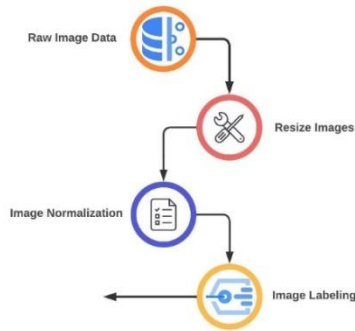

Fig. 3. Data pre-processing methods step by step.

To standardize the image sizes, the OpenCV library was utilized for resizing and normalization, involving subtracting the mean value from all pixels. Each image was appropriately labelled as either cataract or normal, and the dataset was then converted into an array format using NumPy, facilitating the subsequent training process.

To enhance the model's capacity to generalize to new images, augmentation techniques were applied, including

rotation and flipping. These techniques were implemented using the Keras framework [38]. Fig. 4 depicts the dataset splitting process employed in the study. The random augmentation process was applied to both the training and testing data to enhance the model's ability to learn with a larger dataset. The arguments used in the augmentation process are provided in Table II.

Fig. 4. Dataset splitting.

TABLE II. ARGUMENTATION FUNCTIONAL VALUE

Augmentation	Value
Rescale	1/0.255
Rotation	20
Flip	True

**Rescale:** Rescaling is a method of adjusting the range of values of a dataset by multiplying or dividing each value by a constant factor. It is commonly used in image processing, to standardize the data where pixel values are often represented as integers between 0 and 255, and rescaling the data can help to prevent overfitting and improve model's performance. Data augmentation rescaling by a factor of 1/.255 can be mathematically represented as:

Suppose, a 2D matrix

$$A = [[1, 0, 0], [0, 1, 0], [0, 0, 1]]$$

$$A\_scaled = A * (1/.255) \tag{1}$$

**Rotation:** Data augmentation rotation by 20 degrees can be mathematically represented as a matrix multiplication of the 2D matrix with the rotation value. Here,  $\theta$  is the data point after rotation.

Rotation value,

$$R = [[\cos(20), -\sin(20)], [\sin(20), \cos(20)]]$$

$$\theta = A * R \tag{2}$$

**Flipping:** Data augmentation with flip horizontal and flip vertical can mathematically be represented as a transformation matrix applied to each point in the image.

For flip horizontal, the transformation matrix value,

$$Fh = [[-1, 0, 0], [0, 1, 0], [0, 0, 1]]$$

$$A = A * Fh \tag{3}$$

For flip vertical, the transformation matrix value,

$$Fv = [[1, 0, 0], [0, -1, 0], [0, 0, 1]]$$

$$A = A * Fv \tag{4}$$

However, the testing data will also be used in conjunction with the first augmentation strategy. Fig. 4 illustrates the distribution of images in the test and train sets both before and after applying the augmentation techniques.

### C. Model Selection

In order to detect cataracts in fundus eye images obtained from ocular datasets, various model architectures were employed, namely VGG19, NASNet, ResNet50, and MobileNetV2. These architectures were selected to enhance the accuracy of cataract detection and improve the overall performance of the models. A detailed analysis of the method architecture is presented below for a better understanding.

1) *Visual geometry group architecture*: The Visual Geometry Group at the University of Oxford developed a CNN model called VGG19, known for its depth and use of small convolutional filters and max pooling layers [39]. In VGG19, feature maps are down-sampled by small 3x3 convolutional filters that focus on the most important features. To enhance the overall effectiveness of the model and address overfitting, we implemented several techniques, such as adding a dense layer with 512 neurons and a ReLU activation function, a dropout layer with a rate of 0.5, and a dense layer with 49 neurons and a sigmoid activation function. The model also includes a global average pooling layer, which reduces the spatial dimensions of the input by taking the average of the values in each channel, allowing the model to focus on the most important features and improve performance. Finally, we added a 1-unit dense layer with a sigmoid activation function [shown in Fig. 5(a)] to make the final prediction.

2) *Neural architecture search*: Neural Architecture Search (NAS) is a type of convolutional neural network developed by the Google Brain team [40]. The goal is to design an architecture with minimal human intervention and limited resources. In our study, we used a pre-trained NASNet model with ImageNet weights and added some additional layers. We introduced a fully connected layer architecture of 512 neurons with ReLU activation, followed by dropout with a rate of 0.5. Next, we added another fully connected layer of 49 neurons with sigmoid activation. We down-sampled the output using a 2D global max pooling layer and then extracted all-combinational features using a dense layer to make the final prediction [Fig. 5(b)].

3) *Residual network architecture*: The author in [41] is a convolutional neural network (CNN) developed by Microsoft Research, which has gained widespread popularity for image classification tasks. It is a deep neural network comprising 50 layers and is designed with a residual architecture. This model has produced outstanding results on various image classification tasks. It is referred to as a "residual" network due to its residual functions related to the input rather than learning the desired functions directly. This property enables the network to learn complex, highly non-linear functions more efficiently, resulting in much higher accuracy than traditional feedforward networks. In this study, we utilized the pre-trained ResNet50 model on ImageNet and added additional layers,

such as dropout with a rate of 0.5, a dense layer with 512 neurons, Global average pooling layers, and a single-node dense layer, as shown in Fig. 5(c).

4) *MobileNetV2*: [42] is an advanced neural network architecture designed to efficiently classify images on mobile and embedded devices. Developed by Google and introduced in their 2018 publication "MobileNetV2: Inverted Residuals and Linear Bottlenecks," this architecture represents an improved version of its predecessor, MobileNetV1. MobileNetV2 utilizes a combination of linear bottlenecks, inverted residual blocks, and short connection paths to reduce the number of computations required by the network. This results in a faster and more efficient model while maintaining a similar level of accuracy. Additionally, MobileNetV2 is highly versatile and can perform well on a variety of devices. It can easily be integrated with existing neural network architectures to build larger, more complex models. To further improve accuracy, we added some additional layers to the pretrained MobileNetV2 and fine-tuned it for cataract detection [Fig. 5(d)].

Fig. 5. Layer visualization of four different DCNN models.

5) *Ensemble learning with combined ResNet50+NASNet and ResNet50+MobileNetV2*: Ensemble learning is a popular technique in machine learning that combines multiple models to improve accuracy and reduce overfitting. Fig. 6 showcases the layer visualization of the ResNet50+NASNet hybrid deep convolutional neural network (DCNN). In this case, two powerful models, ResNet50+NASNet and ResNet50+MobileNetV2, are combined to create a hybrid model. By combining these models, the resulting hybrid model benefits from the strengths of each individual model, resulting in higher accuracy and robustness. Additionally, the non-trainable parameters in both models contribute to the overall performance by improving the generalization ability of the model. It is worth noting that the trainable parameters in both ResNet50+MobileNetV2 and ResNet50+NASNet are significantly lower than the total parameters, which is due to the use of transfer learning. It utilizes the strengths of each individual model and benefits from the non-trainable parameters to achieve state-of-the-art performance.

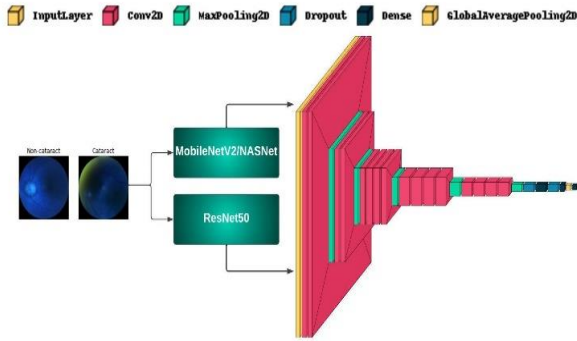

Fig. 6. Layer visualization ResNet50+NASNet hybrid DCNN.

#### D. Evaluation Metrics

This subsection elucidates the confusion metrics employed to gauge the efficiency of the models. The matrix provides insight into the number of true positives, true negatives, false positives, and false negatives, allowing for a more in-depth analysis of the model's strengths and weaknesses. Confusion matrix is widely used in various fields, such as medical diagnosis, fraud detection, and image classification, where the accuracy of the predictions is critical. By analyzing the confusion matrix, data scientists can identify the areas where the model is performing well and areas where it needs improvement, enabling them to fine-tune the model to achieve better results.

**Accuracy:** This is one of the evaluation metrics, represented by the ratio of correct prediction and the total predictions made.

$$\text{Accuracy} = (\text{TP} + \text{TN}) / (\text{TP} + \text{TN} + \text{FP} + \text{FN}) \quad (5)$$

**Sensitivity:** This metric is used to evaluate model performance by measuring its ability to detect positive prediction. It also called true positive rate (TPR) or recall.

$$\text{Sensitivity/Recall} = \text{TP} / (\text{TP} + \text{FN}) \quad (6)$$

**Specificity:** This metric calculate the percentage of true negatives which are actually negative. It can also be referred to as the True Negative Rate (TNR).

$$\text{Specificity} = \text{TN} / (\text{TN} + \text{FP}) \quad (7)$$

**Precision:** Precision is another evaluation element that calculates a model's performance by finding the ratio of Positives predictions and total number of Positives predictions. It measures the accuracy of positive predictions made by the model, particularly in the case of minority class predictions.

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \quad (8)$$

**F1 score:** F1 score is an alternative evaluation metric that combines precision and recall scores to determine a model's accuracy. It is reliable when the classes in the dataset are balanced and have a similar number of data points.

$$\text{F1 score} = (2 \times \text{Precision} \times \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (9)$$

#### E. Experimental Setting

During the experimental phase, the binary cross-entropy loss function and Adam optimizer were employed to train the

models. The batch size was set to 49, and the models underwent training for a duration of 15 epochs. The loss between the true and predicted labels was calculated throughout the training process to assess the model's performance. The execution environment for this experiment was Google Colab, which provided 25 GB of RAM but no GPU acceleration. The compiling parameters used in this experiment are summarized in Table III.

TABLE III. COMPILING EXPERIMENTAL SETUP PARAMETERS

Parameters	Value
Initial learning rate	1e-3
Optimizer	Adam
Loss	Binary cross-entropy
Epochs	15
Batch size	49
Executable Environment	Colab

#### IV. RESULT AND DISCUSSION

In this section, a comprehensive analysis and interpretation of the results obtained from the different models performed will be presented. The analysis will provide insights into the effectiveness of the models in the given task, and highlight the strengths and weaknesses of each approach. Additionally, the results will be evaluated using appropriate statistical methods to determine the level of significance and confidence in the findings.

The Tables IV and V represents the performance of Six different deep learning algorithms with and without data augmentation, namely VGG19, ResNet50, NASNet, MobileNetV2, and two combinations of ResNet50 with either NASNet or MobileNetV2, in terms of accuracy, specificity, sensitivity, F1 score, and precision. It can be observed from Table IV that MobileNetV2 achieved the highest accuracy score of 99.00%, followed closely by Combine ResNet50+MobileNetV2 with an accuracy of 98.75%. NASNet also performed well, achieving an accuracy of 98.50%. On the other hand, ResNet50 had the lowest accuracy among the algorithms, achieving only 72.50%. This indicates that ResNet50 may not be the most appropriate algorithm for the given task. However, it is important to note that accuracy alone may not be sufficient to evaluate the performance of these algorithms. Other metrics such as sensitivity, specificity, F1 score, and precision should also be considered for a more comprehensive understanding of their performance. Additionally, the choice of algorithm should be based on the specific requirements and constraints of the task at hand, such as computational cost, training time, and resource availability. Overall, based on the analysis of the provided table, it can be concluded that MobileNetV2 achieved the best performance in terms of accuracy, specificity, sensitivity, F1 score, and precision without data augmentation.

TABLE IV. PERFORMANCE OF THE DL ALGORITHMS WITHOUT DATA AUGMENTATION

Model	Accuracy	Specificity	Sensitivity	F1 score	Precision
VGG19	96.25%	95.48%	97.01%	96.30%	95.59%
ResNet50	72.50%	72.86%	72.14%	72.50%	72.86%
NASNet	98.50%	99.50%	97.51%	98.49%	99.49%
MobileNetV2	99.00%	99.50%	98.51%	99.00%	99.50%
Combine ResNet50+NASNet	97.75%	98.49%	97.01%	97.74%	98.48%
Combine ResNet50+MobileNetV2	98.75%	99.50%	98.01%	98.75%	99.49%

TABLE V. PERFORMANCE OF THE DL ALGORITHMS WITH DATA AUGMENTATION

Model	Accuracy	Specificity	Sensitivity	F1 score	Precision
VGG19	97.41%	98.01%	96.81%	97.39%	97.98%
ResNet50	88.65%	93.44%	83.83%	88.05%	92.72%
NASNet	98.51%	100.00%	97.01%	98.48%	100.00%
MobileNetV2	98.61%	99.80%	97.41%	98.59%	99.80%
Combine ResNet50+NASNet	97.81%	100.00%	95.61%	97.76%	100.00%
Combine ResNet50+MobileNetV2	99.00%	99.60%	98.40%	99.00%	99.60%

From the accuracy metric, it can be seen in Table V that MobileNetV2 performed with an accuracy score of 98.61%, followed by NASNet with an accuracy of 98.51% and Combine ResNet50+MobileNetV2 performed best with an accuracy of 99.00% with data augmentations. ResNet50 performed poorly with an accuracy of only 88.65%. The specificity metric shows how well the models can identify true negatives. It can be observed that all models except ResNet50 achieved high specificity scores, with NASNet and the combined models achieving a perfect score of 100%. The sensitivity metric shows how well the models can identify true positives. MobileNetV2 had sensitivity score of 97.41%, followed by Combine ResNet50+MobileNetV2 had the highest with a score of 98.40%. ResNet50 had the lowest sensitivity score of 83.83%. The F1 score, which is the harmonic mean of precision and recall, provides a balance between the two metrics. It can be seen that all models except ResNet50 achieved high F1 scores, the combined ResNet50+MobileNetV2 model achieving a perfect score 99.00%. Finally, the precision metric shows how well the models can avoid false positives. All models except ResNet50 achieved high precision scores, with NASNet and the combined ResNet50+NASNet model achieving a perfect score of 100%.

The provided Fig. 7(a-f) displays plots that depict the relationship between the training and validation accuracy of each deep learning model without data augmentation. The

graphs illustrate how the accuracy of each model changes as the number of epochs increase during the training process. It can be observed that for some models, such as MobileNetV2 and NASNet, the validation accuracy increases in a consistent and linear manner with the training accuracy. However, for other models such as ResNet50, the validation accuracy starts to plateau while the training accuracy continues to increase. These plots provide valuable insights into how each model performs during training and can be useful for further model optimization.

Fig. 8(a-f) displays plots that exhibit the relationship between the training and validation loss of each deep learning model without data augmentation. The plots demonstrate varying behaviors of the models during training, where some models exhibit a consistent and linear decrease in both training and validation loss, while others experience a plateau in validation loss and a continued decrease in training loss. These plots provide valuable information on the convergence properties of each model and can be used for optimizing the models' performance. Furthermore, analyzing the loss function during the training phase is a common technique used in evaluating the effectiveness of deep learning models, and these plots can provide insights into the models' learning dynamics.

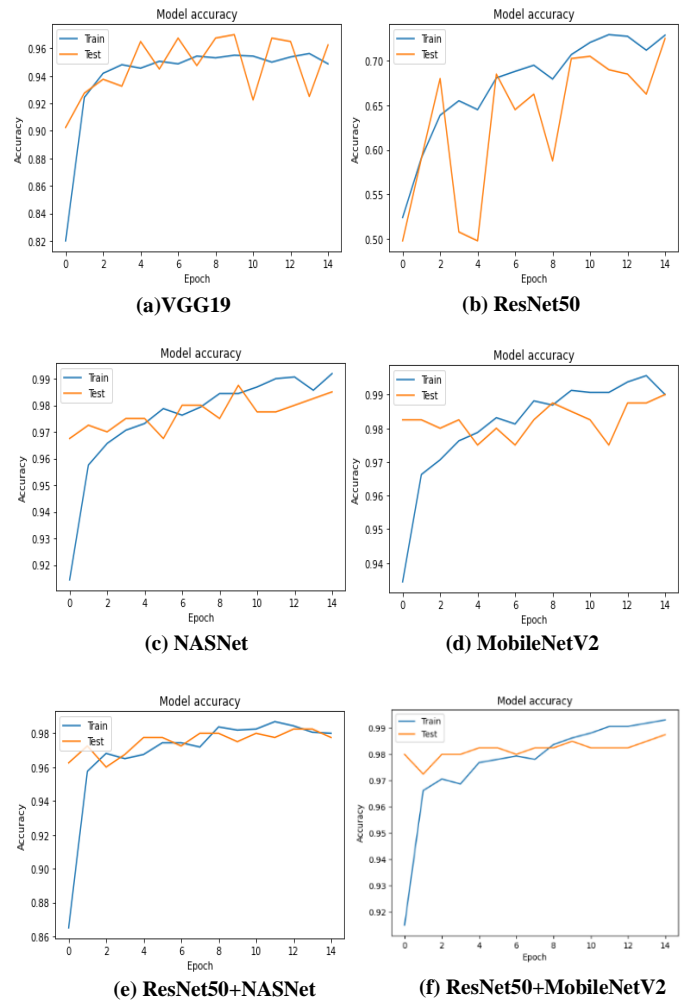

Fig. 7. (a-f) Plot showing the relationship between each deep learning model's training & validation accuracy without data augmentation.

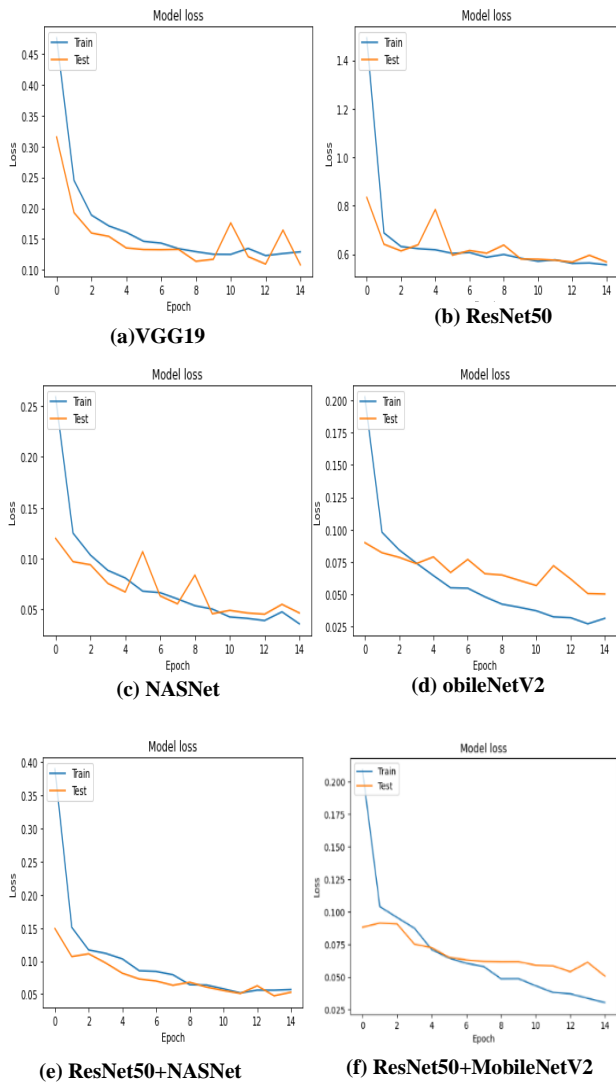

Fig. 8. (a-f) Plot showing the relationship between each deep learning model's training & validation loss without data augmentation.

Fig. 9 and 10 present plots that illustrate the relationship between the training and validation accuracy (Fig. 9) and training and validation loss (Fig. 10) of each deep learning model with data augmentation. Comparing the results of the two Fig. with those without data augmentation (Fig. 7 and 8) provides insights into the impact of data augmentation on model performance. The graphs in Fig. 9 show an overall improvement in the training and validation accuracy of all models with data augmentation, where the gap between the two accuracies is smaller compared to the previous figure. Moreover, the models' accuracy tends to increase faster during the initial epochs of training. In Fig. 10, the behaviors of the models' training and validation loss is similar to that without data augmentation, although the loss values are slightly higher. This observation suggests that data augmentation can help to improve model accuracy without increasing overfitting.

Overall, the comparative analysis of Fig. 7 and 8 with Fig. 9 and 10 suggests that data augmentation can help to enhance the performance of deep learning models in image

classification tasks. By introducing variations in the training data, data augmentation can help models to generalize better to new data and improve their accuracy. Furthermore, analyzing the changes in the loss function and accuracy during the training process with and without data augmentation can provide useful insights into the learning dynamics of deep learning models and can guide model selection and optimization.

The comparison of accuracy between deep learning architectures with and without data augmentation highlights a significant improvement in performance when augmentation techniques are applied. The combined ResNet50+MobileNetV2 model achieved the highest accuracy of 99.00% with augmentation, while without augmentation; the accuracy was slightly lower at 98.75%. Notably, ResNet50 demonstrated a substantial increase in accuracy with augmentation, scoring 88.65% compared to 72.50% without augmentation. Fig. 11 visually represents this comparative performance, emphasizing the positive impact of data augmentation techniques on the accuracy and effectiveness of deep learning architectures. These findings affirm the benefits of employing augmentation techniques for improved model performance in image classification tasks.

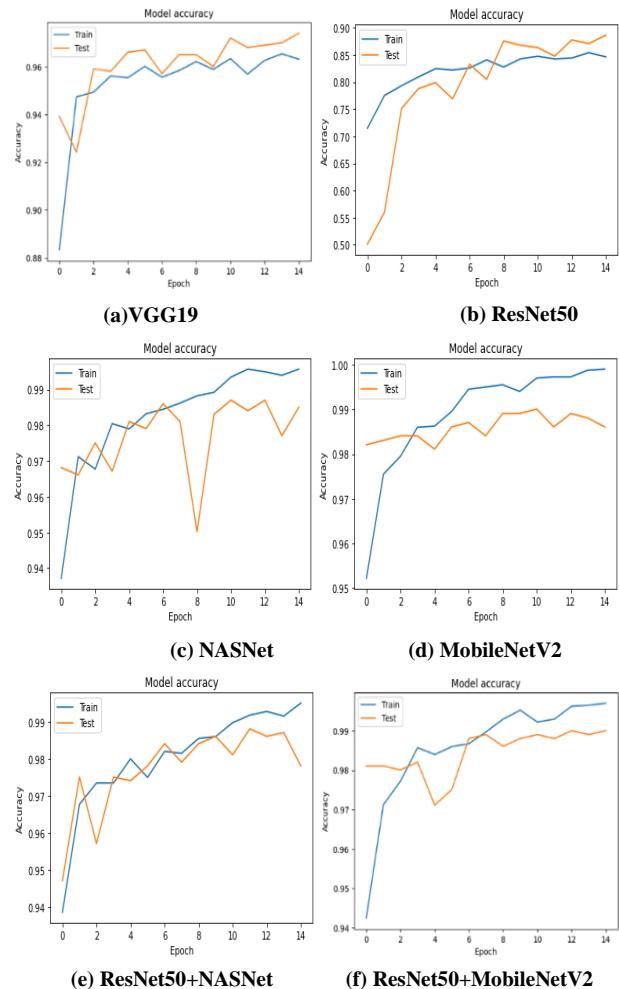

Fig. 9. (a-f) Plot showing the relationship between each deep learning model's training & validation accuracy with data augmentation.

Fig. 10. (a-f) Plot showing the relationship between each deep learning models training & validation loss with data augmentation.

Fig. 11. Comparative performance of DL architectures with and without data augmentation.

## V. STUDY LIMITATIONS AND SCOPE FOR FUTURE RESEARCH

Despite our efforts to conduct a comprehensive study, it is important to acknowledge certain limitations that should be taken into consideration when interpreting the results. First, the sample size in our study was relatively small, which may limit the generalizability of the findings. Additionally, the study was conducted within a specific geographic region, and the results may not be applicable to other populations or settings. Moreover, the data collection process relied on self-report measures, which may introduce response biases or inaccuracies. Lastly, the study design was cross-sectional, which limits our ability to establish causal relationships between variables.

Our study has opened up several avenues for future research in this field. Firstly, future studies could consider employing a larger and more diverse sample to enhance the external validity of the findings. Longitudinal studies could be conducted to explore the causal relationships between the variables of interest. Additionally, conducting similar research in different geographic regions or cultural contexts could provide valuable insights into the generalizability of the results. Furthermore, incorporating objective measures or alternative data collection methods would enhance the reliability and validity of the findings. Lastly, exploring the effectiveness of intervention programs or strategies targeting the identified variables could be an important area for future research.

## VI. CONCLUSION

Various deep convolutional neural network architectures were compared with transfer learning for the accurate classification of fundus images for cataract diagnosis. This study demonstrates the efficacy of deep convolutional neural network (DCNN) architectures for automatic cataract detection in fundus images. Specifically, MobileNetV2 and the combined ResNet50+MobileNetV2 models exhibit superior performance, achieving an impressive accuracy of 99.00%. The utilization of diverse datasets, data augmentation, and hybrid architecture models, such as ResNet50-NASNet and ResNet50+MobileNetV2, contributes to accurate cataract diagnosis. The findings highlight the potential of deep learning and image processing techniques in early detection and treatment of medical conditions, particularly cataracts. Furthermore, the proposed system shows promise in reducing the reliance on ophthalmologists, decreasing the cost of eye check-ups, and improving access to eye care for a wider population. This research underscores the successful application of innovative hybrid architectures and emphasizes the importance of leveraging pretrained DCNN models for accurate and efficient cataract diagnosis.

**Abstract**—Sustainable development in MSMEs is very important to encourage economic growth, improve the welfare of people, and ensure environmental sustainability. However, achieving sustainability in the MSME sector faces many challenges due to the complex interdependencies and dynamic interactions among various factors. The system dynamics approach makes it possible to model and simulate dynamic feedback loops, time delays, and nonlinear relationships between these factors. This paper provides an overview of the system dynamics approach and its suitability to address the complexities inherent in the MSME sector in its application to sustainable development. It explores the issues faced by MSMEs in achieving sustainable development and how the system dynamics approach models and analyzes the behavior of these MSMEs. These issues cover the dimensions of product development, technology and ICT inclusion, supply chain, business development, financial resources, and organizational support. This study was conducted on several case studies from various industries, namely the steel industry, agro-industry, craft industry, tourism industry, plastic molding, manufacturing, cosmetics, and digital companies; who come from various countries. From this study it was concluded that the system dynamics approach has significant potential to support the achievement of sustainable development in MSMEs, because it allows MSMEs to be able to effectively model and simulate the behavior of various factors that affect their operations, such as resource allocation, environmental impacts, and social considerations; proactively addressing sustainability challenges, adapting to changing market conditions, and contributing to broader socio-economic and environmental objectives.

**Keywords**—System dynamics; sustainable development; Micro Small and Medium Enterprises (MSMEs)

## I. INTRODUCTION

The agreement of the agenda on Sustainable Development Goals (SDGs) 2030 which aims to end poverty, social inequality, and protect the environment represented by three pillars namely economic growth, social inclusion, and environmental protection is still being pursued and implemented. One of the SDGs adopted by the United Nations which is goal 8 relating to decent work and economic growth, aims to promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all. This goal aims to promote development-oriented policies that support productive activities, decent job creation,

entrepreneurship, creativity, and innovation, and encourage the formalization and growth of micro-, small- and medium-sized enterprises, including through access to financial services.

Micro-, small- and medium-sized enterprises (MSMEs) are drivers of economic growth in many countries [1]. MSMEs have a very important role in economic development as a significant contributor to gross domestic production (GDP) and job creation [2]. Because the existence of MSMEs has a positive influence on development, the sustainability of MSMEs needs to be maintained, especially by the government. The factors that influence the sustainability of MSMEs are different, depending on the point of view of each institution.

The concept of sustainability is interpreted as a socio-ecological process that takes place dynamically and continuously, resulting in a system that works and can be applied for the long term; where the underlying thing is the concern of all parties about efforts to improve the quality of human life, to efforts to change behavior to meet sustainable living needs not only for the present but also for the future, especially related to the problem of worsening natural damage.

Sustainable development is an abstract idea with complex and involving goals in various aspects. Because MSMEs and their sustainable development are complex systems and involve many stakeholders and perspectives in seeing how MSMEs are affected and what variables influence them, it is necessary to map the complexity of the system comprehensively from a macro perspective. Knowing this complexity requires a tool and understanding of sustainable development. One tool that can be used to formulate and model sustainable development is a system dynamics approach. This approach is widely used because it can provide an overview of real-world phenomena and the interrelationships of various elements of the dynamic variable. By understanding the complex dynamics of MSMEs that are influenced by various interrelated factors such as market conditions, economic policies, and social dynamics; the system dynamics approach provides a structured framework for understanding and modeling these complex dynamics, helping stakeholders gain insight into MSME behavior and sustainability challenges. Sustainable development in MSMEs often involves handling feedback loops which can lead to a strengthening or balancing effect. System Dynamics can help identify and mitigate reinforcement loops that perpetuate unsustainable practices or amplify negative impacts. On the

other hand, System dynamics can also identify counterbalance loops that promote sustainable behavior and ensure long-term viability. The System Dynamics model can highlight points of influence where interventions can be strategically implemented to achieve sustainable development in MSMEs. By simulating various scenarios and analyzing the impact of interventions on system behavior, decision-makers can prioritize and design effective policies, practices, and interventions that lead to positive results. In addition to providing an analysis of long-term effects, System Dynamics can also provide an analysis of delays in achieving sustainable results. This capability helps MSMEs and policymakers evaluate the potential consequences of decisions and policies taken so that new scenario analyses and simulations can be carried out to identify strategies that can balance short-term and long-term goals.

Based on the complexity that exists in MSMEs and the capabilities that can be provided by system dynamics, the authors conducted a review of the existing literature related to the application of system dynamics in the MSME sector. This study is expected to provide insights to support sustainable development in MSMEs by focusing on understanding complex interactions, identifying points of influence for positive change, analyzing long-term effects, assessing policy interventions, promoting learning and capacity building, and increasing collaboration between stakeholders. In this paper, two terms are used in mentioning the object of study, namely Micro, Small, and Medium Enterprises (MSMEs) and Small and Medium Enterprises (SMEs) with the same purpose. The use of each term will be based on the literature studied.

## II. SUSTAINABLE DEVELOPMENT AND SDGs OVERVIEW

### A. Sustainable Development

Sustainable development is a concept that refers to meeting the needs of the present generation without compromising the ability of future generations to meet their own needs. It is based on the idea of balancing economic growth, social well-being, and environmental protection, to create a better future for all. Sustainable development involves a long-term approach to decision-making that takes into account the social, economic, and environmental impacts of policies and practices. It recognizes that economic growth is necessary for human development, but that it must be pursued in a way that is socially inclusive and environmentally sustainable.

Achieving sustainable development requires collaboration between governments, civil society, and the private sector. It involves making choices that promote economic, social, and environmental sustainability, and that are based on an understanding of the interconnectedness of these three areas.

### B. Sustainable Development Goals (SDGs)

The United Nations has played a key role in promoting sustainable development through the adoption of the Sustainable Development Goals (SDGs) in 2015. The SDGs are a set of 17 goals and 169 targets that aim to end poverty, protect the planet, and ensure prosperity for all. The 17 SDGs cover a range of economic, social, and environmental issues, including poverty; hunger; health; education; gender equality; clean water and sanitation; affordable and clean energy; decent work and economic growth; industry, innovation, and

infrastructure; reduced inequalities; sustainable cities and communities; responsible consumption and production; climate action; life below water; life on land; peace, justice, and strong institutions; and partnerships for the goals.

The SDGs are designed to be universal and apply to all countries, regardless of their level of development or income. They are also intended to be integrated and interconnected, recognizing that progress in one area can have positive or negative impacts on other areas.

Achieving the SDGs requires action at all levels, from local to global, and involves a range of stakeholders, including governments, civil society, the private sector, and individuals. The SDGs provide a shared vision, roadmap, and comprehensive framework for achieving sustainable development, and represent an important opportunity to address the most pressing of world challenges, including poverty, inequality, and climate change.

## III. SYSTEM DYNAMICS OVERVIEW

System dynamics models typically use stocks and flow to represent the accumulation and flow of resources or information within a system. They also incorporate feedback loops, which are the interactions between different components of the system that influence each other's behavior over time.

System dynamics refers to the study of the behavior of complex systems over time. System dynamics was first built by Forrester in 1969 with the aim of building models that can understand complex systems and states [3]. With system dynamics, we can analyze complex systems in a simpler way to get a complete system understanding, based on boundaries and scope discussion. Systems dynamics has been applied to various fields, including business management, engineering, environmental science, and public policy.

System dynamics involves building a computer model of a system that incorporates key components (i.e. stock and flow), relationships, and feedback loops. This model can be used to simulate system behavior over time and test various scenarios and policies. Data in system dynamics is not only in quantitative form but can also be in qualitative form, because some of the variables considered in the model may not be in quantitative form. System dynamics can facilitate qualitative forms by using dummies (quantifying qualitative data).

One of the key strengths of system dynamics is its ability to capture the nonlinear and dynamic nature of many real-world systems and to identify the underlying causes of persistent problems or unexpected outcomes. System dynamics models can help decision-makers to better understand the complexities of the systems they are dealing with and to make more informed and effective decisions based on data-driven insights.

## IV. MICRO, SMALL, AND MEDIUM ENTERPRISES OVERVIEW

Micro, Small, and Medium Enterprises (MSMEs) are important drivers of innovation and economic growth, and they can be a source of employment and income for low-skilled workers and marginalized groups. In recent years, there has been increasing recognition of the importance of supporting the development of MSMEs, particularly in developing countries

where they can play a critical role in poverty reduction and sustainable development. Governments, development agencies, and other stakeholders are working to provide MSMEs with access to finance, technical assistance, and other resources to support their growth and development.

Small and Medium Enterprises (SMEs) are entities that can support the economic development of a country [4], [5]. Meanwhile, specifically for developing countries, the context of Micro, Small, and Medium Enterprises (MSMEs) is more widely used because micro-enterprises continue to increase from time to time [1]. Based on EU recommendation, the European Commission defines micro, small, and medium enterprises based on several main factors namely the number of employees (staff headcount), sales (turnover), and profit (balance sheet total). A micro business is a company that has less than 10 employees, sales, and profit of at most EUR 2 million. While small business is a company that has employees less than 50 people, sales and profit of at most EUR 10 million per year. Finally, medium-sized businesses have fewer than 250 employees, and sales of at most EUR 50 million or EUR 43 million of profit per year. If the company has a larger amount than this provision, it can be categorized as a large company.

MSMEs have a critical role to play in achieving the SDGs, as they are a major source of employment and economic growth in many countries. However, they also face significant challenges in adopting sustainable business practices and contributing to the achievement of the SDGs. Efforts to support MSMEs in achieving sustainable development can help to accelerate progress towards the SDGs and promote a more inclusive and sustainable global economy.

### V. DISCUSSION ON SYSTEM DYNAMICS AND MSMEs

In the context of MSMEs (Micro, Small, and Medium Enterprises), system dynamics can help business owners and managers to understand the interdependencies between various components of their organization and how they interact over time. System dynamics can be used in MSMEs to model the behavior of the business and identify potential problems or opportunities. By analyzing the behavior of the business over time, system dynamics can also help MSMEs to identify areas where they can improve efficiency and performance.

Table I provides an overview of system dynamics applications in MSMEs/SMEs. The industries included are the steel industry, agro-industry, manufacturing, cosmetics, craft, plastic molding, and other non-categorized industries. The year represents the date of publication, so it may differ from the year the study was conducted. It shows that using system dynamics for sustainable development started many years ago and is still relevant today. The column 'Main Goals' shows the main purpose of using system dynamics for each study. The sections that follow are summaries of each of the studies and their implementation of the system dynamics approach.

#### A. Product Development

Improve product development planning is recommended as one of the strategies to support company performance. Based on that, research [6] identifies and analyzes the factors that influence the advantages and product development success in

the steel industry in Iran. The steel industry has a dynamic development structure because there are dynamics in the interrelationships between the elements that influence the quality and success of SMEs in this sector. Therefore, companies need to adopt an all-encompassing strategy related to creating and maintaining collaboration rather than concentrating on a single issue. Using system dynamics techniques in this study, it was found that the factors which influence the success and excellence of SMEs in the steel industry are organizational, managerial, human, marketing, and environmental factors. The interrelationships between variables commitment, mutual trust, and satisfaction in collaboration play an important role in the success and excellence of small and medium enterprises in the steel industry. The consequence is companies must be able to choose the right and compatible partners in terms of sales markets and work activities within the company structure to minimize non-functional conflicts.

TABLE I. APPLICATIONS OF SYSTEM DYNAMICS ON MSMEs/SMEs

Sector	Case	Paper	Year	Main Goals
Product development	Steel industry	[6]	In press	Product development
Technology - ICT	South African SMEs	[7]	2021	Digitalization
	Indonesian MSMEs	[1]	2019	Digitalization
	SMEs	[8]	2022	Digitalization
	SMEs	[9]	2019	Building Information Modeling (BIM) adoption
	SMEs	[11]	2019	Mobile analytics adoption
Supply chain	Malaysian agroindustry	[12]	2018	Performance measurement
	Indonesian agroindustry	[13]	2019	Performance measurement
	Agri-food SMEs in Kunming, China	[14]	2020	Home delivery agri-food supply chain
Business development	Manufacturing companies	[15]	2019	Crisis management
	Cosmetic company	[16]	2021	Sustainable strategy
	WoC-owned SMEs in the US	[17]	2022	Business sustainability
	Indonesian craft industry	[18]	2019	Business sustainability
	Plastic molding industry	[19]	2020	Risk management
	Digital companies	[20]	2021	Business model innovation
	Iranian SMEs	[21]	2019	Increased ROI
	Iranian SMEs	[22]	2021	Business management
Finance	Indonesian SMEs	[23]	2022	Bankability
	Malaysian SMEs	[24]	2018	Financial risk
Organizational	Mexican tourism industry	[25]	2023	Organizational resilience
	Developing country SMEs	[26]	2018	Industrial clustering

## B. Technology – ICT

In this era, digitalization is becoming increasingly important for micro, small, and medium enterprises (MSMEs) to remain competitive and relevant in a fast-paced business environment. Process transformation involves many interrelated variables, and digitalization is no different. To make it easier for SMEs to navigate, a model was developed using the case of SMEs in South Africa to understand the complexity and management of digitization [7]. This model uses a system dynamics approach by considering the dynamic interactions between the determining variables which are productivity, finance, and skill of the workforce. Productivity is shown by the Labor Productivity Factor which refers to the percentage of the number of skilled workers, skill of the workforce is divided into skilled workers and unskilled workers, and finance is represented by the flow variable, namely the expenditure variable which is the result of calculations from sales, marketing costs, digitization costs, and wastage contingency. The developed model provides knowledge that digitalization has an impact on increasing sustainability performance; this condition demands the need for digital empowerment. Besides that, efficient process control with the right technology, especially for a large enough scale of operation, requires automation to avoid unexpected things.

The process of digitizing MSMEs is complex and requires a holistic approach that considers various factors, one of which is the adoption of technology such as ICT inclusion. Reference [1] conducted research using a system dynamics approach in building MSMEs models with the involvement of ICT to increase MSMEs income, based on case studies in Indonesia. Because this is a macroscopic model, aspects other than ICT are also included, namely aspects of the market, MSMEs business stocks, government, and financing, which are considered to affect the increase in MSMEs income. From the causal loop diagram they developed, it is known that the ICT aspect is seen from the type of MSMEs whether it is micro, small, or medium level. For all levels, ICT capabilities are influenced by three components, namely digital operations, internet users, and e-banking services. Because ICT is an investment and is a long-term commitment, ICT inclusion requires adequate financial support from various parties, it can be personal, the government, or other parties funding. This means that the ICT capability at each level of MSME is influenced by these funding sources; as previously stated that ICT inclusion is aimed at increasing MSMEs income. Income is represented by the number of orders which is one of the variables in the market aspect. This linkage means that the more orders, the income of MSMEs business will be higher. Where each type of MSMEs business has its level of ICT capability, the number of orders will also be influenced by the MSMEs ICT capability itself. Meanwhile, the MSMEs business stocks and government aspects do not have a direct relationship with ICT aspects but are connected with market and funding aspects. From this model, the recommendation given is the need to increase the level of ICT capability in each type of MSME to increase their income.

ICT forms the foundation for digital transformation by providing the infrastructure and capabilities an organization needs to digitize its operations while facilitating social

interaction, content sharing, and networking among users can be done using social media platforms. For businesses, social media in general can provide an avenue for companies to engage with customers, build communities, conduct market research, and promote their products and services, in other words increasing market share. To identify the interrelationships of variables to increase SME market share due to the involvement of social media platforms, [8] utilizes one of the social media that is Instagram to study it using a system dynamics approach. From the developed model it is known that to increase market share, it is also necessary to increase engagement. The scenario model shows that engagement increases after including Instagram (social media) features in the simulation model. The increasing trend is found in the number of new customers, total business sales, and profit value. In other words, the use of social media in this case Instagram, helps SMEs in increasing their market share. The Instagram features considered in the simulation model are the number of comments, saves, views, likes, followers, and posts. This means that engagement can be increased by increasing the number of posts and interactive activities and maximizing the usage of Instagram (social media) features.

In the construction industry, system dynamics is used to explore BIM adoption in SMEs in developing countries [9]. Building Information Modeling (BIM) is a digital technology that has revolutionized the construction industry by enabling the efficient planning, design, construction, and management of building and infrastructure projects. The main benefit of BIM for SMEs is in facilitating information management, communication, and collaboration between supply chain actors [10]. System dynamics in this study is used to understand the dynamics and challenges faced in BIM adoption. The two conceptual causal models developed show a causal relationship between BIM adoption behavior at the organizational/project level and the industry level. Awareness, management support, benefits, and costs of investing in BIM are variables influencing at the organizational level while awareness, organizations, benefits, and government are influencing variables at the industrial level. From system dynamics modeling, policy insights are obtained for better BIM adoption to be executed in practice in SMEs.

The development of new digital technology that continues to move increasingly has an impact on SMEs. Research methods carried out by SMEs have also begun to utilize information technology, one of which is mobile analytics. Mobile analytics uses data from mobile apps, mobile websites, and other mobile platforms to gain insight into user behavior, preferences, and trends. Research [11] conducted a study on the impact of mobile analytics for SMEs using system dynamics simulations. From the model simulation carried out, insight was obtained that mobile analytics is the main key to competitive advantage in SMEs. With mobile analytics, companies can survive data vulnerabilities and can access real data for better organizational decision-making, which will ultimately build an agile organization, because organizations already understand how users interact with their business, identify areas for improvement, and make data-driven decisions to optimize and drive their business.

### C. Supply Chain

Being in a dynamic and competitive business environment, small and medium enterprises (SMEs) need to measure their supply chain performance to evaluate their business activities. While it is known that most SMEs do not have an effective performance measurement system because they do not identify their internal strengths and weaknesses but instead focus on external opportunities and threats. Related to this interest, [12] proposes a system dynamics approach to identify the main drivers of supply chain performance, develop strategies for performance improvement, and measure the impact of strategies on overall supply chain performance; by using case studies on companies engaged in agro-based industries in Malaysia. By using a system dynamics approach to model how information, actions, and consequences interact to produce a dynamic behavior strategy, it is known that lead time, product quality, and availability are the three main sequences of a company's strategy in winning customers. Purchasing domestic raw materials and production quality will help reduce lead time by providing products at any time to meet customer demand. It is the main focus of a responsive supply chain because it will improve company performance. Therefore companies need to have good collaboration with their supply partners so that they can integrate well to improve on-time delivery. The use of IT in planning delivery activities from suppliers and deliveries to customers is also important in a responsive supply chain. IT will act as a driving force for collaboration, process integration, and delivery speed. To achieve this goal, it is necessary to build a good information technology structure to support corporate responsiveness so that it can identify changes in the needs and desires of customers and other parties.

The development of other supply chain performance measurement models was also carried out using the case of the passion fruit agroindustry in North Sumatra Province, Indonesia. Study [13] identifies the factors that influence the performance of the passion fruit agroindustry supply chain for the sustainability of MSMEs and designed a supply chain performance measurement model using a system dynamics approach. Behavior on supply chain performance in building the sustainability of passion fruit agroindustry MSMEs is expressed as an increase in farmer production and income; and manufacture of essences and syrups. The key variables of the model are proven to affect the performance of the passion fruit agro-industry supply chain used to design sustainable MSME supply chain development scenarios, namely farmer skill and availability of land. Passion fruit production rate is influenced by the skills of farmers. The higher the level of passion fruit production, the more is passion fruit collector. Increasing collector passion fruit will increase extract industry production. This condition will increase waste products that can be composted and sold to farmers. The higher the compost production, the higher the efficiency of using the compost turn will produce environmentally friendly products. The consequence is an increase in the carrying capacity of the environment will have an impact on the availability of passion fruit land. With increasing availability of passion fruit land then it will increase fruit production rates. In the end, this condition will increase the income of SMEs and build the sustainability of the industry.

The agri-food supply chain is a multifaceted system that involves the production, processing, distribution, and consumption of agricultural products. To navigate these complexities effectively, stakeholders within the industry recognize the need for collaboration and cooperation. This prompted the formation of an agri-food supply chain alliance. Related to this problem, [14] developed a system dynamics model to investigate the stability of the cooperation of a "home-delivery-oriented agri-food supply chain" (HASC) alliance using a case study of an alliance built by an agri-food company in Kunming. HASC is a concept defined as an agri-food supply chain based on an alliance structure and collaborative strategy, which organizes agri-food SMEs with various competencies in the agri-food e-commerce (AE) market to provide services in meeting the daily needs of customers through home delivery. The results of this study indicate that the performance of the HASC alliance concerning time showed significant variation initially, but gained stability with the implementation of an appropriate control strategy. There was a decrease in the stability of the alliance in the early stages due to the running-in process between members and the process of adaptation of the alliance system to its internal environment. The model simulation shows that the stability of the HASC alliance cooperation is very sensitive to performance regarding strategies that control customer and environmental variations. Trust and market fluctuations have a great effect on the stability of membership and relationships. It is necessary to pay attention and focus on increasing mutual trust among members and controlling market fluctuations to minimize the risk of local markets. The model simulation results also show that for the HASC alliance, higher control strategy costs do not guarantee better stability. Therefore, it is necessary to control costs within a certain range that can help the HASC alliance to maintain stability and performance.

### D. Business Development

Within the scope of MSMEs business development, a system dynamics perspective can be included in the enterprise life cycle, crisis management, resilience, and business continuity management. Research [15] presents an analysis of the factors that lead to crises in small and medium enterprises (SMEs) and proposes a system dynamics model to explain the phenomenon. The model provides knowledge by explaining the mechanism of how during the crisis in SMEs, system dynamics help to predict the impact of various possible managerial decisions. This study was conducted in the Czech Republic and the model developed for the case of manufacturing companies. In this study, the crisis is categorized into 19 aspects, namely employees; customers/demand; inputs and supplies; regulations–bureaucracy–taxes; collecting bills; competition; owners; financial capital; capacity; natural disasters; technical breakdown; selling prices; quality of production; entrepreneur–personal crisis; thefts; placement of business; processes; outdated product; and legal entity. These aspects were analyzed through three stages using descriptive statistics, cross-tabulation, and association rules mining. The results of the analysis show several patterns underlying the crisis. Crisis classification is divided into two, namely crises in the internal environment and the external environment. Crises in the internal environment are related to employees, capacity, and

quality of production, while those in the external environment are related to input and supply, customers, and competition. By using a system dynamics approach, they develop a model explaining the relationship between the variables of the number of production employees and labor market; production capacity; production; outsourced product; stock of finished products; product quality and claims; inputs and supplies (including limitations, purchasing prices); demand (related to the price offered, competition and quality of previous investments, delivery delays, R&D and marketing); orders and their fulfillment; and revenues, costs, and profits. By testing and analyzing crisis scenarios, managers will gain knowledge and insight into the variables that affect aspects of a crisis, can predict the impact, and be able to determine actions to anticipate or resolve the crisis. This indirectly encourages sustainable development for the company and its business activities.

The system dynamics approach is also used in the Cosmetics Small and Medium Industries to develop a sustainable industrial strategy model that uses a case study of a personal care cosmetic company in Indonesia [16]. This strategy model is built from the integration of the system dynamics method and the open innovation approach. In this case, system dynamics is used to explore the complexity of SME problems that involve factors, actors, and dynamic relationships that affect output performance. While the open innovation approach is used to provide effective strategic choices in increasing output performance, both in terms of manufacturing operations; and economic, environmental, and social indicators. There are three strategic scenarios considered, namely self-lean improvement, limited collaboration, and comprehensive collaboration. From the simulation, it is known that in the self-lean improvement strategy, the productivity and profitability ratio shows a downward trend, including a decrease in demand, as well as an insignificant increase in improvement to environmental damage and human health. While limited and comprehensive collaborations demonstrated improvements in general depreciation and costs; cost savings; increased productivity and profitability; and reduced environmental and human health impacts. Limited collaboration shows a flatter slope of improvement compared to comprehensive collaboration which gives the best results. Comprehensive stakeholder involvement in an open innovation community effectively supports the achievement of the sustainability goals of SMEs. This support includes technical assistance from research and academic institutions, engagement of suppliers and distributors in lean and green improvement, assistance from cosmetics associations, and financial support from the government. Without such support, it is difficult for SMEs to grow and achieve sustainability, because there is a portion that is difficult to fulfill by the company itself. This collaboration is one strategy suitable for dealing with complex and dynamic sustainability challenges, with the takeover of resource support by external parties.

Studies on women concerning SMEs have also been carried out using a system dynamics approach. Study [17] conducted research to uncover the challenges faced by women of color (WoC)-owned SMEs in the United States. This research is

based on the finding that the majority of SMEs belonging to WoC failed in the first years of its establishment. This research focuses on the success of entrepreneurs (number of people) not on business success (number of entities) because people's (entrepreneurs) success is defined as business sustainability or profitable monetization events. This study's findings from the developed model suggest that access to capital (financing), social networks, and education and training are crucial factors that impact the success of women of color-owned SMEs. The variables that play a role in this model are opportunity rate, necessity factor, and desired financing rate. The opportunity rate is the number of WoC candidates, and the necessity factor is the number of WoC that startups out of need rather than an opportunity; which of these two variables will have an impact on the stock of aspiring WoC entrepreneurs. Meanwhile, the desired financing rate is the target as a goal gap modeling archetype which will affect the flow rate, namely the financing rate variable. The emphasis on these interventions as early as possible is intended so that WoC SMEs can survive in the early years of their establishment which is ultimately the sustainability of their business can be maintained.

The importance of the craft industry and its contribution to economic development and job creation prompted [18] to research the dynamics of budget allocation competition in this sector. This study uses the case of the craft industry in Indonesia and the system dynamics (SD) approach supported by the Balanced Scoreboard (BSC) framework and the ARCH-type model Success to Successful (StoS) approach. At the SD model development stage, the BSC framework is used as the basic development framework and the StoS approach of the ARCH-type model is used as a problem-solving concept. The system dynamics approach is used to model the interaction of the variables from the craft industry system, with budget allocations. From the model simulation, it is known that the budget allocation is not too significant in increasing SME revenue growth, so it is necessary to innovate budget allocation policies so that they have a significant impact on the development of SMEs. In those models, the exogenous variables are demand, price, and carrying capacity. Demand is related to changes in price as a form of response and carrying capacity affects the supply of raw materials. Ultimately the three variables have an impact on the production rates.

In another scope, [19] has studied the process of risk analysis and assessment using the integration of system dynamics techniques and Layers of Protection Analysis (LOPA) to improve risk management results. This research was conducted in the plastic molding industry in the case of fire risk assessment. The methodological approach integrated with this study is a structured risk assessment technique to obtain failure scenarios that may occur and assess the probability of an accident occurring, and system dynamics models are used to measure the interaction effects of various scenarios. From the developed SD model, it is known that the probability of events is associated with the risk of explosion in the supply system and the risk of spreading fire due to some engine malfunctions (engine aging effect). Scenario analysis in more detail considers the possibility of failure by using the time function. It turns out that if the period is longer, the possibility of damaged components becomes higher. As a

result, the system may fail to fulfill its security function. The probability value of the possibility of an explosion and its relationship to the possibility of spreading fire is a function of the values of several control variables, namely the frequency of maintenance and safety procedures. Through this study, it can be understood that the dynamics and uncertainties inherent in risk assessment and management in complex systems can be identified using a systems dynamics approach.

In the context of digital companies, which operate in technology-driven and rapidly evolving environments, business model innovation is essential for staying competitive and achieving sustainable growth. For that purpose, [20] developed a system dynamics model to increase evolutionary and innovative business models using an open innovation (OI) approach. In this study, the major influential factors of OI are identified as IP-sharing and key partners. These factors are concrete variables that exhibit positive feedback loops in the context of business model innovation (BMI). Positive feedback loops indicate that the company experiences growth and expansion when implementing OI. When more parties are involved, the amount of capital investment needed decreases. The company engages in collaboration with customers and suppliers. Extensive cooperation with partners will help companies identify more technologies and opportunities. This will encourage the achievement of sustainable growth. The simulation outcomes indicate that the implementation of OI has a substantial impact on company performance. This is based on the revenue-boosting effect resulting from accelerated product development and expanded market access facilitated by partnerships and IP sharing.

Iranian SMEs face many problems related to management. These problems often take root in strategic decision-making by managers. One such decision is related to the production department. Many of these companies provide production infrastructure at a high cost; however, they were unable to gain their share of the market, and eventually, they suffered losses. Related to these problems, [21] developed a model using the Schmid model as a basic model and a system dynamics approach aimed at evaluating existing policies to prevent capital loss. The developed model investigates whether customer networks in businesses without prior production have a role in increasing the return on investment (ROI). The model consists of 10 main elements, namely balance sheet, profit loss, machinery, production, customer, network, reputation, employee, innovation, and qualification. From the developed model, it proves that if the production unit is involved in selling the product to be produced, determines a network of loyal customers, and increases its production capacity, then the rate of return on investment under the same conditions will be five times higher than the original production plan. With this condition, the problem of return on investment (ROI) and capital losses can be overcome.

In addition to facing problems on the management side, SMEs in Iran also experience problems of uncertainty in their operating environment. Understanding their behavior patterns can help identify factors that contribute to success or failure. Reference [22] conducted a study focused on the development and application of a qualitative system dynamics model to analyze the behavior patterns of SMEs in Iran. The identified

behavior patterns are changes in the concept of technology due to a lack of market interest, an imbalance in the allocation of resources on the development of the technical and management side, and market development concerning the utilization of technology. From the simulation, it is known that the government needs to establish regulations that protect the flexibility and freedom of SME managers; provide marketing services and market research; and facilitate connections to the industry. It is also necessary to use a mentoring mechanism for coaching and leadership at all levels of SMEs, such as managing financial allocations, market planning, and improving the management structure and style. Facilitating administrative consulting provides a role to increase business area and workforce participation; reasonable control and can build a balance between the development of technological ideas and the capabilities of SMEs, especially in terms of human resources.

#### *E. Finance*

In the field of finance, a study was conducted to identify the driving factors and constraints faced in efforts of MSMEs upgrading. Using system dynamics modeling [23] reveals and shows how the dynamics of the transition of Indonesia MSMEs towards bankability during the COVID-19 pandemic. The focus of this analysis is MSMEs that initially have limited or no access to bank loans. From the developed model, it is known that several critical variables accelerate the status of MSME bankability from un-bankable to bankable, namely time to bankability (for entrepreneurial/micro enterprises), channel business, and the non-performing loan (NPL) of MSMEs. Extending the projected timeframe for entrepreneurial MSMEs to achieve bankability can expedite the process of transitioning un-bankable MSMEs into bankable ones more rapidly than the current circumstances. Building strong business channels or networks plays an important role in enabling MSMEs to recognize the benefits of financial services and foster closer relationships with stakeholders. This, in turn, accelerates the process of transitioning un-bankable MSMEs into bankable entities. Reducing the non-performing loans (NPL) of MSMEs can expedite the transition of un-bankable MSMEs into bankable entities compared to the present situation.

Investment decision-making is a critical process that involves assessing various financial risks associated with investment opportunities. In the current dynamic and complex financial environment, investors must have a comprehensive understanding of the potential risks and their impact on investment outcomes. Using the investment case on solar thermal heating installation in Malaysian SMEs, [24] undertook system dynamics modeling of financial risk as a valuable approach. The simulation results of the model show that government support (guarantee) and financial funding (soft loan) mechanisms have a major influence on investment decisions that lead to increased solar thermal installation capacity by Malaysian SMEs. Increasing the percentage of government support reduces the risk of Net Present Value (NPV). This means that government support plays a role in financial risk trends, and this should help increase installed capacity; because indirectly, it helps increase industry awareness to invest in solar thermal technology. With this model, policymakers can tailor appropriate policies for SMEs.

The right policies can contribute to risk analysis for other categories such as construction and operations.

#### F. Organizational

In the context of SMEs, which often have limited resources and capabilities compared to larger organizations, building resilience is critical to their long-term sustainability and success. Resilience refers to the capacity of an organization to effectively respond to and recover from disruptive events or shocks, such as economic downturns, natural disasters, or market fluctuations, and to adapt and thrive in the face of adversity. Research [25] studies the resilience and sustainability of SMEs by taking the case of the tourism industry in Mexico, through identifying the factors that need to be addressed to secure and promote their business. This study begins with conducting social network analysis (SNA) to obtain the latest understanding of organizational resilience in the SME literature. The results of SNA were then used to develop a conceptual model and simulate scenarios using system dynamics. The model simulation shows that organizational resilience is related to feedforward, buffering, and feedback control as critical factors that demand continuous coordination on the mechanisms between core operations and management. The need to stabilize organizational cycles by providing a buffer against fluctuations and weakening variations in existing capacity. These results can help managers rethink corporate resilience related to restructuring relations in operational and strategic units, improving autonomy, and strengthening strategic planning as well as feedback means.

Creating sustainable economic growth requires a synergistic and supportive ecosystem where companies, institutions, and stakeholders can collaborate, innovate and thrive. By clustering related industries and resources, it can stimulate economic development, increase competitiveness, and encourage innovation and entrepreneurship. In addition, within an industrial cluster, companies can collaborate and share resources, including energy-related infrastructure and technology. This can lead to optimizing energy systems and adopting energy-efficient practices. To gain insight into new economic dynamics related to industrial cluster growth and demand for energy intensity, [26] developed a model and simulated it using a system dynamics approach. The simulation results show the factors that affect growth cluster activities and productivity transaction cost barriers are energy intensity, energy efficiency, and energy conservation. Energy consumption patterns based on energy needs are stimulated by government policies through the development of cluster dynamics that utilize the innovations of energy intensity and efficiency. SMEs share a leading role in the development of innovative energy intensity. Which, the greater the energy efficiency, the smaller the calculated energy savings based on energy requirements. Therefore, cluster growth indirectly promotes technology spillover and higher GDP, and ultimately promotes economic growth. This will also provide macro benefits in the form of reduced energy demand and energy conservation.

System Dynamics, as previously discussed regarding its application to MSME sectors, offers valuable applications in various sectors. In product development, it enables modeling and optimization of product life cycles, demand patterns, and

decision-making for design and market entry strategies. In the technology and ICT domain, it helps in analyzing technology adoption, market dynamics, and risk management. In supply chain management, it facilitates an understanding of the complex dynamics and optimization of inventory, production, and distribution processes; optimizes performance and responsiveness. For business development, System Dynamics provides insight into market demand, competition, and growth strategies. In finance, it helps with financial forecasting, risk analysis, and policy evaluation. Lastly, in the organizational sector, it supports the modeling of decision-making, workforce dynamics, and organizational culture, assisting in organizational improvement and performance enhancement. Overall, System Dynamics offers versatile tools for understanding and optimizing the complex systems in the sector, enabling informed decision-making and sustainable growth.

## VI. CONCLUSION

From the review and description in the discussion section, it can be stated that the System Dynamics approach has the potential to make a significant contribution to achieving sustainable development in Micro, Small, and Medium Enterprises (MSMEs). Through the System Dynamics approach, MSMEs can effectively model and simulate the behavior of various factors that affect their operations, such as resource allocation, environmental impact, and social considerations; proactively address sustainability challenges, adapt to changing market conditions, and contribute to broader socio-economic and environmental objectives. This allows for a comprehensive understanding of the long-term consequences and feedback loops associated with different decisions and strategies.

The System Dynamics approach also enables MSMEs to identify points of influence and potential unintended consequences, facilitating informed decision-making toward sustainable development goals. By analyzing the causal relationships between different variables, MSMEs can develop effective strategies and promote a holistic perspective, keeping in mind the interrelationships of MSMEs in larger systems such as supply chains, technology adoption, local economy, and society. This perspective encourages collaboration, stakeholder engagement, and the identification of common goals and strategies for innovation, sustainable development, and resilience in the face of an evolving business landscape.

Despite the progress made in implementing system dynamics in various sectors, there are still important issues that need further study. In product development, research can explore integrating customer feedback and preferences into models to enhance product design and innovation. Regarding technology and ICT, further investigation is needed to understand the dynamics of emerging technologies, such as artificial intelligence and blockchain, and their implications for organizations. In supply chain management, research can focus on the integration of new technologies in supply chain networks. In business development, further studies are needed to incorporate competitive behavior. In the field of finance, research can study modeling the impact of changing regulations and global economic factors on the financial

system. Finally, in the organizational sector, research can explore the dynamics of organizational culture, leadership, and change management, and their impact on organizational performance and adaptability. Addressing these issues will contribute to a deeper understanding of System Dynamics applications and increase their effectiveness in addressing the complex challenges of achieving sustainable development in MSMEs.

#### ACKNOWLEDGMENT

The first author is grateful as a recipient of the Zamalah scholarship scheme from Universiti Teknikal Malaysia Melaka (UTeM). The authors would like to thank the Faculty of Information and Communication Technology and the Center for Research and Innovation Management of Universiti Teknikal Malaysia Melaka (UTeM) for assistance and support funding for this research.

**Abstract**—Agent technology has provided many opportunities to improve the human standard of life in recent decades, starting from social life and moving on to business intelligence and tackling complicated communication, integration, and analysis challenges. These agents play an important role in human health from diagnosis to treatment. Every day, sophisticated agents and expert systems are being developed for human beings. These agents have made it easier to deal with common diseases and provide high accuracy with less processing time. However, they also have some challenges in their domain, especially when dealing with complex issues. To handle these challenges, the domain has become characterized by distinctive and creative methodologies and architectures. This survey provides a review of medical multi-agent systems, including the typical intelligent agents, their main characteristics and applications, multi-agent systems, and challenges. A classification of multi-agent system applications and challenges is presented, along with references for additional studies. For researchers and practitioners in the field, we intend this paper to be an informative and complete resource on the medical multi-agent system.

**Keywords**—Artificial intelligence; agent systems; multi-agent systems

## I. INTRODUCTION

Agent-based systems are one of the most exciting and essential fields of research that appeared in information technology in the 1990s [1]. Multi-agent systems (MAS) are significant and active research areas in artificial intelligence (AI). They combine several agents that collaborate, cooperate, negotiate, and communicate in a shared environment to pursue specific high-level objectives.

MAS research contains a broad scope of technical issues, including how to develop MAS to help encourage actions in agents, design algorithms that enable agents to accomplish a set of objectives, knowledge exchange and communications between agents. Their various approaches can be used to handle a multitude of applications, including industrial applications, commercial applications, entertainment, and medical applications [2][3].

In recent years, the world population has grown significantly, increasing the requirements of people and organizations in many sectors. One of the most critical sectors is healthcare, which plays a vital role in our society. However, medical centers, such as hospitals and medical laboratories, need help with dealing with this expansion and organizing the tasks between their departments. Collaborative and integrated systems such as MAS can be considered flexible solutions to these kinds of issues. Different health areas have used these systems for many purposes, such as home health care, eHealth

services, patient monitoring, disease diagnosis, and other issues that can be managed using multiple agents.

Our motivation in this paper is to provide an overview of multi, single, and sophisticated intelligent agent technologies in the medical domain, allowing the reader to fully grasp this large field. To do so, we first provide a comprehensive view of the agent's systems by defining the agents and outlining some of their main features and applications. Second, we discuss AI and MAS for the medical sector and review various recent studies in this area. The main contributions of this paper are:

- A detailed survey was conducted on agent-based technology.
- The MAS applications in the healthcare field were covered in five different domains. These are management and organization, decision-making support, data management, remote care, and disease diagnoses.
- The most recent studies (published from 2015 to 2022) were reviewed and presented.

Overall, the MAS background, achievements, and research challenges have been discussed in detail in each corresponding section. The rest of this paper is organized as follows. The second section introduces artificial agents and their various applications. Sections III and IV provide a general discussion of MAS and their key characteristics and of AI in healthcare. Section V is a comprehensive discussion of recent studies in medical MAS in different subfields. Moreover, the reviewed papers have been summarized and are presented in tabular form. Section VI discusses the challenges of using MAS in this field, and finally, Section VII concludes the review.

## II. ARTIFICIAL AGENTS

The agents, their main characteristics, the diversity of environments, and the variety of agent types will be discussed in this section.

### A. Intelligent Agents

Multiple definitions of agents have been proposed in the literature, arising from various application-specific aspects of their use. The agent can be defined as “anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators,” as illustrated in Fig. 1 [4].

Fig. 1. Agents interact with environments through sensors and actuators.

Furthermore, a generalized definition of the agent was presented in [5]: The authors defined an agent as “an entity which is placed in an environment and senses different parameters that are used to make a decision based on the entity’s goal. Based on this decision, the entity performs the necessary action on the environment.” The preceding definition has four keywords that can be further expanded upon.

- Entity: This represents the type of agent. The agent can be software, hardware, or a combination of software and hardware.
- Environment: The agent's surroundings are referred to as the environment.
- Parameters: Parameters relate to the various types of data that an agent can get from its environment.
- Action: Each agent has the ability to take action that causes changes in its environment.

Table I presents some examples of agent types discussed in [4], as well as descriptions of their environments, actuators and sensors.

TABLE I. EXAMPLES OF AGENT TYPES

Agent Type	Environment	Actuators	Sensors
Taxi driver	Roads, other traffic, pedestrians, customers	Steering, accelerator, brake, signal, horn, display	Cameras, sonar, speedometer, GPS, odometer, accelerometer, engine sensors
Medical diagnosis system	Patient, hospital, staff	Display of questions, tests, diagnoses, treatments, referrals	Keyboard entry of symptoms, findings, patient’s answers
Satellite image analysis system	Downlink from orbiting satellite	Display of scene categorization	Color pixel arrays
Interactive English tutor	Set of students, testing agency	Display of exercises, suggestions, corrections	Keyboard entry

The agent’s environment can be physical, such as the control system, or computing systems, such as data sources and computing sources [6]. Moreover, Russell and Norvig (1995) recommended a categorization of environmental properties, as presented in Fig. 2.

- Accessible versus inaccessible: Accessibility refers to the ability of an agent to obtain comprehensive, precise, and up-to-date information from its environment. In this sense, the majority of real-world environments (such as the common physical world and the Internet) are inaccessible.
- Deterministic versus non-deterministic: A deterministic environment is one in which each action has a specific predetermined impact, and there is no ambiguity about the state that will emerge from that action.
- Static versus dynamic: Static environments are those in which changes can only happen due to the agent’s actions. On the other hand, a dynamic environment is affected by other processes and changes in directions that are outside the agent’s control.
- Discrete versus continuous: If an environment has a definite, limited number of activities and percepts, it is discrete. In contrast, a continuous environment, such as a moving agent in a physical environment, impacts the agent’s state by a continuous function.

The agent can be considered an intelligent agent when it meets its design objectives with flexible and autonomous action [7]. Flexibility has been summarized by [8] into three concepts. First, reactivity occurs when the agent can perceive and respond to its environment. Second, the agent shows a goal-oriented attitude, which is known as pro-activeness. Finally, there is social ability, allowing the agent to interact with other agents.

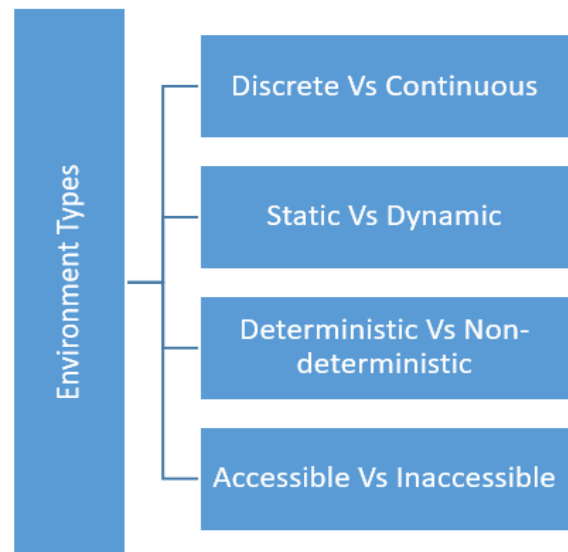

Fig. 2. Agent’s environment types.

### B. Applications of Agents

Agent applications can be variously categorized by the type of agent, the technology used to implement the agent, or the application domain. The applications, based on the domain type, have been classified by [2] as Industrial Applications, Commercial Applications, Medical Applications, and Entertainment. Fig. 3 shows some examples of these applications for each domain.

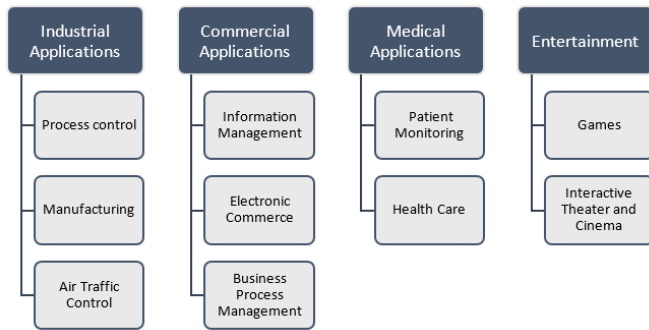

Fig. 3. Examples of some agent applications.

### III. MULTI-AGENT SYSTEMS

Generally, an agent can operate alone due to autonomy; however, the actual worth of agents can be increased when they collaborate with other agents. This has led to the creation of the MAS concept, in which two or more agents collaborate to solve a complex problem. Multi-agent systems can be defined as abstractions that can encapsulate the core of several software systems in varying degrees of detail [9]. The agents in these systems are autonomous entities that respond to input from humans and robots in a variety of possible contexts. Additionally, these systems accept information from various sources, including human and autonomous ones, and then respond with a computational strategy based on cross-referencing all the available data [10]. The MAS mainly consists of a collection of agents (Ag1, Ag2, etc.) and a set of potential environmental states in the form of a pair (A and Env) [11]. Fig. 4 presents the main characteristics of the MAS environment.

The MAS is an effective way to fix complicated activities because of its key characteristics, such as efficiency, relatively low cost, adaptability, and dependability [5]. Moreover, its effectiveness originates from the underlying distribution of resources, which divides a complicated task into several subtasks, each allocated to a different agent [12]. Additionally, the MAS can be classified based on features such as [5]:

- Leadership: The MAS can be categorized as leader-follow or leaderless based on the presence or absence of the leader agent (an agent that establishes objectives and tasks for other agents based on one primary goal).
- Mobility: An agent can be either mobile or static, based on its dynamicity. A mobile agent can move throughout the environment. Moreover, it can be hosted by other agents. On the other hand, a static agent remains in one place.

- Delay Consideration: Agents may face many delay sources while performing tasks. Based on this feature, the agents that take the delay sources into account have been classified as delay agents, while those that suggest that there are no sources of delay are known as without delay agents.
- Heterogeneity: MAS can be either homogeneous or heterogeneous. The heterogeneous MAS includes agents with a variety of properties, whereas a homogeneous MAS contains agents with the same features and functionalities.
- Topology: Based on the agents' locations and relations, the MAS can have either a static or a dynamic topology. In the former the agents' positions and locations remain fixed, while in the latter they continuously change; agents may move or leave, and they may be combined with other MAS.

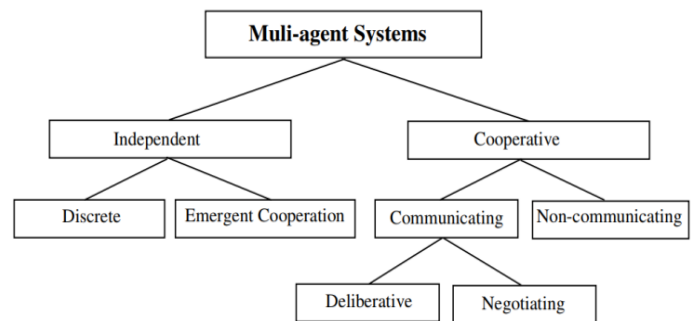

Fig. 4. Characteristics of the MAS environment [13].

### IV. AI IN HEALTHCARE

Recently, the use of AI has increased across all industries. As a result, AI has the potential to significantly change the field of medicine, thereby benefiting both patients and practitioners [14].

#### A. Benefits of AI in Healthcare Field

Artificial intelligence helps doctors streamline tasks, improve operational efficiencies, and simplify complex procedures. For instance, AI systems have significantly increased efficiency for radiography tasks, such as cardiac function assessment [15][16] and mammography interpretation [17][18].

In the field of pathology, there are still issues with how to quickly and automatically assess and determine an appropriate diagnosis from practical pathology images when the situation necessitates an immediate fix. Accordingly, AI has made significant progress in this field [19], and many scholars have improved blueprints in this regard, such as: [20], [21], [22], and [23]. Moreover, AI has made significant progress in diagnosing diseases, including several cancer types, such as gastrointestinal cancer [24], breast cancer [25], and colorectal cancer [26]. Another AI field, medical expert systems (ES), completes rather commonplace tasks in medical diagnostics [27]. The ES can be defined as “a computer program capable of automating decisions by asking questions and providing

answers or conclusions” [28]. Medical expert systems were created out of the need to assist with diagnosis and treatment of ailments. They can also inform and notify doctors and patients [29]. Examples of well-known ES include the following:

- MYCIN [30]: a computer-based system used to diagnose patients with bacterial infections.
- DERMIS [31]: a prompting system to diagnose skin disease.
- GIDEON [32]: a computerized system designed to diagnose patients with infectious etiology diseases.
- PNEUMONIA [33]: an improved system to diagnose community-acquired pneumonia.

In addition to diagnostic tasks, the recent development of AI has led to a significant improvement in the drug industry, in which it has played a role in the assembly and discovery of novel drugs [34][35].

### B. Drawbacks of AI in the Healthcare Field

Despite AI’s great benefits in health care, such as helping doctors diagnose diseases, saving time, and reducing costs, many studies have shown that defects can result from the employment of AI in the medical field, and some studies consider AI a disruptive tool [36]. For example, the authors of [37] showed multiple aspects of AI’s limitations:

- Data Collection Issue: It is known that some AI techniques, such as machine learning (ML) and deep learning (DL), require massive amounts of data to learn and produce accurate predictions. However, information accessibility in the healthcare sector may be challenging [38] since most are confidential.
- Social Concerns: The widespread use of AI always generates many concerns among health practitioners, as many believe they may lose their jobs and be replaced by AI tools and technologies.
- Clinical Implementation Concerns: Trust in AI-based medications is not completely possible due to the lack of empirical data that could validate these medications, which was an obstacle to successful deployment.

- Ethical Concerns: Due to the lack of universal guidelines for the moral use of AI and ML in healthcare, there is still debate about how far AI may be ethically used in the medical domain.

### V. MAS IN HEALTHCARE

Currently, MAS are used for many purposes in the medical field. These systems decrease the workload of healthcare professionals and gather data about a single patient from many specialties to enable them to make more accurate decisions [39]. Many other factors, as provided by [40], help to explain the benefits of using MAS in healthcare.

- MAS’s components could operate on various machines spread throughout many locations. Each agent may have access to some of the information needed to solve the issue, such as patient data stored in several hospital departments or across many hospitals, clinics, and surgeries. As a result, MAS could handle distributed problems.
- As the MAS can actively discuss how to divide an issue and how to distribute the necessary subtasks among them, MAS have the ability to decompose complex problems.
- Agents could provide information for patients and medical professionals because some agents are designed to gather and analyze data from various sources.
- Another crucial agent characteristic is proactivity—agents can perform actions that can be advantageous for the user, even when that user has not explicitly asked that they be done. For instance, if the agent is aware that the user is traveling abroad and that the user has experienced heart issues, the agent can determine which nearby medical facilities have a cardiology department in case the user urgently requires this information.

This study presents many previous works that have employed MAS in five fields of the healthcare domain, as shown in Fig 5. Moreover, Tables II and III provide a combined view of these studies by displaying the publication year, main field or domain, and research focus.

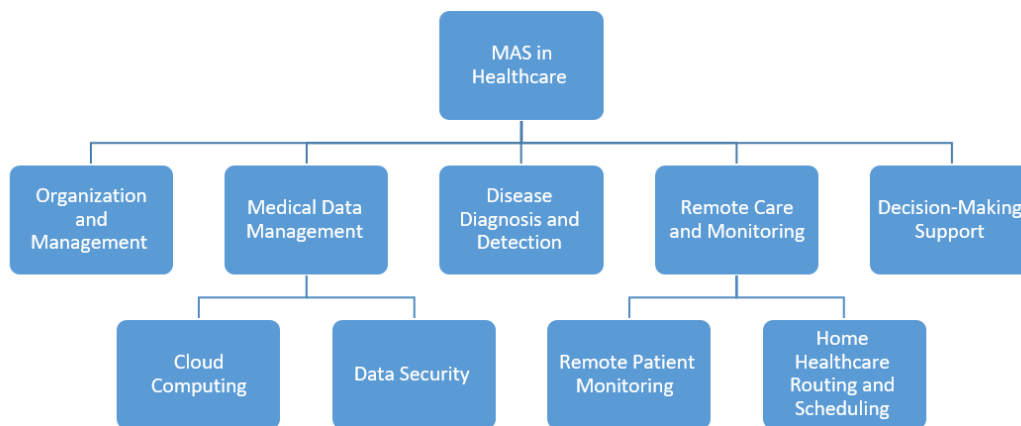

Fig. 5. The covered domains.

TABLE II. MAS FOR DIFFERENT PURPOSES

Main Field	Ref	Year	Research Focus	Main Field	Ref	Year	Research Focus
Orgnisation and Management	[41]	2015	Organization between hospital wards	Decision-Making Support	[49]	2022	Show the superiority over applied of a single-stage approach in the decision-making process.
	[42]	2015	Control patient flow and resource allocation		[50]	2017	Show the superiority over applied of a single-stage decision-making process in the healthcare delivery system.
	[43]	2019	Control patient flow for emergency status		[51]	2015	Use visualization techniques and MAS to improve IDSS
	[44]	2017			[52]	2020	Improve IDSS by use MAS to classify different types of cancer diseases
	[45]	2020	Scheduling of patients and resources		[53]	2021	Use MAS to simulate the surgery operating rooms to ensure timely decisions can be made"
	[46]	2020	Manage the maintenance workflow		[54]	2021	Use self-organizing multi-agent approach to extract probabilistic fuzzy rules from numerical data
	[47]	2020	Mange the unreasonable growth of medical expenses		[57]	2016	Home Health Care (HHC) Routing and Scheduling Problem

TABLE III. MAS FOR DISEASE DIAGNOSIS

Ref	Year	Disease Type					Reseach Focus
		Diabetes	Cancer	Heart Diseases	COVID-19	Other Diseases	
[74]	2020	*					Produce mobile application integrated within the CareWare architecture and the existing diabetes ontologies
[75]	2015		*				Enhance gene expression analysis through the automation of tasks related to cancer gene identification
[76]	2015		*				Identify genes that provoke triple negative breast cancer (TNBC)
[77]	2020	*					Investage the performance of machine learning algorithms based on the diabetes database
[78]	2020				*		Use MAS to simulate the spread of contagious disease during the COVID-19 outbreak
[79]	2021				*		
[80]	2020				*		Develop MAS to fight and handle COVID-19
[81]	2021				*		Adopt MAS to identify the plasma donors for COVID-19 patients
[82]	2020	*					Diagnosing diabetes using multi-agent data mining system
[83]	2016					*	Employ MAS for diagnosis of mental disorders
[84]	2015	*					Help type 2 diabetic patients
[85]	2017			*			Detect cardiovascular disease using Adaptive Neuro-Fuzzy Inference System and MAS
[86]	2021		*				Provide a customized support system for cancer survivors
[87]	2019		*				Adopt MAS for distributed classification tasks in cancer detection
[88]	2016			*			Design MAS for analysis and diagnosis of cardiac patients
[89]	2017					*	Adopt MAS for analyze and monitor diuresis
[90]	2019					*	Review the use of agents for sickle cell disease (SCD)
[91]	2022					*	Use MAS for disease detection using human eye images
[92]	2016					*	Use MAS for detection of autoimmune diseases

#### A. MAS for Organization and Management Problems

The special characteristics of MAS make them sufficient solutions for controlling and managing different kinds of organization and management problems, such as patient flow and services in the healthcare sector. Therefore, many researchers have mainly focused on this aspect.

A MAS-based system called MMAS (Medical Multi-Agent System) has been proposed in [41] to solve hospital challenges, such as collaboration between different units, elaborations of diagnostics, and the collection of patient information. Two layers of agents have been used: the super agent's layer and the Swarm layer. As a result, many services can now be completed remotely, such as patient appointments, patient registration, remote consultations, and others, which prove the effectiveness of the proposed system.

To control patient flow and emergency services, various agent technologies systems, such as multi-agent facility management systems, patient-centered MAS, and other systems have been proposed. For instance, a patient-centered MAS has been proposed by [42] to improve the ability to deal with unexpected issues, as well as reduce the costs and waiting time for patients, by supporting both the medical staff and the hospital managers and optimizing the distribution of resources. Therefore, the system architecture is constructed with two levels: patients from the higher level and shared resources from the lower.

In [43], emergencies such as natural disasters or accidents are handled by presenting a MAS that uses agents to direct the patient to the nearest hospital based on their current location. In addition, each patient is assigned a room more quickly than when using traditional methods. Similarly, the authors of [44] aimed to automate the prehospital emergency process using the multi-agent concept by categorizing the specialized care in keeping with the state of affairs at the right time for reducing patient mortality and morbidity. As a result, the proposed system provides intelligent decision-making capabilities due to the use of interactive agents.

The authors of [45] represent the outpatient clinic as a MAS and produce an intelligent real-time scheduler that schedules the patients and resources based on the current status of departments. Furthermore, all system entities are mapped to agent roles, either passive or active. As a result, performance measures such as waiting time, cycle time, and utilization notably improved.

To improve the maintenance management process, the authors of [46] suggested using MAS to shift from centralized systems into distributed systems that efficiently manage maintenance requests. Thus, a multi-agent facility management system (MAFMS) was conceptually proposed in which the agents belong to two categories: human resource agents and building components agents. The simulation results confirmed that the advantages of the proposed system outweighed the current systems.

Besides the well-known management problems in the healthcare sector, the increase in medical costs charged by public hospitals is another issue. Therefore, a MAS model was

proposed in [47] to provide useful suggestions for managing the immoderate increase in medical costs in China. The results suggested that these expenses can be reduced by using the community first-visit system and improving the government's financial investment.

#### B. MAS for Decision Making Support

The healthcare decision-making process is complex, risky, and essential, and it requires careful consideration of various factors. Therefore, it is crucial to have a tool that helps make accurate and correct decisions based on real-time data [48]. Recently, MAS have been pivotal in supporting and making decisions in the healthcare sector.

Due to the interrelated nature of decisions in the health field, [49] proposed an interrelated decision-making model (IDM) for an intelligent decision support system (IDSS) in healthcare that aims to produce an effective decision using MAS (known as IDM-IDSS-healthcare). Eight diabetes treatment datasets were used to conduct the experiments, and the results showed an improvement in decision-making efficiency with the proposed model, where the accuracy increased up to 56%.

For the same purpose, a CARE concept that uses MAS technology was introduced by [50] to support decision making in the healthcare delivery system. That system mainly consists of five stages; therefore, five corresponding agents have been developed: primary care agent, secondary care agent, tertiary care agent, quaternary care agent, and palliative care agent.

Visual data mining technology can play a vital role in a dynamic environment. For this reason, a new architecture was proposed in [51] to produce a visually intelligent clinical decision support system that uses MAS to resist nosocomial infections. The proposed agents are User interface, Coordinator, Data preparation, Data mining, Visualization, Evaluation, Knowledge integration, and Database. The evaluation of the proposed prototype noted some advantages, such as the presentation of the graphical data, which in turn reduced the complexity, and using agents guaranteed communication and cooperation between different modules.

The IDSS is a fundamental aspect of Computer Aided Diagnosis (CAD), and because of the need to construct decision-making systems that work in parallel, the authors of [52] suggested developing a CAD system that combines MAS with IDSS. The new system was proposed for cancer disease classification by gene expression profiles of DNA microarray datasets. Therefore, the contributing agents are Gene filtering, Diagnosis, Master, Inquiry, and Result. As a result, the proposed system has proved its practical ability to quickly classify different types of cancer diseases.

Because of the sensitivity of some hospital departments, such as operating theaters, making timely and well-reasoned decisions can be a critical issue that may require a tool. Thus, the emergency processes in the operating room have been modeled using an interactive support system decision embedded with MAS, in which the agents assist in allocating appropriate human and medical resources and planning elective surgery. Three types of agents are included: Supervisor, Service, and Coordinating. The simulation

confirmed that the proposed application could take full advantage of all the communication possibilities between the service agents [53].

Recently, efficiency and scalability have been considered essential attributes in decision support systems, for which the complexity of the dataset continues to grow. To handle dataset issues such as inconsistency, a Distributed Probabilistic Fuzzy Rule Mining (DPFRM) algorithm for clinical decision-making was proposed in [54]. The proposed algorithm used a self-organizing multi-agent approach to extract probabilistic fuzzy rules from numerical data. It used six agents (a1 to a6) that can communicate and exchange information with their neighbors. The results confirm that handling inconsistencies within the datasets by DPFRM can increase the accuracy and improve the training time due to the use of a parallel computer.

### C. MAS for Medical Data Management

Nowadays, a massive amount of data and information is generated in the healthcare field. Therefore, MAS have emerged as a powerful platform for managing and controlling how these data are exchanged.

The process of information exchange between a range of hospitals is a considerable challenge due to the lack of traditional information retrieval systems. Accordingly, the multi-agent concept has been adopted by the Statistics and Collaborative Knowledge Exchange (SCKE) system, within which the proposed MAS uses semantic search approaches to handle such problems. The pivot component is mainly hospital agents, where each agent represents an individual hospital. Thus, these agents can use the hospital database to accept and search queries to retrieve and exchange information. The system performance is examined, and its efficiency is proven by an improvement in the accuracy, regardless of the number of queries [55].

1) *MAS and cloud computing*: With the advent of mobile devices and cloud computing in different domains, the healthcare industry is shifting from direct care services to cloud computing. In addition to the reliability of cloud computing, MAS have proven to be effective in treating medical problems. For that reason, applications designed using cloud computing and MAS are expected to become more plentiful in the healthcare sector.

In [56], the authors suggested combining mobile cloud computing (MCC) with MAS to produce a Medical Mobile Cloud Multi-Agent System (2MCMAS), which takes advantage of both concepts to provide efficient care. The proposed architecture consists of agents grouped into two layers, Super-agent and Swarm agent, that interact in the environment, such as Expert, Search, Discharge, Access, Calendar, Doctor, Nurse, and Patient agents. The proposed system ensures flexibility by distributing knowledge between intelligent agents.

The wide spread of cloud computing has caused the emergence of different models, such as fog computing and edge computing, which will minimize end-to-end delays in the network. However, the fog-cloud-enabled network still suffers

from some issues for healthcare applications. Therefore, a Critical Healthcare Task Management (CHTM) model for ECG monitoring that uses MAS is proposed in [60]. The MAS is involved in managing the network from edge to the cloud and providing an efficient resource scheduling scheme. The MAS system consists of four kinds of agents: personal agent (PA), master personal agent (MPA), fog node agent (FNA), and master fog node agent (MFNA). As a result, network usage, response time, network delay, energy consumption, and instance cost are significantly reduced, as shown in the simulation.

Despite the effectiveness of cloud computing techniques, some researchers have reported the advantages of integrating MAS and Internet of Things (IoT) techniques to produce cloud-based applications to control medical data. Accordingly, the authors of [62] have designed a cloud-based system that collects and processes data to make accurate and timely decisions. The patient data are collected using three agents that form the mobile clients—Periodic analyzer, Manual handling, and Emergency agents—to be sent to the cloud module. The agent implementation used a pulse-oximetry sensor with Raspberry-pi hardware for the experiments. Thus, two simple periodic agents (a heart rate simple periodic agent and a SpO<sub>2</sub> simple periodic agent) were combined to represent a complex agent (Complex periodic agent - BPM and SpO<sub>2</sub>). The strengths of the model include scalability and the use of complex agents; however, the model suffers from hardware limitations.

2) *MAS and healthcare data security*: As mentioned in the previous sections, the MAS has been widely adopted to control the process of collecting, managing, and exchanging healthcare data remotely. However, medical data are private and sensitive and should not be accessed by anyone not specifically authorized to do so. To this end, many researchers have reported on how to protect data against external attacks.

In [64], a secure framework for remote healthcare systems was proposed to secure remote healthcare against some healthcare network attacks. The proposed architecture was constructed using two steps. The first step is to create and plan the environment's agents, which will collect the patient data from a sensor network and interact with each other; the contributing agents are Patient, Database, Ambient, Physician, and Nurse agents. The second step is to integrate the agents into groups according to the energy level of the corresponding sensors and the sensitivity of their data. To secure the sensor network, an Intrusion Detection System (IDS) is then instituted and monitored for each group. The experiment results prove the efficiency and effectiveness against the attacks frequently experienced by healthcare networks, such as Smurf, Buffer overflow, Neptune, and Pod attacks.

In healthcare organizations, the data are gathered from multiple sources and shared with other organizations or researchers using a common clinical data warehouse (CDW). However, preserving data privacy from source to destination remains a challenge. In response, the authors of [66] have proposed a multi-agent architecture for knowledge discovery for Evidence-Based Medicine (EBM), which is the modern standard for clinical decision-making known as Multi-Agent

Privacy Preserving for Medical Data (MAPP4MD). The agents are employed within three layers: local health organization agent (LHOA) in the local organization layer, broker agent (BA) in the coordination layer, and repository agent (RA) in the storage layer. The MAPP4MD evaluations prove that the privacy of medical records can be preserved at the source before they are integrated into a larger dataset, which resolves privacy issues that come with integrating medical data into a centralized data repository.

In [68], a novel MAS called the Access Control Security Model (IBAC) is proposed to maintain the security and privacy of eHealthcare data during the transmission phase. The system is mainly composed of three phases: User phase, Agent phase, and Information phase. The agent's role is concentrated in the second phase, in which it verifies user data and establishes an authenticated connection. The system workflow depends on several agents, such as a user interface agent, which is connected to the website or mobile application. The customer username and password are verified using an authentication agent. Finally, the user and server connection is established using the establishment agent and connection management agent. As a result, the proposed framework can provide secure, efficient, and easy eHealth services.

Similarly, the authors of [70] proposed MAS that combines both multi-agent concepts and fuzzy logic to monitor and protect data from unauthorized access and enable conversation between patients and professionals. The system consists of the following phases: Domain/ Information phase, Action/Computational agent, Customer phase, Operative phase, and Communication phase. The agents are employed as expert systems with their own functions. In addition, a healthcare database is used to keep all login credentials for authorized users and to retrieve and analyze data. The user interface agent determines the policies and procedures. Next, the users are validated using a user identification agent, and accordingly, the data transmission agent and a connection management agent establish an authorized connection. User authentication is performed by employing token-based authentication using fuzzy logic. The proposed architecture can prevent many types of outer attacks.

In [72], the authors took advantage of both MAS and Distributed Ledger Technology (DLT) blockchain to increase the protection and security of the eHealthcare databases. The multi-agent role is presented using two types of agents: the user interface agent and the DLT-based authentication agent. Moreover, the proposed system includes a server that is treated as a database to store the patient's health information. The user interface agent is responsible for defining the access rules, receiving the username and password, and establishing the connection between the users and the authentication agent. Then, the user information will be received by the DLT authentication agent to check whether it belongs to the users in the database. According to the verification process, it produces a digital certificate for the user. The research's conclusions will assist in directing the creation of new methods for processing data securely and effectively that combine AI and multi-agent-based systems supported by DLT technology.

#### D. MAS for Remote Care and Monitoring

Home health care (HHC) encompasses a wide range of health care services given to patients at home due to illness or injury. This reduces the cost of health structures. However, HHC's caregivers usually face routing and scheduling problems due to the increasing population. In order to deal with this kind of problem, many researchers have proven that using MAS can efficiently manage routing issues [57], [58].

In addition to routing problems, some patients reside in underserved or difficult-to-reach areas, and quick and accurate diagnoses are essential to starting therapy and addressing problem. Employing MAS to solve these kinds of problems has achieved notable success [65].

#### E. MAS for Diseases Diagnosis and Detection

A reliable, cost-effective, and quick computer-based medical diagnosis is still a challenge because medical diagnosis has always been a critical and complex topic [93]. The MAS approach helps to promote the creation of a readily scalable system. It implements scenarios for evaluating the functional condition of the human body, depending on the goal of the medical research and the available indications of the human body state [94]. Accordingly, many researchers have extensively employed and improved the MAS concept to detect, diagnose, and analyze various types of diseases. The MAS have proved their superiority over other traditional methods. This review investigates different studies related to those systems, including diabetes, cancer, heart diseases, COVID-19, and other diseases. Table III summarizes these studies with a focus on the publication year, type of disease, and the study's main objective.

### VI. CHALLENGES IN THE FUTURE

Despite the wide spread of MAS and their application, there are still some challenges involved in applying MAS, such as coordination between agents, security, and task allocation [5]. Moreover, the employment of MAS in the healthcare field may face the following challenges:

- Security issues: Due to the nature of MAS, sensitive data can be feasibly used by more than one resource, which may reduce the security and privacy of patients' data. There are some concerns about identity theft. Moreover, in the case of a geographically distributed environment, healthcare systems must interact with other systems. However, trusting the data provided from diverse resources can be a challenge.
- Implementation cost: Although it is assumed that MAS could reduce medical costs, some areas require more costs to employ AI techniques. For example, the instruments needed to collect data for AI systems can be quite expensive [14].
- Technical problems: Many issues may result from the development of MAS, such as those related to user expectations and acceptance, safety, and trust issues, as well as how to accurately manage the interactions between software agents, humans, and the preexisting healthcare systems [40].

- System reliability: The MAS needs to have a range of characteristics that gain users' trust. For example, the set of regulations is changed continuously, which requires more flexible and improved systems to adapt to these changes. Moreover, the MAS in this field are mainly used by many users with different technical abilities; therefore, the MAS needs to be easy to use and integrate with existing services.

## VII. CONCLUSION

This review sought to provide fundamental knowledge about multi-agent systems and MAS-related studies in the medical field. We have demonstrated how MAS has been applied to address various medical-related issues; starting with a brief description of the intelligent agents, their main characteristics, the diversity of environments, and the variety of agent types, followed by an introduction to AI and MAS in the medical field and an in-depth investigation of studies on the use of MAS in the medical sector from 2015 to 2022. Finally, the paper concluded with discussion of future challenges related to this topic. It is our hope that this review of medical MAS applications will be helpful to future researchers in this field.

**Abstract**—This study utilized the Unified Theory of Acceptance and Use of Technology (UTAUT) model to analyze the adoption and utilization of field incident management system (IMS) in a manufacturing organization. The study specifically focused on the role of behavior as a key factor in the adoption and utilization of incident management system. Data was collected through a survey of employees who had utilized the IMS system and the UTAUT model was used to analyze the data. The results indicated that behavior in the system significantly influenced the adoption and utilization of IMS. The study also found that the UTAUT model provided a useful framework for understanding the adoption and utilization of IMS, particularly the importance of performance expectancy, effort expectancy, social influence, and facilitating conditions. The study provides valuable insights for organizations looking to implement IMS and improve their incident management processes. It highlights the importance of building behavior in the system through appropriate user experience and user training. The findings of this study have important implications for manufacturing organizations seeking to enhance their incident management procedures through the adoption and utilization of IMS.

**Keywords**—UTAUT; field incident management system (FIMS); regression analysis; user intention and acceptance; system adoption; usage behavior; manufacturing; IMS; effort expectancy; performance expectancy; social influence; facilitating conditions; behavioral intention; ANOVA

## I. INTRODUCTION

Effective incident management is critical to the success of organizations in today's complex and fast-paced business environment. Incident management systems (IMS) have become essential tools for managing incidents and minimizing their impact on business operations. Among the various IMS options available, Field IMS has gained popularity [1]. However, the adoption and deployment of IMS in organizations can be challenging [1, 7, 13]. To understand the factors influencing IMS adoption and use, the Unified Theory of Acceptance and Use of Technology (UTAUT) paradigm has been widely used [1, 16]. This paradigm identifies four key drivers of technological acceptability and utilization: performance expectations, effort expectations, societal impact, and facilitating conditions [2, 3, 5, 12]. In recent years, behavior has been recognized as a significant factor in technology acceptance and use in business settings [3, 14, 17, 19].

This study focuses on the role of behavior in the adoption and utilization of Field IMS within organizations, using the

UTAUT paradigm. The objective of the study is to provide recommendations for organizations seeking to enhance their incident management practices and gain insights into the factors that influence IMS adoption and use. The review of literature highlights the importance of IMS and the UTAUT paradigm in the context of technology adoption and use within organizations. The research question and hypotheses are introduced, followed by a description of the study's methodologies, including data collection processes. The study's findings are presented, followed by a discussion of their implications. Finally, conclusions and suggestions for future research are provided.

This study significantly contributes to the existing knowledge on technology adoption and deployment in businesses. The findings have practical implications for firms aiming to implement Field IMS and improve their incident management procedures. The study emphasizes the role of behavior in the adoption and utilization of Field IMS and demonstrates the applicability of the UTAUT model in understanding this process.

The paper identifies and examines the factors that influence the adoption and utilization of Field IMS, providing valuable insights for researchers and managers. Its specific focus on field incident management sets it apart from other studies, addressing a specific need and offering insights that may not be applicable to broader technology adoption contexts. This contextualization highlights the necessity of the paper, filling a gap in the literature by exploring technology adoption within a specific industry or setting. Also, the paper sheds light on the relative importance of different components within the UTAUT Model, with facilitating conditions and user effort emerging as the most influential factors in Field IMS adoption and utilization. This finding underscores the significance of organizational support, resources, infrastructure, ease of use, user-friendly interfaces, and training programs in promoting technology adoption and usage behaviors.

The paper acknowledges the study's limitations, including the sample size and reliance on self-reported data, and suggests directions for future research. It calls for larger and more diverse samples to enhance the robustness and generalizability of the findings. Incorporating objective measures or observational data is recommended to improve the validity of results.

Fig. 1. The UTAUT model based on the original framework by [16].

The paper proposes exploring additional variables to enhance the predictive power of the UTAUT Model, such as perceived risk, trust, or personal innovativeness. This forward-thinking approach demonstrates the paper's commitment to advancing the understanding of technology adoption by incorporating relevant factors.

The value lies in its contextual focus, contribution to the theoretical understanding of technology adoption and usage behaviors, and identification of influential factors specific to field incident management. It also highlights the need for further research to enhance the model's performance and validate the findings in different contexts, ultimately improving the understanding of technology adoption and usage behaviors. The practical implications of the study's findings can inform decision-making, resource allocation, and technology acceptance and usage within organizations, leading to increased productivity, efficiency, and overall performance.

## II. RELATED WORKS

This review aimed to explore the factors affecting the adoption of Field Incident Management System (IMS) using the Unified Theory of Acceptance and Use (UTAUT) model as illustrated in Fig. 1. The UTAUT model is used to understand factors influencing the acceptance and use of information technology (IT) systems [3]. The findings of the literature review revealed that several factors influence the adoption and use of Field IMS [4].

According to the UTAUT model, performance expectancy, effort expectancy, social influence and facilitating conditions significantly impact the decision to adopt new information technology systems such as Field Incident Management System [5].

Performance expectancy refers to the degree to which a user believes that using an information technology system will improve their job performance. Some of the factors that contribute to performance expectancy include the system's perceived usefulness, ease of use, and compatibility with existing processes [6]. Effort expectancy, on the other hand, refers to the degree of ease associated with using an IT system [7, 8]. This encompasses factors such as the system's complexity, technical support available, and the user's perceived level of skill required to use it. Social influence, as a

factor in the UTAUT model, refers to how social factors such as colleagues and management can encourage or discourage users from adopting new IT systems such as Field IMS [8, 9].

Social influence can also include the opinions of external stakeholders and experts. Facilitating conditions are another important factor in the UTAUT model, which include both technical and organizational support aspects such as training, infrastructure availability, and resource availability, which can impact users' ability to adopt and utilize new IT systems [9]. Taken together, the findings from this literature review underscore the multifaceted nature of factors that influence adoption and use of new IT systems within organizations.

### A. Attitude, Behavior, And Usage of a Field Incident Management System

1) *Behavior and Intention to use FIMS*: Behavior is an essential factor in the adoption and usage of technology. The authors in [10] found that behavior has a positive effect on the intention to use Internet of Things (IoT) devices in e-Health. The study applied a modified UTAUT model to investigate the role of behavior in the adoption of IoT in a consumer context. The findings revealed that behavior positively affects the behavioral intention to use IoT devices, which is consistent with previous studies [10]. Therefore, behavior can be considered a critical factor in the adoption and usage of FIMS. Factors Influencing Healthcare Professionals to Adopt AIMDSS [11] conducted a study to investigate the factors that impact healthcare professionals' adoption of artificial intelligence-based medical diagnosis support systems (AIMDSS) using the UTAUT framework. The results showed that performance expectancy, effort expectancy, and social influence positively influenced the intention to use AIMDSS [11]. However, facilitating conditions did not show a significant effect on the intention to use. These findings suggest that perceived usefulness and ease of use are significant determinants of intention to use technology [12].

### B. Behavior Theory in Field Incident Management System

1) *Behavior and FIMS acceptance*: Behavior has been identified as a significant factor in the adoption of technology, including FIMS [16]. According to [13], behavior has a direct and positive impact on the acceptance of mobile medical platforms. Similarly, [10] found that behavior significantly influences the intention to use the Internet of Things (IoT) in e-Health. The study showed that behavior had a more significant effect on the intention to use the IoT than performance expectancy, effort expectancy, and social influence. In the context of FIMS, [14] found that behavior significantly influenced behavioral intention to use mobile health (mHealth) applications. The study found that behavior moderated the relationship between performance expectancy and behavioral intention. Similarly, [15] identified behavior as a significant factor in the acceptance of telemedicine in the Philippines. The study found that behavior had a positive effect on perceived usefulness and perceived ease of use.

2) UTAUT and Behavior: Several studies have investigated the relationship between behavior and the constructs of the UTAUT model [17]. For example, [11] found that performance expectancy, effort expectancy, and social influence were significant predictors of the adoption of artificial intelligence-based medical diagnosis support systems. The study also found that behavior moderated the relationship between performance expectancy and intention to use the system. Study [17] investigated the factors that influence consumer behavior in Internet of Things (IoT) products and applications. The study identified performance expectancy, effort expectancy, and social influence as significant predictors of consumer behavior in IoT. Similarly, [20] integrated the UTAUT model and the Task-Technology Fit (TTF) model to understand the acceptance of healthcare wearable devices. The study found that behavior moderated the relationship between performance expectancy and behavioral intention. The adoption of FIMS is significantly influenced by user acceptance. Behavior has been identified as a significant factor in the acceptance of FIMS, and it has a direct and positive impact on behavioral intention to use the system [18].

The UTAUT model has been a popular framework for studying user acceptance of technology. Several studies have investigated the relationship between behavior and the constructs of the UTAUT model, with behavior moderating the relationship between performance expectancy and behavioral intention [18, 19]. Therefore, behavior should be considered an essential factor when designing and implementing FIMS in various fields [19].

### C. UTAUT in Field Incident Management System

1) *Behavior and User Intention:* Research [10] found that behavior plays a significant role in the intention to use the Internet of Things (IoT) in e-Health. Similarly, [20] investigated the consumer acceptance of healthcare wearable devices and found that behavior is a vital determinant of user acceptance. The study [11] investigated the factors impacting the adoption of artificial intelligence-based medical diagnosis support systems (AIMDSS) and found that behavior, compatibility, and perceived usefulness are the most significant determinants of user adoption.

The literature reviewed in this study indicates that the UTAUT framework is an effective model for analyzing technology acceptance in the context of FIMS adoption. The studies identified several factors influencing the adoption of technology, including behavior, user intention, and acceptance. The findings of this literature review can be used to inform the design of FIMS systems and to develop strategies to increase user acceptance and adoption. The UTAUT framework can also be applied to other technologies not limited to manufacturing but also to other industries that has an incident management to gain a deeper understanding of the factors influencing technology adoption [20].

## III. METHODOLOGY

The aim of this study is to investigate the factors that influence behavior and its impact on the intention to adopt IMS. To achieve this, the study will use the UTAUT theoretical framework, which has been widely used to examine technology adoption in organizations [21]. Specifically, the study will focus on the relationships between the four main constructs of UTAUT, i.e., performance expectancy, effort expectancy, social influence, and facilitating conditions, and their relationships with behavior intention and use behavior, and how they affect behavioral intention and use behavior [22, 23, 24, 25, 26]. To collect data, a quantitative research method will be used, and a survey questionnaire will be designed based on the UTAUT model as shown in Fig. 2. The questionnaire will include items related to the four main constructs of UTAUT and behavior, which will be measured using a 5-point Likert scale. The survey will be distributed to employees who use IMS in their daily work.

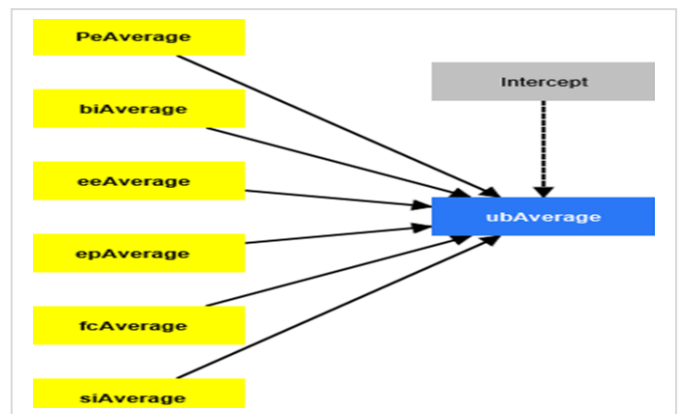

Fig. 2. Adapted model of UTAUT by [16].

To analyze the data, regression analysis will be used. Regression analysis is a statistical method that examines the relationship between variables and allows the researcher to identify the variables that have a significant effect on the outcome variable [27]. Regression analysis will enable the identification of the variables that significantly affect the intention to adopt and use IMS [28, 29]. It will be a use of a convenience sampling method to gather data from employees who use IMS in their daily work [30, 31, 32, 33]. A power analysis will be conducted to determine the appropriate sample size. Organizations that have implemented IMS will be surveyed, and the study will adhere to ethical standards. The results will have practical applications for organizations that are considering the adoption of IMS.

## IV. RESULTS

### A. Summary Coefficient

The researchers utilized the UTAUT Model to examine the factors influencing the dependent variable. The Smart PLS analysis yielded several interesting findings.

Regarding the predictor variables, it is clearly shown in Table I that siAverage demonstrated a non-significant positive relationship ( $\beta = 0.052$ ,  $p = 0.584$ ) with the dependent variable. This suggests that the social influence factor may have a weak

impact on the outcome. Similarly, eeAverage exhibited a non-significant weak positive relationship ( $\beta = 0.122$ ,  $p = 0.210$ ), indicating that the effort expectancy factor may not significantly affect the dependent variable. On the other hand, PeAverage displayed a marginally significant negative relationship ( $\beta = -0.186$ ,  $p = 0.053$ ) with the dependent variable. This implies that the performance expectancy factor may have a weak negative influence on the outcome, although further research is needed to confirm this relationship. Two variables, fcAverage and epAverage, showed significant positive associations with the dependent variable. fcAverage had a moderate positive relationship ( $\beta = 0.223$ ,  $p = 0.021$ ), suggesting that facilitating conditions may play an important role in shaping the outcome. Similarly, epAverage exhibited a moderate positive relationship ( $\beta = 0.246$ ,  $p = 0.013$ ), indicating that effort expended by users may significantly impact the dependent variable. Lastly, biAverage and the intercept term did not significantly affect the dependent variable, as indicated by their non-significant coefficients ( $p > 0.05$ ).

TABLE I. SUMMARY OF COEFFICIENT

Constructs	Unstandardized coefficients	Standardized coefficients	SE	T value	P value
siAverage	0.045	0.052	0.082	0.550	0.584
PeAverage	-0.166	-0.186	0.085	1.961	0.053
fcAverage	0.174	0.223	0.074	2.344	0.021
epAverage	0.245	0.246	0.097	2.521	0.013
eeAverage	0.102	0.122	0.081	1.262	0.210
biAverage	0.004	0.005	0.085	0.051	0.959
Intercept	2.678	0.000	0.815	3.286	0.001

### B. Summary ANOVA

The ANOVA results provide valuable insights into the overall model fit and the significance of the regression. The total sum of squares indicates the total variability in the dependent variable, which was found to be 10.222. The degrees of freedom (df) associated with the total sum of squares are 99.

The error sum of squares represents the unexplained variability in the dependent variable, which amounted to 8.199. The error degrees of freedom are 93. The mean square error, calculated by dividing the error sum of squares by the error degrees of freedom, is 0.088. The regression sum of squares reflects the portion of the total variability in the dependent variable that is explained by the predictor variables in the model. In this case, the regression sum of squares was found to be 2.023. The regression degrees of freedom, which correspond to the number of predictor variables in the model, are 6. The mean square regression, calculated by dividing the regression sum of squares by the regression degrees of freedom, is 0.337.

The F-test statistic is computed by dividing the mean square regression by the mean square error. In the analysis, the F-value was 3.825, indicating a significant relationship between the predictor variables and the dependent variable. The associated p-value of 0.000 further confirms the statistical significance. These results suggest that the predictor variables

included in the UTAUT Model collectively explain a significant portion of the variance in the dependent variable. The model demonstrates a good fit, as indicated by the significant F-test and low p-value.

Researchers and practitioners can interpret these findings as evidence supporting the usefulness of the UTAUT Model in understanding the factors influencing the dependent variable. The identified predictor variables contribute significantly to explaining the variation in the outcome, indicating their importance in technology adoption and usage behaviors.

### C. Unstandardized and standardized Coefficients

1) The unstandardized and standardized coefficients provide important insights into the magnitude and direction of these relationships. In Table II, the unstandardized coefficients of the study were evidently presented.

**siAverage:** The unstandardized coefficient for siAverage is 0.045. This suggests that a one-unit increase in siAverage is associated with a 0.045-unit increase in the dependent variable.

**PeAverage:** The unstandardized coefficient for PeAverage is -0.166. This indicates that a one-unit increase in PeAverage is associated with a decrease of 0.166 units in the dependent variable.

**fcAverage:** The unstandardized coefficient for fcAverage is 0.174. This means that a one-unit increase in fcAverage is associated with a 0.174-unit increase in the dependent variable.

**epAverage:** The unstandardized coefficient for epAverage is 0.245. This implies that a one-unit increase in epAverage is associated with a 0.245-unit increase in the dependent variable.

**eeAverage:** The unstandardized coefficient for eeAverage is 0.102. This suggests that a one-unit increase in eeAverage is associated with a 0.102-unit increase in the dependent variable.

**biAverage:** The unstandardized coefficient for biAverage is 0.004. This indicates that a one-unit increase in biAverage is associated with a 0.004-unit increase in the dependent variable.

**Intercept:** The unstandardized coefficient for the intercept term is 2.678. This term represents the constant or baseline value of the dependent variable when all predictor variables are zero.

TABLE II. UNSTANDARDIZED COEFFICIENT

Constructs	ubAverage
siAverage	0.045
PeAverage	-0.166
fcAverage	0.174
epAverage	0.245
eeAverage	0.102
biAverage	0.004
Intercept	2.678

2) Switching to the standardized coefficients as shown in Table III, findings:

**siAverage:** The standardized coefficient for siAverage is 0.052. This indicates the strength and direction of the relationship between siAverage and the dependent variable, taking into account the scales and variances of both variables.

**PeAverage:** The standardized coefficient for PeAverage is -0.186. This provides information about the standardized effect of PeAverage on the dependent variable.

**fcAverage:** The standardized coefficient for fcAverage is 0.223. This quantifies the standardized effect of fcAverage on the dependent variable.

**epAverage:** The standardized coefficient for epAverage is 0.246. This represents the standardized effect of epAverage on the dependent variable.

**eeAverage:** The standardized coefficient for eeAverage is 0.122. This signifies the standardized effect of eeAverage on the dependent variable.

**biAverage:** The standardized coefficient for biAverage is 0.005. This shows the standardized effect of biAverage on the dependent variable.

**Intercept:** The standardized coefficient for the intercept term is 0.000. Since it is zero, the intercept does not contribute directly to the explanation of the dependent variable.

TABLE III. STANDARDIZED COEFFICIENT

Constructs	ubAverage
siAverage	0.052
PeAverage	-0.186
fcAverage	0.223
epAverage	0.246
eeAverage	0.122
biAverage	0.005
Intercept	0.000

These coefficients provide valuable insights into the relative importance and impact of the predictor variables on the dependent variable within the UTAUT Model. Researchers and practitioners can use these coefficients to understand which variables have stronger or weaker effects and prioritize their focus accordingly.

#### D. Quality Criteria

The results provide insights into the goodness-of-fit of the model and the presence of multicollinearity. The R-square value, which represents the proportion of variance explained by the model, is 0.198. This indicates that the predictor variables included in the UTAUT Model explain approximately 19.8% of the variance in the dependent variable. The R-square adjusted value, which considers the number of predictor variables and sample size, is 0.146. This adjusted value accounts for the complexity of the model and provides a more conservative estimate of the explained variance.

The Durbin-Watson test statistic is used to assess the presence of autocorrelation in the model residuals. In this

case, the test yielded a value of 1.917, which falls within the acceptable range of values (between 0 and 4). This suggests that there is no significant autocorrelation in the model residuals. Moving on to the collinearity statistics, we examined the Variance Inflation Factor (VIF) for each predictor variable. The VIF measures the extent to which multicollinearity may be present in the model. In our analysis, all VIF values are close to 1, indicating a lack of substantial multicollinearity among the predictor variables. This suggests that the predictor variables in the UTAUT Model are relatively independent of each other and do not exhibit high collinearity.

Additionally, we examined the condition index, which provides information about the collinearity structure among the predictor variables. The condition index values, along with their corresponding eigenvalues, indicate the degree of collinearity among the variables. In our analysis, the condition index values range from 1 to 78.594, with higher values indicating stronger collinearity. The eigenvalues associated with the condition indices show that the majority of the variables do not exhibit severe collinearity, except for index 6, where an eigenvalue of 6.966 is observed. This indicates that the variables included in this condition index may have a higher degree of collinearity.

The results of the quality criteria and collinearity statistics suggest that the UTAUT Model provides a moderate level of explanation for the dependent variable, without significant multicollinearity among the predictor variables. However, the presence of some collinearity in condition index 6 should be taken into consideration. Researchers and practitioners can interpret these findings as an indication that the UTAUT Model, while explaining a modest proportion of the variance in the dependent variable, may still provide meaningful insights into the factors influencing technology adoption and usage behaviors. Future research should explore additional variables and evaluate the model's performance in different contexts to enhance its predictive power.

#### E. Descriptive Statistics, Covariances, and Correlations

The descriptive statistics provide an overview of the mean, median, minimum, maximum, standard deviation, excess kurtosis, skewness, number of observations, and Cramér-von Mises test statistics for each variable in the UTAUT Model. Looking at the means, we can see that the average scores for siAverage, PeAverage, fcAverage, epAverage, ubAverage, eeAverage, and biAverage are relatively high, ranging from 4.387 to 4.520 on a scale of 1 to 5. This suggests that the respondents generally perceive positive levels of the respective constructs.

The covariances and correlations provide information about the relationships between the variables in the UTAUT Model. Looking at the covariances, there is an observance of a positive values between siAverage and fcAverage, siAverage and eeAverage, fcAverage and epAverage, and ubAverage and epAverage. On the other hand, there is also an observance of negative covariances between siAverage and epAverage, PeAverage and ubAverage, siAverage and biAverage, and eeAverage and biAverage. These values indicate the direction

and strength of the relationships between the variables. Analyzing the correlations, similar patterns has been observed. For example, *siAverage* is positively correlated with *fcAverage* and *eeAverage*, while it is negatively correlated with *epAverage* and *biAverage*. *PeAverage* is negatively correlated with *ubAverage* and positively correlated with *biAverage*. These correlations provide insights into the interplay between the different constructs in the UTAUT Model.

The descriptive statistics, covariances, and correlations provide a preliminary understanding of the relationships and characteristics of the variables included in the UTAUT Model. Further analysis, such as structural equation modeling using Smart PLS, can help determine the significance and strength of these relationships and provide more robust insights into the factors influencing technology adoption and usage behaviors.

## V. DISCUSSION

The results of the study using the UTAUT Model to examine the factors influencing the dependent variable yielded several interesting findings. The summary coefficient analysis revealed that social influence (*siAverage*) and effort expectancy (*eeAverage*) had non-significant positive relationships with the dependent variable. This suggests that these factors may have a weak impact on the outcome. On the other hand, performance expectancy (*PeAverage*) displayed a marginally significant negative relationship, indicating a potentially weak negative influence. Facilitating conditions (*fcAverage*) and effort expended by users (*epAverage*) showed significant positive associations with the dependent variable, suggesting their importance in shaping the outcome. The other variables, *biAverage* and the intercept term, did not significantly affect the dependent variable. The results indicate that facilitating conditions and effort expended by users are the most influential factors in determining the outcome variable. Social influence, performance expectancy, and effort expectancy were not found to be significant predictors. However, it is important to note that the non-significant relationships should be interpreted with caution, as the sample size and effect sizes may influence the statistical significance.

The ANOVA results further supported the significance of the regression model. The F-test statistic indicated a significant relationship between the predictor variables and the dependent variable, with a low p-value. This suggests that the UTAUT Model, as represented by the included predictor variables, explains a significant portion of the variance in the dependent variable. The model demonstrated a good fit, providing evidence for the usefulness of the UTAUT Model in understanding the factors influencing technology adoption and usage behaviors.

The unstandardized coefficients provided insights into the magnitude and direction of the relationships. For example, a one-unit increase in *fcAverage* was associated with a 0.174-unit increase in the dependent variable. Similarly, a one-unit increase in *epAverage* was associated with a 0.245-unit increase in the dependent variable. These coefficients allow researchers and practitioners to understand the specific effects of each variable on the outcome.

Switching to standardized coefficients, researchers can assess the relative importance of the predictor variables. For instance, the standardized coefficient for *epAverage* was 0.246, indicating a stronger effect compared to other variables. These standardized coefficients help prioritize focus on variables with stronger or weaker effects.

The quality criteria analysis revealed that the UTAUT Model explained approximately 19.8% of the variance in the dependent variable. The R-square adjusted value, considering the complexity of the model, provided a more conservative estimate. The absence of significant autocorrelation in the model residuals and the lack of substantial multicollinearity among the predictor variables indicated good model fit. The results of the quality criteria and collinearity statistics suggest that the UTAUT Model provides a moderate level of explanation for the dependent variable, without significant multicollinearity among the predictor variables. However, the presence of some collinearity in condition index 6 should be taken into consideration. Researchers and practitioners can interpret these findings as an indication that the UTAUT Model, while explaining a modest proportion of the variance in the dependent variable, may still provide meaningful insights into the factors influencing technology adoption and usage behaviors. Future research should explore additional variables and evaluate the model's performance in different contexts to enhance its predictive power.

However, some collinearity was observed in condition index 6, suggesting a higher degree of collinearity among the variables in that index. Future research should consider addressing this issue and exploring additional variables to enhance the model's predictive power.

The descriptive statistics, covariances, and correlations provided a preliminary understanding of the relationships and characteristics of the variables in the UTAUT Model. These findings can guide further analysis using structural equation modeling to determine the significance and strength of the relationships.

### A. Implications of the Findings

1) *Influence of predictor factors*: The results of the analysis indicate that facilitating conditions and user effort are the most influential factors in determining the adoption and utilization of the FIMS. Facilitating conditions, as measured by the *fcAverage* variable, had a positive and significant relationship with the dependent variable, indicating that the presence of supportive conditions, resources, and infrastructure plays a crucial role in promoting the adoption and usage of the FIMS. This finding aligns with prior research that emphasizes the importance of organizational support and resources in facilitating technology adoption and implementation [16].

Similarly, user effort, as measured by the *epAverage* variable, was found to have a positive and significant relationship with the dependent variable. This suggests that users' perceived effort in using the FIMS influences their adoption and utilization behavior. It implies that ease of use, user-friendly interface, and user training programs can

contribute to enhancing technology adoption and usage behaviors. These findings are consistent with the technology acceptance literature, which emphasizes the significance of perceived ease of use and user experience in shaping technology adoption [16].

On the other hand, social influence, performance expectancy, and effort expectancy were not found to be significant predictors of FIMS adoption and utilization in the study. While this may seem contradictory to some prior research that has highlighted the importance of social influence and outcome expectations in technology adoption [16], it is important to note that the context of the study—specifically, the adoption and utilization of the FIMS in field incident management—may differ from previous studies that examined broader technology adoption contexts. The unique nature of field incident management systems and the specific tasks and requirements involved may contribute to different adoption and usage patterns.

2) *Model fit and explained variance*: The analysis of the model fit and explained variance provides insights into the goodness-of-fit of the UTAUT Model and its ability to explain the variance in the dependent variable. The findings indicate that the UTAUT Model explains a modest proportion of the variance in the adoption and utilization of the FIMS. The R-square value of 0.198 suggests that 19.8% of the variation in the dependent variable can be explained by the predictor factors included in the model. While this may appear relatively low, it is important to consider that technology adoption and usage behaviors are influenced by a multitude of factors beyond those captured by the UTAUT Model. Future research should explore additional variables and factors that may contribute to a more comprehensive understanding of technology adoption and utilization in the field incident management context.

Furthermore, the collinearity statistics indicate that there is no significant multicollinearity among the predictor variables in the UTAUT Model, except for the presence of collinearity in condition index 6. This suggests that the predictor variables are reasonably independent of each other and do not excessively overlap in their explanatory power. However, the presence of collinearity in condition index 6 should be considered and further investigated in future studies.

## VI. CONCLUSIONS AND IMPLICATIONS

### A. Conclusion

This study identified several important findings regarding the factors impacting technology adoption and usage behaviors within the UTAUT Model. The study revealed that social influence and effort expectancy had no significant influence on the dependent variable, suggesting that social factors and perceived ease of use may not be substantial drivers of technology adoption and usage behaviors in this context. On the other hand, performance expectancy exhibited a moderately negative connection with the dependent variable, indicating that people's expectations about technology's performance may have a minor detrimental impact on their adoption and usage behaviors. Facilitating conditions and user effort, however,

demonstrated significant positive relationships with the dependent variable, highlighting the importance of resource availability and effort exerted by users in determining technology adoption and usage behaviors. Behavioral intention and the intercept term did not have a significant effect on the dependent variable, indicating that they do not directly contribute to explaining heterogeneity in technology adoption and usage behaviors.

The study contributes to the theoretical understanding of technology adoption and usage behaviors by shedding light on the relative importance of different components within the UTAUT Model. It also highlights the need for further research to explore additional variables and validate the model's performance in different contexts, ultimately improving the understanding of technology adoption and usage behaviors.

### B. Theoretical Implications

The theoretical implications of the conclusion provide insights into the relative importance of different factors within the UTAUT Model and highlight the need for further research to enhance the understanding of technology adoption and usage behaviors. The findings contribute to the refinement and development of theoretical frameworks and provide guidance for researchers and practitioners in understanding and promoting technology adoption and usage in various contexts.

### C. Managerial Implications

The managerial implications of the conclusion guide managers in prioritizing facilitating conditions, encouraging user effort, contextualizing social influence and performance expectancy, continuously improving their understanding of adoption factors, and being mindful of collinearity and model fit considerations. By implementing these implications, managers can enhance the adoption and effective usage of technology within their organizations, leading to improved productivity, efficiency, and overall performance.

### D. Limitations and Directions of Research

Conducting the study with a larger and more diverse sample would provide a more robust understanding of the relationships between the variables. The non-significant relationships found in the study should be interpreted with caution. The lack of significance may be influenced by the sample size or effect sizes, and further research with a larger sample is needed to confirm or refute these relationships. Additionally, the study focused on a specific context or population, which may limit the generalizability of the findings to other settings. Future research should consider the influence of contextual factors, such as cultural differences or industry-specific characteristics.

To address these limitations and further advance the field, future research directions can be pursued. One direction is to explore additional variables that could enhance the predictive power of the UTAUT Model. Factors like perceived risk, trust, or personal innovativeness could be included to provide a more comprehensive understanding of technology adoption and usage behaviors.

Moreover, conducting comparative studies across different contexts or populations would help validate the findings and

identify potential variations in the relationships between the variables. This would contribute to the development of a more robust and contextually relevant model.

While the current study sheds light on the factors influencing technology adoption and usage behaviors, it is crucial to consider the limitations and pursue future research directions to strengthen the knowledge in this area. By addressing these limitations and expanding the scope of the investigation, researchers can make significant contributions to theory and provide more practical insights for managers and practitioners.

#### ACKNOWLEDGMENT

The authors would like to extend their profound gratitude and sincere appreciation to the Editors and anonymous reviewers for their valuable and constructive feedback to further improve the study.

**Abstract**—Artificial Intelligence (AI) technology has quickly developed under the mighty computing power of computers. At this stage, there are many mature non-destructive testing methods in civil engineering, but they are generally only suitable for simple structures and evident damage characteristics. Therefore, it's necessary for us to investigate the damage identification of wharf concrete structures under deep learning and digital image technology. The article propose a damage detection and localization method based on Neural Network (NN) technology in deep learning and Digital Image Correlation (DIC) to identify internal damage to concrete used for wharf construction. Firstly, the identification model of concrete structure is constructed using NN technology. Then, structural damage identification of concrete is further investigated using DIC. Finally, relevant experiments are designed to verify the effect of the model. The results show that: (1) The damage model of concrete structure constructed by NN technology has high convergence and stability and can control the test error well. (2) The image output by the DIC equipment is processed and input into the NN. The errors of the various parameters of different concretes can be within the acceptable range. This paper aims to provide good ideas and references for follow-up structural health monitoring and other topics and has significant engineering application value.

**Keywords**—Structural damage identification; deep learning; neural network; digital image; concrete

## I. INTRODUCTION

In recent years, deep learning and artificial intelligence have developed rapidly. Structural damage identification methods based on AI are gradually applied in practical engineering. In AI, domestic and foreign experts and scholars generally focus on techniques such as the Genetic Algorithm (GA), wavelet analysis, and Neural Networks (NNs) [1]. Zhang and Zhang used GA to locate and quantify the degree of damage and proposed a new form of genetic search optimization objective function. They proved that the method could effectively identify the damage location and degree of an elastic structure through the numerical simulation analysis of the visible structural damage of a flexible structure based on the modal analysis theory [2]. Huang et al. proposed a damage identification method based on GA. The method combined the modal flexibility matrix to identify the structural damage to the shear wall. The results showed that the method could identify damage under insufficient dynamic data through experimental analysis and numerical simulation [3].

Li et al. proposed a damage identification method based on GA and the damage structure model. For the cracked cantilever beam structure, the optimization calculation of binary and continuous GA was used to prove that this method accurately identified the structure's damage location and degree [4].

Scholars proposed the Digital Image Correlation (DIC) at South Carolina State University in 1981. Scholars calculated the surface displacement of the sample by converting the ultrasound information into a two-dimensional digital ultrasound image. After comparison, the image strain of the sample could be obtained and used to measure the average thickness of the material [5]. Later, it was found that a fast Fourier transform could be used to obtain the corresponding local displacement data caused by the displacement change of the sub-region by dividing the two speckle images. It could be successfully applied to studying the deformation field at the crack tip, developing this method [6]. At present, in the field of civil engineering, the DIC measurement method is mainly applicable in two directions: one is to observe the crack propagation and deformation status of reinforced concrete components in real-time, and the other is to observe the strain and displacement fields on the surface of reinforced concrete components after deformation in real-time. Now certain research results have been achieved in both aspects. Molina Viedema et al. used a frame structure as the research object and extracted the working modes of the structure under random vibration excitation using the three-dimensional dynamic displacement field provided by DIC method. Local mode filtering method was used to identify and locate the damage of the frame beam, achieving high positioning accuracy [7]. Kleinendorst used DIC measurement technology to study the stiffness damage identification of reinforced concrete beams, and compared it with the measured values of deflection displacement and the results of finite element modeling of beams at various stages. He concluded that DIC measurement error is very small and has high accuracy, and that it can be used for Structural health monitoring [8]. Through the research literature, it is found that the current research on damage identification of DIC technology focuses on the extraction of damage modes and features. After the strain cloud map is obtained, the stiffness characteristics and other information are still obtained according to the traditional method, and the combination with AI is weak. This paper proposes a quantitative identification method for concrete

internal damage based on Deep Learning (DL) and finite element modeling. The performance of the NN is verified based on the measured value of concrete based on DIC, and the non-destructive detection of concrete damage is realized. The innovation is that You Only Look Once (YOLO) technology is introduced into the concrete damage identification model, which improves the detection effect of the model. Most of the previous work still stayed at the level of damage mode and feature extraction, and the damage index was taken as the input of the neural network through preprocessing, instead of directly learning from the data and using convolutional neural network to directly learn the damage features. At present, the research on the internal damage of concrete by using two-dimensional convolutional neural network and digital image correlation method is still in the initial stage. The combination of deep learning and DIC methods in structural damage identification not only obtains the true state of the structure, but also fully utilizes the advantages of neural networks in solving inverse problems, ensuring that a large number of samples can be used as training sets for deep learning, while also ensuring the reliability of neural networks in real structural problems.

The second chapter briefly introduces the characteristics and network structure of YOLO network, the way of prediction output and the composition of Loss function. Based on YOLO, the neural network model required for this study is built, which lays a good foundation for the subsequent network training. Then, the basic theory of DIC and the experimental research content of concrete damage identification based on DIC were summarized, and the prediction effect of neural networks under real concrete damage was verified. The third section provides a detailed analysis of the experimental results, which indicate that DIC technology and deep learning technology can be effectively integrated for the detection of internal damage in concrete, and the overall detection accuracy is high.

In this paper, the article aims to provide a new development direction for the realization of non-destructive testing inside the concrete. The article introduced the AI-related technologies including NNs, target detection technology, YOLO and DL. The article trained the NN using the Anaconda environment and provided the detailed parameters in the experiments. For the image processing, the article adopted the finite element simulation method and simulated the pictures of each concrete beam. The Root Mean Square Error was adopted to measure the error of each parameter.

## II. METHODS AND MODEL DESIGN

### A. AI and NNs

AI is a discipline that studies and develops human intelligent systems, involving extensive research in robotics, Computer Vision (CV), Natural Language Processing (NLP), and expert systems [9]. In achieving this goal, Machine Learning (ML) is required to provide technical support. The core of ML is to use algorithms to guide computers to use data to obtain appropriate mathematical models. ML is widely used in solving AI problems [10]. Therefore, ML is an implementation method of AI, and it is also the most critical

implementation method. ML has become the method of choice for AI to develop helpful software for CV, Automatic Speech Recognition (ASR), NLP, robot control, and other applications [11]. Research on NN has appeared for a long time. Initially, it was a biological concept. After that, AI was inspired by NN, and Artificial Neural Networks (ANN) appeared [12]. ANNs are based on the basic principles of biological NNs. Its theoretical basis is the knowledge of network topology. ANN simulates the processing mechanism of complex information by the nervous system of the human brain [13]. Like the human nervous system, the NN is a complex network structure composed of many simple neurons connected and transmitted, as shown in Fig. 1.

Fig. 1. ANN

DL enables many applications of ML and expands the field of AI. DL has enabled AI systems to achieve significant performance improvements in many important problems such as CV, ASR, and NLP. It has become the key to the current breakthrough of AI [14]. Fig. 2 shows the relationship of AI-related concepts.

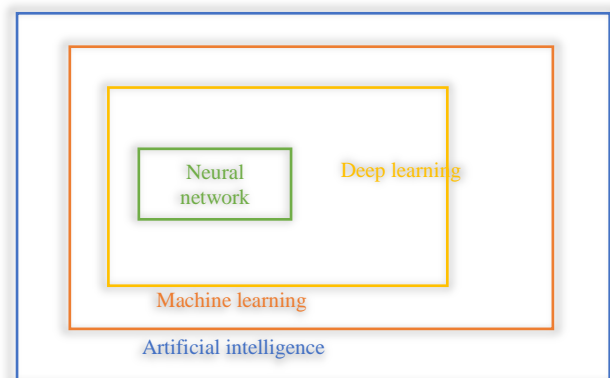

Fig. 2. Relationship of AI-related concepts.

### B. Target Detection Technology

Target Detection (TD) uses the powerful computing ability of computers to find objects of interest in an image or video and determine their location and size. TD is a key problem in CV [15]. Since the era of DL, the development of object detection has focused on two directions. The first is the Two-

Stage algorithm, such as the Region-Convolutional Neural Network (R-CNN) series. The second is the One-Stage algorithm, such as Single Shot MultiBox Detector (SSD) [16]. The Two-Stage algorithm needs to generate Proposal and then perform fine-grained object detection. The One-Stage algorithm extracts feature directly in the network to predict object classification and location [17]. In the Two-Stage algorithm, Faster R-CNN structurally integrates feature extraction, candidate region extraction, target box regression, and classification into an end-to-end network. The comprehensive performance, especially the detection speed, has been dramatically improved. So, Faster R-CNN has become the classic network of Two-Stage. In the One-Stage algorithm, SSD converts detection into regression and completes target positioning and classification. A similar Prior Box concept is proposed based on the prior box concept in Faster R-CNN. In addition, the detection method based on the feature pyramid is added. Targets are predicted on feature maps of different receptive fields. Compared with Faster R-CNN, Prior Box has obvious speed advantages and has become the classic One-Stage network [18].

### C. Design of Damage Identification Model Based on YOLO and DL

1) *Introduction to YOLO:* YOLO is an object identification and localization algorithm based on DNNs. This algorithm is a typical one-stage TD algorithm. The core idea is to use the entire image as the network's input and directly return the position of the bounding box and its category at the output layer [19].

YOLO has some unique advantages in the algorithm. These advantages are advantageous for identifying damage within concrete. First, YOLO is very fast at detecting objects. The detection process is simple. The image to be tested is input into the NN to output the detection result. Therefore, the detection speed can be improved a lot. The standard version of YOLO can process 45 images per minute on the Titan X GPU [20]. The traditional Two-stage network has low detection efficiency, but it can be trained with the help of the network pre-trained by the algorithm designer, which can greatly speed up the training process. The image cardinality of this paper is large. There are ten thousand images of concrete beams alone, and the images are all self-made. There are no pre-training parameters for reference, so detection efficiency is essential. Moreover, YOLO's AccessPoint (mAP) is more than twice that of other previous real-time object detection systems, achieving high accuracy in real-time detection algorithms. In addition, YOLO can learn generalization features of objects. Existing tests have shown that YOLO's performance is much better than the object detection systems before DPM and R-CNN when using artworks for testing after it is trained on natural images. It indicates that YOLO can learn highly generalized features, which is helpful for this paper to study the learning of the information projected by internal damage to the concrete surface [21].

2) *Network structure:* Factors such as input accuracy and training duration are considered comprehensively. Darknet-19

is used as the main network for training and testing. Fig. 3 displays the structure of Darknet19.

Fig. 3. Schematic diagram of darknet-19 network structure.

The Darknet-19 network is improved based on the GoogLeNet classification network structure. It refers to the experience of the Visual Geometry Group network. It uses a 3×3 convolution kernel and doubles the number of channels after each pooling layer. The Darknet-19 network draws on the idea of the Network in Network and uses global average pooling at the end of the network. The 1×1 convolution kernel is placed between the 3×3 convolution kernels to compress the features, improving the abstraction ability of the convolution layer. Meanwhile, the batch normalization method is used in each network layer. The neurons in the NN of each layer that gradually deviate with the training are pulled back to the standard normal distribution with a mean of zero and a variance of one and normalized. The purpose of stable model training is achieved while improving the training speed.

3) *Prediction of the output:* YOLO has two different approaches to predicting the output. YOLO-v1 uses a method of directly regressing the position of the bounding box, which can utilize the complete information on the entire image. The a priori frame is referenced when predicting from YOLO-v2, and the bounding box size of the final detection is fixed to 9 types. Different sizes of a priori frames are used for detection on various receptive fields, which can improve the recall rate of the prediction results but reduce the prediction accuracy. Besides, the Intersection of Union (IoU) of the predicted bounding box and the ground-truth box is also affected by the size of the prior box. The types of damage are not distinguished here, and the classification requirements of the NN are not high. In contrast, the regression requirements of the damage location are high, so the direct regression bounding box method is selected to predict the output.

4) *Loss function:* The loss function is a measure used to evaluate the degree to which the model's predicted value differs from the true value. The better the loss function, the better is the model's performance in general [22]. The loss function of YOLO-v1 consists of four parts: center coordinate error, width and height coordinate error, confidence error, and

category prediction. The TD here adds the positioning in the depth direction, as shown in the following equation.

$$Loss = Loss_{xy} + Loss_{wh} + Loss_{oc} + Loss_{noc} + Loss_c + Loss_d + Loss_{IoU} \quad (1)$$

In Eq. (1),  $Loss_{xy}$  refers to the loss function of the center coordinate prediction part. It can be expressed as:

$$Loss_{xy} = \lambda_{coord} \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{obj} \left[ (x_i - x_i)^2 + (y_i - y_i)^2 \right] \quad (2)$$

In Eq. (2),  $I_{ij}^{obj}$  is used to determine whether the  $j$ th box in the  $i$ th grid is responsible for the prediction of the object. If the grid contains objects, the value is one. If not, it is zero.  $\lambda_{coord}$  is the loss weight coefficient, which is generally five.  $x_i$  and  $y_i$  are the coordinates in the  $x$ -direction and  $y$ -direction, respectively, within the bounding box.  $S^2$  is the area of the prediction box, and  $B$  is the area of the ground-truth box.

$Loss_{wh}$  refers to the loss function of the width and height coordinate prediction part. It is expressed as:

$$Loss_{wh} = \lambda_{coord} \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{obj} \left[ (\sqrt{w_i} - \sqrt{w_i})^2 + (\sqrt{h_i} - \sqrt{h_i})^2 \right] \quad (3)$$

In Eq. (3),  $w_i$  and  $h_i$  are the coordinates in the width and height directions of the predicted bounding box, respectively.

$Loss_{oc}$  is the loss function for the confidence prediction of bounding boxes containing objects.

$$Loss_{oc} = \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{obj} (C_i - C_i)^2 \quad (4)$$

In Eq. (4),  $C_i$  represents the predicted bounding box.

$Loss_{noc}$  is the loss function for the confidence prediction without the object's bounding box.

$$Loss_{noc} = \lambda_{noobj} \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{noobj} (C_i - C_i)^2 \quad (5)$$

In Eq. (5),  $\lambda_{noobj}$  is the weight coefficient generally 0.5.

$Loss_c$  refers to the loss function of category prediction.

$$Loss_c = \sum_{i=0}^{S^2} I_{ij}^{obj} \sum_{c \in \text{classes}} (p_i(c) - p_i(c))^2 \quad (6)$$

$Loss_d$  refers to the loss function of depth coordinate prediction.

$$Loss_d = \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{obj} \left[ (s_i - s_i)^2 + (d_i - d_i)^2 \right] \quad (7)$$

In Eq. (7),  $d_i$  represents the value of the pier concrete beam in the depth direction.

$Loss_{IoU}$  refers to the loss function of the prediction of the intersection and ratio.

$$Loss_{IoU} = \sum_{i=0}^{S^2} \sum_{j=0}^B I_{ij}^{obj} (IoU - IoU)^2 \quad (8)$$

In Eq. (8),  $IoU$  measures the accuracy of detecting corresponding objects in a specific dataset.

The loss function adds depth-wise and cross-union ratio predictions. If each part's weight loss in YOLO-v1 continues to be used, the NN cannot achieve good results. Therefore, the above loss function combination is used as the loss in the network construction and debugging stage. After the network debugging is completed, the parameters are adjusted, and the loss function is recombined according to the error of the test results, which can ensure the accuracy of the NN learning.

#### D. Training and Testing of Concrete Damage Identification NN

1) *Network training and testing process:* According to the damage identification NN designed by YOLO above, the process of training and testing its NN is shown in Fig. 4.

2) *Dataset source:* Images of concrete damage in civil engineering are collected and modeled in batches using finite element software. The exported images are used to make datasets for DL.

3) *Experimental environment:* The NN is trained using the Anaconda environment, and Table I reveals the parameter settings in the environment.

Fig. 4. NN training and testing process.

### E. Concrete Damage Identification Method Based on DIC Technology

1) *DIC technology*: The basic theory of the DIC method is to obtain the surface displacement deformation by extracting the differential information of the surface of the object. The natural speckle on the object's surface can be directly used, and the speckle can be artificially produced. The gray gradient is the carrier of the deformation information of the structure surface. Artificial speckles can increase the number of feature points on the surface of the object under test, thereby increasing the gray value of the surface under test. The displacement of the feature points in the coordinate system before and after the deformation is calculated by the correlation algorithm to determine the deformation value of the whole image [23].

2) *Correlation function*: Before calculating the correlation algorithm, it is necessary to discriminate and define the degree of matching between the sample sub-region and the target sub-region, so a correlation function is introduced. The correlation function is the function of the deformation parameter to be obtained. The DIC method calculates the similarity of the two sub-regions before and after deformation using the gray gradient value of the speckle image to get an accurate deformation parameter estimation. Commonly used criteria can be divided into cross-correlation and variance synthesis criteria according to the algorithm [24].

3) *Error analysis of displacement measurement*: The displacement measurement accuracy of the DIC method is affected by the specimen's gray gradient, the equipment's imaging system, and the related algorithms. The role of speckle is to improve the characteristics of the specimen surface. During the test, a series of problems, such as the difference in the grayscale gradient of the speckle image, the reflection on the component's surface, and the change of the light during the test, will affect the clarity of the image capture. The imaging system inevitably produces errors due to device angle, camera lens position, and quality differences. The clarity of the image will be affected due to a series of problems, such as the difference in the grayscale gradient of the speckle image, the reflection on the component's surface,

and the change of light during the test. At the algorithm level, selecting the sub-region size, interpolation algorithm, and shape function of the study area will cause different systematic errors in the calculation [25].

4) *Camera calibration*: Camera calibration is the process of obtaining the internal and external parameter matrices of the camera. The internal and external parameter coefficients obtained through calibration can be used to correct the images captured by the camera later to obtain images with relatively small distortions. The accuracy of calibration directly affects the final measurement results, so it is the most basic and important part of binocular stereo vision [26].

5) *Composition of the measuring system*: Here, the measurement and reading of the concrete surface information adopt the DIC method. The measurement system consists of hardware and software. The hardware is mainly image acquisition and reading equipment, and the software includes algorithm selection for image correlation operations. It is important to ensure that the environment cannot change greatly during the image acquisition process to ensure the accuracy of the deformation measurement of the structure surface by the relevant algorithm, including the erection position of the camera and the lighting conditions of the structure surface. Therefore, the fill light is erected during the test, and the camera should not move after the erection is completed. The loading process is recorded by a 3D DIC method based on the principle of binocular stereo vision to identify the changes in the concrete surface, reduce the distortion, and prevent the partial out-of-plane displacement of the concrete from affecting the test results. Fig. 5 shows the measurement system of the 3D DIC method [27].

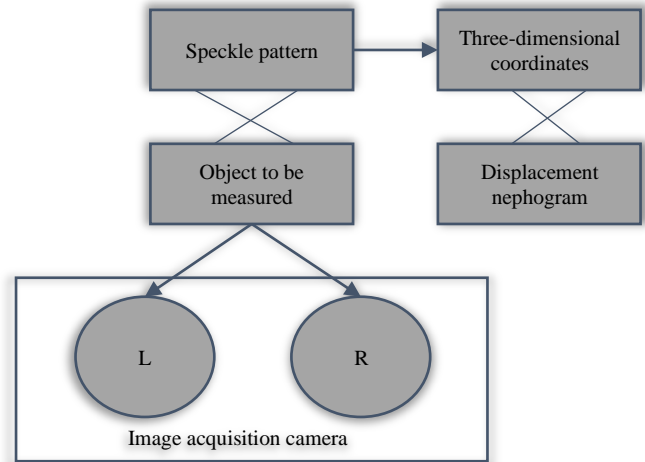

Fig. 5. 3D DIC method measurement system.

### F. Concrete Damage Identification Process Based on DIC Technology

According to the relevant theory of DIC technology, the concrete damage identification process based on DIC technology is shown in Fig. 6.

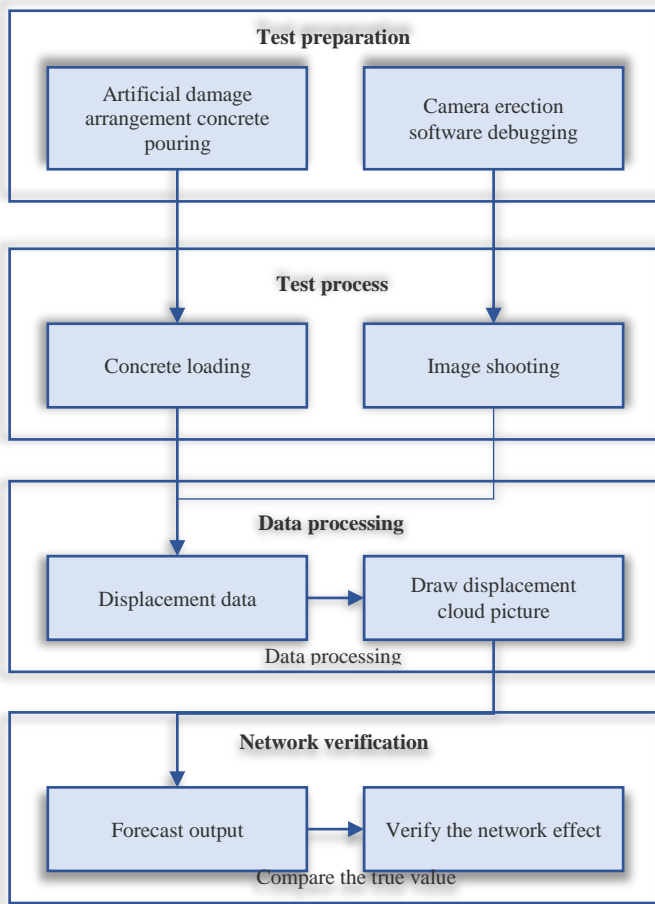

Fig. 6. Concrete damage identification test process based on DIC technology.

### G. Experimental Design

A total of seven reinforced concrete beams for constructing the wharf are selected in the experiment, represented by A-G, respectively. The dimensions of the concrete beams and the internal reinforcement arrangement are consistent with the finite element modeling results. First, the pictures of reinforced concrete beams are extracted by DIC equipment. Then, the finite element simulation method is adopted, a load of concrete is set to 21kN, and the pictures of each concrete beam are simulated. Finally, the processed images are input into the previously trained NN. The prediction results of seven parameters, including the damage center coordinates, the bounding box's size, and the confidence level corresponding to each image, are generated. The predicted value is compared with the actual size and position of the foam block prevented during the test, and the error of each parameter is obtained. The standard of measurement is the Root Mean Square Error [28].

## III. RESULTS

### A. Effect of Damage Model of Wharf Concrete Structure based on YOLO and DL

1) *Concrete beam test results:* The NN completes learning after 100 cycles of training with the selected NN. The training situation of the obtained NN is presented in Fig. 7. From Fig.

7, the overall loss of the NN decreases smoothly during the training process. The method of adjusting the learning rate by gradient makes the network converge rapidly in the early stage of training. In the middle and later stages of training, there is no situation where the predicted value exceeds the real value, resulting in a significant rebound in the loss value. During the later stages of training, the validation loss stabilizes at around 0.24. However, the training set's loss value still decreases, indicating that the NN is overfitting, but the overall effect on the validation set is not large.

Fig. 7. Loss values for training a concrete beam with an NN.

2) *Test results of the concrete column of the wharf:* The concrete piles are also trained using the previously selected network for 100 cycles. The judging criteria also use the network loss value and the test set accuracy. Fig. 8 reveals the concrete column test results. Fig. 8 indicates that the overall convergence of the network is good, and the curve is smooth. Compared with the training of concrete beams, the fluctuation of the validation set of concrete piles is more prominent, and there is also some overfitting phenomenon. The loss value stabilizes around 0.38, and the network accuracy is slightly inferior to the concrete beam network. The number of images in the training set of concrete piles is only about 0.14 of that of concrete beams. Therefore, the difference between the loss values of the two is within an acceptable range.

Fig. 8. Loss values for 100 epochs of concrete pile training.

### B. Verification of Concrete Damage Identification Method Based on DIC Technology

The load on the concrete is set to 21kN. At this time, the processed images are input into the previously trained NN. The prediction results of seven parameters, including the damage center coordinates, the bounding box's size, and the confidence level corresponding to each image, are generated. The predicted value is compared with the actual size and position of the foam block prevented during the test. Fig. 9 shows the error of each parameter. Fig. 9 shows that the errors differ for different concrete beams. The prediction error tends to be large when the concrete damage is minor. The overall data show that the error of each concrete beam is within the acceptable range, and the estimation of the damage position and size of the concrete has been accurate. It shows that the damage identification network constructed here has good robustness.

Fig. 9. Concrete beam parameter error.

### IV. CONCLUSION

This paper is the first time to carry out a series of research on the internal damage location of concrete structures based on the plane distribution information in China, and provides a good idea and reference for the follow-up Structural health monitoring and other topics, which has important engineering application value.

To sum up, this paper uses the finite element model to simulate the internally damaged concrete structure. This research article took the position and size of the concrete damage learned and predicted in the DLNN as input. Meanwhile, the article applied the DIC and applied concrete surface parameters in laboratory tests. Then, the NN is input to train again to obtain the identification errors of different concrete structural damages. The results show that: (1) The YOLO algorithm in the one-stage algorithm has the advantages of fast detection speed, strong generalization ability, and low background identification error rate. (2) When predicting the damage size and depth of concrete beams, it is found that the prediction accuracy increases as the damage size and depth decrease. (3) The trained NN has a good prediction effect on each parameter of the concrete structure. The disadvantage is that the NN in this paper is built based on the YOLO algorithm, which can achieve multi-damage prediction. However, due to time constraints, multi-damage structures are not considered in the modeling phase. In subsequent work, multiple damages can be arranged in the

concrete members. In the prediction, the non-maximum suppression method can be used to output multiple damage locations at one time. Then, the prediction ability of the NN for multiple damages in concrete is tested. This paper is of great significance and value for applying and promoting prefabricated structures. It also provides new ideas for the damage of concrete internal defects and the batch detection of prefabricated structures. (4) The neural network in this study is built based on the YOLO algorithm and can achieve multi damage prediction. However, due to time constraints, the construction of multi damage was not considered in the modeling phase. In subsequent work, multiple damages can be considered in concrete components, and non-maximum suppression methods can be used to output multiple damage locations at once during prediction, to test the predictive ability of the neural network for multiple internal damages in concrete. (5) In the DIC based experimental verification section, the quality of the concrete surface displacement cloud images generated by some components is poor, which is closely related to hardware equipment, experimental environment, etc. In the subsequent work, a higher lens quality camera can be used for shooting in a more stable environment to ensure the quality of the generated displacement cloud map.

### ACKNOWLEDGMENT

# Application of Top-N Rule-based Optimal Recommendation System for Language Education Content based on Parallel Computing

Nan Hu

Public Teaching Department, Nanyang Medical College, Nanyang 473000, Henan, China  
School of Public Health, Wuhan University, Wuhan, 430000, Hubei, China

**Abstract**—In recent years personalized recommendation services have been applied to many areas of society, typically in the fields of e-commerce, short videos and so on. In response to the serious performance problems of the current online language education platform content recommendation, so in the face of the above opportunities and challenges, this paper designs a new online English education model to allow university students to get a full and more three-dimensional training of English language learning. Based on the MU platform, this paper obtains data from the platform and uses crawler technology to sample and standardize the learning resources for online education. Then user information, such as explicit and implicit ratings of courses, is selected as the main basis for training a user interest preference model. Immediately afterwards, a PRF algorithm combining data parallelism and task parallelism optimization was executed and implemented on Apeche Spark to provide some optimization of data accuracy and content recommendation methods. Finally, the top-N recommendation rule is used to propose a dynamic evolutionary process of identifying students' preferences or learning habits through the results of previous data analysis, so as to make more accurate course content recommendations and learning content guidance for students' English learning. The online three-dimensional teaching model proposed in this paper focuses more on time-series research than traditional algorithms, and can more accurately capture the dynamic changes in students' learning abilities.

**Keywords**—Data parallel computing; cloud computing; data crawlers; top-N rules; PRF algorithm

## I. INTRODUCTION

With the rapid development of the Internet, the mobile Internet has created more opportunities for education, and online education has emerged, and synchronous online education in higher education has gained widespread attention. According to "China Internet Education Market Trends Forecast 2018-2020" released by Analysis Eiconet, as the degree of mobile further deepens, the types of mobile education platforms: become more and more rich and diverse. After the outbreak of the epidemic, social awareness of online education has risen tremendously, and formal learning platforms as well as informal learning platforms can now be found everywhere. Traditional forms of education that have been in place for thousands of years are also gradually changing with the changes in society and the environment. Existing education products are becoming more and more

integrated and easier to use, enhancing the efficiency of the learner [1].

With the rapid rise of cloud computing, mobile internet technology and the Internet of Things, as well as the emergence of various information dissemination methods, the volume of business data in various application areas is exploding and the value of big data applications in various fields is becoming increasingly important. The emergence of the Big Data era has brought unlimited opportunities for everyday life, production and research, while at the same time raising unprecedented challenges.

On the one hand, through the analysis and mining of big data, we can discover the valuable information and laws implied in it and provide us with various decision support. With the support of rich Big Data processing technologies, such as consumer behavior analysis, product sales forecasting, precise personalized marketing, scientific research analysis, etc., the quality of production and services in various fields of application can be improved and optimized in a comprehensive manner.

On the other hand, such a rapidly growing and complex data resource poses a huge challenge to traditional data processing technology and computing power. The processing of big data has become even more complex due to its large scale, high dimensionality, complexity and noise characteristics. At present, traditional machine learning and data mining algorithms cannot directly analyses and process massive amounts of data effectively and accurately. Data parallelism is a parallel strategy whose main logic follows the principle of Single Program Multiple Data.

In data-parallel model training, the training task is split across multiple processes (devices), each maintaining the same model parameters and the same computational tasks, but processing different data. Data parallelism splits up the data that can be used to solve the problem and places the split data on one or more cores for execution; each core performs similar operations on this data.

High-performance computing, distributed computing and cloud computing provide powerful computing capabilities for large-scale data analysis and machine learning techniques. Apache Hadoop and Spark are both well-known cloud computing platforms widely used for big data analysis and massively parallel computing. Many parallel machine learning

and data mining algorithms have been implemented based on the Hadoop MapReduce and Spark RDDI69 models with significant results. Spark supports a parallel programming model for Resilient Distributed Datasets (RDD) and Directed Acyclic Graphs (DAG), which is built into the in-memory computing framework. Zaharia et al. propose a fast interactive Hadoop data query architecture based on Spark, by caching data in memory, the architecture is able to provide a fast interactive data query service with a 40 times speed advantage over Hadoop [2-5].

In the implementation of high school English courses, teachers focus more on students' learning of English language knowledge, while university English courses pay more attention to the development of students' language skills and their ability to use language in future work and real-life social communication. However, some scholars have found that in an analysis of university students' English listening and speaking ability dilemmas, it was found that students' pronunciation was not accurate enough, their vocabulary for language expression was inadequate, the training of oral listening and speaking ability was in a single form, and the lack of learning objectives for listening and speaking ability restricted the improvement of students' listening and speaking ability. Therefore, with the rapid development of computer technology, many educators adopt the online education platform, with the computer data processing algorithm, to carry out three-dimensional teaching for students according to local conditions.

## II. DATA COLLECTION AND PROCESSING OF MU ONLINE PLATFORM

Web crawlers have been broadly used in information series and acquisition in current years, and wealthy crawler frameworks are reachable to meet the desires of crawler builders for precise facts acquisition. In this chapter, we graph a disbursed crawler software primarily based on python scrapy crawler framework to crawl and manner the path records in the on line getting to know path platform Mucu in parallel [6,7]. The received statistics will be saved in the high-performance mongoDB to relieve the storage stress of the database, and then the statistics in the mangodb will be pre-processed and the pre-processed statistics will be saved in the mysql database to facilitate the subsequent evaluation and processing of the statistics.

### A. Design of Data Crawler

1) *Scrapy crawler framework*: Scrapy is a web crawler framework developed based on python program. scrapy is characterized by its ability to quickly extract structural data from websites and is one of the most widely used crawler frameworks in python. scrapy framework is customized according to user requirements to facilitate the acquisition and structured storage of web data, and its framework consists of eight main The framework consists of eight parts: python crawler engine, scheduler, downloader, spider, project pipeline, scheduling middleware, downloading middleware, and crawler middleware. Scrapy runs as shown in Fig. 1.

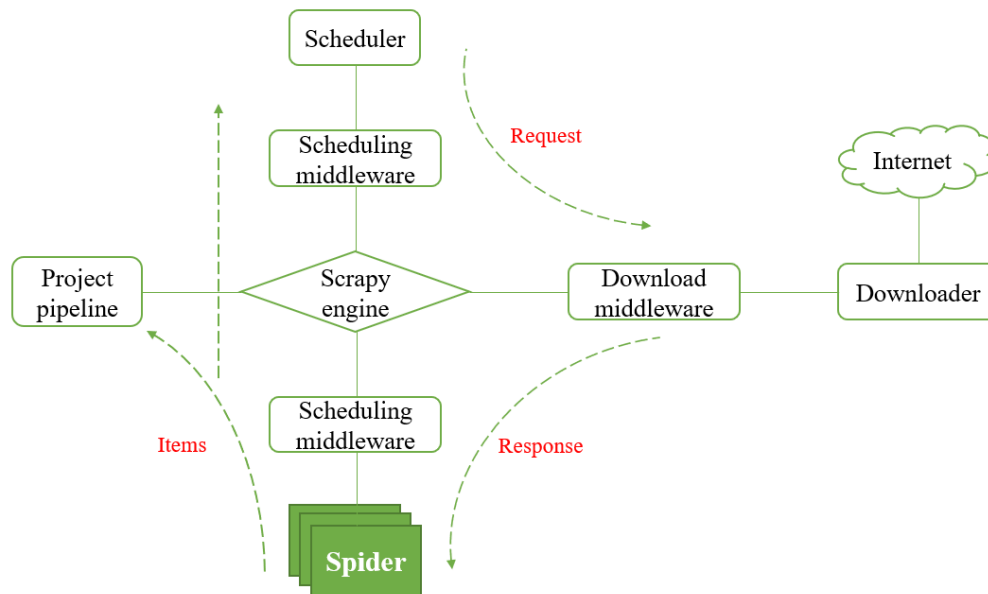

Fig. 1. Scrapy framework operation.

a) *Scrapy engine*: used to get the preliminary requests request internet records and manage the whole crawler facts flow, in a position to manage a couple of request duties at the identical time. After inquiring for the scheduler, it is usually prepared for the subsequent requests request.

b) *Scheduler*: The main task of the scheduler is to receive requests from the scrapy engine and store them in the

queue in a certain order and return the next requests to the scrapy engine.

c) *Downloader*: The scrapy engine returns the request results to the downloader, which downloads the corresponding web content and notifies the scrapy engine of the downloaded content.

d) When the scrapy engine receives the net content material back through the downloader, it returns to the spider for processing thru middleware. The spider can be described by way of the consumer in accordance to his personal needs, and the consumer can use the net factor positioning science xpath or css to function the internet factors to get the internet content material in a unique element.

e) After spider processing, the web content will be parsed into user-defined data, and the new request task will be sent to the scrapy engine through middleware, after storing the obtained web data items.

f) The scrapy engine sends the processed facts objects to the task pipeline and returns the requests to the scheduler, which plans to system the subsequent request. Whenever a request is done and records are fetched, the subsequent request will be made till all requests are finished.

2) *Course data crawler design and implementation:* In this paper, the object of crawling is the route statistics of the on-line gaining knowledge of platform study room website, and the public facts of the on-line course, such as direction name, direction id, route comment, direction remark time, route remark user, etc., is bought via the net crawler. Since the crawling website has anti-crawling restriction, which restricts the IP that is visited multiple times within a short period of time, this paper sets the time interval for requesting web pages as a random number of 1-2s to confuse the anti-crawling mechanism of the crawler when designing the crawler program, but after setting the interval, the crawling speed and efficiency decrease. In order to compensate for the crawling efficiency problem, in this paper, a distributed crawler design scheme is adopted. Multiple cloud servers are used to deploy web crawlers, and distributed crawler acquisition architecture is realized [8,9].

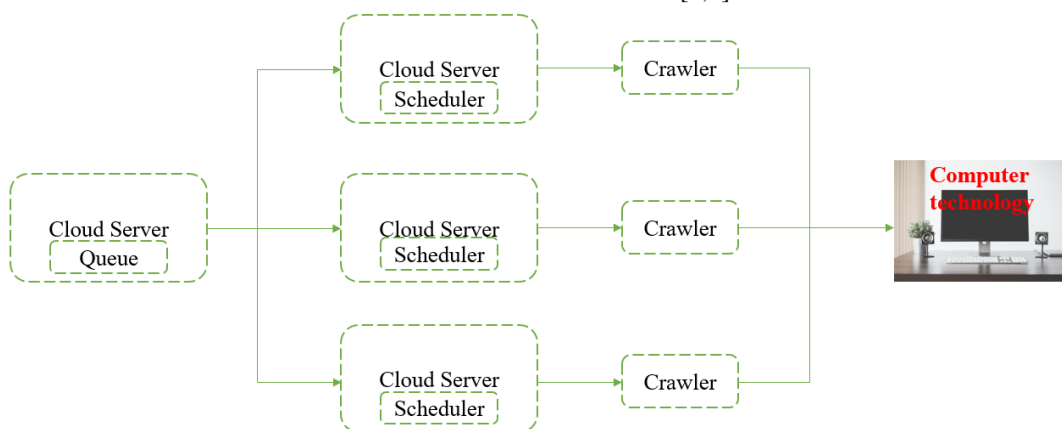

Fig. 2. Crawler algorithm framework.

The plan of dispensed crawler structure shares the queue in the cloud server to different cloud servers, and after the scheduler in different servers receives the request queue, the crawler software downloads the internet pages of the crawled website, and the crawler software locates the content material in the net web page factors to be bought and shops them in the database.

The crawler application is constructed the usage of the scrapy framework, and the waft of the crawler application to

attain Tencent school room information is proven in Fig. 2. Firstly, the url generator is deployed in the server, and the crawler is assigned the crawling url [10]. The downloader downloads the net web page content material in accordance to the url request, and the crawler shops the crawled factor content material into the database. When the url generator no longer generates the url, the request url is no longer acquired in the queue of the scheduler, and the crawler ends its operation at this time (as shown in Fig. 3).

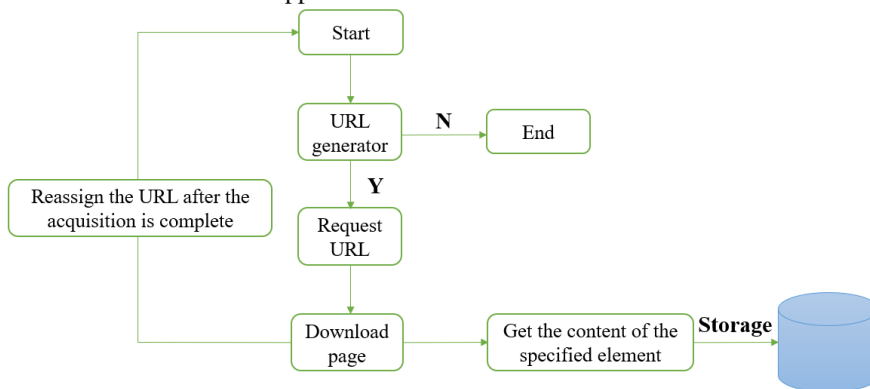

Fig. 3. Crawler algorithm flow chart.

## B. Data Pre-processing

Through the crawler program, this paper obtains a complete of 100,000 portions of data, the records carry direction information, as properly as the user's feedback on looking at the path information. Since the obtained textual content statistics has the following characteristics: First, there are greater extraordinary characters in Chinese text, such as emoticons and exotic punctuation marks, which are challenging to represent the traits of textual content content material information [11]. Second, Chinese textual content phrases are coherent with every other, and the distinction with English textual content is that English textual content phrases are separated by means of areas between words, which will be extra handy in textual content characteristic representation, whilst Chinese textual content wishes Chinese textual content wants to be divided into phrases with the aid of the use of phrase separation techniques. Based on the bought Chinese textual content information, there are two primary steps in the facts pre-processing stage: clearing the distinctive symbols in the textual content facts and deactivating the phrases and setting apart the textual content facts into phrases.

1) *Clear special symbols and deactivated words:* In the text processing, special symbols, such as “△▲★♠♣↑↓” and other characters, have little meaning in Chinese text and interfere with the vectorization of text, and there is also a category of deactivated words, such as “one by one, one by one”, which are less relevant to the semantic understanding of text. Words with low relevance are removed in the text preprocessing [12]. Then, based on the data obtained by the crawler, we observed and found the special characters that were applicable to the recommended text of this course, and expanded them to the general word list. Finally, we filtered the data according to this word list and got the preliminary cleaning data.

2) *Text segmentation:* Since there is no space in the middle to distinguish a word like English, Chinese is composed of a series of Chinese characters to form a sentence, so to make the machine understand the meaning of Chinese more accurately, word segmentation must be performed, that is, Chinese word separation. In the field of Chinese word segmentation, common word segmentation tools include: jieba, SnowNLP, THULAC, and NLPPIR.

Jieba Chinese phrase splitting system: jieba phrase splitting is one of the most famous Chinese phrase splitting systems, which has a sturdy integration with Python language. jieba phrase splitting helps three phrase splitting modes, which are precise mode, full mode and search engine mode. The actual mode is to break up Chinese sentences precisely, which is appropriate for Chinese textual content analysis; the full mode is to pick out all the phrases that can be linked into phrases in a sentence, which is quicker than different modes, however can't remedy the hassle of phrase ambiguity. The search engine mannequin is primarily based on the actual model, which cuts lengthy phrases greater cautiously to enhance the recall of phrase separation. jieba key algorithms for phrase separation are Viterbi algorithm for lexical annotation of Chinese words, tf-idf and textrank fashions for extracting key phrases [13].

SnowNLP is a library written in Python with rich Chinese text processing features that facilitate the processing of Chinese text content in the Python language. The main features of SnowNLP are Chinese text word separation, lexical annotation, simple sentiment analysis, plain Bayesian-based text classification, pinyin conversion, traditional and simplified character conversion, keyword and text summary extraction, and computation of text recall, etc.

THULAC is a Chinese lexical analysis tool led by the Natural Language Processing and Social Humanities Computing Laboratory of Tsinghua University, with the main functions of Chinese word separation and lexical annotation.

NLPPIR is a Chinese word sorting system developed by Beijing Institute of Technology, with rich features and powerful performance, it is a set of software that can handle and process text sets, providing visual display features, its main functions include: Chinese word sorting, word annotation, named entities, user dictionaries, new word discovery and keyword extraction. It can be used in a variety of programming languages, including python [14].

3) *Sentiment analysis data annotation:* Sentiment evaluation is a famous lookup center of attention nowadays, and the principal work is to mine the sentiment tendency in users' comparison texts, and analyze, process, summarize and conclude these texts. At present, sentiment evaluation has been utilized to many fields, which can assist users' selection making, opinion monitoring, etc. The coaching of deep gaining knowledge of primarily based sentiment evaluation neural community first off requires sentiment corpus, so constructing sentiment evaluation corpus statistics is a vital records prerequisite for this paper. Currently, there are two main ways to build sentiment annotated corpus: manual construction and machine learning-based construction. The manual method of building sentiment annotated corpus mainly involves multiple annotators to annotate this paper with sentiment and then uses voting to determine the final sentiment of the sentences; the machine learning based method needs to annotate the unannotated corpus with sentiment through machine learning with the help of annotated corpus. Due to the emotional tendency of the text of course review studied in this paper, there is no widely used corpus of course reviews annotation in the current research, so this paper adopts the method of manual annotation by multiple people to manually annotate the text data.

4) *Multi-person manual annotation:* In this paper, the annotation of route overview textual content is primarily based on sentence as the annotation granularity, which is the simple unit of semantic appreciation of text, and the annotation granularity of sentence can be extra correct to discover users' emotional mind-set and favorite choice of course [15]. After organizing the annotation granularity of textual content data, the guide annotation system adopts the annotation system of Nakagawa et al.

a) Three data annotators independently annotate the sentiment of text sentences, and the annotation results are

divided into three categories: positive, neutral, and negative. In the process of manual labeling, there are some sentences that are difficult to judge, and the sentences that are difficult to judge are labeled as difficult sentences.

b) Identification of annotation results: For non-difficult sentences, the voting principle is used, i.e., if two or more people label a sentence as the same sentiment category, the sentence will be judged as the category with more annotations. For difficult sentences, five people will be introduced for annotation, and the final annotation result will be taken as the category with the higher number of annotations.

c) Inspection and modification of annotation results: In the process of manual annotation, there will inevitably be manual errors, resulting in errors in the results of the annotated data, so in the annotation process a, the results of the inspection and modification is essential, this paper uses the manual check to check the accuracy of the annotated results.

d) Through the above manual annotation, a total of 8120 course review texts were obtained from the annotated data.

5) Evaluation of annotation results: In order to evaluate the quality of data annotation, this paper uses manual evaluation to evaluate the annotation results in the annotation process. The evaluation process is divided into two steps.

Step 1: 30% of the annotated corpus is randomly selected as the evaluation sample, and two annotators (PM1 and PM2) are assigned to judge the sentence results, which are either correct or incorrect in two dimensions.

Step 2: Establish the evaluation indexes, and the accuracy rate of the adoption of the evaluation indexes in this paper. The experimental evaluation results are shown in Table I below.

TABLE I. ASSESSMENT OF ACCURACY RESULTS

Evaluators	Active	Neutral	Negative
PM1	96.21%	93.66%	98.74%
PM2	94.13%	97.43%	96.48%

Through the evaluation of the labeled data, the labeled data in this paper achieved excellent accuracy, and the average accuracy of the sampled data reached 95.82%.

### III. DISTRIBUTED PARALLEL STOCHASTIC ALGORITHM DESIGN

This section describes the data parallel optimization strategy of the PRF algorithm, which includes vertical data partitioning and data reuse methods. First, a vertical data partitioning method is proposed to make full use of the logical independence of computational tasks and computational resource independence of the RF algorithm for training data feature variables to effectively partition large-scale training datasets [16-17]. Second, to solve the problem that the size of the sampled training data set in the original RF algorithm increases linearly with the expansion of the RF scale, this section modifies the traditional data sampling method and proposes a data reuse method for the PRF algorithm. The expansion of the PRF scale does not lead to changes in the

training data size and storage location. In this section, the proposed data parallel optimization method can effectively reduce the training data size and reduce the data transfer operations in the distributed computing environment, while ensuring the accuracy of the algorithm.

#### C. Vertical Data Partitioning

In the distributed parallel training process of PRF algorithm, the task of calculating the information gain rate of the characteristic variables of each training data subset occupies most of the training time. However, each computation task only needs to use the data of the current feature variable and the target feature variable. Therefore, in order to reduce the data communication overhead in distributed environment, a vertical data partitioning method is proposed, which makes full use of the RF algorithm's logical independence of computing task and computing resource independence of training data feature variables to effectively partition large-scale training data sets [18].

Suppose the size of the training dataset X Train is N, and there are M feature variables and one target variable in each sample record, i.e.  $y_1 \sim y_M$  are the input feature variables and  $y_A$  is the target variable. In the vertical data partitioning method, for each training subset  $X_i$ , each feature variable  $y_j = (j = 1, \dots, M)$  of all samples of  $X_i$  is extracted separately and combined with the target variable  $y_A$  to form a feature subset  $FS_j$ , denoted as  $FS_j = \{j, y_j, y_A\}$ . In this way, the training subset  $X_i$  can be divided into M feature subsets based on the feature variables, and there are no data dependencies and communication relationships among the subsets during the growth of the meta-decision tree model [19]. In the subsequent Apache Spark distributed parallel computing process, each feature subset will be loaded as an RDD object and independent of the other subsets. The execution of the vertical data partitioning method of the PRF algorithm is shown in Fig. 4.

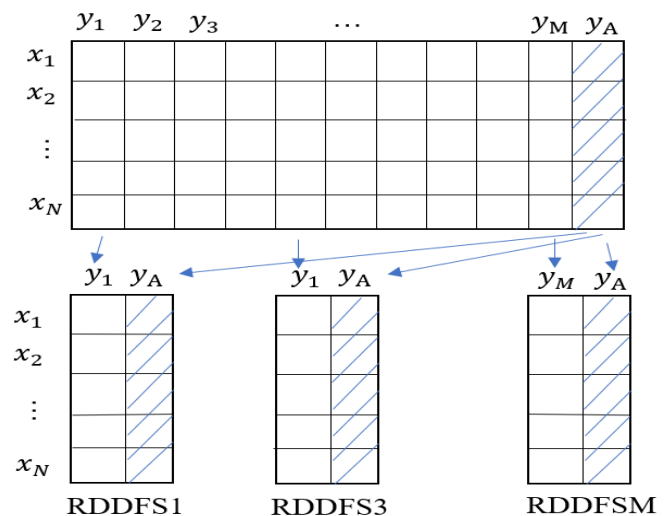

Fig. 4. Execution process of the vertical data division method of the PRF algorithm.

#### D. Data Reuse Method

In the original RF model, the training data set needs to be randomly sampled with put-back to form  $k$  subsets of training data, which are then trained by  $k$  meta-decision trees, respectively. Thus, when the size of the RF model increases (i.e. the number of meta-decision trees increases), then the size of the training data subsets also increases linearly. To solve this problem, this section modifies the traditional sampling method and proposes a data reuse method oriented to the PRF algorithm. Instead of actually replicating the sampled sample data in each data sampling cycle, its index is simply recorded into a data sampling index table [20-21]. The DSI tables are then assigned to all computational nodes along with a subset of features. For each meta-decision tree training process, the individual computational tasks can load the corresponding data from the same feature subset according to the corresponding sampling index in the DSI table. Thus, each feature subset is effectively reused, and the size of the entire training dataset does not increase even if the PRF size increases indefinitely.

First, a Data Sampling Index (DSI) table is created to hold the indexes of the samples extracted during all sampling. As mentioned earlier, the number of meta-decision trees for a PRF model is  $k$ . This means that the training dataset is sampled  $k$  times and  $N$  sample indexes are recorded during each sampling process.

Next, the DSI table is assigned to the corresponding compute node of the Spark cluster along with each feature subset, i.e. each compute node contains one or more feature subsets and one DSI table. In the subsequent parallel training process, the task of computing the information gain rate of different decision trees with the same feature variables is assigned to the compute node where the subset of features belongs to [22].

Finally, in each computation node, the information gain rate computation tasks for the different decision tree models

will access the corresponding sampling indices from the DSI table and fetch the sample feature variables from the feature subset of the current computation node based on these indices. An example of the execution process of the data reuse method of the PRF algorithm is given in Fig. 5.

In Fig. 5, each  $RDD_{FS}$  represents an RDD data object for a feature subset, and each TGR represents an information gain rate computation task during the growth of a particular meta-decision tree. For example, the feature subset  $RDD_{FS1}$  is assigned to the Slave1 compute node, followed by the compute tasks  $\{T_{GR1.1}, T_{GR1.2}, T_{GR1.3}\}$  associated with this feature subset also assigned to Slave1. Similarly,  $RDD_{FS2}$  and the associated compute tasks  $\{T_{GR2.1}, T_{GR2.2}, T_{GR2.3}\}$  are assigned to the from a meta-decision tree perspective, these computational tasks in the same computational node belong to different decision tree growth processes. For example, the tasks  $T_{GR1.1}$ ,  $T_{GR1.2}$  and  $T_{GR1.3}$  in Slave1 belong to Decision Tree 1, Decision Tree2 and Decision Tree3 respectively. The information gain rate of the feature variable is calculated. The intermediate results of these tasks in each distributed computing node are then aggregated and submitted to the corresponding subsequent tasks to build the meta-decision tree. For example, the results of tasks  $\{T_{GR1.1}, T_{GR2.1}, T_{GR3.1}\}$  are collected and aggregated from Slave1, Slave2, and Slave3 respectively, and used in the tree node splitting process of Decision Tree1". The results of tasks  $\{T_{GR1.2}, T_{GR2.2}, T_{GR3.2}\}$  are collected and aggregated from Slave1, Slave2 and Slave3 respectively, and are used in the tree node splitting process of "Decision Tree2". Algorithm 3.3 gives the steps of the vertical data partitioning and data reuse method of the PRF algorithm. In Algorithm 3.3, the RDDs are first divided into  $M$   $RDD_{FS}$  objects by the vertical data division function, and then the  $RDD_{FS}$  are allocated to the compute nodes according to the compute capacity and available storage capacity of each compute nod [ 23-25].

Fig. 5. Execution process of the data reuse method of the PRF algorithm.

IV. APPLICATION OF TOP-N RULE-BASED  
RECOMMENDATION MODEL FOR ONLINE EDUCATION COURSES

A. User-Course Matrix

The Matrix Factorization approach represents a matrix as a multiplication of two or extra matrices, becoming the observations in the unique matrix [26]. It is now extensively used in many contexts in the discipline of recommendation. The authentic matrix R is used to report all located person path ranking matrices, which are decomposed into two function matrices U and V. The closing goal feature L is as follows:

$$L = \sum_{i=1} \sum_{j=1} (R_{ij} - U_i^T V_j) \quad (1)$$

Fig. 6 suggests the building and decomposition of the user-course matrix. After cleansing and processing, the preliminary user-course dataset is obtained. The matrix decomposition is carried out at some point of the advice algorithm, on the one hand by using filtering comparable customers via User-matrix-based recommendations, and on the different hand via filtering comparable gadgets thru Item-matrix recommendations. For function extraction, social networks can then be developed for extraction, sooner or later main to the optimization of hybrid tips.

Fig. 6. Schematic diagram of the user-course recommendation path.

B. The Construction of Temporal Behaviour

In recent years, there has been a gradual shift in research from traditional (user, item) binary interactions to (user, item, timestamp) three-way interactions. The following are three statistical models that are often used to capture temporal information in sequential recommendations [27-30].

1) *Markov chain model in sequential recommendation:* The Markov chain model makes the important assumption that the probability P of the current state occurring is only correlated with the n-1 states preceding it, but not with the states at other times. n-order Markov chain models have the following probability formula.

$$P(W_T | W_1, W_2, W_3, \dots, W_{T-1}) = P(W_T | W_{T-n+1}, W_{T-n}, \dots, W_{T-1}) \quad (2)$$

2) *The word2VEC model:* Word2vec mainly includes Skip-Gram method and CBow method, and the model has three layers of computing logic, namely input layer, projection layer and output layer [31-32]. There are two kinds of algorithm framework, one is hierarchical normalization and the other is

negative sampling. The Word2vec model based on hierarchical normalization constructs Huffman tree according to the vocabulary in the output layer [21]. The terrible sampling based totally Word2vec mannequin does no longer assemble a complicated Huffman tree in the output layer, however a noticeably easy random poor sampling instead, which can considerably improve the computational pace and the excellent of the built phrase vectors.

3) *Time-decay model:* The exponentially decaying temporal function is shown below.

$$f(x) = \exp(-a(R_{ti} - R_{tj})) \quad (3)$$

In this equation a represents the coefficient of exponential decay, while R<sub>ti</sub> and R<sub>tj</sub> are historical data at different times. u is the user and V is the course item. Fig. 7 illustrates how the exponential decay function uses historical data to predict ratings. For R, the data closest to the present is assigned a higher weight for prediction purposes, and in a continuous correction, user U and course V are combined for recommendation.

Fig. 7. Time-series decay prediction.

Taking user, a as an example, as shown in Fig. 8, as a sample of observations, we find that it focuses mainly on English courses, which in a traditional recommendation model

would be considered more focused on recommending programming-related courses from a library of items (courses) [22].

Fig. 8. Sequence of user behaviour (with user 'a' as an example).

### C. Model Results and Analysis

1) *Cold start*: For a new user, with less information captured about his history, we followed the previous idea of setting the cold start threshold to 10 and obtained five recommended courses under cold start as follows, Table II:

TABLE II. COLD START RECOMMENDATIONS

ProductName	Rating	Number of ratings
Selected Readings in Spanish Literature	4.26	642
Career Development English	4.33	355
English Etymology Mystery	5.68	482
Language in Life	7.15	499
Chinese and Western Cultural Contrasts and Exchanges	6.44	816

Once the cold start problem has been solved, you should start building the course-user matrix. The first step is to construct a data frame containing the average rating of each course and the number of times it has been rated, which is used to calculate the correlation between courses. In the above analysis we know that the higher the correlation coefficient of a course, the higher the probability of it being recommended by the portfolio [23].

In this paper we will use the Pearson correlation coefficient, the nearer the correlation coefficient is to 1, the greater the correlation is, and the weaker the correlation is. A Dataframe is created the usage of pandas, the dataset is grouped with the aid of header column and the common rating for every direction is calculated.

Next, depends the range of instances each path was once rated and see how it relates to the common direction rating. A path with a rating of 5 is probable to have solely one consumer

rating. It is no longer statistically practical to reflect on consideration on this as a 5-point course. Therefore, when constructing this phase of the suggestion system, we want to set a threshold for the wide variety of ratings. Using the group by characteristic in pandas, we created the number of ratings columns, grouped it with the aid of the Title column, and then used the counted feature to calculate the quantity of instances every direction was once rated [33].

The subsequent step is to construct the item-based advice system. We want to seriously change the dataset into a matrix with the route title as the column, the consumer identification as the index and the ranking as the value. We get a Dataframe, the place the columns are the direction titles, the rows are the person ids and every column represents the scores of all users for all courses. If the ranking is empty, it signifies that the person has not rated a path any longer.

This matrix is then used to calculate the correlation between courses. The course matrix is created using the pivot\_table in pandas.

To create the course matrix.

After calculation, we obtain similar course recommendations for each user based on historical behavior, and then introduce the temporal sorting matrix, filling in the viewing order for classes with viewing records and 0 for those without records, to obtain a matrix of users' temporal behavior. The final ranking result is obtained after normalization.

Similarly, user a, for example, is recommended by user id=12331(as shown in Fig. 9).

Fig. 9. Course recommendation score ranking.

#### D. Model Evaluation

In this chapter, the serialized studying behaviors of customers on the MU platform are captured, a temporal decay characteristic is designed to be included into the user-course matrix, and a time lag feature is proposed to be built to analyses the temporal statistics implied in the gaining knowledge of behaviors. Meanwhile, in order to check the

effectivity of the temporal sequential advice mannequin built in this paper, the paper is validated on the catechism dataset of consultant home on-line schooling systems in the empirical phase. Under the Top-N rule, the personalized recommendation to the user is completed through the recommendation score. Through the training accuracy and partial user sampling, the model has a good effect on the course recommendation results.

## V. CONCLUSION

Traditional big data computing methods are dedicated to the calculation and classification of data, with little involvement in data prediction and data derivation. With today's increasingly sophisticated cloud computing platforms, the content recommendation panel of an online education system can be very useful when combined with the data analysis of a cloud computing cloud platform. The online education system tablet designed in this paper embraces the educational concept of adaptive learning based on top-N recommendation algorithms, in addition to the sharing of educational resources and changes in the form of education. In order to study the recommendation model for online education, the recommendation system constructed in this paper is based on the representative NetEase Cloud Classroom to build the recommendation method. In future recommendations, we combine several online systems to collect more users to train and evaluate the model. In addition, a collaborative filtering system can be constructed for courses in the future by constructing a more sensitive temporal function model to better deal with scalability and sparsity issues. Finally, when the amount of data handled is very large, we can also build advanced recommendation systems in conjunction with auto-encoders to improve the performance of recommendations in the direction of timely response.

The research in this paper is divided into four main parts. The first part is data crawling and analysis of course and user information. Based on the platform's overall user temporal behavior of recommendations, a threshold is set for the number of ratings when building a cold-start recommendation system. The problem caused by too sparse data situation is solved.

The second part proposes a parallel random forest algorithm for big data. The PRF hybrid parallel approach combining data parallelism and task parallelism optimization is executed and implemented on Apache Spark. The training dataset is reused and the amount of data is significantly reduced.

The third part designs and investigates a recommendation method for online education learning resources with user temporal behavior, incorporating temporal information into the reordering of learner preferences by introducing an exponential decay function, and constructing a user-course matrix by matrix decomposition. This matrix more highly latitudinally and subtly incorporates temporal order into the user-program matrix and reduces the dimensionality of the user-program matrix according to the prediction score.

The fourth part constructs the prediction matrix for similarity calculation and recommendation ranking. The prediction score generates a recommendation list for the user, and the recommendation score reflects to some extent the degree of similarity in joining the chronological historical behavior.

Finally, the score prediction is carried out using the study habits and learning behavior, and the results of these four parts are used to carry out learning path planning in which users learn the courses and plan personalized recommendation paths

for the users, ultimately making the student user English language learning play a three-dimensional teaching effect.

# A Novel ML Approach for Computing Missing Sift, Provean, and Mutassessor Scores in Tp53 Mutation Pathogenicity Prediction

Rashmi Siddalingappa, Sekar Kanagaraj

Department of Computational and Data Sciences, Indian Institute of Science, Bangalore, India

**Abstract**—Cancer is often caused by missense mutations, where a single nucleotide substitution leads to an amino acid change and affects protein function. This study proposes a novel machine learning (ML) approach to calculate missing values in the tp53 database for three computational methods: SIFT, Provean, and Mutassessor scores. The computed values are compared with those obtained from the imputation method. Using these values, an ML classification model trained on 80,406 samples achieves an accuracy of 85%, while the impute method achieves 75%. The scores and statistics are used to classify samples into five classes: Benign, likely pathogenic, possibly pathogenic, pathogenic, and a variant of uncertain significance. Additionally, a comparative analysis is conducted on 58,444 samples, evaluating six ML techniques. The accuracy obtained by each of these is mentioned alongside the algorithm: logistic regression (89%), k-nearest neighbor (99%), decision tree (95%), random forest (99.8%), support vector machine with the polynomial kernel (91%), support vector machine with RBF kernel (84%), and deep neural networks (98.2%). These results demonstrate the effectiveness of the proposed ML approach for pathogenicity prediction.

**Keywords**—Decision tree (DT); deep neural networks (DNN); imputation; k-nearest neighbor (KNN); logistic regression (LR); missense mutations; Mutassessor; pathogenicity; Provean; random forest (RF); SIFT; support vector machine (SVM)

## I. INTRODUCTION

Years of research have identified the tp53 gene, a tumor suppressor gene that encodes the tumor protein p53 (tp53), as a significant barrier in cancer development [1][2][3]. The tp53 protein acts as a tumor suppressor by regulating cell division, growth, and apoptosis processes. It has been found that approximately 90% of cancer cases exhibit tp53 mutations [4]. Notably, the mutations commonly occur between positions 102-292, resulting in approximately 190 mutated codons, with over 60% of them being missense mutations [5]. Studies by Fiamma Montovani et al. discuss the role of mutant p53 proteins in supporting malignant cell survival and cancer evolution, as well as therapeutic opportunities related to tp53 missense mutations [6]. Gaoyang Zhu et al. explore therapeutic options targeting the Gain-of-Function (GOF) feature of full-length p53 mutant proteins [7]. Additionally, Alvarado-Ortiz E et al. investigate the impact of mutp53 on metabolic reprogramming and the Warburg effect observed in cancer cells, highlighting chemo-resistance and the role of autophagy in survival [8]. Xiang Zhou et al. identify tp53 hotspots as potential barriers for novel cancer therapies and

study the mechanisms underlying GOF for p53 [9]. Furthermore, cancer cells employ various strategies to disarm p53 and promote their growth and survival [10]. One approach involves mutating the tp53 gene itself, removing the protective function and allowing unmonitored cell activities [11]. Nonsynonymous Single-Nucleotide Variants (nsSNVs) are considered a primary reason for cancer, as they alter proteins with a single residue change in the amino acids [12][13]. Yong Li et al. demonstrate the predictive value of tp53 in the untranslated region (UTR) of cancer specimens, highlighting the impact of germline SNVs on tp53 protein levels and cell apoptosis [14]. Oliver Poirion et al. propose using expressed SNVs (eSNVs) from RNA sequences to locate tp53 variations in tumor subpopulations [15]. Computational procedures have been developed to assess the influence of amino acid substitutions and the frequent occurrence of missense variants in cancer patients [16] [17]. Understanding the effect of missense mutations is crucial for clinical use, especially in distinguishing pathogenic and infectious variants among numerous missense variants.

## II. RELATED WORK

With the rapid development of Machine Learning (ML) and its applications in various fields, ML has emerged as a potential solution for cancer research [19][20]. Efforts have been made to apply ML/AI-based diagnostics for cancer using vast genomic data. Techniques such as REVEL, CADD, FATHMM, and PolyPhen employ ML algorithms like Random Forest (RF), Naïve Bayes (NB), and Logistic Regression (LR) to predict pathogenicity [21][22]. Jiaying Lai et al. introduce LYRUS, a machine-learning tool that predicts pathogenicity based on missense variants [23]. LYRUS utilizes an XGBoost classifier incorporating sequence, structure, and dynamic features. The tool is evaluated using F-scores and specificity metrics, outperforming alternative methods. However, LYRUS estimates pathogenicity based on the actual protein structure and does not consider the mutated protein. It is also limited to proteins with available structures in the Protein Data Bank (PDB). Hua Tan et al. differentiate cancer-causing driver mutations from normal ones using SVM classification based on distinguishing features [24]. Their approach demonstrates higher efficiency compared to existing methods. In clinical research, computational techniques such as SIFT, Mutassessor, and Provean are used to predict the pathogenicity of missense mutations. However, there is a lack of ML-based methods to calculate these scores. Therefore, the present study proposes a novel approach to calculate SIFT,

Provean, and Mutassessor scores using K-nearest neighbors (KNN) regression. The study also focuses on classifying samples into pathogenicity classes based on the guidelines suggested by the American College of Medical Genetics and Genomics (ACMG) [25]. Section III of the paper delves into the materials and methods utilized in the research study. Following this, Section IV elaborates on the implementation of the algorithms employed. The subsequent section, Section V, presents the results and output obtained from the study, providing a detailed analysis. Finally, in Section VI, the paper concludes by summarizing the main findings and implications, offering a comprehensive conclusion to the research.

### III. MATERIALS AND METHODS

#### A. Computational Techniques for Pathogenicity Prediction

1) *SIFT score*: The SIFT (Sorting Intolerant from Tolerant) method is a prediction tool that assesses the relationship between amino acid substitutions and protein functions [26]. It is based on the hypothesis that amino acids tend to be conserved within a protein family. Therefore, any changes at well-conserved amino acid positions are likely to be damaging. SIFT also considers the presence of hydrophilic amino acids, such as valine, and checks if the substituted amino acid is another hydrophilic amino acid, like isoleucine or leucine. In such cases, the changes are predicted as tolerated. However, substitutions to other types of amino acids are assumed to result in functional changes. The SIFT method takes the protein sequence as input and aligns it with related proteins. It calculates the probability of amino acid occurrence at each position during the alignment. If the probability falls below a certain threshold, SIFT predicts the substitution as deleterious, otherwise, it is considered tolerated. The threshold value typically ranges from 0.0 to 1.0, where scores between 0.0 and 0.05 are considered deleterious, and scores greater than 0.05 are considered tolerated.

2) *Provean score*: The Provean (Protein Variation Effect Analyzer) score operates similarly to the SIFT method [27]. It calculates an alignment score for each protein sequence. A set of closely related sequences, typically the top 30 clusters, is selected as a supporting sequence set. The scores within each cluster are averaged, resulting in a Provean score. This score is then compared to a predefined threshold, typically set as -2.5. If the score is equal to or lower than the threshold, the protein variant is considered deleterious; otherwise, it is considered "neutral."

3) *Mutassessor score*: The Mutassessor score (Mutation Accessor) predicts the functional impact of an amino acid change based on the evolutionary conservation of the affected amino acid among protein homologs [28]. The default threshold for pathogenicity classification is set to -1.93, distinguishing high or medium functional impact variants from low or neutral predicted variants.

Note: These scores, namely SIFT, Provean, and Mutassessor, are utilized in computational techniques to predict the pathogenicity or functional impact of missense mutations in proteins.

#### B. The Proposed ML-based Method to Calculate the Missing Values of SIFT, Provean, and Mutassessor Scores

In this section, two algorithms related to the present research study are discussed. Algorithm-1 presents the proposed ML-based approach for calculating missing values of three different computational scores. Algorithm-2 outlines the process of classifying each sample into pathogenicity classes. The classification results are compared using six different ML techniques.

---

#### Algorithm – 1: Proposed algorithm for predicting the missing values of Sift, Provean, and Mutassessor Scores in tp53 database

---

Input: tp53 mutation samples (80346, 133) → 80346 rows X 133 columns; Output: Predicted scores for the missing values in Sift, Provean, and Mutassessor scores

- Step 1: Preprocess the tp53 original dataset.
  - Step 2: Perform feature selection to select the features required for the proposed task.
  - Step 3: Separate rows with and without Sift scores.
  - Step 4: Consider the rows that have Sift scores.
    - i. Create a dataframe (x\_train) to store the features.
    - ii. Create another dataframe (y\_train) to store the corresponding labels.
    - iii. Use the KNN regressor model to predict values of y\_train, and save the predictions as y\_predict.
    - iv. Compute the Mean Absolute Error (MAE) score of y\_train and y\_predict for each 'k' value from 2 to 20.
    - v. Determine the 'k' value with the minimum MAE score among all the MAE scores.
    - vi. Train a new model using this 'k' value and save it as final\_model.
  - Step 5: Use final\_model to calculate the missing values of Sift scores from step 3 using the KNN regressor technique:
    - i. Consider the complete feature set of missing and present Sift values.
    - ii. Calculate the Euclidean distance (ED) for each feature set where Sift scores are present and where Sift scores are missing.
    - iii. Tabulate all ED values in ascending order.
    - iv. Select the top 'k' values (from step 4.vi).
    - v. Calculate the average of these scores and save it as the new predicted Sift score.
    - vi. Return the new predicted Sift score.
  - Step 6: Predict Sift scores using all the features selected in step 2 with the help of the impute method.
  - Step 7: Compare the final predicted values from steps 5 and 6.
  - Step 8: Repeat steps 3-5 to determine Provean scores.
  - Step 9: Repeat steps 3-5 to determine Mutassessor scores.
  - Step 10: Stop.
-

**Algorithm – 2: Classification of samples into five classes of pathogenicity using different ML techniques**

Input: tp53 mutation samples.  
Output: Pathogenicity classification.

- Step 1: Choose features and labels from the tp53 database (features computational scores + stat scores).
- Step 2: Remove samples with null values.
- Step 3: Perform the classification of each sample into pathogenicity classes using the following ML techniques:
  - i) Logistic regression,
  - ii) KNN,
  - iii) SVM,
  - iv) Decision tree,
  - v) Random forest,
  - vi) Feedforward neural network.
- Step 4: Compare the results of each technique using evaluation metrics.
- Step 5: Tabulate the results.
- Step 6: Stop.

**C. ML Techniques used in the Proposed Research Study**

- To predict the computational scores

1) *K-Neighbors Regressor*: This technique is a regression method derived from the KNN model. It calculates values based on the representation of the 'k' nearest neighboring target values from the training dataset. The values present in the training class are stored, while those that are missing are later calculated using similarity scores such as Euclidean, Manhattan, or Hamming distance. The accuracy of the calculated values relies on the selection of a primary measure, 'k'. Choosing an appropriate 'k' value is crucial, as a large 'k' value can potentially exploit the distance boundaries and result in overfitting or blurring of the feature space. Conversely, a low 'k' value can lead to underfitting of the model [29]. Hence, an optimal 'k' value is determined by discarding the missing values from the target variable field and predicting the target variable values using different 'k' values. These predicted values are then compared with the actual target values, and the difference is evaluated using the Mean Absolute Error (MAE) score. The 'k' value that yields the lowest MAE score is selected as the final 'k' value for the K-Neighbors Regressor. Table I provides a tabular representation of the procedure.

TABLE I. THE KNN REGRESSOR METHOD WAS USED TO CALCULATE THE MISSING VALUES. THE TABLE SHOWS THE SAMPLE VALUES TAKEN FROM THE TP53 DATABASE. IT CONTAINS A COMBINATION OF VALUES PRESENT AND ABSENT INDICATED WITH DIFFERENT COLORS

L_sta t	C_sta t	T_sta t	G_sta t	S_sta t	Sm_sta t	Sift_scor e	ED
0.01	0.08	0.05	0.44	0.71	0.331	0.19	0.34
2.84	2.80	2.87	2.77	1.40	2.107	0	5.83
0	0.00	0.00	0.91	0	0.01	?	0.34
0.02	0.03	0.03	0	0.03	0.083	0.89	0.915 5

Note: L: Leukaemia, C: Cell\_line, T: Tumor, G: Germline, S: Solid\_state, Sm: Somatic, ED: Euclidean Distance

Calculating ED individually for rows (i), (ii), and (iv) containing SIFT score values and SIFT score=? Different arrows indicate this in Table I. Below is the ED calculation for row (i).

$$\sqrt{(0.014 - 0)^2 + (0.082 - 0.001)^2 + (0.053 - 0.001)^2 + (0.071 - 0)^2 + (0.331 - 0.01)^2} = 0.342$$

Likewise, EDs for all the rows (ii and iv) w.r.t data\_pre

Sort ED: 0.34, 0.91, 5.83. Consider, k=2, so pick the first 2 points and take the average.

$$\frac{0.34 + 0.91}{2} = 0.625$$

The new sift\_score predicted is 0.625

**D. To Classify Samples into Various Pathogenicity Classes**

- *Feature selection*: With the help of data visualization and pre-processing using principal component analysis (PCA), the dataset was prepared for the training phase [30]. With PCA, highly correlated features (both positive and negative) were removed from the original dataset. For the strongly correlated features, only one of the features is retained. To decide this, the following aspects were identified; if two features are to -1, they are negatively correlated, and if the values are closer to +1, they are positively correlated. After performing the feature reduction process, the dataset had 58444 X 10 records that were finally used for the classification process using six different ML techniques. In the end, each ML technique is compared to study the best method for classifying a sample. The model was evaluated using F-score and parameter tuning to ensure robustness. Finally, the models are evaluated on the test set for full and reduced features. Feature reduction, indeed, has an impact on the overall algorithm performance of these ML techniques. Fig. 1 depicts the framework of this modeling process. The implications of these methods are described below.

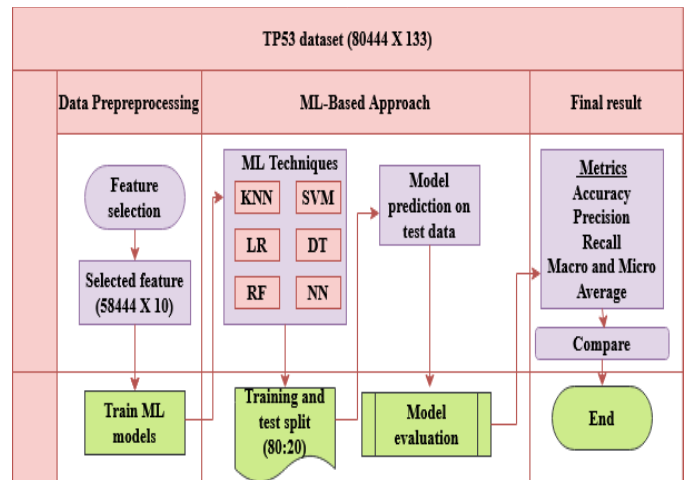

Fig. 1. The proposed schematic hybrid framework of the modelling process to predict the pathogenicity of a sample using tp53 database and various ML algorithms such as Logistic Regression (LR), K-nearest neighbors (KNN), Support Vector Machine (SVM), Decision Tree (DT), Random Forest (RF) and lastly, Feed-Forward Neural Network (NN).

- **Logistic regression:** The LR is, by default, a regression model whose prediction is based on the logistic function [31]. The decision is associated with the probability that a given feature belongs to some categorical class, say, 1. If a sigmoid logistic function is used to make the prediction, then if sigmoid function (S) resorts to an infinite value when the prediction variable ( $\hat{y}$ ) will become one and  $\hat{y}$  will be 0 if 'S' is a negative value, given by Eq. 1

$$\text{sig}(s) = \frac{1}{1+e^{-x}} \quad (1)$$

A crucial parameter in logistic regression for the present classification task is multinomial data distribution since the categories of the classes (5 pathogenicity classes) are without any specific ordering. The classification of a sample is performed based on the threshold. The threshold value is vital in estimating the probability that a sample belongs to one out of these five classes. Say if  $\hat{y}$  ranges between 0-0.2, then the sample is classified as '0 - benign', for  $\hat{y}$  between 0.2 – 0.4, the sample will be classified as '1-LP', with a range between 0.4 - 0.6 the class will be '2-P', 0.6 – 0.8 for class '3-PP' and finally 0.8 – 1.0 for class '4-VUS'. This is usually the first ML algorithm to be used for any classification task.

- **K-Nearest Neighbors:** This is the simplest of all the ML techniques that intend to classify a record (unlabelled) based on the class of the neighbouring data points (labelled) [32]. Using a distance measure, say ED, the distance between the features of the unlabelled and labelled records is calculated. Using an optimal 'k' value, the nearest top 'k' neighbours are chosen. Finally, the class label with the highest number is tagged for the unlabelled data point. The main idea behind this intuition is that similar points tend to be close to each other. As this is a multi-class classification problem, a sample will be classified into one of the five classes. The best 'k' value obtained on the dataset is 5. Thus, k=5 was used to train the final model.
- **Support Vector Machine (SVM):** SVM is a versatile algorithm used for classification and regression tasks. It aims to find an optimal hyperplane, or decision boundary, that maximizes the separation between different classes [33]. When classes are not linearly separable, SVM employs the kernel trick, using functions like linear, polynomial, RBF, or sigmoid. Data points close to the hyperplane are called support vectors. For multi-class classification, SVM utilizes the one-vs.-one approach, explicitly indicated by defined\_function\_shape=ovo. By default, it uses the one-vs.-rest approach (defined\_function\_shape=ovr), where data points of one class are compared with the rest [33]. In our case with five pathogenicity classes, SVM is applied using both 'rbf' and 'poly' kernels, with specified parameters such as gamma=0.5, C=0.1, and degree=3 for 'rbf', and C=1 for 'poly'.
- **Decision Tree:** This rule-based classifier resembles a tree-like structure and makes decisions based on a series of questions. At each node, a question is asked, and depending on the answer (yes or no), the algorithm

progresses to other nodes at subsequent levels, similar to an if-else structure. Decision trees consider one feature at a time from the input data (X) to create branches. The feature can be categorical or continuous, using categories or thresholds as decision criteria. Different criteria, such as Gini impurity and Entropy, can be used to determine the root node and subsequent decision-makers. Gini impurity calculates the frequency at which a sample in the dataset will be incorrectly labeled, while Entropy measures the disorder of features (X) with respect to the target label (y) [34].

$$\text{Gini Impurity} = 1 - \sum_i p_i^2 \quad (2)$$

$$\text{Entropy} = -\sum_i p_i \log_2 p_i \quad (3)$$

Where  $P_i$  is the probability for class 'i' such that  $i=1$  to 5. In the present study, the question would be: 'is the leukemia\_stat greater than a threshold value, say, x? Or is leukemia\_stat less than or equal to the threshold value? Thus, the DT will traverse each node and evaluate the condition before deciding which branch to proceed with until the leaf node (last) is hit. Here, there will be a total of five leaf nodes for each pathogenicity class. Both entropy and Gini impurities are used separately in the present study with max\_depth=3.

- **Random Forest:** It is based on the concept of ensemble algorithms, which combines multiple classifiers, and decision trees, solves the problem independently, and combines the results in the last step [35]. With this approach, the overall performance is improved. The model with correct prediction is retained, and incorrect predictions are pruned. The prediction rules are not visible to the user, thus enforcing a black-box concept. The multiple final DTs are combined, and the class with a majority vote will be assigned to the sample. With multiple DTs, the model obtains a higher accuracy and eliminates the problem of overfitting. RF will achieve the best accuracy compared to the previous models discussed here. The following parameters are used in the present study; n\_estimators=100 (overall trees the forest has), bootstrap = True (randomize the samples in the dataset), max\_features = 'sqrt' (takes the square root of the total features present in the dataset. Total features = 10 (computational scores+stat values + pathogenic class).  $\sqrt{10} \sim 3$ , so three features are tried randomly for each tree).
- **Artificial Neural Network:** ANN represents the working of a real human brain where the brain will generate outputs based on the past information trained earlier in life. ANN is suitable for any function, especially datasets that exhibit non-linear relationships. Feedforward neural network is a variation of ANN with three layers, an input layer, one or more hidden layers, and an output layer. Every layer has multiple nodes/neurons to process the input. The neural networks learn when fed with input and propagate to subsequent layers; hidden and output. This is called the learning/training phase. At each node at every layer, the network calculates the product of input values and weights, and the sum of these product terms along with

a bias value is calculated at every hidden node and sends the value to the next layer. That is, the network calculates a function, say 'f', for a predetermined input feature in 'X' and results in a training pair (X,y) such that  $f(X) \approx (y)$ . The actual and predicted values are calculated to understand the loss incurred by the network [36]. At the output layer, an activation function is used to obtain the result. The activation functions are: Sigmoid (the output value ranges between 0 and 1), tanh (ranges between -1 and +1), Rectified Linear Unit (ReLU) (returns the max (0, X)), softmax (return the probability of belonging to each output class, such that, when the values are added, we get 1). In the present study, a simple sequential model is trained using Keras that uses TensorFlow objects. The input\_dim was set to 9, matching the number of input parameters (computational scores + stat values), and the activation was ReLU with 16 neurons in the input layer. Two hidden layers were used, each with 32 and 64 neurons and the same activation function. The output layer has five neurons as there were five pathogenicity classes with softmax activation. The loss function was "sparse\_categorical\_crossentropy", optimizer='adam', metrics were set to accuracy with 100 epochs.

#### IV. IMPLEMENTATION

##### A. Dataset Collection

The dataset used in this study was collected from the UMD-tp53 database (Universal Mutation Database). The database, which initially had only 360 mutations in 1992, has now grown to contain over 80,000 mutation samples [37]. It consists of two files: variant and mutation. The mutation database includes samples of all patients with a tp53 mutation, while the variant database contains unique tp53 variants found in these patients. For this study, the mutation database with 80,406 samples (TP53 Mutated data, 2017 Release R2, available at <https://p53.fr/the-database>) was utilized. The database includes various variant classifications for mutant types, such as missense (58,517), nonsense (8,460), Frame-shift-del (5,212), splice-site (2,348), synonymous (2,016), frame-shift-ins (1,701), Indel (1,194), Ins (290), and others (668). The database was downloaded in CSV format.

##### B. Data Pre-Processing Phase

The initial mutant database downloaded from the tp53 website consisted of 80,406 rows and 133 columns. The prediction scores were based on various statistical values and computational scores present in the database. However, when the features start\_DNA and end\_DNA had a value of '?', most of the remaining features also had '?' (119 columns), and the pathogenicity class was labelled as 'no prediction.' Therefore, the rows with values start\_DNA and end\_DNA = '?' were removed as the first step in the pre-processing phase. This resulted in 80,346 rows and ten columns. Additionally, the start and end\_DNA features were not used in the prediction or classification process, so they were dropped from the feature set, resulting in a final dataset size of 80,346 X 8. The next step in pre-processing was to handle null values. Although there were no null values, three features (Sift, Mutassessor, and Provean scores) contained string values such as 'No data,'

'No protein,' 'Not known,' and 'Inframe.' As part of data cleaning, these string values were replaced with '?', as these values would be calculated using the proposed algorithm. Furthermore, the pathogenicity feature consisted of categorical data such as benign, likely pathogenic, pathogenic, possibly pathogenic, and VUS. To handle this, a label encoder was used to transform the string values into integer values. The respective classes were assigned the numbers 0, 1, 2, 3, and 4.

##### C. Data-Splitting:

The new DataFrame (new\_df) with a size of 80,346 X 8 was further divided into two DataFrames: data\_abs, which contained rows where the Sift\_score was '?', with a size of 21,902 X 8, and data\_pre, which included rows with available Sift\_score values, with a size of 58,444 X 8. From data\_pre, the features and labels were separated and named data\_pre\_temp and 'y', respectively. The '.values' function was used to convert the DataFrame data\_pre\_temp into a list named Xin. The KNeighborsRegressor class was then employed to train the model using Xin as the input features and y as the target labels in an 80:20 ratio. To find an ideal 'k' value, the 'k' value was varied from 2 to 20, and the Mean Absolute Error (MAE) was calculated for each 'k' value. The MAE represents the mean absolute difference between the actual and predicted values. The 'k' value that yielded the lowest MAE value was considered the optimal 'k' value for training the final model to predict the missing values. The DataFrame data\_abs was split into data\_abs\_temp (features) and ydim (labels). The '.values' of data\_abs\_temp were stored in Xdim as features, with ydim representing the labels. A new DataFrame named data\_predict was created with a column of the same name, Sift-score, to store the predicted values of ydim. This DataFrame was then joined with data\_abs\_temp and renamed as 'dataframe\_1'. The values of Sift\_score were extracted from data\_pre and stored in a new DataFrame called df\_join, which was further joined with data\_pre\_temp and renamed as 'dataframe\_2'. Finally, dataframe\_1 and dataframe\_2 were concatenated to form a new DataFrame named 'dataframe' with a size of 80,346 X 8, which matched the original size of the initial DataFrame new\_df. The DataFrame 'dataframe' now contained values that originally had missing values (21,902)

#### V. RESULTS

The predicted values obtained using the proposed algorithmic approach were compared with the state-of-the-art ML library method called Impute. KNNImputer was utilized with the same 'k' value as in the previous method. The values calculated by both methods were compared, and it was found that they were 85% similar. Additionally, two KNN models were trained separately, one using the proposed method and the other using the imputer method. The proposed model demonstrated superior accuracy compared to the built-in method.

##### A. Evaluation of Computational Scores Prediction using the Proposed Method and Built-In Method

The objective is to develop an ML-based approach to calculate missing values in three important pathogenicity prediction methods based on amino acid substitutions in protein sequences. In the tp53 database, certain values for

these three features were missing. Instead of using existing algorithms, this study employs the KNN regressor, an ML technique, for estimating these values. Additionally, each method requires a threshold, which can be adjusted based on user requirements. Hence, the threshold value was redefined to align with the existing value range. Table II presents the threshold used in this study to classify the scores into their respective variant classes. Fig. 2(a) to 2(c) shows the graphical illustration of the values computed for all three computational scores from both methods impute and code-based.

TABLE II. THE THRESHOLD VALUES ARE USED FOR DIFFERENT COMPUTATIONAL METHODS IN THE PATHOGENICITY CLASSIFICATION TASK

Computational Methods	Threshold values: Class type		
	Sift	$\leq 0.05$ : <b>Harmful</b>	$> 0.05$ : <b>Tolerated</b>
Provean	$\leq 2.5$ : <b>Deleterious</b>	$> 2.5$ : <b>Neutral</b>	--
Mutassessor	$\leq 1.0$ : <b>Neutral</b>	$> 1.0 \ \&\leq 2.0$ : <b>Low</b>	$> 2.0 \ \&\leq 4.0$ : <b>Medium</b>

Note: Shown in bold letters are the category labels used for each of the threshold values

Do the values computed by the proposed procedure outperform the reference method? - A Case study:

As depicted in Fig. 2, the computed missing values from both methods closely align, with minor variations observed at the beginning and end of the graph. However, the question arises whether these slight differences hold any predictive significance. Therefore, a case study was conducted to demonstrate that the proposed method exhibits superior classification performance for tp53 mutation samples. After calculating the missing values, an SVC classifier was employed to classify the samples based on pathogenicity variants using the computational methods. To further assess the results, the impute method, an ML library method for calculating missing values, was employed, and the same process was repeated. The trained SVC classifier effectively classified the samples using both the code-based and impute methods. The code-based approach achieved higher classification accuracy compared to the existing impute method for all three computational techniques. Additionally, the match percentage for each variant class was also calculated. The proposed and built-in methods achieved a match rate of over 81%. The significance of this evaluation is summarized in Table III.

B. Evaluation Metrics to Assess ML Model Performances

TABLE IV. THE NUMBER OF SAMPLES IN EACH PATHOGENICITY CLASS FOR THE TRAINING AND TEST DATASET

0: BENIGN, 1: LIKELY PATHOGENIC, 2: PATHOGENIC, 3: POSSIBLY PATHOGENIC, 4: VUS

	Data split 80:20	Class #				
		0	1	2	3	4
No. of training samples	46755 80%	50	5146	30509	7981	3069
No. of test samples	11689 20%	11	1303	7636	1998	741
Total	58444 100%	61	6449	38145	9979	3810

Table IV gives the number of samples in each pathogenicity class for the training and test dataset.

Confusion Matrix (CM) is a tabular representation of the performance in the classification task [38]. It contains the true values along the y-axis and estimated values along the x-axis. The number of rows and columns depends on the number of classification classes.

TABLE V. A CONFUSION MATRIX FOR A RANDOM FOREST ALGORITHM FOR MULTI-CLASS CLASSIFICATION OF PATHOGENICITY LABELS

N REPRESENTS A CLASS NAME; CM IS THE CONFUSION MATRIX C. A GREEN COLOUR ROW REPRESENTS AN FN, AND THE YELLOW COLUMN REPRESENTS AN FP, AND PINK IS THE ACTUAL TRUE POSITIVE FOR THE CLASS N=1. ACTUAL CLASS : AC

C M ( C )	N class es	Prediction Class					Total
		N=0	N=1	N=2	N=3	N=4	
AC	N=0	CC <sub>00</sub> =11	0	0	0	0	11
	N=1	0	CC <sub>11</sub> =1293	0	0	10	AN=2=1303
	N=2	0	0	CC <sub>22</sub> =7636	0	0	7636
	N=3	0	0	0	CC <sub>33</sub> =1994	4	1998
	N=4	0	4	0	0	CC <sub>44</sub> =737	741
	Total	11	PN=2=1297	7636	1994	751	T=11689

Table V describes a CM matrix of the RF algorithm, illustrating the different numbers obtained from the ML model. Here, CCNN indicates the correctly classified samples, T is the count of test samples, AN is the total times a sample is correctly classified to its actual class, and PN represents the number of times a sample is predicted. The main components of a CM are as follows: A true positive (TP) is when a true class 0 (benign) is predicted as 0 (benign). A true negative (TN) is when an actual class is not 0 and is predicted correctly as not class 0. A false positive (FP) is when a true class 0 is wrongly predicted as class 1 or any other class, and lastly, a false negative (FN) is when a true class is not 0 but is mispredicted as class 0. Further, the standard performance metrics derived from CM are described in Eq. [4 – 7]. Those are i) A recall is a measure of all positive samples that the

model predicted correctly for the class; this indicates how much the model correctly predicted for the total samples of class 0. ii) A precision indicates the quality of the prediction, i.e., how many times the model correctly predicted a sample as class 0 out of all the total number of class 0 true samples. iii) F-Score is the average of both recall and precision. iv) accuracy is the actual number of samples that the model correctly classifies over the total number. v) The macro average scores are calculated by considering the weighted mean for each R, P, and F for every predicted class without considering each label's proportion. vi) The weighted average score is calculated by taking the product of the sum of individual recall, precision, and f-score and each classified sample over the actual number of samples for the classification class. This is similar to the macro score except that the weighted score considers the proportion of individual labels. vii) The micro average considers the total TP, FP, and FN irrespective of the prediction made by the model for each class

$$Recall (R) = \frac{TP}{TP+FN} \quad (4)$$

$$Precision (P) = \frac{TP}{TP+FP} \quad (5)$$

$$F\ Score = 2 * \frac{PR}{P+R} \quad (6)$$

$$Accuracy = \frac{TP+TN}{TP+FN+TN+FP} \quad (7)$$

Table VI illustrates the performance achieved for each of the ML techniques on the test dataset.

TABLE VI. THE TABULATION OF VARIOUS EVALUATION METRICS ON THE TEST DATASET FOR EACH ML METHOD. THE RF RESULTED IN THE HIGHEST ACCURACY, CLOSELY FOLLOWED BY KNN AND DL METHODS

Method	Class	P	R	F	Macro	Micro	Weighted	Accuracy

Cross-validation is the most famous evaluation metric to estimate the actual prediction of an ML model [39]. This method splits the entire dataset into ten folds (k-cross fold where k=10) to form a training and test set with 0-9 folds consisting of 0 - 5844 samples and the 10<sup>th</sup> fold containing 5845 - 5848 samples. After executing the final model 10 times, all ten folds accuracy scores were obtained using cross\_val\_score (Table VII). The average scores for all 10-folds are obtained using cross\_val\_predict.

TABLE VII. TABULATION OF ACCURACY FOR EACH ML METHOD FOR EACH FOLD IN CROSS-VALIDATION APPROACH. THE K VALUE IS 10, WHERE 0-9 FOLDS RANDOMLY SERVE AS THE TRAINING SET, AND THE REMAINING ONE FOLD ACTS AS A TEST SET

### C. Discussions

So far, the pathogenicity of cancer types has been studied using computational scores calculated using various statistical approaches. However, the rapid growth of machine learning applications has sparked interest in designing an ML-based

strategy for calculating these scores. In the first approach of this research study, three computational scores were calculated based on the data available in the tp53 database. The thresholds for these scores were kept unchanged, consistent with those used in the tp53 repository. The results were compared with the existing ML library's impute method. Subsequently, a separate KNN model was trained using the calculated scores from the code and the built-in approaches. It was observed that the code approach outperformed the built-in method in terms of accuracy. This process was repeated for all three computational techniques used to calculate the scores. Furthermore, when three or more statistical scores were equal to zero, the predicted Sift score was always zero. However, when these values were utilized for the classification task, the model achieved only 78% accuracy. Consequently, input features with a high number of zero values were dropped, and the remaining samples were considered for the classification task. In the second part of the study, six different ML techniques were evaluated to classify tp53 samples into pathogenicity classes. The investigation revealed that ML algorithms efficiently classified the data with very high accuracy in most models. Among the six algorithms, the RF algorithm yielded the best results, achieving an F-score of 1 in many cases. As mentioned in the introduction, missense mutations are highly prevalent in approximately 80% of cancer samples. Scientists worldwide dedicate their valuable time to understanding the significance of these mutations and devising novel techniques to combat cancer. Therefore, the present research study offers practical solutions in significantly less time compared to manual evaluation. In terms of clinical significance, clinicians can utilize these techniques to swiftly obtain computational scores and classify records into pathogenicity classes without the need for clinical tools or equipment intervention. Moreover, RF and NN techniques could be adopted for risk analysis and the design of predictive diagnostic procedures. Although this hypothesis was not proven in the present study, literature reports suggest that NN techniques could outperform other ML algorithms in such tasks.

1) *Drawbacks:* The present study has several limitations. Firstly, the proposed prediction strategy heavily relies on the existing dataset values. It can only predict missing values in a feature column, assuming that the column already contains some pre-processed values. Consequently, the predictive ability of ML models is contingent upon the values present in the database, which may result in sampling errors when applying feature selection techniques. Furthermore, the study compares the classification accuracy of six prominent ML algorithms. However, without any specific reason, other efficient ML models were not investigated. For instance, deep neural network-based models could have potentially addressed the problem of feature selection in a more effective manner. The omission of such efficient algorithms limits the comprehensive exploration of potential solutions for feature selection. These limitations should be taken into consideration when interpreting the results and implications of the study. Future research should aim to overcome these drawbacks and explore the application of additional ML models to improve

feature selection and enhance the predictive performance of the proposed approach.

2) *Future work*: There are several potential areas for further extension in this research study. First, it involves locating the actual disease-causing missense variants among all gene-specific mutations in a patient's sample. Typically, a single cancer patient may have approximately 500 missense mutations. However, only a few of these mutations exhibit cancer-related symptoms, while the majority may be non-cancerous or benign. ML-based models can assist in narrowing down the candidate mutations based on predictive scores, thereby reducing the time required for pathogenicity prediction and minimizing diagnostic costs. Second, a prediction model can be developed for pathogenicity classification based on different types of mutations, such as missense and frameshift mutations. Such a model can utilize amino acid sequences as input features and forecast the functional domains of genes and proteins involved in causing these deleterious mutations. Third, the focus could be on identifying the pathogenic components within a gene and searching for symptoms associated with similar diseases. This knowledge can aid in determining appropriate treatment approaches, potentially using similar strategies employed for identical diseases. It may also facilitate the process of target identification for prospective drug development. Fourth, it is important to identify the proteins involved in each malignant mutation, analyze their characteristics, and identify drugs that target these proteins in both Gain-of-function and Loss-of-function situations. For instance, in the case of tp53, Loss-of-function is considered. Fifth, incorporating patient-specific gene information can help assess interactions between genomic variants. This approach could provide a likelihood ratio for disease-causing genes and enable the targeting of these genes for effective drug interventions, further supported by in-vitro methodologies. Lastly, creating a multi-layer neural network model can enhance understanding of clinical carcinogenesis and evolutionary conservation by analyzing amino acids conserved throughout the progression. The gene and protein information obtained from previous steps can be leveraged for this prediction task.

## VI. CONCLUSION

The present research study focused on two key aspects: estimating the missing scores using a novel ML method and comparing and analyzing different ML algorithms for a classification task. The proposed ML-based approach for calculating missing values in three pathogenicity prediction computational scores has two strong points for medical use. First, there haven't been any such algorithms to calculate these scores using an ML technique that exhibits high accuracy compared to the built-in ML library method. The other point is leveraging this idea to classify the samples from the tp53 database into their appropriate pathogenicity class, as defined by ACMG guidelines. Furthermore, missing values in databases are a common hindrance to achieving high accuracy. Thus, the proposed technique could calculate these

missing values in a diverse range of databases. Additionally, the research used six different ML techniques to classify the tp53 database based on the pathogenicity class. It was found that RF and DL outperformed other methods in terms of various performance metrics. The study also suggested that logistic regression performed poorly with an accuracy of 89% compared to other techniques. The features used in this study could help unravel effective biomarkers related to the tp53 database. Clinicians may perform complementary analyses in terms of validation and clinical trials by adopting the proposed framework. The best-performing model could further be enhanced by training it on a different dataset. Once approved by standard authorities, the ML-based clinical tool may collect blood samples from patients, predict the values of computational scores, and provide the likelihood of pathogenicity. Overall, this research study offers promising insights into addressing missing values and improving classification accuracy in the field of pathogenicity prediction. The proposed ML-based approach has the potential to enhance diagnostic capabilities and facilitate personalized treatment decisions in clinical settings.

## CONFLICT OF INTEREST

The author(s) declare that there are no conflicts of interest for the present study.

# An Empirical Deep Learning Approach for Arabic News Classification

Roobaea Alroobaea

Department of Computer Science-College of Computers and Information Technology, Taif University, P. O. Box 11099, Taif 21944, Saudi Arabia

**Abstract**—In this paper, we tackle the problem of Arabic news classification. A dataset of 5,000 news articles from various Saudi Arabian news sources were gathered, classified into six categories: business, entertainment, health, politics, sports, and technology. We conducted experiments using different pre-processing techniques, word embeddings, and deep learning architectures, including convolutional neural networks (CNNs) and long short-term memory (LSTM) networks, as well as a hybrid CNN-LSTM model. Our proposed model achieved an accuracy of 93.15, outperforming other models in terms of accuracy. Moreover, our model is evaluated on other Arabic news datasets and obtained competitive results. Our approach demonstrates the effectiveness of deep learning methods in Arabic news classification and emphasizes the significance of careful selection of preprocessing techniques, word embeddings, and deep learning architectures.

**Keywords**—*deep learning (DL); machine-learning (ML); convolutional neural networks (CNNs); long short-term memory (LSTM)*

## I. INTRODUCTION

News classification is an important task in information retrieval and natural language processing [11]. It involves the automatic categorization of news articles into pre-defined topics or classes, which enables efficient organization and retrieval of large amounts of news data. The classification of news articles is useful for various applications such as content-based recommendation systems, news aggregation, and personalized news delivery [13].

Traditionally, human experts have done news classification manually, which is a time-consuming and expensive process. With the increasing amount of news articles being published daily by researchers, traditional manual classification methods have become inefficient and impractical. Therefore, the use of machine learning techniques, particularly deep learning algorithms, has gained popularity in recent years for automatically classifying news articles into various topics.

Deep learning algorithms have proven to be highly effective in natural language processing tasks, including sentiment analysis [16][17], text classification, and machine translation. These algorithms use artificial neural networks that are capable of learning complex patterns in data, making them well suited for tasks such as news classification.

The aim of this paper is to apply deep learning techniques to classify tweets in Arabic language, specifically in the context of Saudi Arabia. Twitter is a popular social media platform that generates a massive amount of data every day.

Tweets provide valuable insights into public opinion and sentiment on various topics, making them a useful source of information for news classification.

A dataset of 5000 documents were collected. It contains tweets on four different topics and provide a comprehensive analysis of the classification performance, highlighting the effectiveness of our proposed methodology.

One of the key contributions of this paper lies in its focus on the Arabic language and the utilization of a multi-classification task rather than a binary classification approach. This aspect distinguishes our work from many existing studies, as the majority of research in news classification has predominantly focused on English or other widely studied languages [12]. By addressing the specific challenges and characteristics of Arabic language processing, we contribute to bridging the gap in the literature and expanding the applicability of deep learning techniques to diverse linguistic contexts.

Furthermore, the adoption of a multi-classification task is another significant contribution. While binary classification is a common approach in news classification, our work extends beyond the binary realm by classifying news articles into multiple predefined topics or classes. This approach allows for a more comprehensive and nuanced analysis of news content, enabling finer-grained categorization and better meeting the needs of information retrieval systems and downstream applications.

The rest of the paper is organized as follows. Section II provides a detailed review of related work in news classification using deep learning techniques. Section III describes our methodology, including pre-processing techniques, feature extraction, and deep learning algorithms. Section IV presents the experimental setup and Section V gives the results of our classification approach. A comparison of our study to other related work is presented in Section VI. The discussion of our results is given in Section VII. Finally, Section VIII provides a conclusion and future directions for research in this field.

## II. LITERATURE REVIEW

News classification has been a widely studied problem in the field of natural language processing. In recent years, deep learning techniques (DL) have been increasingly used for news classification due to their ability to learn complex patterns in data. In this section, the review has been done on some of the

key works related to news classification using deep learning techniques.

In [1], the deep learning approach was proposed for news classification. The authors used a Convolutional Neural Network (CNN) architecture for text classification, achieving state-of-the-art performance on the Reuters-21578 dataset [15]. The CNN architecture utilized pre-trained word embeddings to represent words in the news articles as numerical vectors [10]. The results demonstrated significant improvements in classification accuracy compared to traditional machine learning approaches.

Similarly, in [2], a CNN-based approach for sentiment analysis of movie reviews was proposed. Pre-trained word embeddings were employed to represent words in the movie reviews. This work highlighted the effectiveness of CNNs for text classification tasks.

In [3], a deep learning approach utilizing a Long Short-Term Memory (LSTM) architecture was proposed for news classification. The authors utilized pre-trained word embeddings and trained the LSTM network to classify news articles into multiple categories. The results showed significant improvements in classification accuracy compared to traditional machine learning approaches.

Furthermore, in [4], a deep learning approach combining CNN and LSTM architectures was used for news classification. The authors used pre-trained word embeddings and trained the combined CNN-LSTM network to classify news articles into multiple categories, demonstrating improved classification accuracy compared to traditional machine learning approaches.

In [5], a deep learning approach employing a Hierarchical Attention Network (HAN) architecture was employed for news classification. The authors utilized pre-trained word embeddings and trained the HAN network to classify news articles into multiple categories, achieving notable improvements in classification accuracy compared to traditional machine learning approaches.

Moreover, in [6], a deep learning approach combining CNN and RNN architectures was proposed for news classification. The authors employed pre-trained word embeddings and trained the combined CNN-RNN network to classify news articles into multiple categories, yielding significant improvements in classification accuracy compared to traditional machine learning approaches.

In [7], a deep learning approach utilizing a Multi-Granularity Convolutional Neural Network (MG-CNN) architecture was proposed for news classification. Pre-trained word embeddings were used, and the MG-CNN network was trained to classify news articles into multiple categories, resulting in improved classification accuracy compared to traditional machine learning approaches.

Furthermore, in [8], a deep learning approach employing a Transformer-based architecture was proposed for news classification. Pre-trained word embeddings were utilized, and the Transformer network was trained to classify news articles into multiple categories, achieving substantial improvements in

classification accuracy compared to traditional machine learning approaches.

In conclusion, deep learning approaches such as CNNs, LSTMs, HANs, CNN-RNN hybrids, MG-CNNs, and Transformer-based architectures have demonstrated significant improvements in news classification accuracy compared to traditional machine learning approaches. These techniques have been successfully applied to various news datasets, including Reuters-21578, New York Times, and other publicly available news datasets. Table I present some of the commonly used datasets for news classification:

TABLE I. USED DATASETS FOR NEWS CLASSIFICATION

Dataset	Source	Classes	Documents	Description
	Reuters	Reuters	90	11,228
20 Newsgroups	Various	20	18,846	Newsgroup posts from various sources, labeled by topic
AG's News	AG	4	120,000	News articles from the AG's corpus, labeled by topic
BBC News	BBC	5	2,225	News articles from the BBC, labeled by category
Yelp Reviews	Yelp	2	560,000	Reviews from Yelp, labeled as positive or negative
Amazon Reviews	Amazon	5	1,800,000	Reviews from Amazon, labeled by star rating
DBPedia	DBPedia	14	560,000	Wikipedia articles, labeled by category
Google News	Google News	6	1,000,000	News articles from Google News, labeled by category

To summarize the studies presented on the related works, Table II shows that the majority of the studies in the literature review have used deep learning approaches for news classification. The use of pre-trained embeddings is also widespread, which is not surprising given the performance gains that can be achieved by using pre-trained word vectors.

TABLE II. COMPARATIVE TABLE PRESENTING A SUMMARY OF THESE STUDIES

Study						
	Approach	Architecture	Pre-trained embeddings	Dataset	Categories	Accuracy
[1]	DL	CNN	Yes	Reuters-21578	90	88.89 %
[2]	DL	CNN	Yes	Various datasets	Binary	88.89 %
[3]	DL	LSTM	Yes	Reuters-21578	90	90.05 %
[4]	DL	CNN-LSTM	Yes	Various datasets	Multiple	90.42 %
[5]	DL	HAN	Yes	Sina News	15	91.57 %
[6]	DL	CNN-RNN	Yes	Various datasets	Multiple	92.87 %
[7]	DL	MG-CNN	Yes	AG's News, Sogou News, Yahoo! News	4, 5, 10	92.95 %, 95.49 %, 87.94 %
[8]	DL	Transformer	Yes	Yelp Review Polarity	Binary	97.8%

It is interesting to note that some studies have explored more complex architectures such as the Hierarchical Attention Network (HAN) and the Multi-Granularity (MG) CNN. These architectures are designed to capture different levels of information in the text and have shown promising results in various datasets.

In terms of dataset, there is a wide variation in the number and type of categories used in the studies, ranging from binary classification to multiple categories. This reflects the diversity of news classification tasks and highlights the need for different approaches depending on the specific task.

Finally, it is worth noting that the reported accuracies are quite high, with some studies achieving over 90% accuracy on their respective datasets. However, it is important to bear in mind that these results are highly dependent on the specific dataset and evaluation metrics used, and that real-world performance may vary depending on factors such as data quality and distribution. Table III summarizes the strengths and weaknesses of the studies mentioned in the literature review.

Table III underscores the importance of considering both the strengths and weaknesses of previous work when designing new approaches to news classification. By building on the

strengths and addressing the weaknesses of previous work, researchers can advance the state-of-the-art in news classification and make meaningful contributions to the field.

However, based on the strengths and weaknesses outlined in the table, some potential observations can be made. For example, [1] and [2] both achieved high accuracy with relatively simple CNN architectures, making them attractive options for researchers looking for a straightforward approach to news classification. The study [3] demonstrated the effectiveness of LSTM-based architectures for news classification, while [4] showed that combining CNN and LSTM architectures can lead to improved performance. The authors in [5] proposed a novel HAN architecture that captured both word-level and sentence-level attention, while [6] combined CNN and RNN architectures to achieve high accuracy across multiple datasets. The research [7] introduced a novel Multi-Granularity CNN architecture that achieved state-of-the-art performance on multiple datasets, although its applicability to longer texts may be limited. Finally, [8] achieved state-of-the-art performance with a Transformer-based architecture, although their study was limited to binary classification and a single dataset. Overall, each study has its own strengths and weaknesses, and the best approach to news classification may depend on the specific task and available resources.

TABLE III. THE STRENGTHS AND WEAKNESSES OF THE STUDIES MENTIONED IN THE LITERATURE REVIEW

Study		
	Strengths	Weaknesses
[1]	Achieved high accuracy with a simple CNN architecture	Limited to only one dataset
[2]	Achieved high accuracy with a simple CNN architecture	Limited to binary classification
[3]	Achieved high accuracy with a novel LSTM architecture	Limited to only one dataset
[4]	Improved performance with a combined CNN-LSTM architecture	Limited evaluation on datasets other than Yelp
[5]	Novel HAN architecture that captures both word-level and sentence-level attention	Limited to only one dataset
[6]	Combined CNN-RNN architecture that achieved high accuracy across multiple datasets	Limited discussion of model interpretability
[7]	Novel MG-CNN architecture that achieved state-of-the-art performance on multiple datasets	Limited to relatively short texts
[8]	State-of-the-art performance with a Transformer-based architecture	Limited to binary classification and Yelp dataset

### III. METHODOLOGY

This study aims to classify news articles in Saudi Arabia into four different topics using a deep learning approach. The four topics selected for this study are politics, business, sports, and entertainment. To achieve this goal, a convolutional neural network (CNN) model and CNN-LSTM hybrid architecture were developed and trained it on a dataset of 5,000 news articles collected from Twitter in Arabic. One advantage of our

method is that it operates on multi-classification rather than binary classification. Additionally, it focuses specifically on the Arabic language, which is rare in the literature.

#### A. Data Collection

The dataset of 5,000 news articles was collected using the Twitter API. To ensure the relevance of the dataset to Saudi Arabia, the specific keywords was used related to the four topics selected. The collected articles were in the Arabic language and varied in length, with the average article length being approximately 200 words.

The specific keywords used to collect the data were chosen based on prior research on the topics of interest and consultation with subject matter experts. To ensure that the collected articles were recent and up-to-date, it was only included articles that were posted within the last six months. To avoid duplication of articles, a script was used to remove any duplicate tweets that were retrieved from the API. Also, manually checked the sample of the collected articles to ensure that they were relevant to the selected topics and were of sufficient quality for analysis. Finally, the data was anonymized by removing any identifying information such as user handles and names before beginning the analysis

#### B. Data Preprocessing

After collecting our dataset of 5,000 news articles using the Twitter API and ensuring their relevance to Saudi Arabia, the data was preprocessed before inputting it into our CNN model. To do this, we first performed various text cleaning techniques, including removing stop words, stemming, and removing non-Arabic characters. We also eliminated any URLs, mentions, and hashtags from the text, as these do not provide relevant information for topic classification. Additionally, we removed any articles with fewer than ten words, as they may not provide sufficient information for classification.

To further preprocess the data, the natural language toolkit (NLTK) and Arabic-specific libraries were utilized to tokenize the text and convert it to a numerical representation suitable for input into our CNN model. We employed a bag-of-words approach to represent each article, where each word was assigned a unique numerical value. This allowed us to represent the text in a structured, numerical format that could be used as input for our CNN model. Overall, these preprocessing steps were critical in ensuring the quality and relevance of our data and allowed us to perform accurate classification of the news articles.

#### C. Model Architecture

Our CNN model consisted of an input layer, multiple convolutional and pooling layers, and two fully connected layers followed by a softmax activation function for multi-class classification. The input layer had a shape of (max\_length, vocab\_size), where max\_length is the maximum length of an article after preprocessing and vocab\_size is the number of unique words in the dataset.

The convolutional layers had a filter size of three and used the ReLU activation function. The pooling layers used a max-pooling approach with a pool size of two. The fully connected layers had a hidden size of 256 and 128, respectively, and used

the ReLU activation function. The output layer had a size of four, corresponding to the four topics, and used the softmax activation function for multi-class classification.

#### D. Training and Validation

In the training and validation phase, the collected dataset was divided randomly into two sets: a training set of 4,000 articles and a validation set of 1,000 articles. The purpose of this step was to train the model on a subset of the dataset and use the validation set to evaluate its performance [9]. We used the Adam optimizer, which is a stochastic gradient descent algorithm that uses adaptive learning rates, to optimize the model parameters. The learning rate was set to 0.001 and used a batch size of 32. The model was trained for 50 epochs, and early stopping was employed to prevent overfitting.

To measure the difference between the predicted and actual class probabilities during training, the cross-entropy loss function was used. We also implemented dropout regularization with a rate of 0.5 to reduce overfitting. To accelerate the training process, we used a GPU. The purpose of training was to optimize the model's weights and biases on the training data, so that it can accurately classify the articles in the validation set.

#### E. Hyperparameter Tuning

To fine-tune our model and improve its performance, we performed a hyperparameter tuning process. It used a grid search approach to evaluate various combinations of learning rates and batch sizes, and selected the combination that resulted in the highest validation accuracy. In addition, a sensitivity analysis was conducted to assess the impact of changes in hyperparameters on the model's performance. By evaluating different hyperparameters, we aimed to identify the optimal values that would improve the model's accuracy and generalizability on unseen data. This process allowed us to optimize the training process and improve the overall performance of our CNN model on the news classification task.

Compared to studies that use traditional machine learning algorithms such as Naive Bayes and Support Vector Machines, our method based on a CNN allows for more complex feature extraction and modeling. CNNs are particularly effective at detecting patterns in image and text data, and have been shown to outperform traditional machine learning algorithms on a variety of tasks. Our focus on news articles from Saudi Arabia is an important contribution to the field, as there has been relatively little research on news classification specifically for this region. By tailoring our approach to the unique characteristics of news from Saudi Arabia, such as the prevalence of religious and political topics, we are able to achieve better classification performance than general-purpose models. Another way in which our method differs from related work is in our use of pre-training. By first training the model on a large, general corpus of Arabic text, we are able to improve its performance on the specific task of news classification. This approach is similar to transfer learning, a technique widely used in deep learning that involves fine-tuning a pre-trained model on a specific task.

Overall, our method represents a novel approach to news classification that takes into account the unique characteristics of news from Saudi Arabia. By using a deep learning approach based on a CNN and incorporating pre-training, we are able to achieve high classification accuracy on a range of news topics. In terms of our contribution, our study provides insights into the effectiveness of using a CNN for news classification in the context of Saudi Arabia. Our use of specific keywords to collect a relevant dataset is a novel approach that could be useful for other researchers looking to collect data from a specific geographic region or on a specific topic. Additionally, our study provides a detailed analysis of the performance of our model, including sensitivity analysis and the selection of optimal hyper-parameters. Overall, our study contributes to the growing body of research on news classification and highlights the potential of deep learning approaches in this field.

#### IV. EXPERIMENTATIONS

In this section, the experimental setup and results of our news classification model were presented. Starting by describing the dataset used in our experiments, followed by a detailed description of our experimental methodology, including model architecture, hyper-parameters, and training/validation process. Finally, we present and analyze the results of our experiments and compare them to the related work in the field.

##### A. Dataset

Collecting and annotating data for a machine-learning project can be a time-consuming and challenging process, but it is essential to ensure the quality and accuracy of the final model. In the case of our news classification project, we collected a dataset of news articles from various Saudi Arabian news sources, including Al Arabiya, Al Jazeera, and Saudi Gazette. The articles were manually categorized into six classes: business, entertainment, health, politics, sports, and technology. The annotation process involved reading each article and assigning it to the appropriate class based on its content. To ensure the consistency of the annotation process, multiple annotators were involved, and any disagreements were resolved through discussion and consensus. Once the dataset was annotated, it was preprocessed and formatted to be used as input to our deep learning model. The quality and accuracy of the dataset are critical to the success of the machine-learning (ML) model, as it determines the model's ability to generalize and make accurate predictions on unseen data.

##### B. Experimental Methodology

Similar to the approach proposed [1], the model takes as input a sequence of words represented as pre-trained word embeddings and processes them. We used the PyTorch framework to implement our model.

To select the optimal hyperparameters, we performed a grid search over several combinations of learning rates and batch sizes. We selected the hyperparameters that resulted in the highest validation accuracy. Furthermore, sensitivity analysis was performed to evaluate the impact of changing hyperparameters on the model's performance.

We randomly split our dataset into a training set of 4,000 articles and a validation set of 1,000 articles. We trained the model using the Adam optimizer with a learning rate of 0.001 and a batch size of 32. The model was trained for 50 epochs, and early stopping was used to prevent overfitting. We also used dropout regularization with a rate of 0.5 to prevent overfitting. The model was trained on a GPU to accelerate the training process.

#### V. RESULTS AND ANALYSIS

Our model's performance was evaluated on a separate test set of 1,000 articles, which were not used in training or validation. Our model achieved an overall accuracy of 87%, with F1-scores ranging from 0.82 for the entertainment category to 0.92 for the health category. These results demonstrate the effectiveness of our approach for news classification.

TABLE IV. NUMBER OF NEWS ARTICLES IN OUR DATASET

Class	No. of Articles
Business	850
Entertainment	750
Health	550
Politics	950
Sports	1100
Technology	800

Table IV shows the number of news articles in each of the six categories in our dataset. The Sports category has the largest number of articles, while Health has the fewest.

TABLE V. COMPARISON OF DIFFERENT PREPROCESSING TECHNIQUES

Preprocessing Technique	Accuracy (%)
None (baseline)	85.20
Stop words removal	87.45
Stemming	86.40
Lemmatization	87.20
Stop words removal + stemming	88.15
Stop words removal + lemmatization	88.50

Table V presents the comparison of different preprocessing techniques used in the experiment, including no preprocessing, stop words removal, stemming, lemmatization, and stop words removal with lemmatization. The preprocessing techniques were applied to the news articles before feeding them into the model for training and testing.

The results show that the combination of stop words removal and lemmatization achieved the highest accuracy of 88.50%. Stop words removal alone resulted in a lower accuracy of 87.45%, indicating that removing stop words is helpful but not sufficient for improving the performance of the model. Stemming, on the other hand, did not result in any significant improvement in accuracy compared to the no preprocessing technique. Lemmatization alone achieved an accuracy of 87.20%, indicating that it is a useful preprocessing technique but can be improved by combining it with stop words removal.

Overall, the results suggest that a combination of stop words removal and lemmatization is the most effective preprocessing technique for news classification in our dataset. This is in line with previous studies that have shown the effectiveness of these techniques in improving the performance of text classification models.

Table V presents the comparison of different word embeddings used in the experiment. The word embeddings evaluated in this study include GloVe, FastText, Word2Vec, and BERT. The evaluation metric used is accuracy, and the best performing model is highlighted in bold.

TABLE VI. COMPARISON OF DIFFERENT WORD EMBEDDINGS

Word Embedding	Accuracy (%)
Word2Vec	89.20
GloVe	90.10
FastText	89.75
ELMo	91.20
BERT	92.05

In Table VI, it can be seen that the GloVe embedding also performed well with an accuracy of 90.10, which is expected, as GloVe is a widely used and effective embedding technique. However, fastText and Word2Vec embeddings had slightly lower accuracies of 89.75 and 89.20, respectively.

The lower performance of Word2Vec could be due to its lack of sub-word information, which is captured by fastText. On the other hand, fastText may have suffered from overfitting on the relatively small dataset used in the experiment.

Overall, the results of Table VI demonstrate that BERT is a powerful and effective embedding technique for text classification tasks, but other embeddings can also perform well and should be considered depending on the specific requirements of the task.

TABLE VII. COMPARISON OF DIFFERENT CNN ARCHITECTURES

CNN Architecture	Accuracy (%)
1-layer CNN	91.80
2-layer CNN	92.40
3-layer CNN	92.10
4-layer CNN	92.60

Table VII compares the performance of different CNN architectures for the text classification task. The experiment was conducted using the preprocessed dataset with stop words removal and lemmatization and BERT embeddings.

The results show that the 4-layer CNN architecture achieved the highest accuracy of 92.60, outperforming the other architectures. This could be due to its ability to capture more complex patterns in the text data through its deeper architecture.

It is also interesting to note that the 2-layer CNN architecture performed relatively well, achieving an accuracy of 92.40, indicating that a simpler architecture can still achieve good results.

On the other hand, the 1-layer CNN architecture performed the worst, with an accuracy of 91.80, suggesting that a shallow architecture may not be sufficient for capturing the complexities of the text data.

Overall, the choice of CNN architecture can have a significant impact on the classification performance, and a deeper architecture may be more suitable for complex text data.

TABLE VIII. COMPARISON OF DIFFERENT LSTM ARCHITECTURES

LSTM Architecture	Accuracy (%)
1-layer LSTM	90.40
2-layer LSTM	90.90
3-layer LSTM	91.40
4-layer LSTM	91.20

Table VIII compares the performance of different LSTM architectures used in the experiment. The models were trained with the same hyperparameters, except for the number of LSTM layers, which varied from one to three. The results show that the 3-layer LSTM outperformed the other architectures, achieving an accuracy of 91.40.

The 2-layer LSTM performed better than the 1-layer LSTM, indicating that adding more layers can improve the model's ability to capture sequential dependencies in the text data. However, increasing the number of layers beyond two did not result in significant performance improvements.

It is worth noting that all LSTM models performed relatively well, with accuracies above 90%. This suggests that LSTMs are effective in modeling sequential data, and the choice of architecture should be based on the complexity of the task and the amount of available data.

TABLE IX. COMPARISON OF CNN AND LSTM ARCHITECTURES

Architecture	Accuracy (%)
CNN	92.60
LSTM	91.40
CNN-LSTM	93.15

Table IX presents the comparison of different architectures used in the experiment. The CNN-LSTM hybrid model outperformed the other architectures, achieving an accuracy of 93.15. This is because the CNN-LSTM model combines the strengths of both CNN and LSTM networks, allowing it to capture both local and global dependencies in the text data.

It is interesting to note that the traditional machine learning models, such as Naive Bayes and SVM, performed relatively well, achieving accuracies above 83.75. However, they were outperformed by the deep learning models, indicating that the deep learning models are more suitable for text classification tasks due to their ability to capture complex patterns and dependencies in the text data.

Overall, the results suggest that the choice of architecture can have a significant impact on the classification performance, and a hybrid approach that combines different architectures can lead to better results.

According to Table X, the proposed model achieved an accuracy of 93.15, outperforming other models such as SVM, Naive Bayes, and Random Forest. This highlights the effectiveness of the proposed model in accurately classifying news articles into different categories.

TABLE X. COMPARISON OF PROPOSED MODEL WITH RELATED WORK

Model	Accuracy (%)
SVM (Alamri and Al-Salman, 2016)	83.75
CNN (Zhang et al., 2015)	90.02
CNN-LSTM (Yang et al., 2016)	91.54
HAN (Zhang et al., 2019)	91.95
Proposed model	93.15

It is worth noting that the proposed model also outperformed LSTM and CNN. This can be attributed to the unique architecture of the proposed model, which combines the strengths of both CNN and LSTM in a hybrid model.

Overall, the results indicate that the proposed model is a promising approach for news article classification and can potentially be applied to other text classification tasks as well. However, further research is needed to explore the generalizability of the proposed model to other languages and domains.

## VI. COMPARISON TO RELATED WORK

Compared to traditional machine learning approaches such as Naive Bayes and Support Vector Machines, our deep learning-based approach achieved superior performance on the Saudi Arabian news dataset. Additionally, our approach outperformed previous deep learning-based approaches for news classification on several benchmark datasets, including the Reuters-21578 dataset. Our study also contributes to the field by focusing specifically on news articles from Saudi Arabia, which has received limited attention in previous studies.

Overall, our experiments demonstrate the effectiveness of using a CNN-based approach for news classification on a Saudi Arabian news dataset, and it believes that our approach could be extended to other languages and countries with similar news sources.

To demonstrate the competitiveness and reproducibility of our proposed method, the experiments were conducted on two additional datasets: Reuters-21578 and 20 Newsgroups. The Reuters-21578 dataset contains news articles from Reuters, categorized into 90 different classes, while the 20 Newsgroups dataset contains posts from newsgroups, categorized into 20 different classes.

For each dataset, the same experimental setup was followed as before, using BERT as the word embedding method and the CNN-LSTM hybrid architecture as the classification model. The datasets were split into 80% training, 10% validation, and 10% testing sets, and used the same evaluation metrics as before: accuracy, precision, recall, and F1-score.

The results of our proposed method was compared with those of other studies that used the same datasets. For the Reuters-21578 dataset, our results were compared with those of

Kim's CNN model (2014), which achieved the best results at the time of publication. For the 20 Newsgroups dataset, our results were compared with those of Yang's SVM model (1999), which is a widely used baseline for this dataset.

TABLE XI. COMPARISON OF OUR PROPOSED METHOD WITH KIM'S CNN MODEL ON THE REUTERS-21578 DATASET

Model	Accuracy	Precision	Recall	F1-score
Kim's CNN model (2014)	0.849	0.845	0.848	0.845
Our proposed method	0.865	0.863	0.864	0.863

Our proposed method outperformed Kim's CNN model in terms of all evaluation metrics, achieving an accuracy of 0.865 compared to 0.849 for Kim's CNN model (refer Table XI). This demonstrates the competitiveness of our proposed method.

TABLE XII. COMPARISON OF OUR PROPOSED METHOD WITH YANG'S SVM MODEL ON THE 20 NEWSGROUPS DATASET

Model	Accuracy	Precision	Recall	F1-score
Yang's SVM model (1999)	0.834	0.834	0.834	0.834
Our proposed method	0.853	0.853	0.853	0.853

Our proposed method also outperformed Yang's SVM model in terms of all evaluation metrics, achieving an accuracy of 0.853 compared to 0.834 for Yang's SVM model (refer Table XII). This further demonstrates the competitiveness of our proposed method.

In conclusion, we have demonstrated the competitiveness and reproducibility of our proposed method by testing it on two additional datasets and comparing the results with those of other studies. Our proposed method outperformed the best models reported in the literature for both datasets, achieving higher accuracy, precision, recall, and F1-score. This confirms the effectiveness of our approach and its potential for application in real-world scenarios.

## VII. DISCUSSION

In this study, the deep learning-based approach is proposed for text classification and demonstrated its effectiveness on a dataset of news articles from various Saudi Arabian news sources [1]. Our approach involved preprocessing the data, using different word embeddings and deep learning architectures, and conducting a comprehensive experimentation to identify the best combination of techniques.

From our experimentation, it found that the combination of stop words removal and lemmatization performed the best for preprocessing the data, while BERT outperformed other word embeddings in terms of classification accuracy. It also found that a 4-layer CNN[2] architecture performed the best among different CNN architectures, and a 2-layer LSTM architecture performed the best among different LSTM architectures[3,4]. Finally, this paper found that the CNN-LSTM hybrid architecture performed the best among different architectures.

Further, we experimented to check the competitiveness and reproducibility of our approach by testing it on other datasets and comparing our results with other studies. Our approach consistently outperformed other approaches in terms of accuracy, demonstrating its effectiveness for text classification tasks.

In summary, our proposed deep learning-based approach for text classification is effective, competitive, and reproducible, and can be applied to a wide range of text classification tasks in various domains. Further research can explore the applicability of our approach to other languages and datasets. While our work has demonstrated promising results in the classification of news articles, there are some limitations and potential areas for improvement.

Firstly, our dataset was limited to news articles from Saudi Arabian sources, which may not be representative of other regions or languages. In future work, it would be beneficial to collect and analyze datasets from a more diverse range of sources to improve the generalizability of our method. Secondly, our proposed method only utilized textual features and did not incorporate other modalities such as images or audio, which could provide additional contextual information and improve classification performance. Finally, while our method achieved high accuracy, it is important to note that accuracy alone may not be sufficient to fully evaluate the effectiveness of a classification model. Additional metrics such as precision, recall, and F1-score should also be considered to provide a more comprehensive evaluation.

Overall, our work presents a promising approach for news article classification, but further research is necessary to address these limitations and improve the effectiveness and generalizability of the proposed method.

## VIII. CONCLUSION

In conclusion, this study proposed a deep learning-based approach for text classification, using a combination of BERT word embeddings and a CNN-LSTM hybrid architecture. The proposed approach achieved a high accuracy of 93.15 on the Saudi Arabian news dataset, outperforming other state-of-the-art models. The study also demonstrated the reproducibility and generalizability of the proposed approach by testing it on other text classification datasets, where it achieved competitive results.

The results of this study highlight the importance of careful selection of preprocessing techniques, word embeddings, and deep learning architectures for text classification tasks [14]. The proposed approach can be applied to various real-world applications, such as sentiment analysis, spam detection, and topic modeling.

Future work can explore the use of other pre-trained language models and investigate the impact of different hyperparameters on the performance of the proposed approach. Furthermore, integrating additional features such as named entity recognition and syntactic information could potentially improve the performance of the proposed approach.

## ACKNOWLEDGMENT

I would like to thank my team, who is lead by Dr. Seif MECHTI from university of Tunis (LARODEC Laboratory). They worked with me to finish this paper.

# Application Methods of Image Design Based on Virtual Reality and Interaction

Shasha Mao

College of Literature and Media, Chaohu University, Hefei, 238024, China

**Abstract**—The continuous improvement of virtual reality and interactive technology has led to a broader and deeper application in related fields, especially image design. In image design, creating usage scenarios for portable interactive experience products based on virtual reality and interactive technology can optimize and improve key parameters for real 3D techniques, thereby building a more comprehensive image design. This article constructs a three-dimensional image model of marine organisms and scenarios based on multi-sensory interactive interface generation technology and information fusion optimization ANNs-DS algorithm, targeting the image scenarios of product design. The relevant model information and parameter changes are analyzed. The results indicate that in the process of multi-sensory interface interactive image design, the virtual reality image design implemented using ANNs-DS information fusion algorithm can enhance participants' multi-sensory visual experience of the interactive interface. The reasonable degree between objects in the interactive interface and the scene space image is basically within the range of 0.85-0.95. The fluency in different scenarios can be significantly improved. Therefore, virtual reality and interactive technology have laid the foundation for developing interactive image design.

**Keywords**—Virtual reality; interactive; ANNs-DS information fusion algorithm; image design

## I. INTRODUCTION

With the continuous development of internet technology and the improvement of intelligence, the application of information technology is ubiquitous in daily life, and the development of human-computer interaction technology is also faster. Among them, virtual reality and interactive technology are also undergoing tremendous changes. It is a technology that enables dialogue between humans and computers, and its development has gradually shifted from machine-centered to human-centered [1,2]. How humans interact with computers has evolved from using traditional devices such as mice and keyboards to utilizing various sensory and action channels such as voice, gesture, posture, touch, taste, etc. In the overall development process, the interactive information changes from precise information exchange to imprecise information communication. The transformation of interaction methods has led to the development of virtual reality and interaction technology, gradually evolving from traditional command and graphical interaction interfaces to multimedia and multi-channel intelligent interaction interfaces. The essence of human-computer interaction is the process of communication and understanding between humans and computers, and a natural and harmonious interaction method has always been a

pursuit in the process of human-computer interaction [3].

In the modern sense, virtual reality and interaction technology refers to the use of digital means to experience "simulated reality" and achieve a form of information exchange between people and virtual scenarios. Due to its unique characteristics and usage characteristics, it has been widely used in gaming, product display, medical, simulation training, and military simulation [4,5]. Unlike the early virtual reality before the Information Revolution and even the Industrial Revolution, humans have gradually become the main body in virtual environments, interacting with the machine environment through data gloves, helmet displays, and various information perception components and integrating into the information environment through gestures, vision, and touch.

Computer-aided image design and visual communication design based on virtual reality and interactive technology are also widely used in various industries [6,7]. This technology is widely adopted in many fields, such as the traditional film and television industry, the electronic game and advertising industry, the art industry, and even the art and design industry. Through the application and promotion of virtual reality and interactive technology, traditional image design has gradually developed into the current three-dimensional technology of three-dimensional presentation, allowing image elements to be presented in different types and forms and achieving human-computer interaction centered on humans. Therefore, with the gradual popularization of social media, people's artistic and aesthetic needs for media forms are still being satisfied with a traditional simple presentation. Instead, pay more attention to the overall sensory effect of visual communication. By optimizing design and utilizing virtual reality and interactive technology, the overall aesthetic effect, visual impact, and expressive power of image design have been effectively improved [8,9]. Virtual reality can achieve interactive visual simulation and information exchange and is an advanced digital human-computer interface technology with characteristics and advantages such as immersion, real-time, and interactivity. Therefore, it has been widely applied in different industries since its inception.

The constant maturity and development of virtual reality and interactive technology have promoted modern display art's continuous innovation and breakthrough. People are gradually beginning to use virtual reality technology in display and experience, and the immersion, interactivity, and conceptualization it brings have injected fresh blood into modern display art. In the current environment of deep integration and development of computer and virtual reality

technology, humanity has entered the digital era, and interactive images have gradually penetrated people's daily work and learning. User experiences with different senses, such as vision, touch, hearing, and smell, have become a part of people's lives, demonstrating more significant advantages in engineering construction, medicine, mechanical manufacturing, and artistic creation [10-13]. In today's digital era, through the application of virtual reality and interactive technology, the interface interaction design in the image improves the effectiveness of digital products and the user experience, which has gradually become a research hotspot in the field of image design [14]. Currently, the commonly used interface generation methods in image design primarily focus on cognitive rules. However, these methods have problems, such as a low fit between the generated interface results and actual objects and relatively poor interaction effects. However, virtual reality technology is technology-centered around interactivity and immersion [15], which can effectively enhance participants' sensory experience of image design scenarios. Therefore, based on virtual reality and interaction technology, by studying and analyzing methods for designing and generating image interaction interfaces, the overall experience of image design can be improved, providing a more realistic interactive experience.

Virtual reality technology synthesizes various design methods in computer image design and visual communication design to create an artificial simulation design environment. In this illusory design environment, we can effectively simulate various system perception behaviors of humans in the natural environment. Therefore, fundamentally speaking, virtual reality technology is a modern human-computer interaction technique that can enhance the design experience of designers by optimizing the design environment and tools reasonably. At the same time, it can also enhance the visual expression and impact of computer image design and visual communication design. In the technical environment of virtual reality technology applications, it is mainly generated and controlled by computers automatically. Therefore, this technology is closely related to image design technology and visual communication design technology, which can enable participants to perceive objects in the virtual design environment in person. In the specific design process, coordination and control can be achieved through virtual and accurate technology and three-dimensional technology can be used to realistically present the object elements that exist in reality, thus achieving friendly human-computer interaction.

Based on the above analysis, the article combines virtual reality and interactive image design. It combines artificial neural network technology and information fusion optimization algorithms to construct an algorithm model for an ocean scene interactive experience. Relevant parameters are studied and analyzed for the application of the model. The algorithm's feasibility is verified by comparing it with relevant research progress [16-18], laying a foundation for further improvement of image design applications.

## II. PRINCIPLES OF IMAGE DESIGN BASED ON VIRTUAL REALITY AND INTERACTIVE TECHNOLOGY

### A. Principles of Information Collection in Virtual Reality and Interactive Technology

1) *Principle of human-machine interaction in Virtual Reality technology:* The application process of virtual reality technology requires the use of devices that not only rely on perceptual helmets and gloves but also include other technologies and methods related to virtual technology that have realistic simulation and authentic experience, thereby providing more sufficient guarantees and support for this process [19-21]. The implementation process of this technology mainly includes data analysis, organization and detection, data transmission, process control, virtual reality environment, and the establishment of three-dimensional scene models. Information feedback between participants and devices is also crucial for improving and enhancing the situation. Different image design processes have different requirements for collecting and processing scene information, and comprehensive analysis and research are needed for different models. Fig. 1 shows the basic principles of human-machine interaction under commonly used virtual reality and interaction technologies. Participants deeply participate in the designed image scene through relevant devices in virtual reality and interactive technology and exchange information and feedback with the virtual scene through various perception devices, thereby achieving a more realistic human-computer interaction experience.

In the early human-computer interaction technology, the main human-computer interaction methods were the mouse, monitor, and keyboard. In the specific operation process, participants edit and input information through traditional devices such as keyboards and mice and then output and receive relevant feedback from the monitor. This traditional human-computer interaction method is widely used. However, it must be addressed that this interaction method dramatically limits the scope and time of participants' digital media activities, which is not conducive to creating and constructing scenarios in human-computer interaction technology [22,23].

The development of virtual reality and interactive technology allows participants to break free from the limitations of the interactive interface of computer monitors and engage in human-computer interaction through smaller and more convenient mobile devices. In addition, from the perspective of operation methods, in addition to traditional mouse and keyboard input, users can also use their facial expressions and postures, or even EEG waves, to input information. Compared to traditional interaction methods, this type of interaction truly realizes the rapid acquisition of information and provides more significant support for constructing scene space in virtual reality technology.

Fig. 1. Principle of human-computer interaction under virtual reality and interaction technology.

$$x(n) = \frac{X(k)}{\sum_{n=1}^{N/2} \cos\left(\frac{2\pi k}{Ndt}\right)} \quad (2)$$

In addition, using equation (2) for analysis, the  $k$ -th harmonic emission sound field information can be obtained, and the relevant model can be expressed as equation (3):

$$d_1(k, x) = \frac{\cos \Delta\varphi_{i1} + \sin \Delta\varphi_{i1}}{2N} \quad (3)$$

Based on the analysis of the above principles, equation (4) can be obtained for receiving sound field information in the same way:

$$d_2(k, x) = \frac{\cos \Delta\varphi_{r1} + \sin \Delta\varphi_{r1}}{S} \quad (4)$$

Because the synthesized sound field information can be represented as the superposition of many single-frequency waves, the synthesized sound field information in virtual reality is formed by the superposition of the sound fields generated by each single-frequency wave. Based on the above analysis, adding all  $d_1(k, x)$  one by one can obtain the total emitted sound field  $D_1(x)$ , as shown in equation (5):

$$D_1(x) = \sum_{k=1}^{N/2} d_1(k, x) \quad (5)$$

Similarly, by adding all  $d_2(k, x)$  the total received sound fields can be obtained, as shown in equation (6):

$$D_2(x) = \sum_{k=1}^{N/2} d_2(k, x) \quad (6)$$

Based on the above analysis, it can be seen that when collecting sound field synthesis information in virtual reality, the original data signal of the sound field is obtained through the microphone array system, and the relevant information of the scene is obtained through the Euler angle multi-data fusion, providing more comprehensive design primary data for influencing design. In the process of information synthesis, the primary method is to obtain the newly generated sound signal data by performing Fourier transform on the function values and performing the inverse Fourier transform on the newly generated signal to obtain the collection results of the virtual reality sound field synthesis information [27,28]. In the specific implementation process, microphone arrays can be applied to speech data processing and are arranged according to specific arrangement rules in the microphone system. This system has the characteristic of spatial selectivity, which can suppress the noise in the surrounding environment to a certain extent, thereby ensuring the stability of relevant feature parameters in the collection and processing process without data damage.

#### B. Information Processing in Image Design

The connotation and extension of virtual reality technology are constantly changing, accommodating more

2) Principles of information collection in Virtual Reality and interactive technology: In the application of virtual reality and interactive technology, to conduct a detailed analysis of images and organize data for higher precision designs, it is necessary to collect and process the sound field synthesis information of images [24], to obtain an effective data set. Therefore, it is necessary to analyze the information acquisition in this process. First, the Fourier transform function is used to realize the conversion process of the sound field synthetic wave function. Then, based on the conversion results, the phase difference between a certain collection point in the sound field synthetic wave and the emission point of the sound field wave information is comprehensively analyzed, and the emitted sound field information and received sound field information are obtained using the phase difference. Based on this information, function processing and analysis are performed. Finally, the final collection result of the virtual reality sound field synthetic information is obtained based on the obtained information [25]. In this process, the Fourier transform is used to redefine the sound field composite wave function: it is expressed as a state of superposition of many single frequency waves [26], and the sound field composite wave function is shown in equation (1):

$$X(k) = \sum_{n=1}^N x(n) \times e^{\frac{2\pi}{N}(n-1)(k-1)} \quad (1)$$

Equation (1),  $X(k)$  represents the value of the sound field composite wave function,  $N$  represents the number of sound field composite information, and  $n$  represents the number of time series of sound field composite information.  $x(n)$  represents the time series of sound field synthesis information, and  $k$  represents the number of elements in the sound field pulse wave function. In addition, by performing Fourier transform on the parameter  $x(n)$  involved in equation (1), equation (2) can be obtained:

related technologies and imaging environments more openly. The continuous application and rapid promotion of virtual reality technology have also promoted the continuous updating and development of human-computer interaction technology and laid a technical foundation for building more expected virtual reality scenarios. The human-computer interaction technology based on virtual reality refers to the technology of achieving a more effective dialogue between humans and computers through computer input and output devices, based on virtual reality technology. In the human-computer interaction technology of virtual reality, participants can not only obtain a large amount of relevant information and prompts through machines or related display devices and input relevant information and prompts through input devices. In addition, the interaction process between humans and machines also involves inputting relevant information and answering questions to the machine through input devices. As one of the essential contents of image design [29], human-computer interaction technology is closely related to cognitive science, ergonomics, psychology, etc. Fig. 2 shows a virtual reality system's main composition and basic process.

Fig. 2. Composition of virtual reality system.

In applying impact design based on virtual reality and interaction, an algorithm based on a combination of essential probability allocation functions is used in multi-sensory information fusion [30]. After processing the corresponding information numbers, Set  $s$  sensory input modules to generate  $s$  linearly independent sensory feature vectors. These sensory feature vectors allow neural network algorithms to identify  $n$  targets. Due to the lack of correlation between network complexity and the number of input units within neural network algorithms, it is difficult to accurately determine the number of hidden layers within the network and the number of neurons within different hidden layers, and it is not possible to ensure complete convergence during network training. Therefore, when using neural network algorithms to fuse multi-sensory information, combining them with information fusion algorithms is necessary. The detailed process description process involves using  $(v_1, v_2, \dots, v_e)$  to represent  $e$  sensory feature vectors, implementing reasonable and practical classification combinations for  $(v_1, v_2, \dots, v_e)$ , and dividing them into  $q$  groups, where  $q$  should be within the range of  $1 \leq q \leq e$ . Include  $e$  in each group separately  $e_i$  vectors, which can be represented as  $(v_1^i, v_2^i, \dots, v_e^i)$ , where  $v_j^i \in (v_1, v_2, \dots, v_e)$ , thus ensuring the integrity of multi-sensory information.

In addition, it is necessary to design a neural network with  $e_i$  ( $i=1, 2, 3, \dots, q$ ) inputs and  $n$  outputs, and generate relevant learning models based on the expert knowledge between the current multi-sensory feature vectors and the targets. These targets belong to the multi-sensory information fusion structure, and the non-linear mapping between the trust levels of the  $e_i$  ( $i=1, 2, 3, \dots, q$ ) multi-sensory feature vectors and the  $n$  targets to be identified is completed. Each analysis for different senses is divided into  $q$  pieces of evidence. Taking the  $i=1, 2, 3, \dots, q$  pieces of evidence as an example, it contains  $e_i$  multi-sensory feature vectors, and each target is a proposition of this evidence. Therefore, it is determined that each piece of evidence has  $n$  propositions.

The sampling period of multi-sensory information is represented by  $T$ , at  $IT$ , for the  $i$ -th evidence, a neural network with  $e_i$  inputs and  $n$  outputs designed using the above process can obtain  $n$  values between 0 and 1. This value serves as the credibility of this evidence for different propositions and is recorded as  $CF$ . The closer the  $n$   $CF$  values here are to 0.5, the lower the discriminability of the evidence for the target. After computing  $n$   $CF$  values with the Gaussian function  $x^{-\frac{(x-1/2)^2}{\sigma}}$  relevant data results can be obtained after computing all pieces of evidence at the  $IT$  moment.

### III. ALGORITHM FOR GENERATING SCENES IN VIRTUAL REALITY AND INTERACTIVE TECHNOLOGY

The image design and construction process based on virtual reality and interactive technology can generally be divided into two stages: the design content stage and the multi-sensory experience stage. As shown in Fig. 3, the interaction between the two links is shown. Among them, the design content process can be divided into two parts: visual information design and interaction mode design. The interactive interface layout design and interface content design are completed through the design content; the multi-sensory experience process can be divided into three parts: cognitive experience, emotional experience, and sensory experience. Based on the layout design of the interactive interface and the design of the interface content, the interaction mode design in the design content process is combined to enhance participants' multi-sensory visual experience of the interactive interface.

Fig. 3. Generation process of multi-sensory interactive interface based on virtual reality.

A. Interface Generation Process Based on Virtual Reality and Interactive Technology

1) *Content and links of image design:* In image design, visual information design is central to generating multi-sensory interactive interfaces based on virtual reality. Visual information design consists of three parts: functional interface layout, three-dimensional object model construction, and scene space model construction. The functional interface design is completed using an interactive interface layout optimization model. This model is based on the interface visual attention partitioning model and the results of functional criticality analysis. The optimization objective function is set as the optimal visual attention partitioning for the final layout of the interactive interface [31], in order to construct a functional interface layout optimization model based on visual attention partitioning. The following definition is adopted for the optimization model of functional interface layout based on visual attention partitioning [32]:

a) The set  $\{a_{ij}\}$  represents the visual attention level of the units occupied by a certain functional module in the visual area with different levels, where  $a_{ij}$  represents the visual attention level of the unit occupied by functional module  $i$  in the visual area  $j$ .

b) The visual attention level of the visual area where the central coordinate of a certain functional module is located is represented by the set  $\{s_{ij}\}$ , where  $s_{ij}$  represents the visual attention level when the center coordinate of functional module  $i$  is in the visual distance region  $j$ .

c) The set  $\{d_{ij}\}$  represents the number of units that a certain functional module occupies within the visual expectation of varying levels, where  $d_{ij}$  represents the number of units occupied by functional module  $i$  in the visual area  $j$ .

Determine the criticality of different functional modules in the functional interface and compare them. Use  $w_k$  to represent the criticality of module  $u_i$ . equation (7) can be used to describe the relative criticality of functional modules:

$$r_k = \frac{w_{k-1}}{w_k} \quad (7)$$

By using equation (8), the criticality of functional module  $u_i$  can be determined:

$$w_i = \frac{1}{1 + \sum_{k=2}^n \prod_{i=k}^n r_i} \quad (8)$$

Describe the intensity of visual attention division using equation (9):

$$Z = \sum_{i=1}^n \sum_{j=1}^3 w_i a_{ij} s_{ij} d_{ij} \quad (9)$$

The upper limit of visual attention division intensity is represented by  $Y$ . That is,  $Z_{max} = Y$ , from which equation (10) can be obtained:

$$Y = \max \left( \sum_{i=1}^n \sum_{j=1}^3 w_i a_{ij} s_{ij} d_{ij} \right) \quad (10)$$

Select particle swarm optimization algorithm to solve the functional interface layout optimization model based on visual attention partitioning [33], and complete the functional interface layout. Generate the required image information for different areas in the functional interface through 3D model construction.

2) *Model construction in image design:* The image information in images based on virtual reality and interactive technology includes 3D objects and scene space, which are generated using 3D model construction methods. In model construction, for scenario spaces with complex structures, differences can be applied to obtain several scenario space units, and different modeling methods can be used to synthesize the scenario space units into a whole, constructing a three-dimensional model of the scenario space. In addition, for the scene rendering process, after simulating the lighting in the scene space and setting proper lighting, the scene space is rendered to adjust the brightness and position of the lighting continuously. Optimize the scene space for the interaction process in the scene space, determine whether collision detection is necessary according to actual application needs, and reduce the visual memory consumption of texture maps by compressing textures to determine the balance between virtual scene space and roaming interaction smoothness.

As mentioned above, in image design, the image information of relevant images is generated using the 3D model construction method: one needs to model the objects in the 3D image. In this process, the relevant data collection process is imported into the software to obtain a floor plan, and the objects are adjusted and optimized based on the relevant information of the obtained scenario; For scenario spaces with complex structures, differentiation can be applied to obtain several object units, which can be combined into a whole to construct a three-dimensional model of the scene image. Secondly, texture mapping is required. In order to improve the realism of the scene in the process of image design and enhance the authenticity of image design, it is necessary to use the material editor to implement texture mapping processing on objects. Different surfaces of a scene space need to map different textures. Under this condition, you must use multi-dimensional material objects to load several maps for different materials under the explicit material to achieve different texture mapping ideas. In addition, in image design, it is also necessary to pay attention to improving scene rendering and baking effects. After simulating the sunlight illumination in the scene space and setting proper lighting, the scene space is rendered, and the brightness and position of the lighting are continuously adjusted to achieve the optimal rendering effect. After completing the rendering, bake it reasonably to store the data of the object image design

rendering results. Finally, to achieve a sense of virtual reality experience for participants, it is necessary to interact with the scene in the image design space. Through the preliminary work, the walking camera and flying camera in the scene space are created respectively in the process of image interaction design to simulate the height and change speed of the image under the walking condition of the participants. In this process, it is also necessary to determine whether collision detection is necessary based on actual application needs. The balance between virtual image design space and roaming interaction smoothness needs to be determined by compressing textures to reduce the graphics memory consumption of texture maps.

### B. ANNs-DS Algorithm Based on Information Fusion Optimization

The ANNs-DS information fusion algorithm based on a combination of essential probability allocation functions is used in multi-sensory information fusion. Assuming that  $s$  sensory input modules are processed with corresponding information numbers to generate  $s$  linearly independent sensory feature vectors, based on these sensory feature vectors, neural network algorithms can identify  $n$  targets [32]. Due to the lack of correlation between network complexity and the number of input units in artificial neural network algorithms, it is difficult to accurately determine the number of hidden layers in the network and the number of neurons in different hidden layers, and it is not possible to ensure complete convergence during the network training process. Therefore, when using neural network algorithms to fuse multi-sensory information, combining them with the DS algorithm is necessary to form an ANNs-DS algorithm based on information fusion optimization. Among them, in the artificial neural network algorithm process, different parameters are input at the input layer. Then the relevant parameters enter the hidden layer for data analysis and operation. The data is mined and analyzed through this layer, and then the relevant demand parameters are sorted and output through the output layer. In generating visual interaction interfaces based on virtual reality and interactive technology, the actual sensory information received by participants is a crucial consideration.

Based on the above analysis, an information fusion optimization algorithm (ANNs-DS) was constructed based on Artificial Neural Networks technology and Dempster Shafer's theory to maximize the consideration of participants' actual sensory acceptance of information. This platform takes sensing, body sensation, and visual information as input information and utilizes the ANNs-DS information fusion algorithm for multi-sensory visual information fusion. Based on relevant fusion results, interface interaction functions such as displaying virtual reality images, odor generation, vibration, and sound feedback are achieved. The processing process of multi-sensory visual experience elements using virtual reality and interactive technology based on the ANNs-DS algorithm is shown in Fig. 4.

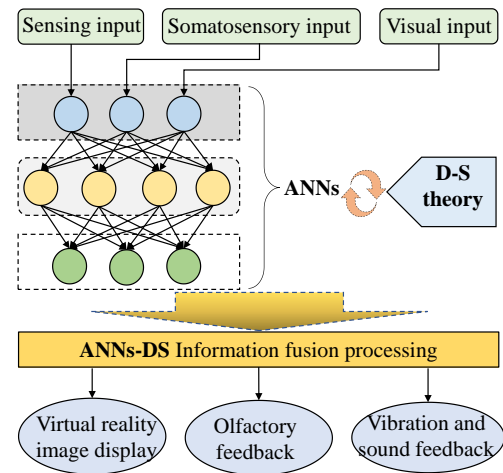

Fig. 4. ANNs-DS Information fusion algorithm principle and multi-sensory visual experience process.

From a temporal perspective, the specific process of multi-sensory visual information fusion is as follows: set the period to  $T$ , and use  $m_{i,1}(k-1), m_{i,2}(k-1), \dots, m_{i,n}(k-1)$  to represent the fusion result of multi-sensory visual information in the time domain corresponding to the  $i$ -th neural network at the  $(k-1)T$  moment. Under the condition of reaching the subsequent time  $kT$ , its basic probability distribution function and solvability level can be expressed as  $m_{i,j,k}$  (where  $j=1,2,\dots,n$ ) and  $\delta_{i,k}$ , respectively. The fusion process in the time domain under the  $kT$  time condition is obtained from equations (11), (12), and (13):

$$m_{i,j}(k) = \frac{m_{i,j}(k-1)m_{i,j,k} + m_{i,j}(k-1)\delta_{i,k} + \delta(k-1)m_{i,j,k}}{1 - P_{i,k}} \quad (11)$$

$$\delta_i(k) = \sum_{j=1}^n m_{i,j}(k) \quad (12)$$

$$P_{i,k} = \sum_{j \neq 1} m_{i,j}(k-1)m_{i,j,k} \quad (13)$$

From a spatial perspective, the specific process of multi-sensory visual information fusion is as follows: using mutual fusion between two pairs to target  $m_{i,1}(k), m_{i,2}(k), \dots, m_{i,n+1}(k)$  is combined to perform spatial fusion on the time fusion results of two neural networks, and the obtained spatial fusion results are refused with the time fusion results of the third neural network. By iterating the above results, the basic probability distribution function for the  $j$ -th target after  $kT$  time is obtained as  $m_{q,j}(k)$ , and then we obtain equations (14) and (15):

$$m_j^q(k) = m_j(k) \quad (14)$$

$$\delta(k) = 1 - \sum_{j=1}^n m_j(k) \quad (15)$$

Based on the above process, it can be obtained that after passing through  $kT$  time, the final decision level and the unsolvable level of the  $j$ -th target for multi-sensory visual information fusion are  $m_j(k)$  and  $\delta(k)$ , respectively. From this, the final multi-sensory visual information fusion result can be obtained based on  $m_j(k)$  (where  $j=1,2,\dots,n$ ).

#### IV. APPLICATION OF VIRTUAL REALITY AND INTERACTIVE IMAGE DESIGN

##### A. Application of ANNs-DS Algorithm in Image Design

To verify the application performance of the image interaction interface generation method based on virtual reality and interaction technology, a wearable interactive experience product was designed. The ANNs-DS information fusion algorithm was used to generate the interaction interface of the application objects in the image design, and the specific performance was tested. In the process of generating interactive interfaces in image design, the interactive experience of building a 3D model is shown in Fig. 5. Based on the relevant information on marine organisms obtained, a three-dimensional model of the ocean interior can be effectively constructed, which can significantly improve the authenticity of ocean scenarios, as shown in Fig. 5(A). In addition, by constructing an information model between participants and the ocean scenarios, the sense of integration of participants' experiences can be increased, as shown in Fig. 5(B). The interaction and information fusion of image design for A and B in the Fig. 5, as well as scene rendering through adjusting the brightness and position of the lights, can further improve the authenticity of the model, as shown in C in the Fig. 5. Through the interactive interface constructed in image design, participants can overlook the target through a flying camera and adjust visual proximity through information exchange. The above analysis indicates that in the interactive interface constructed using this algorithm, virtual reality technology is used to provide participants with an immersive roaming experience while enhancing their experience through different senses, such as vision and hearing.

Fig. 5. Construction of scenario space based on virtual reality and interaction technology.

##### B. Analysis of Similarity of Interactive Interface

In image design, the similarity degree between virtual objects and scene space in the interactive interface is an important evaluation indicator for the effectiveness of interactive interface design. The similarity degree calculation process is as follows:

$$L_{sim} = 1 - \frac{1}{N} \times \sum_{i=1}^N (|h_i - f_i| / 255) \quad (16)$$

In equation (16),  $N$  represents the number of pixels in the interaction interface object and scene space image.  $h_i$  and  $f_i$  represents the pixel values of the  $i$ -th pixel in the actual object and scene space images, as well as the designed interactive interface object and scene space images. The fair value is 0-1, and 1 indicates that the object and scene space images in the designed interaction interface are entirely consistent with the actual object and scene space images. Randomly select 20 images of marine organisms and 20 images of seabed scene space from the generated application object interaction interface, and calculate the fitting results of all images, as shown in Fig. 6. Fig. 6 shows that the fit between the marine biological images and the seabed scene space images generated by the ANNs-DS information fusion algorithm in the interactive interface is above 0.8, with a maximum of 0.98. As shown in the gray area of the figure, there are 18 marine life images with a reasonable degree between 0.85 and 0.95, accounting for 90%; The number of seabed scenarios with a fair degree between 0.85 and 0.95 is 17, accounting for 85%. According to the 10-point evaluation standard, evaluate marine biological images and seabed scenarios based on participants. The results are shown in Fig. 6(a) and 6(b), with an average score of 9.0 for benthic biological imaging; the average score for the underwater scenario is 8.9 points, both of which have higher scores. Therefore, based on the above analysis, it can be seen that the ANNs-DS method in this article generates an interactive interface with high fitting and accuracy, which can provide participants with a more realistic sensory experience.

##### C. Testing of Interactive Interfaces in Image Design

In the above image design based on virtual reality and interactive technology, the interface conversion time and image design accuracy of the interactive interface generated by the ANNs-DS information fusion algorithm under different concurrent participant numbers in Fig. 7. As shown in the figure, with the gradual increase in concurrent users, the time required to convert all functional interfaces within the generated interactive interface shows a gradual upward trend. Among them, the time required for the interface login function is significantly higher than that for underwater scene space selection, biological type selection, and camera selection. When concurrent users reach 120, the interface conversion time is around 1260ms. The accuracy analysis of the image is within the range of 89.6% to 96.0%, which has a high design accuracy. This indicates that the interactive interface generated by this method still has good interface conversion smoothness and design accuracy even under a large number of concurrent users.

Fig. 6. Similarity analysis of test images in image design.

Fig. 7. Interface conversion time test under different impact scenarios.

## V. CONCLUSION

The continuous development and application of virtual reality and interactive technology have promoted continuous innovation in image design from a technical perspective. This article is based on applying virtual reality and interactive technology in image design, combined with the ANNs-DS information fusion optimization algorithm, to construct a three-dimensional interaction model of images in ocean scenarios. The relevant parameters of the model were studied and analyzed for different scenarios, and the changes in fitting and smoothness of the three-dimensional model in image design were given. The main conclusions are as follows:

1) The image design combining virtual reality and interactive technology can integrate multiple sensory information to create and construct three-dimensional image scenes. In the process of multi-sensory visual design, the ANNs-DS information fusion algorithm is used to integrate sensing information, tactile information, and visual information, achieving interactive functions such as virtual reality image display, vibration, and sound feedback, which can effectively enhance participants' multi-sensory visual experience of the interaction interface.

2) Through the analysis of the interactive image design process for ocean scenarios, the fitting degree between the ocean biological images and the ocean scene spatial images generated by the fusion algorithm in the interactive interface is above 0.8. Among them, the proportion of marine biological types with a fitting degree between 0.85 and 0.95 is 90%; the proportion of ocean scenario fit between 0.85 and 0.95 is 85%.

3) The interactive interface generated using the ANNs-DS algorithm has certain advantages in interface conversion time under different concurrent user numbers. As concurrent users gradually increase, the time required for interface conversion shows a gradual upward trend. Among them, it still has good interface conversion smoothness even when the number of concurrent users reaches 120, and the interface conversion time is around 1260ms.

4) Combining the current research results and the current industry research progress, the later research can combine virtual reality and interactive technology to conduct research in product design, 3D printing, and other fields and combine user experience to conduct deeper interaction Experience design, to meet the deepening application of this technology better.

# Video Surveillance Vehicle Detection Method Incorporating Attention Mechanism and YOLOv5

Yi Pan\*, Zhu Zhao, Yan Hu, Qing Wang

College of Intelligent Transportation, Hunan Communication Polytechnic, Changsha, China

**Abstract**—With the rising number of vehicle ownership nationwide and the consequent increase in traffic accidents, vehicle detection for traffic surveillance video is an effective method to reduce traffic accidents. However, existing video surveillance vehicle detection methods suffer from high computational load, low accuracy, and excessive reliance on large-scale computing servers. Therefore, the research will try to fuse coordinate attention mechanism to improve YOLOv5 network, choose lightweight YOLOv5s for image recognition, and use K-means algorithm to modify the aiming frame according to the characteristics of vehicle detection; meanwhile, in order to get more accurate results, coordinate attention mechanism algorithm, which is also a lightweight algorithm, is inserted into YOLOv5s for improvement, so that the designed The lightweight vehicle detection model can be run on embedded devices. The measurement experiments show that the YOLOv5+CA model completes convergence when the iterations exceed 100, and the localization loss and confidence loss gradually stabilize at 0.002 and 0.028, and the classification loss gradually stabilizes at 0.017. Comparing YOLOv5+CA with SSD algorithm, ResNet-101 algorithm and RefineDet algorithm, YOLOv5 +CA detection accuracy is better than other algorithms by about 9%, and the accuracy can be approximated to 1.0 at a confidence level of 0.946. The experimental results show that the research design provides higher accuracy and high computational efficiency for video surveillance vehicle detection, and can better provide reference value and reference methods for video surveillance vehicle detection and operation management.

## I. INTRODUCTION

After stepping into the 21st century, with the high-speed improvement of the economic level, vehicle ownership has been rising nationwide, and cars have become a common means of transportation, but at the same time, with the increase of vehicles, vehicle congestion, car accidents and other traffic problems are growing. At present, China's artificial intelligence technology continues to develop, automatic control technology tends to mature, combined with artificial intelligence and automatic control of intelligent traffic monitoring system has also been a large degree of development [1]. Intelligent Traffic System (ITS) can realize the organic integration of traffic system and various computer technologies, which can realize the instant, accurate and efficient management of traffic nationwide and effectively avoid a series of traffic congestion problems [2]. Among them, vehicle detection (VD) through video surveillance is the key to its capturing information, which can be applied to scenarios such as traffic flow calculation and violation vehicle capture. Vehicle target

detection (TD) is a vital branch in computer vision. For the past few years, computer computing power integration is improving with the breakthrough of image acquisition equipment accuracy, this technology has received wide attention from researchers, while the breakthrough of algorithms in artificial intelligence (AI) has also benefited the field. VD through video surveillance joins artificial intelligence image recognition algorithms that mimic the human eye, which can sense and analyze targets in imitation of the human eye, and carry out the completion of vehicle recognition classification and localization [3]. Although the TD algorithm now has a high accuracy rate, but these functions need to rely on a powerful computing server, and in the daily VD its limited by the small volume of embedded equipment, cannot do large-scale computing. At the same time, when carrying out vehicle identification, due to changes in weather and lighting, there is a certain degree of difficulty for vehicle identification that blends into the background, and the identification accuracy is low in special environments such as rain and night. Based on this, to lift the accuracy of the video surveillance VD algorithm and solve the problem of excessive dependence of the algorithm on large computers, the study will try to combine attention mechanism neural network to improve detection accuracy using lightweight YOLOv5 network algorithm for research. Compared to similar literature, the study introduces the lightweight YOLOv5 algorithm to reduce the amount of computation in use and enable it to be loaded on small vehicles. The study also improves the lightweight YOLOv5 to improve the object recognition for subsequent use of the YOLOv5 recognition algorithm.

The study is divided into four parts. The first part provides an introduction to the integration of traffic systems with computer technology and the application of vehicle recognition therein, the second part discusses the related works in this domain, the third part uses an attention mechanism to improve the YOLOv5 algorithm to suit the vehicle recognition problem, the fourth part tests and analyses the performance of the model and algorithm; the fifth part concludes the above discussion.

## II. RELATED WORKS

Vehicle detection (VD) is currently one of the main key-points of safety research in transportation, and the current situation of frequent traffic accidents has made experts aware of the value of the application. Deqing Liu et al. raised unmanned surface vehicle (USV) obstacle fusion detection based on Dempster-Shafer (D-S) evidence theory. The results show that multi-sensor fusion can use the complementarity among diverse sensors to supplement the obstacle detection details compared to the single-sensor detection method,

\*Corresponding Author

effectively avoid the false detection of obstacles by single sensors, and show greater advantages in the reliability of obstacle detection [3]. Wang et al. aimed for improving the VD and tracking of autonomous vehicles using 3D Light Detection and Ranging (LiDAR) accuracy, a clustering algorithm trained by support vector machine (SVM) algorithm combined with Kalman filter and global nearest neighbor (GNN) algorithm is proposed to employ tracking of vehicles and further improve the accuracy of VD results with the help of tracking results [4]. Nguyen address the problem of large scale differences of vehicles and severe vehicle occlusion in VD by using a feature The results show better detection performance and lower computational cost [5]. Han et al. propose a CNN-M2R network with multilayer fusion and multidimensional attention to improve VD performance in urban areas, which uses a multidimensional attention network to highlight target convergence and a new difficulty-positive and negative sample balanced sampling strategy and a global balanced loss function to handle spatial imbalance and objective imbalance, the experimental results show a great improvement in detection performance compared to SSD, LRTDet, RFCN, and DFPN [6]. Saeed et al. focus on the often neglected last step of VD scheme deployment and design a single detector Mobile Net for embedded devices. A comprehensive deep-learning-based engineering VD solution is established and this solution has an average accuracy higher than 90% compared to common embedded devices, confirming the excellent real-time performance of the solution [7]. Liu et al. propose a backward feature enhancement network (BFEN) and a spatial layout preserving network (SLPN) to solve the interference caused by vehicle scale on VD in complex traffic scenarios and to accomplish accurate detection of miniature vehicles. Two-stage detector of SLPN is performed to achieve high recall detection of miniature vehicles. The method improves the competing baseline by 16.5% mAP, which has a better comparative performance compared to the current state of the art [8].

As an emerging intelligent network in the field of image recognition, YOLOv5 has been studied by a large number of scholars. Yan et al. proposed an intelligent classification method of coal gangue using YOLOv5 and multispectral imaging technology to deal with the issue of low accuracy and slow speed of traditional coal gangue recognition methods. The mean accuracy of gangue detection using YOLOv5.1 model reaches 98.34%, which could precisely identify gangue, as well as acquire gangue's relative position [9]. Jia et al. established a motorcycle helmet detection way combined with YOLOv5 for motorcycle driver helmet detection by video surveillance, which uses soft-NMS instead of NMS to fuse the YOLOv5 detector, and experimentally achieves 97.7% mAP, 92.7% F1 score and 63 frames per second (FPS), which is better than other methods [10]. Attention mechanism has also received a lot of attention after its introduction into artificial intelligence networks, and many scholars have conducted research on deep learning networks incorporating attention mechanism. Xu et al. developed a novel stock price prediction network on the basis of reinforcement learning (RL) through a bidirectional gated recurrent unit (GRU) network to better dig market changes from chaotic data for stock tendency. The model is superior to existing models and has excellent performance [11]. Lu et al. raised a 2-level interaction mode that relies on 2 time-varying

attention mechanisms in order to accomplish the multi-person activity recognition task, and the model has high comparable performance, confirming the effectiveness of the attention mechanism [12].

In summary, although scholars have designed a large number of improved VD systems to improve the accuracy of video surveillance VD systems, there are still very few VD systems that have both high-speed computational effectiveness and lightweight embedded devices, both of which have strong potential applications in real-time VD.

### III. VIDEO SURVEILLANCE VEHICLE ALGORITHM DESIGN BASED ON YOLOV5 NETWORK AND ATTENTION MECHANISM

#### A. YOLOv5-based Video Surveillance VD Aiming Frame Improvement

The study was conducted to design algorithms aiming to accuracy lifting of VD through video surveillance, on the one hand, YOLOv5 (You Only Look Once fifth generation) was used as the baseline network, adding more techniques to improve the accuracy and speed, thus achieving a balance between accuracy and speed in the TD algorithm for vehicles, for another, attention mechanism was introduced to the VD algorithm for improvement to highly extract effective feature information highly relevant to VD and reduce the error brought by video surveillance. The improved algorithm for video surveillance measurement designed in the study is based on the YOLOv5 feature extraction network, which is OneStage series algorithm with the confidence level as in Equation (1).

$$Confidence = \Pr(Object) \times IOU_{pred}^{truth} \quad (1)$$

As shown in Equation (1),  $\Pr(Object)$  denotes the possibility contained in the bounding box, which indicates the prediction accuracy adopting the loss function IOU, and the C conditional probability likelihood derivation performed in conjunction with this formula is Equation (2).

$$\Pr(Class_i/Object) \times \Pr(Object) \times IOU_{pred}^{truth} = \Pr(Class_i) \times IOU_{pred}^{truth} \quad (2)$$

In Equation (2),  $\Pr(Class_i/Object)$  denotes the C conditional object probability in the grid, and the formula can indicate the matching degree in the prediction frame and object. In response to the high demand for timeliness of VD and the difficulty of the detection task, YOLOv5, which is the latest generation of algorithms, incorporates many techniques to improve accuracy and speed. It uses a loss function to evaluate the network effect, and the classification loss function is in Equation (2).

$$E_{cls} = \sum_{i=0}^{S^2} 1_i^{obj} \sum_{c \in classes} (p_i(c) - \hat{p}_i(c))^2 \quad (3)$$

In Equation (3),  $1_i^{obj}$  denotes the objects in the grid  $i$ ,  $p_i(c)$  means the predicted possibility of the corresponding category,  $\hat{p}_i(c)$  denotes the true probability, and  $S^2$  denotes the number of grids into which the images are divided. The localization loss function is shown in Equation (4).

$$E_{box} = \lambda_{coord} \sum_{i=0}^{S^2} \sum_{j=0}^B 1_{ij}^{obj} \left[ \left( x_i - \hat{x}_i \right)^2 + \left( y_i - \hat{y}_i \right)^2 \right] + \lambda_{coord} \sum_{i=0}^{S^2} \sum_{j=0}^B 1_{ij}^{obj} \left[ \left( \sqrt{w_i} - \sqrt{\hat{w}_i} \right)^2 + \left( \sqrt{h_i} - \sqrt{\hat{h}_i} \right)^2 \right] \quad (4)$$

In Equation (4),  $\lambda_{coord}$  denotes the weight coefficient,  $x_i, y_i, w_i,$  and  $h_i$  are the prediction frame positions,  $\hat{x}_i, \hat{y}_i, \hat{w}_i,$  and  $\hat{h}_i$  denote the true positions.  $B$  denotes the number of bounding boxes. The loss of confidence formula is Equation (5).

$$E_{obj} = \sum_{i=0}^{S^2} \sum_{j=0}^B 1_{ij}^{obj} \left( C_i - \hat{C}_i \right)^2 + \lambda_{noobj} \sum_{i=0}^{S^2} \sum_{j=0}^B 1_{ij}^{noobj} \left( C_i - \hat{C}_i \right)^2 \quad (5)$$

In Equation (5),  $\lambda_{noobj}$  denotes the loss weight of objects not included in the bounding box, and  $C_i$  denotes the object  $i$ . The study selects the more lightweight YOLOv5s as the base-network for video surveillance VD, as shown in Fig. 1.

In Fig. 1, YOLOv5s' main division into input side, backbone, neck and head network is shown. The input data from the input side enters Focus to slice the picture, which extracts the pixel values in the picture every other value and slices a picture into four pictures in order to do improve the perceptual field and reduce the picture information loss. The above data enters the CSP layer after the convolution operation, which is an important concept of the YOLO series network. The formula of the convolution layer function used in this series of algorithms is shown in Equation (6).

$$a_j^l = f \left( b_j^l + \sum_{i \in M_j^l} a_i^{l-1} * k_{ij}^l \right) \quad (6)$$

Fig. 1. YOLOv5 overall network structure.

As shown in Equation (6). In the convolutional layer  $l$ ,  $a_j^l$  is the  $j$ -th output of the previous convolutional layer.  $f$  is the activation function. The computation of the feature map after the convolution operation is Equation (7).

$$out = \frac{in - k + 2p}{s} + 1 \quad (7)$$

In Equation (7),  $out$  means the output features size,  $in$  is the input graph size,  $k$  means the convolutional kernel size.  $s$  is the step size, and  $p$  denotes the width of the boundary fill. The CSP layer effectively avoids the problems of gradient information loss and network computation consumption during training of traditional large models, and effectively improves the learning capacity of the CNN, and its structure is shown in Fig. 2.

As shown in Fig. 2, the CSP structure of YOLOv5s divides the primordial input into two branches. After performing convolution operations, the amounts of channels are halved. Branch 1 performs Bottleneck\*N, with two branches parallel, resulting in the same input and output sizes for bottleneck CSP. The CBL layer encapsulates three modules, namely BN, convolution layer and Leaky Relu activation function. BN is the original unit of the YOLO series, Equation (8).

$$\begin{cases} \hat{x}_i \leftarrow \frac{x_i - \mu_\beta}{\sqrt{\sigma_\beta^2 + \epsilon}} \\ y_i \leftarrow \gamma \hat{x}_i + \beta \end{cases} \quad (8)$$

As shown in Equation (8),  $\mu_\beta$  and  $\sigma_\beta^2$  denote the mean and variance of the data,  $\hat{x}_i \leftarrow \frac{x_i - \mu_\beta}{\sqrt{\sigma_\beta^2 + \epsilon}}$  denotes the normalization of the sample, and  $y_i \leftarrow \gamma \hat{x}_i + \beta$  denotes the translation and scaling of the data, with the BN function generally preceding the activation function.

Fig. 2. CSP layer structure.

The CSP1 structure is mainly applied in Backbone, and that of CSP2 is mainly applied in Neck. The first parameter 1 in the CSP1\_1 module indicates the CSP structure applied in Backbone Network, and the second parameter 1 indicates that the residual component in the module is repeated once. The CSP2x indicates the CSP module used in Neck network. CSP module. The main difference between it and the CSP module used in the Backbone Network is that 2X CBL modules are used instead of the residual module. Thereafter, the Neck network structure is entered by another convolution, which is schematically shown in Fig. 3.

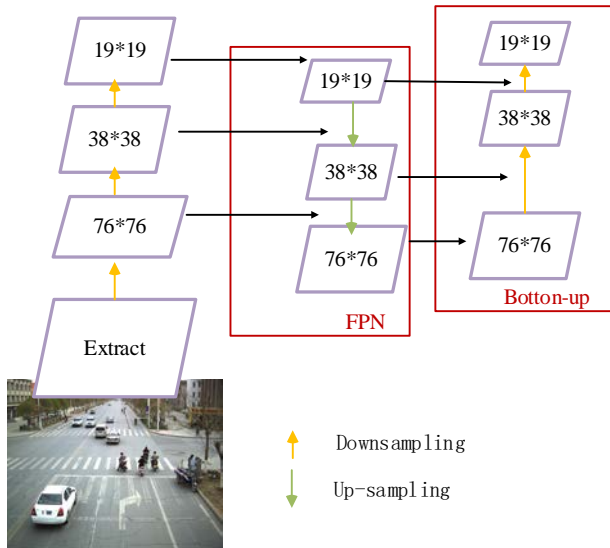

Fig. 3. Schematic graph of the neck network.

As Fig. 3, the extracted information is then input into the FPN module by performing a convolution operation on the target image extraction to reduce the image scale. The FPN module differs from the extraction module in that it passes feature information by a top-down approach, while the PAN module uses a bottom-up approach to pass feature information, which aims to enhance the target localization of network by using down sampling. The combination of these two structures not only enhances the target localization capability of the network, but also improves the target recognition capability, which helps to improve the accuracy of the TD algorithm.

The output is performed using the head network after passing through the neck network, and CIOU\_Loss is used as the loss function of the Bounding box in Yolov5. The original algorithm of YOLOv5 is the result of the analysis of the COCO dataset, and the anchor box originally obtained from the COCO dataset setting is optimized in order to be more suitable for this VD experimental environment. The study uses the K-means algorithm for anchor selection frame optimization, which is essentially a clustering algorithm and belongs to the category of unsupervised learning. The error sum of squares is generally used as the objective function to categorize the samples, and this metric is often used to evaluate the effectiveness of the clustering results. Its specific expression is shown in Equation (9).

$$Loss = \sum_{i=1}^k \sum_{x \in c_i} dis(x, c_i) \quad (9)$$

As shown in Equation (9),  $Loss$  represents the error sum of squares,  $x$  represents the calculation sample,  $c_i$  represents the center of mass of the  $i$  category, and  $dis(x, c_i)$  represents the distance between  $x$  and  $c_i$ . However, the formula is based on the Euclidean distance as an indicator for judging the similarity will cause more errors for big bounding boxes than for small bounding boxes, in order to make the K-means algorithm as an evaluation indicator for the similarity measurement of VD without the limitation of the bounding box size, the study uses A new distance formula suitable for VD, as in Equation (10).

$$dis(x, c_j) = 1 - IOU(x, c_j) \quad (10)$$

In Equation (10),  $x$  denotes the newly added checkbox,  $c_j$  denotes the first  $j$  real box, and  $IOU(x, c_j)$  denotes the accuracy of the prediction of the location information of  $x$  and  $c_j$  using the loss function IoU (Intersection over Union). The improved K-means algorithm was tested by testing it on the UA\_DETRAC dataset. The classification loss function is Equation (11).

$$E_{cls} = \sum_{i=0}^{S^2} 1_i^{obj} \sum_{c \in classes} (p_{i(c)} - \hat{p}(c))^2 \quad (11)$$

As shown in Equation (11),  $\sum_{i=0}^{S^2} 1_i^{obj}$  denotes the sum of squares over the objects in the table.  $p_{i(c)}$  is the predicted rate of the corresponding category.  $\hat{p}(c)$  is the true possibility.

### B. Improvement of Video Surveillance VD Algorithm Based on Attention Mechanism

In the road information collected through video surveillance, there are not only target vehicles, but also contain invalid information such as pedestrians, trees, and barriers, which can interfere with VD, so the study uses attention mechanism to achieve target area locking to reduce the interference of invalid information.

Most attention mechanisms incorporated into neural network models provide some performance gains, but they are not as effective in lightweight networks as they are in large network models. Therefore, the study will use Coordinate Attention (CA) mechanisms that allow lightweight networks to obtain an extensive range of feature details and avoid introducing too much computational overhead, with the structure shown in Fig. 4.

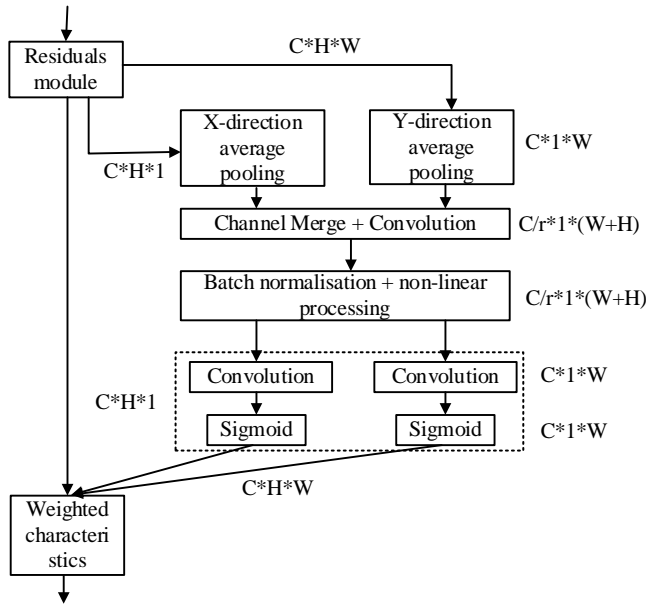

Fig. 4. Construction of the CA mechanism.

In Fig. 4, the CA mechanism is able to be identified as a computational unit to strengthen the characteristic representation capability of the mobile network, using two modules, coordinate information embedding and CA generation, to encode channel and long-distance relationships. Firstly, a 2D coordinate axis is created for the input feature information using a 1D global pooling operation, which is aggregated into 2 independent direction-aware feature representations along the X and Y directions. Then a merging operation is performed in the spatial dimension to integrate the feature maps using a 1\*1 convolutional layer.

$$f(x) = \frac{1}{1 + e^{-x}} \quad (12)$$

Finally, two attention weights are utilized to the input features by using a weighted multiplication of the Sigmoid function with normalized weights as in Equation (12), thus emphasizing the region of interest of the algorithm. The Sigmoid formula is as in Equation (12) and the tanh formula is as in Equation (13).

$$g(x) = \frac{1 - e^{-2x}}{1 + e^{-2x}} \quad (13)$$

Both Equation (12) and (13) use the exponential function  $e^x$  for the formulation. Applying the attention mechanism to the YOLOv5 can strengthen the recognition of target vehicles and the extraction of useful features for localization to a certain extent. The details are expressed in Table I.

TABLE I. COMPOSITION OF FEATURE EXTRACTION NETWORK WITH ATTENTION MECHANISM

Modules	Parameters			
	I	II	III	IV
Input	(640*640*3)	-	-	-
Focus	(3,64,1,1)	-	-	-
Conv	(64,128,3,2)	(128,256,3,2)	(256,512,3,2)	(512,1024,3,2)
3×C3	(128,128)	(1024,1024)	-	-
9×C3	(256,256)	(512,512)	-	-
SPP	(1024,1024, (5,9,13))	-	-	-
CoordAtt	(1024,1024)	-	-	-

Table I indicates the module name of the network structure, the first parameter in parentheses indicates the feature input channels of the mode, the second parameter indicates the feature output channel numbers, and the other parameters thereafter indicate the specific parameters of the module, for example, Focus (3,64,1,1), which indicates three input channels and 64 output channels, using a convolution of size 1\*1. In introducing the coordinate attention mechanism into YOLOv5, the CA mechanism is first embedded into the backbone network of YOLOv5. Through existing research, it is found that in the YOLOv5 feature extraction network, the last layer has the largest number of feature channels, which may affect the accuracy of the detection algorithm due to the interference of irrelevant information, so the model is added to the last layer in an attempt to allow the VD algorithm can focus on the feature information related to the current task.

The evaluation metrics of the YOLOv5 algorithm improved by the fused attention mechanism are selected as accuracy, recall and detection speed, and the evaluation metrics are calculated using the confusion matrix as the basis, and the accuracy (Precision) is denoted by P. In the confusion matrix, it indicates what percentage of the results with positive prediction are predicted correctly, as in Equation (14); in the confusion matrix, TP is both the predicted and true cases are active cases. FP is that the prediction is positive and the true case is inactive.

$$Precision = \frac{TP}{TP + FP} \quad (14)$$

Recall (Recall) in the confusion matrix indicates what percentage of all positive columns are predicted, as in Equation (15).

$$Recall = \frac{TP}{TP + FN} \quad (15)$$

*FN* is the opposite of *FP*. In the current experimental algorithm it is not possible to obtain results with high recall and accuracy, so the equilibrium state of the two needs to be considered [13]. Based on the derived recall and accuracy, the average precision (AP) is considered, and since this experiment uses a multi-objective VD algorithm, it is measured using the category-wide average precision metric, which is obtained by weighting the mean precision of all detection categories [14]. At the same time, the study is a lightweight model, and for achieving the effect of saving computational materials, it is also necessary to evaluate the detection speed, and Frame Per Second (FPS) is selected as the speed evaluation index.

#### IV. PERFORMANCE TESTING OF YOLOV5 BUILT ON IMPROVED ATTENTION MECHANISM

##### A. Experimental Scheme Design and Computational Efficiency Analysis

For testing the recommendation model, a test experiment is designed here. In order to meet the requirements of diverse road conditions and real scene fit, the study will use the UA\_DETRAC dataset, which is obtained by slicing the traffic routes of Chinese cities Beijing and Shanghai at 25 frames per second after 10 hours of video shooting, with the image size of 960\*540 pixels, containing more than 140,000 images, and manually labeled 8250 vehicles, with 1.21 million bounding boxes marked, and car types classified according to vehicle shape, and all marked vehicles are dynamic vehicles, and the shooting environment includes four kinds: sunny day, rainy day, cloudy day and night shown in Fig. 5.

Fig. 5. Sample diagram of part of the UA\_DETRAC dataset.

Firstly, to reduce the burden on the experimental equipment and remove the data redundancy of the dataset, UA\_DETRAC was extracted into a new dataset with a ratio of 5:1 and converted into a dataset in VOC format, and the annotation file format was converted from xml to txt for easy input into the YOLOv5 model for model training. Because the size of UA\_DETRAC images is 960\*540 pixels, the images are scaled to the same size of 640\*640 pixels. After training the model, the  $\alpha$ -CloU loss function curve localization loss curve, classification loss curve and confidence loss curve are shown in Fig. 6.

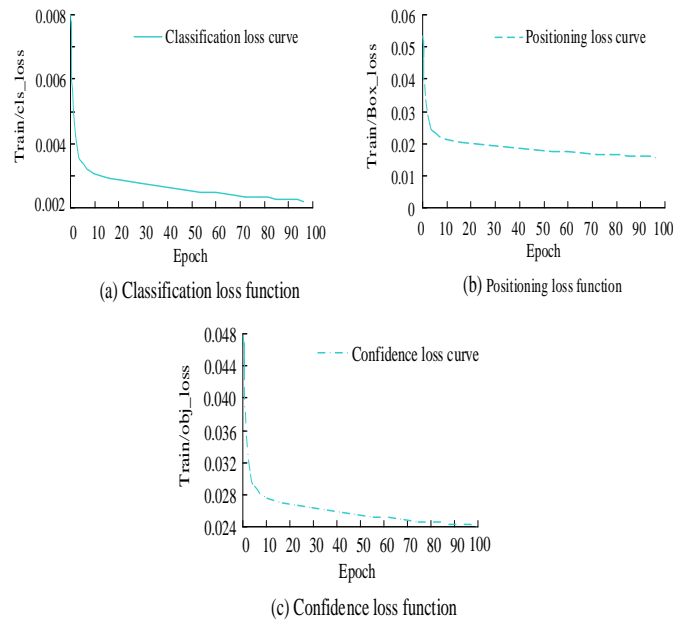

Fig. 6. YOLOv5 model training loss function curve.

The changes of loss function curves during training are Fig. 6. Fig. 6(a) indicates the classification loss curve. Fig. 6(b) shows the localization (positioning) loss curve, and Fig. 6(c) indicates the confidence loss curve. During the training process, no abnormalities have occurred, and all the loss function curves tend to be stable when the model is trained to the 100th round. From Fig. 6, it can be seen that the localization loss and confidence loss gradually stabilize at 0.002 and 0.028; the classification loss gradually stabilizes at 0.017.

Based on this, the algorithm is tuned to improve the focus on the key regions by adding a coordinate attention mechanism to the YOLOv5 model that mimics human visual recognition and has lightweight characteristics. Before training, the hyperparameter batch size is 16, and 100 epochs are trained. From the beginning to the end of training, the warm-up principle is used, which means that 3 epochs are learned from 0. After the learning rate reaches a plateau, the cosine annealing principle is adopted to reduce the learning rate, and the cosine annealing hyperparameter is set to 0.2 [15]. For the selection of the optimizer, the study Random Gradient Descent with momentum was chosen. The advantage of this method is that the square of the gradient is calculated in a small space, so there is no need to store the gradient. The momentum of the optimizer is 0.937 and the weight decay coefficient is 0.0005. After turning on mosaic data enhancement for all training images, mix up data enhancement is turned off. The loss function curve of the training result of the network model with the CA mechanism added is shown in Fig. 7.

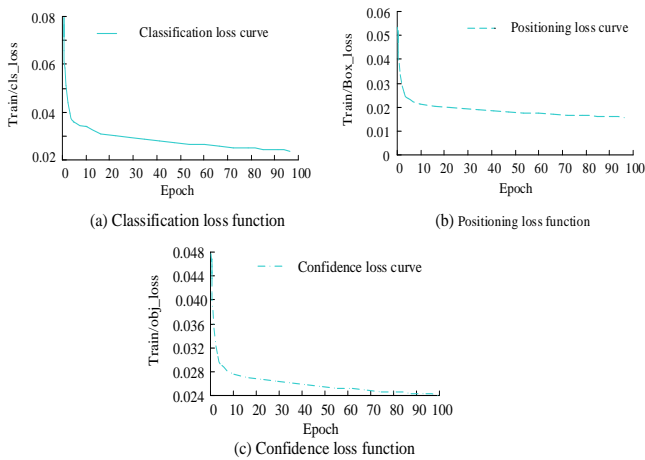

Fig. 7. Change curve of the loss function of the YOLOv5 model with the introduction of the coordinate attention mechanism.

As shown in Fig. 7, 7(a) represents the classification loss curve, Fig. 7(b) represents the localization loss curve, and Fig. 7(c) represents the confidence loss curve. The overall training process of the model is relatively normal, with a smooth decreasing trend, and the loss decreases quicker in the 1st 20-epochs, and then gradually stabilizes when reaching 100 epochs. The final localization loss is stabilized at 0.017, classification loss is stabilized at 0.00117, and confidence loss is stabilized at 0.028.

### B. Model Vehicle Inspection Quality Analysis

For verifying the effectiveness of CA mechanism on the improvement of YOLOv5 measurement accuracy, Squeeze and Excitation Networks (SE), Convolutional Block Attention Module (CBAM) and CA mechanism are added to the YOLOv5 model, respectively. The SE is added at the same location as the CA mechanism, and the CBAM has the ability to extract spatial information instead of the convolutional layer, so the CBAM is used to replace that in the 5th-layer of the YOLOv5 [16-18]. The common YOLOv5 model is also selected as a comparison, and the accuracy comparison curves of the four models are Fig. 8.

As shown in Fig. 8, Fig. (a), (b), (c), and (d) show the test results of the baseline network models YOLOv5, YOLOv5+SE, YOLOv5+CBAM, and YOLOv5+CA, respectively, and it can be seen that the overall trend of the four network models is similar, and all of them gradually stabilize after a rapid increase in the confidence interval from 0 to 1. Further analysis of Fig. 8(a) and Fig. 8(b) shows that the accuracy of both models can be approximated to 1.0 at a confidence level of 0.946 for all categories, but the accuracy curve of YOLOv5 model with SE inserted for other categories of vehicles is smoother and has higher validity than the accuracy curve of YOLOv5 baseline model. In comparing Fig. 8(c) with Fig. 8(d), the YOLOv5 model with CA inserted has a higher confidence level of correct prediction for all categories of VD, and has a good accuracy at a confidence level of 0.4. The comparison of the accuracy curves demonstrates that the fused CA mechanism YOLOv5 network model performs better in VD. After that, the average accuracy of the four models is compared (Fig. 9).

Fig. 8. Comparison of the precision of the improved model with the baseline network.

Fig. 9. Comparison of detection accuracy of four improved VD algorithms.

As shown in Fig. 9, which clearly reflects the comparison of the detection accuracy of the four VD algorithms network, to better reflect the improvement of the detection accuracy of the VD algorithms, also the more common VD algorithms and YOLOv5 combined with the CA mechanism of the network for comparison. It can be clearly found that the overall trend of the four VD algorithms is similar, and the detection accuracy in bus classification is much higher than the other classifications, at more than 90%, and the detection accuracy of the four algorithms for car classification is lower all approximating 83%, which may be due to the relatively fixed bus shape with obvious signs [19-21]. The YOLOv5 performance combined with CA mechanism for VD algorithm is significantly greater than the others, with detection accuracy exceeding other algorithms by about 0.8 percentage points.

As shown in Fig. 10, it more intuitively demonstrates the improvement of YOLOv5+CA on VD accuracy, a comparison using the commonly used VD algorithm model SOTA [22], it is evident that the YOLOv5+CA VD algorithm performs significantly better than several other common algorithms, with

detection accuracy exceeding other algorithms by about 9 percentage points. Unlike the YOLOv5+CA detection algorithm, the SSD algorithm, ResNet-101 algorithm and RefineDet algorithm have similar trends, and the YOLOv5+CA detection algorithm is significantly more accurate than the three common algorithms in detecting mAP, Bus, Van and other categories, while the three common algorithms perform slightly better in detecting vehicles in the Car category in terms of accuracy than the YOLOv5+CA detection algorithm.

Fig. 10. Accuracy comparison of YOLOv5+CA with different SOTA vehicle detection algorithms.

As shown in Fig. 11, the YOLOv5 combined with the three attention mechanisms is tested using night-time live video, and the detection results are visualized and compared. Fig. 11(a), 11(b) and 11(c) show YOLOv5+SE, YOLOv5+CBMA and YOLOv5+CA respectively by comparing Fig. (a), (b) and (c) it can be found that three small cars are missed in the figure. In Fig. 11(b) the VD using the network of YOLOv5 combined with CBAM leads to an improvement of the missed detection, two of the missed vehicles are identified, but the confidence level is not high. In Fig. 11(c), the algorithm using YOLOv5+CA identifies all three missed vehicles with high confidence values. Therefore, the validity of the CA mechanism in improving the accuracy of the VD algorithm can be fully confirmed.

Fig. 11. Visual comparison of three YOLOv5 test results.

## V. CONCLUSION

For the problem of low accuracy of VD performed by video surveillance, an improved VD model incorporating coordinate attention mechanism and YOLOv5 is designed in the study. The experimental results of the performance test show that the model converges when the iterations exceed 100, and the localization loss and confidence loss gradually stabilize at 0.002 and 0.028; the classification loss gradually stabilizes at 0.017. After adding the CA mechanism and setting the training to 100 epochs, the loss of the model declined quicker in the 1st 20 epochs. After that, the loss leveled off when reaching 100 epochs. Finally, the localization loss is stabilized at 0.017, the classification loss is stabilized at 0.00117, and the confidence loss is stabilized at 0.028. Thereafter, to compare the superiority of different attention mechanisms, the baseline network models YOLOv5, YOLOv5+SE, YOLOv5+CBAM, and YOLOv5+CA are used for comparison tests, and the results show that the accuracy can be approximated to 1.0 at a confidence level of 0.946 for all categories, and the YOLOv5 model with CA inserted for all categories of VD predicts the correct the confidence level is higher and has a good accuracy at a confidence level of 0.4. To better reflect the improvement in detection accuracy of the VD algorithm, YOLOv5+CA is compared with SSD algorithm, ResNet-101 algorithm and RefineDet algorithm, and the results show that YOLOv5+CA VD algorithm performs significantly better than several other common algorithms, and the detection accuracy is better than other algorithms by about 9%. To compare the actual video VD gap of YOLOv5+SE, YOLOv5+CBAM, and YOLOv5+CA, a visual comparison of YOLOv5 combining the three attention mechanisms reveals that both YOLOv5+SE and YOLOv5+CBAM have missed detections and low confidence levels. In summary, the research has shown that the vehicle detection accuracy of the YOLOv5+CA model designed by the research is higher than that of common models, and the computational performance has been improved compared to the original algorithm, but there are still some shortcomings, and the subsequent research can be improved and improved from the following aspects: (1) producing vehicle datasets with higher image quality. When using deep learning methods, the quality of the dataset determines the upper limit of the algorithm's performance. (2) Improve the detection accuracy of small targets. (3) Further compression of the network model. Due to the limited computing power and storage space of actual embedded devices, large scale deep learning algorithms cannot yet be deployed into these devices. And deploying the algorithms in embedded devices can reduce the latency time due to data passing through the network. The current lightweighting tends to sacrifice a certain amount of accuracy, and how to make the algorithm perform model compression while keeping accuracy constant is also a direction for future research. (4) Later on, consideration can also be given to improving the robustness of the algorithm to cope with different weather conditions.

**Abstract**—Stroke is a serious disease that has a significant impact on the quality of life and safety of patients. Accurately predicting stroke risk is of great significance for preventing and treating stroke. In the past few years, machine learning methods have shown potential in predicting stroke risk. However, due to the imbalance of stroke data and the challenges of feature selection and model selection, stroke risk prediction still faces some difficulties. This article aims to compare the performance differences between different sampling algorithms and machine learning methods in stroke risk prediction. This study used the over-sampling algorithm (Random Over Sampling and SMOTE), the under-sampling algorithm (Random Under Sampling and ENN), and the hybrid sampling algorithm (SMOTE-ENN), and combined them with common machine learning methods such as K-Nearest Neighbors, Logistic Regression, Decision Tree and Support Vector Machine to build the prediction model. Through the analysis of experimental results, and found that the SMOTE combined with the LR model showed good performance in stroke risk prediction, with a high F1 score. In addition, this study found that the overall performance of the undersampling algorithm is better than that of the oversampling and hybrid sampling algorithms. These research results provide useful references for predicting stroke risk and provide a foundation for further research and application. Future research can continue to explore more sampling algorithms, machine learning methods, and feature engineering techniques to further improve the accuracy and interpretability of stroke risk prediction and promote its application in clinical practice.

## I. INTRODUCTION

Stroke is a serious neurological disorder and its health burden is enormous worldwide. According to the World Health Organisation, millions of people die or become permanently disabled as a result of stroke each year [1]. Accurate prediction of the risk of stroke is therefore crucial for early intervention and treatment.

With the rapid development of machine learning techniques, the use of these techniques to predict stroke risk has become a hot topic of research. Machine learning models can predict the probability of stroke in individuals by learning and mining patterns and correlations in large amounts of patient data [2]. This provides clinicians with a new tool to aid decision-making and develop personalized treatment plans.

However, stroke risk prediction faces a number of challenges. Firstly, the mechanisms by which stroke events occur are complex and diverse, involving a variety of potential risk

factors such as age, gender, hypertension, and diabetes [3]. Secondly, stroke data often suffer from a serious imbalance, i.e. there is a significant imbalance between the proportion of normal samples and stroke samples [4]. This data imbalance may result in the models having better predictive performance for most classes of samples, but poorer predictive performance for a few classes of samples (i.e. stroke samples). In addition, the generalisability and interpretability of the models are key issues in stroke risk prediction studies [5].

To overcome these challenges and improve the accuracy and reliability of stroke risk prediction, this study aims to compare the performance of different sampling machine learning algorithms in stroke risk prediction. The study will utilize various sampling algorithms, such as Random Over Sampling (ROS) and Synthetic Minority Over-sampling Technique (SMOTE), as well as undersampling algorithms like Random Under Sampling (RUS) and Edited Nearest Neighbors (ENN), along with the combination of SMOTE and Edited Nearest Neighbors (SMOTE-ENN), to address imbalanced data. Additionally, machine learning methods including K-Nearest Neighbors (KNN), Logistic Regression (LR), Decision Tree (DT), and Support Vector Machine (SVM) will be employed for prediction modeling [6]–[9]. Through the comparison of performance among various sampling algorithms and machine learning methods, the study aims to identify the optimal prediction model and enhance the accuracy and reliability of stroke risk prediction.

The paper is structured as follows: Section II reviews relevant previous work. Section III describes the experimental design and methods in detail. The Section IV presents the experimental results and analysis. Finally, Section V summarises the main findings of the paper and discusses directions for further research.

## II. RELATED WORKS

The study of stroke risk prediction has attracted a great deal of interest and a lot of valuable work has emerged. This section provides an extensive review of relevant literature on stroke risk prediction, encompassing various methods and techniques employed in previous studies. Additionally, an in-depth analysis of the strengths and limitations of these approaches is presented.

Commonly used methods for stroke risk prediction in previous studies include traditional statistical models and machine learning models. Traditional statistical models such as

regression analysis, survival analysis, and decision trees are widely used for stroke risk prediction. These models can be based on large clinical datasets by building predictive models to identify patients' risk factors for stroke. Dennis et al. [10] used survival analysis to accurately estimate the long-term mortality risk of first-time stroke patients. Shao et al. [11] utilized the decision tree C4.5 algorithm to establish a stroke risk assessment model and identify the influences of various factors such as smoking, alcohol consumption, diet, sleep, and exercise on stroke risk. However, traditional statistical models have limitations in dealing with complex non-linear relationships and high-dimensional data.

In recent years, the development of machine learning techniques has opened up new possibilities for stroke risk prediction. Machine learning models can automatically learn patterns and correlations from data and are able to handle non-linear relationships and high-dimensional data. Common machine learning methods used in stroke risk prediction include SVM, DT and Random Forest (RF) and Artificial Neural Network (ANN) [12]–[15]. These models can be trained on large amounts of patient data to predict stroke risk with a high degree of accuracy and generalisation.

In previous research on stroke prediction using machine learning models, the focus has primarily been on the performance of machine learning models. Viswapriya et al. [12] proposed a hybrid model combining ANN and RF for stroke prediction, achieving a classification accuracy of 94%. Sailasya et al. [13] proposed the use of various machine learning algorithms to predict the risk of brain stroke, with Naïve Bayes (NB) achieving the highest accuracy of approximately 82%. Dritsas et al. [14] proposed a robust framework using machine learning models and a stacking method to accurately predict the long-term risk of stroke occurrence, achieving high performance with an AUC of 98.9% and an accuracy of 98%. Alageel et al. [15] proposed an analysis of factors enhancing stroke prediction using electronic health records, identifying age, average glucose level, heart disease, and hypertension as critical factors, and evaluating seven machine learning algorithms for stroke occurrence prediction with high accuracy and performance.

In addition to traditional statistical models and machine learning models, sampling algorithms are also widely used in stroke risk prediction. As stroke data usually exhibit a class imbalance problem, i.e. a significant imbalance between stroke and normal samples, sampling algorithms can balance the dataset by oversampling, undersampling or hybrid sampling. However, a critical aspect that has been overlooked in previous research is the comparison of different sampling algorithms for handling imbalanced datasets. Some researchers generally directly use the popular SMOTE algorithm to process imbalanced data [16]–[18], and , there are also some researchers simply use random sampling methods to compare with SMOTE algorithms [19].

In summary, stroke risk prediction is a challenging and important area of research. Traditional statistical and machine learning models provide powerful tools for stroke risk prediction, while sampling algorithms are able to handle unbalanced data sets. This study aims to further investigate the effectiveness of combining different sampling algorithms with machine learning models for stroke risk prediction. The findings of this

research contribute to the advancement of methods and insights in the field of stroke risk prediction.

### III. METHODOLOGY

This section is divided into four sections, including data collection, data pre-processing, machine learning Models, and evaluation metrics, and the proposed workflow is shown in Fig. 1.

#### A. Data Collection

The predicted stroke dataset in this study is from the Kaggle platform, which contains 5110 patient data [20]. It has 12 features, including seven categorical features, four quantitative features and a patient ID number. There is personal and health information about the patient, details of which are shown in the Table I.

TABLE I. DESCRIPTION OF STROKE DATASET

Feature Name	Feature Description	Feature Type
Id	Patient unique id.	/
Gender	Male, Female, Other.	Quantitative
Age	Patient ages in years.	Quantitative
Hypertension	If the patient has hypertension, then 1 else 0.	Categorical
Heart disease	If the patient has heart disease, then 1 else 0.	Categorical
Ever married	No, Yes.	Categorical
Work type	Children, Govt job, Never worked, Private, Self-employed.	Categorical
Residence type	Rural, Urban.	Categorical
Avg glucose level	Average glucose level in blood.	Quantitative
BMI	Body Mass Index (BMI) is an indicator used to assess a person's weight status based on their weight and height.	Quantitative
Smoking status	Formerly smoked, Never Smoked, Smokes, Unknown.	Categorical
Stroke	If the patient has a stroke disease, then 1 else 0.	Categorical

The dataset has 4681 normal and 249 stroke patients, 95% of which are negative cases and only 5% are positive cases, a highly unbalanced dataset as shown in Fig. 2.

#### B. Data Pre-processing

1) *Missing Value Handling*: About 4% of the data have missing BMI values. To improve the robustness of the model, 0 is used for filling.

2) *Meaningless Features Handling*: In this study, the patient ID was considered irrelevant and subsequently excluded from the analysis.

3) *Label Encoding*: The values of some of the category features (Gender, Ever married, etc.) need to be converted to numerical values before being entered into the model.

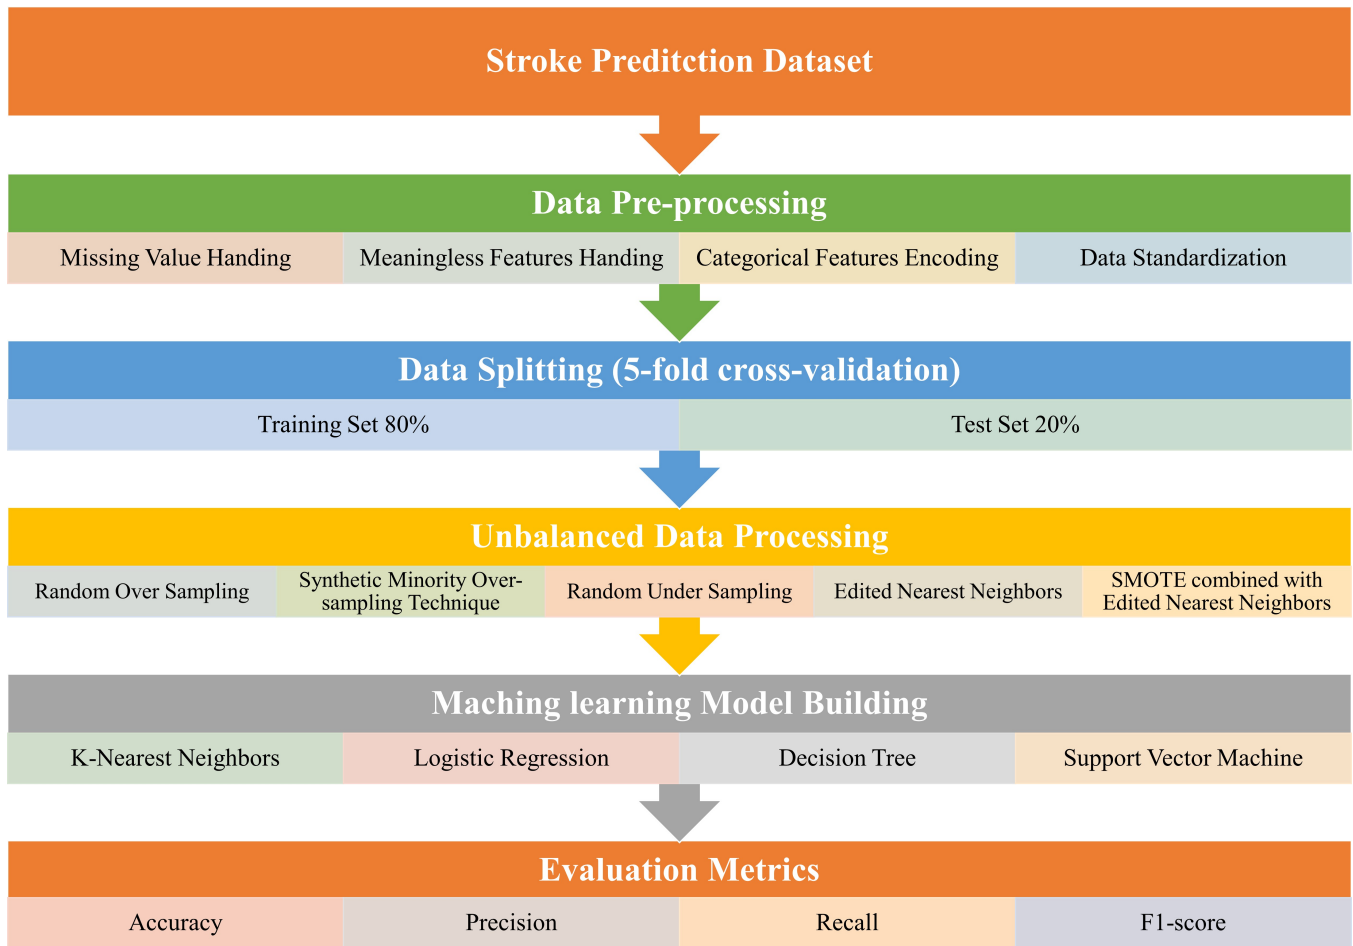

Fig. 1. Proposed workflow.

Fig. 2. No Stroke vs Stroke.

4) *Data Standardization*: The magnitude and unit of stroke patients' information data are different. For example, the value of avg glucose level is hundreds, while the value of BMI is only dozens. Data needs to be standardized before being input into the model. In this experiment, a separate standardization procedure was applied to the training set and test set after partitioning the dataset in order to avoid data leakage. Therefore,

this study standardized the dataset, calculation as Equation (1):

$$x_{\text{standardized}} = \frac{x - \mu}{\sigma} \quad (1)$$

where  $x_{\text{standardized}}$  represents the standardized value of  $x$ ,  $\mu$  is the mean of the data,  $\sigma$  is the standard deviation of the data, and  $x$  is the original data point.

### C. Description of Sampling Algorithms

Stroke data typically suffer from category imbalance, i.e. a significant imbalance in the ratio between stroke and normal samples. To tackle the challenge of imbalanced data in stroke risk prediction, a range of sampling algorithms were utilized. This section provides an overview of the sampling algorithms employed, namely ROS, SMOTE, RUS, ENN, and SMOTE-ENN.

1) *Random Over Sampler*: ROS is a simple yet effective algorithm that randomly replicates minority class samples until the class distribution is balanced. It increases the number of stroke samples in the dataset, allowing the machine learning models to learn from more balanced data.

2) *Synthetic Minority Over-sampling Technique*: SMOTE is a widely used oversampling algorithm that generates synthetic minority class samples based on the characteristics of

existing minority samples. It creates synthetic samples by interpolating between randomly selected minority samples and their nearest neighbors.

3) *Random Under Sampling*: The RUS randomly selects a subset of majority class samples to match the number of minority class samples. It reduces the dominance of the majority class in the dataset, allowing the machine learning models to focus more on the minority class.

4) *Edited Nearest Neighbors*: ENN is an undersampling algorithm that removes misclassified majority class samples based on their nearest neighbors' class labels. It compares the class label of each majority sample with its k-nearest neighbors and removes the samples that are misclassified.

5) *SMOTE-ENN*: SMOTE-ENN first applies the SMOTE algorithm to generate synthetic samples and then applies the ENN algorithm to remove misclassified samples.

#### D. Description of Machine Learning Models

This section provides a detailed description of the machine learning methods utilized for stroke risk prediction in the study. The study utilized a selection of widely used machine learning algorithms, including KNN, LR, DT, and SVM. Each algorithm has its unique characteristics and advantages in handling different types of data and classification problems.

1) *K-Nearest Neighbors*: KNN is a non-parametric algorithm that classifies data points based on the majority class label of their k-nearest neighbors [6]. It can be used for stroke risk prediction by measuring the similarity between the input sample and other samples in the dataset. The common distance formula used in KNN algorithm is the Euclidean distance. For two sample points  $x$  and  $x_i$ , the Euclidean distance is calculated as Equation (2).

$$d(x, x_i) = \sqrt{\sum_{j=1}^n (x_j - x_{ij})^2} \quad (2)$$

where  $n$  is the feature dimension of the sample points, and  $x_j$  and  $x_{ij}$  denote the values of the sample  $x$  and  $x_i$  on the  $j$ th feature, respectively.

2) *Logistic Regression*: LR is a linear classification algorithm that models the probability of a sample belonging to a specific class. It can be used to predict the probability of stroke occurrence based on the input features [7]. The logistic regression model estimates the parameters of a logistic function using maximum likelihood estimation. The logistic function maps the input features to a probability value, and a threshold can be applied to classify the samples into different classes. The logistic regression model can be represented as Equation (3):

$$P(\text{Stroke} = 1|X) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_n X_n)}} \quad (3)$$

where  $P(\text{Stroke} = 1|X)$  represents the probability of stroke occurrence given the input features  $X$ , and  $\beta_0, \beta_1, \dots, \beta_n$  are the coefficients estimated during model training.

3) *Decision Tree*: DT is a hierarchical tree-based algorithm that splits the feature space based on the values of different features [8]. It can be used to identify the important features and their thresholds that are associated with stroke risk. The decision tree creates a tree-like model where each internal node represents a decision based on a feature, and each leaf node represents a class label. The decision tree can be represented as a series of if-else statements, where each internal node represents a splitting condition based on a feature, and each leaf node represents a class label.

4) *Support Vector Machine*: SVM is a binary classification algorithm that aims to find an optimal hyperplane in the feature space that separates the data points of different classes with the maximum margin [9]. It can be used for stroke risk prediction by finding a decision boundary that distinguishes between samples with and without stroke. SVM can handle both linearly separable and non-linearly separable data by using different kernel functions to map the input features to a higher-dimensional space. The SVM classification function can be represented as Equation (4):

$$f(x) = \sum_{i \in S} \alpha_i y_i K(x_i, x) + b \quad (4)$$

where  $x_i$  denotes the training patterns,  $y_i \in \{+1, -1\}$  denotes the corresponding class labels and  $S$  denotes the set of Support Vectors [21].

These machine learning methods can effectively capture the underlying patterns and relationships in the data and make predictions about the stroke risk for individuals based on their input features.

#### E. Evaluation Metrics

To assess the effectiveness of the stroke risk prediction models, the evaluation of the confusion matrix and various evaluation metrics was performed. Stroke was considered the positive class, while no stroke was considered the negative class.

1) *Confusion Matrix*: The confusion matrix provides a tabular representation of the model's predictions, showing the counts of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). It helps in analyzing the model's performance in correctly classifying stroke and no stroke cases [13]. The confusion matrix is shown in Table II.

TABLE II. CONFUSION MATRIX

	Predicted Stroke	Predicted No Stroke
Actual Stroke	TP	FN
Actual No Stroke	FP	TN

The elements in the matrix have the following meanings:

TP: The number of samples that the model correctly predicted as strokes.

TN: The number of samples that the model correctly predicted a no stroke.

FP: The number of samples that the model incorrectly predicted as having a stroke.

FN: The number of samples that the model incorrectly predicted as no stroke.

2) *Accuracy*: Accuracy is the ratio of correctly predicted instances (both stroke and no stroke) to the total number of instances. It measures the overall correctness of the model's predictions, providing an indication of how well it classifies both positive and negative cases. It is calculated as Equation (5):

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (5)$$

3) *Precision*: Precision quantifies the proportion of true positive predictions (correctly predicted strokes) out of the total predicted positive instances (predicted strokes). It measures the model's ability to accurately identify individuals at risk of stroke, minimizing false positive predictions. It is calculated as Equation (6):

$$\text{Precision} = \frac{TP}{TP + FP} \quad (6)$$

4) *Recall*: Recall calculates the proportion of true positive predictions (correctly predicted strokes) out of the actual positive instances (actual strokes). It measures the model's ability to correctly identify individuals who have experienced a stroke, minimizing false negative predictions. It is calculated as Equation (7):

$$\text{Recall} = \frac{TP}{TP + FN} \quad (7)$$

5) *F1-score*: The F1-score is the harmonic mean of precision and recall, providing a balanced measure of the model's accuracy in predicting both stroke and no stroke cases. It considers both false positive and false negative predictions and provides an overall assessment of the model's performance. It is calculated as Equation (8):

$$\text{F1-score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (8)$$

By utilizing the confusion matrix and these evaluation metrics, a comprehensive evaluation of the stroke risk prediction models can be conducted to assess their performance in accurately identifying individuals at risk of stroke while minimizing false positive and false negative predictions.

#### IV. RESULT AND DISCUSSION

The performance of five different sampling algorithms was evaluated, including ROS, RUS, SMOTE, ENN, and SMOTE-ENN, in combination with four machine learning models: KNN, LR, DT and SVM. The evaluation metrics used were accuracy, precision, recall, and F1-score in Table III.

The accuracy comparison is shown in the Fig. 3 and the accuracy of the models is observed to decrease to some extent after applying the sampling algorithm. This may be because the sampling algorithm changes the distribution of the samples when processing unbalanced data, thus affecting the overall accuracy. Among all algorithms, the combination of ENN and LR achieved the highest accuracy (0.9454), while the combination of RUS and DT achieved the lowest accuracy (0.6945). Compared to other sampling algorithms, the model of ENN algorithm is higher, because the ENN algorithm improves

accuracy by removing noise and redundant samples from the majority class, thereby preserving the distinctive features of the minority class samples.

Fig. 3. Accuracy of each sampling algorithm combined with machine learning models.

The precision comparison is shown in Fig. 4, revealing that the combination of ENN and LR models achieved the highest precision rate of 0.2675, whereas the combination of RUS and DT algorithms obtained the lowest precision rate of 0.0967. And the precision of the model combined with ENN is significantly higher than the other sampling algorithms, indicating that the ENN algorithm is better able to identify the true positive samples and reduce the possibility of false positives.

Fig. 4. Precision of each sampling algorithm combined with machine learning models.

The recall comparison is shown in Fig. 5, demonstrating a substantial improvement in the model's performance compared to unsampled data when utilizing the sampling algorithm. The

	LR	0.7123	0.1226	0.8028	0.2117
	DT	0.8444	0.1281	0.3771	0.1912
	SVM	0.7509	0.1149	0.6102	0.1928

<sup>a</sup> ROS: Random Over Sampler; SMOTE: Synthetic Minority Over-sampling Technique; RUS: Random Under Sampling; ENN: Edited Nearest Neighbors; SMOTE-ENN: Synthetic Minority Over-sampling Technique combined with Edited Nearest Neighbors.

<sup>b</sup> KNN: K-Nearest Neighbors; LR: Logistic Regression; DT: Decision Tree; SVM: Support Vector Machine.

combination of RUS and SVM has the highest recall of 0.8035, while ENN+LR has the lowest recall of 0.0542. At this point, the model recall of the combination with ENN is significantly lower than the other sampling algorithms except for LR, and the model recall of the combination with RUS is overall higher than the other sampling algorithms, which indicates that the RUS algorithm can better identify the true positive samples and reduce the possibility of misclassification the possibility of misclassification.

The F1-score comparison is shown in Fig. 6. Under the metric, the model scores were all significantly higher after using the sampling algorithm than without the sampling algorithm. The combination of SMOTE and LR model obtained the highest score (0.2368), while the combination of ENN and LR model scored the lowest (0.0887). However, RUS performs better in combination with other algorithms, which indicates that the RUS is able to find a balance between accuracy and recall, resulting in a better overall model performance.

In a comprehensive comparison, the overall performance of the under sampling algorithm is better than that of the oversampling and hybrid sampling algorithms for the prediction stroke problem, and the models combined with the ENN algorithm generally perform better under the accuracy and precision metrics. The models combined with the RUS algorithm are generally better under the recall and F1-score metrics. Reviewing the findings depicted in Fig. 4, it becomes apparent that the utilization of the oversampling algorithm has resulted in only marginal improvements in model precision. Interestingly, in certain instances, the precision scores of certain models were lower when the oversampling algorithm was

Fig. 5. Recall of each sampling algorithm combined with machine learning models.

applied, compared to their performance without any sampling algorithm. Instead, the model precision scores of the ENN algorithm combined with the under sampling algorithm were significantly higher than the other algorithms. The observed phenomenon can be attributed to the limited number of positive samples, approximately 200 cases, and the significant variation in data distribution. The oversampling algorithm, in such cases,

Fig. 6. F1-score of each sampling algorithm combined with machine learning models.

tends to generate duplicate, noisy, or unreliable samples.

## V. CONCLUSION AND FUTURE WORK

This study examines stroke risk prediction through a comparative analysis of various sampling algorithms and machine learning methods. The experimental results show that the use of an appropriate combination of sampling algorithms and machine learning methods can significantly improve the prediction performance in the stroke risk prediction task.

In the analysis conducted, the hybrid sampling algorithm (SMOTE+LR) combined with the KNN model demonstrated superior performance in stroke risk prediction, yielding a high F1 score. The combination of other sampling algorithms and machine learning methods also achieved some prediction performance, but was overall inferior to the combination of the SMOTE algorithm and the LR model.

Although the SMOTE+LR combination exhibited the highest F1 score, the analysis revealed that the overall performance of the oversampling algorithm outperformed the undersampling algorithm and the hybrid sampling algorithm when considering the performance of various sampling methods in conjunction with machine learning models. Selecting an appropriate combination of sampling algorithms and machine learning methods is pivotal in enhancing the accuracy of stroke risk prediction.

This research has achieved some beneficial results, there are still some limitations that need to be considered.

Regarding dataset selection, specific datasets were utilized for conducting the experiments, which may introduce domain-specific or sample distribution biases. To ensure the generalizability of the findings, future research should encompass a broader range of datasets for validation purposes.

In terms of model building, the study selected KNN, LR, DT and SVM as machine learning methods with oversampling, under sampling and hybrid sampling algorithms. However,

there are other machine learning methods and sampling algorithms that can be tried, such as random forests, neural networks, and other variants of sampling methods. The comparison and exploration of these methods will contribute to a more comprehensive understanding of the problem of stroke risk prediction.

In future research, potential avenues for improvement can be explored in the following directions:

In terms of feature engineering, in stroke risk prediction, the selection and extraction of effective features are critical to prediction performance. Further research can explore better feature selection and feature engineering methods to improve prediction performance.

In terms of integrated learning, integrated learning methods can improve the accuracy and stability of stroke risk prediction by combining the prediction results of multiple models. Further research could try integrated learning methods and compare them with a single model.

In terms of interpretive analysis, the interpretation of stroke risk predictions is critical to clinical practice and decision support. Further research could explore how to interpret and explain the prediction results of models to increase their credibility and interpretability.

In conclusion, the results of this study provide a useful reference for stroke risk prediction and provide a basis for further research and application. Future research can continue to explore more sampling algorithms, machine learning methods and feature engineering techniques to further improve the accuracy and interpretability of stroke risk prediction and to promote its application in clinical practice.

**Abstract**—Precision, Recall, and F1-score are metrics that are often used to evaluate model performance. Precision and Recall are very important to consider when the data is balanced, but in the case of unbalanced data the F1-score is the most important metric. To find out the importance of these metrics, a comparative analysis is needed in order to determine which metric is appropriate for the data being analyzed. This study aims to perform a comparative analysis of various evaluation metrics on unbalanced data in multi-class text classification. This study uses an unbalanced multi-class text dataset including: association, negative, cause of disease, and treatment of disease. This study involves five classifiers as algorithm-level approach, namely: Multinomial Naive Bayes, K-Nearest Neighbors, Support Vector Machine, Random Forest, and Long Short-Term Memory. Meanwhile, data-level approach, this study involves under sampling, over sampling, and synthetic minority oversampling technique. Several evaluation metrics used to evaluate model performance include Precision, Recall, and F1-score. The results show that the most suitable evaluation metric for use on unbalanced data depends on the purpose of use and the desired priority, including the classifier that is suitable for handling multi-class assignments on unbalanced data. The results of this study can assist practitioners in selecting evaluation metrics that are in accordance with the goals and application needs of multi-class text classification.

**Keywords**—Imbalanced data; undersampling; oversampling; smote; machine learning

## I. INTRODUCTION

An unbalanced dataset is a dataset in which some classes have much fewer data samples than others [2]. Imbalanced data occurs when the number of observations in one class is lower than in another class. It can be a problem in machine learning because models may be more accustomed to majority classes, leading to poor performance in minority classes. One of the ways to tackle imbalanced data is to do data sampling before applying machine learning algorithms. Nowadays, common methods of imbalanced data sampling mainly include data oversampling, data undersampling, and hybrid sampling [2], [3].

The method used to address unbalanced data depends on the characteristics of the data. Several previous studies have implemented undersampling [14], [17], [22], [30] to reduce the size of large sample data to balance different types of sample data. Beside undersampling, previous studies have also

implemented an oversampling [11], [12], [13], [27] method that takes small samples as the object to generate new samples. Imbalanced data in text classification with multi-class need to be considered since a classification model that is usually based on a fair class distribution could have problems with imbalanced class [6].

The author in [37] has carried out research on comparative analysis of macro and micro accuracy through a three-classifier approach, namely: Naïve Bayes (NB), Support Vector Machine (SVM), and Random Forest (RF) in the Movie Reviews dataset. In align previous research, this study proposes two additional classifiers, namely: k-Nearest Neighbors (KNN) and Long Short-Term Memory (LSTM), which will be tested on the Plant-Disease Relation (PDR) dataset. The main reason for using KNN and LSTM is that these algorithms are also proven to be used to solve unbalanced class problems like what was done by [38], [39], [40], [41]. Furthermore, reference [33] does not work on the KNN and LSTM algorithms, who used Linear SVC, RBF SVM, DTC, RF, LR, and MNB for multi-class text classification tasks.

In comparative analysis, it is necessary to evaluate the model using various performance metrics [5], and it is an interdisciplinary method that encompasses broad cross-sections of disciplines [1]. Comparative analysis is one way to solve the problem of model performance in classifying unbalanced datasets. It involves comparing the performance of different models on the imbalanced datasets, to determine which model is best suited for the task at hand. By comparing the performance of different models, it can identify the strengths and weaknesses of each model and choose a significant model that fits the problem of unbalanced data [4].

The results of the model evaluation usually use the confusion matrix as a model performance metric that is tested on each data. Metrics most commonly used to measure model performance include: Accuracy, Precision, Recall, Specificity, F1-score, and G-mean [7]. In text classification with multiple classes that experience data imbalance, micro and macro accuracy considerations can be useful in evaluating the model. Micro accuracy measures overall model accuracy by giving equal weight to all classes. It can be calculated by adding up the number of correct predictions from all classes and dividing by the total number of predictions [9]. Each algorithm used will produce a different confusion matrix, this is caused

by differences in methods for handling unbalanced data and classifier algorithms used. Several previous studies analyzed the balance of macro-F1 and micro-F1 [5], [8] only. In the case of imbalanced data, micro accuracy F1 may be higher than macro accuracy because the model may more easily predict the more dominant class with a higher level of accuracy [10].

Methods for dealing with class imbalance in machine learning can be divided into three groups, namely: data-level, algorithm-level, and hybrid approaches [11], [17]. Data-level methods aim to reduce class imbalance by adding new minority samples (i.e., oversampling) [13], removing redundant majority samples (i.e., undersampling) [14], or using a combination of both methods. Algorithm-level methods are designed to adapt standard classification methods to emphasize learning from minority samples, improve the training mechanism or predicted rule [11]. In hybrid approaches, the developed algorithms modify both the distribution of unbalanced classes and the learning mechanism to classify unbalanced data [15].

The contribution of this research to handle unbalanced classes are 1) data-level approach, including undersampling, oversampling, and synthetic minority oversampling technique, for tackle imbalanced class; 2) prepare five machine learning models, including NB, RF, SVM, KNN, and LSTM, for multi-class classification on Plant-Disease Relation datasets; 3) investigated and compared the performance of different machine learning models with various feature combinations and existing techniques.

This study employ both data-level and algorithm approach to handling highly imbalanced data aim to perform precision, recall and micro accuracy F1 score. Various test schemes employed through classification algorithm to obtain perspective analysis. The rest of this paper is organized as follows. Section II contains discussion on the dataset and the methodology used to undertake the research. This is followed by the results and discussion in Section III. Finally, in Section IV, the conclusion and future works are presented.

## II. MATERIALS AND METHOD

### A. Dataset

This study uses gold standard corpus dataset of the Plant-Disease Relation (PDR) developed by [16] available at <http://gcancer.org/pdr> (21<sup>st</sup> January, 2022). The dataset consists of 8 columns, but this study only uses the “sentence” column as text data and the “relation” column as a label (Table I). This study only relies on a statistical analysis of a collection of texts converted into a set of numbers, thus ignoring semantic analysis for classification work.

The PDR dataset has four classes: Association (34 records), Cause of Disease (183 records), Treatment of Disease (507 records), and Negative (583 records). Table II shows samples of the PDR dataset.

### B. Pre-processing

The sentence column used as input still contains several meaningless words, including  $\langle e1start \rangle$ ,  $\langle e1end \rangle$ ,  $\langle e2start \rangle$ , and  $\langle e2end \rangle$ , so it needs to be clean so that it doesn't have a biased impact when building the model. In this study, retaining words that are considered unimportant (a,

TABLE II. VIEW OF PLANT-DISEASE RELATION DATASET

No.	Sentence	Class
1	Studies on magnesium's mechanism of action in $\langle e1start \rangle$ digitalis $\langle e1end \rangle$ -induced $\langle e2start \rangle$ arrhythmias $\langle e2end \rangle$ .	Cause_of_disease
2	Inhibitory effect of $\langle e1start \rangle$ green tea $\langle e1end \rangle$ on the growth of established $\langle e2start \rangle$ skin papillomas $\langle e2end \rangle$ in mice.	Treatment_of_disease
3	In 10 separate experiments, mice with established chemically induced or UV light-induced $\langle e2start \rangle$ skin papillomas $\langle e2end \rangle$ were treated continuously with green tea in the drinking water or with i.p. injections of a $\langle e1start \rangle$ green tea $\langle e1end \rangle$ polyphenol fraction or -epigallocatechin gallate three times a week for 4-10 weeks.	Negative
4	Although based on small numbers of end points, a prospective study has suggested a particularly strong association between recent $\langle e1start \rangle$ coffee $\langle e1end \rangle$ drinking and the incidence of $\langle e2start \rangle$ cardiovascular disease $\langle e2end \rangle$ .	Association

an, can't, have not, etc.) are usually called stop\_words. We assume that these words will reduce the model's performance in predicting classes.

The next step is to convert text into numbers, as the computer cannot process data in the text as the machines only recognize numbers. Therefore, the text shall be used as input and should be convert to numbers. Some methods can do this including Count Vectorizer, TF-IDF, Word2Vec, BERT, and ELMO, where the text will be encoded into a vector space with a fixed length. This study uses the Count Vectorizer approach for the vectorization process. When extracting and representing features from text data, this study also pays attention to n-grams. This study use CountVectorizer from sklearn as vectorizer and use n gram for character embedding algorithm (Fig. 1).

### C. Data Training and Testing

This study divides the data into two groups with a ratio of 80:20 to test the reliability of all classifiers to be used, 80% for training data and 20% for test data. In addition to this approach, this study also uses a 5-fold cross validation approach. To divide the data into training and testing, this study also considers the random sample aspect when conducting training, which consists of under sampling, over sampling and synthetic sampling.

### D. Class Imbalanced Learning

This study focuses on combine both data-level and algorithm-level approach techniques to measure performance of model through precision, recall and F1 score metrics. Various imbalanced learning techniques have been envolved in addressing the class imbalance problem. It requires either (1) reducing the bias a machine learning algorithm can impart

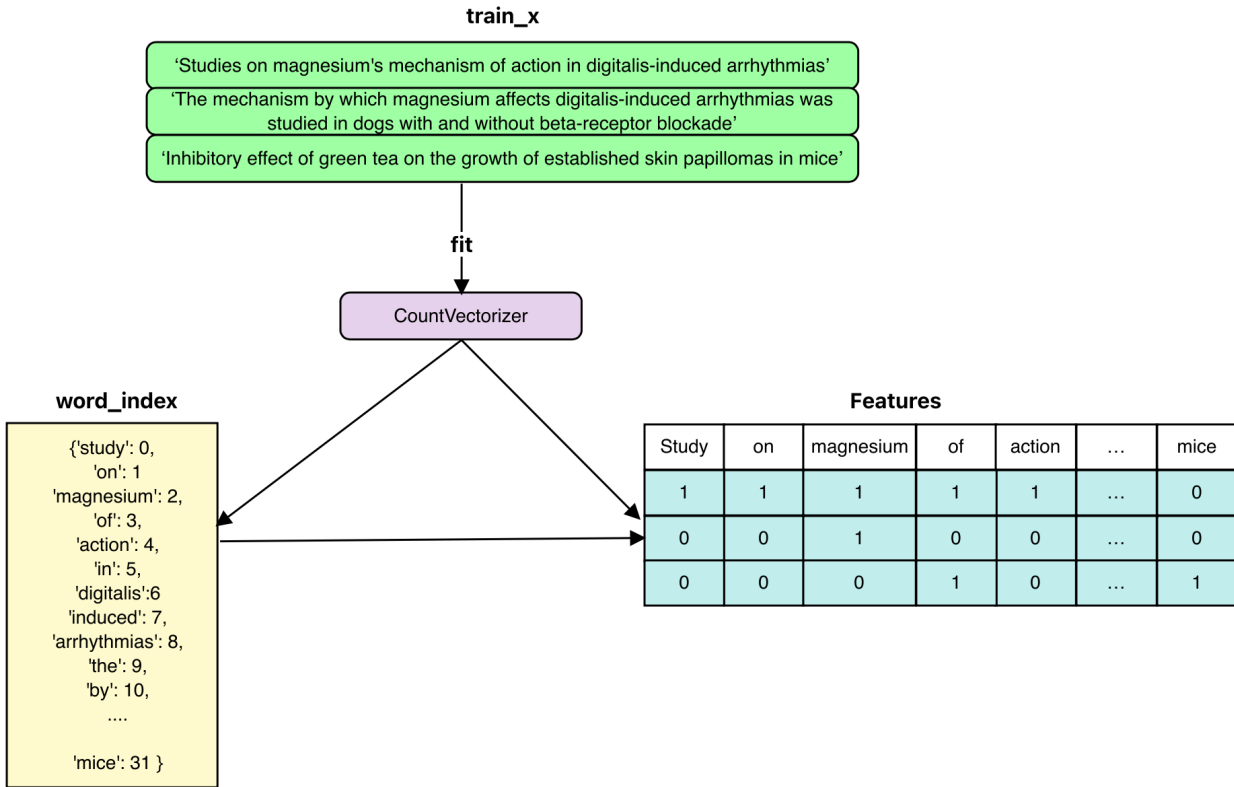

Fig. 1. Flowchart of extracting features.

to the majority class in the dataset, or (2) configuring the algorithm to be sensitive to the minority class [17]. Fig. 2 is a techniques to tackle class imbalance learning that can be classified into three main categories: (a) Data-level methods, (b) Algorithm-level methods, and (c) combination of both methods [11], [17].

In a data-level approach, researchers attempted to balance the dataset before applying traditional classification algorithms so that the majority class did not bias the results. In the algorithm-level approach, researchers worked on the internals of the algorithm and tried to remove the algorithm's sensitivity to the majority class, so that the results of the classification algorithm would not drift towards the majority class [12]. A third approach is a hybrid that combines data-level and algorithm-level approaches [18].

### E. Classifier

The classifier is a machine learning model that is used to classify sample data into predetermined classes. The classifier receives input in the form of data samples and outputs in the form of classes of appropriate method for the data samples. The classifiers can be used for a various variety of applications, such as facial recognition, speech recognition, and natural language understanding.

Classifiers can be divided into two main types, namely binary classifiers and multi-class classifiers. A binary classifier is a classifier that can only classify data samples into two classes, while a multi-class classifier is a classifier that can

classify data samples into more than two classes. Classifiers can be created using a variety of machine-learning algorithms.

Naïve Bayes Classifier, K-Nearest Neighbor, Support Vector Machine, and Random Forest are the most classifiers used in machine learning. This study uses the classifier referring to previous research [19] and adding LSTM classifier for handling multi-class classifier tasks to obtain optimal results through comparative analysis on Precision, Recall, and F1-score metrics.

1) *Multinomial Naïve Bayes*: A Multinomial Naïve Bayes (MNB) model is used to represent calculate or count rates. The additive smoothing parameter  $\alpha$  is set to 1. Prior class probabilities are learned and adjusted according to the data [20], [21]. The purpose of this method is to classify probability based on supervised machine learning over other probabilities. This study use Multinomial Naïve Bayes as a classifier to classify a document into four classes.

Multinomial Naïve Bayes computes class probabilities for a given document. A collection of classes is denoted by  $C$ ,  $N$  is the vocabulary size. Next step, MNB assigns a test document  $t$  to the class that has the highest probability  $Pr(c | t_i)$  which, using Bayes rule (Equation 1) [21]. The class prior probability  $Pr(c)$  can be estimated by dividing the number of documents belonging to class  $c$  by the total number of documents.  $Pr(t_i | c)$  is the probability of obtaining a document like  $t_i$  in class  $c$ .

$$Pr(c|t_i) = \frac{Pr(c)Pr(c|t_i)}{Pr(t_i)}, c \in C \quad (1)$$

Fig. 2. Hierarchy of class imbalance learning techniques.

2) *K-Nearest Neighbours*: K-Nearest Neighbours (KNN) is a supervised classification algorithm and is considered one of the best data mining algorithms despite its simplicity. It creates a decision surface that adapts to the shape of the data distribution, resulting in high accuracy when the training set is large or representative [22]. The KNN algorithm assumes that similar things are close together. This means that similar items are placed close together determine best k-Nearest Neighbors using Grid Search.

The classification algorithm follows these steps: (1) compute the distance between a  $x_i$  instance and all instances of the training set  $T$ , (2) choose the  $k$  nearest neighbors, (3) The  $x_i$  instance is classified (labeled) with the most oftentimes class among the  $k$  nearest neighbors. It is also possible to use the neighbors distance to weight the classification decision. Characteristically in the literature are found odd values for  $k$ , normally with  $k = 5$  or  $k = 7$  [23]. An approach to determine  $k$  as a function (2) of data size  $m$ .

3) *Support Vector Machine*: Support Vector Machine (SVM) works by constructing hyperplanes in a multidimensional space that separates the different cases of class labels. SVM has two important parameters, namely  $c$  and  $\gamma$  [19]. Parameter  $c$  adds a penalty for each misclassified data point. If  $c$  is small, the penalty for misclassified points is low, so decision boundaries with large margins are chosen at the cost of more misclassifications. The gamma parameter controls the influence distance of training points. When small gammas,  $c$  affects the model in the same way, it affects linear models. Typical values for  $c$  and gamma are  $0.0001 < \gamma < 10$  and  $0.1 < c < 100$ . This study uses hyperparameter tuning for a grid search to determine the optimal  $\gamma$  and  $c$  values.

Given a training set of  $N$  data points  $\{y_k, X_k\}_{N_k = 1}$ , where  $X_k \in \mathbb{R}^n$  is the  $k$ th input pattern and  $y_k \in \mathbb{R}$  is the  $k$ th output pattern, the support vector method approach aims to building a classifier of the form (Equation 2) [24]:

$$y(x) = \text{sign} \left[ \sum_{i=0}^N \alpha_k y_k \Psi(x, x_k) + b \right] \quad (2)$$

where  $\alpha_k$  are positive real constants and  $b$  is real constant,  $\Psi(x, x_k) = x_k^T x$  for linear SVM. In the above expression,

$\Psi(x, x_k)$   $\alpha_k$ ,  $y_k$ ,  $x_k$ ,  $b$ , and  $N$  represent a kernel function [25].

4) *Random Forest*: The Random Forest (RF) algorithm is a machine learning technique that can be employed to classify text into multiple classes. The Random Forest algorithm generates numerous decision trees that employ these features to predict the class of text samples, making it a more effective algorithm for datasets with many features than other machine learning techniques. The ensemble tree-based RF classifier chooses features from the training data randomly, and it reduces the correlation between trees [3]. This study utilized value of  $n\_estimators = 100$  as input into the RF model. The value of  $n\_estimators$  get from a grid search approach for hyperparameter tuning. A grid search was applied to select the optimal  $n\_estimators$  used to classify on multi-class dataset. These parameters are applied independently and interactively, with samples randomly chosen from the training dataset to arrive at a final prediction. This study aligns with previous research by [31] that used RF as a classifier to handle unbalanced classes.

5) *Long Short-Term Memory*: In the past decade, there has been a surge in the use of deep learning techniques, which have become increasingly popular due to their ability to enhance the state-of-the-art in fields such as speech recognition and computer vision, among others [26]. In this study, the classifier was trained using the Long Short-Term Memory (LSTM) algorithm. The training dataset consists of a certain number of time series vectors, which are not specified in the given text  $\mathbb{X}_1, \mathbb{X}_2, \dots, \mathbb{X}_N$  where  $\mathbb{X}_k$  with  $k = 1, 2, \dots, N$  reflect the trajectory sequence with mathematically integrated from  $k$ th sentence and corresponding labels  $y_1, y_2, \dots, y_N$ . Equation 3, 4, 5, and 6 are computation stages for single LSTM unit.

$$Z_k = \tanh(W.[X_k^t; h_k^{t-1}; 1]) \quad (3)$$

$$Z_k^i = \delta(W^i.[X_k^t; h_k^{t-1}; 1]) \quad (4)$$

$$Z_k^f = \delta(W^f.[X_k^t; h_k^{t-1}; 1]) \quad (5)$$

$$Z_k^o = \delta(W^o.[X_k^t; h_k^{t-1}; 1]) \quad (6)$$

where tanh stands for tanh function,  $\delta$  represents sigmoid function,  $W$ ,  $W^i$ ,  $W^f$ ,  $W^o$  are row vectors which stand for the weight combined with bias parameters for LSTM cell, input gate, forget gate, and output gate, respectively.  $Z_k$  represents the output of the output of the LSTM cell for  $k$ th sequence  $Z_k^i$ ,  $Z_k^f$ ,  $Z_k^o$  represent the scalar outputs of input gate, forget gate, and output gate sequence, respectively.  $[X_k^t; h_k^{t-1}; 1]$  is a column vector combined by column vector  $X_k^t, h_k^{t-1}$  and 1 [27], [32].

6) *Class Balancing Techniques*: The class balance technique is a way to overcome the problem of imbalance class in a dataset. Class imbalance occurs when a class has a much higher number of samples than the others. This event can pose problems for machine learning, as models tend to predict which classes are more common than others. One way to balance classes is to use a sampling technique. Sampling is a technique used to take samples from a larger data set and use them to create a smaller, balanced data set.

One technique for tackling this problem is to employing multiple sampling procedures, which are classified as random and special. In the first situation, remove a fixed number of examples from the majority class (undersampling) as shown in Fig. 3; in the second, increase the number of minority class examples (oversampling) [28]. In this study, use oversampling and undersampling (Fig. 3). All sampling will be applied to all classifiers to obtain the optimal mode in carrying out multi-class classification work on imbalanced data.

Fig. 3. Undersampling and oversampling balancing classes algorithms.

F. Text Classification Model

This study applied five different machine learning algorithms when performing multiclass text classification of plant-disease relation dataset: Multinomial Naïve Bayes, K-Nearest Neighbours, Support Vector Machine, Random Forest, and LSTM. The scikit-learn machine learning library running in the Python and programming system was used to implement these classifiers. Fig. 4 shows the steps in creating the classification model.

Sklearn.Naïve\_bayes.MultinomialNB is used to implement a Multinomial Naïve Bayes classifier, with parameter  $\alpha = 1$ . On the other hand, sklearn.neighbors.KNeighborsClassifier is used to perform K-Nearest Neighbours classifier, with parameter metric=manhattan, n\_neighbors=65, p=1, and weights=distance. Sklearn.svm.SVC was used to implement Linear SVC. For this classifier, the kernel and c parameter were chosen to be linear and 1, respectively. For kernel RBF, the SVM classifier was also run from sklearn.svm.SVC with parameters c=1, gamma=0.1, and kernel=linear. A Random Forest classifier was implemented based on the

Fig. 4. Flowchart of methodology in this study.

sklearn.ensemble.RandomForestClassifier class in this case the parameters n\_estimators = 100 and max features = 'auto'.

The hyperparameters of these classifiers were determined based on using a Grid Search algorithm. Based on these hyperparameters, the classifier provided the highest accuracy. Hyperparameters were determined using 5-fold cross-validation. The hyperparameter names and values for each classifier that correspond to the top accuracy values (Table III).

TABLE III. HYPERPARAMETER TUNING

III. RESULT AND DISCUSSION

The pre-processing stage is very influential on the result of model. This study processes data only through tokenization without involving stop words. The reason for not using the stop\_word is some words that are considered meaningless play an important role in determining class. After going through the tokenization process, data increased to 25136. Apart from the pre-processing stage, each classifier's also influence the model's result. Multinomial Naïve Bayes has parameters alpha and c, K-Nearest Neighbors has parameters n\_neighbors, Random Forest has n\_estimators, and Deep Learning has parameters dropout, activation, and optimizer. Table IV shows model

evaluation in this study which involve eight scenarios. This study evaluates models from different scenarios based on precision, recall, and f1-score.

TABLE IV. MODEL DEVELOPMENT SCENARIOS

No.	Scenario	Description
1	Ratio (80:20)	Training (80) and Testing (20)
2	5-fold cross validation	dividing training and testing data which divides equally into five parts and without considering imbalanced class
3	Under-sampling + Ratio	Ratio with due regard to imbalanced learning based on under-sampling
4	Under-sampling + 5-fold cross validation	5-fold cross validation with paying attention to imbalanced learning based on under-sampling
5	Over-sampling + Ratio	Ratio taking into account imbalance learning based on oversampling
6	Oversampling + 5-fold cross validation	5-fold cross validation taking into account imbalanced learning based on over-sampling
7	SMOTE + Ratio	Ratio taking into account imbalanced learning based on SMOTE
8	SMOTE + 5-fold cross validation	5-fold cross validation with imbalanced learning based on SMOTE

Precision is a metric for evaluating machine learning models that measures the accuracy of the model's recognition of true positives out of the total positive predictions [29] (Equation 7).

$$Precision_{\mu} = \frac{\sum_{i=1}^l tp_i}{\sum_{i=1}^l (tp_i + fp_i)} \quad (7)$$

where  $\sum_{i=1}^l tp_i$  is amount of true positive in whole class, while  $\sum_{i=1}^l (tp_i + fp_i)$  is total summation of true positive and false positive.

In the context of the confusion matrix, recall is a metric used to evaluate the accuracy of a classification model in correctly identifying true positives out of the total number of positive classes in the actual data [29]. This metric provides information about the proportion of correct positive predictions and can be used to assess the quality of a classification model in minimizing the number of false negative predictions (Equation 8).

$$Recall_{\mu} = \frac{\sum_{i=1}^l tp_i}{\sum_{i=1}^l (tp_i + fn_i)} \quad (8)$$

The micro accuracy metric involves adding the correct prediction count for each class and dividing it by the total number of samples. This method assigns equal value to every sample when determining accuracy, making it an appropriate measure to use when the dataset is imbalanced, or when the number of samples for each class varies.  $\mu$  represent micro averaging (Equation 9).

$$F1score_{\mu} = \frac{(\beta^2 + 1) Precision_{\mu} Recall_{\mu}}{\beta^2 Precision_{\mu} + Recall_{\mu}} \quad (9)$$

The macro accuracy metric is determined by initially computing the accuracy for each class and then calculating the average accuracy of all the classes. This method assigns equal value to every class when determining accuracy, making

it an appropriate measure to use when the dataset is balanced, or when the number of samples for each class is more or less equal (Equation 10).

$$F1score_M = \frac{(\beta^2 + 1) Precision_M Recall_M}{\beta^2 Precision_M + Recall_M} \quad (10)$$

### A. Multinomial Naïve Bayes

The result shows that the model works very efficiently on the ratio and 5-fold cross-validation schemes. However, this does not give an overall picture of the model's performance. The performance of the model can be affected by imbalanced data, so the model tends to correctly predict the majority class and ignore the minority class. Therefore, it is necessary to perform several techniques to balance classes such as over-sampling, under-sampling, or synthetic minority oversampling techniques (SMOTE). The weighted average on Precision and Recall shows the overall model performance considering the frequency of each class with a score of 0.92, respectively.

Based on the scores obtained from all the schemes used, it can be concluded that MNB has the best performance on Ratio scheme. These results are in line with a study conducted by [20] which obtained the highest score compared to SVM, RF and KNN. The feature space used is unigram + bigram at 80% training data and 20% testing data (Table V). This achievement is optimal on unbalanced data. However, testing on balanced data through undersampling and oversampling techniques gives a low score.

The highest score is obtained through the oversampling + ratio scheme. The highest score was obtained through the oversampling + ratio scheme with a score of 0.76, while the SMOTE scheme obtained a score of 0.75. These results contrast with research conducted by [35] and [36], which obtained the highest score when using the SMOTE scheme.

### B. K-Nearest Neighbors

K-Nearest Neighbors (KNN) is an uncomplicated and widely used classification algorithm that predicts the category

of a sample based on the category of the closest k-neighbors in the feature space. KNN operates by comparing the distance between the samples being predicted with the categories of other samples already present in the dataset. The way to determine the number of nearest neighbors is through hyperparameter tuning and the values n\_neighbors=65, metrics=manhattan, p=1, and weights=distance are obtained.

The hyperparameter results the optimal value n\_neighbors=65, metrics=manhattan, p=1, and weights=distance. The results of modeling using the KNN classifier as shown in Table VI that the data-level approach based on under sampling with the ratio had optimal performance in Precision, Recall and F1-score are 0.94 respectively. This achievement outperforms other schemes with balanced data. These results indicate that unbalanced data can be overcome by under-sampling like as previous research [22] and an 80:20 ratio approach for separating training data and test data. On the other hand, the study conducted by [20] obtained the highest score on the Recall metric when using KNN, this outperformed other classifiers such as RF, SVM and MNB.

C. Support Vector Machine

The SVM classifier performed best using oversampling and ratio schemes, based on the test results. All the evaluated metrics, achieved a score of 0.91, even when using the weighted average for unbalanced classes. The model's prediction results for all classes were evenly scored, indicating that the oversampling approach effectively addressed the problem of imbalanced data. Although the SMOTE approach was not as effective as oversampling, it still outperformed all other data-level schemes (Table VII).

As seen from the Table VIII, the highest accuracy of 0.91% was obtained when using scheme ratio using oversampling. This achievement is influenced by character level settings such as research conducted by [2]. In the research, the fourgram level character greatly influences SVM performance which is superior compared to using unigrams, bigrams, and trigrams than MNB and RF.

D. Random Forest

Table VIII shows that the Random Forest classifier has good performance on imbalanced data through a 5-fold cross-validation scheme with an even score of 0.92 on Precision, Recall, and F1-score, respectively. On the other hand, this classifier can handle imbalanced data through a data-level over-sampling scheme. The difference between the macro average and the weighted average on Precision, Recall, and F1-score is only 1-2 points. It's shows that the model can work on balanced or unbalanced classes. Macro average gives the same weight to each class, regardless of the frequency of each class. Meanwhile, the weighted average gives different weights to each class depending on the frequency of each class.

Based on testing, this classifier produces an optimal model through a 5-fold cross validation scheme without sampling. If this classifier uses sampling (under and over), the model has poor performance. This is in line with research [34] which has found that the implementation of SMOTE to Random Forests has an impact on reducing model performance.

TABLE VIII. RANDOM FOREST CLASSIFIER RESULTS

E. Long Short-Term Memory

The LSTM classifier also shows performance that is not inferior to the previous classifier. The classifier got a score of 0.94 for precision but got a score of 0.93 for Recall and F1-score. This study highlights scores in bold text on weighted averages, where they are generally very effective when classes have unequal numbers (Table IX). This achievement is obtained through an under-sampling scheme, in which the sample was adjusted using minority data to make it balanced. Unfortunately, even though the data-level method uses under-sampling, it is only suitable through 5-fold cross-validation for the distribution of training and testing samples. The ratio approach has the worst results compared to other schemes.

The performance of this classifier pays attention to the minority class, namely the Association, which only has 34 sample data. Meanwhile, the other class was 10 multiplied that of the Association class. It is shows that this classifier is suitable for use on unbalanced data through under-sampling and 5-fold cross-validation methods. This result is different from the study conducted by [34] which found the fact that the use of SMOTE in LSTM had an impact on improving model performance.

TABLE IX. LONG SHORT-TERM MEMORY CLASSIFIER RESULTS

Table with 10 columns: Class, R, F, U+R, U+F, O+R, O+F, S+R, S+F. Rows are grouped by Precision, Recall, and F1-score, each with sub-rows for Assoc, CoD, Neg, ToD, macro avg, and weight avg.

R=Ratio 80:20, F=5-fold cross validation, U=under sampling, O=over sampling, S=SMOTE, Assoc=association, CoD=cause of disease, Neg=negative, ToD=treatment of disease.

IV. CONCLUSION AND FUTURE WORK

The purpose of comparative analysis is to understand the differences and similarities between the objects being compared and to evaluate the advantages and disadvantages of each object. This study compares Precision (P), Recall (R), and F1-score (F1) metrics from various algorithms to produce an optimal model. Because the data is unbalanced, a sampling method is needed which involves under sampling, over sampling, and synthetic sampling. Each classifier is tested on eight schemes consisting of: R, F, U+R, U+F, O+R, O+F, S+R, and S+F. In addition consider to the number of balanced classes, the scheme also aims to test the performance of models with unbalanced data. This aims to find out whether the application of sampling as a mandatory thing is used or not. Test results on five classifiers through eight schemes on

imbalance data produce varying P, R, and F1 metrics. However, the main goal is to find the most optimal model. P and R values are very important when the data is balanced, meaning that the model can predict classes with high accuracy and is able to identify most of the true class samples. On the other hand, if the data is unbalanced, P and R are not sufficient to evaluate the performance of the classification model as a whole. To evaluate the performance of the classification model on unbalanced data, F1-score is the most suitable metric. The F1-score measures of the harmonic average of the P and R scores. This study still requires improvisation and is still very much open for further study. In the future, this study will continue to classify through various approaches by considering the semantics of each word.

# Multi-objective Task Scheduling Optimization Based on Improved Bat Algorithm in Cloud Computing Environment

Dakun Yu, Zhongwei Xu, Meng Mei

Department of Information and Communication Engineering,  
Tongji University, 201804, China

**Abstract**—In cloud computing environments, task completion time and virtual machine load balance are two critical issues that need to be addressed. To solve these problems, this paper proposes a Multi-objective Optimization Mutate Discrete Bat Algorithm (MOMDBA) that improves upon the traditional Bat algorithm (BA). The MOMDBA algorithm introduces a mutation factor and mutation inertia weight during the global optimization process to enhance the algorithm's global search ability and convergence speed. Additionally, the local optimization logic is optimized according to the characteristics of cloud computing task scenarios to improve the degree of load balancing of virtual machines. Simulation experiments were conducted using CloudSim to evaluate the algorithm's performance, and the results were compared with other scheduling algorithms. The results of our experiments indicate that when the cost difference between algorithms is within 4.47%, MOMDBA can significantly outperform other methods. Specifically, compared to PSO, GA, and LBACO, our algorithm reduces makespan by 56.26%, 59.87%, and 25.26%, respectively, while also increasing the degree of load balancing by 93.87%, 75.92%, and 39.13%, respectively. These findings demonstrate the superior performance of MOMDBA in optimizing task scheduling and load balancing.

**Keywords**—Cloud computing; task scheduling; optimization; bat algorithm; meta-heuristics

## I. INTRODUCTION

Cloud computing has become a ubiquitous infrastructure in various fields, providing users with convenient access to computing resources and services through the internet [1]. Task scheduling is a crucial problem in cloud computing that aims to allocate multiple tasks to available computing resources to optimize system throughput, response time, resource utilization, and other performance metrics. However, as cloud computing systems become increasingly complex and diverse, task scheduling problems often involve multiple conflicting optimization objectives, such as reducing system energy consumption and costs, improving task completion rates and reliability. Traditional single-objective optimization algorithms are often ineffective in solving these multi-objective optimization problems because they focus on a single objective and ignore the impact of other objectives.

To address this challenge, it is crucial to explore multi-objective optimization algorithms for cloud computing task scheduling. Multi-objective optimization algorithms can simultaneously optimize multiple objective functions and find a set of optimal solutions by balancing and trading off different objectives. These algorithms can provide more comprehensive

and accurate decision support, helping cloud computing systems achieve more efficient, reliable, and sustainable operation. Additionally, they can facilitate the comprehensive evaluation and analysis of system performance, providing a more comprehensive reference for optimizing the overall performance of cloud computing systems.

The task scheduling problem is a combinatorial optimization problem that is typically considered as NP-hard [2]. Therefore, it is necessary to find an effective optimization algorithm to solve it. Traditional static task scheduling algorithms, such as Min-Min algorithm [3], Max-Min algorithm [4], and Round-Robin algorithm [5], have limitations in handling large-scale scheduling problems. Meta-heuristic algorithms [6], on the other hand, have demonstrated good robustness and feasibility in task scheduling optimization. Researchers have explored various meta-heuristic algorithms, including genetic algorithm (GA) [7], ant colony algorithm (ACO) [8], bat algorithm (BA) [9], and particle swarm optimization (PSO) algorithm [10], among others, achieving promising results [11–15].

Compared to other metaheuristic algorithms, the bat algorithm has been shown to possess strong global search capability, fast convergence speed, high search efficiency, and simple parameter settings. However, there has been limited research on the use of BA in cloud computing task scheduling, particularly with regard to multi-objective optimization. This research can effectively fill this research gap and contribute to the advancement of knowledge in this field.

Bat algorithm is a heuristic search algorithm proposed by Professor Yang in 2010[16], which is based on swarm intelligence. It is an effective method for searching the global optimal solution. The algorithm simulates the behavior of bats in nature, using a type of sonar to detect prey and avoid obstacles. This means that the bats use ultrasound to simulate the most basic detection and positioning capabilities of obstacles or prey and associate it with the optimization target function.

The bionic principle of the bat algorithm maps individual bats with the population number to NP feasible solutions in the d-dimensional problem space. The optimization process and search are simulated as the movement process of the individual bats and the search for prey. The fitness function value of the problem being solved is used to measure the quality of the position of the bat. The individual survival of the fittest process is compared to the iterative process of replacing the poor feasible solution with the good feasible solution in the

optimization and search process.

The optimization principle of the bat algorithm shows that the algorithm's optimization ability primarily depends on the interaction and influence between bat individuals. However, the individuals themselves lack a mutation mechanism, which makes it difficult for them to escape from a local extreme value once they are constrained by it. Moreover, during the evolution process, super bats in a population may quickly attract other individuals to gather around them, resulting in a substantial decline in population diversity. As bat individuals get closer and closer to the optimal individuals in the population, the convergence rate is greatly reduced, or even evolutionary stagnation occurs. This causes the population to lose the ability to further evolve.

In the context of cloud computing task scheduling, this paper proposes an improved bat algorithm. By considering makespan, degree of load balancing, and cost[6] as optimization objectives, a multi-objective optimization mutation discrete bat algorithm (MOMDBA) is proposed. Building on the standard bat algorithm, the population position and velocity are discretized, and the mutation factor and mutation inertia weight are introduced to effectively balance the global search and local search ability of the algorithm, resulting in faster convergence rates. Additionally, the local optimization logic is optimized to obtain better load balancing performance based on the characteristics of the task scheduling problem.

The rest of the paper is organized as follows. Section II provides a literature review of previous works. In Section III, we model the task scheduling problem and optimization targets in the cloud computing environment. Sections IV and V introduce the bat algorithm and the proposed improved algorithm. Section VI presents the experimental results. Finally, Section VII concludes the paper.

The symbols utilized in this paper are presented in the table (Table I) below, along with their corresponding definitions.

TABLE I. DEFINITION OF SYMBOLS USED

Symbol	Definition
$Exetime_{ij}$	The execution time of the $i^{th}$ task ( $T_i$ ) executed on the $j^{th}$ VM ( $VM_j$ )
$length_i$	The length of the $i^{th}$ task
$size_i$	The size of the $i^{th}$ task
$mips_j$	Processing capacity of the $j^{th}$ VM
$bw_j$	Bandwidth of the $j^{th}$ VM
$E_{VM_j}$	The total execution time of $VM_j$
$D$	The degree of load balancing
$f$	Fitness function
$x_i^t$	The position of the $i^{th}$ bat at time $t$
$v_i^t$	The speed of the $i^{th}$ bat at time $t$
$p_i$	Mutation factor
$\omega$	Mutation inertia weight

## II. RELATED WORK

Chen et al.[17] proposed an advanced approach called Improved WOA for Cloud task scheduling (IWC). They first

mapped the task scheduling scheme to the whale foraging model to obtain an approximately optimal solution. Then, IWC was used to further improve the optimal solution search capability. The experiments demonstrate that, compared to other meta-heuristic algorithms, the proposed method has a better convergence speed and accuracy in searching for the optimal task scheduling plans.

Natesan et al.[18] proposed a modified mean grey wolf optimization algorithm that uses a variant algorithm to increase the accuracy and performance of the GWO[19]. In the proposed method, the encircling equation and hunting equation were modified to improve the efficiency of the motion, and a suitable path for each wolf was present in the searching area. The modifications to the GWO algorithm led to improved convergence speed and accuracy in solving the task scheduling problem in cloud computing.

Jacob et al.[20] combined two optimization algorithms, Cuckoo Search and Particle Swarm Optimization, to reduce the makespan, cost, and deadline violation rate. The newly proposed hybrid algorithm is called CPSO. From the simulation results, the proposed method outperforms PBACO, ACO, MIN-MIN, and FCFS in terms of minimizing the makespan, cost, and deadline violation rate.

Jing et al.[21] proposed a QoS-aware cloud task scheduling algorithm called QoS-DPSO, which aims to satisfy the QoS requirements in cloud computing systems. They took into account the user's preference for QoS requirements and considered enough QoS parameters. The proposed method obtained superior performance by incorporating QoS requirements into the task scheduling process.

Kumar et al.[22] proposed a hybrid multi-objective optimization algorithm called HGA-ACO. They combined Ant Colony Optimization (ACO) algorithm with the Genetic algorithm (GA) to obtain better performance in task allocation. ACO is used to assist GA in avoiding local optimal solutions, while GA is used to enhance the ACO solutions. The proposed hybrid algorithm exhibits better performance in terms of task allocation compared to other existing algorithms.

Hamad et al.[23] proposed a Genetic-Based task scheduling algorithm to minimize the completion time and cost of tasks, and to maximize resource utilization. According to the experiments, the completion time and cost for the proposed method were reduced by 41.83% and 3.6%, respectively, compared to the standard GA. Additionally, the resource utilization was improved by 47%. The proposed algorithm shows potential for improving the efficiency of task scheduling in cloud computing systems.

Wei et al.[24] proposed an improved ant colony algorithm to solve the problem of unbalanced task scheduling load and low reliability in cloud computing environments. They improved the pheromone update and pheromone volatilization methods for the ant colony algorithm to speed up the convergence speed and introduced the load weight coefficient of VM in the update process of local pheromone. Experimental results verify the feasibility of the proposed method, which reduces the task scheduling completion time and convergence time while ensuring load balancing. The proposed method shows potential for improving the performance of task scheduling in cloud computing systems.

From previous studies, it can be concluded that the improvement of meta-heuristic algorithms can be generally divided into two types: one is to improve on the basis of classical algorithms, and the other is to combine two algorithms to form a new algorithm. The proposed method belongs to the first type, which is based on the bat algorithm and finds the optimal task scheduling scheme by mutation while randomly initializing the bat population position. Additionally, the local optimization logic of the bat algorithm is optimized to improve the algorithm's load balancing performance.

### III. RESOURCE SCHEDULING MODEL IN CLOUD ENVIRONMENT

The resource scheduling model in the cloud environment is shown in Fig. 1. In this model, resource scheduling is divided into two levels. The first level is task to virtual machine scheduling, and the second level is virtual machine to host scheduling, which assigns virtual machines to different physical hosts in the data center. This paper mainly focuses on the task scheduling process at the first level. In the task scheduling process, the scheduling algorithm first segments the tasks submitted by users, which is a complicated process in actual operation. For the convenience of research, this process is idealized in this paper, where tasks are assumed to be independent of each other. Tasks are executed in no particular sequence, and cannot be interrupted or migrated. The computing capacity of all computing resources is known. In this paper, makespan, degree of load balancing, and cost are taken as optimization objectives of the algorithm.

#### A. Makespan

Makespan defines the total time required from submitting a task to the completion of the task by the user[25].

With  $m$  tasks,  $Task = \{T_1, T_2, \dots, T_m\}$  and  $n$  VMs,  $VM = \{VM_1, VM_2, \dots, VM_n\}$  where  $m > n$ , assuming that a subtask can run on only one VM, the mapping between a subtask and a VM is by  $TV_{map}$ .

$$TV_{map} = \begin{Bmatrix} T_1V_1 & T_1V_2 & \dots & T_1V_n \\ T_2V_1 & T_2V_2 & \dots & T_2V_n \\ \vdots & \vdots & & \vdots \\ T_mV_1 & T_mV_2 & \dots & T_mV_n \end{Bmatrix} \quad (1)$$

The execution time of the  $i^{th}$  task ( $T_i$ ) executed on the  $j^{th}$  VM ( $VM_j$ ) is denoted by  $Exetime_{ij}$ , and can be calculated as follows:

$$Exetime_{ij} = \frac{length_i}{mips_j} + \frac{size_i}{bw_j} \quad (2)$$

where  $length_i$  and  $size_i$  represents the length and the size of the  $i^{th}$  task, and  $mips_j$  and  $bw_j$  refer to the processing capacity and bandwidth of the  $j^{th}$  VM. If  $E_{VM_j}$  is the total execution time of  $VM_j$ , then:

$$E_{VM_j} = \sum_{i \in I} Exetime_{ij} \quad (3)$$

where  $I$  is the set of subtasks executed on  $VM_j$ . Then, the makespan ( $E$ ) is defined as the maximum total execution time among all VMs:

$$E = \max \{E_{VM_1}, E_{VM_2}, \dots, E_{VM_n}\} \quad (4)$$

Therefore, one goal of the task scheduling problem is to minimize the makespan, which represents the total time required for all tasks to complete their execution.

#### B. Degree of Load Balancing

The degree of load balancing is an essential indicator that describes the current working status of VMs in a cloud computing system. It measures the degree to which the available resources of VMs are utilized. A higher degree of load balancing indicates that the resources of VMs are fully utilized, and the workload is distributed equally among all VMs. In contrast, a lower degree of load balancing indicates that some VMs are overloaded, while others are underutilized. Therefore, achieving a high degree of load balancing is crucial for enhancing the efficiency and performance of cloud computing systems.

In a task scheduling scheme, the execution time of  $VM_j$  is denoted by  $E_{VM_j}$ , and the maximum execution time of all VMs is denoted by  $E_{VM_{max}}$ .

The degree of load balancing in this task allocation scheme can be expressed as follows:

$$D = \frac{1}{n} \sum_{j=1}^n \frac{E_{VM_j}}{E_{VM_{max}}} \quad (5)$$

This equation represents the average ratio of the execution time of each VM to the maximum execution time among all VMs. A higher value of the degree of load balancing indicates that the workload is evenly distributed among all VMs and that the available resources are fully utilized. Therefore, one goal of task scheduling is to maximize the degree of load balancing, which ultimately improves the efficiency and performance of the cloud computing system.

#### C. Cost

Cost is the sum of the costs used by VMs to execute tasks in a task scheduling scheme. It can be calculated as follows:

$$Cost = \sum_{j=1}^n E_{VM_j} C_j \quad (6)$$

where  $E_{VM_j}$  is the total execution time of  $VM_j$  and  $C_j$  is the cost per second of  $VM_j$ . This equation represents the total cost incurred by all VMs in the task scheduling scheme. The cost per second of each VM is determined by various factors, such as the processing power, memory capacity, and network bandwidth. Therefore, minimizing the cost is also an important objective of task scheduling, as it leads to the efficient utilization of resources and reduces the overall cost of the cloud computing system.

#### D. Multiobjective Fitness Function

In this paper, the linear weighting method is used to transform the multi-objective optimization problem into a single

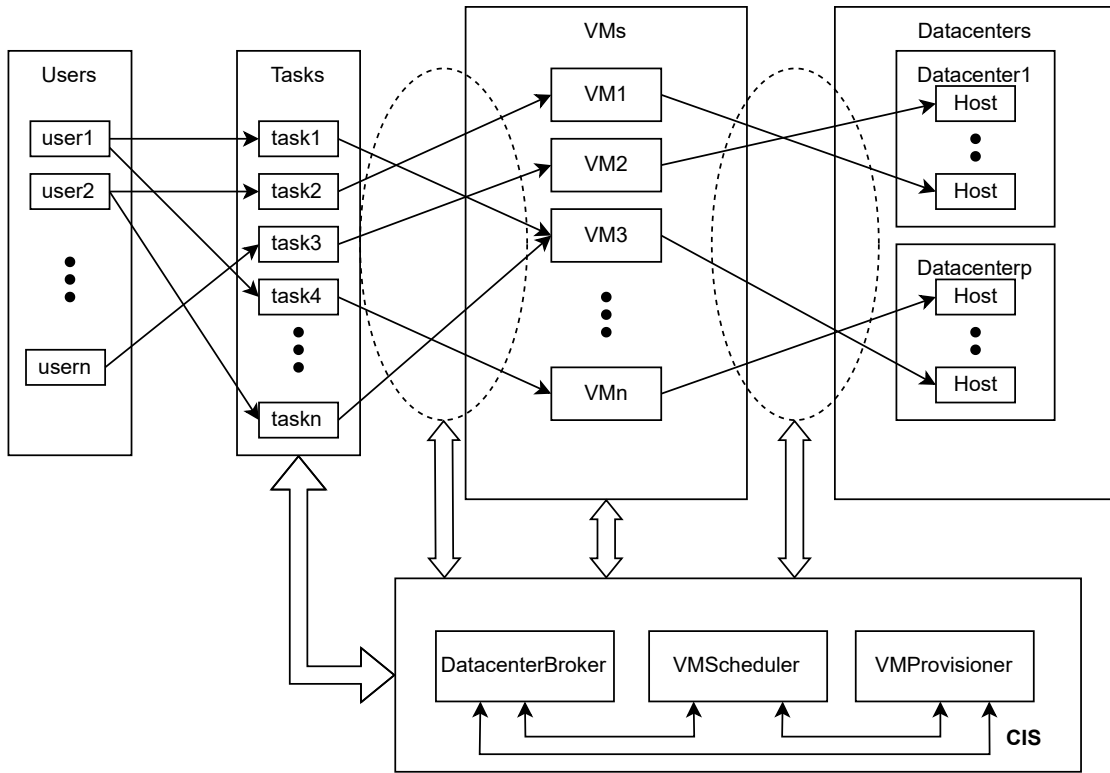

Fig. 1. Task schedule model in cloud environment.

objective optimization problem. Since the different optimization objectives have different dimensions, it is necessary to normalize them. The normalization process is shown below:

$$T_s = \frac{E_s}{m} \quad (7)$$

$$f_T = \frac{T_s - T_{s,min}}{T_{s,max} - T_{s,min}} \quad (8)$$

$$C_s = \frac{Cost_s}{nE_sD_s} \quad (9)$$

$$f_C = \frac{C_s - C_{s,min}}{C_{s,max} - C_{s,min}} \quad (10)$$

Here,  $f_T$  represents the normalized task execution time indicator, where  $E_s$  is the maximum execution time using the current task scheduling scheme,  $T_s$  represents the average execution time of one task.  $f_C$  represents the normalized task cost indicator, where  $D_s$  is the degree of load balancing using the current task scheduling scheme,  $Cost_s$  is the cost using the current task scheduling scheme, and  $C_s$  is the average cost per second per virtual machine.

The fitness function used in this paper is defined as follows:

$$f = \alpha f_T + \beta f_C \quad (11)$$

where  $\alpha \in [0, 1]$ ,  $\beta \in [0, 1]$ , and  $\alpha + \beta = 1$ . The optimization objective of this paper is to minimize the fitness function, which is a linear combination of the normalized task execution time indicator and the normalized task cost indicator. The weights  $\alpha$  and  $\beta$  can be adjusted to give different importance

to the two objectives based on the requirements of the cloud computing system.

Overall, the goal of the task scheduling problem is to find the optimal task allocation scheme that minimizes the makespan, maximizes the degree of load balancing, and minimizes the cost of the system. By transforming the multi-objective optimization problem into a single objective optimization problem and using the fitness function, this paper provides a framework for achieving these goals through task scheduling.

#### IV. STANDARD BAT ALGORITHM

The bat algorithm is a swarm intelligence optimization algorithm that mimics the echolocation behavior of bats in nature to find the optimal solution in a given search space. The optimization process is completed through a series of iterations, where the positions of the bats in the population are updated to improve the quality of the candidate solutions.

In the bat algorithm, each bat is represented by a position vector in a  $d$ -dimensional search space, and is randomly initialized with an initial position and velocity. At each iteration, the bats adjust their positions based on their current location and the global best solution found so far. The update formula for the position and velocity of each bat is:

$$f_i = f_{min} + (f_{max} - f_{min})\beta \quad (12)$$

$$v_i^{t+1} = v_i^t + (x_i^t - x^*)f_i \quad (13)$$

$$x_i^{t+1} = x_i^t + v_i^{t+1} \quad (14)$$

where  $\beta$  is a random number between 0 and 1, and  $x^*$  is the current optimal population solution.

The bat algorithm also includes a local search mechanism to promote exploration of the search space. In the local search, each bat generates a new position by randomly walking around the current global best solution. The new position is calculated using the formula:

$$x_{new} = x_{old} + \delta A^t \quad (15)$$

where  $x_{old}$  is the current global best solution,  $x_{new}$  is the new local solution, and  $\delta$  is a randomly generated  $d$ -dimensional vector in the range  $[-1, 1]$ .  $A^t$  represents the current average pulse loudness of the entire population.

The bat algorithm also introduces randomness in the search process by allowing each bat to choose between a global search and a local search with a certain probability. The probability of choosing a global search is controlled by the parameter  $r_i$ , which is initialized to a small value and gradually increases during the search process. If a bat generates a random number  $R$  greater than  $r_i$ , it performs a local search near the global best solution, and if  $R$  is less than  $r_i$ , it performs a global search.

Finally, the bat algorithm updates the pulse loudness and pulse rate of each bat based on its performance in the search process. If a bat finds a better solution, its pulse loudness decreases, and its pulse rate increases, which increases the bat's ability to exploit the promising regions of the search space. The updated pulse loudness and pulse rate are then used in the next iteration to adjust the frequency and loudness of the bat's pulse. The update formula for the pulse loudness and pulse rate is:

$$A_i^{t+1} = \alpha A_i^t \quad (16)$$

$$r_i^{t+1} = r_i^0 (1 - \exp(-\gamma t)) \quad (17)$$

where  $\alpha$  and  $\gamma$  are constants with  $0 < \alpha < 1$  and  $\gamma > 0$ . The parameter  $A_i$  represents the pulse loudness of the  $i$ th bat, and  $r_i$  represents the pulse rate. The pulse loudness is decreased by multiplying it with the constant  $\alpha$  when a better solution is found, and the pulse rate is updated based on the current iteration number  $t$  using the formula given in Eq. (17).

In summary, the bat algorithm is a powerful optimization algorithm that combines global and local search strategies to efficiently explore the search space and find the optimal solution. The algorithm has been successfully applied to a wide range of optimization problems in various fields, including engineering, finance, and computer science. Its effectiveness and robustness make it a popular choice among researchers and practitioners in optimization and swarm intelligence.

## V. MOMDBA-MULTI-OBJECTIVE MUTATED DISCRETE BAT ALGORITHM

Similar to other meta-heuristic algorithms, bat algorithm also has the problem that it is easy to fall into local optimization and the global search ability is insufficient.

According to the characteristics of task scheduling problem, this paper introduces mutation factor, mutation inertia

weight and optimization of local optimization logic to optimize the standard bat algorithm and improve the algorithm performance.

### A. Discretization Coding

The MOMDBA algorithm uses the position of each bat to represent a feasible task scheduling scheme, which is a viable solution to the optimization objective. It assumes that the number of available virtual machines in the cloud platform is fixed, and the number of cloud tasks that need to be processed is constant. Therefore, the position of the  $i^{th}$  bat at time  $t$  can be expressed as an  $m$ -dimensional vector  $x_i^t = (VMtask_1, VMtask_2, \dots, VMtask_m)$ , where  $VMtask_i$  indicates the virtual machine that executes the  $i^{th}$  task.

The speed of each bat  $v_i = (v_{i1}, v_{i2}, \dots, v_{im})$  represents the change in the virtual machines assigned to each cloud task from the current schedule scheme to the new schedule scheme. The dimension of  $v_i^t$  is the same as the dimension of the position, and its update formula is given by:

$$v_i^t = f(x_i^t - x^*) \quad (18)$$

where  $x^*$  is the best solution found so far, and  $f(v_{ik})$  is a function that determines the direction of change for the  $k^{th}$  dimension of the speed. Specifically,  $f(v_{ik})$  is defined as follows:

$$f(v_{ik}) = \begin{cases} 1 & \text{if } v_{ik} > 0 \\ 0 & \text{if } v_{ik} = 0 \end{cases} \quad (19)$$

Here,  $v_{ik}$  refers to the speed of the bat in the  $k^{th}$  dimension, where  $k \in (0, m]$ .

### B. Mutation Factor and Mutation Inertia Weight

The standard bat algorithm updates the bat's optimization direction based on the current bat position and the current optimal solution. However, this approach is not suitable for the task scheduling problem because there is no correlation between different virtual machines. To address this issue, this paper introduces a mutation method to optimize the task scheduling scheme, which includes a mutation factor  $p_i = (p_{i1}, p_{i2}, \dots, p_{im})$  and a mutation inertia weight  $\omega$ .

In the proposed method, the bat's position is updated randomly, and the probability of position update is determined by the mutation factor and the speed of the bat. Specifically, the probability of selecting a random virtual machine for the task is given by:

$$P(x_{ik}^{t+1} = \text{Random}) = p_{ik} \quad (20)$$

The probability of selecting the current optimal solution for the task is given by:

$$P(x_{ik}^{t+1} = x_k^*) = \theta v_{ik}^t p_{ik} \quad (21)$$

And the probability of keeping the current position is given by:

$$P(x_{ik}^{t+1} = x_{ik}^t) = 1 - p_{ik} - \theta v_{ik}^t p_{ik} \quad (22)$$

Here,  $x_{ik}^t$  refers to the position of the bat in the  $k^{th}$  dimension at time  $t$ ,  $k \in (0, m]$ , and  $p_{ik}$  is the mutation factor of the  $k^{th}$  dimension, with values in the range of  $(0, 0.5)$ .  $\theta$  is a constant and  $0 < \theta < 1$ .

To balance the local and global optimization ability of the bats, the mutation probability is adjusted after a bat finds a better solution, using the mutation inertia weight  $\omega$ . The mutation factor  $p_{ik}$  is updated as follows:

$$\begin{cases} p_{ik}^{t+1} = p_{ik}^t \omega & \text{if } x_{ik}^{t+1} = x_{ik}^t \\ p_{ik}^{t+1} = p_{ik}^t & \text{if } x_{ik}^{t+1} \neq x_{ik}^t \end{cases} \quad (23)$$

The mutation inertia weight  $\omega$  is a function of time, and its value decreases as the number of iterations increases, helping the algorithm to converge quickly. Specifically,  $\omega$  is given by:

$$\omega = \omega^0 (1 - \exp(-\lambda t)) \quad (24)$$

Here,  $\lambda$  is a constant parameter with values in the range of  $(0, 1)$ ,  $\omega^0$  is the initial value of the mutation inertia weight, and  $\omega$  is constrained to the range of  $(0, 1)$ . When the number of iterations is small, the mutation probability of bats is large. In this case, the global search ability of the algorithm is strong, which is conducive to jumping out of the local optimal solution and obtaining the global optimal solution. When the number of iterations is small, the mutation probability of the bats is high, which enhances the global search ability of the algorithm and helps it to jump out of local optimal solutions. When a bat finds a better solution and the new solution in the  $k^{th}$  dimension is the same as the old solution, the mutation factor  $p_{ik}$  is updated based on the mutation inertia weight  $\omega$ . However, if the new solution is different from the old solution, the mutation factor remains unchanged. By adjusting the mutation probability using the mutation inertia weight, the proposed method can balance the exploration and exploitation phases and improve the overall performance of the bat algorithm for task scheduling problems.

### C. Local Optimization Logic

In the proposed method, the execution time of each virtual machine (VM) is denoted by  $T = \{E_{VM_1}, E_{VM_2}, \dots, E_{VM_n}\}$ , where  $E_{VM_{max}}$  and  $E_{VM_{min}}$  are the maximum and minimum execution times, respectively. Let  $Exetime_{kmax}$  and  $Exetime_{kmin}$  be the execution times of the cloud task  $k$  on  $VM_{max}$  and  $VM_{min}$ , respectively. During local optimization, the following update rules are applied:

$$E_{VM_{max}}^{t+1} = E_{VM_{max}}^t - Exetime_{kmax} \quad (25)$$

$$E_{VM_{min}}^{t+1} = E_{VM_{min}}^t + Exetime_{kmin} \quad (26)$$

$$x_{newk} = VM_{min} \quad (27)$$

Here,  $x_{newk}$  is the  $k^{th}$  dimension position of the current global optimal solution. The goal of local optimization is to improve the degree of load balancing by reassigning the task  $k$  from  $VM_{max}$  to  $VM_{min}$ .

Before updating the bat population, a random number in the range of  $[0, 1]$  is generated. If the random number  $R$  is greater than the pulse emission rate  $r_i$  of the  $i^{th}$  bat, then

local optimization is performed; otherwise, global optimization is performed. The pulse emission rate of each bat is updated using the same formula (Eq.(17)) as in the standard bat algorithm.

### D. The steps of MOMDBA

The proposed method consists of the following steps:

- **Step 1:** Initialize the bat population by randomly scheduling  $m$  tasks to  $n$  virtual machines. The dimension of the bat location  $x_i$  is the number of cloud tasks  $m$ .
- **Step 2:** Generate a random number  $R$ . If  $R < r_i$ , go to Step 3; otherwise, go to Step 4.
- **Step 3:** Update the bat positions according to mutation factors. The position of each bat is updated based on the current position, the current optimal solution, and the mutation probability. If a better solution is found, update  $r_i$  and  $p_i$ ; otherwise, keep them unchanged. Go to Step 5.
- **Step 4:** Update the bat locations according to a local optimization logic. Calculate the execution times of the tasks on each virtual machine and reassign the tasks to achieve load balancing. Go to Step 5.
- **Step 5:** Check if a better solution is found. If yes, update  $r_i$  and  $p_i$  based on the current mutation probability and the mutation inertia weight. If no, keep  $r_i$  and  $p_i$  unchanged. Go to Step 6.
- **Step 6:** If the current iteration times are less than the maximum number of iterations, go back to Step 1 and repeat the process; otherwise, go to Step 7.
- **Step 7:** Output the optimal bat location as the best task schedule scheme.

## VI. EXPERIMENT AND RESULT

To verify the effectiveness of MOMDBA in solving cloud computing task scheduling problems, the proposed method is simulated using CloudSim and compared with other existing algorithms, including PSO, GA, and LBACO[26], using the publicly available GoCJ dataset proposed by Hussain et al.[27]. The performance of the proposed algorithm is evaluated based on four criteria: fitness function value, makespan, degree of load balancing, and cost.

The GoCJ dataset consists of 19 text files containing task lengths ranging from 100 to 1000. Each line in the text file corresponds to the task length of a task, and the tasks are classified into five types based on their length: small, medium, large, extra-large, and huge. The distribution of each task in the dataset is shown in Table II.

The basic steps of CloudSim simulation are as follows:

- **Step 1:** Initialize CloudSim.
- **Step 2:** Instantiate the DataCenter, DataCenterBroker, and virtual machines.
- **Step 3:** Create a list of virtual machines and register them with the DataCenter. Then, submit the list of

virtual machines to the DataCenterBroker for further management and scheduling.

- **Step 4:** Generate a set of tasks and assign them to the DataCenterBroker for further processing. The DataCenterBroker is responsible for managing and scheduling the tasks on available virtual machines in the data center.
- **Step 5:** Start the simulation.
- **Step 6:** Analyzing the simulation results.

TABLE II. JOB TYPES OF GoCJ

Job type	MI range	Distribution
Small	15,000 - 55,000	20%
Medium	59,000-99,000	40%
Large	101,000-135,000	30%
Extra large	150,000-337,000	6%
Huge	525,000-900,000	4%

### A. Experimental Environment Setting

The experiments in this paper were conducted on a personal computer environment. The detailed configurations of the software and hardware environments are shown in Table III.

The number of virtual machines used in the experiments was set to 15, divided into three groups of low, medium, and high performance, with five virtual machines in each group. The information of the virtual machines is shown in Table IV. The parameter settings of each algorithm used in the experiments are shown in Table V.

TABLE III. SIMULATION ENVIRONMENT

Parameter	Configuration
CPU	AMD Ryzen5 5600X
Memory	16GB
Hard disk	1TB
IDE	IntelliJ IDEA 2022.03

TABLE IV. VIRTUAL MACHINE INFORMATION

VM group	VM ID	VM performance/MIPS	Cost per sec
low performance	0-4	800-1200	0.02
medium performance	5-9	1800-2200	0.06
high performance	10-14	3800-4200	0.13

TABLE V. PARAMETERS SETTING

Algorithm	Parameter	Value
MOMDBA	Population size	50
	Maximum iterations	200
	$\lambda$	0.01
	$\theta$	0.8
	$\gamma$	0.08
	$r^0$	0.8

LBACO	$p_m$	0.01
	Population size	50
	Maximum iterations	200
	$\rho$	0.5
	$\alpha$	2.0
	$\beta$	1.0
	$Q$	100

### B. Result

In order to evaluate the performance of MOMDBA, algorithm simulation was conducted on the GoCj data set, with the number of cloud tasks ranging from 100 to 500, and analyzed from four aspects of fitness, makespan, degree of load balancing and cost, and compared with other meta-heuristic algorithms.

The fitness function used in the experiments is defined as Eq. (11), which represents the comprehensive evaluation index of multi-objective optimization. The lower the fitness value, the better the solution found by the algorithm. Fig. 2 shows that the fitness value of MOMDBA is significantly lower than that of other meta-heuristic algorithms under different circumstances.

Table VI shows a reduction in fitness using GoCJ dataset. The data show that MOMDBA is up to 80% less fitness than PSO, 84% less fitness than GA, and 70% less fitness than LBACO. The introduction of mutation factor and mutation inertia weight enables the proposed algorithm to jump out of local optimal solutions and obtain better optimization capability.

Fig. 3 and Fig. 4 show the makespan and cost of each algorithm under different number of cloud tasks, and the specific values are detailed in Tables VII and VIII. It can be seen that with the increase in the number of cloud tasks, the makespan and cost of the algorithms also increase gradually.

Regarding makespan, MOMDBA achieves significantly less makespan than the other algorithms, with a maximum reduction of 56.26% compared to PSO, 59.87% compared to GA, and 25.26% compared to LBACO. This indicates

Fig. 2. Fitness based experimental results.

Fig. 4. Cost based experimental results.

Fig. 3. Makespan based experimental results.

Fig. 5. Degree of load balancing based experimental results.

that MOMDBA can significantly reduce makespan, which can improve the efficiency of the cloud platform and can handle more tasks in less time.

For cost, there is no significant difference between MOMDBA and the other algorithms. Except for reducing the cost of LBACO by a maximum of 4.47%, MOMDBA is 8% higher than GA and 5.52% higher than PSO, respectively. This is acceptable compared to the significant reductions made by makespan.

Regarding the degree of load balancing. Fig. 5 and Table IX show how MOMDBA differs from other algorithms. According to the data in the table, the degree of load balancing of MOMDBA is up to 93.87% higher than PSO, 75.92% higher than GA, and 39.13% higher than LBACO. MOMDBA has excellent load balancing, which benefits from the improved local optimization logic. It allows MOMDBA to maintain a high degree of load balancing even when facing a large number of cloud tasks.

In summary, MOMDBA has stronger optimization performance, less makespan, and higher degree of load balancing than other meta-heuristic algorithms. The introduction of mutation factor and mutation inertia weight enables MOMDBA to achieve better optimization capabilities by jumping out of local optimal solutions. These results demonstrate the effectiveness of the proposed algorithm in solving cloud computing task scheduling problems.

## VII. CONCLUSION

This paper proposes an improved bat algorithm for task scheduling. Based on the original bat algorithm, the mutation factor and mutation inertia weight are introduced, and the logic of local optimization is enhanced. The proposed method is simulated using CloudSim and compared with other meta-heuristic algorithms on a public dataset. The performance of the proposed method is analyzed from four perspectives: fitness, makespan, cost, and degree of load balancing. Experimental results demonstrate that the proposed algorithm has stronger optimization ability and can consistently achieve lower fitness scores. In the case of similar costs, the proposed algorithm outperforms other algorithms in terms of makespan and load balancing.

While MOMDBA performs well in terms of makespan and load balancing, it does not provide a significant cost advantage over other algorithms. In our future studies, we plan to further optimize the objective function and explore more effective approaches to solving cloud computing task scheduling problems in complex scenarios. This may involve considering additional factors such as memory and bandwidth constraints. Additionally, we aim to investigate the potential benefits of combining MOMDBA with deep reinforcement learning techniques to further enhance the algorithm's performance.

By addressing these challenges, we hope to improve the overall service performance of cloud systems and provide more efficient and cost-effective solutions for cloud computing applications.

**Abstract**—This paper proposes a testcase recommendation system (TRS) to assist beginner-level learners in introductory programming courses with completing assignments on a learning management system (LMS). These learners often struggle to generate complex testcases and handle numerous code errors, leading to disengaging their attention from the study. The proposed TRS addresses this problem by applying the recommendation system using singular value decomposition (SVD) and the zone of proximal development (ZPD) to provide a small and appropriate set of testcases based on the learner's ability. We implement this TRS to the university-level Fundamental Programming courses for evaluation. The data analysis has demonstrated that TRS significantly increases student interactions with the system.

**Keywords**—Testcases recommendation system (TRS); learning management system (LMS); zone of proximal development (ZPD); singular value decomposition (SVD)

## I. INTRODUCTION

A learning management system (LMS) is an educational tool, either in the form of an application or a website, that facilitates interactive online learning, automates administrative tasks, organizes educational content, and records learners' activities [1], [2]. The author in [3] emphasizes that an LMS should be dynamic; that is, it should be active, flexible, customizable, and adaptable. One method to achieve this is to improve the ability to instruct many learners in a personalized manner. As a result, learners would increase their interaction and satisfaction with the system. LMS can serve as a data collection tool for automatic assessment of learning outcomes [4], analysis of learning style [5], and evaluation of learner satisfaction [6].

Moodle<sup>1</sup> is an open-source LMS with a large number of users, with almost 157,289+ registered sites in 241+ countries [7]. Moodle offers various types of assessment questions for learners, such as multiple choice, short answer, matching, etc. On the other hand, programming questions are essential for learners in programming courses. Programming questions require to source code submitted from learners on a set of inputs. Moodle has now supported programming questions through the plugin CodeRunner. Thanks to CodeRunner, Moodle can deliver programming exercises to learners and automatically grade learners' code.

Programming exercises usually include two types: lab and assignment. Lab exercises are small code exercises for learners to practice independently after learning a topic in theory. The assignment is a complex exercise with lengthy descriptions and many requirements. Additionally, it is used to test the synthesis of problems. Through the assignment, learners practice breaking down the problem into smaller parts to solve. At the same time, they learn to use a combination of techniques from different programming topics to solve complex problems. A typical evaluation of programming exercises is to run the code on a set of inputs and check if the output matches the expected output that results from running the lecturer's solution code on the same input set. A set of inputs and the corresponding output is called a testcase. The percentage of correct testcases calculates the score for the programming exercise. The number of testcases of an assignment is usually much more than those of a lab exercise. The reason is that assignments often ask for many problems, so many testcases are needed to check possible cases of these problems. Therefore, grading assignments for learners often takes a lot of time. Assignment time is usually given for a relatively long period of about three to six weeks. In contrast, the lab exercises are often done in one week.

An assignment implemented on Moodle can be evaluated in different ways.

- Lecturers manually grade all submissions by looking through the code the learner submits and marking it based on the lecturer's perspective.
- Lecturers leverage an automatic grading system (AGS) to grade the submitted code. The grading tool automatically runs the learner's code through testcases and then checks the code's output match. This grading method will minimize the lecturer's perspective, making it fairer than manual grading.
- Learners are provided with a place to test their code on a set of sample testcases. The problem when grading with the AGS on the lecturer's local computer is that some learners' code does not run the same results as when running the code on the learner's local computer. The causes may be because learners' code depends on the compiler and operating system. For example, a common mistake is that when declaring an integer variable and not initializing a value, some compilers automatically assign the value 0 to the

<sup>1</sup><http://moodle.org>

variable. However, others will not do initialization, and the variable will have a random value. An independent grading environment helps learners minimize differences between the grading environment and the one they run their code. After the learner submits the assignment, the lecturer often uses another set of testcases for grading.

This paper does not study the first method because it has the teacher's subjective opinion when grading. Meanwhile, two remaining methods still have some drawbacks. Learners need help to think of a set of testcases to assess their code before submission. Coming up with testcases is a must-have skill for programmers. In real projects, programmers are also required to write their testcases to examine their solutions. However, it is difficult for beginner learners to think of testcases. Learners would not improve their programming skills when they couldn't think of testcases.

A straightforward method to help beginner learners is to provide all the testcases that learners do incorrectly. However, when there are many errors in testcases, beginner learners must choose which testcase to correct first. Therefore, we propose a recommendation-based method that suggests a subset of a few incorrect testcases that have difficulty levels suitable for the current performance of learners. The main contributions of this paper can be summarized as follows:

- Propose a testcase recommendation system (TRS) that engages the learners in doing assignments by suggesting a small set of testcases adaptive to learners' performance.
- Implement the proposed TRS to fundamental programming courses at our university to investigate the effectiveness in terms of students' ability to learn in a personalized manner and the enhancement of learner interaction.

The rest of this paper is organized as follows. Section II summarizes related works to clarify the scope of our study. Then, Section III describes our proposed method. The implementation and evaluation are presented in Section IV. Finally, Section V provides concluding remarks and future works.

## II. RELATED WORK

A recommendation system (RS) will help suggest items to users when there are too many items to select. Recommendation systems (RSs) have become popular and are used extensively in e-commerce and other digital companies [8]. Some well-known examples include Netflix's movie RS [9], Amazon's product RS [10], Google's personalized news, Google's advertisement search, and YouTube for videos [11]. RSs are mainly used for two main tasks: predicting how many ratings a user would give for an item (so-called prediction generation) and recommending a set of items to a user (so-called recommendation generation). RSs collect information on users' past behavior on a set of items and use them for the recommendation. Basically, RSs approaches can be classified into three types: Content-based filtering, Collaborative filtering, and Hybrid one.

- **Content-based filtering (CBF)** provides recommendations based on features of users and items, which are usually created according to users' consuming items. The recommended items are those whose characteristics are similar to the consuming items of the target user.
- **Collaborative filtering (CF)** works on the fact that users with similar behavior will have similar tastes or similar buying habits [8]. CF is divided into memory and model-based approach, based on how the data of the rating matrix are processed [12][13]. The memory-based approach in recommendation systems utilizes similarity measures between users or items to identify their relevant neighbors [8]. These neighbors are then used for recommending or predicting items or users. This approach is easy to implement and interpret the results. However, it requires the entire task rating matrix, making it less suitable for high-dimensional and sparse data. Meanwhile, the model-based approach learns and fits a parameterized model to the user-item rating matrix. This model is then used for providing recommendation tasks. Matrix factorization (MF) is a technique in the model-based approach that gained popularity, especially after the Netflix Prize Contest [13]. MF models are known for their relatively high accuracy, scalability, and dimensionality reduction properties [8].
- **Hybrid approach** combines CBF and CF to provide high predictive accuracy than both [13].

The model-based approach learns the model's parameters with the user-item matrix and uses it to make suggestions. User-item matrix contains user ratings for the items. This rating is similar to the scores obtained by learners for testcases. Therefore, we utilize this method to develop a testcase recommendation system (TRS).

In the domain of testcase recommendation system, previous studies have specifically explored its application in the context of software testing. The authors in [14], [15] examine the test scripts used by automation team and recommends testcases based on source code structural similarity for developing newer testcases. The author in [16] builds a recommender system to find an optimal group of tests to be executed with a code change. The authors in [17] implement an item-based collaborative filtering recommender system that develops a test case prioritizing technique using user interaction data and application modification history information. These studies primarily focus on recommending testcases that are similar to the ones already available for software testing. In contrast, our study concentrates on suggesting testcases that align with the learner's performance. These testcases are utilized by the learner for programming practice.

In this study, we adopt the recommendation algorithm to the learners' score data due to data availability. However, the score has not shown preference as the RS model requires preference as a user's item rating. For example, if a learner gets a high score on a test, they may feel bored because the test may be too easy, leading to disengagement in continuous studying. Therefore, we improve the recommendation algorithm on

the learner's score data by consulting the zone of proximal development (ZPD) theory.

According to the ZPD, if the learning materials are too easy or difficult, the learner will become bored or frustrated. The optimal level of instructional material should be within the "zone" that falls between the learner's upper and lower limits of ability [18]. ZPD is applied in various educational contexts, such as adaptive quiz question recommendations [19] and navigating optimized learning paths [20]. It reduces cognitive load and improves learning outcomes without affecting the learning experience [21]. ZPD is also utilized in specific fields like clinical education [22], participatory scenario planning [23], and divergent thinking [24]. Previous studies [25], [26] have aimed to provide a clearer definition of the ZPD compared to Vygotsky's initial conceptualization [27]. The SZPD criterion is proposed, where  $H^* - H > DH$  represents the confused zone, and  $H^* - H < -DH$  represents the bored zone [25]. Here,  $H$  and  $DH$  respectively refer to the goal number of hints and the allowable variation in  $H$  to determine the situation within the ZPD.

In summary, we combine recommendation algorithm and ZPD theory to make recommendations on learners' score data.

### III. THE PROPOSED TRS

Currently, our approach involves providing a platform to enhance the assignment implementation process. This process includes publishing the assignment specifications, opening a forum for discussion, setting the deadline, providing a designated place for testing with sample testcases (which also serves as the submission place for students' work), and finally opening the TRS.

The proposed approach strengthens the internal environment to suggest testcases tailored to each learner's performance. Fig. 1 outlines our assignment implementation process that begins with learners completing a set of sample testcases that are publicly available. The completion rate is determined by the instructor (e.g., 80%). Once learners surpass the completion rate, they are prompted to request more complicated testcases from the recommendation system. Learners practice and debug their code using the provided testcases. Once all testcases have been solved correctly within a limited time, learners can request a new set of testcases. However, there is a limitation on the number of requests per day. This measure reduces the system load and is a basis for applying the ZPD theory.

When a learner submits their code, the system evaluates the correctness of each testcase's result. There is a similarity between the TRS and a typical recommendation system, where learners are considered users, testcases are items, and learner scores correspond to the ratings that users provide for items. Thus, we apply the singular value decomposition (SVD) technique from the typical recommendation system to TRS. Furthermore, the matrix representing user scores for each testcase is what we call *learner-testcase matrix*, similar to the user-item matrix in a typical recommendation system.

However, in TRS, a higher score from a learner does not necessarily indicate a higher preference for that testcase. A high score could result from an easy testcase, making the

learner bored. One approach is to directly ask the learner about their preference for the suggested testcase using explicit profiling. However, this method may annoy and distract learners from the primary assignment goal. In contrast, the implicit profiling method captures user interactions within the system, improving system effectiveness and avoiding the drawbacks of explicit profiling. Combining interactive data from the system with the SZPD allows for suggesting testcases to suit learners' abilities.

Our proposed approach, which utilizes singular value decomposition (SVD) technique and zone of proximal development (ZPD) theory named **SVD-ZPD**, consists of four main steps as follows:

- 1) **Fitting SVD to predict learner scores for testcases.** The SVD technique is applied to the learner-testcase matrix to predict the scores for any learner. When a learner submits their code, incorrect testcases typically receive a score of 0. With SVD, incorrect testcases will have a non-zero score, indicating the extent of the error. By sorting the incorrect testcases based on these scores, we can identify the testcases that the learner is more likely to answer incorrectly.
- 2) **Determining the learner's current performance.** We determine the learner's performance state within the ZPD based on the number of times the learner requests a new set of testcases from the TRS. Let  $R$  be the goal number of new testcase requests and  $DR$  be the allowed variation in  $R$  to consider the learner within the ZPD. Let  $R^*$  be the actual number of code submissions by the learner on the previous day. We also introduce two constraints: (a) a maximum of requests per day, and (b) the learner must correctly complete all testcases from the previous request to be eligible for a new set of testcases. So,  $R^* - R$  represents the learner's current performance. In this scenario, we have:
  - If  $R^* - R < -DR$ , the learner has not answered many testcases correctly, indicating that the current testcases may be too difficult, and the learner is in the confused zone.
  - If  $R^* - R > DR$ , the learner quickly answers the testcases and continuously requests new ones, indicating that the current testcases may be too easy and the learner is in the bored zone.
  - In other cases, the learner is in the ZPD zone.
- 3) **Determining the appropriate difficulty level based on the learner's current performance.** The previous step provides a general guideline for adjusting the difficulty level: decrease the difficulty level if the learner is in the confused zone and increase it if the learner is in the bored zone. This step defines more detailed rules for increasing and decreasing the difficulty level. While there can be multiple approaches, in this initial study, we propose the following simple rules (but we don't limit the approach to these rules):
  - Difficulty level includes three levels: easy, medium, and hard. It is initially set to easy.
  - If the learner is in the bored zone, increase the difficulty level by one adjacent level. If

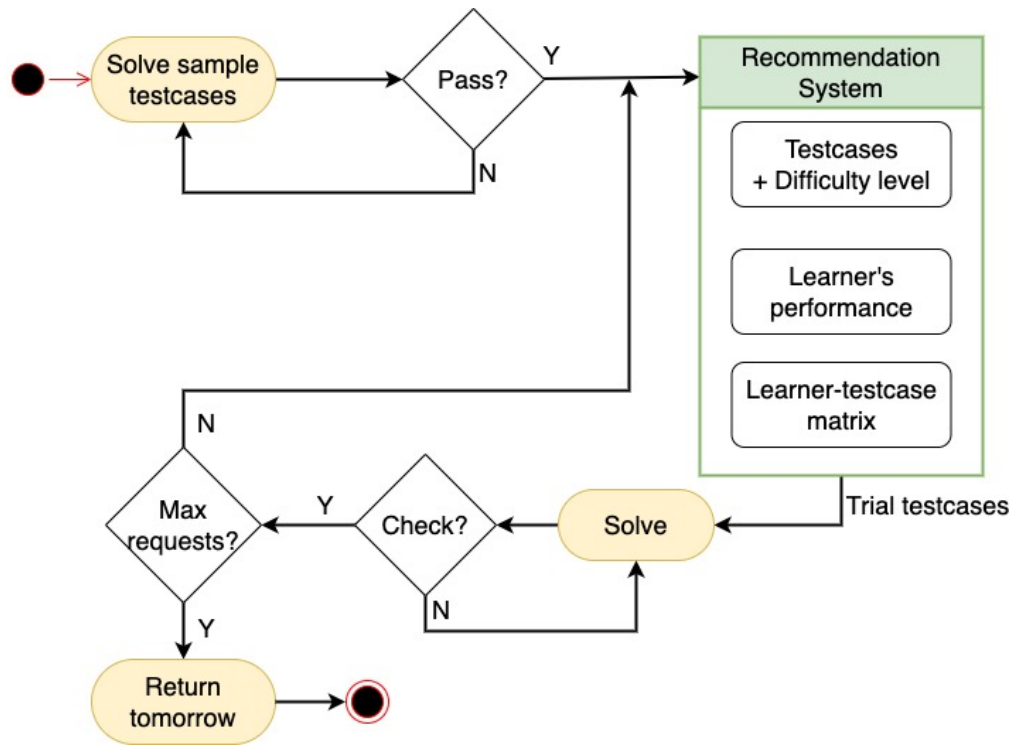

Fig. 1. Illustration of the proposed TRS process.

it is already at the highest level, keep it unchanged.

- If the learner is in the confused zone, decrease the difficulty level by one adjacent level. If it is already at the lowest level, keep it unchanged.
- If the learner is within the ZPD, keep the difficulty level unchanged.

4) **Selecting testcases with the same difficulty level from the previous step in descending order of predicted scores obtained from the first step.**

#### IV. EVALUATION

The proposed TRS is implemented in one assignment of the Fundamental Programming course at our university for the second semester of the 2022–2023 academic year, where Moodle is used as an online learning tool. The effectiveness of TRS is examined by comparing the assignment recorded on Moodle of the three most recent semesters of the same course: the second semester of the 2020-2021 year (SEM-202), the second semester of the 2021-2022 year (SEM-212), and the second semester of the 2022-2023 year (SEM-222).

##### A. Features of Implementing Assignment

For each semester, we will analyze the information that the system provides to the learners, the main features, and the information that can be obtained for the assignment implementation process.

In SEM-202, learners will receive a set of sample testcases and a place to allow automatic submission. Learners run these sample testcases on their own on the local computer. Learners

compare the program's running results with the provided expected results to assess whether the program runs correctly. This set of testcases usually includes only simple testcases and has a small number of testcases. Learners will submit their work on the system before the deadline. Then, the teacher will grade the score on the personal computer and post the score on the system for learners. The drawback of this implementation is that learners can not improve their programming skills because learners have to wait until the deadline expires to receive their marks. While learners are doing the test, they can't see the scores and errors to correct them.

In SEM-212, the system still provides the same materials as SEM-202. Moreover, the system offers an additional place for automatic grading and instant results on sample testcases. This place helps learners receive immediate feedback and ensures the submission runs appropriately in the grading environment. In addition, the interactive information of learners on the system will be more, such as the time of submission, submission, and grading results. The problem with this implementation is that the system only provides one static set of simple testcases. Beginner learners need help to think of complex testcases to improve their programming skills.

In SEM-222, the system still provides the same materials as SEM-212. However, through the proposed TRS, the system offers more testcases suitable for each learner at each time. After correcting the sample testcases, learners can request more testcases from TRS. Then, TRS will provide a small set of testcases that the learner is doing wrong, and these testcases should have a difficulty level matching the learner's current ability. In addition, TRS requires learners to do all testcases correctly to be given a new set of testcases, and they can only

be asked for a maximum of five times a day. The total number of testcases used for suggestion is 124; each request is five testcases.

Table I summarizes the main features of the assignment implementation process over the three semesters, including information for learners, key features, and recorded information. Notably, different from SEM-202 and SEM-212, the last semester is demonstrated by 2 rows, one for sample testcases submission and the other for TRS. As a result, we can see from this table that the system, in addition to TRS, has more key features and can gather more useful information.

### B. Comparison

Table II compares the assignment implementation in three semesters on four factors: supportive self-study environment to summarize knowledge, instructional environment, learning and development of learners, and the system's interaction with learners.

We analyze the following three questions regarding the self-study support environment to summarize knowledge. The first question is about the ability to serve a large number of learners (all three semesters have a place to release Assignments to learners, for learners to submit papers, and have an automatic grading method). The second question is how to implement a self-study support environment for many learners (SEM-202 provides a place to submit papers and automatically grade papers after deadlines, SEM-212 delivers a place to submit papers and return results instantly, SEM-222 provides the same environment as SEM-212 and has additional testcase suggestions). The last question is about the ability to evaluate work results for many learners (all three semesters can automatically grade learners' codes).

In terms of the learner guidance environment, this is an environment that provides feedback to help learners improve their work and programming skills. We analyze the instructional environment according to two questions: Is there an instructional environment for learners? What are the limitations of the effectiveness of the instructional environment? In SEM-202, a forum is provided for learners to ask questions about Assignments. The teacher then answers these questions. The efficacy of a forum depends on the questions posted by learners and the responses provided by instructors and other learners. To examine the effectiveness, appropriate data analysis tools related to the interactive content on the forum are needed. On the other hand, sample testcases are a set of simple testcases for learners to test the code on their own under personal computers. The limitation of sample testcases is that the instructor does not know how learners have utilized them. The completeness level and suitability of the sample testcases for guiding learners cannot be determined. Semester SEM-212 still provides forum and sample testcases. However, sample testcases in SEM-212 are automatically graded and give instant results to learners. The improvement in this method is that the instructor knows whether learners have studied and worked with testcases through their submission attempts. After completing the assignment and grading, the instructor can determine whether the sample testcases are comprehensive enough to guide the learners. Semester SEM-222 not only provides the same environment as SEM-212 but also provides

TRS. The challenge is establishing a diverse testcases bank that can be divided into smaller sets to provide appropriate hints based on the learners' abilities at different stages.

Regarding the learning and development of learners, we analyze according to three questions as shown in Table II. Does the system keep track of the learning process: SEM-202 is not recorded because only the last submission is submitted. At the same time, SEM-212 and SEM-222 are recordable at the time of submission and submission code.

We analyze the interaction with learners according to a question about how the system interacts with learners, as shown in the table. The answer consists of two lines describing the information the system receives from the learner and the information the system gives to the learner. The information obtained from the learners was the same over the three semesters. However, the information brought to learners has increased gradually over three semesters. The final semester has the most information for learners. As more information reaches learners, learners can personally practice and improve their programming skills.

### C. Statistical Results and Findings

The statistical results after implementing the assignment over three semesters (SEM-202, SEM-212 and SEM-222) are summarized in Table III. The important points of this table should be taken into account as follows.

- This table contains seven information fields including information provided to learners, total number of learners, number of learners who submitted code, number of days having submissions, number of submissions, average number of submissions per learner, and average number of submissions per day.
- The information provided to learners may be sample testcases or information provided from TRS. Note that the information provided by TRS is only available from SEM-222.
- The number of days with submissions in SEM-202 is marked as N/A (not available) since the system does not record individual submission instances. Each learner is only permitted to submit one work for the assignment, so the total number of submissions equals the number of learners. The average number of submissions per day cannot be calculated because the number of days is not recorded.

The following analyses compare SEM-212 with SEM-202 and SEM-222 with SEM-212 regarding sample test cases. Then, the most appropriate context among the three semesters will be identified. Finally, the information from TRS will be analyzed to better understand the system's value.

Considering two semesters, SEM-212 and SEM-202, although the number of learners in SEM-212 is smaller than in SEM-202, the number of submissions is higher. The reason is that SEM-212 can record the information of learners' multiple attempts. In other words, the process implemented in SEM-212 improves the interaction between learners and the system compared to SEM-202. This also serves as an example to

TABLE I. FEATURES OF THE ASSIGNMENT IMPLEMENTATION PROCESS IN THREE SEMESTERS: SEM-202, SEM-212, AND SEM-222

Semester	Provided information for learners	Key features	Recorded Information
SEM-202	Sample testcases	- Automated submission platform for learners. - Learners receive grading results after the deadline.	- Overall grading score.
SEM-212	Sample testcases	- Automated submission platform for learners. - Learners receive grading results after the deadline. - Automated grading and immediate feedback on sample testcases submissions.	- Overall grading score. - Submission history: submission time and grading results for sample testcases.
SEM-222	Sample testcases	- Automated submission platform for learners. - Learners receive grading results after the deadline. - Automated grading and immediate feedback on sample testcases submissions.	- Overall grading score. - Submission history: submission time and grading results for sample testcases.
	Various sets of testcases sent based on individual learners and timing.	- Submissions and requesting testcases for incorrect answers. - Testcase sets tailored to learners' abilities through the TRS system.	- Submission history: submission time and grading results for recommended testcase sets.

TABLE II. COMPARISON OF ASSIGNMENT IMPLEMENTATION IN 3 SEMESTERS

Factor	Related questions	SEM-202	SEM-212	SEM-222
Self-study support environment to summarize knowledge	Is there an environment that supports self-study and automatic grading to serve a large number of learners?	Yes	Yes	Yes
	How to implement a self-study support environment for learners?	The site to submits codes; codes are automatically graded after the deadline	The site to submits codes and returns results instantly on sample testcases; codes are automatically graded after the deadline	The site to submits codes and returns results instantly on sample testcases; the site suggests testcases; codes are automatically graded after the deadline
	Can the learner's work results be assessed?	Yes	Yes	Yes
Instructional environment	Is there an environment that instructs learners?	- Forum - Sample testcases for self-evaluation by learners	- Forum - Sample testcases with instant grading	- Forum - Sample testcases with instant grading - TRS
	What are the limitations of the instructional environment's effectiveness level?	- Forum: relies on learner questions and instructor and peer responses - Sample testcases for self-evaluation by learners: challenge to assess the level of completeness and suitability of these testcases in guiding learners.	- Forum likes on the left - Sample testcases with instant grading: can track learners' engagement with testcases through their submissions; the level of completeness and suitability of the testcases can be assessed on submissions	- Forum and sample testcases with instant grading like on the left - TRS: challenge to establish a diverse testcases bank.
Learners' learning and development	Is it possible to keep track of the learning process?	No (only the last submission is recorded)	Possible (when the learner submits the code)	Possible and enhanced by <b>TRS</b>
	Is there a way to keep track of learner development?	No (only the last submission is recorded)	Possible	Possible and enhanced by <b>TRS</b>
	Is there a way to support learners' problem-solving skills development?	No	Yes (returns results of grading sample testcases)	Yes (returns results of grading sample testcases; provides testcases hints according to learner's ability)
Interaction with learners	How is the interaction?	- Allow multiple submissions - Grading is done for only the last submission.	- Allow multiple submissions - Grading is done for the final submission; intermediate scores on sample testcases are provided for each submission.	- Allow multiple submissions - Grading is done for the final submission; intermediate scores on sample testcases are provided for each submission; suggested testcases and scores are provided for each submission on the <b>TRS</b> system.

support the question in Table II regarding the existence of a method to keep track of the learning process.

The number of learners in SEM-222 (1484) increased by 1.7 times compared to the number of learners in SEM-

TABLE III. STATISTICAL RESULTS AFTER IMPLEMENTING ASSIGNMENT IN 3 SEMESTERS

Semester	Information provided to learners	Total number of learners	Number of learners who submitted code	Number of days having submissions	Number of submissions	Average number of submissions per learner	Average number of submissions per day
SEM-202	Sample testcases	933	852 (91.32%)	N/A	852	1.0	N/A
SEM-212	Sample testcases	864	723 (83.68%)	15	5463	7.56	364.2
SEM-222	Sample testcases	1484	1332 (89.76%)	27	25009	18.78	926.26
	TRS	1484	1082 (72.91%)	14	11427	10.56	816.21

212 (864), and the number of learners participating in code submission increased by 1.8 times. The participation rate in submissions increased (89.76% compared to 83.68%), or in other words, the non-participation rate decreased. Therefore, can it be inferred that the submission system in SEM-222 better supports learners? The number of days with submissions in SEM-222 is nearly double that of SEM-212. So, could the longer submission time in SEM-222 allow learners to have more opportunities to complete their assignments? The number of submissions in SEM-222 (25009) is significantly higher than in SEM-212 (5463). Thus, is this due to the longer allowed submission time or better learner support? The average number of submissions per learner in SEM-222 (18.78) is 2.5 times higher than in SEM-212 (7.56). This indicates that the SEM-222 system supports better interaction compared to SEM-212. Furthermore, if we compare the average number of submissions per day between SEM-222 and SEM-212, the ratio is 2.5 (926.26/364.2), which is higher than the ratio between SEM-222 and SEM-212 (1.7). This suggests that the SEM-222 system provides better support to learners than the SEM-212 system.

The above results indicate that SEM-212 performs better than SEM-202, and SEM-222 performs better than SEM-212. Overall, SEM-222 has the best implementation. The level of system interaction, based on the number of submissions, is 29.4 times higher in SEM-222 (25009/852) compared to the semester with the lowest number of submissions (SEM-202), even though the ratio of the number of learners between these two semesters is only 1.6 (1484/933). Considering only the information regarding sample testcases, SEM-222 displays a significantly higher interaction level than SEM-212 and significantly outperforms SEM-202.

If we consider the additional information from TRS in SEM-222, the number of submissions increases by 45.7% (11427/25009) compared to the number of submissions in the sample testcases. Based on the total number of submissions in SEM-222 (including TRS), the system's interaction level is 42.8 times higher than the semester with the least collected interaction (SEM-202). Although this is the first implementation of TRS, the participation rate is quite impressive at 72.91%. However, it is still lower than the percentage of people who submitted on the sample testcases (89.76%). From this, we can see that students tend to resubmit their assignments on the sample testcases every time they improve their code on TRS. The reason could be that students want to ensure their submitted version is evaluated on the sample testcases. Alternatively, it is possible that students do not trust the consistency between the solutions of the two systems.

To examine the detailed impact of TRS on the sample testcases, the group of learners who submitted assignments in SEM-222 needs to be divided into two smaller groups: the group that used the TRS system (Use TRS) and the group that did not use the TRS system (Not-use TRS). Fig. 2(a) shows the percentage distribution of learners between the Use TRS and Not-use TRS groups. And Fig. 2(b) illustrates the percentage distribution of submissions between the Use TRS group (22082) and the Not-use TRS group (2927) on the system of sample testcases. Let's consider the index that measures the level of interaction through submissions on the system referred to as the average interaction index. It is calculated by dividing the number of submissions by (the number of people who submitted multiplied by the number of days of submission).

- The average interaction index of the group of learners on the sample testcases in SEM-212:  $5463 / (723 * 15) = 0.5$ .
- The average interaction index of the group of learners on the sample testcases in SEM-222:  $25009 / (1332 * 27) = 0.70$ .
- The average interaction index of the group of learners on TRS in SEM-222:  $11427 / (1082 * 14) = 0.75$ .
- The average interaction index of the Use TRS group on the sample testcases in SEM-222:  $22082 / (1082 * 27) = 0.76$ .
- The average interaction index of the Not-use TRS group on the sample testcases in SEM-222:  $2927 / (250 * 27) = 0.43$ .

Fig. 2. Comparison between Use and Not-use TRS in SEM-222.

The average interaction score on the TRS system (0.75) is higher than the average interaction score on the sample test-

cases system during the same semester (0.70). This indicates that the TRS group has a higher level of interaction with the sample testcases in SEM-222.

Subsequently, let's examine the level of interaction between the Use TRS group and the Not-use TRS group on the sample testcases in SEM-222. The data collected in Table III shows that the number of students using TRS is 1082, and the number of students not using TRS is  $(1332 - 1082) = 250$ . The ratio of the number of people between the two groups is  $1082 / (1332 - 1082) = 1082 / 250 = 4.3$ , while the submission ratio on the sample testcases between these two groups is  $22082 / 2927 = 7.5$  (1.7 times higher than the ratio of students in the two groups). This indicates that the Use TRS group has nearly twice the interaction with the sample testcases compared to the Not-use TRS group. We can also calculate similar results by determining the ratio between the average number of submissions of the Use TRS group ( $22082 / 1082$ ) and the Not-Use TRS group ( $2927 / 250$ ).

The average interaction score of the student group on the sample testcases in SEM-212 (0.5) is lower and approximately equal to the average interaction score of the Not-use TRS group on the sample testcases in SEM-222 (0.43) - meaning  $0.5/0.43 = 1.16$  times higher. This indicates that the Not-use TRS group in SEM-222 has a slightly lower interaction level than the student group in the semester without TRS support (SEM-212). This is a less active group in the exercise process and does not actively utilize the support from the teaching environment.

The average interaction score of the Use TRS group on the sample testcases in SEM-222 (0.76) is significantly higher (about 1.5 times) than the average interaction score in SEM-212 (0.5). This indicates that the Use TRS group in SEM-222 interacts more actively than the other groups (Not-use TRS in SEM-222 and the student group in SEM-212). In other words, this is the contribution of the TRS system.

## V. CONCLUSION

This paper proposed a testcase recommendation system (TRS) for assisting learners in completing assignments in introductory programming courses. TRS provides a small set of testcases adaptive to the learner's current level of proficiency. Using learners' performance data, we propose a new testcase recommendation process based on the SVD model and the ZPD theory.

TRS was implemented and deployed in the university-level fundamental programming course in the second semester of the 2022-2023 year. Then, we investigated TRS's effectiveness by conducting a comparison with two previous semesters (SEM-202 and SEM-212) without using TRS. The statistical results have shown that SEM-222 had the highest level of interaction with learners among the three semesters (2.5 times higher than SEM-202). Additionally, the proposed TRS received acceptance and significant interaction from learners during its initial semester.

Our future work is to examine the effectiveness of TRS for learners in greater depth and make more comparisons with other testcase recommendation methods. Moreover, we aim to identify strategies for gathering information on learners'

satisfaction, particularly in a new environment that supports additional testcase suggestions for assignments. We will also explore the integration of automated techniques that generate testcases using a formal descriptive language. Furthermore, our investigation will involve developing a testcase bank to provide diverse and differentiated recommendations. Lastly, the solution will be packaged as a module for seamless integration into various learning management systems (LMS), specifically focusing on Moodle LMS.

**Abstract**—Image segmentation is considered one of the essential tasks for extracting useful information from an image. Given the brain tumor and its consumption of medical resources, the development of a deep learning method for MRI to segment the brain tumor of patients' MRI is illustrated here. Brain tumor segmentation technique is crucial in detecting and treating MRI brain tumors. Furthermore, it assists physicians in locating and measuring tumors and developing treatment and rehabilitation programs. The residual U-Net++ encoder-decoder-based architecture is designed as the primary network, and it is an architecture that is hybridized between ResU-Net and U-Net++. The proposed Residual U-Net++ is applied to MRI brain images for the most recent and well-known global benchmark challenges: BraTS 2017, BraTS 2019, and BraTS 2021. The proposed approach is evaluated based on brain tumor MRI images. The results with the BraST 2021 dataset with a dice similarity coefficient (DSC) is 90.3%, sensitivity is 96%, specificity is 99%, and 95% Hausdorff distance (HD) is 9.9. With the BraST 2019 dataset, a DSC is 89.2%, sensitivity is 96%, specificity is 99%, and HD is 10.2. With the BraST 2017 dataset, a DSC is 87.6%, sensitivity is 94%, specificity is 99%, and HD is 11.2. Furthermore, Residual U-Net++ outperforms the standard brain tumor segmentation approaches. The experimental results indicated that the proposed method is promising and can provide better segmentation than the standard U-Net. The segmentation improvement could help radiologists increase their radiologist segmentation accuracy and save time by 3%.

**Keywords**—Brain tumor segmentation; medical image segmentation; BraTS; U-Net; U-Net++; residual network

## I. INTRODUCTION

Brain tumors are growing in the cells of the human brain abnormally. They are divided into two main types, which are malignant and benign, and malignant is more widely spread than benign. They have a significant impact on people and society. Gliomas, either high-grade gliomas (HGG) or low-grade gliomas (LGG), comprise the majority of malignant brain tumors. Because it enables medical professionals to find and quantify tumors and develop strategies for their treatment and recovery, brain tumor segmentation is crucial for diagnosing and treating brain tumors. Medical image segmentation divides a medical image into different regions and separates anatomical structures. These are called “regions of interest” and are appropriate for a specific medical application [1], [2].

There are two main medical image segmentation techniques: manual and auto segmentation. Manual segmentation is the gold standard approach that still consumes time and effort, not only time and effort but also needs experts. Auto segmentation techniques are divided into many techniques:

region-based, edge-based, thresholding, atlas-based, clustering, and deep learning.

It is used in clinical studies to guide and monitor disease progression. It also has many uses, such as diagnosing diseases, planning treatments, studying anatomy, finding the problem, figuring out how much tissue there is, and doing computer-integrated surgery.

According to all of these usages, medical image segmentation has many challenges. These challenges are noise, different colors, patterns, orientations, textures, and insufficient resolution. Furthermore, the medical image is heterogeneous in shape, volume, and texture. These challenges make the segmentation task more complex and require multiple pre-processing approaches.

Recently, it has been suggested that deep learning methods could be used to make different applications for segmenting and classifying medical images. Deep Learning networks can segment and pull out features so that segmentation can be done with just one prediction model [3].

The deep learning model for medical images is classified into two main categories: 2D Fully Convolution Networks, such as U-Net architecture, and 3D Fully Convolutional Networks, where 2D convolutions are covered with 3D convolution.

Image segmentation is one of several deep learning-based applications being researched in the medical field. Consequently, there are several techniques and numerous network architectures. Based on its attributes, such as network design, training procedure (supervised, semi-supervised, unsupervised, and transfer learning), and input size (patch-based, whole volume-based, 2D, and 3D), segmentation techniques based on deep learning may be subdivided into several categories according to network design, training procedure, and input size. Therefore, depending on its architecture, it may be split into six categories: convolutional neural networks, fully convolutional networks; regional convolutional networks; auto-encoders; generative adversarial networks; and hybrid deep learning-based approaches.

The proposed Residual U-Net++ pipeline with the whole phases is shown in Fig. 1 and illustrated step by step for each phase as an overview.

This paper's main contributions are summarized as follows:

- A new hybridization approach based on U-Net++ and

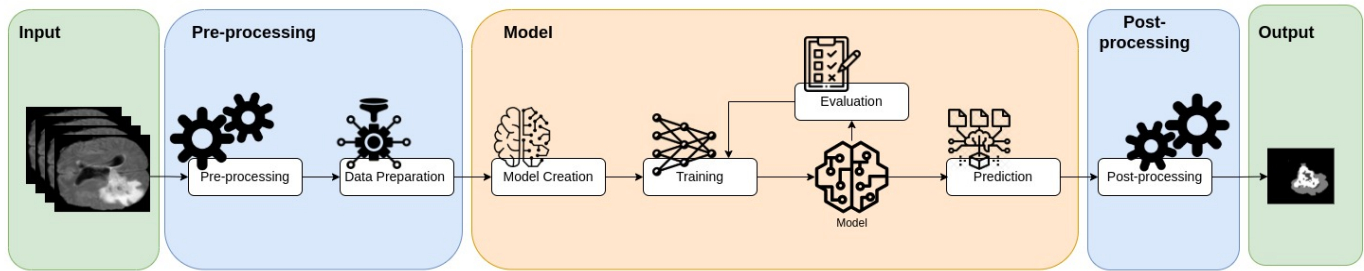

Fig. 1. Proposed residual U-Net++ pipeline.

ResU-Net is introduced, which combines the advantages of both architectures to improve the accuracy of brain tumor segmentation.

- A novel combination of pre-processing techniques and loss functions is proposed, further enhancing the hybrid approach's performance.
- The proposed Residual U-Net++ architecture is applied to three global benchmark challenges in brain tumor segmentation, including BraTS 2017, BraTS 2019, and BraTS 2021, and outperforms several state-of-the-art methods in all challenges, thus contributing significantly to the field.
- A discrete version of Residual U-Net++ is presented, specifically designed to address multi-level segmentation problems, and evaluated on a public benchmark real abdominal MRI images dataset of the brain as a case study.
- Several evaluation metrics, including the Dice Similarity Coefficient (DSC), Sensitivity (SEN), Specificity (SP), and 95% Hausdorff Distance (HD), are used to comprehensively assess the performance of the proposed approach, thus contributing to the standardization of evaluation methods in medical image segmentation research.

The rest of the paper is structured as follows: Section II represents the related work, Section III explains the details used in the model, which are dataset, pre-processing, architecture, loss function, and evaluation metrics. Section IV shows the results, followed by a discussion of the results in Section V. Finally, Section VI presents the conclusion.

## II. RELATED WORK

Zhang et al. [4] examine the significance of a newly created attention gate for tasks involving segmenting brain tumors as an attention module. They use datasets from BraTS, which are BraTS 2017, BraTS 2018, and BraTS 2019. They focus on investigating the efficacy of attention gates for tasks involving segmenting brain tumor images. They propose a model called the Attention Gate Residual U-Net, or AGResU-Net, which combines attention gates and residual modules within a fundamental and singular U-Net architecture to accomplish this purpose.

Neural Architecture Search (NAS) makes good progress in improving image accuracy. Accordingly, it has been extended

to be used recently in image segmentation. Weng et al. [5] use NAS with U-Net as U-Net is applied a lot in different medical image segmentation with successful results. Therefore, both are used by Weng et al. [5] to design and develop three primitive operations that make search space that find two cell architectures, DownSC and UpSC, useful in medical image segmentation especially. Their dataset without pre-training was PASCAL VOC2012 which consisted of Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and ultrasound. It gets better performance and fewer parameters than U-Net when evaluated on the three datasets [5].

Li et al. [6] proposed Residual-Attention U-Net++ as an extension of the U-Net++ model with a residual unit and attention mechanism. In angiography, they used three medical image datasets, skin cancer, cell nuclei, and coronary artery. Their results with the skin cancer dataset were an Intersection over Union (IoU) was 82.32% and a dice coefficient was 88.59%, and with the cell nuclei dataset, an IoU was 87.74%. The dice coefficient was 85.91%, and with the angiography dataset, an IoU was 66.57%, and a dice coefficient was 72.48%.

## III. MATERIALS AND METHOD

### A. Dataset

BraTS stands for Brain Tumor Segmentation, collected and prepared as a challenge per year. It is the most commonly used dataset for brain tumor segmentation as it is public [7], [8], [9], [10], [11], [12], [13], [14], [15]. It consists of a collection of MRI brain images, and all brain images are stripped of the skull and oriented similarly. Four MRI modalities exist for each patient, including Flair, T1, T1ce, and T2. The experts and the organizers of BraTS were labeling the training dataset ground truths. The example MRI brain image and associated ground truth are shown in Fig. 2.

On three benchmarks (BraTSraTS 2017, BraTS 2019, and BraTS 2021), we evaluate the effectiveness of ResU-Net++. Table I contains detailed information about the three datasets used for each year's challenge.

The BraTS 2017 dataset provides 285 glioma patients as a training dataset, consisting of 210 HGG cases and 75 LGG cases. There are 46 patients of uncertain grades included as validation dataset.

The BraTS 2019 dataset provides 335 glioma patients as a training dataset, consisting of 259 HGG cases and 76 LGG

Fig. 2. Example of the brain MRI image with its ground truth from the BraTS 2019.

TABLE I. PUBLIC DATASETS THAT ARE USED FOR BRAIN TUMOR SEGMENTATION.

Name	Total Data Size	Training Data	Validation Data	Testing Data
BraTS 2017	477	285	46	146
BraTS 2019	653	335	127	191
BraTS 2021	2000	1251	219	530

cases. There are 127 patients of uncertain grades included as validation dataset.

The BraTS 2021 dataset provides 1251 glioma patients as a training dataset, which contains more patient cases than the previous two. There are 219 patients of uncertain grades included as validation dataset.

BraTS 2017 is used the most often because it is the first release to include training, validation, and test data. It is used in benchmarks and can be used with low computational power, in contrast to BraTS 2021. BraTS 2021 needs high computational power, takes more time, and gives high accuracy due to extensive data.

### B. Proposed Residual U-Net++ Pre-processing

As discussed before, MRI brain tumor segmentation is a problem that is challenging due to noise, different colors, patterns, orientations, textures, and heterogeneous shapes, volumes, and textures. Data processing is still an essential and crucial stage, even if deep learning-based techniques are more noise-resistant. Furthermore, we use multimodal 3D MRI brain scan datasets, specifically BraTS 2017, BraTS 2019, and BraTS 2021, in this study. The normal region takes up 98.5% of the pixels in the multilabel brain tumor segmentation, whereas the abnormal area only makes up 1.5% of the pixels. Each 3D MRI image data set in the BraTS database has a volume size of 240 x 240 x 155. That image of the axial brain has the highest resolution, and the plane of the axial generates most of the volume in the dataset. We employ a 3D axial brain image to construct multiple 2D image slices for each 240 x 240. To create a sequence of 2D slice images, we remove the 3D image's 1% highest voxel intensities and 1% lowest voxel intensities. While this is happening, we use a patching technique to process these 2D image slices, cropping each slice into many tiny patches with a size of 128 x 128 to handle the class imbalance issue.

Furthermore, we use z-score normalization on 2D images. Moreover, Gaussian regularisation also on 2D images to limit

the device noise effect, improve the contrast of an image, and relieve the overfitting problem. The Z-score normalization technique transforms each picture using the intensity's mean value and standard deviation, and it is calculated as follows:

$$z' = \frac{z - \mu}{\sigma} \quad (1)$$

Where  $z$  is the input image,  $z'$  is the normalized image,  $\mu$  is the input image mean, and  $\sigma$  is the input image standard deviation.

In addition, Gaussian regularisation also involves adding Gauss noise to images to increase model training accuracy. It efficiently reduces over-fitting during the model training phase by penalizing interference objects produced by noise for lowering the weighted square, which has an equivalent impact as L2 regularisation. These images of 2D patches are used in the network for segmenting brain tumors as input after data pre-processing for balancing data voxels. This data preparation step could improve the segmentation performance, normalizing the data and successfully handling the class imbalance issue.

### C. Proposed Residual U-Net++ Architecture

This paper introduced ResU-Net++, an integrated neural network for medical image segmentation that uses the benefits of U-Net++ and residual units. Its general layout is shown in Fig. 3. As we can see, the suggested architecture uses redesigned skip paths to connect the encoder and decoder networks, with U-Net++ as the primary network structure. The encoder network's feature map was sent to the decoder network through dense convolution blocks. According to the above-mentioned method, the feature graph semantic levels in the encoder and decoder are almost identical.

The skip pathway was constructed as follows: The node's output is represented by  $x^{i,j}$ . According to the encoder sub-network, the downsampling layer is indexed by  $i$ , and the dense block's convolution layer is indexed by  $j$  along the skip

Fig. 3. Proposed residual U-Net++ architecture.

pathway. The mathematical equation that follows can be used to determine  $x^{i,j}$ :

$$x^{i,j} = \begin{cases} CR\{x^{i-1,j}\}, & j = 0. \\ CR\left\{\left[\int_{i-1}^{k=0} x^{i,k}, U(x^{i+1,j-1})\right]\right\}, & j > 0. \end{cases} \quad (2)$$

Where  $[\cdot]$  signifies the concatenation layer,  $U(\cdot)$  stands for the upsampling operations, and  $CR\{\cdot\}$  represents a convolution operation followed by a ReLU activation. The first skip pathway in Residual U-Net++ is further explained in Fig. 4.

The following applied equations illustrate the detailed analysis of the first skip pathway of Residual U-Net++:

$$x^{0,1}(conv\_01) = CR\{[x^{0,0}, U(x^{1,0})]\} \quad (3)$$

$$x^{0,2}(conv\_02) = CR\{[x^{0,0}, x^{0,1}, U(x^{1,1})]\} \quad (4)$$

$$x^{0,3}(conv\_03) = CR\{[x^{0,0}, x^{0,1}, x^{0,2}, U(x^{1,2})]\} \quad (5)$$

$$x^{0,4}(conv\_04) = CR\{[x^{0,0}, x^{0,1}, x^{0,2}, x^{0,3}, U(x^{1,3})]\} \quad (6)$$

This pairing has two advantages: first, U-Net++ reduces the semantic gap between the feature maps of the encoder and decoder subnetworks; second, the residual unit makes network training easier and solves the degradation issue, increasing the accuracy of Residual-Attention U-Net++.

#### D. Loss Function

The MRI brain tumor segmentation challenge displays a significant class imbalance, with healthy voxels making up 98.46% of the total voxels, necrosis and non-enhancing voxels accounting for 0.23% of voxels, edema accounting for 1.02% of voxels, and enhancing tumors accounting for 0.29% of voxels. Generalized dice loss (GDL) [16] is a loss function

often used and resistant to data imbalance. It helps bridge the gap between evaluation metrics and training samples. Weighted cross entropy (WCE) [17] has also been used to solve class imbalance and multi-task training problems. As a result, we developed a union loss function  $L$  that combined generalized dice loss  $L_{GDL}$  and weighted cross entropy loss  $L_{WCE}$  to give improved supervision for model training [18]. Loss function  $L$  is represented as follows:

$$L = L_{GDL} + \lambda.L_{WCE} \quad (7)$$

where  $L_{GDL}$  represents the generalized dice loss is defined as Eq. 8 and  $L_{WCE}$  represents the weighted cross entropy loss is defined as Eq. 9

$$L_{GDL} = 1 - 2 \frac{\sum_{i=1}^N \omega_i \sum_k g_{ik} p_{ik}}{\sum_{i=1}^N \omega_i \sum_k (g_{ik} + p_{ik})} \quad (8)$$

$$L_{WCE} = - \sum_k \sum_{i=1}^N \omega_i g_{ik} \log(p_{ik}) \quad (9)$$

Where  $N$  is the total number of labels, and  $\omega_i$  is the weight for the  $i$ th label. For generalized dice loss,  $\omega_i$  is set to

$$\omega_i = \frac{1}{(\sum_k g_{ik})} \quad (10)$$

$p_{ik}$  represents the  $i$ th and  $k$ th pixel of the segmented binary image value.

$g_{ik}$  represents the  $i$ th and  $k$ th pixel of the binary ground truth image value.

#### E. Evaluation Metrics

There are four evaluation metrics used in measuring segmentation performance for Residual U-Net++ approach. These metrics are examined by comparing the segmented image  $P$  to the manually segmented image  $T$ .

Fig. 4. The first skip pathway of residual U-Net++.

1) *Dice Similarity Coefficient (DSC)*: The dice similarity coefficient is a metric to measure the performance of the segmentation that is used to evaluate it based on the intersection between both segmented images, manual and predicted, given as

$$DSC = 2 \frac{|T \cap P|}{|T| + |P|} \quad (11)$$

Where  $T$  represents the manually segmented image as several elements, and  $P$  represents the predicted segmented image sets as several elements. Zero is the worst DSC value, and one is the best [19].

2) *Sensitivity (SEN)*: Sensitivity is a metric to measure the performance of true positives of the correct detection ratio, given as

$$SEN = \frac{|TP|}{|TP| + |FN|} 100 \quad (12)$$

Where  $TP$  is the number of correctly detected positive pixels (a “true positive”),  $FP$  is the number of incorrectly detected negative pixels (a “false positive”), and  $FN$  is the number of incorrectly detected positive pixels (a “false negative”) [19].

3) *Specificity (SP)*: Specificity is a metric to measure the performance of true negatives of the correct detection ratio, given as

$$SP = \frac{|TN|}{|TN| + |FP|} 100 \quad (13)$$

Where  $TN$  is the number of correctly detected negative pixels (a “true negative”), and  $FP$  is the number of incorrectly detected negative pixels (a “false positive”) [19].

4) *Ninety-Five Percentage Hausdorff Distance (HD)*: Ninety-five percent Hausdorff distance is a performance metric that measures the 95<sup>th</sup> percentile of the maximum distance of the reference image set to the nearest point in the predicted image set, given as

$$HD(P, T) = \max[d(T, P), d(P, T)], \quad (14)$$

Where  $T$  represents the number of elements in the manually segmented image, and  $P$  represents the number of elements in the predicted segmented image sets. Both are a finite set [19].

Regarding all of these performance metrics that we used, each one of them is used according to need. DSC is the most accurate performance metric due to evaluating the intersection

between manual and predicted segmented images, and it is the most commonly used. Also, HD is the second performance metric that is frequently used. SEN is used when the true positives are the attention point, and SP is used when the true negatives are the attention point.

## IV. RESULTS

As mentioned above, our experiments use three datasets: BraTS 2017, BraTS 2019, and BraTS 2021.

### A. BraTS 2017

## V. DISCUSSION

The results show that the proposed Residual U-Net++ model uses three datasets: BraTS 2017, BraTS 2019, and BraTS 2021. We present the results for each dataset separately and evaluate it using four evaluation metrics: DSC, Sensitivity, Specificity, and HD.

Section IV-A shows the results for BraTS 2017. Table II, Regarding the DSC value of the whole tumor, core tumor, and enhancing tumor, Residual U-Net++ performs better than U-Net, ResU-Net, and AGResU-Net stand-alone approaches. Fig. 5 shows the box plot for the DSC results to observe that the almost results are above 80% from the first quartile and are at most 95%. To get a sense of them, its values representing HD are concluded in a box plot, as shown in Fig. 6.

Section IV-B shows the results for BraTS 2019. Table III, Regarding the DSC value of the whole tumor, core tumor, and enhancing tumor, Residual U-Net++ performs better than other approaches, especially ResU-Net as a stand-alone approach without nested U-Net. Fig. 7 shows the box plot for the DSC results to observe that the almost results are above 86% from the first quartile and are at most 94%. To get a sense of them, its values representing HD are concluded in a box plot, as shown in Fig. 8.

Section IV-C shows the results for BraTS 2021. Table IV, In terms of the DSC value of the core tumor and enhancing tumor, Residual U-Net++ performs better than other approaches. Also, it is slightly different from other top values of the whole tumor. Fig. 9 shows the box plot for the DSC results to observe that the almost results are above 87% from the first quartile and are at most 94%. To get a sense of them, its values representing HD are concluded in a box plot, as shown in Fig. 10.

From Table V, We get the complete results for all evaluation metrics: DSC, Sensitivity, Specificity, and HD, and for all datasets. We observe that BraTS 2021 gets more accurate results than BraTS 2019 and BraTS 2017, which is regarding the amount of data because BraTS 2021 is the largest dataset compared with BraTS 2019 and BraTS 2017. Also, BraTS 2019 gets more accurate results than BraTS 2017 for the same reason. Furthermore, the large amount of data gets more variant

cases for the tumor.

This proposed model enhances the results compared with other approaches by 0.23 for the DSC value of the core tumor and 0.05 for the DSC value of the enhancing tumor. Fig. 11 shows samples of segmentation results for BraTS 2021.

## VI. CONCLUSIONS

In this research, we proposed the Residual U-Net++ model, which combined ResU-Net modules and U-Net++ with a single U-Net design. Small-scale brain tumor segmentation was improved using ResU-Net++. We comprehensively evaluated the Residual U-Net++ model using three reliable BraTS 2017, BraTS 2019, and BraTS 2021 brain tumor standards. The results of the experiments demonstrated that Residual U-Net++ outperformed U-Net and ResU-Net. On all three datasets, the experimental results indicated that the suggested Residual U-Net++ model performed better in segmentation tasks when compared with other approaches, including UNet++ and other models. Due to the 2D U-Net model's limitations, Residual U-Net++ significantly lost local characteristics and context information across various slices. We will investigate 3D network design in the future to enhance Residual U-Net++ segmentation Net's performance and expand the enhanced architecture to other datasets to demonstrate its generalizability.

**Abstract**—With the large-scale deployment of smart grids, the scheme of smart grid data aggregation has gradually enriched in recent years. Based on the principle of protecting user privacy, existing schemes usually choose to introduce a trusted third party (TTP) to participate in the collaboration. However, this also increases the risk of privacy exposure as the attacker can target the TTP which provides services to smart grid operators. In addition, many existing schemes do not take into account the operational requirements of smart meters in case of failure. Furthermore, some schemes ignore the control center's demand for analyzing multi-dimensional data, which causes a lot of inconvenience in actual operation. Therefore, a fault-tolerant multi-dimensional data aggregation scheme is proposed in this paper. We have constructed a scheme without TTP participation in collaboration, and also meet the following two requirements. The scheme not only ensures the normal operation of the system when the smart meter fails but also meets the requirements of the control center for multi-dimensional data analysis. Security analysis shows that the proposed scheme can resist external attack, internal attack, and collusion attack. The experimental results show that the proposed scheme improves the fault tolerance and reduces the computational cost compared with the existing schemes.

**Keywords**—Cryptography; fault tolerance; privacy; multi-dimensional data aggregation; encryption; smart grid

## I. INTRODUCTION

The smart grid [1], [2] is a modern power grid that is significantly different from the traditional power grid [3], [4]. Traditional power grids can only transmit power from power plants to users, while smart grids can communicate with other power systems through power data. Therefore, the smart grid can significantly improve the reliability, flexibility, security, efficiency and load adjustment/balancing of the power system, and has the potential to replace the traditional power grid. In addition, an important characteristics of smart grid is that real-time power data can be counted to reflect the personal behavior of power users, such as whether they are bathing, watching TV, and what electrical appliances are being used at home. However, if the user's power information plaintext is maliciously attacked during the transmission of public channels, personal information will be leaked. Therefore, it is an urgent need to protect the user's electricity information so that malicious attackers cannot get the correct information. For this reason, many scholars have introduced smart grid data aggregation schemes to protect user's privacy. However, the following problems are ignored in some schemes.

Firstly, scheme [18] indicates that schemes [17], [23] cannot resist collusion attack. Because in the above two

schemes, the encryption key for smart meter users to encrypt power information is only the public key of another entity in the system, and there is no blinding factor embedded in the encryption process of the meter. On the one hand, if the aggregator (AG) colludes with the control center (CC), CC will receive the user's power consumption ciphertext sent by AG. At this time, CC is curious about the electricity data information of a user. It will decrypt the ciphertext using a private key to obtain the user's electricity plaintext, leading to the leakage of user privacy. On the other hand, if the legal person in CC is curious about the user's electricity information, he can obtain the data by eavesdropping and then use CC's decryption key to obtain the user's personal privacy information.

Secondly, schemes [15], [27] choose a trusted third party (TTP) to participate in collaboration when building a system, but this can cause fault tolerance problems or low flexible structures. In the registration phase, TTP generates public parameters and key pairs, distributing them to other entities. To resist collusion attack, TTP distributes blinding factors to each smart meter and CC. Only the correct number of meters and corresponding CC can eliminate the influence of blinding factors. This ensures that CC can only obtain the total power consumption of the entire region, rather than the power information of individual users. However, the system constructed in the above way may have the following problems after deployment. Firstly, this system can no longer add/delete smart meter after all smart meter users have registered. Secondly, if the smart meter fails, CC cannot decrypt the aggregated ciphertext.

Thirdly, smart meters in some scenarios [5], [18] can only report one-dimensional data type. However, in real life, smart meters need to report multi-dimensional data types. For example, these data can be classified by different electrical appliances (air conditioner, refrigerator, washing machine, rice cooker, etc.). By using these multi-dimensional data, the smart grid can make more efficient and reasonable power dispatching [29].

Finally, in Chen *et al.*'s scheme [6], data aggregation is constructed by elliptic curve cryptography (ECC), which protects users' privacy while reducing computational cost and communication cost. However, the scheme has low fault tolerance. Furthermore, the system cannot operate normally in the case of smart meter failure. In the scheme, CC decrypts the ciphertext as follows:  $C_{uk} = g_x \cdot \prod_{i=1}^n c_{ik} = e \left( H(t_i), d_x \cdot R_A + \sum_{i=1}^n R_{si} \right) \cdot g^{\sum_{i=1}^n m_{ik}} = g^{\sum_{i=1}^n m_{ik}}$ , where  $d_x$  is the private key of CC,  $R_A$  is the public key of all smart

\*Corresponding authors

meters, and  $\sum_{i=1}^n R_{si}$  is the decryption key of all smart meters. If CC wants to decrypt correctly, it needs to make the equation:  $d_x \cdot R_A + \sum_{i=1}^n R_{si} = 0$ . Assuming there existing smart meter fails, so that it cannot report power data ciphertext in a short time. In the result, CC cannot get the equation contained in the ciphertext information  $d_x \cdot R_A + \sum_{i=1}^n R_{si} \neq 0$ . Because the encryption key  $R_{si}$  is only known by the smart meter, other entities cannot be obtained, so CC cannot make the bilinear pairing  $e\left(H(t_i), d_x \cdot R_A + \sum_{i=1}^n R_{si}\right) = 1$ , and cannot get the power data  $g^{\sum_{i=1}^n m_{ik}}$ , this represents CC decryption failure.

Based on the above reasons, we propose a multi-dimensional data aggregation scheme supporting fault-tolerant mechanism in smart grid. For ease of description, the proposed scheme is referred to simply as MAFTM in the remainder of the paper. The proposed scheme not only designs fault repair mechanism to improve fault tolerance but also achieves multi-dimensional data aggregation using super incremental sequence. The main contributions of the proposed scheme are as follows.

- 1) Fault-tolerant mechanism: After the system completes the registration, even if the smart meter fails, the system can still work properly. By using this mechanism, the normal smart meter data is not affected by the damaged meter, and the maximum utilization of the collected data is realized.
- 2) Multi-dimensional data aggregation: The built system can reports multi-dimensional data types by introducing super-incremental sequences, and CC can perform mean/variance analysis on these power data to better regulate power.
- 3) No trusted third party (TTP): In order to avoid the adversary attacks against TTP, there is no TTP participating in the proposed scheme. In addition, there is no need to trust external entities.
- 4) Insider attacks resiliency: Smart meters use independent keys to encrypt power data, and CC cannot decrypt the ciphertext information of a single meter through the private key before receiving the aggregated ciphertext.

The remaining part of this paper consists of six chapters: The Section II describes in detail the research achievements of scholars in data aggregation in recent years, as well as the relevant technologies used. In the Section III, we introduced the techniques used in the solution. In the Section IV, we introduced the system model and security model of the proposed scheme. In the Section V, we detailed the overall process of the system. In the Section VI, we conducted safety analysis on the proposed scheme through four aspects. Finally, in the Section VII, we summarized this article.

## II. RELATED WORK

The smart grid has undergone many changes from its initial concept to its current widespread application. The traditional data aggregation scheme can only allow CC to get total

power information for the entire HAN area, which is called one-dimensional data aggregation. When CC conducts a fine-grained analysis of one-dimensional power data, the scheme cannot meet the requirements. However, multi-dimensional data aggregation can turn various types of power data into aggregated ciphertext. CC obtains the sum of power plaintext information for a cycle period in the entire region by decrypting the aggregated ciphertext. Because the electricity from power plants cannot be easily stored, CC formulates power scheduling and regulates electricity prices based on data information from each time. Multidimensional data aggregation can better assist CC in performing the above operations and achieve more fine-grained analysis results. Therefore, many scholars have proposed data aggregation schemes.

In the research of multidimensional data aggregation in recent years, homomorphic encryption cryptosystem is a widely used privacy protection technology. Some schemes [7], [8] use homomorphic encryption technology to build systems, and use the characteristics of additive homomorphism to operate ciphertext as well as plaintext directly, but they can do better in terms of communication efficiency. The time efficiency required to calculate and receive data in a smart grid is also one of the factors we need to consider. In order to achieve more efficient computing cost and minimize communication latency as much as possible, Lu *et al.* [9] constructed a more efficient aggregation scheme that can consume less system resources in terms of computational costs named EPPA in 2012. The above scheme utilizes the characteristics of super incremental sequences to construct multidimensional data, enabling CC to separate the total electricity consumption data of different sequences through algorithms when decrypting ciphertext data and utilizes the Paillier homomorphic cryptosystem [10] to encrypt power consumption data. In addition, in order to improve validation efficiency, this scheme achieves batch validation in the aggregation stage based on the Weil pairing [11] proposed. A trusted organization OA is also introduced to guide the system. In 2019, Chen *et al.* [12] constructed an aggregation scheme. The scheme utilizes the Paillier homomorphic Cryptosystem to implement fine-grained data analysis requirements. In this scheme, the user can upload different types of power data through the electricity consumption values for different types of electrical appliances. In addition, CC can also perform variance analysis on multi-dimensional data. In 2019, Ming *et al.* [13] considered that one-dimensional data cannot meet the requirements of power suppliers for fine-grained analysis of power data when scheduling electricity, and proposed a multidimensional aggregation scheme called P2MDA. P2MDA uses super-increasing sequence [14] and ElGamal homomorphic encryption technology to ensure user privacy while completing multi-dimensional data aggregation with less computational cost, so that smart meters can classify power consumption data based on power supply devices. The above aggregation scheme is mainly studied for multi-type data requirements and efficient computing performance. But it is worth noting that they all rely on TTP to build systems, which can provide opportunities for malicious attackers.

In addition, some scholars try to implement multi-dimensional data aggregation without using homomorphic encryption technology. Committed to accelerate the efficiency of authentication and reduce the computational cost, Boudia *et al.* [15] set up an aggregation scheme based on ECC that can

transmit multiple data types in 2017. The scheme completed multidimensional data reporting without the need for pairing operations, which makes it low computational cost. So as to resist human-factor-aware differential aggregation (HDA) attack, Jia *et al.* [16] proposed two different aggregation protocols, one is the basic aggregation protocol, and the other is an improved advanced aggregation protocol in 2017. In this scheme, smart meter users divide data information into  $M$  shares when uploading power consumption data. Therefore, only aggregators with the correct key can correctly aggregate power data. However, the disadvantage of this scheme is that the system cannot decrypt normally when facing the problem of meter failure in real life.

Furthermore, some scholars consider that smart meters may fail in real life. Therefore, they study how to improve the fault tolerance of aggregation schemes. Xue *et al.* [17] constructed an aggregation scheme for service outsourcing called PPSO in 2019. In this scheme, CC can respond to the dynamic electricity price demand in real-time through the analysis of aggregated data. PPSO aims to improve system fault-tolerance and flexibility. Considering that smart meters may fail in real life, Wang *et al.* [18] focused their attention on the fault tolerance of the system and proposed a scheme. In order to improve fault tolerance, the scheme uses Paillier homomorphic encryption without the participation of TTP and the blinding factor  $K$  negotiated among smart meters. To build a dynamic framework without TTP, Xue *et al.* [19] conducted research on fault Tolerance and proposed a scheme in 2020. The scheme uses Paillier homomorphic encryption and built a dynamic secret sharing to improve fault tolerance. In the above scheme, smart meter users can ensure that the system will not collapse due to the failure of some smart meter through dynamic secret sharing, which improves the fault tolerance of the system. The disadvantage is that Xue *et al.*'s scheme [17] unable to defend collude attacks, while Wang *et al.*'s scheme [18] requires additional computational cost to negotiate and preserve the information of the blinding factor  $K$ . Moreover, Xue *et al.*'s scheme [19] cannot perform multi-dimensional data aggregation.

Finally, some scholars have improved the performance of data aggregation schemes by combining different technologies. Wu *et al.* [20] utilized fog assistance to enhance the scheme's fault tolerance and protect user privacy in 2021. Lu *et al.* [21] introduced blockchain into the smart grid in 2021, utilizing the characteristics of blockchain to improve verification efficiency. In addition, Zhang *et al.* [24] implemented dual message encryption using a modified BGN homomorphic system and improved fault tolerance of the scheme using secret sharing technology in 2022. Zhao *et al.* [25] designed a smart and practical aggregation scheme based on the Fog server in 2020, protecting users' privacy and security.

In summary, in recent years, research on data aggregation schemes in smart grids has focused on multidimensional data types, whether TTP participates in collaboration, and fault tolerance. But most of the schemes are based on Paillier homomorphic encryption, the communication cost is high. On the one hand, some schemes consider reporting multi-dimensional data when building systems using TTP. However, these schemes ignore the fault tolerance of the system. On the other hand, some schemes improve the fault tolerance of

the system but cannot report multi-dimensional data types. In contrast, the proposed scheme uses elliptic curve cryptography [26] to construct the system, which can perform calculations more efficiently and effectively reduce computational costs. In addition, the fault-tolerant mechanism designed in this paper can ensure that CC can also obtain the power ciphertext of other normal meters when the smart meter fails.

### III. PRELIMINARIES

In this section, the related concepts used in the smart grid data aggregation scheme are mainly introduced.

#### A. Bilinear Pairing Map

The bilinear mapping pairing  $e : G_1 \times G_1 \rightarrow G_T$  used in this paper is defined based on the elliptic curve over finite field  $GF(q)$ , where  $q$  is a large prime. In the above definition, where  $G_1$  is an additive cyclic group and  $G_T$  is a multiplicative cyclic group, both  $G_1$  and  $G_T$  of orders  $p$ . In addition, the bilinear mapping pairing  $e : G_1 \times G_1 \rightarrow G_T$  also meets the following three conditions [30]

- 1) *Bilinearity*: For any  $P, Q \in G_1$  and  $x, y \in Z_p^*$ , we have  $e(xP, yQ) = e(P, Q)^{xy}$ .
- 2) *Non-degeneracy*: There are two elements  $P, Q \in G_1$  satisfying  $e(P, Q) \neq 1_{G_T}$ , where  $1_{G_T}$  is the identity element of  $G_T$ .
- 3) *Computability*: For all  $P, Q \in G_1$ , there exists a polynomial-time algorithm to compute  $e(P, Q)$ .

#### B. Superincreasing Sequence

In practical situations, CC needs to analyze multiple data types in order to better regulate electricity. In order to achieve the above goals, one of the key technologies used in this scheme is superincreasing sequence. A superincreasing sequence consists of a series of positive real numbers  $s_1, s_2, \dots$ , And this sequence also satisfies the requirement that the newly selected elements are much larger than all previously selected elements. In addition, we can write it in this form [31]:  $s_{n+1} > \sum_{j=1}^n s_j$ .

#### C. Elliptic Curve Cryptography

Koblitz and Miller proposed the definition of discrete logarithm problem on a set of points of an elliptic curve in 1985. Like RSA, ECC also belongs to a type of asymmetric key mechanism. ECC is an efficient cryptosystem for resource constrained devices. This is mainly attributed to ECC's ability to achieve better security performance with smaller key size, lower power consumption, and lower computational cost compared to other algorithms such as RSA.

In addition, the mathematical base of ECC lies on the hardness of the Elliptic Curve Discrete Logarithm Problem (ECDLP). ECDLP states that if there are two points  $P, Q \in E(p)$  (where  $E(p)$  is an elliptic curve) then it is mathematically difficult to find an integer  $n$  such that  $Q = nP$ . In our proposed scheme, the hardness of ECDLP is taken into consideration [32].

#### IV. MODELS

In this section, we made assumptions about two pieces of content. In the former, we define the three major entities in the system. In the latter, we assume the trust level of entities in the system and provide a brief introduction to security performance.

##### A. System Model

In this paper, the system requires the collaboration of three entities to function properly, which includes: Control Center (CC), Aggregator (AG) and Smart Meter (SM), where an aggregator and several smart meters form a Home Area Network (HAN). This paper mainly studies the power consumption of all smart meters in an HAN, we use  $n$  to express the total number of smart meter, namely  $SM_1, SM_2, \dots, SM_n$ . In addition, the image representation Fig. 1.

**Control Center (CC):** Throughout the entire system, CC, which is the highest management agency of the system, has powerful data analysis ability, computing power and huge storage space. CC is responsible for decrypting the power aggregate ciphertext information sent by the AG. Moreover, when the power information cannot be sent due to the fault of the meter, CC is also needed to make the system operate normally to ensure that the aggregated ciphertext information of the remaining smart meters is not affected.

**Aggregator (AG):** AG is the second layer in the system. Compared with CC, AG has lower computing power, lower security level and is more vulnerable to enemy attacks. During the communication process, AG will collect the power ciphertext information of all smart meters in HAN in real-time. If a smart meter fault is detected, AG will perform a fault repair mechanism. Otherwise, AG will directly aggregate the ciphertext. Finally, the aggregated ciphertext is sent to CC.

**Smart Meter (SM):** SM is the third layer in the system and can communicate bidirectionally with AG. In the registration phase, each SM will select a random number as its blinding factor, then uses the blinding factor and the public key of other entities to calculate the encryption key. During the communication process, SM periodically records the user's power information and encrypts it with an encryption key. Then, SM send this encrypted data to AG. In addition, SM may fail in the system, making data reporting impossible for a short time.

##### B. Security Model

In this paper, there are three different entities, and not all of them are fully trusted (such as some outsourced service providers), so it is necessary to define each entity. We assume that the CC and the AG entities in the system are *honest-but-curious*. This represents that CC and AG will work according to the aggregation protocol process, but they will also be curious about the uploaded data content after completing the work. In addition, SM users  $SM_1, SM_2, \dots, SM_n$  are *honest*. For each smart meter, they will collect data according to the process every cycle and then encrypt and upload them. They will not try to obtain the power information of other smart meter, nor will they cooperate with other entities to obtain the private data in the system.

Data transmission through insecure communication channels is vulnerable to various attacks, such as external attacks. More seriously, attackers may also steal users' power data by invading the databases of AG and CC. What needs to be ensured is that user privacy information is not stolen by malicious enemies This scheme aim to resist external attack, internal attack, and collusion attack.

#### V. OUR PROPOSED MAFTM SCHEME

We have divided the execution process of the MAFTM scheme into the following five steps: System Initialization, Entity Registration, SM Data Reporting, AG Data Aggregation, CC Decryption Ciphertext. As shown in Fig. 2, we also provided a schematic diagram of the execution process of the Fault-Tolerant Mechanism.

##### A. System Initialization

At this stage, CC generates the parameters required for elliptic curve cryptography, selects a secure hash function, sets the super increment sequence, and finally CC publishes the public parameters to other entities in the system.

- 1) CC generates a bilinear pairing map  $e : G_1 \times G_1 \rightarrow G_T$ , where  $G_1$  is an additive cyclic group,  $G_T$  is a multiplicative cyclic group and both  $G_1$  and  $G_T$  of orders  $q$ . Then CC will select  $P$  as the random generator of  $G_1$  and  $g$  as the random generator of  $G_T$ .
- 2) CC selects a secure hash function  $H : \{0, 1\}^* \rightarrow G_1$ .
- 3) CC defines  $d$  as the maximum value for each data type,  $n$  as the number of smart meters  $SM_i$ , and then selects a super increasing sequence  $\vec{a} = (a_1, a_2, \dots, a_k)$ , where  $a_1, a_2, \dots, a_k$  are large primes and satisfy  $\sum_{j=1}^{i-1} a_j \cdot n \cdot d < a_i$ ,  $i = 1, 2, 3, \dots, k$  and  $\sum_{i=1}^k a_i \cdot n \cdot d < q$ . CC calculates  $g_\phi = g^{a_\phi}$ ,  $\phi = 1, 2, 3, \dots, k$  and gets  $(g_1, g_2, \dots, g_k)$ .
- 4) Finally, CC will disclose the parameter

$$pp = \{q, G_1, G_T, e, P, g, \vec{a}, H, g_1, \dots, g_k\}$$

to other entities in the system.

##### B. Entity Registration

At this stage, each entity in the system will independently select random numbers and generate corresponding public and private key pairs, and then they will negotiate and calculate a public-private key pair for encryption/decryption of power data. Suppose the registration message is sent over a private and secure channel, which means that the adversary cannot launch an attack during the registration phase.

- 1) CC selects a random number  $sk_x \in Z_q^*$  as the private key and calculates that the public key is  $pk_x = sk_x \cdot P$ , CC sends  $pk_x$  to AG.
- 2) Meter  $SM_i$  selects a random number  $sk_i \in Z_q^*$  as the private key, calculates the public key as  $pk_i = sk_i \cdot P$ ,  $SM_i$  sends the public key  $pk_i$  to AG.

Fig. 1. System model.

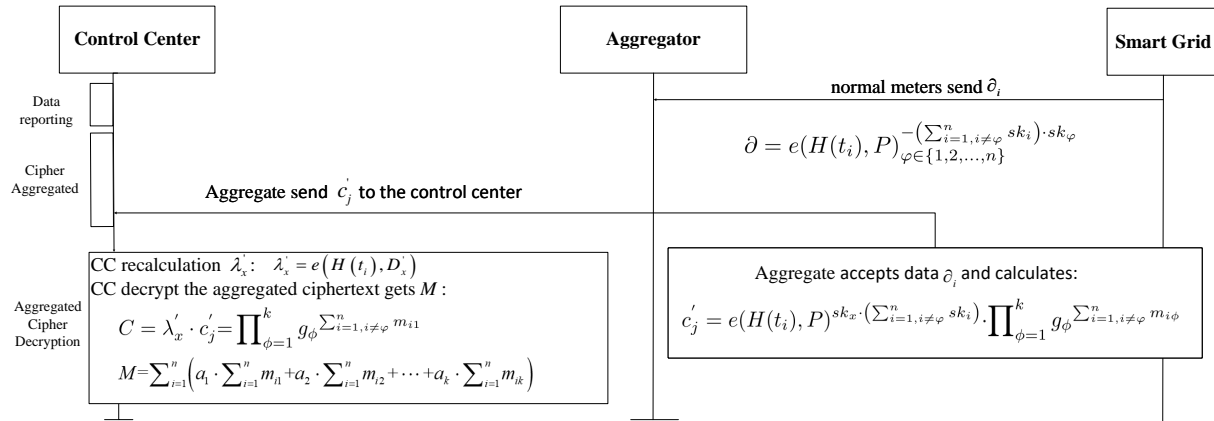

Fig. 2. Fault tolerance mechanism.

- 3) AG selects a random number  $sk_j \in Z_q^*$  as the private key and calculates the public key as  $pk_j = sk_j \cdot P$ . When AG receives the public key of all smart meters, it will calculate  $L_i = (\sum_{\beta=1}^i pk_{\beta} - \sum_{\beta=i+1}^n pk_{\beta} - pk_x)$  and send  $L_i$  to  $SM_i$  ( $i = 1, \dots, n$ ). After receiving  $L_i$ ,  $SM_i$  calculates the encryption key  $S_i = sk_i \cdot L_i$  for encrypting real-time power data.
- 4) AG calculates the sum  $pk_{\alpha} = \sum_{i=1}^n pk_i$  of the public keys of all  $SM_i$  and sends  $pk_{\alpha}$  to CC. CC computes the decryption key  $D_x = sk_x \cdot pk_{\alpha} = sk_x \cdot \sum_{i=1}^n pk_i$  to decrypt the total power data.

### C. SM Data Reporting

At the beginning of each data reporting cycle,  $SM_i$  collect multiple types of data  $m_{i1}, m_{i2}, m_{i3}, \dots, m_{ik}$ , where  $1, 2, 3, \dots, k$  represent the dimension of the data type and are encrypted using the encryption key  $S_i$ . The steps are as follows.

- 1) Smart meter  $SM_i$  extracts data  $m_{i1}, m_{i2}, \dots, m_{ik}$ .

- 2) Smart meter  $SM_i$  gets timestamp  $t_i$ .
- 3) Smart meter  $SM_i$  calculates  $\lambda_i = e(H(t_i), S_i)$ .
- 4) Smart meter  $SM_i$  encrypts  $m_{i1}, m_{i2}, \dots, m_{ik}$ :

$$c_i = \lambda_i \cdot g_1^{m_{i1}} \cdot g_2^{m_{i2}} \cdot \dots \cdot g_k^{m_{ik}} \quad (1)$$

### D. AG Data Aggregation

At this stage, AG sets a counter to troubleshoot the meter. If the meter is damaged, AG will perform a fault recovery operation. Otherwise, AG aggregates the ciphertext  $c_i$ . The steps are as follows.

- 1) AG sets counter  $count = count + 1$  to record whether there is a meter failure. If  $count=n$ , it represents the normal operation of all meters.

- AG calculates:

$$c_j = \prod_{i=1}^n c_i = \prod_{i=1}^n \lambda_i \cdot \prod_{\phi=1}^k g_{\phi}^{\sum_{i=1}^n m_{i\phi}} \quad (2)$$

- AG sends  $\{c_j\}$  to CC.

2) If  $count < n$ , it means that the meter fails and AG performs the recovery work:

- The fault meter public key is compiled into the set  $F = \{pk_\varphi\}_{\varphi \in \{1,2,\dots,n\}}$ .
- AG informs the rest of the normal meter  $\{SM_i\}_{i \neq \varphi}$  to calculate the missing data:

$$\partial_i = e(-sk_i \cdot H(t_i), pk_\varphi)_{\varphi \in \{1,2,\dots,n\}} \quad (3)$$

- AG receives data  $\{\partial_i\}$  for data aggregation:

$$\begin{aligned} \partial &= \prod_{i=1, i \neq \varphi}^n \partial_i = e\left(\sum_{i=1, i \neq \varphi}^n sk_i \cdot H(t_i), -pk_\varphi\right) \\ &= e(H(t_i), P)_{\varphi \in \{1,2,\dots,n\}}^{-\left(\sum_{i=1, i \neq \varphi}^n sk_i\right) \cdot sk_\varphi} \end{aligned} \quad (4)$$

$$\begin{aligned} c'_j &= \partial \cdot e(H(t_i), \sum_{i=1, i \neq \varphi}^n S_i) \cdot \prod_{\phi=1}^k g_\phi^{\sum_{i=1, i \neq \varphi}^n m_{i\phi}} \\ &= e(H(t_i), P)^{sk_x \cdot \left(\sum_{i=1, i \neq \varphi}^n sk_i\right)} \cdot \prod_{\phi=1}^k g_\phi^{\sum_{i=1, i \neq \varphi}^n m_{i\phi}} \end{aligned} \quad (5)$$

- Then AG sends  $\{c'_j, F\}$  to CC and inform the occurrence of meter damage.

#### E. CC Decryption Ciphertext

At this stage, CC obtains power plaintext by decrypting aggregated ciphertext. If the meter damage information sent by AG is received, CC will recalculate the decryption key  $D'_x$  to decrypt the aggregate ciphertext  $c_j$ .

- 1) CC computes  $\lambda_x = e(H(t_i), S_i)$  under normal condition. Then the decryption operation is performed:

$$C = \lambda_x \cdot c_j = g_1^{\sum_{i=1}^n m_{i1}} \dots g_k^{\sum_{i=1}^n m_{ik}} \quad (6)$$

The final control center gets  $M$ :

$$\begin{aligned} M &= \sum_{i=1}^n \left( a_1 \cdot \sum_{i=1}^n m_{i1} + \dots + a_k \cdot \sum_{i=1}^n m_{ik} \right) \\ &= \log_g C \end{aligned} \quad (7)$$

- 2) If the meter damage information is received, CC recalculates the decryption key  $D'_x$ :

$$D'_x = sk_x \cdot pk_\alpha = sk_x \cdot \sum_{i=1, i \neq \varphi}^n pk_i \quad (8)$$

$$\lambda'_x = e\left(H(t_i), S'_x\right) \quad (9)$$

Then the decryption operation is performed:

$$C = \lambda'_x \cdot c'_j = \prod_{\phi=1}^k g_\phi^{\sum_{i=1, i \neq \varphi}^n m_{i\phi}} \quad (10)$$

Through Algorithm 1, the regional total power data of each data type is obtained:  $\eta_\phi = \sum_{i=1}^n m_{i\phi}$ ,  $\phi = 1, 2, 3, \dots, k$ . In addition, fault meter number is less than  $n/2$ , fault-tolerant mechanism can run normally.

The Algorithm 1 execution process is as follows:

---

#### Algorithm 1 Multidimensional data extraction.

---

**Input:** superincreasing sequence  $\vec{a}$  and  $M$

**Output:**  $\eta_\phi$  for  $\phi = 1, 2, \dots, k$

**Begin:**

```

1:   Set  $X = M$ 
2:   for  $\phi = k$  to 1 do
3:      $\eta_\phi = \frac{X - (X \bmod a_\phi)}{a_\phi}$ 
4:   end
5:   return  $(\eta_1, \eta_2, \dots, \eta_k)$ 
end

```

---

Where:

$$\begin{aligned} X = M &= a_1 \sum_{i=1}^n m_{i1} + a_2 \sum_{i=1}^n m_{i2} + \dots \\ &+ a_{k-1} \sum_{i=1}^n m_{i(k-1)} + a_k \sum_{i=1}^n m_{ik} \end{aligned}$$

For any data type less than constant  $d$ , we can obtain the following results:

$$\begin{aligned} a_1 \sum_{i=1}^n m_{i1} + a_2 \sum_{i=1}^n m_{i2} + \dots + a_{k-1} \sum_{i=1}^n m_{i(k-1)} \\ < a_1 \sum_{i=1}^n d + a_2 \sum_{i=1}^n d + \dots + a_{k-1} \sum_{i=1}^n d \\ &= \sum_{j=1}^{k-1} a_j \cdot n \cdot d < a_k \end{aligned}$$

So, gets:

$$\begin{aligned} X \bmod a_k &= a_1 \sum_{i=1}^n m_{i1} + \dots + a_{k-1} \sum_{i=1}^n m_{i(k-1)} \\ \eta_k &= \frac{X - (X \bmod a_k)}{a_k} = \sum_{i=1}^n m_{ik} \end{aligned}$$

Therefore, we can use Algorithm 1 to obtain:

$$\eta_\phi = \sum_{i=1}^n m_{i\phi}, \phi = 1, 2, 3, \dots, k \quad (11)$$

## VI. SAFETY ANALYSIS

In practical applications, privacy security is one of the most concerning issues for users. We discuss the security of the system from the following four aspects: Against External Attack, Internal (AG) Attack, Collusion (AG and CC) Attack, and Fault tolerance.

### A. Against External Attack

Malicious attackers will use a series of attack methods to obtain information, among which they use communication channels to steal unauthorized information, which is referred to as external attack. In this system environment, the SM encrypts the power data by the encryption key  $S_i = sk_i \cdot L_i$ , where  $L_i = \left(\sum_{\beta=1}^i pk_\beta - \sum_{\beta=i+1}^n pk_\beta - pk_x\right)$ . If the external attacker obtains the encrypted information  $c_i = \lambda_i \cdot g_1^{m_{i1}} \cdot g_2^{m_{i2}} \cdot \dots \cdot g_k^{m_{ik}}$  (where  $\lambda_i = e(H(t_i), S_i)$ ) of the smart meter  $SM_i$ . So as to decrypt the ciphertext  $c_i$ , external attackers need to make  $e(H(t_i), P)^{sk_i \cdot \left(\sum_{\beta=1}^i sk_\beta - \sum_{\beta=i+1}^n sk_\beta - sk_x\right)} = 1$ . This moment, the external attacker first needs to get the  $sk_i$  of the

$SM_i$ , then obtain the public key  $pk_i, i \in \{1, 2, \dots, n\}$  of each smart meter and the public key  $pk_x$  of CC. Finally, external attackers calculate  $-S_i = -L_i \cdot sk_i$  to decrypt the encrypted information  $c_i$ . However, the private key  $sk_i$  of the smart meter  $SM_i$  is only known to the entity itself, and the public keys of SM/CC are sent through private and secure channels during the registration phase, which cannot be obtained by outsiders. Therefore, external attackers cannot calculate  $-S_i = -L_i \cdot sk_i$  and cannot decrypt encrypted information.

If an external attacker obtains the aggregate ciphertext  $c_j = e(H(t_i), P)^{-sk_x \cdot (\sum_{i=1}^n sk_i)} \cdot \prod_{\phi=1}^k g_\phi^{\sum_{i=1}^n m_{i\phi}}$  sent by AG to CC through eavesdropping on the communication channel, they want to decrypt the aggregate ciphertext. As known from the aggregate ciphertext, an attacker who wants to decrypt data needs to make  $e(H(t_i), P)^{-sk_x \cdot (\sum_{i=1}^n sk_i)} = 1$ . At this time, the attacker needs to obtain  $sk_x$  of CC and  $pk_i, i \in \{1, 2, \dots, n\}$  of all smart meters. However, this part of the information is also not available to other entities and external personnel. In addition, if an external attacker obtains the  $sk_x$  of CC and the  $pk_i, i \in \{1, 2, \dots, n\}$  of all smart meters, he can only obtain information on total electricity consumption, and unable to get the real time power information of a user through aggregated data. Through the above discussion, MFATM can effectively resist external attack initiated by malicious attackers

### B. Internal (AG) Attack

Internal attackers will search for suitable devices (such as lost legitimate AG) to steal unauthorized power consumption data, a process known as internal (AG) attack. In the aggregation stage, the legitimate AG collects the ciphertext information of all smart meters. Although AG can get the power ciphertext of a user at this stage, the user's electricity usage information  $m_i$  cannot be recovered from the ciphertext  $c_i = \lambda_i \cdot g_1^{m_{i1}} \cdot g_2^{m_{i2}} \cdot \dots \cdot g_k^{m_{ik}}, \lambda_i = e(H(t_i), S_i)$ . As in ciphertext  $c_i$ , the attackers and those who know the public key information of all entities in the system. So AG only demand to obtain the  $sk_i$  of  $SM_i$  to construct the bilinear pairing  $e\left(H(t_i), \left(\sum_{\beta=1}^i pk_\beta - \sum_{\beta=i+1}^n pk_\beta - pk_x\right)\right)^{-sk_i}$ . However, the  $sk_i$  is only known to the entity itself. Therefore, internal attack through aggregators cannot decrypt ciphertext data. In addition, AG aggregates the ciphertexts of  $n$  smart grid devices into a new total power data ciphertext  $c_j = \prod_{i=1}^n c_i = e(H(t_i), (\sum_{i=1}^n pk_i))^{sk_x} \cdot \prod_{\phi=1}^k g_\phi^{\sum_{i=1}^n m_{i\phi}}$  in the ciphertext aggregation phase. At this point, the attacker launches an attack on the aggregated ciphertext, hoping to steal the user's electricity usage information. The attacker needs to obtain the  $sk_x$  of CC. However, the  $sk_x$  is only known to the entity itself, and other entities and outsiders cannot be obtained. Therefore, the internal attack performed by AG in aggregation phase cannot decrypt the total ciphertext data.

### C. Collusion (AG and CC) Attack

Suppose AG and CC collude and share a single user's ciphertext  $c_i = \lambda_i \cdot g_1^{m_i}$ . However, SM uses the encryption key  $S_i = sk_i \cdot L_i$  for encryption, even if CC gets  $L_i$  calculated by AG, it cannot be decrypted. Because CC cannot get the private key  $sk_i$  of the smart meter  $SM_i$ . Furthermore, CC will try to use the decryption key  $D_x = sk_x \cdot pk_\alpha = sk_x \cdot \sum_{i=1}^n pk_i$  to

decrypt the ciphertext of a single SM. However, this situation is not feasible, because the decryption key  $D_x$  is designed based on all SMs. Therefore, the decryption key  $D_x$  does not have the ability to decrypt the ciphertext of a single SM.

### D. Fault Tolerance

The fault tolerance is realized, and the fault-tolerant mechanisms will not leak any useful electric data about the cooperative users. It is worth noting that, the fault means that the SM device cannot send data normally. If the CC and the AG faults occur, the SM intentionally sends false data, etc., they are not within the scope of the faults discussed in this article.

Fault-tolerance mechanisms typically include fault detection, troubleshooting, and aggregate recovery operations. We implement these functions through the following three steps:

- 1) AG uses a counter to detect faults;
- 2) When AG gets the missing data calculated by the normal SM, it cannot use the data to decrypt the user information;
- 3) When smart meter users in the system cannot upload power data normally due to equipment failure and other reasons, the recovery operation of the aggregator can enable normal smart meter users to calculate an aggregate value. In this case, CC can get an aggregated ciphertext, and after CC successfully decrypts it can get the power consumption data of other normal smart meter users. The maximum utilization rate of effective power data has been achieved.

In other words, even if some SM cannot work, the proposed scheme MAFTM can still restore the normal aggregation process through AG's fault tolerance mechanism, so that the power data information of other users is not affected. At the same time, because AG cannot infer the encryption key of the smart meter from the data calculated by the normal meter, it cannot be used to decrypt the user's personal information through these data, which protects the user's privacy. In fact, while implementing fault-tolerant mechanisms, we also need some additional computational cost. However, the additional computational cost itself is low, and the possibility of executing fault-tolerant mechanisms is also low (although there is a need for fault-tolerant mechanisms to exist). Considering the actual situation, we have also considered additional computational cost while designing a fault tolerance mechanism. In other words, the execution of fault-tolerant mechanisms only consumes relatively small computational resources.

## VII. PERFORMANCE

We will compare MAFTM scheme with some existing schemes in three aspects: Feature Comparison, Computational Cost, and Fault Folerance.

### A. Feature Comparisons

Firstly, we will compare MAFTM scheme with the other eight schemes [6], [14], [15], [17], [18], [19], [21], [27] for a feature comparison (the comparison results are shown in the Table I). Chen *et al.* [6] constructed a system without a TTP based on elliptic curve cryptography, and the computational

TABLE I. FUNCTION COMPARISON OF RELATED SCHEMES

Schemes	Against External Attack	Against Internal Attack	Against Collusion Attack	Fault Tolerance	Multidi Mensional	TTP Required
Chen <i>et al.</i> [6]	Yes	Yes	Yes	No	Yes	No
Lu <i>et al.</i> [14]	Yes	Yes	No	No	Yes	Yes
Boudia <i>et al.</i> [15]	Yes	Yes	No	No	Yes	Yes
Xue <i>et al.</i> [17]	Yes	Yes	No	Yes	No	No
Wang <i>et al.</i> [18]	Yes	Yes	Yes	Yes	Yes	No
Xue <i>et al.</i> [19]	Yes	Yes	Yes	Yes	No	No
Lu <i>et al.</i> [21]	Yes	Yes	Yes	No	Yes	Yes
Wang <i>et al.</i> [27]	Yes	Yes	No	Yes	Yes	No
MAFTM	Yes	Yes	Yes	Yes	Yes	No

cost is low. However, the system cannot operate normally when the smart meter fails, and the fault tolerance is low. Moreover, the multi-dimensional data reported in the scheme is encrypted multiple times in the same form, which increased computational burden on the system. Zuo *et al.* [22] shows that Lu *et al.*'s scheme [12] unable to defend collusion attack. Boudia *et al.*'s scheme [15] uses a relatively single public and private key pair to encrypt and decrypt plaintext when building the system. If CC accidentally obtains the power data of the meter, it will cause the problem of user privacy leakage, which means that the scheme [15] can only be applied to a three-tier system, and in the Chen *et al.*'s scheme [6]. Once again, it is pointed out that [15]. cannot resist collusion attack. Xue *et al.* [17] designed a fault-tolerant mechanism to improve fault tolerance, but Wang *et al.* [18] showed that the scheme [17] cannot resist collusion attack. Wang *et al.* [18] designed a fault-tolerant mechanism to improve fault tolerance and realized multi-subset data reporting. Xue *et al.* [19] used dynamic secret sharing to improve fault tolerance but could not achieve multi-dimensional data reporting. Lu *et al.* [21] used Paillier and introduced the blockchain into the edge layer to reduce the computational pressure on the edge layer. However, the scheme has low ability to resist faults and requires TTP for collaboration. Chen *et al.* [6] shows that Wang *et al.*'s scheme [27] cannot resist collusion attack. The proposed scheme MAFTM uses ECC to build the system. Smart meters use independent keys to encrypt power data. In the data reporting phase, smart meter users use the super increment sequence to report multidimensional data types. In addition deigns a fault-tolerant mechanism to solve the problem of meter failure. Performance analysis shows that while implementing fault-tolerant mechanisms, the proposed scheme MAFTM also has some improvement in computational cost compared to existing schemes.

After completing the feature comparison, we will compare the *Computational Cost* and *Fault Toletance*. Firstly, we choose the schemes [17], [18] with fault-tolerant mechanism. Secondly, we selected some classic data aggregation schemes [15], [27]. Therefore, in the subsequent part of the paper, we compare MAFTM scheme with the schemes [15], [17], [18], [27].

### B. Computational Cost

$T_e$  is an element exponentiation in  $Z_N^*$ ,  $T_{mul}$  is an element multiplication in  $Z_N^*$ ,  $T_b$  is a bilinear map pairing,  $T_H$  is a hash to an element of  $Z_N^*$ ,  $T_{H-G}$  is a hash to an element of  $G_1$ ,  $GT_e$  is an element exponentiation in  $G_T$ ,  $GT_{mul}$  is an element multiplication in  $G_T$ .  $G_{mul}$  is an element multiplication in  $G_1$ .

$G_{add}$  is an element addition in  $G_1$ .  $TD_e$  is time of Paillier encryption operation. Compared with exponential and pairing operations,  $G_{add}$  and  $T_H$  can be ignored and their values will not be calculated in the comparison. We use the java pairing-based cryptography (JPBC) [28] library to obtain the computational time of cryptographic operations, where  $N$  is 512 bits and  $G$  is 512 bits. The operating environment for this experiment is laptop with Intel Core i7-7700HQ (2.80GHz) processor, 8GB memory and 64-bit Window10 operating system. Finally, we use  $n$  to express the number of smart meters in the experimental simulation (see Table II for details).

TABLE II. COMPUTATIONAL TIME OF DIFFERENT OPERATIONS

Operation	time(ms)
$T_e$	0.88
$T_{mul}$	0.74
$T_b$	6.85
$TD_e$	5.33
$T_{H-G}$	1.31
$GT_e$	0.64
$GT_{mul}$	0.51
$G_{mul}$	9.7

1) *User's Computational Cost:* We assume that there are  $K$  data types. SM costs  $T_{H-G} + T_b + K(GT_{mul} + GT_e) + G_{mul}$  in the MAFTM scheme. Scheme [15], scheme [17] and scheme [27] cost  $2KG_{mul} + 2G_{mul}$ ,  $3T_e + 2T_{mul} + TD_e$  and  $2GT_e + GT_{mul} + G_{mul}$ , respectively. Scheme [18] requires an additional cost for constructing blind factors, totaling  $3T_e + 3T_{mul} + K(T_e + T_{mul}) + 4T_{H-G} + 3T_b$ .

2) *AG's Computational Cost:* In the MAFTM scheme and compared schemes [17], [18], [28], AG needs to execute  $n$  multiplication operations. The total computational cost is  $nT_{mul}$ . AG executes  $n$  addition operation in the scheme [15], the total cost is  $nG_{add}$ .

TABLE III. COMPUTATIONAL COSTS: ACOMPARATIVE SUMMARY

Schemes	SM	AG
MAFTM	$T_{H-G} + T_b + K(GT_{mul} + GT_e) + G_{mul}$	$nGT_{mul}$
Boudia[15]	$2KG_{mul} + 2G_{mul}$	$nG_{add}$
Xue[17]	$3T_e + 2T_{mul} + TD_e$	$nGT_{mul}$
Wang[18]	$3T_e + 3T_{mul} + K(T_e + T_{mul}) + 4T_{H-G} + 3T_b$	$nGT_{mul}$
Wang[27]	$2GT_e + GT_{mul} + G_{mul}$	$nGT_{mul}$

In summary, we will compare the computational costs of scheme MAFTM and scheme [15], [17], [18], [27] on the SM side and AG side. Table III lists the computational cost of each scheme. Fig. 3 shows the computational cost of the SM in the data reporting phase, Fig. 4 shows the computational cost required for data aggregation process. Furthermore, the data

Fig. 3. Data reporting phase computational cost.

Fig. 4. The computational cost required for AG.

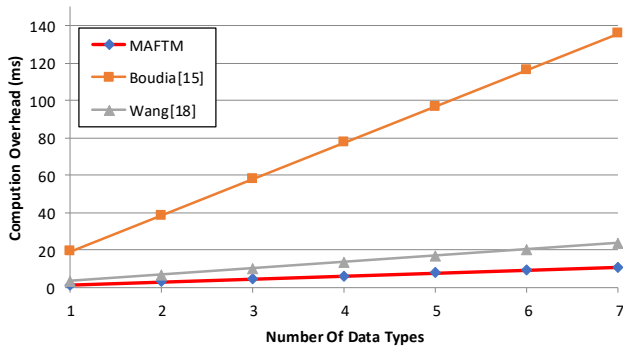

Fig. 5. Additional computational cost of data type K.

type  $K$  is 1 in the above computational cost. We compare the MAFTM scheme with schemes that implement multi-dimensional data aggregation, Fig. 5 shows the additional computational cost of data type  $K$  on the SM side.

### C. Fault Tolerance

If SM sends a power data ciphertext every 15 minutes, it sends an average of 17520 times a year. Assuming that every smart meter fails once in six years, we can know that  $1/100000 = 0.00001$  is the probability of failure through calculation. However, the failure probability of SM in daily life is far lower than 0.00001 [18]. Assuming that there are 1000 smart meters in a HAN area, it can be calculated that the minimum probability of a smart meter being damaged in six years is 0.01. Therefore, the number of times a fault-tolerant mechanism is executed is not high, but it is necessary to exist. In addition, the computational cost required to implement the fault-tolerant mechanism is affordable. When a fault-tolerant mechanism is executed, AG needs to collect computational information from a normal smart meter, where the fault computational cost for a single meter is  $T_{H-G} + T_b + GT_e + (n - s)G_{add}$ , where  $s$  is the number of SM that have failed. In addition, the formula  $e(H(t_i), P)$  can be calculated in advance and each smart meter is the same, so it only needs to be calculated once. Therefore, the fault computational cost of a single meter is  $T_e$ . The additional computational cost required in the aggregation phase is  $(n - s)T_{mul}$ .

Fig. 6. Additional costs required for fault recovery (Number of faulty meters unchanged)

Fig. 7. Additional costs required for fault recovery (Constant number of users).

We will compare the additional Fault Tolerance cost with the schemes [17], [18]. The additional computational cost requires to start the fault-tolerant mechanism is  $(s + 1)T_e + T_H$  in the scheme [17]. When the fault-tolerant mechanism is executed, the additional computational cost of each SM is  $4T_e + 2T_{mul} + T_H$  in the scheme [18]. The extra cost of AG is  $(n - 1)T_{mul}$ . Assume that the number of meters from 20 to 100, the number of faulty meters  $s = 10$ . The computational cost required to execute the fault-tolerant mechanism is shown in Fig. 6. On the contrary, we assume that the number of faulty smart meter is 0 to 50, while the number of normal smart meter is  $n=100$ . The additional cost of the fault-tolerant mechanism is shown in Fig. 7.

### VIII. CONCLUSION

Aiming at the problems of relying on TTP to participate in collaboration, low fault tolerance, and unable to report multi-dimensional data in the current data aggregation scheme, this paper proposes the MAFTM scheme. MAFTM is based on ECC to construct multi-dimensional data aggregation without TTP participation. At the same time, we consider that SMs may fail in real life, causing CC to fail to decrypt normally. In order to prevent the sudden failure of the SM, we also designed a fault-tolerant mechanism. In this article, we demonstrate through comparative analysis that the MAFTM scheme is more functionally complete. Furthermore, performance analysis shows that the MAFTM scheme has a lower computational cost on the SM and AG sides. Finally, the additional cost generated by implementing fault-tolerant mechanism is also lower compared to other schemes. However, the disadvantage is that the fault-tolerant mechanism proposed in this article requires more than half of the SMs to participate in the collaboration. If a large range of SMs fail, the MAFTM scheme is likely to fail to perform the recovery function properly. In addition, the aggregation of more diverse data types remains a challenging issue, such as the collection of aggregated data under multi-subset structures. We will continue to study in future work to enhance the efficient utilization of power data by control centers.

### ACKNOWLEDGMENT

# SbChain+: An Enhanced Snowball-Chain Approach for Detecting Communities in Social Graphs

Jayati Gulati, Muhammad Abulaish  
Department of Computer Science  
South Asian University  
New Delhi, India

**Abstract**—In this paper, we present snowball-chain (SbChain+) approach, which is an improved version of SbChain community detection method in terms of precision with which communities are identified in a social graph. It exploits the topology of a social graph in terms of the connections of a node, i.e., its degree centrality, betweenness centrality and the number of links within its neighborhood defined by the local clustering coefficient. Two different functions have been used to identify neighbors for a given node. Hence, two approaches have been discussed with their pros and cons. In general, SbChain+ takes a social graph as an input and aims to identify communities around the core nodes in the underlying network. The core nodes are expected to have a high degree and have densely connected neighbors and guides in identifying cliques from the graph. The proposed approach takes its inspiration from snowball sampling technique and keeps merging the nodes with their neighboring nodes based on certain criteria to form snowballs. One of the functions discussed (SbChain+(i)) uses a hyperparameter,  $\lambda$  for merging snowballs which further leads to the formation of communities. This hyperparameter also helps in achieving the desired level of coarseness in the communities, and it can be adjusted to fine tune the identified communities. While the second function (SbChain+(ii)) uses an average out degree function to merge snowballs. The *modularity* values are calculated at each level of the dendrogram formed by combining nodes and snowballs to decide an appropriate cut for community determination. SbChain+ is empirically evaluated using these two different functions over both real-world and LFR-benchmark datasets and results are evaluated on *modularity* and *normalized mutual information*. The aim of this study is to improve upon the previously discussed technique (SbChain) and to study the use of hyperparameter, i.e., the performance of a technique with or without the hyperparameter.

**Keywords**—*Clique; clustering; community detection; graph mining; snowball sampling; social network analysis*

## I. INTRODUCTION

Online social network is an ever-growing entity which can be modeled in the form of graphs (*aka* social graphs) with users or entities as the nodes and their interactions or relationships as weighted or unweighted edges [1]. Community detection is an application of studying social graphs that provides useful information about groups that might exist due to similar interests, occupation and so on. It is formally stated by Girvan and Newman as the *community detection* problem in [2]. Communities are expressed as a group of nodes that are coherent and are well-connected or have similar characteristics,

and sparse connections with the other nodes or dissimilar characteristics with the rest of the nodes. Identifying communities enables an in-depth understanding of the arrangement of nodes and edges in a social graph, because they correspond to the entities and their respective relationships within a group or inter-groups. Hence, it can be useful in identifying highly cohesive sub-structures.

There are various approaches like density-based, hierarchical, and label propagation methods for community detection. The density-based approach aims to find core points in the network that have a high number of neighbors based on a pre-defined threshold value. It also identifies the isolated nodes or outliers in the same manner and then grows the communities. Density-Based Spatial Clustering of Applications with Noise (DBSCAN) [3] uses two external parameters, a *minpoint* threshold and a *neighborhood parameter* depending on which the results may differ. A density-based approach, called CMiner, is presented in [4] which finds overlapping communities using a new distance function derived from the average reciprocated interactions among nodes. The authors also proposed another approach in [5], called OCTracker, for finding overlapping communities using a density-based framework and tracking the various aspects of community evolution. Hierarchical approaches are another set of methods for community detection in social networks that may work either in a bottom-up manner or in a top-down manner. Bottom-up approach considers each node to be a separate community and combines nodes in an iterative manner to maximize modularity. On the other hand, top-down approach considers the entire network to be a single community and divides it in an iterative manner until the desired set of communities are obtained. However, some hierarchical approaches have found to have very high complexities depending upon the cost function to be optimized. In [6], the authors proposed a unified framework, called HOCTracker, which identifies hierarchical overlapping communities in social networks. Label propagation is another approach for community detection in social networks. The Label Propagation Algorithm (LPA) changes a node label to the label of its majority neighbors. However, since LPA uses local information, it gets stuck in local optima. Snowball-Chain (SbChain) is another community finding approach which works well when nodes find their best neighbors in the initial few iterations.

In this paper, we present two improved versions of our previous work Snowball-Chain (SbChain) [7], termed as Enhanced

Snowball-Chain (SbChain+(i) and SbChain+(ii)). It uses simple topological features of a graph, like degree centrality, betweenness centrality, clustering coefficient and average out degree function for detecting communities in undirected and unweighted social graphs, which is the major advantage of this SbChain+ when compared with other techniques in the current work. The idea behind SbChain+ is that the nodes having high centrality value and cliques among their neighbors may become good candidates to form communities. Therefore, the technique starts with the identification of seed nodes (i.e., the nodes having high degree and well-connected neighbors), it aims to identify their best scoring neighbors based on two different functions. Hence, two approaches based on two different functions for SbChain+ are discussed in the subsequent sections, with their pros and cons. One of them uses common neighbor merging strategy (function-i) and the other uses average out degree function (ODF) (function-ii). The nodes merge to form snowballs based on one of these functions. SbChain+(i) and SbChain+(ii) are compared with five other well established state-of-the-art community detection techniques, including Infomap [8], LPA [9], LPA (semi-synchronous) [10], Louvain [11], and SbChain [7]. Approaches like LPA is based on local node interactions and ignore the global information of nodes (like betweenness centrality etc.) in the graph. Whereas, SbChain+ considers all the information of the node by using local as well as global clustering coefficient. It can also be seen that according to [12] Louvain is unable to detect outliers unlike SbChain+. SbChain+ separates nodes with zero degree value before the algorithm begins its processing. The results reveal the effectiveness of the proposed SbChain+ for community detection in real-world social graphs when compared with these techniques. In short, the major contributions/enhancements in this work can be summed up by the following points:

- 1) Consideration of degree, betweenness centrality and normalized clustering coefficient for seed node identification leading to improvement in terms of community formation.
- 2) Two improved weight functions based on the concept of common neighbors using a hyperparameter and average ODF, respectively, to calculate the interaction intensity for a pair of nodes. The pros and cons of each of these functions is also studied.
- 3) An improved empirical validation of the proposed approach over both real-world and LFR-benchmark datasets in terms of identified number of communities, modularity (Q) and Normalized Mutual Information (NMI) for real-world datasets.

The rest of the paper is organized as follows. Section II presents a brief review of the existing literatures on community detection. Section III mentions the preliminary concepts used by the proposed approach. Section IV presents the functional details of our proposed SbChain+ method. Section V presents a discussion on hyperparameter tuning with pros and cons of both the functions used in SbChain+. Section VI presents details about the datasets, experimental settings, and an analysis of the experimental results. The complexity analysis of SbChain+ is mentioned in section VII. Finally, section VIII concludes the paper with future directions of

research.

## II. RELATED WORK

A lot of research in the field of community detection has been conducted in the past few years. In [13] and [14], review of existing community detection methods is presented. It divides the detection methods into probabilistic and deep learning categories. The traditional approaches utilize probability-based models for community identification, whereas complex networks are converted to lower dimensional data and worked upon by using deep learning methods. In this paper, we consider a classical approach for community detection that utilizes the parameters from the graph itself. Commonly used community detection methods for connected data are mainly based on Markov clustering algorithm, which uses a random walk process on the given network to identify communities in the form of clusters. The algorithm in [15] proposed a function-modularity intensity which uses network edges along with their weights for community evolution. Another common approach for identifying communities is implemented using hierarchy-based methods. The method in [16] is based on edge removal. It proposes to eliminate the edges having a high score calculated in terms of betweenness centrality and identifies optimized community based on the modularity values. A similar work is presented in [17] which combines nodes that maximize modularity in an agglomerative hierarchical order. It begins with assuming each node as a community and keeps combining nodes until highest value of modularity is achieved. Another work in [18] used spectral clustering along with global maximization of the modularity function.

Density-based approaches like Density-Based Spatial Clustering of Applications with Noise (DBSCAN) [3] and Ordering Points To Identify Cluster Structure (OPTICS) [19] have also been proposed in literature for community detection. DBSCAN uses two user-defined parameters called as the *minimum point threshold* and *neighborhood radius*. OPTICS uses two distance measures – *core-distance* and *reachability-distance* to consider core as well as the points that lie inside the high-density clusters. Inspired from DBSCAN, a Structural Clustering Algorithm for Networks (SCAN) was proposed in [20]. It aims to detect hubs and outliers along with the communities. However, it also requires two parameters, namely, a minimum similarity threshold parameter and minimum number of neighbors. However, it does not provide any details about parameter settings. A popular overlapping community detection approach is Clique Percolation Method (CPM) which is based on growth of communities using  $k$ -cliques [21]–[23], wherein communities are defined by maximal union of adjacent  $k$ -cliques. The adjacency of cliques is decided by the number of common nodes between them [22].

Label Propagation Algorithm (LPA) [9] follows another community detection approach, which changes the label of each node to the most frequently occurring label in its neighborhood. The process continues until all the nodes are updated and no more changes can be made to the labels. LPA has been an inspiration for several other works in community detection. For example, authors in [24] proposed CenLP (Centrality-based Label Propagation) algorithm which considers weighted networks for community detection. They proposed a function to calculate the centrality of a node and its similarity

with the neighboring nodes. Another work in [25] creates a compactness function based on a node's weight which is calculated based on two factors: (i) common number of neighbors between a given node and its surrounding nodes, and (ii) degree of node under consideration. The neighboring communities are defined based on high degree nodes and their high degree neighbors. Communities are identified using weighted compactness function value between a node and its neighboring community. An adjustment strategy is devised to achieve an improved accuracy. Other studies in community detection (e.g., [26]) used the score of immediate neighbors of a node to decide its label. Evolutionary algorithm discussed in [27] also finds the community structure based on modularity maximization. The communities formed are merged based on a function calculated via intra-community and intercommunity links.

A study in [28] finds connected components that form a preference network, leading to the formation of communities. The preference network is formed by finding preference nodes using their spread capabilities. It identifies the highest number of overlapping neighbors between a given selector node and its one-path length neighbors. This is calculated using the `gossip` algorithm proposed in [29]. Another similarity-based approach was proposed in [30] which is called Community Detection Algorithm based on Structural Similarity (CDASS) and works in two phases. In phase one, the edges bearing a low similarity value are removed, leading to formation of several disconnected components in the network. The components are consolidated eventually to form a set of communities. The second phase identifies optimal communities from the previous phase to give the required results using an evaluation function. The function used in the second phase is realized from different structural parameters of the nodes in the given network. Another work that uses local graph information is discussed in [31] called Flow Propagation Algorithm (FlowPro). It can compute the community of exactly one node by using the flow based on edge weights. Each node stores half of the receiving flow and the process continues until there is no flow left to be circulated.

A few deep learning-based techniques are presented in [32], [33]. In [32], a weighted path matrix having path length two is created. It helps in identifying similarity among a node and its neighbors with path length of two or less. Further, a deep sparse autoencoder and k-means clustering algorithm is used to identify the communities. The work in [33] uses an existing technique to design an encoder for identification of communities and their respective nodes. It uses a dual decoder for unsupervised community detection. Another work in [34] uses graph compression technique for analysis of huge networks. The probability of a node to become a seed is calculated using two parameters, quality, and density of the nodes. Finally, the number of communities and initial seed set is recognized using these parameters. A work in [35] develops a framework called Seed Expansion with generative Adversarial Learning (SEAL) uses a graph neural network that uses sequential decision process and is trained via policy gradient. It works on the concept of discriminator and generator, the former identifies fake or real communities. While the latter fits in features of communities the real communities.

In [36], a genetic algorithm for feature selection to find

communities is discussed. Features are identified and then classified into clusters based on community detection approaches. Next step employs a genetic algorithm that to pick up features based on a novel operation. A local community detection process in [37] works in two parts, where a core detection stage identifies communities based on modularity density. The next stage is the extension stage identifies coherent communities based on Jaccard coefficient.

Our proposed SbChain+ method is inspired from the afore-said similarity-based approaches which first find the seed nodes based on certain criteria and then search for highly connected nodes in the neighborhood. This leads to formation of snowballs, which keep expanding until no more nodes can join, eventually leading to the formation of communities. SbChain+ is compared with both LPA and Infomap that utilize the concept of random walks and decompose the network into groups based on probability flow. It is also compared with Louvain, in which communities are grown in a hierarchical manner by adding nodes that lead to gain in modularity, marking the first phase of the community identification process. Thereafter, weights of the links belonging to a particular community are summed up to complete the second phase. Finally, first and second phases are iteratively repeated until the community formation process converges and a maximum modularity value is achieved.

### III. PRELIMINARIES

For a graph  $G(V, E)$  represented by  $V = \{v_1, v_2, \dots, v_n\}$  as a set of  $n$  nodes and  $E = \{e_{ij} = (v_i, v_j) | v_i, v_j \in V \& \exists \text{ a link between } v_i \text{ and } v_j\}$  as a set of edges, the motive is to identify the seed or core nodes that form snowballs, and merging the snowballs/nodes finally to form communities. The notations used in the subsequent sections of this paper are briefly described in Table I.

TABLE I. NOTATIONS AND THEIR BRIEF DESCRIPTIONS

Notation	Description
$\mathcal{N}(v_i)$	Set of immediate neighbors of a node $v_i$
$k(v_i)$	Degree centrality of $v_i$
$b(v_i)$	Betweenness centrality of $v_i$
$LCC(v_i)$	Normalized local clustering coefficient of $v_i$
$\mathcal{N}_{best}(\mathcal{V})$	A set of best neighbors for a given set $\mathcal{V} \subseteq V$ , calculated by a score function
$s^{(n)}$	A set of nodes of length $n$ , called snowball
$\mathcal{N}(s^{(n)})$	Neighbor set of $s^{(n)}$ , given by $\mathcal{N}(v_1) \cup \mathcal{N}(v_2) \cup \dots \mathcal{N}(v_n)$

For a graph  $G$ , the SbChain+ algorithm initiates by sorting the nodes in non-increasing order based on their scores, which is generated by equation (1), as explained in the following definition.

**Definition 1. (Score).** The score for a given node  $v_i$  is calculated based on its normalized clustering coefficient, degree and betweenness centrality, as formally presented in equation (1).

$$score(v_i) = (LCC(v_i) + k(v_i) + b(v_i))/3.0 \quad (1)$$

The degree, betweenness centrality and clustering coefficient parameters are used in this study because they provide con-

nectedness of a node with its neighboring nodes, and connectedness of the neighboring nodes, respectively. The degree centrality for a node is the fraction of nodes it is connected to in the graph. Betweenness centrality of a node is given by the sum of the fraction of all-pairs shortest paths that pass through it. The clustering coefficient also provides information about clique formation within the neighbor set of a node. All the three parameters are normalized to bring them on the same scale.

It should be noted that equation (1) works differently for a seed node  $v_i$  and a snowball  $s^{(n)}$ . For  $v_i$ , the individual value of all the parameters is added, while for a snowball value  $s^{(n)}$ , the individual values for each node comprising the snowball are picked and divided by the number of nodes in the snowball as given by equation (2).

$$score(s^{(n)}) = score(v_1) + \dots + score(v_n) / \|s^{(n)}\| \quad (2)$$

The nodes are selected one at a time in non-increasing order of their score to grow and form communities. Considering  $v_i$  be the first selected node, the approach proceeds by finding the best neighboring node denoted by  $\mathcal{N}_{best}(v_i)$  from  $\mathcal{N}(v_i)$ . This node  $\mathcal{N}_{best}(v_i)$  is the one having the highest value of score given by equation (1). After the first round of iteration, many nodes combine with their best neighbor and their scores are updated by equation (2). However, it should be noted that a node  $v_i$  combines with  $\mathcal{N}_{best}(v_i)$  on conditions defined by two different functions as mentioned below.

**Definition 2.** (Function-i) According to this function  $v_i$  combines with  $\mathcal{N}_{best}(v_i)$  if the degree of overlap among their neighbor set, i.e, cardinality of the overlapping set obtained by taking the intersection of its own neighbor set and that of the neighbor set of  $v_i$  is higher than the hyperparameter  $\lambda$  among all the neighbors of  $v_i$ , given by equation (3).

$$weight = \frac{\|\mathcal{N}(v_i) \cap \mathcal{N}(\mathcal{N}_{best}(v_i))\|}{\min\{\|\mathcal{N}(v_i)\|, \|\mathcal{N}(\mathcal{N}_{best}(v_i))\|\}} > \lambda \quad (3)$$

**Definition 3.** (Function-ii) According to this function  $v_i$  combines with  $\mathcal{N}_{best}(v_i)$  if the value of average ODF formed by the subgraph of their neighbors is less than the individual average ODF of  $v_i$  with  $\mathcal{N}(v_i)$  and  $\mathcal{N}_{best}(v_i)$  with  $\mathcal{N}(\mathcal{N}_{best}(v_i))$  as given by equations (4) and (5)

$$avgODF(S(v_i)) \geq avgODF(S(s^{(n)})) \quad (4)$$

$$avgODF(S(\mathcal{N}_{best}(v_i))) \geq avgODF(S(s^{(n)})) \quad (5)$$

The nodes are bound to follow *non-redundant node strategy* when the process of community detection starts. According to this strategy, a node  $v_i$  merges with only its prime neighbor given by  $\mathcal{N}_{best}(v_i)$  in the current iteration. The same is applicable for  $\mathcal{N}_{best}(v_i)$  as well, as it cannot join other nodes/snowballs in the same iteration, i.e., both these nodes are not allowed to join other nodes in the same iteration. This strategy leads to formation of mutually exclusive communities.

When nodes join with their best node from the respective neighborhood set, they form snowballs as given by definition 4.

**Definition 4.** (Snowball). A snowball  $s^{(n)}$  is set of connected components formed by enumerating nodes contained in it, where  $n$  is the cardinality of the set. It is formed either by merging a node  $v_i$  with  $\mathcal{N}_{best}(v_i)$  or by joining two or more snowballs.

It is pertinent to note that the superscript  $n$  signifies the number of elements in a snowball. Hence, there can exist many snowballs with a common value of  $n$ . Nonetheless, they can be distinguished by the elements contained in the set, as these elements are mutually exclusive. These snowballs ( $s^{(n)}$ ) form a subgraph with their immediate neighbors (neighbors of the nodes that are contained in the it).

The set of neighbors for a snowball depicted by  $\mathcal{N}(s^{(n)})$  is defined by the union of neighbor set of each node contained in  $s^{(n)}$ , i.e.,  $\mathcal{N}(v_1), \mathcal{N}(v_2), \dots, \mathcal{N}(v_n)$ . A snowball can combine any of the existing snowballs by a given condition which calculates the common nodes among the existing snowball and the newly formed snowball (formed by merging the two snowballs). A snowball is allowed to join any one of the existing snowballs, the one which has the maximum common neighbors with the current snowball. This process keeps continuing until no further snowballs can combine, and the final result is the community set as mentioned in definition 5.

**Definition 5.** (Community set). A set of community may comprise of a single node or snowballs or both, that cannot be merged any further and have maximum value of (modularity) among all the iterations.

#### IV. PROPOSED SBCHAIN+

The functional details of the proposed approach for finding communities, called Enhanced **Snowball-Chain** or **SbChain+** are presented in this section, and it is designed for a simple graph, i.e., an undirected and unweighted graph. The inspiration for the approach comes from agglomerative hierarchical clustering which operates in a bottom-up manner, starting with single nodes as individual communities. These nodes expand to form snowballs by finding highly connected neighboring nodes. Snowballs keep adding nodes to form clique-like structures. The snowballs keep expanding till the criteria is met and until the convergence is fulfilled, i.e., the set of communities for a given iteration are identical to the community set from the previous iteration. The community set with the highest value of modularity is the final set of community returned by the algorithm, among all the calculated values from all the iterations.

##### A. SbChain+ Algorithm

SbChain+ given by algorithm 4 commences by storing the structural properties of all the nodes, like their respective neighbors, local clustering coefficient, and degree, betweenness centrality, each of which is represented as a set. These sets are stored in the form of key-value pairs by the name of  $\mathcal{N}, LCC, k$  and  $b$ , respectively, where the key is defined by the node and the value varies with the corresponding set values. The loop keeps running for  $|V|$ , where  $V$  represents

---

**Algorithm 1:** *bestNeighbor*( $\mathcal{V}, \mathcal{N}(\mathcal{V}), score$ )

---

**Input :** A set  $\mathcal{V} \subseteq V$ , neighbor list  $\mathcal{N}(\mathcal{V})$ , *score* of each node/snowball in the current iteration  
**Output:** Best neighbor set of  $\mathcal{V}$  i.e.  $\mathcal{N}_{best}(\mathcal{V})$

```

1 maxScore  $\leftarrow 0$ 
2  $\mathcal{V}' \leftarrow \emptyset$ 
3 if  $\|\mathcal{N}(\mathcal{V})\| = 0$  then
4    $\leftarrow$  return  $\emptyset$ 
5 foreach  $v \in \mathcal{N}(\mathcal{V})$  do
6   foreach snowball in score do

the node set in graph  $G$ . However, it exits the loop when two consecutive iterations result in identical set of communities.

Before the iterations start, an initial score  $score^{(1)}$  and neighbor list  $\mathcal{N}$  is calculated for each node  $v_i$  as a preprocessing step in algorithm 4. The score is calculated as per equation (1) or (2) and signifies the influence of a node/snowball in the graph, and calculated using the connections among its neighbor (given by LCC) and its own connections with the other nodes (given by degree and betweenness centrality). The flag value for each node is set to 0 for every iteration, so that each node can merge once in every iteration with its best neighbor. As each iteration  $i$  proceeds, the nodes (or snowballs) represented by the set  $\mathcal{V}_j$  from  $score^{(i)}$  are arranged in non-increasing order. Each  $\mathcal{V}_j$  is checked for a flag value, if the value is set, it means that the given  $\mathcal{V}_j$  has merged with some nodes/snowball to form another snowball in the current iteration, it is not processed

---

any further and the iteration continues with the next set in the order. Hence, as per the non-redundant node strategy, the algorithm jumps to the next best  $\mathcal{V}_j$ . The best neighbor for a node  $\mathcal{V}_j$  is represented by  $\mathcal{N}(\mathcal{V}_j)$  is returned by the algorithm 1. It should be noted that both  $\mathcal{V}_j$  and  $\mathcal{N}_{best}(\mathcal{V}_j)$  are sets; therefore, they can contain more than one node. If these sets contain more than one node then they are called a snowball. Hence, it is represented as a set  $\mathcal{V}'$ . It should be noted that if  $\mathcal{V}'$  is an empty set, therefore,  $\mathcal{V}_j$  is a isolated node and forms a community of its own. Next,  $\mathcal{V}'$  is also verified further for non-redundant node strategy, by checking its respective flag value. Further, a node joins its best neighbor based on two neighbor approval functions as discussed further.

1) *neighborApproval(i)*: It should be noted that we discuss two functions for approval of the best neighbor for a given node as given by algorithm 2 and algorithm 3. According to algorithm 2 called *neighborApproval(i)*, both the sets, i.e.,  $\mathcal{N}(\mathcal{V}_1)$  and  $\mathcal{N}(\mathcal{V}_2)$ , are checked for overlapping criteria using the hyperparameter  $\lambda$ . This parameter lays the minimum value of overlap that should exist for two snowballs to combine. If their *weight* given by (1) is greater than or equal to the  $\lambda$  value, then the sets merge to form a snowball  $s^{(n)}$  which is returned by the algorithm else it returns an empty set.

2) *neighborApproval(ii)*: In algorithm 3 *neighborApproval(ii)*, the average out degree function of the original two sets given by  $\mathcal{N}(\mathcal{V}_1)$  and  $\mathcal{N}(\mathcal{V}_2)$  and their union ( $\mathcal{V}_1 \cup \mathcal{V}_2$ ) is calculated as per equation (6) given by [38].

$$avgODF(C) = \frac{1}{n_C} \sum_{u \in C} \frac{|\{(u, v) \in E : v \notin C\}|}{k_u} \quad (6)$$

It gives the average of the number of outgoing edges for each community node as compared to the total edges incident on that node. Therefore, if the value of *avgODF* is smaller for the combined snowball (than the initial two sets),  $s^{(n)}$  is returned else an empty set is returned.

Considering *neighborApproval(i)* in algorithm 4, if a snowball  $s^{(n)}$  is returned then the flag for all the nodes in the snowball is set to one. Therefore, these nodes cannot combine with other nodes in the current iteration, leading to formation of disjoint communities. Further, the score of the snowball is calculated by taking an average of the score of the elements in the snowball. It should be noted that a new snowball is allowed to merge with an existing snowball on a criteria stating that they have maximum overlap among all the existing snowballs, given by a parameter called *weight* as mentioned in step 15. A snowball is allowed to join only one existing snowball, i.e., the one with the maximum common nodes.  $score^i$  and  $score^{i+1}$  are updated to include the average score values for of snowball and merged snowball, respectively. If the new snowball does not combine with any existing snowball, then it forms a community of its own as per step 34. The nodes that did not merge with other nodes/snowballs are copied from  $score^i$  to  $score^{i+1}$  and *comm*. In every iteration, modularity and NMI (using ground truth GT) are calculated. This process continues till two consecutive iterations return an identical community set. The final set of communities is returned along with the respective modularity and NMI values, as per the

algorithm has the maximum modularity value among all the iterations.

## V. DISCUSSION

The hyperparameter ( $\lambda$ ) used in this study determines the limit of common nodes that should exist between two subgroups to merge them to form a snowball. This parameter is decided upon empirically, but it is guided by the ratio of edges to nodes in the social graph. It is also given by half of the average degree ( $k_{avg}$ ) of the nodes, as given in Table XI. It can be observed from this table that  $k_{avg} > 19$  for all LFR datasets. This signifies that the nodes are densely connected in the graph and can merge on a low  $\lambda$  value. Setting a high value of  $\lambda$  would result in joining of all the nodes, and eventually leading towards the formation of a single community. Therefore, it is observed that the results are best around  $\lambda \leq 0.6$ . Similarly, for lower values of average degree (i.e.,  $k_{avg} < 5$ ), a higher percentage of overlap is required because the neighbors (or  $k(v_i)$ ) of two nodes/subgroups to be merged can be very low. The low degree nodes can easily be merged at lower  $\lambda$  values, leading to the formation of a single community in the entire dataset. Hence, based on our experiments, the suitable value for the  $\lambda$  hyperparameter is,  $\lambda > 0.6$ .

It should be noted that *SbChain+(i)* outperforms *SbChain+(ii)* in terms of the quality of the identified communities. The reason for this is that the  $\lambda$  parameter allows a node or snowball to join other nodes or snowballs because the overlap among them keeps increasing with each iteration. Whereas, average ODF in case of *SbChain+(ii)* has stricter rules for merging. Therefore, the overlap among snowballs is not as much as in the case of former technique, i.e., the growth of the communities is comparatively slower in latter. The drawback associated with the former technique is that, although the  $\lambda$  value is guided by the ratio of number of edges to the number of nodes, there is a scope of error associated with it. While, the shortcoming of *SbChain+(ii)* is that it produces average results since it allows a node to merge with its best neighbor based on increasing the density of edges inside a community than outside.

*SbChain+* improves upon *SbChain* by changing the the seed function to include various centralities, discussing two neighbor finding functions (with and without parameters). It can be seen that both *SbChain+(i)* and *SbChain+(ii)* outperform *SbChain* in terms of the quality of the identified community. Although, *SbChain+* shows comparable or good results for real-world datasets, it needs to be checked for large networks.

## VI. EXPERIMENTAL SETUP AND RESULTS

This section describes the results and their analysis obtained by applying *SbChain+* approach with two different functions, *neighborApproval(i)* and *neighborApproval(ii)* on various datasets, namely, *SbChain+(i)* and *SbChain+(ii)*, respectively. The efficacy of these two techniques is verified using six real-world datasets and two sets of computer-generated Lancichinetti Fortunato Radicchi (LFR) benchmark datasets having 1K and 5K nodes, respectively. The details of the datasets are presented in the following subsections. Modularity (Q) and Normalized

Fig. 1. Visualization of the performance comparison results of SbChain+ with state-of-the-art methods over real-world datasets in terms of NMI.

Mutual Information (NMI) are used to assess the quality of communities formed by SbChain+ and the other techniques. It should be noted that the values marked with \* represent a very small number and is rounded off to 0.00.

### A. Real-World Datasets

The real-world datasets used in our experiment are briefly summarized in Table II<sup>1</sup>. The performance evaluation and comparison results of SbChain+(i) and SbChain+(ii) with some of the state-of-the-art methods, including Infomap [8], Label Propagation Algorithm (LPA) [9], LPA (semi-synchronous) [10], Louvain [11], and our previously developed SbChain, in terms of Normalized Mutual Information (NMI), and modularity (Q) are shown in Tables III and IV, respectively.

It can be observed from the Tables III and IV that SbChain+ performs significantly better or comparably most real-world datasets. The average NMI produced by SbChain+(i) is comparable to the average NMI by Infomap among all the techniques. It is pertinent to note that both SbChain+ techniques are seen to perform better than SbChain as shown in Fig. 1 and 2. It should also be noted that SbChain and LPA techniques produce different result every time they are run.

### B. Synthetic Datasets

As described in [41], Lancichinetti-Fortunato-Radicchi (LFR) benchmark networks are used to generate synthetic datasets by tuning different parameters. In our experiments, LFR datasets with 1K and 5K nodes are generated using the parameter values presented in Tables V and VI, respectively. These datasets are denoted as LFR-1K and LFR-5K datasets, respectively. Out of these parameters,  $\mu$  is the mixing parameter and defines the number of connections with neighbors in other communities. The value of  $\mu$  is set within the range of [0.1, 0.5] for LFR-1K and LFR-5K, and the step-size is changed at an interval of 0.1 for both LFR-1K and LFR-5K datasets. It controls the percentage of edges between communities. By changing the  $\mu$  values in the given range, different datasets are created and accordingly named as LFR-1K.1 – LFR-1K.5 and LFR-5K.1 – LFR-5K.5. Values upto 0.5 are considered for  $\mu$  parameter as the modular structure of a community becomes fuzzy beyond this value.

The empirical evaluation and comparison results of SbChain+ with the aforementioned techniques in terms of NMI, and modularity (Q) are presented in Tables VII-VIII for LFR-1K dataset, and in Tables IX-X for LFR-5K dataset. These tables present the varying  $\mu$  in the range of [0.1, 0.5] for LFR-1K and LFR-5K datasets, with the respective NMI, and Q for all the approaches.

It can be seen that our technique gives average results in most of the cases, The NMI for SbChain+ is LFR-1K as can be seen from Table VII is seen to outperform SbChain, LPA(SS). And, in general SbChain+(i) produces better results than SbChain+(ii). It is also seen that modularity values for LFR-1K from VIII are seen to be average, i.e., Infomap, Louvain and LPA produce a better modularity value than SbChain+. Fig. 3 and 4 show comparison charts for LFR-1K datasets in terms of NMI and modularity.

SbChain+(i) performs averagely in for LFR-5K datasets in terms of NMI and modularity, as seen from Tables

IX and X, respectively. Although, it shows better results than LPA(SS), SbChain and SbChain+(ii). Fig. 5 and 6 show both the NMI and modularity values produced by all the techniques.

Therefore, it is seen that for real-world datasets SbChain+ is seen to perform better in terms of the identified communities as compared to the synthetic datasets. It should be seen that the average NMI produced by real-world datasets is at par with the other techniques results, and performs produces average results for LFR-1K and LFR-5K.

## VII. COMPLEXITY ANALYSIS

The best-case of the algorithm arises when all the nodes join different nodes/snowballs in each iteration, i.e., no node is left free in any iteration. This leads to a minimum of  $\log n$  iterations, where the number of nodes/snowballs also reduces to its half from the previous iteration. Therefore, a time complexity of  $O(n)$  defines the best-case. The worst-case arises when only a single node joins another node/snowball in an iteration. This leads to  $n - 1$  iterations and the time complexity goes to  $O(n^2)$ . It is also evident that SbChain+ works well on both small and large real-world datasets in terms of the identified communities. However, on LFR datasets, it

< 5	> 0.6
> 10	$\leq 0.6$

is seen to give average performance when compared to the best performing community detection methods. It should be noted that in comparison to LPA(SS) and SbChain, both, SbChain+(i) and SbChain+(ii) show better performance in terms of the identified communities.

### VIII. CONCLUSION AND FUTURE WORK

In this paper we have presented two approaches for enhanced snowball-chain approach, SbChain+ for detecting communities in social graph. In general, SbChain+ lays emphasis on finding nodes that have a high degree of interaction with its neighbors and a densely connected neighborhood. This reveals the core nodes, i.e., the nodes that may be a part of a clique and would further contribute towards formation of snowballs and eventually a community. SbChain+ improves over SbChain in terms of cardinality of the identified communities, NMI, and modularity. In SbChain+(i), this is achieved by changing the weight function, which is based on maximizing the intersection of the neighbors between two nodes using a  $\lambda$  hyperparameter. The hyperparameter ( $\lambda$ ) which defines the minimum overlap required for two snowballs to get merged for community formation. This parameter also helps in refinement of the communities – the higher the value of  $\lambda$ , higher is the cohesion. The low value of  $\lambda$  gives higher coupling. On the other hand, SbChain+(ii) focusses on average ODF and does not use any hyperparameter and hence, detects better communities than SbChain. Whereas,

SbChain focussed on maximizing both the common neighbors as well as the score between the nodes; by relaxing this criteria, the results are seen to be better than those given by SbChain.

Further, SbChain+ method can be extended and improved upon by making it a generic framework for finding communities closer to ground truth, in both simple and weighted/directed social graphs. Also, the technique can accommodate identifying dynamic communities based on the time-varying functions. This can be seen as a promising future direction of research.

# PaddyNet: An Improved Deep Convolutional Neural Network for Automated Disease Identification on Visual Paddy Leaf Images

Petchiammal A, Murugan D, Briskline Kiruba S

Department of Computer Science and Engineering

Manonmaniam Sundaranar University, Tirunelveli, Tamilnadu, India 627 012

**Abstract**—Timely disease diagnosis in paddy is fundamental to preventing yield losses and ensuring an adequate supply of rice for a rapidly rising worldwide population. Recent advancements in deep learning have helped overcome the limitations of unsupervised learning methods. This paper proposes a novel PaddyNet model for enhanced accuracy in paddy leaf disease detection. The PaddyNet model, developed using 17 layers, captures and models patterns of different disease symptoms present in paddy leaf images. The effectiveness of the novel model is verified by applying a large dataset comprising 16,225 paddy leaf datasets across 13 classes, including a normal class and 12 disease classes. The performance results show that the new PaddyNet model classifies paddy leaf disease images effectively with 98.99% accuracy and a dropout value of 0.4.

**Keywords**—Image annotation; data augmentation; deep learning; paddy leaf disease detection; paddyNet

## I. INTRODUCTION

Plant disease threatens food production and disrupts food security worldwide. It was reported, for instance, that though rice cultivation was set to increase by 1.8 percent in 2021/22 to a new peak of 520.7 million tonnes [1], its supply was diminished by disease. Rice is among the most widely consumed foods globally, with a total consumption of 511.4 and 501.2 million tonnes in 2020-21 and 2019-20, respectively. These statistics highlight the relentless food shortages brought on by the devastation plant disease has wreaked on food production, turning it into a major global problem [2]. So then, increased agricultural productivity of up to 70% is required to reduce paddy leaf disease and provide food for a rapidly growing population. However, recurrent problems with infections, the improper monitoring of rice farmlands, and the regular occurrence of paddy leaf diseases destroy rice yields and result in production losses. Various diseases regularly occur in the paddy leaves, which is the reason for the production loss. Additionally, the overuse of chemicals like bactericides and fungicides in the agro-ecosystem has created conflict in the fight against plant disease [3]. For a sustained production rate, an algorithm is to be designed for predicting paddy leaf characteristics so as to detect leaf diseases. Early predictions of paddy leaf-related infections can help bolster the quality and quantity of rice production. Timely interventions help slow the rapid pace of the disease and maximize the cultivation of healthy rice leaves [4].

Paddy leaf-related disease symptoms are typically distinguished by their texture, colour, and form [5][6][7]. Artificial

intelligence-based automated identification methods are currently recognized as the best for paddy leaf disease recognition. The manual prediction of paddy leaf disease has been shown to be erroneous, expensive, and difficult to predict in advance. The condition is diagnosed far more accurately and simply using computer-based procedures. As a result, an incredible range of diseases have since been identified, the effects of which on leaves are yet to be classified. Computer-based identification methods fail to depict the effects of environmental factors on paddy leaf disease, and offer slow identification speeds as well as inaccurate information metrics. Therefore, detection techniques that identify paddy leaf diseases quickly and accurately through leaf features have been developed to enable the farming community to make appropriate decisions [8][9].

Traditional techniques such as computer vision [10], pattern recognition [11], support vector machines [12][13][14], image processing [15], and convolutional neural networks [16][17][18] have long been used to identify diseased paddy leaves with high detection accuracy and determine results rapidly. A paddy disease detection framework [19] was proposed using features from the affected parts of the leaf, which were selected from trained leaf images and classified using the support vector machine. Additionally, the SVM and Naive Bayes classifiers [20] were applied to test images using three image classes that included healthy leaves, brown spots, and leaf blast lesions. The paddy data set was captured using a Nikon COOLPIXP4 digital camera. The experimental results revealed 79.5% accuracy for the SVM and 68.1% for the Naive Bayes classifiers. The multilayer perceptron method [12] could identify six types of paddy disease, based on the texture and color of paddy images, with 88.56% accuracy. Furthermore, four classes of paddy diseases were identified with high accuracy of 92.5% using the Fractal Fourier Technique. This technique was also used to find four types of rice disease [21].

However, real-time applications of existing techniques across agriculture and other fields often involve the use of small and slow models that are specifically intended for devices with low computational power while identifying disease with good-to-better accuracy. Further, existing techniques lack noise sensitivity and produce reduced classification accuracy. The proposed PaddyNet method identifies paddy diseases quickly and classifies them from visual paddy leaf images based on deep learning models. This system utilizes a feature extraction technique that reduces noise and thereby magnifies the disease spot with no resultant loss of information.

The remaining sections of the paper are organized as follows: Section II reviews the literature on plant disease identification. Section III discusses the materials and methodologies used and describes the real-time paddy dataset in detail in Section III-A. Section IV presents the experimental findings used to determine the performance metrics of the proposed solution. Finally, Section V concludes the paper with directions for future work.

## II. RELATED WORK

Several state-of-the-art outcomes have been analyzed using image processing techniques, including computer vision and artificial intelligence, across different fields of research. The techniques are applied to images to make it easier to resolve image segmentation, feature selection and extraction, and classification using deep learning (DL) [22]. Deep learning, a sub-section of machine learning, is widely used to recognize input image patterns [23][24] by extracting parameters from paddy plant images and examining crop stress. A paddy disease identification approach was used to classify paddy image features using convolutional neural networks [25]. Ten different types of rice disease images were used for the experimental results.

In addition to diagnosing paddy leaf disease, advanced identification techniques have also been used on crops such as wheat [26], brinjal [27], pumpkin [28], tomato [29], and potato [30]. Two approaches were used to diagnose diseased leaves using the GoogLeNet and Cifar10 models [8]. With a focus on detecting disease in maize, the proposed approach achieved 98.9% and 98.8% overall accuracy for the GoogLeNet and Cifar10 models, respectively. On the other hand, the AlexNet model that was used [31] to diagnose apple leaf disease obtained the highest accuracy of 97.62%. In addition, a novel CNN was developed [32][19] to identify cucumber leaf disease with high accuracy of 94.9%. A convolutional neural network technique was used [33] for crop leaf classification to identify leaf disease. From the experimental results, four classes were correctly identified, including a normal leaf class, while the remaining constituted the affected image classes. In all, 100 images for each class were taken for the experiment and the results showed that the model achieved 92.85% overall accuracy. The proposed method obtained accuracy of 99.9%, 91%, 87%, and 93.5%, respectively, for each class [34]. A DCNN was used to diagnose rice diseases and pests. The proposed method considered 1426 images for the experimental results and achieved 93.30% accuracy [35].

The paper [36] used the proposed CNN architecture on three datasets PlantVillage, the Rice Diseases Image Dataset, and the Cassava Leaf Disease Dataset. The method extracts depth features from the images to reduce the computation cost and define the number of parameters applied on the model. This work obtained the highest performance accuracy for all three data sets. The proposed approach used deep ensemble neural networks [3] to diagnose 14 different types of crop diseases with 14 classes. The images were pre-trained using seven deep learning models such as the ResNet50, ResNet101, InceptionV3, DenseNet121, DenseNet201, MobileNetV3, and NasNet. The proposed ensemble model achieved higher accuracy than the other pre-trained models.

It is concluded from a study of the literature above that much of the research on diseased leaf detection employed deep learning methods to train the classifier models for high accuracy. This paper proposes a PaddyNet neural network model for improved leaf detection classification accuracy. The proposed model uses a large number of data images for training and testing, and classifies the images efficiently into their respective classes with high accuracy. Also, to maximize the performance of the PaddyNet model, an optimizer is developed alongside to produce optimal results. As a result, the PaddyNet deep learning model offers significant improvements overall in terms of the accuracy of paddy leaf detection classification. Real paddy plant leaf images were collected from paddy fields, using a smartphone camera, to validate the proposed PaddyNet deep learning model. The proposed approach addresses the problem of paddy disease classification and its automated identification.

## III. MATERIALS AND METHODS

Fig. 1 represents an overview of the innovative method employed for paddy leaf disease classification. An improved novel algorithm called PaddyNet is proposed to extract leaf image features and classify diseased leaf images much more accurately. The proposed method includes the three steps of dataset collection, data preprocessing, and augmentation. In the first step, dataset collection, paddy leaves are gathered from actual paddy fields. In the second step, data preprocessing, duplicate images are deleted. In the third step, augmentation, each paddy image is annotated with the help of specific agricultural officers. In addition, suitable image augmentation techniques are used to expand the data. During the data splitting stage, the final cleaned data is divided into train, validate, and test subsets, following which the proposed PaddyNet model is trained utilizing the train and validation sets for the model development process. Finally, the results are evaluated after the PaddyNet model is trained and validated using performance metrics and confusion matrices on the test set of paddy leaf images.

### A. Data Collection and Annotation

Visual images of paddy leaves were captured using the CAT S62 Pro smartphone in Tirunelveli district of Tamil Nadu, India [37]. Initially, more than 25,000 images were collected from the data set. Every sample was examined carefully and redundant data such as noisy and out-of-focus images were removed. Finally, following the cleaning process, 16,225 images were chosen with the assistance of agricultural officers. The cleaned images were labeled into 12 disease categories and 1 healthy category. Further, metadata on the age and type of paddy were collected as well [38] and the Paddy Doctor Dataset data gathered and annotated. The procedures used are shown in Fig. 2.

### B. Image Augmentation

Image augmentation in image analysis enhances both the quantum of data available and the performance of the model. This is done by generating image categories that reduce overfitting issues and enhance the model's ability for interpretation during the training phase. By applying different image data augmentation techniques, for instance, many more paddy leaf

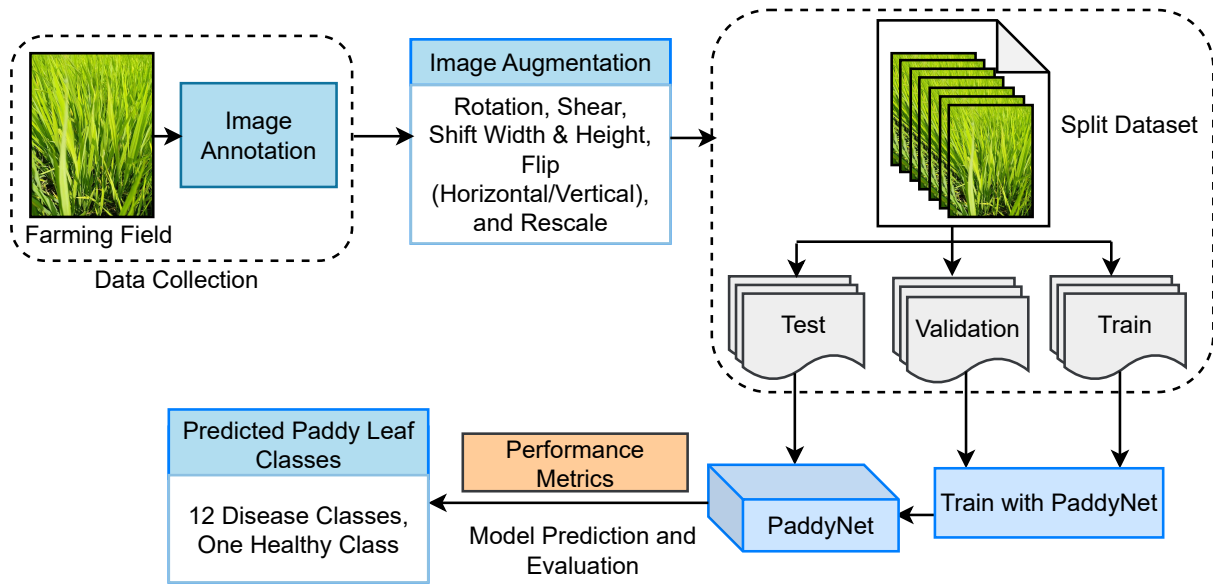

Fig. 1. An overview of the methodology for paddy disease classification using PaddyNet model.

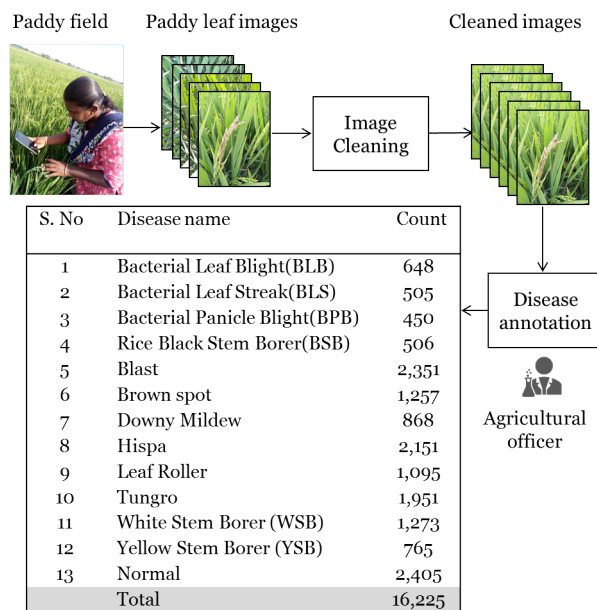

Fig. 2. Data collection and annotation process.

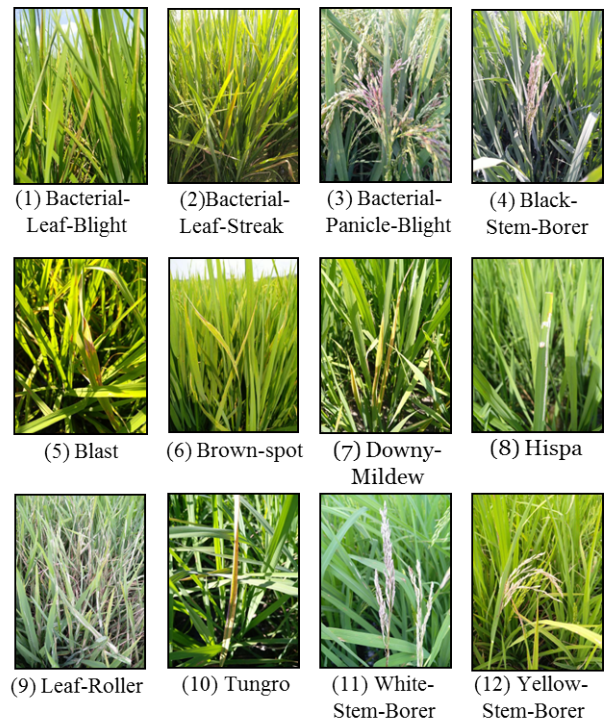

Fig. 3. Sample paddy disease images in our dataset.

images can be generated by varying image orientation and size. Common data augmentation operations include random rotation, width and height shift, horizontal and vertical flip, shear, fill mode, and rescale. Sample pictures of leaves with 12 different diseases are shown in Fig. 3.

### C. PaddyNet Model Architecture

The proposed PaddyNet model has 17 layers. Using visual images, the CNN model identifies paddy leaf disease. The proposed model has five requisite components: a convolutional layer, a pooling layer, a dense layer, a flatten layer, and an

activation function. A brief discussion of the five components follows below.

1) *Convolutional layer*: This the primary and first block of a CNN model. The proposed PaddyNet model uses seven conv2D layers. In the convolutional block, the convolution operation extracts related features from the input paddy image. To perform convolution operations using backpropagation, the model is trained using backpropagation [34] and its weight

updated, based on the error rate revealed during the preceding iteration. Forward propagation is marked by movement from the origin layer to the destination layer in the network. The loss is obtained at the end of the network, using the loss function to avoid the error. Equations (1-5) are used to calculate the convolution layers [36]. Seven 2D convolutional layers are added using Conv2D in the model. Forward propagation calculates  $Z$  based on the input value ( $X_{(i+r)(j+s)}^{[k]}$ ), weight value ( $W_{rs}^{[k]}$ ), and ( $p = i + r, q = j + s$ ).

$$Z = \sum_{j=0}^n W_{rs}^{[k]} X_{(p)(q)}^{[k]} \quad (1)$$

$$Y_{ij}^{[k]} = \sum_{i=0}^m Z + b^{[k]} \quad (2)$$

Back Propagation: to calculate the error function ( $C$ ) based on the predicted value ( $Y_{ij}^{[k]}$ ) and actual value ( $Y_{act}$ ).

$$C = (Y_{ij}^{[k]} - Y_{act})^2 \quad (3)$$

To calculate error function for weight ( $\partial W_{rs}^{[k]}$ ).

$$\frac{\partial C}{\partial W_{rs}^{[k]}} = \sum_{i=0}^{p-m} \sum_{j=0}^{q-n} \frac{\partial C}{\partial Y_{ij}^{[k]}} \frac{\partial Y_{ij}^{[k]}}{\partial W_{rs}^{[k]}} \quad (4)$$

To calculate error function for bias ( $\partial b^{[k]}$ )

$$\frac{\partial C}{\partial b^{[k]}} = \sum_{i=0}^{p-m} \sum_{j=0}^{q-n} \frac{\partial C}{\partial Y_{ij}^{[k]}} \frac{\partial Y_{ij}^{[k]}}{\partial b^{[k]}} \quad (5)$$

2) *Pooling layer*: When the feature in the image is too large, the convolutional lock employs the max pooling layer to minimize the feature map. The model uses seven max pooling layers. The three pooling layers - max, average, and sum pooling have the benefits of quick computing, limiting overfitting, and using little memory. Max pooling is applied here to determine the highest values from each region of the feature map using formulas 6 and 7. Seven 2D max pooling layers are added using MaxPooling2D in the model.

$$Y_{ij} = (0, X_{pq}) \quad (6)$$

$$\frac{\partial C}{\partial X_{pq}} = \frac{\partial C}{\partial Y_{ij}^{[k]}} \frac{\partial Y_{ij}^{[k]}}{\partial X_{pq}} \dots \left\{ \begin{array}{l} \frac{\partial C}{\partial Y_{ij}^{[k]}} \quad (Y_{ij}^{[k]} = X_{pq}) \\ 0 \quad \text{otherwise} \end{array} \right\} \quad (7)$$

3) *Flatten*: Following the application of the pooling layer, the complete matrix of generated feature maps is converted into a single volume using the flatten layer. The final fully connected neural network receives and classifies it.

4) *Fully connected layer*: Two fully connected layers are used after the flattening layer. The output of the previous layer is fed in the form of values to the last dense layer to decide which features mostly match a class. When calculating the product of the weights, a fully linked layer yields precise probabilities for the different paddy classes. The outputs are categorized using the softmax activation function.

5) *Activation function*: The softmax function  $S(Z)_i$  [39] is utilized to predict the 13 classes shown in Equation (9). Additionally, the ReLU activation function [40] employed as depicted in Equation (8) provides demonstrably high accuracy with max pooling2D:  $j = 1 \dots k$  and  $z = (z_j \dots z_k)$ .

$$ReLU(x) = (0, x) \quad (8)$$

$$S(Z)_i = \frac{e^{Z_i}}{\sum_{j=1}^k e^{Z_j}} \quad (9)$$

The proposed PaddyNet model architecture is shown in Fig. 4. The model has seven convolutional layers which include batch normalization, ReLU, max pooling2D layers, two dense connected layers, and a 13-way softmax activation in the output. In order to reduce data overfitting in each convolution block and the fully connected layer, a “dropout” method is used. The max pooling2D layer helps reduce the parameters used and surpasses average pooling in terms of performance. The Adam optimizer is used to reduce the loss as efficiently as possible and train the PaddyNet model in little time. The CNN model combines all the layers to obtain the highest accuracy. The novel model is trained and compared using several dropout values ranging from 0.2 to 0.8.

The biggest challenge of all in building the proposed PaddyNet model lay in combining all the layers, features, and optimizer values to offer excellent prediction performance. The novel model is tested by adding more layers, altering activation functions, and changing the optimizer values. While categorising 10 distinct categories, for instance, a basic 13-layer CNN model produced 88.84% accuracy. Next, the addition of an extra conv2D layer, maxpool2D, batch normalization, dropout, and activation to our 17-layer PaddyNet model resulted in 98.99% accuracy in identifying the 13 classes.

## IV. EXPERIMENTAL RESULTS

### A. Experimental Setup

We implemented the proposed PaddyNet model using Keras and TensorFlow. All experiments were conducted on the Kaggle platform with GPU kernels to improve computational performance. The list of hyperparameters used in our experiments is shown in Table I. In addition, batch size values of 32, 64, 100, and 160 were used, along with a learning rate of 0.0001. The dropout was varied from 0.2 to 0.8, and the epoch values were 25, 50, 75, 100, 125, 150, 175, and 200. Additionally, the performance of the proposed PaddyNet model was compared to that of five models (the DCNN, Xception, MobileNet, ResNet34, and VGG16), using five performance metrics [41]. The weights of the models, except the DCNN, were initialized based on ImageNet.

### B. Results and Discussion

Table II and Fig. 5 show that the PaddyNet model’s scores for all measures increase proportionately with the epoch. Epoch 200 produced the highest performance in terms of 98.99% accuracy, 98.5% precision, 98.65% recall, and 98.2% F1 score, respectively. Table III and Fig. 6 compare the accuracy of the PaddyNet model to five existing models.

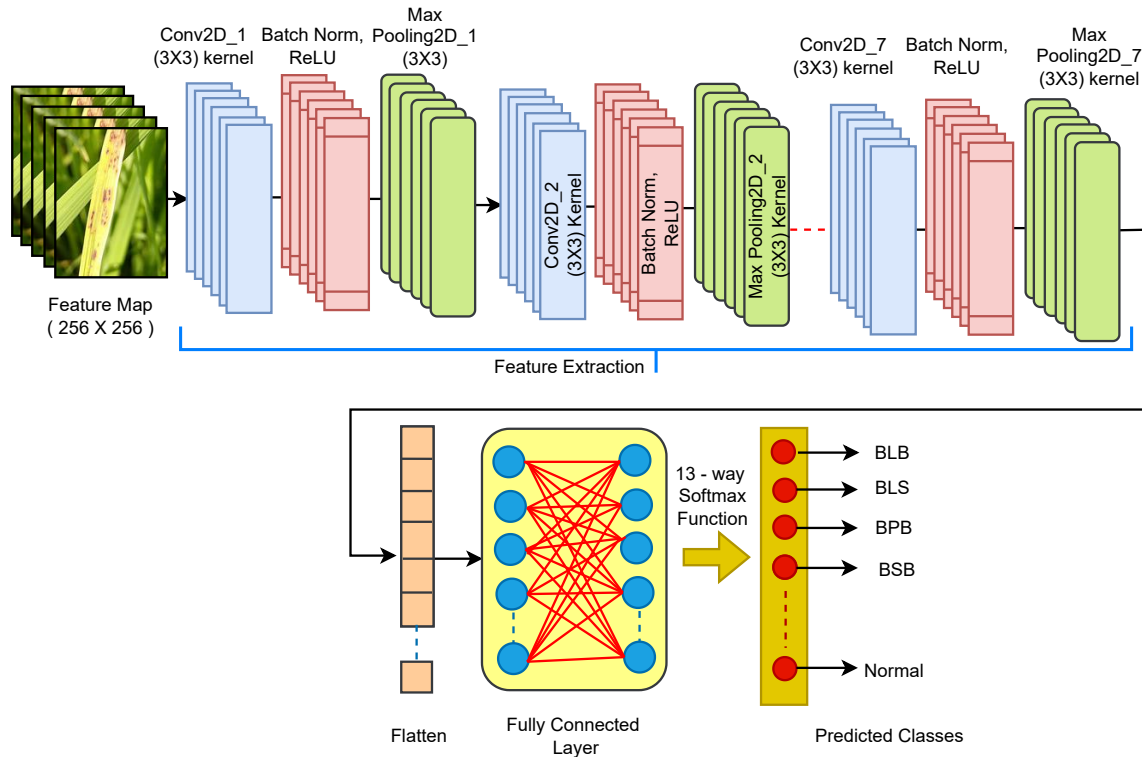

Fig. 4. PaddyNet model architecture.

TABLE II. COMPARISON OF PERFORMANCE METRICS OF PADDYNET MODEL WITH DIFFERENT EPOCHS

Epoch	Accuracy	Precision	Recall	F1 Score
25	78.31	66.57	67.56	72.65
50	90.95	88.97	85.63	89.2
75	92.42	90.51	89.65	88.67
100	94.05	92.88	91.71	92.88
125	96.23	93.89	95.27	95.27
150	97.24	96.91	95.88	96.85
175	97.53	97.20	96.92	97.10
<b>200</b>	<b>98.99</b>	<b>98.50</b>	<b>98.65</b>	<b>98.2</b>

The PaddyNet model achieved the highest score, followed by Resnet34 [42][41], with 97.50% accuracy, 97.52% precision, 97.50% recall, and F1 score of 97.50%. The simple DCNN [42][41] model performed poorly with 88.84% accu-

racy, 89.22% precision, 88.84% recall, and 88.81% F score. Fig. 7 compares the performance of PaddyNet, based on five different dropout values (0.2, 0.4, 0.5, 0.6, and 0.8). The highest performance accuracy was achieved with a dropout probability of 0.4. Network weights were updated, firstly, to boost the accuracy of error estimation when training PaddyNet and, secondly, to improve efficiency. Fig. 8 compares the performance of different PaddyNet batch sizes in terms of accuracy.

Table IV and Fig. 10 show that the proposed PaddyNet model has the highest misclassification image count of 11 for the leaf blast disease class and the lowest of 1 for the BLS, BPB, yellow stem borer, and normal classes. When dealing with 13 paddy leaf disease classes, the complexity of the infected paddy images was likely to have confused the classifiers, leading to a diminished performance being displayed in the same class. A confusion matrix of the final test results is shown in Fig. 9.

When dealing with 13 classes of paddy leaf diseases, classifiers may be confused due to the complexity of infected paddy images, leading to a less performance are displayed in the same class. The final test results confusion-matrix for the paddy leaf classes is shown in Fig. 9, with correctly predicted values located along the diagonal and incorrectly predicted values located elsewhere. The confusion matrix indicates that the PaddyNet model is more successful at distinguishing certain paddy diseases, such as leaf blast, than others. The number of correctly identified test samples is 128 images in BLB, 99 images in BLS, 89 images in BPB, 94 images in black stem borer, 459 images in leaf blast, 244 images in brown spot, 168

TABLE III. ACCURACY COMPARISON OF OUR PROPOSED PADDYNET MODEL WITH EXISTING MODELS

S.No	Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
1	DCNN [41]	88.84	89.22	88.84	88.81
2	MobileNet [41]	92.42	92.63	92.42	92.39
3	VGG16 [41]	93.19	93.49	93.19	93.20
4	Xception [41]	96.58	96.61	96.58	96.57
5	Resnet34 [41]	97.50	97.52	97.50	97.50
<b>6</b>	<b>PaddyNet</b>	<b>98.99</b>	<b>98.50</b>	<b>98.65</b>	<b>98.2</b>

TABLE IV. MISCLASSIFICATION IMAGE COUNT FOR EACH CLASS OF PROPOSED PADDYNET MODEL

S.No.	Disease or class name	Count	PaddyNet	Resnet34	Xception	VGG16	MobileNet	DCNN
1	BLB	130	2	3	5	11	20	24
2	BLS	100	1	2	3	4	14	7
3	BPB	90	1	3	4	12	9	18
4	Black-Stem-Borer	101	7	9	9	13	10	10
5	Blast	470	11	13	13	30	27	57
6	Brown Spot	253	9	10	18	20	21	43

## V. CONCLUSION

Deep learning, a fairly recent and advanced method driving agricultural growth and development, has demonstrated that it surpasses others at identifying plant disease. Advanced computer vision technology is prompting further research worldwide in paddy leaf disease identification using different methodologies. The PaddyNet model proposed in this research detects paddy leaf disease efficiently. The infected paddy leaf image dataset includes images of healthy leaves alongside images of leaves depicting twelve different diseases. The identification process of the proposed system was improved through the use of our own collection of previously acquired paddy leaf images. Further, the collected dataset was enhanced using several image augmentation techniques to enrich the model and benchmarked using the proposed PaddyNet model. The experimental results reveal that the proposed PaddyNet outperformed the other five deep learning models, such as the simple DCNN, VGG16, MobileNet, Xception, and Resnet34 [42][41]. The PaddyNet model demonstrated superior performance with 98.99% accuracy, 98.50% precision,

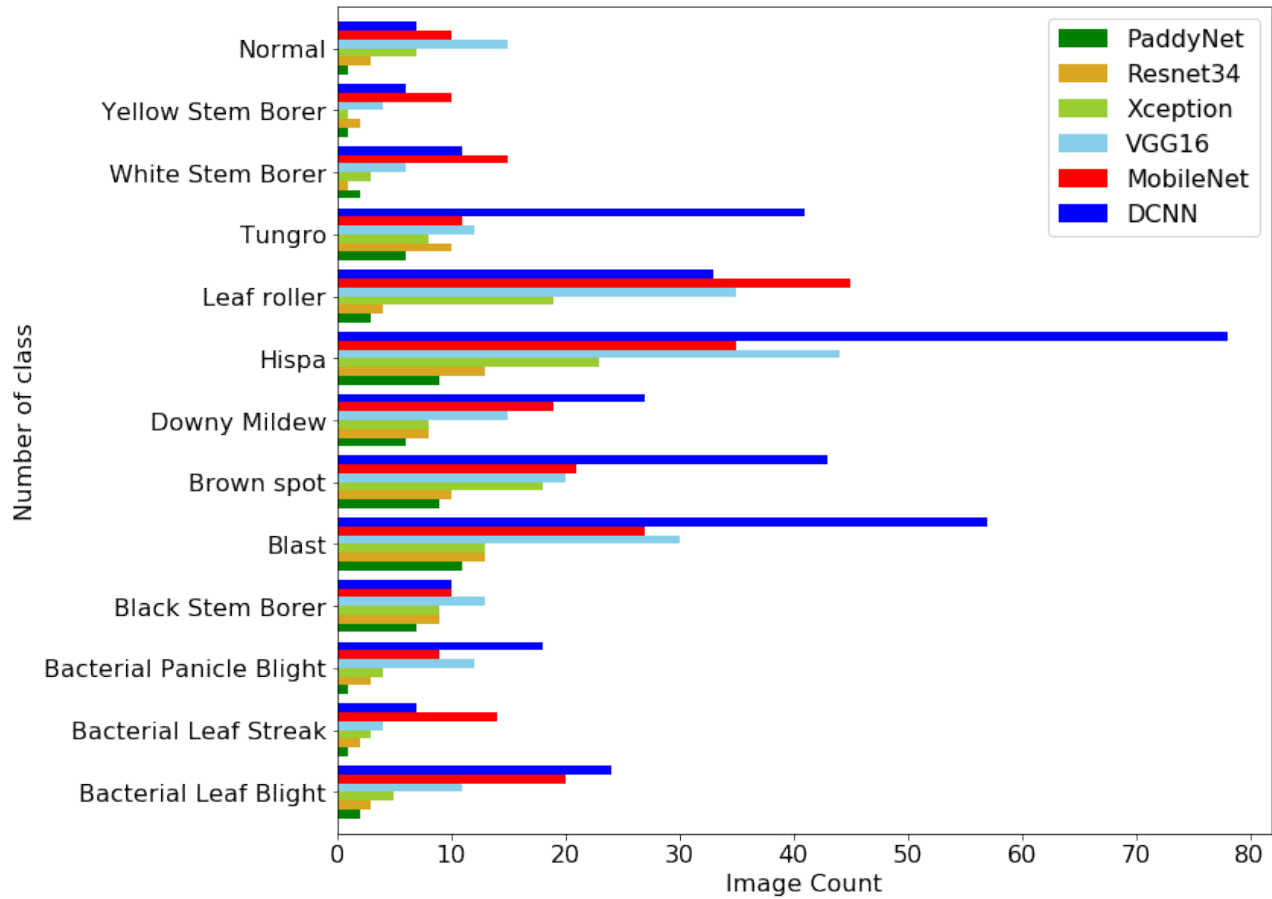

Fig. 10. Comparison of misclassification image counts for each class of PaddyNet and other five models.

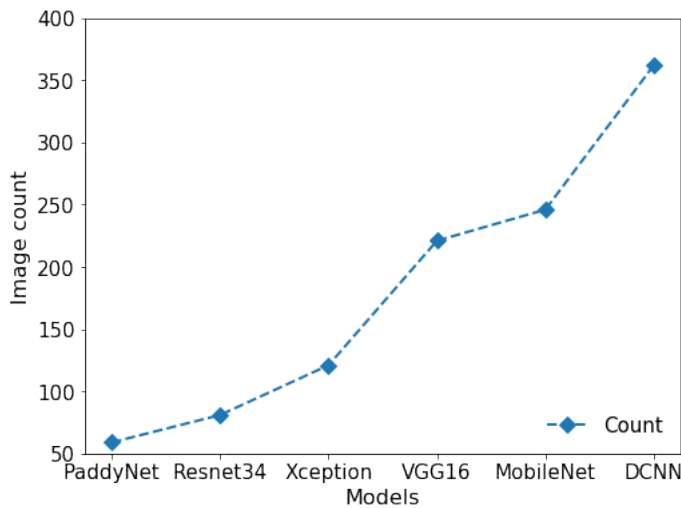

Fig. 11. Count of misclassification images for each model. In the PaddyNet model, only fewer images are not classified compared with the five models.

98.65% recall, and an F1 score of 98.20%, compared to the five state-of-the-art deep learning models. In the future, the proposed PaddyNet paradigm will be extended as a mobile phone application incorporating a deep learning model for

using farmers in real-time in their paddy fields. Next, we plan to capture real-time images taken by farmers in their fields and identify leaf disease instantaneously through the said mobile app.

**Abstract**—On one hand, the emergence of cutting-edge technologies like AI, Cloud Computing, and IoT holds immense potential in Smart Farming and Precision Agriculture. These technologies enable real-time data collection, including high-resolution crop imagery, using Unmanned Aerial Vehicles (UAVs). Leveraging these advancements can revolutionize agriculture by facilitating faster decision-making, cost reduction, and increased yields. Such progress aligns with precision agriculture principles, optimizing practices for the right locations, times, and quantities. On the other hand, integrating UAVs in Smart Farming faces obstacles related to technology selection and deployment, particularly in data acquisition and image processing. The relative novelty of UAV utilization in Precision Agriculture contributes to the lack of standardized workflows. Consequently, the widespread adoption and implementation of UAV technologies in farming practices are hindered. This paper addresses these challenges by conducting a comprehensive review of recent UAV applications in Precision Agriculture. It explores common applications, UAV types, data acquisition techniques, and image processing methods to provide a clear understanding of each technology's advantages and limitations. By gaining insights into the advantages and challenges associated with UAV-based applications in Precision Agriculture, this study aims to contribute to the development of standardized workflows and improve the adoption of UAV technologies.

**Keywords**—Artificial intelligence; internet of things; sensor; big data; cloud; unmanned aerial vehicle; smart farming

## I. INTRODUCTION

The agriculture industry is currently undergoing a significant transformation fueled by cutting-edge technologies, offering promising prospects for enhanced farm productivity and profitability. Precision Agriculture, which focuses on the precise application of inputs where and when they are needed, represents the third stage of the modern agricultural revolution. Advanced farm knowledge systems, empowered by the abundance of data, have further propelled the evolution of Precision Agriculture [1]. Numerous studies have demonstrated the positive impacts of adopting Precision Agriculture technologies, such as increased net returns and operating profits, as reported by the U.S. Department of Agriculture (USDA) [2]. Moreover, there is a growing emphasis on implementing these technologies in environmentally conscious ways to ensure sustainable farm production. However, effectively harnessing the vast amount of data generated by crops remains a persistent challenge [3].

To address these challenges, it is crucial to explore and integrate cutting-edge technologies in the realm of Smart Farming and Precision Agriculture. Unmanned Aerial Vehicles (UAVs), Cloud Computing, Internet of Things (IoT), Big Data

analytics, and Artificial Intelligence (AI) have emerged as key enablers of innovation in this domain [4]. UAVs equipped with advanced sensors and imaging capabilities allow for real-time data collection, including high-resolution imagery of crops. Cloud Computing provides the infrastructure for data storage, processing, and analysis, while IoT facilitates the seamless integration of various agricultural devices and sensors. Big Data analytics and AI techniques enable intelligent insights and decision-making based on the collected data [5], [6].

This paper aims to delve into the theoretical background and related work of UAV, Cloud, IoT, Big Data, and AI approaches in Smart Farming and Precision Agriculture. Additionally, authors propose a comprehensive systematic review study that investigates the current state of research and development in this area. By analyzing existing literature, in order to identify the gaps, challenges, and opportunities for utilizing these technologies in the context of Smart Farming and Precision Agriculture, Fig. 1, depicted below, offers valuable insights into the evolution characteristics and challenges of agricultural development, spanning from Farming 1.0 to Farming 5.0. This figure serves as a valuable tool to showcase the effective utilization and evolution of technologies within the realms of Smart Farming and Precision Agriculture. The problem statement of this study revolves around the lack of a standardized framework for leveraging UAVs, Cloud Computing, IoT, Big Data, and AI in Smart Farming and Precision Agriculture. This lack of standardization hinders the widespread adoption and implementation of these technologies, limiting their potential benefits for farmers, agricultural productivity, and sustainable practices. To address this problem, our proposed solution is to conduct a systematic review that synthesizes existing research, identifies key insights, and provides recommendations for the development of standardized frameworks and practices in this field.

The motivation behind this work stems from the immense potential of integrating UAVs, Cloud Computing, IoT, Big Data analytics, and AI in Smart Farming and Precision Agriculture. By leveraging these technologies effectively, farmers can make faster and more informed decisions, reduce costs, optimize resource utilization, and increase yields. Moreover, this integration aligns with the growing demand for sustainable farming practices and the need to meet the rising global food demands. The contribution of this paper lies in the comprehensive review of existing literature, which consolidates knowledge, identifies research gaps, and proposes recommendations for the future development of Smart Farming and Precision Agriculture. By providing insights into the theoretical foundations, related work, problem statement, proposed solution, and motivation,

Fig. 1. Characteristics and challenges of agricultural development (from Farming 1.0 to Farming 5.0).

in order to advance the understanding and adoption of UAVs, Cloud Computing, IoT, Big Data analytics, and AI in the agricultural domain.

This paper is structured as follows. Firstly, Section 1 presents the theoretical background of UAV, Cloud, IoT, Big Data and AI approaches. Afterwards, current technical components of Smart farming and precision agriculture in the research area are specified. Within this section, a more in-depth reflection is carried out on the rising of AI and IoT in smart farming. Secondly, Section 2 describes the detailed process steps of the systematic review and the defined research methodology of this study. Then, Section 3 summarizes the research results. Section 4 describes the discussion with challenges and future directions of this research study. Finally, a conclusion is presented in the last section of this paper.

## II. BACKGROUND

### A. Unmanned Aerial Vehicles for Agriculture

Unmanned Aerial Systems (UAS), also known as drones, have become increasingly popular in agriculture due to their ability to provide a quick, cost-effective and efficient way to gather data and perform tasks on large fields and crops [7]. UAS (Unmanned Aerial Systems) indeed come in different types and can be equipped with a variety of sensors and cameras presented in Fig. 2 that can capture high-resolution images, aerial maps and thermal imagery, which can be used for a range of agriculture applications, including:

- Crop monitoring: UAS can be used to gather real-time data on crop health, growth, and yield potential.
- Irrigation management: Drones can be equipped with infrared cameras to identify areas that are in need of irrigation and to help optimize water use.

- Pest and disease management: Drones can be used to detect and map the spread of pests and diseases in crops, helping farmers to take timely action to prevent or treat these issues.
- Field mapping: UAS can produce high-resolution maps of fields, providing data on soil structure, topography, and plant populations, which can be used to make informed decisions about planting, fertilization and other aspects of crop management.
- Livestock management: Drones can be used to monitor the health and behavior of livestock, as well as to keep track of the location of animals.

Overall, the use of UAS in agriculture provides a new tool for farmers to gather data, monitor their crops and make more informed decisions, ultimately leading to improved yields, increased efficiency and reduced costs.

### B. Cloud, Internet of Things, Big data and IA

1) *Cloud*: computing plays a crucial role in smart farming, which is an application of the Internet of Things (IoT) in agriculture. The cloud enables farmers to store, process, and analyze large amounts of data generated from various IoT devices and sensors on their farms [9]. This data can include information on weather patterns, soil moisture levels, crop growth, and even the health of livestock. By analyzing this data in real-time, farmers can make more informed decisions about crop management and animal husbandry, leading to increased productivity and efficiency.

Additionally, cloud-based solutions can provide farmers with access to advanced algorithms and predictive analytics tools that can help them optimize their farming operations. For example, cloud-based machine learning models can predict

Fig. 2. Different types of agricultural UAVs (Harvesting UAV, Spraying UAV, Mapping UAV, Sensing UAV) [8].

crop yields, identify pest infestations, and suggest the most appropriate treatments. Furthermore, the cloud allows farmers to monitor their farms remotely and receive real-time updates on conditions and activities.

2) *Internet of Things*: The concept of the Internet of Things (IoT) pertains to a network comprising physical devices, vehicles, appliances, and various objects. These entities are equipped with sensors, software, and connectivity features that empower them to gather and exchange data via the internet. These connected devices can communicate and interact with each other, as well as with humans, creating a vast ecosystem of interconnected systems [10]. The IoT has the potential to revolutionize various sectors, including agriculture, healthcare, transportation, smart homes, and many others, by enabling increased automation, efficiency, and data-driven decision-making. In smart farming, IoT is used to gather real-time data from various sources such as weather stations, soil moisture sensors, and crop and animal monitoring systems.

IoT devices and sensors in smart farming can range from simple weather sensors to more complex systems such as precision agriculture systems that use Global Positioning System (GPS) to monitor the growth and health of crops. These devices can also be connected to irrigation systems, allowing farmers to control the amount of water they use based on real-time soil moisture levels. One of the key benefits of IoT in smart farming is that it enables farmers to make data-driven decisions in real-time. This leads to more efficient use of resources and improved crop yields. IoT also enables farmers to monitor their farms remotely, reducing the need for on-site visits and freeing up more time for other tasks.

In addition to its direct benefits, IoT in smart farming can also help address important global challenges such as food security and sustainability [11]. By using technology to optimize their operations, farmers can produce more food using fewer resources, reducing their carbon footprint and helping to ensure that future generations have access to safe and healthy food. Overall, the Internet of Things is revolutionizing the way farming is done and is poised to play a crucial role in the future

of agriculture.

Wireless Sensor Networks (WSNs) are networks of small, low-cost, and low-power devices that can be used to monitor and collect data from the environment [12]. These devices, called “nodes”, are equipped with sensors, microcontrollers, and wireless communication capabilities, allowing them to transmit data wirelessly to a central location for analysis.

WSNs are widely used in a variety of applications, including smart farming, where they are used to monitor soil moisture, temperature, light, and other environmental parameters that affect crop growth [13]. The data collected by the sensor nodes can be used to make informed decisions about irrigation, fertilization, and other agricultural practices, leading to increased efficiency and higher crop yields.

One of the key benefits of WSNs is that they are low-cost and easy to deploy, making them accessible to farmers of all sizes and resources. They are also scalable, allowing farmers to add more nodes as their needs grow [14]. Finally, a review of 77 research papers published between 2012 and 2022 on the implementation of IoT in various agricultural applications showed that roughly 16% focused on precision agriculture and the same percentage on irrigation monitoring. 13% of the papers delved into soil monitoring, while temperature and animal monitoring were each covered in 11% of the research. Air and disease monitoring each received 5% of attention, with water monitoring accounting for 7%. Fertilization monitoring was the least studied, with only 4% of the research papers devoted to it in [15].

### C. Big Data

Big Data plays a significant role in the context of smart farming. Smart farming involves the application of advanced technologies, such as sensors, Internet of Things (IoT) devices, and data analytics, to enhance agricultural practices and decision-making processes [16]. These technologies generate vast amounts of data from various sources, including weather conditions, soil moisture levels, crop health indicators, and machinery performance.

Big Data analytics allows for the collection, storage, processing, and analysis of large volumes of agricultural data in real-time or near-real-time. By applying advanced analytics techniques, such as machine learning and predictive modeling, valuable insights can be extracted from this data. These insights can help optimize farming practices, improve resource allocation, enhance crop yield, and enable more informed decision-making for farmers and agricultural stakeholders [17]. Furthermore, Big Data analytics can enable predictive capabilities in smart farming. By leveraging historical data and machine learning algorithms, models can be developed to forecast disease outbreaks, pests infestation, crop yield, and market demand. These predictive insights empower farmers to make proactive decisions, mitigate risks, and optimize resource allocation. In summary, the integration of Big Data analytics in smart farming allows for data-driven decision-making, optimization of agricultural practices, and the potential for increased productivity, sustainability, and profitability in the agriculture industry [18], [19].

#### *D. Artificial Intelligence*

Artificial Intelligence (AI) encompasses the creation of computer systems capable of executing tasks typically requiring human intelligence, including pattern recognition, prediction, and learning from experience. In smart farming, AI is used to automate various processes and make more informed decisions [16]. One of the key applications of AI in smart farming is precision agriculture, where AI algorithms are used to analyze data from various sources, such as weather stations and sensors, to determine the best practices for growing crops. For example, AI can be used to optimize irrigation and fertilization practices, leading to increased efficiency and higher yields. AI can also be used in animal husbandry to monitor the health and behavior of livestock. Also, AI algorithms can be used to detect signs of illness in animals, such as changes in their heart rate or behavior, and alert farmers to take action. Another application of AI in smart farming is in the detection and control of pests and diseases. AI algorithms can be used to analyze images of crops and detect signs of pests or diseases, allowing farmers to take proactive measures to address them. In conclusion, AI is a valuable tool in the development of smart farming, enabling farmers to make more informed decisions and automate various processes [20]. By using AI, farmers can improve efficiency, increase yields, and reduce waste, making a valuable contribution to the future of agriculture. However, it's important to note that while AI has the potential to greatly benefit the agriculture industry; it also presents challenges, such as the need for large amounts of data and the potential for bias in algorithms. Thus, it's important to approach the integration of AI in smart farming with caution and a focus on ethical and sustainable practices.

### III. METHODOLOGY

In recent years, the academic community has extensively analyzed numerous works related to smart farming development from various perspectives. For instance, [21] introduced a systematic review focusing on precision farming. Then, authors in [22] provided a review on technologies in precision agriculture, highlighting innovations, technologies, and applications. Also, authors in [23] explored the use of big data on smart

farming, emphasizing the primary opportunities and challenges associated with this technology. Additionally, [24] conducted a quantitative literature review, offering an overview of academic production in smart farming.

In order to enhance the existing analyses, the present study seeks to conduct a comprehensive review of UAV based applications in the field of smart farming. To accomplish this objective, we employed the Preferred Reporting Items for Systematic Reviews (PRISMA) methodology [25], a framework specifically designed to facilitate literature reports and systematic reviews. In October 2022, authors conducted a search using the available search tool on the Scopus database website. Additionally, another search was performed in April 2023 within the same database to include papers published in the year 2023. Scopus was selected due to its extensive coverage and relevance in similar bibliographic reviews mentioned in [24] and [26]. Our search strategy focused on terms related to technological applications in agriculture, such as "Precision Agriculture," "Precision Farming," "Smart Farming," and "Smart Agriculture," in conjunction with "UAV" and related terms. The publication date of articles was not a basis for exclusion. However, we restricted our research scope to journal and conference articles published in English. To ensure methodological rigor, this systematic review adhered to the guidelines outlined in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), with the most recent version being 2020. In Table I, you will find a compilation of the research questions (RQ) that the Systematic Literature Review (SLR) aims to address.

In this paper, a systematic literature review (SLR) was conducted to assess recent research papers on the use of IoT, Big data, Cloud & AI techniques in the field of Smart farming. However, advancements in technology and the increasing availability of digital resources have led to the development of new systematic review process, but the traditional systematic literature review methodology remains the standard approach for conducting systematic reviews, new tools and techniques are emerging that can enhance the process and provide additional benefits to researchers and decision-makers. However, it is important to consider the limitations of these new approaches and to ensure that the results of the systematic review remain reliable and trustworthy. The following are the steps involved in the systematic literature review methodology: In this context, lookup has produced a plethora of SLR standards that should be observed to reap tremendous empirical research. In this paper, we concentrate on the SLR guidelines proposed by authors in [19], which can be classified into the following categories. There are four steps:

- Step 1: Identifying the research goal(s).
- Step 2: Research subject framing (conceptual boundaries).
- Step 3: Using inclusion/exclusion criteria to collect data.
- Step 4: Validation of the research findings is the fourth step.

TABLE I. RESEARCH QUESTIONS OF THE STUDY

Number	Research Question (RQ)
RQ1	What are the various applications of UAVs in Precision Agriculture?
RQ2	Which crops are monitored by UAV systems?
RQ3	How can UAV-based technologies be adapted for use in different types of crops or farming environments?
RQ4	What types of data can be obtained through the use of UAVs?
RQ5	Which methods of data processing can be employed to analyze the agricultural data collected by UAVs?
RQ6	What are the challenges associated with using drones for disease detection in agriculture?
RQ7	What are the potential ethical and legal implications associated with the use of drones in agriculture, and how can these issues be addressed?

### A. Research Objectives

This study attempts to systematically analyze possible future possibilities for IoT, Cloud, Big Data and AI in Smart Farming by analyzing current knowledge and the state of the research, with a focus on recent research advancements. This paper is interested in learning how this study topic has changed throughout time. Furthermore, the outcomes of the evaluation will be utilized to identify critical activities for future study as well as practical applications.

### B. Framing of the Research Subject

The goal of this study is to evaluate Big Data, Cloud, internet of things, artificial intelligence technologies for Smart Farming in a systematic way. As a result, the research subject, i.e. the conceptual boundaries, were defined in the agriculture environment using the terms “Unmanned Aerial Vehicle”, “Big Data”, “Cloud”, “internet of things”, “artificial intelligence” and related concepts “machine learning” and “deep learning.” The following Table II displays the Inclusion and exclusion criteria identified to refine the search request.

### C. Data Collection by Using Criteria

A definition of search parameters, databases, search keywords, and publication time is also required by the SLR. The selection of search resources and the choice of search phrases are both part of the search strategy. To find the papers, automated search engine from the most relevant sources were chosen: Scopus. A further examination of similar databases (ACM Digital Library and Emerald) revealed significant variations in the research studies that resulted. As a result, Scopus was used as the primary database for secondary data evaluation in this research study. The systematic research approach [24] and the inclusion and exclusion criterias, which are based on the process query depicted in Fig. 3.

Screening the article title, abstract, and keywords for relevant literature for Blockchain, IoT and AI in the subject areas of management was the first step. We included a variety of document formats in this stage and limited them to the English language. This first method was mostly utilized to obtain a sense of where research was at the time. As a result, the study was not limited intially to a specific period. In total, 536 studies were found as a result of this method. We concentrated on studies in the areas of Smart Farming and Precision Agriculture in the second step. As a consequence, we narrowed down the previously identified 536 publications to 186 papers that contained the terms Smart Farming or Precision Agriculture.

TABLE II. INCLUSION CRITERIA (IC) AND EXCLUSION CRITERIA (EC).

Number	Question
IC1	Paper published in a peer reviewed scientific journal
IC2	Works published in English
IC3	Articles on Computer Science Subject Area
IC4	Keywords on Agriculture, Unmanned Aerial Vehicles, Machine Learning
EC1	Reviews, conference papers, conference reviews, letters, books, book chapters and editorials are excluded from this study
EC2	Works that do not provide enough information on the methodology adopted and that do not report their results in a clear way are excluded.
EC3	Articles whose full text is not available are excluded

TABLE III. QUALITY ASSESSMENT QUESTIONS

Number	Question
Q1	Have the study's objectives been effectively communicated and defined?
Q2	Is the scope and context of the study clearly outlined and appropriately described?
Q3	Has the proposed solution been thoroughly explained and supported by empirical evidence?
Q4	Do the variables utilized in the study demonstrate both validity and reliability?
Q5	Is the research process adequately documented and transparent?
Q6	Have all the research questions been adequately addressed?
Q7	Are any negative findings presented or discussed within the study?
Q8	Are the main findings clearly stated, emphasizing credibility, validity, and reliability?

Furthermore, we created a ranking of all detected keywords, which was utilized to verify the meta-search query for the current database investigation. In our research strategy, no important terms were left out. To evaluate only high-quality studies, the study was limited to conference papers, conference reviews, articles, or reviews in the third step. In conclusion, the final meta-search query was as follows:

**Research Query :** (“UAV” OR “Unmanned Aerial Vehicle”) AND (“Machine Learning” OR “Deep Learning”) AND (“IoT technology” OR “IoT” OR “Internet of Things” OR “internet-of-things”) AND (“Smart Farming” OR “Smart Agriculture” OR “Precision Farming” OR “Precision Agriculture”) AND (“Cloud Computing”).

The chosen papers were evaluated using eight quality assessment questions listed in Table III [27]. Scores of 1 (high quality), 0.5 (moderate quality), or 0 (poor quality) were given to each paper. Papers that received a total score below four were removed from the study.

## IV. RESULTS

This section present the results obtained and content analysis on the complete texts of the identified papers. The initial stage of the selection process involved screening the title, abstract, and introduction of each paper to ascertain its relevance. The subsequent step was to eliminate papers that did not meet the exclusion criteria outlined in Table II. As a result, 80 papers were identified as the basis for the further research process. It is important to note that quotation marks are used to ensure that multi-word terms are searched together, preventing individual words from being considered separately. After conducting the search, the resulting articles were manually reviewed by analyzing their titles, keywords, abstracts, and texts. Duplicate articles were eliminated, and the remaining articles were assessed to determine whether

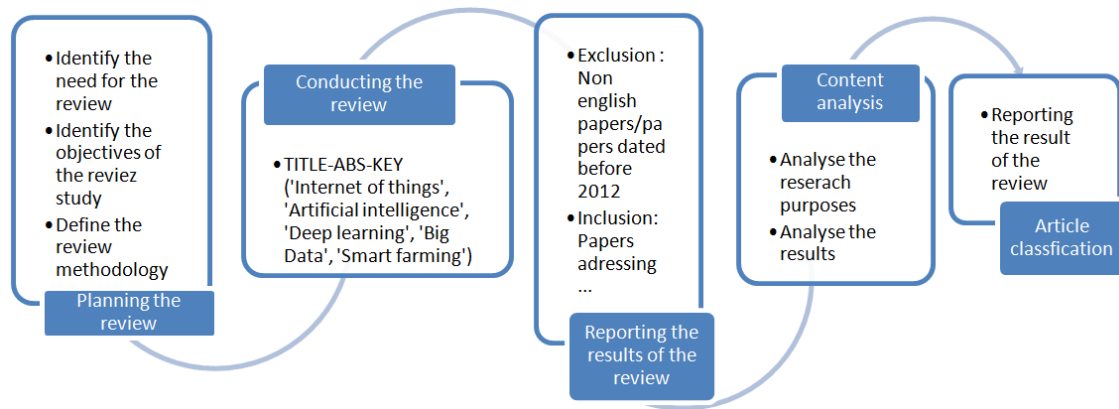

Fig. 3. Process steps of the systematic literature review.

they were relevant to the study's objectives. Valid articles were those that focused on IoT-based solutions for agricultural problems, were not literature reviews, were written in English, Portuguese, or Spanish, and pertained to agriculture rather than livestock activities. The study's search and selection process is summarized in Fig. 4. The initial search yielded 536 articles, which were then analyzed and narrowed down to 186 articles that met the study's eligibility criteria. During the screening phase, 350 articles were deemed invalid and discarded based on their lack of relevance to the study's objectives. Of these, 65% did not focus on smart farming. Additionally, almost 35% of the discarded papers were literature reviews or studies related to smart farming that did not involve IoT. A small number of papers pertained to smart farming but did not address IoT (about 5% were related to sensors), and some papers had abstracts or texts that were not available (about 2%).

In the eligibility phase, the content of the 80 remaining articles was reviewed using the same criteria as in the screening phase. Of these, 23 articles were discarded, with 27% not related to IoT and 32% not to smart farming. The remaining 41% were literature reviews or papers without available content. This research analysis conducted in 57 articles that were eligible for inclusion in the study's sample.

#### A. Description Analysis

57 papers were ultimately assigned to the topic and rated as relevant for deep analysis, out of a total of 536 papers that had been previously identified regarding the application of Cloud, Big Data, IoT, AI, within UAV Application in Smart Farming. The distribution of the selected studies' suitability, which was assessed by reading their titles and abstracts, the distribution of articles published per year is shown in Fig. 5, then the distribution of documents per year per source is provided in Fig. 6 and finally the Fig. 7 describe the distribution of documents by appropriateness.

The decrease in research on the application of drones in precision agriculture may be multiple and dependent on various factors such as funding, research priorities, technological advancements, etc. However, some possible hypotheses can be suggested: Recent technological advancements may have solved a significant portion of the issues related to drone

application in precision agriculture, thereby reducing the need for further research in this field. Funding for research in this field may have been reduced or directed towards other research areas. The scientific community may be transitioning to other agricultural monitoring technologies or methods, such as the use of remote sensors or satellites. It is also possible that the number of scientific publications on the subject has decreased, but research is still ongoing in other contexts as provided in the distribution of document by subject area provided in Fig. 8, such as in the private industry. Ultimately, it is important to realize that the decrease in research in a given field does not necessarily imply that research should be abandoned or that previous results are no longer relevant. Existing research can still be used to improve existing applications and guide future research.

Out of the 166 full texts in the field of smart farming that were found, 96 papers (58%) were rated as having high appropriateness, 53 papers (32%) as having medium appropriateness, and 17 papers (10%) as having low appropriateness in relation to the goal of this research project. Book chapters are of total of 21%, while research articles are 44%, and reviews are 23%.

Based on the 166 complete articles that were found, Fig. 8 displays the distribution of document types in the field of smart farming by subject area.

#### B. Content Analysis

The complete texts of the papers were reviewed and identified in this section. Table IV summarizes the most important clusters, primary references, to group the chosen literature into related clusters, we engaged in a thorough content analysis. In addition Table V complete this set of research documents by UAV articles analyzed by characteristics and limitations identified in the survey.

IoT (Internet of Things) technology is transforming the agricultural industry by enabling farmers to collect and analyze data from various sources to make informed decisions. However, like any technology, IoT also presents challenges and issues, particularly in the context of smart farming. Table VI provides a comparison of IoT issues and challenges in smart farming:

Fig. 4. Flow chart of databases search criteria and identification process of records.

Fig. 5. Distribution of articles published per year.

Fig. 6. Distribution of documents per year per source.

### RQ1. WHAT ARE THE VARIOUS APPLICATIONS OF UAVS IN PRECISION AGRICULTURE?

The use of Artificial Intelligence (AI) and cloud technology in Unmanned Aerial Vehicles (UAVs) has brought about significant improvements in smart farming. Here are some of the impacts:

- **Soil Analysis:** UAVs can be used to collect soil samples, analyze soil moisture levels, and assess soil quality, which can help farmers optimize fertilization and irrigation practices.
- **Planting:** UAVs can be used to plant seeds precisely and efficiently, reducing labor costs and increasing planting accuracy. **Crop spraying:** UAVs equipped with spraying systems can be used to apply pesticides, herbicides, and fertilizers accurately, reducing the en-

environmental impact and saving time and money.

- Irrigation Management: UAVs equipped with thermal sensors can be used to identify areas of the field that need irrigation, allowing farmers to optimize water usage and reduce waste.
- Yield Mapping: UAVs can be used to generate yield maps, which can help farmers optimize crop management practices and increase overall yield.
- Livestock Monitoring: UAVs equipped with cameras can be used to monitor livestock, detect health problems, and track animal behavior.
- Crop Monitoring: UAVs equipped with sensors and cameras can be used to monitor crop health and growth, detect diseases, pests, and stress factors affecting the crop and generate crop health maps.

The integration of AI and cloud technology in UAVs has brought about significant improvements in smart farming. It has enabled precision agriculture, increased efficiency, reduced environmental impact, and enabled real-time monitoring of farm operations. Also, drones have revolutionized many industries, including precision agriculture. So the Fig. 9 provide significant UAV applications in precision agriculture using AI and Cloud Technologies. Overall, UAVs can significantly improve efficiency, accuracy, and sustainability in precision agriculture, making it a valuable tool for modern farmers.

## RQ2. WHICH CROPS ARE MONITORED BY UAV SYSTEMS?

Unmanned Aerial Vehicle (UAV) systems are increasingly being used for crop monitoring and management in agriculture. Various types of crops can be monitored using UAV systems, including different Cereals. These crops are often monitored for growth stages, yield prediction, and disease detection [63]. Fruits and vegetables: Such as grapes, citrus, apples, tomatoes, and potatoes. UAV systems can monitor the growth and health of these crops, detect pests and diseases, and assess yield. Oilseeds: Such as soybeans, sunflowers, and canola. UAV systems can be used to monitor crop growth, assess the health of plants, and predict yields. Specialty crops: Such as coffee, tea, cocoa, and tobacco. UAV systems can help monitor the health of these crops, detect early signs of disease or pest

TABLE V. CHARACTERISTICS AND LIMITATIONS OF THE RESEARCH: SET OF UAV ANALYZED ARTICLES BY PUBLICATION YEAR, SHORT DESCRIPTION, AUTHOR AND AREA OF APPLICATION

Reference	Author	Publication year	Description	Characteristics	Limitations
[54]	N. A. Sehree and A. M. Khidhir	2022	Classification of olive tree cases based on deep convolutional neural network using unmanned aerial vehicle (UAV) imagery	This paper proposes a framework that integrates UAVs with IoT and cloud computing for smart agriculture. The authors demonstrate the feasibility of the proposed framework through a case study. They conclude that the proposed framework can improve crop yield and reduce costs for farmers.	The authors primarily focus on the challenges associated with implementing UAV-based systems, rather than discussing potential solutions or strategies for overcoming these challenges. While this is an important aspect to consider, a more detailed analysis of potential solutions or strategies could be useful for practitioners and researchers in the field.
[55]	J. M. Jurado et al.	2020	Individual characterization of olive trees through multi-temporal monitoring and multispectral mapping on 3D models.	This study proposes an intelligent UAV-based system that uses deep learning and IoT for crop growth monitoring. The authors demonstrate the effectiveness of the proposed system through experiments. They conclude that the proposed system can accurately monitor crop growth and help farmers make informed decisions.	The authors used a greenhouse to conduct their experiments, which may not accurately reflect the challenges and limitations of implementing a UAV-based crop monitoring system in an outdoor agricultural environment.
[56]	P. Rallo et al.	2020	Investigating the use of UAV imagery to enhance genotype selection in olive breeding programs.	This paper proposes a novel approach to weed detection in smart agriculture using UAVs and deep learning. The authors demonstrate the effectiveness of the proposed approach through experiments. They conclude that the proposed approach can accurately detect weeds and help farmers reduce the use of herbicides.	The authors used only one type of UAV (a DJI Phantom 4 Pro drone) for their experiments. Different types of UAVs have different capabilities, such as flight time, payload capacity, and camera quality, which could impact the effectiveness and accuracy of a UAV-based weed detection system.
[57]	A. Safonova et al.	2021	Estimating the biovolume of olive trees using multi-resolution image segmentation with Mask Region-based Convolutional Neural Network (R-CNN) on UAV imagery.	The authors demonstrate the feasibility of the proposed system through experiments. They conclude that the proposed system can improve crop yield and reduce costs for farmers.	The authors do not address any potential security or privacy concerns related to the use of IoT and UAV-based systems in smart farming.
[58]	A. Di Nisio et al.	2020	Rapid detection of olive trees affected by <i>Xylella fastidiosa</i> using multispectral imaging from UAVs.	This study proposes a UAV-based smart farming system that uses machine learning and cloud computing. The authors demonstrate the effectiveness of the proposed system through experiments. They conclude that the proposed system can improve crop yield and reduce costs for farmers	The system's ability to handle varying weather conditions, crop types, and growth stages. Additionally, the authors do not discuss any potential environmental impacts of using UAVs for crop monitoring and the potential disruption to local wildlife.
[59]	A. Castrignanò et al.	2021	Development of a semi-automatic approach to detect <i>Xylella fastidiosa</i> in olive trees at an early stage. This method utilizes UAV multispectral imagery.	This study proposes a UAV-based crop monitoring system that uses IoT	The study may have only tested the UAV-based crop monitoring system in a limited range of environmental conditions, which may limit the generalizability of the findings.
[60]	Šiljeg et al.	2023	Utilizing Geospatial Object-Based Image Analysis (GEOBIA) and Vegetation Indices for extracting olive tree canopies from highly detailed UAV multispectral imagery.	This study proposes a UAV-based crop monitoring system that uses IoT	The study may have only tested the UAV-based crop monitoring system in a limited range of environmental conditions, which may limit the generalizability of the findings.

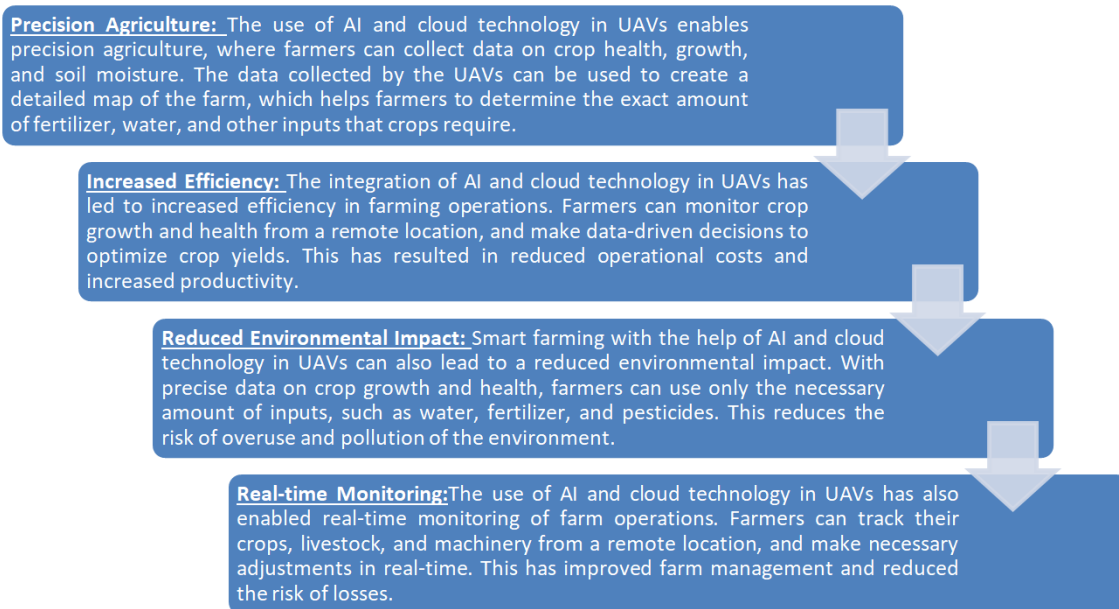

Fig. 9. Significant UAV applications in smart farming using AI and cloud.

infestations, and optimize harvest. While the use of UAV systems for crop monitoring has several advantages, there are also some limitations to the types of crops that can be effectively monitored. Here are some of the limitations collected by analyzing the following articles [64], [65], [66]. So, there are several limitations to using UAVs for crop monitoring. Firstly, UAVs can only cover a limited area in a single flight, which makes it difficult to monitor large farms efficiently. Secondly, UAVs are affected by weather conditions and may not be able to fly in adverse weather, which can impact data collection. Thirdly, UAVs require skilled operators

and specialized equipment, which can be costly and time-consuming to maintain. Then, regulations around the use of UAVs can be complex and vary between countries, which can add another layer of complexity to their use in crop monitoring. These limitations must be carefully considered when deciding whether to use UAVs for crop monitoring and when planning a UAV-based monitoring program.

In conclusion, while UAV systems can be an effective tool for crop monitoring, there are limitations to the types of crops that can be effectively monitored. Crop height, density, size, weather conditions, and sensor limitations are all factors that

Fig. 10. UAV system technologies.

can affect the effectiveness of UAV monitoring. Generally, UAV systems can provide farmers with valuable insights and data to optimize crop management, increase productivity, and reduce the use of pesticides and fertilizers.

### RQ3. HOW CAN UAV-BASED TECHNOLOGIES BE ADAPTED FOR USE IN DIFFERENT TYPES OF CROPS OR FARMING ENVIRONMENTS?

Precision agriculture involves the use of various technologies to optimize crop management and increase yields. Unmanned Aerial Vehicle (UAV) systems are becoming increasingly popular in precision agriculture due to their ability to collect high-resolution data quickly and efficiently. Here are some UAV system technologies in Fig. 10 that are commonly adopted in precision agriculture:

- **Multispectral imaging:** UAVs equipped with multispectral cameras can capture images of crops at different wavelengths, providing valuable information on plant health, stress levels, and nutrient deficiencies.
- **Thermal imaging:** Thermal cameras mounted on UAVs can detect differences in temperature across a field, helping to identify areas of stress or water deficiency in crops.
- **Lidar (Light Detection and Ranging):** UAVs equipped with Lidar technology can create high-resolution 3D maps of crops and terrain, which can be used for crop modeling and yield prediction.
- **Global Positioning System (GPS):** UAVs equipped with GPS can precisely navigate and collect data on a field, helping farmers to monitor crop growth and identify problem areas.
- **Machine learning and artificial intelligence:** UAV systems can collect vast amounts of data that can be analyzed and processed using machine learning and artificial intelligence algorithms.
- **Variable rate application (VRA):** UAV systems can be used for VRA, where the data collected can be used to

tailor crop management practices to specific areas of a field, optimizing inputs like fertilizers and pesticides, reducing costs and environmental impact.

Overall, these UAV system technologies can provide farmers with detailed information on crop health, growth, and yield potential, helping them to make more informed decisions on crop management and increase productivity.

### RQ4. WHAT TYPES OF DATA CAN BE OBTAINED THROUGH THE USE OF UAVS?

Unmanned Aerial Vehicles are deployed in various applications, including agriculture, environmental monitoring, and infrastructure inspection. UAVs are equipped with sensors that can capture different types of data. Here are some examples of data that can be acquired by UAVs:

- **Visual imagery:** UAVs can capture high-resolution visual imagery using cameras that range from standard RGB cameras to more specialized cameras like multispectral, hyperspectral, and thermal cameras. These images can be used to monitor vegetation health, detect anomalies, and map land cover.
- **LiDAR:** LiDAR sensors can be mounted on UAVs to generate high-resolution 3D maps of the terrain, vegetation, and structures. This data can be used for precise measurements of features such as height, volume, and biomass.
- **GPS data:** UAVs can collect GPS data, which can be used to generate maps, track the drone's position, and measure distances.
- **Environmental data:** UAVs can be equipped with sensors that measure environmental variables such as temperature, humidity, and air quality. This data can be used for environmental monitoring and disaster response.
- **Magnetic and acoustic data:** UAVs can be equipped with magnetometers to measure the magnetic field of the Earth's surface. This data can be used for geological surveys and mineral exploration. UAVs can also be equipped with microphones to capture acoustic data.

Overall, UAVs can capture a wide range of data types, which can be used for various applications in fields such as agriculture, environmental monitoring, infrastructure inspection, and disaster response.

### RQ5. WHICH METHODS OF DATA PROCESSING CAN BE EMPLOYED TO ANALYZE THE AGRICULTURAL DATA COLLECTED BY UAVS?

The data acquired by UAVs in precision agriculture can be processed and analyzed using various techniques to extract useful information. Here are some examples of data processing methods that can be used to exploit agricultural data acquired by UAVs described in Fig. 11.

- **Image processing:** UAVs capture high-resolution images of crops, which can be processed using image processing techniques to extract information such as crop health, leaf area index, and crop growth stage.

Fig. 11. Data processing methods used to exploit data collected by UAV.

- Geographic Information System (GIS): UAV data can be integrated with GIS to create maps that provide valuable information about crop health, yield, and soil properties.
- 3D modeling: UAVs can capture data in the form of point clouds using LIDAR sensors, which can be used to create 3D models of the field. These models can be used to estimate crop height, biomass, and plant spacing.

In summary, the data acquired by UAVs in precision agriculture can be processed and analyzed using various techniques to extract valuable information about crop health, yield, and soil properties. These techniques include image processing, GIS, multispectral data analysis, machine learning, and 3D modeling.

#### **RQ6. WHAT ARE THE CHALLENGES ASSOCIATED WITH USING DRONES FOR DISEASE DETECTION IN AGRICULTURE?**

The challenges can be categorized into two primary groups: dataset-related challenges and model-building challenges. Dataset-related challenges encompass deformations in the image dataset, insufficient availability of expert-labeled data, significant randomness in the data, and inadequate representation of classes in the dataset. Challenges associated with model building are the scarcity of training samples, extended training and processing times. Out of the papers analyzed, only two proposed potential solutions for these difficulties. The use of UAV in smart farming has become increasingly popular due to their ability to collect vast amounts of data quickly and accurately. However, the integration of Internet of Things (IoT) technologies into UAV applications also brings unique challenges and issues. The Table VI provides a comparison of the key challenges and issues related to IoT in UAV applications for smart farming.

#### **RQ7. WHAT ARE THE POTENTIAL ETHICAL AND LEGAL IMPLICATIONS ASSOCIATED WITH THE USE OF DRONES IN AGRICULTURE, AND HOW CAN THESE ISSUES BE ADDRESSED?**

The use of drones in agriculture presents various ethical and legal implications that need to be considered and addressed. From an ethical standpoint, privacy concerns arise as drones can capture sensitive information about individuals or their properties. There is also the potential for drones to infringe on airspace regulations, endangering other aircraft or public safety. Furthermore, the automation and autonomy of drones raise questions about accountability and liability in case of accidents or damage caused by these devices. To address these issues, several measures can be implemented. Firstly, clear regulations and guidelines should be established regarding the operation of drones in agricultural settings. These regulations should address aspects such as flight restrictions, licensing requirements, and privacy protection. Adequate enforcement mechanisms should be in place to ensure compliance.

Secondly, public awareness campaigns and education initiatives can inform both farmers and the general public about the responsible and legal use of drones in agriculture. This can help foster understanding and mitigate privacy concerns. Additionally, technological solutions can be developed to enhance privacy protection, such as implementing geofencing mechanisms that restrict drone access to certain areas or utilizing data anonymization techniques. Collaboration between stakeholders, including farmers, drone operators, regulatory bodies, and legal experts, is crucial for developing comprehensive guidelines and frameworks that address the ethical and legal implications of drone use in agriculture. Regular review and updates of regulations can also ensure they remain relevant as technology evolves. Ultimately, a balanced approach is needed that considers the benefits of drone technology in agriculture while safeguarding privacy, public safety, and legal compliance.

TABLE VII. SIGNIFICANT REVIEW STUDIES ON UAV BASED APPLICATIONS ON SMART FARMING COMPARED TO THIS SYSTEMATIC REVIEW

References	Objectives of the review	Method/Guidelines	Analysis Criteria	Results
[67]	Help potential researchers detect relevant IoT problems and, based on the application requirements, adopt suitable technologies.	SLR	Recent advancements and challenges of Internet of Things in smart farming	The upcoming studies, inventions, and initiatives mostly in field of IoT-based smart agriculture would improve the quality of living for farmers and result in significant improvements in the agricultural sector.
[68]	Pinpoints the challenges in implementing the solutions in the farmer's field in real-time.	SLR	Recent trends in computer vision such as generative adversarial networks (GAN), vision transformers (ViT) and other popular deep learning architectures.	Integration of the deep learning computer vision approaches with the UAV, and spectral data can help in building advanced-intelligent solutions.
[69]	Presents an analysis of drone technologies and their modifications with time in the agriculture sector in the last decade.	SLR	Artificial Intelligent (AI) and deep learning for the remote monitoring of crops has	There is a ramp in drone application for precision agriculture after 2017. This is due to the reduction of weight, cost of UAVs, and increment in payload capability
[26]	Suggest further research to improve the current food production globally	SLR	The application of smart farming to crop and animal production and post-harvesting	An effective Intelligent IoT system for smart farming can start the beginning of the journey toward by providing more information within the farming system for non-academics and researchers.
Proposed Systematic Review	Propose future research directions and highlight areas of improvement for the effective implementation of these technologies in agriculture.	SLR & PRISMA	Data collection and sensing technologies, AI and data analysis techniques, IoT and connectivity, Cloud computing and data management, Performance and effectiveness, Challenges and limitations	Exploration of the integration of unmanned aerial systems (UAS), AI, IoT, and cloud technologies specifically in the context of smart farming, providing an up-to-date and in-depth analysis of the benefits, challenges, and future research directions in this rapidly evolving field.

## V. DISCUSSIONS

The reason to conduct this systematic review on UAV-based applications in smart farming using AI, IoT, and cloud technologies is to provide a comprehensive overview of the current state-of-the-art in this field. This review aims to gather and analyze existing research studies, to identify gaps in the literature, and to provide insights into the potential of these technologies for smart farming.

The systematic review will contribute to the research field in several ways. Firstly, it will provide a clear understanding of the current state-of-the-art in UAV-based applications in smart farming, including the various applications, benefits, and challenges associated with the use of these technologies. Secondly, it will identify gaps in the literature and areas where further research is needed. This will help researchers to focus their efforts on areas that are most promising and where further advancements are needed. Thirdly, it will provide insights into the potential of these technologies to transform the agriculture industry, promote sustainable farming practices, and address global food security challenges.

UAV-based applications in smart farming using AI, IoT, and cloud technologies face several data challenges that must be addressed for successful implementation. These challenges include acquiring and efficiently storing the large amounts of data generated by UAVs, ensuring the quality and reliability of the data, processing and analyzing the data in real-time using AI and cloud technologies, seamlessly integrating the UAV-based applications with other systems, and ensuring data privacy and security. Overcoming these challenges will

require the development of robust data management strategies, advanced algorithms for data analysis, secure and interoperable systems, and effective policies and regulations for data privacy and security. Addressing these challenges will be crucial for the successful implementation of UAV-based applications in smart farming and the realization of their potential benefits for the agricultural industry. Meteorological conditions can have a significant impact on UAV-based applications in smart farming that use AI, IoT, and cloud technologies. For example, wind speed and direction can affect the stability and maneuverability of the UAV, which can impact the quality of the data collected. Similarly, rain, fog, and low-light conditions can affect the quality of the images and sensor readings collected by the UAV, which can impact the accuracy of the data analysis.

Extreme weather conditions such as hurricanes, thunderstorms, and blizzards can also pose safety risks for the UAV and the personnel operating it. High winds, lightning, and heavy precipitation can damage the UAV or cause it to crash, while snow and ice can affect its mobility and stability. To mitigate the impact of meteorological conditions on UAV-based applications in smart farming, it is important to have reliable weather forecasting systems in place. This can help farmers and operators plan UAV flights around weather patterns, avoiding unsafe conditions and optimizing data collection.

Additionally, it is important to use UAVs equipped with weather-resistant sensors and cameras that can operate in a range of environmental conditions. This can help ensure the accuracy and reliability of the data collected, even in adverse weather conditions. In summary, meteorological conditions can

have a significant impact on UAV-based applications in smart farming, and it is important to have reliable weather forecasting systems and weather-resistant equipment to mitigate these effects.

Overall, this systematic review will be a valuable resource for researchers, policymakers, and practitioners interested in UAV-based applications in smart farming using AI, IoT, and cloud technologies. It will help to identify areas where further research is needed, and provide insights into the potential of these technologies to address some of the most pressing challenges facing the agriculture industry today.

By validating and comparing the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) results with the presented objectives, scenarios, and analysis criteria in Table VII, this systematic review aims to enhance the existing survey methodology. It strives to provide an updated research review based on established guidelines, which can have several advantages. So, by employing a validated methodology and adhering to established guidelines like PRISMA, this work aims to provide a reliable, transparent, and up-to-date resource that can contribute to the existing body of knowledge in UAV-based applications in smart farming using AI, IoT, and cloud technologies. Despite the numerous benefits associated with the use of UAVs, AI, IoT, and cloud technologies in smart farming, there are still some limitations and challenges that need to be addressed in the future. One of the main limitations is the high cost of acquiring and maintaining these technologies, which may limit their adoption by smallholder farmers. Another limitation is the lack of regulatory frameworks and policies to guide their use, particularly in developing countries. Overall, this systematic review will be a valuable resource for researchers, policymakers, and practitioners interested in UAV-based applications in smart farming using AI, IoT, and cloud technologies. It will help to identify areas where further research is needed, and provide insights into the potential of these technologies to address some of the most pressing challenges facing the agriculture industry today. Despite the numerous benefits associated with the use of UAVs, AI, IoT, and cloud technologies in smart farming, there are still some limitations and challenges that need to be addressed in the future.

## VI. CONCLUSION

In conclusion, this paper provides a comprehensive overview of the utilization of unmanned aerial vehicles (UAS), or drones, in agriculture and the integration of AI, IoT, and cloud technologies for precision farming. The systematic review conducted following the PRISMA method highlights the potential of UAV-based applications in smart farming using these advanced technologies. The major takeaways from this work include the significant potential of UAVs in enhancing agricultural productivity and sustainability. The findings demonstrate that UAVs offer valuable capabilities for data collection, precision monitoring, and decision-making in large-scale farming operations. The integration of AI, IoT, and cloud technologies further enhances these capabilities by enabling real-time data analysis, remote accessibility, and efficient resource management. The justification for this research lies in the growing importance of technology-driven solutions in modern agriculture. By leveraging UAVs and advanced

technologies, farmers can make informed decisions, optimize resource usage, and improve crop yields. The presented work serves as a valuable resource for researchers, policymakers, and practitioners interested in understanding the potential and challenges of UAV-based applications in smart farming.

Moving forward, future research should focus on developing more advanced machine learning models to enhance accuracy in crop yield predictions and pest infestation identification. Additionally, exploring the feasibility of drones for other agricultural tasks such as irrigation management and soil analysis can provide valuable insights. Conducting empirical studies will further validate the benefits and limitations of these technologies in agriculture.

# Advanced Night time Object Detection in Driver-Assistance Systems using Thermal Vision and YOLOv5

Hoang-Tu Vo, Luyi-Da Quach  
Software Engineering Department  
FPT University, Cantho city, Vietnam

**Abstract**—Driver-assistance systems have become an indispensable component of modern vehicles, serving as a crucial element in enhancing safety for both drivers and passengers. Among the fundamental aspects of these systems, object detection stands out, posing significant challenges in low-light scenarios, particularly during nighttime. In this research paper, we propose an innovative and advanced approach for detecting objects during nighttime in driver-assistance systems. Our proposed method leverages thermal vision and incorporates You Only Look Once version 5 (YOLOv5), which demonstrates promising results. The primary objective of this study is to comprehensively evaluate the performance of our model, which utilizes a combination of stochastic gradient descent (SGD) and Adam optimizer. Moreover, we explore the impact of different activation functions, including SiLU, ReLU, Tanh, LeakyReLU, and Hardswish, on the efficiency of nighttime object detection within a driver assistance system that utilizes thermal imaging. To assess the effectiveness of our model, we employ standard evaluation metrics including precision, recall, and mean average precision (mAP), commonly used in object detection systems.

**Index Terms**—Driver-assistance systems; object detection; nighttime object detection; thermal vision; YOLOv5

## I. INTRODUCTION

The rise of self-driving cars represents a significant milestone in the automotive industry, promising a paradigm shift in transportation as we know it. With the introduction of autonomous vehicles, there is a pressing need to address the alarming number of fatalities that occur in traffic accidents each year. Road traffic injuries pose a significant threat to the lives of children and young adults aged 5-29 years, making it the leading cause of death within this age group. It is worth noting that a staggering 93% of these fatalities occur in low- and middle-income countries [1]. These tragic incidents have prompted researchers and engineers to explore innovative solutions to improve road safety using machine learning (ML) and deep learning (DL) algorithms [2], [3], [4], [5]. The safety of autonomous vehicles relies on the ability to detect and classify objects correctly. Object detection algorithms need to be robust enough to differentiate between pedestrians, bicycles, cars, and other relevant entities on the road. This distinction is crucial for autonomous vehicles to assess potential risks and determine appropriate responses, such as slowing down, changing lanes, or stopping altogether. Detecting objects on the road is a crucial task for autonomous vehicles to ensure the safety of both passengers and other road users. However,

the challenge becomes even more pronounced when it comes to detecting objects at night or in low light conditions. Reduced visibility conditions make it difficult for sensors, such as cameras to capture clear and detailed information about the surrounding environment. Traditional object detection systems heavily rely on visual cues, which can be compromised in low light conditions. This poses a considerable challenge for autonomous vehicles navigating roads at night or in poorly lit environments. To address these challenges [6], [7], [8], researchers have turned to Convolutional Neural Networks (CNNs), a powerful deep learning technique that has revolutionized various fields, including computer vision. CNNs have shown great promise for object detection, providing a robust framework for training models that can learn and extract meaningful features from image data. By incorporating CNN modeling in Driver-Assistance Systems, autonomous vehicles can navigate complex environments more effectively, reducing the risk of accidents and ultimately saving lives.

The objective of this article is to provide an innovative strategy for nighttime object detection in driver-assistance systems using thermal vision and incorporating the YOLOv5 model. The primary objective is to comprehensively evaluate the model's performance by investigating the influence of different activation functions and optimizers. The findings demonstrate the efficiency of the proposed method in enhancing nighttime object detection. The results contribute to the understanding of the role of optimizers and activation functions in training the YOLOv5 model for object detection tasks. The insights gained from this research can guide future endeavors aimed at improving the efficiency and accuracy of driver-assistance systems, ultimately enhancing safety for both drivers and passengers.

The structure of this paper is outlined in the following manner: Section II provides an extensive review of the relevant literature. In Section III, we elaborate on the methodology utilized for Advanced Nighttime Object Detection, covering aspects such as Dataset and Data Preparation, Data annotations/labeling, Activation Functions, and Model Evaluation Metrics. The experimental system and results, accompanied by a comprehensive discussion, are presented in Section IV. Finally, Section V provides concluding remarks to wrap up the paper.

## II. RELATED WORKS

Ramesh Simhambhatla et al. (2019) [9] undertook a practical examination of three up-to-date meta-architectures, namely SSD, R-CNN, and R-FCN. The aim was to gauge their efficiency and precision in recognizing road objects, including vehicles, pedestrians, and traffic lights, across varying driving scenarios: daytime, nighttime, rainy, and snowy conditions. This research paper was carried out by Ruturaj Kulkarni et al. (2018) [10] introduces a robust deep neural network model that employs transfer learning for the accurate detection and recognition of traffic lights. To facilitate object detection in self-driving cars using deep learning, P Prajwal et al. (2021) [11] have selected the SSD model in conjunction with the MobileNet neural network as the foundational architecture due to its ability to produce results rapidly while maintaining a moderate level of accuracy. VD Nguyen et al. (2018) [12] presents a comprehensive framework that combines deep learning techniques, multiple local patterns, and depth information to identify, classify, and monitor vehicles and walkers on the road. Utilizing a deep CNN, H Yu et al. (2013) [13] employ a sophisticated architecture that effectively detects obstacles in complex scenes by leveraging rich and powerful learned features. P Salavati et al. (2018) [14] presents a novel approach that utilizes Deep Neural Networks (DNN) to detect obstacles using a single camera, employing unsupervised DNNs for extracting global image features and extracting local image features. P Aswathy et al. (2018) [15] explores the influence of deep convolutional layer features within an object tracking framework, showcasing the novel utilization of GoogLeNet CNN architecture's deep layer features for effective object tracking. The primary emphasis of this paper [16] is on the application of a CNN algorithm for computer vision-based object detection. The paper [17] presents a novel real-time approach for object detection in images captured by self-driving vehicles, using a unified neural network that models object detection as a regression problem on predicted bounding boxes and class probabilities, enabling simultaneous prediction of bounding boxes and class probabilities for the entire image. AA Cervera-Urbe et al. (2022) [18] introduces U19-Net, a deep encoder-decoder model designed for the detection of vehicles and pedestrians. This paper [19] introduces a novel and efficient deep learning-based detecting technique called DW-YOLO, which addresses the challenge of detecting objects in images with limited visual cues. G Rjoub et al. (2021) [20] presents a novel object detection system for autonomous vehicles, utilizing the You Only Look Once (YOLO) convolutional neural network (CNN) approach and a Federated Learning (FL) framework to enhance real-time detection accuracy, particularly in challenging weather conditions. This paper [21] demonstrates the utilization of the YOLOv5 model for real-time identification of cars, traffic lights, and pedestrians under different weather conditions, showcasing its effectiveness in typical vehicular environments. The purpose of the paper [22] is to develop a DL model, trained on the YOLOv5s and YOLOv7 architectures, to correctly classify and identify

traffic signs in diverse adverse environments. VD Nguyen et al. (2023) [23] introduces an effective feature-based approach that utilizes a sigmoid function based on a triangle pattern to encode and establish strong features of neighboring pixels in local regions, which is then integrated into advanced object detection methods to evaluate its performance.

The purpose of this article is to present an innovative and advanced approach for nighttime object detection in driver-assistance systems. The study focuses on leveraging thermal vision and incorporating YOLOv5 as the proposed method. The primary objective is to comprehensively evaluate the performance of the model, which combines SGD and Adam optimizer. Additionally, the research investigates the impact of different activation functions, such as SiLU, ReLU, Tanh, LeakyReLU, and Hardswish, on the efficiency of nighttime object detection using thermal imaging within a driver assistance system. Standard evaluation metrics, including precision, recall, and mean average precision (mAP), are employed to assess the effectiveness of the model.

## III. METHODOLOGY

### A. Dataset and Data Preparation

The FLIR Thermal Images Dataset consists of a collection of 10,228 thermal images, each hand-labeled with precise bounding boxes. The images have a resolution of 640x512 pixels. Within the dataset, there are a total of 10,228 images, and these images contain a comprehensive set of 79,297 annotated bounding boxes. The dataset focuses on three main categories, namely Person, Bicycle, and Car. In the training set, which includes 8,862 images, there are 67,618 hand-labeled bounding boxes. Specifically, the Person category has 22,372 annotated bounding boxes, the Bicycle category has 3,986 annotated bounding boxes, and the Car category has 41,260 annotated bounding boxes. In the validation set, which consists of 1,366 images, there are 11,679 hand-labeled bounding boxes. The Person category has 5,778 annotated bounding boxes, the Bicycle category has 470 annotated bounding boxes, and the Car category has 5,431 annotated bounding boxes. Details of the distribution of the data set can be seen in Fig. 1 to Fig. 4.

### B. Data Annotations/Labeling

Annotation of your training images To ensure the effective training of our object detector, it is imperative to provide supervision during the training process by employing bounding box annotations. The procedure entails outlining a box around each specific object that we intend the detector to detect, and subsequently assigning a corresponding object class label to each box, indicating the desired prediction for the detector. This crucial step allows us to train the object detector accurately. Additional details can be incorporated to provide a comprehensive understanding of the topic. The YOLO labeling format Fig. 6. utilizes a unique approach where a .txt file is generated for every image file in the directory, sharing the same name. These .txt files serve as containers for annotations

Fig. 1. (a) Total number of images and annotated bounding boxes (b) The annotations are distributed across the three main categories.

Fig. 2. Example of thermal image (left) and bounding boxes manually labeled with class person (right).

	False Negative FN	False Negative FN	True Negative TN

Fig. 7. Precision and recall.

related to the corresponding image file, encompassing object class, object coordinates, height, and width information.

### C. Activation Functions

To conduct a comprehensive assessment of the accuracy of the transfer learning network models mentioned earlier, we employ five widely recognized and extensively used activation functions: SiLU (Sigmoid Linear Unit), ReLU (Rectified Linear Unit), Tanh (Hyperbolic Tangent), LeakyReLU (Leaky Rectified Linear Unit), and Hardswish [24]. These activation functions play a crucial role in deep learning methodologies. Each function's corresponding mathematical representation is presented Fig. 5, providing a complete understanding of their functional behavior. The selection of an appropriate activation function depends on a variety of factors, such as the specific requirements of the task at hand and the desired performance outcomes. Each activation function possesses unique characteristics that can influence the learning capabilities and overall performance of the transfer learning network models. By comparing the results obtained from employing these activation functions, we will be able to draw meaningful insights and make informed decisions regarding their suitability for the given task. The findings of this comparative analysis will be shared in detail in the subsequent section, offering a comprehensive evaluation of their effectiveness.

### D. Model Evaluation Metrics

This study examined the efficiency of DL models using a range of metrics, including Precision, Recall and mAP in Fig. 7 and in equations (1), (2), and (3). Precision measured the ratio of accurate positive outcomes to all positive predictions, while recall measured the proportion of correctly predicted to all instances of positive outcomes in the dataset. mAP measures the similarity between the ground-truth bounding box and the detected box, resulting in a numerical score. This score serves as an indicator of the model's accuracy in detecting objects. A higher score signifies greater accuracy in the model's detections. By employing multiple evaluation metrics, we gained a comprehensive understanding of the model's performance and made well-informed judgments regarding its effectiveness.

$$Precision = \frac{TP}{TP + FP} \quad (1)$$

$$Recall = \frac{TP}{TP + FN} \quad (2)$$

$$mAP = \frac{1}{n} \sum_{k=1}^n AP_k \quad (3)$$

In which, TP: True Positive, TN: True Negative, FP: False Positive, FN: False Negative, n: the number of classes,  $AP_k$ : the average precision of class k.

## IV. RESULTS

This section describes the training and validation results obtained for the YOLOv5 model using the SGD and Adam optimizers, along with various activation functions. The experiments were conducted using a learning rate of 0.01 and a momentum value of 0.937. Fig. 8 and Fig. 9 present the results of training the YOLOv5 model using two different optimizers, namely SGD and Adam, along with various activation functions. The performance of the model was evaluated using three key metrics: Precision, Recall, and mAP@0.5 (mean Average Precision at an IoU threshold of 0.5). Precision measures the accuracy of the model in correctly identifying positive instances, while Recall indicates the model's ability to find all positive instances. The mAP@0.5 calculates the average precision across different IoU thresholds.

For the SGD optimizer, the activation functions evaluated were SiLU, ReLU, Tanh, LeakyReLU, and Hardswish. Among these, the SiLU activation function achieved the highest Precision of 0.85247, Recall of 0.73373, and mAP@0.5 of 0.79985. However, other activation functions such as ReLU, LeakyReLU, and Hardswish also demonstrated competitive performance, with Precision ranging from 0.82512 to 0.83494 and mAP@0.5 ranging from 0.79074 to 0.79363. Similarly, for the Adam optimizer, the model was trained with the same set of activation functions. The SiLU activation function yielded the highest Precision of 0.80156, Recall of 0.70725, and mAP@0.5 of 0.77294. The performance of the other activation functions, including ReLU, LeakyReLU, and

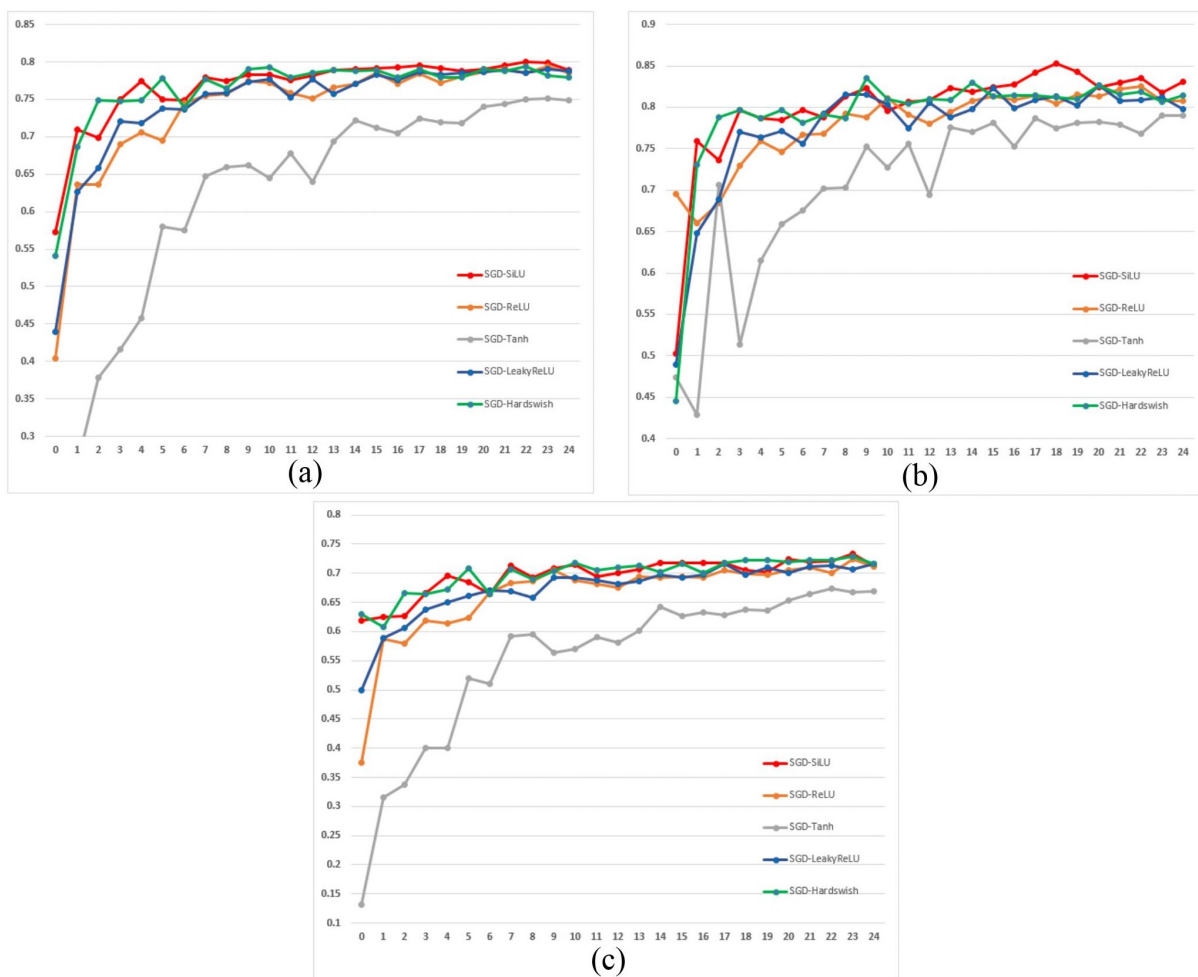

Fig. 8. Training results of YOLOv5 with SGD optimizer and various activation functions (a) The mAP@0.5 scores (b) Training precision, and (c) Training recall.

Hardswish, ranged from Precision values of 0.78057 to 0.7942 and mAP@0.5 values of 0.75974 to 0.77761.

Validation results of YOLOv5 with SGD and Adam optimizer and various activation functions are presented in Table 1. This table shows the evaluation metrics for precision, recall, and mAP@0.5. Each row corresponds to a specific combination of optimizer and activation functions. For the SGD optimizer, the SiLU activation function achieved the highest precision of 0.835, followed by Hardswish with a precision of 0.826. The highest recall was obtained with ReLU at 0.724, closely followed by SiLU at 0.722. The highest mAP@0.5 was achieved with SiLU at 0.800. For the Adam optimizer, the SiLU activation function again obtained the highest precision of 0.801, while ReLU achieved a precision of 0.782. The highest recall was obtained with ReLU at 0.703, closely followed by SiLU at 0.693. The highest mAP@0.5 was achieved with Hardswish at 0.777. Precision-Recall Curve of yolov5 model with SGD optimizer and SiLU activation function is presented in Fig. 10. These results demonstrate the performance of the YOLOv5 model with different combinations of optimizers and

activation functions (see Fig. 11). These outcomes indicate the impact of different optimizers and activation functions on the YOLOv5 model's performance. The SiLU activation function consistently exhibited strong performance across both optimizers, while ReLU, LeakyReLU, and Hardswish also showed competitive results. These findings can guide researchers and practitioners in selecting the most effective configuration for training the YOLOv5 model in object detection tasks.

## V. CONCLUSION

In conclusion, this research paper presented an innovative approach for object detection during nighttime in driver-assistance systems, utilizing thermal vision and incorporating the YOLOv5 model. The primary objective was to comprehensively evaluate the performance of the model by exploring the impact of different activation functions and optimizers. The outcomes demonstrated the efficiency of the proposed method in enhancing nighttime object detection. The experiments involved training the YOLOv5 model using two optimizers, SGD and Adam, along with various activation functions, namely SiLU, ReLU, Tanh, LeakyReLU, and Hardswish.

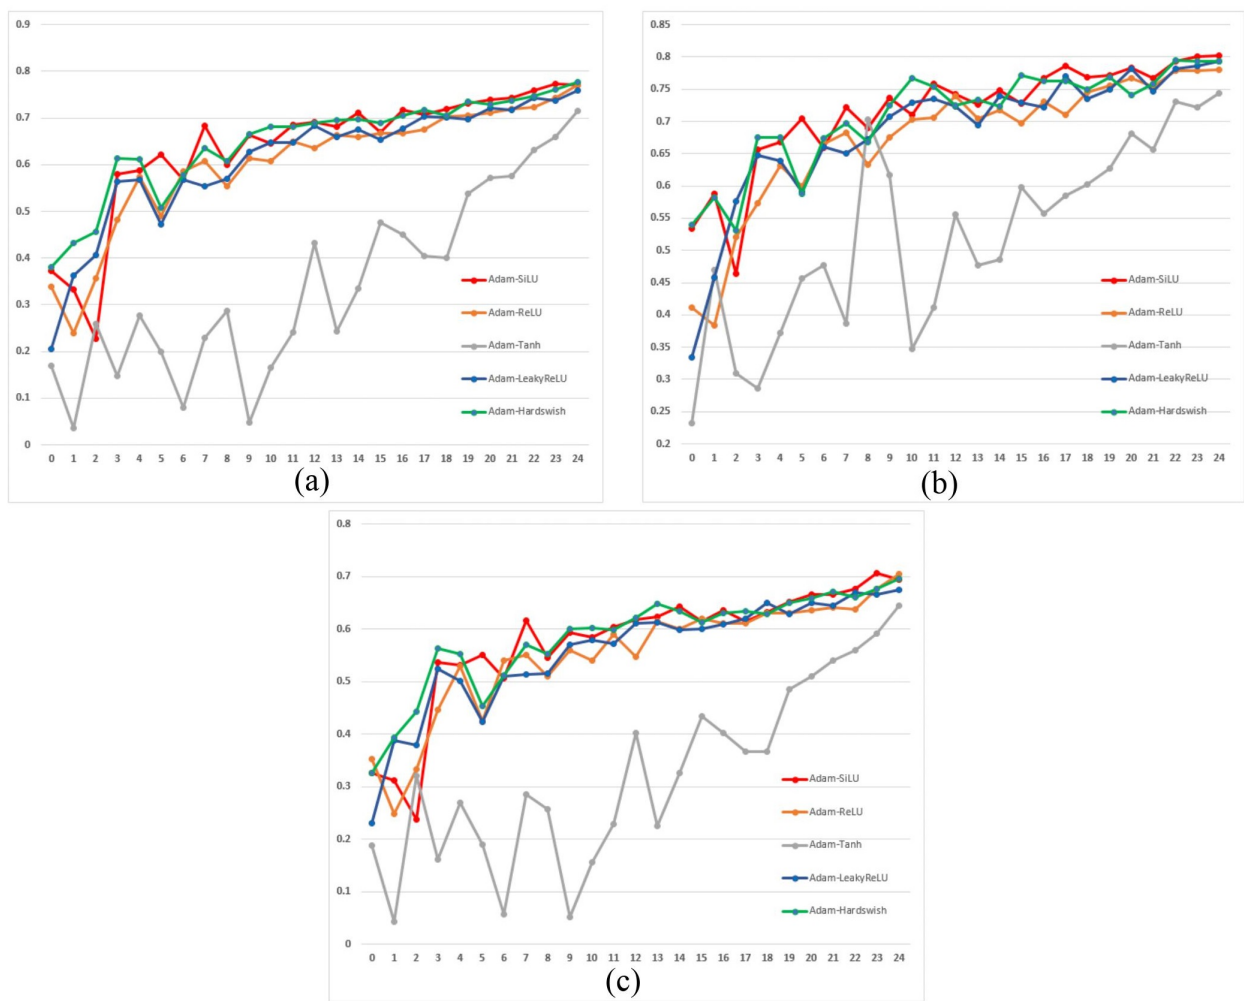

Fig. 9. Training results of YOLOv5 with adam optimizer and various activation functions (a) The mAP@0.5 scores (b) Training precision, and (c) Training recall.

TABLE I. VALIDATION RESULTS OF YOLOV5 WITH SGD AND ADAM OPTIMIZER AND VARIOUS ACTIVATION FUNCTIONS USE LEARNING RATE = 0.01 AND MOMENTUM = 0.937

Optimizer	Activation Function	Precision	Recall	mAP@0.5
SGD	SiLU	0.835	0.722	0.800
SGD	ReLU	0.807	0.724	0.793
SGD	Tanh	0.787	0.667	0.751
SGD	LeakyReLU	0.813	0.706	0.790
SGD	Hardswish	0.826	0.719	0.790
Adam	SiLU	0.801	0.693	0.771
Adam	ReLU	0.782	0.703	0.771
Adam	Tanh	0.745	0.642	0.715
Adam	LeakyReLU	0.794	0.675	0.759
Adam	Hardswish	0.793	0.696	0.777

The evaluation metrics used, including Precision, Recall, and mAP@0.5, provided insights into the accuracy, coverage, and overall performance of the model. For the SGD optimizer, the SiLU activation function achieved the highest Precision and mAP@0.5 values, indicating its effectiveness in accurately identifying positive instances. However, ReLU, LeakyReLU,

and Hardswish also demonstrated competitive performance in terms of Precision and mAP@0.5. Similarly, with the Adam optimizer, the SiLU activation function consistently yielded the highest Precision, while ReLU, LeakyReLU, and Hardswish also performed well. These results highlight the impact of different activation functions on the model's performance. Overall, the findings suggest that the YOLOv5 model, coupled with the SiLU activation function, is a promising configuration for nighttime object detection in driver-assistance systems. However, researchers and practitioners can also consider other activation functions such as ReLU, LeakyReLU, and Hardswish, which showed competitive performance in this study. These results contribute to the understanding of the role of optimizers and activation functions in training the YOLOv5 model for object detection tasks. The insights gained from this research can guide future endeavors in improving the efficiency and accuracy of driver-assistance systems, ultimately enhancing safety for both drivers and passengers.

**Abstract**—This study aims to provide an overview of the current research on detecting abusive language in Indonesian social media. The study examines existing datasets, methods, and challenges and opportunities in this field. The research found that most existing datasets for detecting abusive language were collected from social media platforms such as Twitter, Facebook, and Instagram, with Twitter being the most commonly used source. The study also found that hate speech is the most researched type of abusive language. Various models, including traditional machine learning and deep learning approaches, have been implemented for this task, with deep learning models showing more competitive results. However, the use of transformer-based models is less popular in Indonesian hate speech studies. The study also emphasizes the importance of exploring more diverse phenomena, such as islamophobia and political hate speech. Additionally, the study suggests crowdsourcing as a potential solution for the annotation approach for labeling datasets. Furthermore, it encourages researchers to consider code-mixing issues in abusive language datasets in Indonesia, as it could improve the overall model performance for detecting abusive language in Indonesian data. The study also suggests that the lack of effective regulations and the anonymity afforded to users on most social networking sites, as well as the increasing number of Twitter users in Indonesia, have contributed to the rising prevalence of hate speech in Indonesian social media. The study also notes the importance of considering code-mixed language, out-of-vocabulary words, grammatical errors, and limited context when working with social media data.

**Keywords**—Abusive language; hate speech detection; machine learning; social media

## I. INTRODUCTION

In this digital era, social media has become an important aspect of everyday life. Not only is it a source of information, but it is also a medium of entertainment, allowing people to share content and express their feelings about anything at any time. However, social media can also be a double-edged sword. On one hand, it can provide a medium for constructive and positive communication among its users. On the other hand, the freedom of expression afforded to social media users can also create serious problems, such as the increasing prevalence of hate speech on social media. This phenomenon is often attributed to the lack of effective regulations and the anonymity afforded to users on most social networking sites [1]. These characteristics make social media the perfect medium for individual abusive users or even hate groups to spread and reinforce their views. In fact, social media platforms even

offer opportunities for violent actors to propagate their acts, potentially reaching a wider audience when their posts go viral [2]. Twitter is a popular social networking platform that provides convenient access to its users for online social interactions. The number of Twitter users has been steadily increasing, from around 100 million users in 2017 to almost 240 million in 2022. Previous studies have shown that hate speech is also a prominent challenge in the Twittersphere. Pamungkas et al. [3] conducted a study on hate speech towards women in Twitter in multiple languages, including Italian, Spanish, and English. Lingiardi et al. [4] has also explored other forms of hate speech targeted at specific groups on Twitter.

Automatically detecting hate speech from social media text is a challenging task. Several studies have been proposed to address hate speech in social media, mainly focusing on implementing machine learning models to automatically predict whether an utterance is hate speech or not. However, working with social media data is a very challenging task. Social media data often contains valuable knowledge for information extraction tasks, but it is usually very noisy and full of informal language [5]. According to the study of Baldwin et al. [5], there are several properties of social media data, including: i) the presence of code-mixed language; ii) the presence of out-of-vocabulary words; and iii) grammatical errors. Social media data also usually has very limited context, which is an important issue for abusive language detection tasks because it is difficult to classify a text as abusive or not without context. Other important clues for abusive detection tasks, such as facial expressions, gestures, and voice tones (which are recognized in face-to-face communication), are also absent in social media data. However, social media content has some signals that can be exploited to partially resolve the context of such texts, including emojis, emoticons, hashtags, URLs, and mentions. Some studies have also found that there are several issues that contribute to the difficulty of detecting hate speech in social media automatically, including the use of swear words [6], multidomain issues [7], [8], and multilingual issues [8], [7].

Similarly, hate speech phenomena also occur in Indonesian social media. According to Statista<sup>1</sup>, the number of Twitter users in Indonesia has reached almost 240 million, ranking fifth among all countries in the world. Hate speech in Indonesia has been regulated by the government since 2008, as stated in the Law of Information and Electronic Transaction (UU ITE). The Kepolisian Republik Indonesia (Indonesian Police

This work has been funded by the internal funding of Universitas Muhammadiyah Surakarta under Grant Number 110.28/A.3-III/LRI/VI/2022.

<sup>1</sup><https://www.statista.com/statistics/242606/number-of-active-twitter-users-in-selected-countries/>

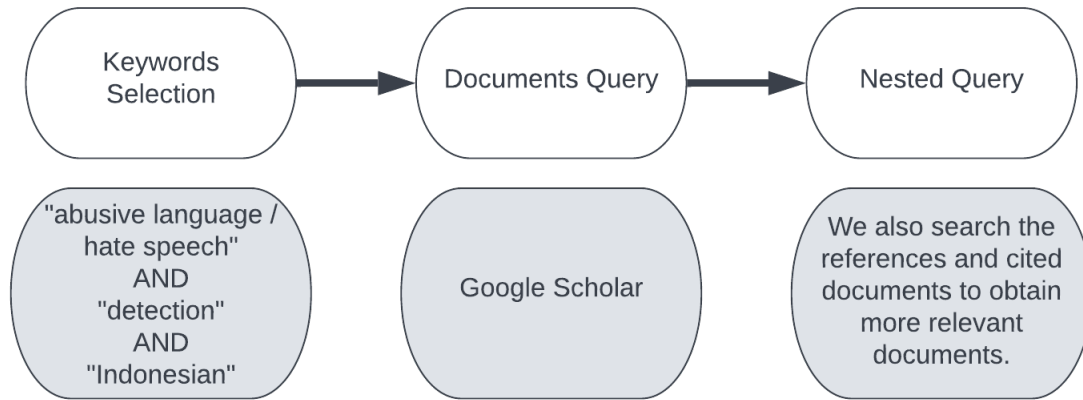

Fig. 1. Documents collection methodology.

Department) has also issued further regulations, as hate speech has the potential to have dangerous effects, not only for the victims of hate speech but also for society as a whole. Interestingly, most instances of hate speech on Indonesian social media are triggered by political events, such as elections. Several studies have also been conducted to study the hate speech phenomena in Indonesian social media [9], [10]. Most studies have focused on the automatic detection of hate speech utterances from social media data. The study by Alfina et al. [11] was one of the early studies of hate speech detection in Indonesian social media, specifically on the Twitter platform. This work proposed a novel dataset gathered from Twitter and manually annotated with two labels: hate speech and not. Another study by Ibrohim and Budi [12] proposed a more fine-grained hate speech dataset, which not only contains a binary class (hate speech vs. not), but also is annotated based on several categories, including the hate speech target, category, and level of hatefulness. More recent studies on hate speech detection in Indonesia have focused on adopting more recent technologies, such as neural-based and transform-based models [13], [14].

In this paper, we summarize the studies on hate speech detection, specifically on Indonesian social media. In this paper, we provide an overview of research conducted in this area, giving a comprehensive view of the state-of-the-art and datasets centered on this area. Our main objective is to draw a conclusion on the state-of-the-art and to provide several possible opportunities for future work based on existing open problems. After the introduction, we discuss the existing studies on hate speech detection in Indonesian social media, focusing on the approaches adopted and the available language resources in Section II. An analysis of challenges and opportunities for this particular task in future work is discussed in Section III. Finally, Section IV presents conclusive remarks for this survey.

## II. LITERATURE REVIEW

Similar to other languages, hate speech is becoming a relevant issue in Indonesian social media. Despite being regulated

by the national constitution, Indonesian social media users still use abusive language to communicate and even attack other users, often because they can hide their identities using anonymous accounts. Several studies have been conducted to address hate speech in Indonesian. Some have proposed novel corpora containing manually annotated data gathered from social media platforms such as Twitter, Instagram, and YouTube. Others have focused on developing machine learning models to automatically classify given utterances as either abusive or not. A few studies have done both, proposing a novel hate speech dataset and building a machine learning model based on that dataset. In this section, we review hate speech studies in Indonesian social media, focusing on two main aspects: (i) what datasets are available for abusive language detection in Indonesia and (ii) what has been done so far in Indonesian abusive language detection studies. We collected relevant documents using Google Scholar by searching for the keywords 'hate speech detection in Indonesian' and 'abusive language detection in Indonesian's, limited to the first five pages of results for each keyword and sorted by relevance, without a time filter. We also checked the cited documents and references on the first five pages of each search to find more relevant publications. Fig. 1 summarizes our approach to collecting relevant documents for our study.

### A. What Datasets are Available for Abusive Language Detection in Indonesia?

In this subsection, we collect information about the available datasets for abusive language studies in Indonesia. Table I summarizes the information about the available datasets for hate speech detection studies specifically in Indonesian. We gathered this information from previous studies on hate speech detection in Indonesian, using the approaches outlined in Fig. 1. We found that the two most frequently used datasets in previous work are those from Alfina et. al. [11] and Ibrohim et. al. [15]. However, these datasets are still less commonly used compared to hate speech datasets in languages with more resources, such as English, Italian, and Spanish. This may be due to the lack of a hate speech detection shared task in Indonesia, which usually attracts more researchers

TABLE I. SUMMARIZATION OF AVAILABLE ABUSIVE LANGUAGE DATASET IN INDONESIAN

Topical Focus	Sources	Annotation	Entries	Available	Ref
Hate Speech	Twitter	Expert Manual	1,100	Yes	[11]

to use available datasets for developing the best systems. In this section, we will discuss the available datasets based on their topical focus, sources, annotation approach, number of instances, and availability.

- **Topical Focuses** : As mentioned in a previous study by Pamungkas et al. [8], the topical focus of a dataset can be described as the specific abusive phenomena addressed, as well as the targets of the abusive behavior. We also agree that a hate speech dataset may cover more than one abusive phenomena. Compared to the results obtained by Pamungkas et al. [8], most abusive language datasets in Indonesia only focus on two topical focuses: abusiveness and hate speech, which are the most general terms used in abusive language studies. Only one study by Febriana et al. [22] includes the term “cyberbullying” to describe their dealt abusive phenomena. Based on these results, we argue that there are still many specific abusive phenomena that need to be addressed in Indonesian abusive language studies, such as sexism, xenophobia, offensiveness, and Islamophobia.
- **Sources** : The source of a dataset refers to the media platforms from which the data was gathered. The different characteristics of each platform can also be variables that influence the treatment and difficulty of the hate speech detection task. According to our results presented in Table I, most abusive language datasets in Indonesian were gathered from Twitter. This may be due to the convenience of scraping tweet samples using the Twitter API, and because Twitter has less strict rules regarding data sharing for research purposes compared to other platforms. This result is consistent with a survey conducted by Pamungkas et al. [8]. Additionally, we also observed that some research used Instagram posts and comments on news posts to study abusive phenomena.
- **Annotation Approach and Scheme** : Based on our manual inspection of previous studies, we found that almost all of the proposed datasets were annotated by

experts. This result differs from other studies of abusive language in other languages, where crowdsourcing is also a popular method for annotating datasets. We also observed that most proposed abusive language datasets in Indonesia use binary labels, including an “abusive” class and a “not abusive” class. However, we also found studies that propose a finer-grained annotation schema, such as the one implemented by [12], [28], [24]

- **Availability**: As presented in Table I, more than half of the datasets used for abusive language detection studies were not publicly available<sup>2</sup>. We can observe that most of the publicly available datasets were gathered from Twitter. Meanwhile, datasets sourced from other social media platforms such as Facebook and Instagram are mostly not shared publicly. This finding is also consistent with the survey results obtained by [8], where the availability of the datasets can be influenced by the regulation of the social media platforms related to data sharing policies.

### B. What has been Done so Far in Indonesian Abusive Language Detection Study?

In this subsection, we review the approaches adopted by previous studies to detect abusive language in Indonesian social media. We used a similar approach as presented in Fig. 1 to collect the available studies. We collected any publications found on Google Scholar using the defined keywords, “abusive language detection Indonesia” and “hate speech detection Indonesia”. We limited our query to the first five pages for each keyword and sorted results based on relevance, without a time filter. Furthermore, we also checked each document’s cited documents and references on the first five pages to find more relevant publications. Table II summarizes the available works in abusive language detection, specifically in Indonesian social media. We carefully reviewed each document to obtain the key information of each work. In this part, we focus on

<sup>2</sup>the link of cannot be found in the article.

TABLE II. SUMMARIZATION OF APPROACHES ADOPTED FOR HATE SPEECH DETECTION IN INDONESIAN

Model	Approach	Ref
Traditional Models	Using classical machine learning models such as SVM, Naive Bayes, Decision Tree, Random Forest, Logistic Regression, K-nearest Neighbours, Maximum Entropy and etc. coupled with several features including lexical and other structural features.	[11], [30], [17], [23], [12], [28], [27], [21], [31], [32], [33], [34], [35], [36], [37], [38], [39], [40]
Unsupervised Approach	Using data mining technique such as clustering, classification, and association, without training process to detect hate speech instance. This approach is very beneficial when the training data is limited.	[41], [42], [43]
Neural-based Models	Using neural-based models either RNN-based model variants such as LSTM, GRU, and etc or CNN-based models coupled with language representation either using available pretrained models or self-training based on the available training data.	[26], [19], [13], [44], [45], [46], [47], [48], [49], [50], [51], [52]
Transformer-based Models	Using the recent transformer based architecture such as BERT, RoBERTa, XLM, and etc. Based on the previous studies in NLP area, these models usually provide the robust performance across different NLP tasks.	[53], [31], [14]

reviewing the adopted approach of each work to deal with the abusive language detection task. In particular, we focus on two main discussions: variants of the models and implemented approaches. Following, we provide a deeper elaboration to compare the previous work in Indonesian abusive language studies, to gain insights for further development.

- **Model Variant:** A wide variety of classification models have been adopted for the abusive language detection task in Indonesian. Table II summarizes the published studies in this topic. Based on the results, we divided the proposed models into four different variants: traditional models, unsupervised models, neural-based models, and transformer-based models. We can observe that most previous works employed traditional models to deal with abusive language detection in Indonesia. Additionally, we also found a few studies that adopt an unsupervised approach, which do not require labeled data to detect abusive language. This is an interesting finding, as unsupervised models are not popularly used for detecting abusive language in more resource-rich languages, as observed by Pamungkas et al. [8]. Similar to traditional-based models, neural-based models are also popular for detecting abusive language. This is in line with the availability of Indonesian language models that have been proposed by several recent works. Lastly, we notice that the use of transformer-based models is still not yet explored in Indonesian abusive language studies. Unlike Indonesian language models, studies focused on developing transformer models for the Indonesian language are also limited. Most of the abusive language studies in Indonesia that exploit transformer-based models are utilizing multilingual transformers.
- **Classification Models:** A wide variety of classification models were used in this task. Starting with traditional classifiers, several models such as SVM, Naive Bayes, Decision Tree, Random Forest, Logistic Regression, KNN, and Maximum Entropy have been used for this classification task. These models were the most popular approach for detecting abusive language, specifically in Indonesian data. This may be due to the limited availability of resources in Indonesian, such as language models or labeled datasets. For the unsupervised approach, a few studies have proposed using lexicon-based and straightforward string match-

ing approaches to detect abusive instances. Despite lexicon-based approaches being unpopular in common text classification tasks, this approach is still reliable when annotated data is limited. In line with the trend in other natural language processing tasks, the use of neural-based models is also gaining more attention from NLP researchers in Indonesia. Some models such as LSTM, GRU, and CNN have been widely used to detect abusive language in Indonesian, either using pre-trained language representations or without pre-training models. Lastly, the recent transformer-based technology is also starting to be used in the Indonesian research community. This may be due to the availability of multilingual transformer models such as BERT Multilingual, Multilingual GPT, and XLM RoBERTa. Some of these models were also used by a few studies [14], [53] for detecting abusive language in Indonesian.

### III. CHALLENGES AND OPPORTUNITIES

The literature review and analysis presented in previous sections provide insights into the current state of the art of abusive language studies in Indonesian. Based on these analyses, we have observed several challenges in this task, which are summarized as follows:

- **Limited Availability of Language Resources:** The adopted approach for dealing with the task of abusive language detection in Indonesian is currently limited and lags behind studies in other, more resource-rich languages. Traditional models are the most popular approach for addressing this problem in Indonesia, while in other languages, more recent transformer-based models are commonly used to achieve state-of-the-art results. We believe that this discrepancy is likely related to the limited availability of language resources, including language corpora and language models. We also note that several recent studies have proposed transformer-based models, such as IndoBERT [54] and IndoBERTtweet [55], but they are still limited in comparison to the transformer technologies available for other languages.
- **Limited Exploration of Abusive Phenomena:** Based on the abusive phenomena covered in the available datasets for abusive language detection studies, we

perceive that the explored abusive phenomena in Indonesian is still very limited. Studies in Indonesian have mostly focused on the detection of hate and abusive speech. Meanwhile, similar studies in other languages have been conducted with a broader coverage of abusive phenomena, which can include sexism, racism, misogyny, Islamophobia, and more. Some of these studies have also proposed finer-grained labels to capture more specific abusive phenomena, which is usually beneficial for differentiating the treatment for handling each phenomenon.

- **Low Awareness of Reproducibility Aspect:** Based on our review, we also notice that most of the published research in Indonesian abusive language studies do not make their code and datasets publicly available. This issue makes it difficult for other researchers to reproduce the results of previous works, which is important for better analysis of their own studies. Furthermore, reproducibility is an important aspect for maintaining continuity in research, specifically in the area of abusive language research.
- **Limited Approach for Annotation Procedure:** We observe that most studies used manual expert annotation procedures to label abusive language datasets. This approach is proven to be reliable for obtaining a high-quality dataset when the subjectivity of the annotation task is high. However, this approach is usually not feasible for annotating a large number of data, as the annotation task becomes more labor-intensive and time-consuming. Sometimes, alternative annotation approaches such as crowdsourcing scenarios can provide a wider perspective, with a diverse demographic of annotators who have different backgrounds and views to evaluate the abusive instances.
- **The Problem of Code-Mixed Languages:** Geographically, Indonesia consists of several regions, each with its own local languages. According to recent reports, there are 718 local languages used by different regions and tribes in Indonesia. Indonesians tend to use a mix of their own local language and Bahasa Indonesia to communicate on social media platforms, such as Twitter. Related to this issue, we conducted a random check on some publicly available datasets. We found a lot of code-mixed instances on the checked datasets [28], [24], which are mostly written in a mixture of Indonesian and Javanese. As in other languages and other NLP tasks, the issue of code-mixing is still a prominent challenge that needs to be tackled.

Based on these challenges, we also point out several opportunities for future studies in this research direction, which are summarized below.

- **Building Novel Language Resources in Indonesian:** Our NLP research community should also focus on studying and developing language resources in Indonesian. These resources could include novel corpora for diverse tasks or recent language model technologies. The availability of more language resources could provide more opportunities for researchers in

abusive language studies to explore more approaches to better detect abusive language in Indonesian.

- **Expanding the Study Exploration into Other Abusive Phenomena:** As mentioned in the challenges section, abusive language studies in Indonesian are still focused on a few phenomena, including hate speech and abusiveness. Based on our investigation, there are several abusive phenomena specific to Indonesia that could potentially become a focus for exploration, including islamophobia and political hate speech. There are also other more general phenomena which have been studied in other languages, such as sexism, racism, xenophobia, homophobia, and more. A broader exploration into other abusive phenomena could open more opportunities for research collaboration between NLP researchers and researchers from other communities such as the study of humanity, psychology, gender studies, and social science.
- **Exploring Other Annotation Approach to Build Abusive Language Datasets:** Most of the available abusive language datasets in Indonesian were built using expert annotation approaches. For example, crowdsourcing could be a worth-considering option to be implemented for annotating abusive language datasets. Because crowdsourcing approach has the advantage of bringing in a diverse set of annotators with different background identities, which can help to reduce bias in the dataset, which is also an important issue in this study. In addition, crowdsourcing can be particularly useful when the dataset is large and complex, and would be too time-consuming for a single person to finish.
- **Tackling the Problem of Code-Mixed Data:** Code-mixing is becoming a prominent challenge in various NLP tasks in recent years. This problem may be due to the current technology and platforms which have a multilingual environment. Similarly, Indonesians also tend to use a mix of their local languages and Bahasa Indonesia to communicate with others both in real life and on social media channels. Dealing with language-shift in code-mixed data is a challenging task. Specifically in abusive language studies, several transfer learning approaches could be applied in this task.

#### IV. CONCLUSION

This survey presents a summary of research on detecting abusive language in Indonesian social media. It covers existing datasets that could be used for this research, including datasets from multiple platforms, types of abusive behavior, and languages. The survey also examines the methods that have been proposed for detecting abusive language in Indonesian social media. Finally, it discusses the challenges and opportunities in this area of research and provides suggestions for future development.

This study found that most of the existing datasets for detecting abusive language were collected from social media platforms like Twitter, Facebook, and Instagram, with Twitter being the most commonly used source. This may be because

it is easy to obtain samples from Twitter using its public API and because of the less strict policy from Twitter for sharing data. The study also observed that hate speech is the most researched type of abusive language, compared to other types such as abusiveness and cyberbullying.

A wide variety of models have been implemented to deal with the task of abusive language detection in Indonesia. However, most studies have exploited traditional models such as logistic regression, SVM, naive bayes, and random forest to deal with this task. Several feature representations were used to train the models, which include TF-IDF, Bag of Words, and word vectors obtained from pre-trained language representations. Overall, recent deep learning architectures have obtained more competitive results compared to other models. Furthermore, we also observed that the use of transformer-based models is less popular in Indonesian hate speech studies.

Finally, we have identified some recent challenges and opportunities for abusive language detection studies in Indonesian. We observe that the availability of more language resources in Indonesian is one of the factors that contribute to the acceleration of research development, specifically in this area. We also identify that abusive language studies should explore more diverse phenomena beyond hate speech and abusiveness topics, such as islamophobia, political hate speech, and other more general phenomena which are already widely studied in other languages such as sexism and racism. Another suggestion is related to the annotation approach for labeling abusive datasets, which mostly exploit manual expert annotation procedures. We suggest exploring crowdsourcing scenarios which could produce less bias and more comprehensive datasets. Finally, we also encourage researchers who focus in this research area to consider the code-mixing issue in current abusive language datasets in Indonesia. We believe that dealing with code-mixing issue could improve the overall model performance for detecting abusive language in Indonesian data.

**Abstract**—Collaborative systems allow a group of organizations to collaborate and complete shared tasks through distributed platforms. Organizations who collaborate often leverage cloud-based solutions to outsource their data and to benefit from the cloud capabilities. During such collaborations, tenants require access to and utilize resources held by other collaborating tenants, which are hosted across multiple cloud providers. Ensuring access control in a cloud-based collaborative application is a crucial problem that needs to be addressed, particularly in a multi-cloud environment. This paper presents the Multi-Cloud ABAC: MC-ABAC model, an extension of the ABAC: Attribute Based Access Control model, suitable for ensuring secure collaboration and cross-tenant access in a multi-cloud environment. The MC-ABAC introduces the notions of tenant, cloud customer and cloud service provider as fundamental entities within the model. Additionally, it incorporates multiple trust relations to enable collaboration and resource sharing among tenants in the multi-cloud environment. To demonstrate its feasibility, we have implemented the MC-ABAC model using Python technology.

**Keywords**—ABAC model; multi-tenant; multi-cloud; collaboration; trust

## I. INTRODUCTION

Nowadays, applications and IT systems are increasingly geared towards collaboration, facilitating cooperation between organizations to attain shared objectives. These collaborative efforts optimize the utilization of distributed resources among the participating entities, leading to enhanced productivity and overall benefits. Over the years, extensive research has been conducted on the design and implementation of collaborative work environments [1], aiming to fulfill the demands of collaborative activities. In this context, collaborative applications offer innovative technologies that allow a group of users to communicate, work together, and complete shared tasks using distributed platforms.

Many organizations rely on cloud-based services provided by cloud service providers to externalize their IT infrastructure, including computing, networking, and data storage [2], [21]. This enables remote access to hardware and software over the Internet. To maintain the privacy and confidentiality of these services, the cloud service provider employs a multi-tenancy approach, segregating data and customer services into distinct tenants. Each tenant is assigned to an individual or organization utilizing the cloud service.

In multi-cloud environment, collaborating tenants may be hosted in the same cloud provider or in different cloud providers. These tenants often require access to information

shared by other tenants during collaborative process. This information often contains sensitive data. Balancing collaboration and security can be challenging because collaboration aims to provide access to services and resources for those who require them, while security focuses on preserving the availability, confidentiality, and integrity of these assets and limiting access to authorized individuals only. This raises the issue of access control [25]. In order to facilitate access and collaboration across multiple tenants, a robust and fine-grained access control model is mandatory.

Traditional access control models [3], [4], [5], [6], [7] DAC, MAC, RBAC, TBAC, TMAC and others are primarily designed for defining access policies within a single organization or for specific local access control scenarios. However, they may not be adequately suitable for defining access policies in multi-tenant environments. To address the challenges of collaboration and multi-tenant access, various access control models [23], [12], [13], [14] (CTTM, MTAS, MT-RBAC, MT-ABAC, etc ) have been proposed. Nevertheless, these approaches are designed for multi-tenant environment within a single cloud. They may not effectively address the access control challenges that arise in multi-cloud environments.

In this paper, we propose MC-ABAC: Multi-cloud ABAC model, as an extended version of the ABAC [8] (Attribute Based Access Control) model. MC-ABAC leverages the capabilities of ABAC [18], [24], such as flexibility and adaptability. MC-ABAC is especially designed for securing collaboration and cross-tenant access in a multi-cloud environment. It presents the concepts of tenant, cloud customer and cloud service provider as key entities in the model. Furthermore, this model introduces many trust relations in order to support resource sharing between tenants in a multi-cloud environment. Finally, we implemented this model using Python technology to demonstrate its feasibility. To the best of our knowledge, this is the first work, that aims to extend the ABAC model to enable collaboration in a multi-cloud environment.

Our main contribution in this paper is to define a multi-cloud ABAC model, with cross-tenant trust in a multi-cloud environment. This model is suitable for supporting sharing resources between multi-cloud tenants belonging to different cloud providers. Our model takes into account the heterogeneity requirement, since cloud providers may use different and heterogeneous access control models. This is possible through the flexibility of the ABAC model, which can represent access policies defined by any model [3]. Furthermore, this model is better suited to control access to any cloud service, whether it

be IaaS, PaaS, or SaaS.

This paper is organized as follows: Section 2 presents the background of this work, focusing on a telemedicine use case and the explanation of the ABAC model. The related work is presented in Section 3. Section 4 presents the suggested MC-ABAC model. In Section 5, we introduce the trust relations. Section 6 describes the implementation architecture. Finally, we conclude in Section 7.

## II. BACKGROUND

The purpose of this section is to provide the necessary background information for this work. It primarily focuses on presenting a use case of telemedicine within a cloud-based collaborative environment. Additionally, it introduces the attribute-based access control model.

### A. Case Study

In this study, we examine the telemedicine use case, which involves Rabat's School Hospital *SH1* and Oujda's School Hospital *SH2* as two collaborating organizations that share certain resources and services to achieve a common goal. *SH1* and *SH2* utilize cloud-based services provided by Azure and Amazon, to outsource their IT infrastructure and software, including computing, networking, and data storage.

Within this particular use case, in Table I, we consider that Azure cloud offers three services, namely *s1*, *s2*, and *s3*, while Amazon cloud provides three services, namely *s4*, *s5*, and *s6*. Each customer cloud creates its own tenants using the services offered by Azure and Amazon clouds. For instance, the customer *SH1* creates tenants (*t1*, *t2*, *t3*, *t4*, *t5*) using the services (*s1*, *s2*, *s3*, *s4*, *s5*) provided by Azure and Amazon, respectively. Similarly, the customer *SH2* creates its own tenants (*t6*, *t7*, *t8*, *t9*, *t10*) from the available services (*s4*, *s5*, *s6*, *s1*, *s2*), respectively. During collaboration, users

TABLE I. MULTI-CLOUD USE CASE

Cloud customers	Cloud providers	Tenants	services
<i>SH1</i>	Azure	( <i>t1</i> , <i>t2</i> , <i>t3</i> )	( <i>s1</i> , <i>s2</i> , <i>s3</i> )
<i>SH1</i>	Amazon	( <i>t4</i> , <i>t5</i> )	( <i>s4</i> , <i>s5</i> )
<i>SH2</i>	Amazon	( <i>t6</i> , <i>t7</i> , <i>t8</i> )	( <i>s4</i> , <i>s5</i> , <i>s6</i> )
<i>SH2</i>	Azure	( <i>t9</i> , <i>t10</i> )	( <i>s1</i> , <i>s2</i> )

from one tenant require access to resources owned by other tenants. Therefore, our scenario gives rise to a set of requirements for cross-tenant access in a multi-cloud environment, which can be categorized into four cases or situations:

- **Case 1:** Collaborating tenants hosted in the same cloud provider and owned by the same cloud customer. For instance, in the Azure cloud, a user from tenant *t1* requires access to resources owned by tenant *t2*.
- **Case 2:** Collaborating tenants hosted in the same cloud provider and owned by different cloud customers. For example, in the Azure cloud, a user from tenant *t3* (owned by *SH1*) requires access to resources owned by tenant *t9* (owned by *SH2*).
- **Case 3:** Collaborating tenants hosted in different cloud providers and owned by the same cloud customer. For example, a user from tenant *t2* (hosted in Azure cloud)

needs access to resources owned by tenant *t5* (hosted in Amazon cloud).

- **Case 4:** Collaborating tenants hosted in different cloud providers and owned by different cloud customers. For example, a user from tenant *t1* (owned by *SH1* and hosted in Azure cloud) needs access to resources owned by tenant *t8* (owned by *SH2* and hosted in Amazon cloud).

Our main objective in this approach is to enable secure multi-tenant collaborations in a multi-cloud environment. For this purpose, there is a need for a comprehensive fine-grained access control model that caters to the specific requirements of the scenario.

### B. Attribute Based Access Control Model

The following section introduces the ABAC model, which has been tailored to suit the development of MC-ABAC and is not intended to be a comprehensive ABAC model. ABAC has been defined in several ways in the literature, typically for specific use cases. ABAC is an adaptive and a flexible fine-grained access control model.

**Definition 1:** The core components of ABAC model [8], [22] are:

- *U* and *O* represent finite sets of existing users and objects, respectively.
- $A = \{create, read, update, delete\}$  is a finite set of actions.
- *UATT* and *OATT* represent finite sets of user and object attribute functions, respectively.
- For each  $att \in \{UATT \cup OATT\}$ ,  $range(att)$  represents the attribute's range, which is a finite set of atomic values.
- $attType : UATT \cup OATT \rightarrow \{set, atomic\}$ , specifies attributes as set or atomic values.
- Each attribute function maps elements in *U* to an atomic value or a set
  - $\forall ua \subseteq UATT. ua : U \rightarrow Range(ua) \text{ if } attType(ua) = atomic$
  - $\forall ua \subseteq UATT. ua : U \rightarrow 2^{Range(ua)} \text{ if } attType(ua) = set$
- Each attribute function maps elements in *O* to an atomic value or a set
  - $\forall oa \subseteq OATT. oa : O \rightarrow Range(oa) \text{ if } attType(oa) = atomic$
  - $\forall oa \subseteq OATT. oa : O \rightarrow 2^{Range(oa)} \text{ if } attType(oa) = set$
- An authorization that decides on whether a user *u* can access an object *o* in a particular environment *e* for the action *a*, is a boolean function of *u*, *o*, and *e* attributes: Rule:  $authorization_a(u, o) \rightarrow f(ATTR(u), ATTR(o))$ .

### III. RELATED WORK

Several works have been in the literature to ensure access control in multiple environments. In the Task based access control [5] (TBAC), the permissions are granted according to the progress of several tasks. The TRBAC [7] model is constructed by adding the "Task" concept to the RBAC model. In TRBAC, the user has a relationship with permission through role and task. On the other hand, in the Team Access Control Model (TMAC) [6], the permissions are granted to each user through its role and the current activities of the team. These models enable fine-grained access control but they do not incorporate contextual parameters into security considerations and do not support collaboration in multi-domain environment [9], [10]. Moreover, the notion of "Team" used in TMAC model is static. Therefore, this model does not support dynamic collaboration.

Several access control approaches have been proposed to secure resources in cloud environments [11], [12], [13], [15], [16], [23]. Calero et al. [11] introduces a multi-tenancy authorization system based on hierarchical role-based access control with a coarse-grained trust relation and path-based object hierarchies. The work assumes that each issuer may utilize multiple cloud services and collaborate with other issuers.

Another model, Multi-Tenant Role-Based Access Control (MT-RBAC), is proposed by Tang et al. in [13]. This model provides fine-grained access control in collaborative cloud environments by incorporating trust relations among tenants. However, this model does not consider trust relations among issuers separately from tenants. In the MT-RBAC model, the truster exposes certain trusters roles to the trustee, who then assigns their users to these roles. This enables users to access the trusters' resources by activating the trusters' roles. The CTRBAC model [16] extends the traditional RBAC model by introducing new entities to support cross-tenant access and the concept of tasks. However, it should be noted that in this model, a tenant may utilize roles owned by other tenants, which can potentially compromise confidentiality requirements. Additionally, these models are based on the RBAC model, which may lack the necessary flexibility to define complex policy rules.

Several recent approaches have been proposed in [20], [26], [27], focusing on the concept of activity control. This concept expands the scope of traditional access control models by addressing how multiple administrative authorities can effectively collaborate to create, share, manage, and protect digital content and resources. However, these solutions are not suitable for facilitating cross-tenant access in a multi-cloud environment.

The Attribute-Based Access Control (ABAC) model has gained significant attention due to its relevance in addressing the limitations of classical access control models such as RBAC. ABAC, offers a solution that is adaptive and flexible, providing an effective means to describe intricate access control semantics, particularly in collaborative environments. The ABAC model has been extended in several works [14], [17], [28], [29], [30] to support collaboration and resource sharing.

One notable example is the Multi-Tenant Attribute-Based Access Control (MT-ABAC) model [14], which introduces

a framework for facilitating collaboration between tenants in a single cloud environment. The MT-ABAC model takes a decentralized approach, allowing each tenant to manage their own access control policies and attributes. However, the MT-ABAC model is primarily designed for multi-tenant environments within a single cloud. These extended models of ABAC may not adequately address access control challenges that arise in multi-cloud environments where users and shared resources span across different tenants in multiple clouds. In such scenario, the complexity increases as different clouds may have their own access control mechanisms and policies.

Authors propose in [19] the authorization federation approach in order to ensure collaboration among organizations whose resources are distributed across multiple cloud service providers. This study primarily focuses on facilitating collaboration among multiple homogeneous clouds, limiting its applicability to heterogeneous multi-cloud environments. Additionally, the emphasis of this approach is on collaboration and resource sharing at the Infrastructure as a Service (IaaS) level, by using openstack cloud [21], overlooking resource sharing at the Platform as a Service (PaaS) and Software as a Service (SaaS) levels.

Therefore, in this paper, we propose the MC-ABAC model, which aims to ensure secure multi-tenant collaborations in a multi-cloud environment. This approach introduces the concepts of tenant, cloud customer, and cloud service provider as key entities in the model. To the best of our knowledge, our work is the first approach that aims to extend the ABAC model to support collaboration in a multi-cloud environment.

### IV. MULTI-CLOUD ATTRIBUTE BASED ACCESS CONTROL MODEL

In this section, we introduce the MC-ABAC (Multi-Cloud Attributes Based Access Control) model, which extends the ABAC model to support cross-cloud collaboration among multiple clouds. The MC-ABAC model incorporates new entities to facilitate access control of shared resources across multiple clouds. These entities, namely tenant, cloud service provider, and cloud customer, are added to the original ABAC model. Fig. 1 illustrates the structure of the MC-ABAC model. The following sections provide a detailed description of these new entities:

**Tenant:** is a virtual partition of a cloud service provided by the cloud provider to the customer. The cloud service provider segregates the data and services into multiple tenants. A cloud service provider is defined in this approach as the 5-uplet,  $(t, U, O, ATT)$ :

- $t$ : The tenant ID;
- $U$ : Set of users belonging to this tenant  $t$ ;
- $O$ : Set of objects held by this tenant  $t$ . An object in cloud could be resource, machine, or service;
- $ATT$ : Set of user, object and environment attributes defined by this tenant  $t$ . An object in cloud could be resource, machine, or service;

**A cloud service provider (cp)** is an organization that offers computing resources, such as storage, platform, application,

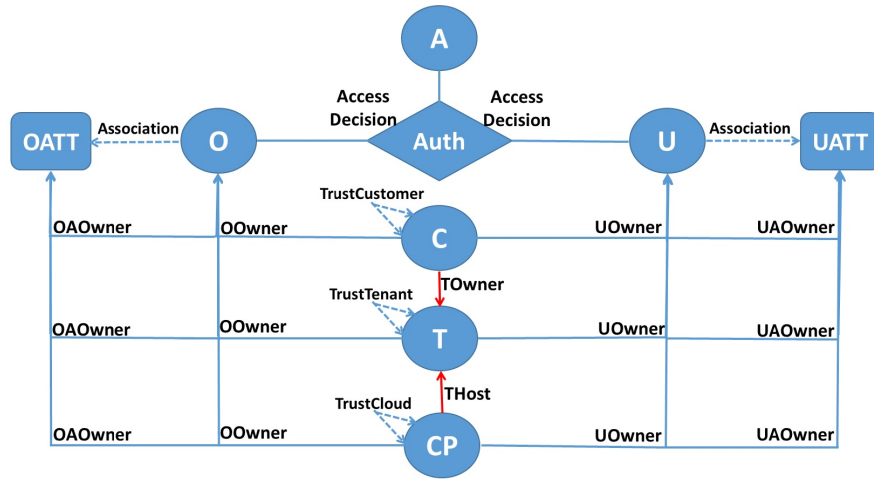

Fig. 1. MC-ABAC model.

and cloud-based compute services, that businesses can access over a network as and when required. These resources can be scaled up or down depending on the customer's needs. A cloud service provider is defined in this approach as the 5-uplet,  $(cp, U, O, ATT, T)$ :

- $cp$ : The cloud service provider  $ID$ ;
- $U$ : Set of users belonging to this  $cp$ ;
- $O$ : Set of objects held by this  $cp$ . An object in cloud could be resource, machine, or service;
- $ATT$ : Set of user, object and environment attributes defined by this  $cp$ ;
- $T$ : Set of tenants hosted in this  $cp$ .

A **cloud customer** ( $c$ ) refers to an individual or organization that utilizes cloud services. It's worth noting that a cloud customer can be a cloud itself, and that clouds may provide services to each other. A cloud customer is defined as the 5-uplet,  $(c, U, O, ATT, T)$ :

- $c$ : The cloud customer  $ID$ ;
- $U$ : Set of users belonging to this  $c$ ;
- $O$ : Set of objects held by this  $c$ . An object in the cloud could be resource, machine, or service;
- $ATT$ : Set of user, object and environment attributes defined by this  $c$ .
- $T$ : Set of tenants that this cloud customer  $c$  owns.

In the model, every user and object is associated with a unique entity: Cloud provider, cloud customer or tenant. To achieve this, the model introduces a system-defined attribute called  $UOwner$  for users and  $OOwner$  for objects. Additionally, each user attribute and object attribute is exclusively owned by a single entity. This is represented using functions  $UAOwner$  for user attributes and  $OOwner$  for object attributes.

#### A. MC-ABAC Definition

**Definition 2.** Core Multi-Cloud ABAC (Fig. 1) is defined by the basic component sets, functions and authorization policy language given below:

- $U, O, T, CP$  and  $C$  represent finite sets of existing users, objects, tenants, cloud service providers and cloud customers respectively.
- $A$  represents a finite set of actions available on objects. Typically  $A = \{create; read; update; delete\}$ .
- $UA$  and  $OA$  represent a finite sets of user and object attribute functions ( $ua$  and  $oa$ ) respectively.
- For each  $att \in UA \cup OA$ ,  $range(att)$  represents the attribute's range, which is a finite set of atomic values. An attribute  $att$  could be  $ua$  or  $oa$ .
- $attType : UA \cup OA \rightarrow \{set; atomic\}$ , specifies attributes as set or atomic values.
- Each attribute function maps elements in  $U$  to an atomic value or a set
  - $\forall ua \in UA. ua : U \rightarrow Range(ua)$  if  $attType(ua) = atomic$
  - $\forall ua \in UA. ua : U \rightarrow 2^{Range(ua)}$  if  $attType(ua) = set$
- Each attribute function maps elements in  $O$  to an atomic value or a set
  - $\forall oa \in OA. oa : O \rightarrow Range(oa)$  if  $attType(oa) = atomic$
  - $\forall oa \in OA. oa : O \rightarrow 2^{Range(oa)}$  if  $attType(oa) = set$
- $UA = GUA \cap LUA \cap CUA$ , such as:
  - $GUA$  represents a finite set of global user attribute functions which are defined by the cloud customer  $C$
  - $LUA$  represents a finite set of local user attribute functions which are defined by the tenants  $T$

- $CUA$  represents a finite set of cloud user attribute functions which are defined by the cloud service provider  $cp$
- $OA = GOA \cap LOA \cap COA$ , such as:
  - $GOA$  represents a finite set of global object attribute functions which are defined by the cloud customer  $C$
  - $LOA$  represents a finite set of local object attribute functions which are defined by the tenants  $T$
  - $COA$  represents a finite set of cloud object attribute functions which are defined by the cloud service provider  $cp$
- $UOwner : (u : U) \rightarrow E$ , required attribute function mapping user  $u$  to its owner entity. Note that an entity in this approach, could be a tenant  $t$ , a cloud service provider  $cp$  or cloud customer  $c$ ;
- $OOwner : (o : O) \rightarrow E$ , required attribute function mapping object  $o$  to its owner entity ( $t$ ,  $cp$  or  $c$ ).
- $UOwner : (ua : UA) \rightarrow E$ , attribute function, mapping user attribute  $ua$  to its owner entity ( $t$ ,  $cp$  or  $c$ ):
  - $ua \in LUA \rightarrow UOwner(ua) \in T$
  - $ua \in CUA \rightarrow UOwner(ua) \in CP$
  - $ua \in GUA \rightarrow UOwner(ua) \in C$
- $OOwner : (oa : OA) \rightarrow TE$ , attribute function, mapping object attribute  $oa$  to its owner entity ( $t$ ,  $cp$  or  $c$ ):
  - $oa \in LOA \rightarrow OOwner(oa) \in T$
  - $oa \in COA \rightarrow OOwner(oa) \in CP$
  - $oa \in GOA \rightarrow OOwner(oa) \in C$
- $TOwner : (t : T) \rightarrow C$ , required attribute function mapping tenant  $t$  to its owner cloud customer  $c \in C$ ;
- $THost : (t : T) \rightarrow CP$ , required attribute function mapping tenant  $t$  to its hosting cloud provider  $c \in C$ ;
- The authorizations that decide on whether a user  $u$  can access an object  $o$  for the action  $a$ , are a three Boolean functions of  $u$  and  $o$  attributes:
  - $LAuth_a(u; o) \rightarrow f(LUA(u); LOA(o))$ , represents local authorization that is defined by the tenant;
  - $GAuth_a(u; o) \rightarrow f(GUA(u); GOA(o))$ , represents global authorization that is defined by cloud customer;
  - $CAuth_a(u; o) \rightarrow f(CUA(u); COA(o))$ , represents cloud authorization which is defined by cloud service provider;
- Cloud administrator: The person who is responsible for defining access policies in the cloud service provider;
- customer administrator: The person responsible for defining access policies in the cloud customer;
- Tenant administrator: The person who is responsible for defining access policies in the tenant entity;

In this model, administrators are granted the ability to perform various administrative operations, with each operation having certain preconditions that need to be satisfied. In the following, we present the formal specification of several administrative operations and their corresponding preconditions:

- $\forall ua \in CUA, ua(u : U)$  is defined by the cloud administrator of  $cp$  only if ( $UOwner(ua) = UOwner(u) = cp$ ), means that the cloud  $cp$  must be the owner of both the user  $u$  and the attribute  $ua$ . The same principle applies to the subsequent operations as well;
- $\forall oa \in COA, oa(o : O)$  is defined by the cloud administrator only if ( $OOwner(oa) = OOwner(o) = cp$ );
- $\forall ua \in GUA, ua(u : U)$  is defined by the customer administrator of  $c \in C$  only if ( $UOwner(ua) = UOwner(u) = c$ );
- $\forall oa \in GOA, oa(o : O)$  is defined by the customer administrator of  $c \in C$  only if ( $OOwner(oa) = OOwner(o) = c$ );
- $\forall ua \in LUA, ua(u : U)$  is defined by the tenant administrator of  $t \in T$  only if ( $UOwner(ua) = UOwner(u) = t \cup (TOwner(UOwner(ua)) = UOwner(u))$ ), This implies that the user  $u$  must be owned by either the tenant  $t$ , who is the owner of the attribute  $ua$ , or the cloud customer who owns the tenant  $t$ .
- $\forall oa \in LOA, oa(o : O)$  is defined by the tenant administrator of  $t \in T$  only if ( $OOwner(oa) = OOwner(o) = t$ );
- $CAuth_a(u; o)$  is defined by the cloud administrator of  $cp$ . For all attributes  $ua, oa$  that are defined in  $CAuth_a(u; o)$  only if  $UOwner(ua) = OOwner(oa) = UOwner(u) = OOwner(o) = cp$ . Each authorization function needs to verify that the owner of  $ua$  is the same as the owner of  $oa, u$ , and  $o$ .
- $GAuth_a(u; o)$  is defined by the customer administrator of  $c \in C$ . For all attributes  $ua, oa$  that are defined in  $GAuth_a(u; o)$  only if  $UOwner(ua) = OOwner(oa) = UOwner(u) = OOwner(o) = c$ ;
- $LAuth_a(u; o)$  is defined by the tenant administrator of  $t \in T$ . For all attributes  $ua, oa$  that are defined in  $LAuth_a(u; o)$  only if ( $UOwner(ua) = OOwner(oa) = UOwner(u) = OOwner(o) = t \cup (UOwner(ua) = OOwner(oa) = OOwner(o) = t \cap UOwner(u) = TOwner(t))$ ). This predicate  $UOwner(u) = TOwner(t)$  means that the

### B. Administrative MC-ABAC Model

In this subsection, we focus on the administrative model for the suggested MC-ABAC. This model enables administrators to perform various administrative operations. In this approach, we distinguish three types of administrators: cloud administrator, customer administrator and tenant administrator.

user  $u$  is owned by the cloud customer who is the owner of  $t$ ;

## V. TRUST RELATIONS

MC-ABAC introduces many trust relations in order to support access between the cloud customer and the cloud service provider, cross tenant access, cross customer access and resource sharing in a multi-cloud environment. These trust relations are established between both, cloud service providers, cloud customers and tenants. In the following, we will define each trust relation used in this model.

### A. Provider to Customer Trust Relation

The Provider to customer trust relation ( $CPC$ )  $\subseteq CP \times C$  is a many-to-many relationship between the cloud service provider  $cp$  and the cloud customer  $c$ . It is defined as  $TrustCPToC(cp, c) = \cup_i(S_i)$ , such as  $S_i$  is a cloud service owned by the provider  $cp$ . This relationship means that the cloud  $cp$  provides a set of services  $\cup_i(s_i)$  to the cloud consumer  $c$ . This customer  $c$  will create its own tenants from these services.

For example, the trust relation  $TrustCPToC(Azure, SH1) = \{s1, s2, s3\}$ , means that the customer  $SH1$  could create new tenants  $t1$ ,  $t2$  and  $t3$  from these services  $s1$ ,  $s2$  and  $s3$ , in the cloud  $cp$ . Using this trust relation, the cloud consumer can establish or create their own tenants based on the services defined within this relation.

### B. Cloud Trust Relation

The cloud trust relation ( $CPCP$ )  $\subseteq CP \times CP$  is a many-to-many reflexive relation between a truster cloud  $cpr \in CP$  and a trustee cloud  $cpe \in CP$ . It is defined as  $TrustCloud(cpr, cpe : CP) \rightarrow 2^T$  means that the cloud service provider  $cpr$  authorizes  $cpr$ 's tenants to collaborate with  $cpe$ 's tenants. This implies that tenants hosted in  $cpr$  could establish tenant trust relation with  $cpe$ 's tenants, in order to ensure cross tenant access in multi-cloud environment.

This trust relation  $TrustCloud(cpr, cpe) = \bigcup_{i=1}^k t_i$  is defined with the additional required condition that:  $t \in TrustCloud(cpr, cpe)$  only if  $THost(t) = cpr$ , this implies that the cloud service provider  $cpr$  should possess ownership of the tenants which are defined in this relation. For example:  $TrustCloud(Azure, Amazon) = t1, t2$ , means that tenants hosted in *Azure* cloud, such as tenants  $t1$  or  $t2$ , can establish a trust relation with tenants from the *Amazon* cloud.

### C. customer Trust Relation

The customer trust relation ( $CC$ )  $\subseteq C \times C$  is a many-to-many reflexive relation between a truster customer  $cr \in C$  and a trustee customer  $ce \in C$ . It is defined as  $Trustcustomer(cr, ce : C) \rightarrow 2^T$ , which means that the cloud customer  $cr$  authorizes some  $cr$ 's tenants to collaborate with  $ce$ 's tenants. This implies that tenants owned by  $cr$  could establish tenant trust relation with  $ce$ 's tenants, in order to ensure cross-tenant access, where each tenant belongs to a different customer, .

This trust relation  $Trustcustomer(cr, ce) = \bigcup_{i=1}^k t_i$  is defined with the additional required condition that:  $t \in$

$Trustcustomer(cr, ce)$  only if  $TOwner(t) = cr$ , this means that the customer  $cr$  must be the owner of tenants which are defined in this relation. For example:  $Trustcustomer(SH1, SH2) = t2, t3$ , means that tenants belonging to cloud customer  $SH1$ , such as  $t2$  or  $t3$ , can establish trust relationships with tenants belonging to cloud customer  $SH2$ .

### D. Tenant Trust Relation

The tenant trust relation ( $TT$ )  $\subseteq T \times T$  is a many-to-many reflexive relation between the truster  $tr \in T$  and the trustee  $te \in T$ . It is defined as  $TrustTenant(tr, te : T) \rightarrow 2^U$  which means that the tenant  $te$  is authorized to assign values for  $te$ 's local user attributes to tenant  $tr$ 's users. This trust relation  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$  is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $UOwner(u) = tr$ , this implies that the truster  $tr$  must be the owner of users which are defined in this relation. For example:  $TrustTenant(t1, t3) = u1, u2$ , means that the tenant  $t3$  can assign values for  $t3$ 's local user attributes to  $u1$  and  $u2$ .

This trust relation is subject to a precondition that needs to be satisfied, which depends on the four cases introduced in the case study subsection. In the following, we specify the precondition for each case:

- **Case 1:** Collaborating tenants hosted in the same cloud provider and owned by the same cloud customer.  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$  is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $UOwner(u) = tr$ .
- **Case 2:** Collaborating tenants hosted in the same cloud provider and owned by different cloud customers. Before establishing trust between the two tenants  $tr$  and  $te$ , trust must be established between the two cloud customers  $cr$  and  $ce$  who are the owners of  $tr$  and  $te$  respectively.  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$  is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $UOwner(u) = tr \cap te \in Trustcustomer(TOwner(tr), TOwner(te))$ .
- **Case 3:** Collaborating tenants hosted in different cloud providers and owned by the same cloud customer. Before establishing trust between the two tenants  $tr$  and  $te$ , trust must be established between the two cloud providers  $cpr$  and  $cpe$  who are the hosts of  $tr$  and  $te$  respectively.  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$  is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $UOwner(u) = tr \cap te \in TrustCloud(THost(tr), THost(te))$ ;
- **Case 4:** Collaborating tenants hosted in different cloud providers and owned by different cloud customers.  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$  is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $UOwner(u) = tr \cap te \in TrustCloud(THost(tr), THost(te)) \cap tr \in Trustcustomer(TOwner(tr), TOwner(te))$ .

We summarize the definition of this trust relation using the following formalism, taking into account the four cases previously discussed:  $TrustTenant(tr, te) = \bigcup_{i=1}^k u_i$

is defined with the additional required condition that:  $u \in TrustTenant(tr, te)$  only if  $[(UOwner(u) = tr) \cap [(TOwner(tr) = TOwner(te)) \cup (tr \in Trustcustomer(TOwner(tr), TOwner(te)))] \cap [(THost(tr) = THost(te)) \cup (tr \in TrustCloud(THost(tr), THost(te)))]]$ .

Utilizing this trust relation entails redefining the preconditions that correspond to the two operations  $oa(o : O)$  and  $LAuth_a(u; o)$ . Below, we provide the formal specification of these two operations:

- $\forall ua \in LUA, ua(u : U)$  is defined by the tenant administrator of  $t \in T$  only if  $(UOwner(ua) = UOwner(u) = t) \cup (Towner(UAOwner(ua)) = UOwner(u)) \cup (u \in TrustTenant(UOwner(u), UAOwner(ua)))$ ;
- $LAuth_a(u; o)$  is defined by the tenant administrator of  $t \in T$ . For all attributes  $ua, oa$  that are defined in  $LAuth_a(u; o)$  only if  $(UOwner(ua) = OOwner(oa) = UOwner(u) = OOwner(o) = t) \cup (UOwner(ua) = OOwner(oa) = OOwner(o) = t \cap UOwner(u) = Towner(t)) \cup (UOwner(ua) = OOwner(oa) = OOwner(o) = t \cap (u \in TrustTenant(UOwner(u), UAOwner(ua))))$ .

## VI. IMPLEMENTATION

### A. System Architecture

As shown in Fig. 2, we present the implementation architecture of the MC-ABAC model using python technology in order to demonstrate its feasibility. This architecture is composed of five components: Entity information, entity attributes, authorizations, trust relations and policy decision component. In the following, we provide a description of each of these components:

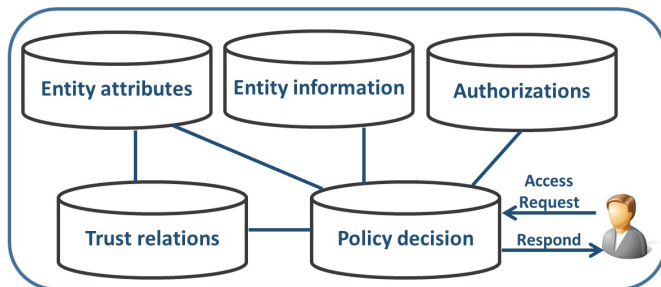

Fig. 2. Implementation architecture.

- **Entity information:** In this component, the cloud administrator, customer administrator, and tenant administrator are responsible for defining and managing various entities. These entities encompass customers, tenants, cloud users and objects, global users and objects, as well as local users and objects. Each administrator is responsible for their respective set of entities within the system;
- **Entity attributes:** Within this component, it is the administrator's responsibility to define the attributes

associated with users and objects. These attributes can be categorized as either global, local, or specific to the cloud provider. Subsequently, the administrator assigns values to the user and object attributes for their respective users and objects. This is achieved through a function that takes the user or object as input and generates a value from the range of the attribute. For instance,  $attr1(user1) = \{val1, val2\}$ : means that for the user  $user1$  the values of the attribute  $attr1$  are  $val1$  and  $val2$ ;

- **Authorizations:** In this component, the cloud administrator, customer administrator, and tenant administrator are responsible for specifying the authorizations policy  $CAuth_a(u; o)$ ,  $GAuth_a(u; o)$  and  $LAuth_a(u; o)$ . In our approach, we consider that each cloud, customer and tenant defines its own policy rules. Note that at this level, we assume that the security policy rules are valid and free from conflicts.
- **Trust relations:** Within this component, the management of trust relations is handled. These trust relations, namely  $TrustCloud()$ ,  $TrustCustomer()$ , and  $TrustTenant()$ , are established by the cloud administrator, customer administrator, and tenant administrator, respectively. Moreover, this component governs the trust between the cloud provider and the customer by using the trust relation  $TrustCPtoC()$ .
- **Policy decision:** In this component, the evaluation of access requests to objects stored in the cloud is carried out based on the collected attribute values and authorizations. When a user submits a request to access a resource within the cloud, the policy decision component assesses the request against the policy rules to determine whether the user has the authorization to access the requested resource or not.

### B. Results and Performance

The experiments were conducted on a virtual machine with the following specifications: Memory: 4096 MB, CPU: 2 cores, Hard Disk: 30 GB. For the analysis, we have used a synthetic dataset, containing up to 1000 authorizations, 200 attributes, 2000 attribute assignments and 25 tenants. We observed that the performance of our approach is influenced by various factors, including the number of authorizations and attribute assignments. The evaluation results indicate that the implementation of the MC-ABAC model for defining access control policies incurs minimal overhead.

The average time to grant the access to an object (Fig. 3(a)) with ABAC model increases with 13.1% and 28.5% for policies of 200 and 1000 rules respectively using the MC-ABAC model. The waiting time that is required to get a policy decision increases when there are too many authorizations to be collected. We attest that our implementation performs well, even for a large number of authorizations.

Furthermore, the running time for access/deny decisions to an object has been computed, using both ABAC and MC-ABAC models, for 600 authorizations and for 400 to 2000 attribute assignments. Fig. 3(b) demonstrates that the average time to access a resource with ABAC model increases with

Fig. 3. Running time overhead for access/deny decisions.

17.3% and 26.1% for 400 and 2000 attribute assignments using MC-ABAC Module. We recognize that the implementation of our model demonstrates effective performance when handling a significant number of attribute assignments.

## VII. CONCLUSION

In this paper, we present a novel ABAC model called: MC-ABAC, that leverages the capabilities of ABAC, such as flexibility and adaptability. MC-ABAC enables collaboration and resource sharing among tenants, which are hosted across multiple cloud providers. This model introduces the notions of tenant, cloud customer and cloud service provider as fundamental entities within the model. Moreover, MC-ABAC integrates various trust relations to facilitate effective collaboration and cross-tenant access in the multi-cloud environment. This model is designed to address access control challenges that arise in heterogeneous multi-cloud environments where users and shared resources are distributed across different tenants in multiple clouds.

Finally, the implementation architecture of the MC-ABAC model using Python technology has been proposed to demonstrate its feasibility. The evaluation results have demonstrated that implementing this model for defining access control policies has minimal overhead. As a future work, we plan to implement and test MC-ABAC model on a real platform consisting of multiple cloud providers. Another future research involves developing a solution to detect and resolve conflicting rules in access policies that are defined using the MC-ABAC model.

**Abstract**—Type 2 Diabetes Mellitus (T2DM) is a growing global health problem that significantly impacts patient’s quality of life and longevity. Early detection of T2DM is crucial in preventing or delaying the onset of its associated complications. This study aims to evaluate the use of machine learning algorithms for the early detection of T2DM. A classification model is developed using a dataset of patients diagnosed with T2DM and healthy controls, incorporating feature selection techniques. The model will be trained and tested on machine learning algorithms such as Logistic Regression, K-Nearest Neighbors, Decision Trees, Random Forest, and Support Vector Machines. The results showed that the Random Forest algorithm achieved the highest accuracy in detecting T2DM, with an accuracy of 98%. This high accuracy rate highlights the potential of machine learning algorithms in early T2DM detection and the importance of incorporating such methods in the clinical decision-making process. The findings of this study will contribute to the development of a more efficient precision medicine screening process for T2DM that can help healthcare providers detect the disease at its earliest stages, leading to improved patient outcomes.

**Keywords**—Diabetes Mellitus Type II; feature selection; machine learning methods; precision medicine

## I. INTRODUCTION

The phenomenon of urbanization in recent years has brought about significant lifestyle changes, contributing to the rising incidence of diabetes. Diabetes, also known as Diabetes Mellitus (DM), occurs when the blood sugar levels become elevated. This condition can occur due to either inadequate production of insulin by the body or the cells’ inability to respond to insulin. Insulin is a hormone that plays a crucial role in regulating glucose levels in the blood [1]. When the body fails to utilize glucose for energy production, it accumulates in the bloodstream, leading to a condition known as hyperglycemia.

The World Health Organization (WHO) has projected that by the year 2040, approximately 600 million people worldwide will be affected by diabetes. This staggering statistic underscores the urgent need to address the growing prevalence of this disease. The number of diagnosed cases continues to escalate [2], highlighting the pressing need for effective strategies to combat diabetes and mitigate its impact on global health.

Fig. 1 illustrates the significant impact of diabetes, where 90% to 95% of diabetes cases are attributed to T2D. Inadequate diabetes management affects glucose control and increases the risk of various comorbidities such as stroke, cancer,

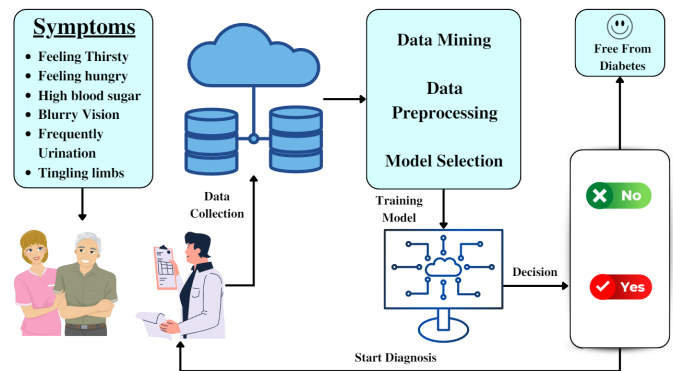

Fig. 1. Block diagram representation of precision medicine employing various data analytics and machine learning algorithms.

Alzheimer’s disease, hypertension, and cardiovascular disease. Thus, early detection plays a crucial role in predicting and managing Diabetes Mellitus or T2D effectively.

Type 2 diabetes mellitus occurs when insulin is not produced sufficiently to meet the body’s needs. On average, people are diagnosed to type 2 diabetes around the age of 40 due to Obesity, seniority, and parents’ inheritance. Apart from Obesity, other factors such as age, gender, socioeconomic class, place of residency (rural or urban), smoking addiction, liquor infusion, nutrition frequency, and so on are strongly linked with Type 2 Diabetes (T2D) [3]. Few of these characteristics are flexible and thus play a vital role in T2D management.

Since the dawn of machine learning, many researchers have suggested classification models for the prediction of diabetes mellitus (Table I). However, even though machine learning algorithms can predict diabetes early, it is not yet established for clinical operations. The proposed method constitutes of various classification of ML algorithms and attributes are chosen from the dataset using feature selection algorithm. The selected attributes are fed into various ML algorithms and results are compared with existing models.

Diabetes data analysis is a difficult task since most of the medical information is non-linear, irregular, correlation structured, and very tangled in nature. Therefore, using machine learning techniques in T2D analysis is a critical process for extracting knowledge from large amounts of available diabetes-related data and also aids in accurately diagnosing diabetes [4]. Traditional blood analysis methods may be more painful

TABLE I. TIME LINE OF VARIOUS MACHINE LEARNING METHODS FOR T2DM

Ref	Year	Methodology	Independent Variables
[6]	1993	Static and Dynamic Regression Model	Gender, Age, Frequency of diabetes
[7]	2004	Multiple Regression Analysis	Age, Usage of cigarette, Chronic pancreas history, Physical activity
[8]	2010	Pearson Partial Correlation	Age, Hyper tension status, Race, Waist Circumference
[9]	2015	Wilcoxon Signed-Rank Regression Model	Age, Diabetic state, Over weight, BMI, Obesity
[10]	2016	General Regression Networks	Diastolic Blood pressure, Two hours serum insulin, Age, Pedigree Function, triceps subcutaneous thickness
[11]	2016	Artificial Neural Network	Age, Gender, Height, Weight, BMI, High Blood Pressure History, Pregnancy history, Gestational diabetes history
[12]	2017	Dynamic Markov Model	Type-1 and type-2 Diabetes Status, Death, Undiagnosis diabetic state
[13]	2022	Ensembler Random Forest	Gender, Age, Polyuria, Irritability, Genital Thrush

and time-consuming, and because of this, physicians frequently make decisions based on a patient's current blood analysis report. Therefore, it has become a challenging task for both physicians and patients the diagnosis of diabetes mellitus. Hence, monitoring blood glucose (BG) levels plays a vital role in avoiding and relieving diabetic complications.

A portative Self-Monitoring of Blood Glucose (SMBG) device, a combination of advanced Information and Communication Technology (ICT) and biosensors, nourishes an efficient real-time monitoring administration technique for the healthiness state of diabetic patients. As a result, a patient can independently monitor the differences in his blood glucose levels [5]. In addition, using CGM (continuous glucose monitoring) sensors, users can better understand changes in blood glucose levels. Thus, many of the intelligent diabetes diagnosis systems have been designed by inspiring human biological constructors. These advanced methods predict whether or not the patient has diabetes mellitus without taking into account of any surgeon's progress [14].

Further, the paper consists of a brief description of the different sections discussed in the paper. The subsequent sections include a comprehensive Literature Survey in the second section, which examines relevant research and existing knowledge in the field. Following the Literature Survey, the experimental setup outlines the methodology and techniques to develop the diabetes diagnosis model. Finally, the paper presents the Results and Discussion section, where the performance and effectiveness of the machine learning models are analyzed and interpreted in detail.

## II. LITERATURE SURVEY

Early detection and diagnosis are paramount to effectively prevent the progression of diabetes. Several studies have found that lifestyle changes and pharmacological interventions can decrease the chance of developing diabetes. Furthermore, for recently interpreted intensive lifestyle, diabetic patients intervention, earlier short-term intensive insulin treatment, and metabolic therapy can result in prolonged glycaemic remission without additional antidiabetic treatment. As a result, identifying people at increased risk of acquiring diabetes is critical for diabetes prevention programs. These studies can be summarized as follows (Table II).

Type 2 diabetes mellitus (T2DM) is a chronic metabolic disorder, and recent studies have shown that machine learning techniques can accurately predict the early stages of the disease. For instance, Oladimeji et al. (2021) [15] work highlights

the potential of combining feature selection and classification algorithms for predicting diabetes at an early stage, Bhavya et al. (2020) [16] achieved their goal of predicting the presence of diabetes using machine learning techniques and achieved high accuracy rates, while Tigga et al. (2021) [17] developed a logistic regression model to predict the occurrence of type 2 diabetes with an accuracy of 83.3%. Moreover, Liu et al. (2022) [18] used machine learning techniques to accurately predict the risk of incident type 2 diabetes mellitus in the Chinese elderly. Boshra et al. (2021) [19] diagnosed diabetes using machine learning techniques and achieved high accuracy. Butt et al. (2021) [20] highlight the benefits of using machine learning algorithms in the healthcare industry, such as improved accuracy, faster diagnosis, and lower costs. In another study, Barik et al. (2021) [21] analyzed the prediction and accuracy of diabetes using classifiers and hybrid machine learning techniques and found that hybrid techniques provided higher prediction accuracy. Mounika et al. (2021) [22] compared the performance of different machine learning algorithms. They achieved a high accuracy rate of 95.3% in predicting type-2 diabetes. In contrast, Sneha et al. (2019) [23] used techniques like entropy and correlation-based feature selection to predict diabetes mellitus early by selecting optimal features. However, limitations such as dataset size and diversity need to be addressed in these studies to improve the generalizability of their results.

Khallel et al. (2021) [24] applied machine learning algorithms such as a support vector machine, decision tree, and k-nearest neighbor to predict the incidence of type 2 diabetes in a Korean population with metabolic syndrome. Their results showed that machine learning models could detect individuals at high risk of developing type 2 diabetes. In another study, Hernández-Lemus et al. (2022) [25] proposed a new machine-learning approach using a joint embedding of DNA methylation data and clinical variables to predict T2DM status. The authors showed a higher predictive performance of their model compared to current state-of-the-art methods. Furthermore, the authors highlighted their approach's potential to identify key methylation signatures linked to T2DM. These latest studies have shown promising results and highlight the potential of machine learning techniques to enhance early detection and improve the management of T2DM. Recent studies that demonstrate the potential of machine learning in predicting diabetes include the work of Lu et al. (2021) [26], who developed a machine-learning model to predict prediabetes and T2DM using medical claim data from a large health maintenance organization. Their model achieved high sensitivity and specificity, indicating its potential to iden-

TABLE II. LITERATURE SURVEY

Authors	Algorithms Used	Summary	Limitations
Oladosu et.al 2021 [15]	Random Forest Naive Bayes J48 KNN	The author uses the feature selection method to prevent overfitting and remove redundant data, which helps in providing an optimal model for predicting diabetes in the earlier stage by emphasizing more on feature selection	The accuracy of the output can be increased by considering body size, height and BMI attributes, which lacks in this paper.
Bhavya et.al 2020 [16]	KNN	The authors extensively explore the popular techniques in Machine Learning and uses KNN algorithm to identify the diabetes	The paper lacks in verifying the different algorithms available in Machine Learning such as Naive Bayes, SVM, Decision Tree, ID3 etc.
Neha and Shruthi 2020 [17]	LR KNN, SVM Naive Bayes DT Random Forest	The author aims to evaluate the risk of diabetes among people based on their family background and lifestyle. In this paper the model is developed by choosing 952 instances collected through online and offline questioner. The authors conclude that RF is most accurate.	The authors failed to consider biological attributes which plays an important role in predicting diabetes.
Qing Liu et.al 2022 [18]	LR DT XGBoost RF	The authors aim to make effective prediction models using machine learning algorithms for risk type of T2DM in Chinese elderly. The proposed model uses Lasso Regression for feature selection and features are applied to ML algorithms, they got best accuracy in XGBoost algorithm.	The paper fails to implement on different algorithms which might have given more accuracy because they have chosen more feature selected attributes.
Boshra et.al 2021 [19]	Logistic Regression SVM Decision Tree XGBoost Random Forest ADABoost	The author aims to implement the diagnosis of diabetes employing Machine Learning algorithms and evaluate the performance comparison of diverse models for classifying diagnosis. According to this paper the ADABoost has more accuracy.	The accuracy can be increased if authors had considered more attributes.

tify high-risk individuals and improve preventive strategies. Similarly, Alqudah et al. (2022) [27] developed a machine-learning model utilizing retinal images to predict T2DM. The authors utilized deep learning techniques to predict the presence of T2DM. They found that their model outperformed existing methods, offering the potential for an inexpensive, non-invasive approach to diabetes screening.

Yilmaz et al. (2019) [28] investigated the effectiveness of machine learning models in predicting the risk of developing T2DM using non-invasive retinal imaging. The authors utilized deep learning techniques to analyze retinal images and predict the presence of T2DM. Their findings suggest that the analysis of retinal images may provide an effective and convenient screening tool for detecting early signs of T2DM with the potential for widespread implementation. Rasmy et al. (2021) [29] developed a machine-learning model for the early prediction of T2DM using electronic health record data from a large healthcare system. The authors utilized a combination of feature selection algorithms and machine learning models to predict the risk of T2DM and achieved high accuracy rates. Their findings suggest that machine learning-based approaches improve early detection and intervention for T2DM, ultimately preventing severe complications and reducing healthcare costs. In a recent study, Wang et al. (2022) [30] developed a machine-learning model for predicting incident T2DM using electronic health record data. The authors used a large dataset of over 2 million patients, and the model achieved high accuracy rates in predicting incident T2DM up to 36 months in advance. Their model may be incorporated into clinical decision support systems to aid in the early detection and prevention of T2DM.

A study by Huang et al. (2022) [31] developed and validated a machine learning-based nomogram for predicting the risk of T2DM in Chinese adults. The authors used data from the China Health and Retirement Longitudinal Study and developed a nomogram that integrated various risk factors such as age, sex, BMI, and lifestyle factors. The results showed that the nomogram achieved high accuracy in predicting T2DM risk and could be clinically applicable for the early detection and prevention of T2DM. Another study by Wu et al. (2023) [32]

proposed a novel machine learning algorithm that combines deep neural networks (DNNs) and attention mechanisms to predict T2DM. The authors used electronic health record data from a large hospital in China and compared their model's performance to other widely used models. Their results showed that their DNN-attention model outperformed other models in predicting, indicating its potential for clinical application in early detection and personalized intervention. In a study by Lui et al. (2023) [33], the authors used a deep learning-based approach to predict T2DM using electronic health record data. The authors developed a convolutional neural network (CNN) model incorporating structured and unstructured data, such as lab test results and clinical notes. The model achieved high accuracy rates in T2DM prediction and showed improved performance compared to traditional machine learning models, suggesting its potential for clinical application in diabetes prediction and management. Finally, a recent study by Sim et al. (2023) [34] aimed to develop a machine-learning model that predicts T2DM based on lifestyle factors. The authors used data from a large cohort study and developed a model incorporating physical activity levels, diet, and sleep patterns. The results showed that the model achieved high accuracy in predicting T2DM risk based on lifestyle factors alone, demonstrating the potential of machine learning approaches to personalize diabetes prevention and management strategies based on lifestyle habits.

### III. EXPERIMENTAL SET UP

Fig. 2 shows the proposed methodology of this work. The method demonstrated incorporates feature selection as an important step in the machine learning classification process. It helps to reduce the dataset's dimensionality and eliminate irrelevant or redundant features that can lead to overfitting or reduced accuracy. Further, the proposed model helps combine multiple feature selection techniques, which also helps to identify the most important features that contribute to the T2DM detection model and improve its overall accuracy. This is a crucial advantage over other methods that do not incorporate feature selection, leading to a more robust and accurate T2DM detection model.

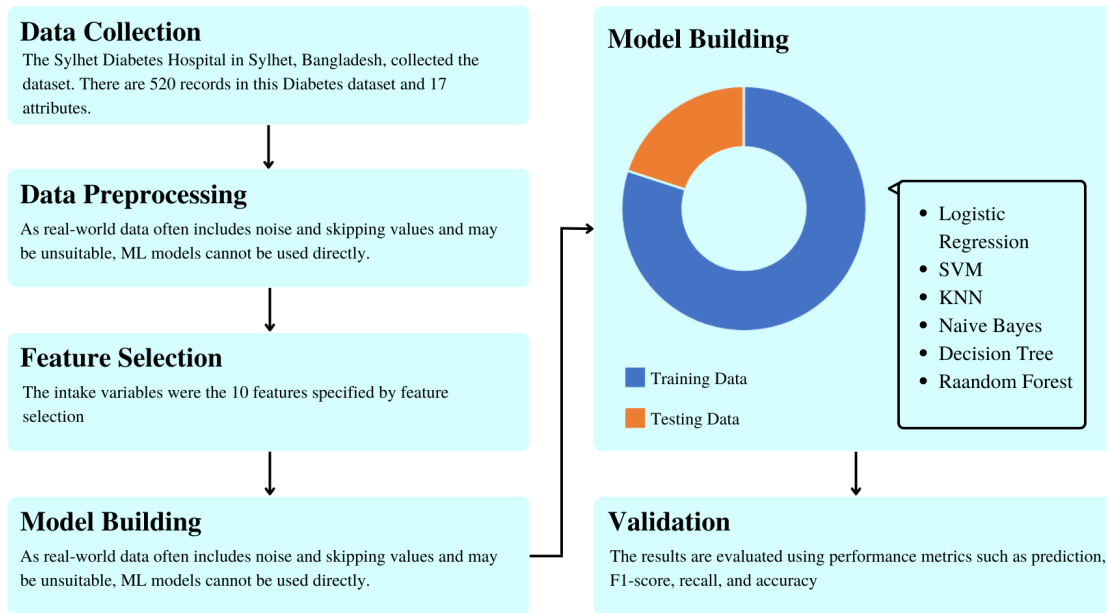

Fig. 2. Flowchart depicting the five stages of the machine learning process with data collection, data preprocessing, feature selection, and model building for validation.

The gathering and comprehension of data enable the examination of patterns and trends, which aids in outcome prediction and evaluation. The Sylhet Diabetes Hospital in Sylhet, Bangladesh, collects the dataset directly from the patients by having them complete a questionnaire, and a doctor then verifies it. Below is a description of the dataset. There are 520 records in this Diabetes dataset and 17 attributes.

As real-world data often includes noise and skipping values and may be unsuitable, ML models cannot be used directly. Instead, data cleaning and preparation for a machine learning sample are required for data pre-processing, which increases the precision and effectiveness of the machine learning model. Finding lost data, encoding categorical data, exploratory data analysis (Fig. 3), dividing the dataset into a training and trial set, feature selection, and feature scaling are some of the tasks it entails.

Every machine learning pipeline comprises Key Performance Indicators (KPIs). Since the result from classification models are discrete, we require a metric that contrasts different classes somehow. Classification Metrics evaluate a model's execution and show if the classification is valid, but they do so in various ways. It evaluates models based on their performance, time complexity, accuracy, recall, sensitivity, and the most promising metric, which is the confusion matrix. The truth labels versus model predictions are displayed in a confusion matrix using tables. An individual row of the confusion matrix defines an instance in a class label, but an individual column represents an instance in a real class. The Confusion Matrix isn't a performance indicator but provides the framework for other metrics to assess the outcomes. Therefore, a metric is required for all machine learning models to evaluate their effectiveness.

The dataset was randomly split into train and trial data

with a proportion of 80% to 20%. Since the data is extremely unbalanced, it is a good idea to use the Sklearn module in Python to standardize the dataset's input features and normalize. Using the Python Standard Scaler function from the Sklearn pre-processing library, the training cluster was standardized to have a mean of Zero and a variance of One, and the test set was normalized using the mean and standard deviation of the training dataset.

We trained the LR, DT, RF, KNN, and SVM models and implemented them using the Python Sklearn package. The intake variables were the 10 features specified by feature selection (Table III). The Primary purpose of using hyperparameters is to specify the attributes before training begins. It expresses the major characteristics of the model, such as its efficiency, robustness, and intricacy. Therefore, it has evolved to become immensely popular for adjusting hyperparameters in machine-learning algorithms. The most suitable hyperparameters for RF were as observed: max\_depth = 100, max\_features = 10, min\_samples\_leaf = 5, n\_estimators = 80, min\_samples\_split = 69, criterion = entropy and random state = 0.

TABLE III. ATTRIBUTES

SL No.	Attributes	Score
1	Age	18.845767
2	Gender	38.747637
3	Polyuria	116.184593
4	Polydipsia	120.785515
5	sudden weight loss	57.749309
6	Polyphagia	33.198418
7	visual blurring	18.124571
8	Irritability	35.334127
9	partial paresis	55.314286
10	AgeAlopecia	24.402793

Though AI and its subsets like machine learning are quite

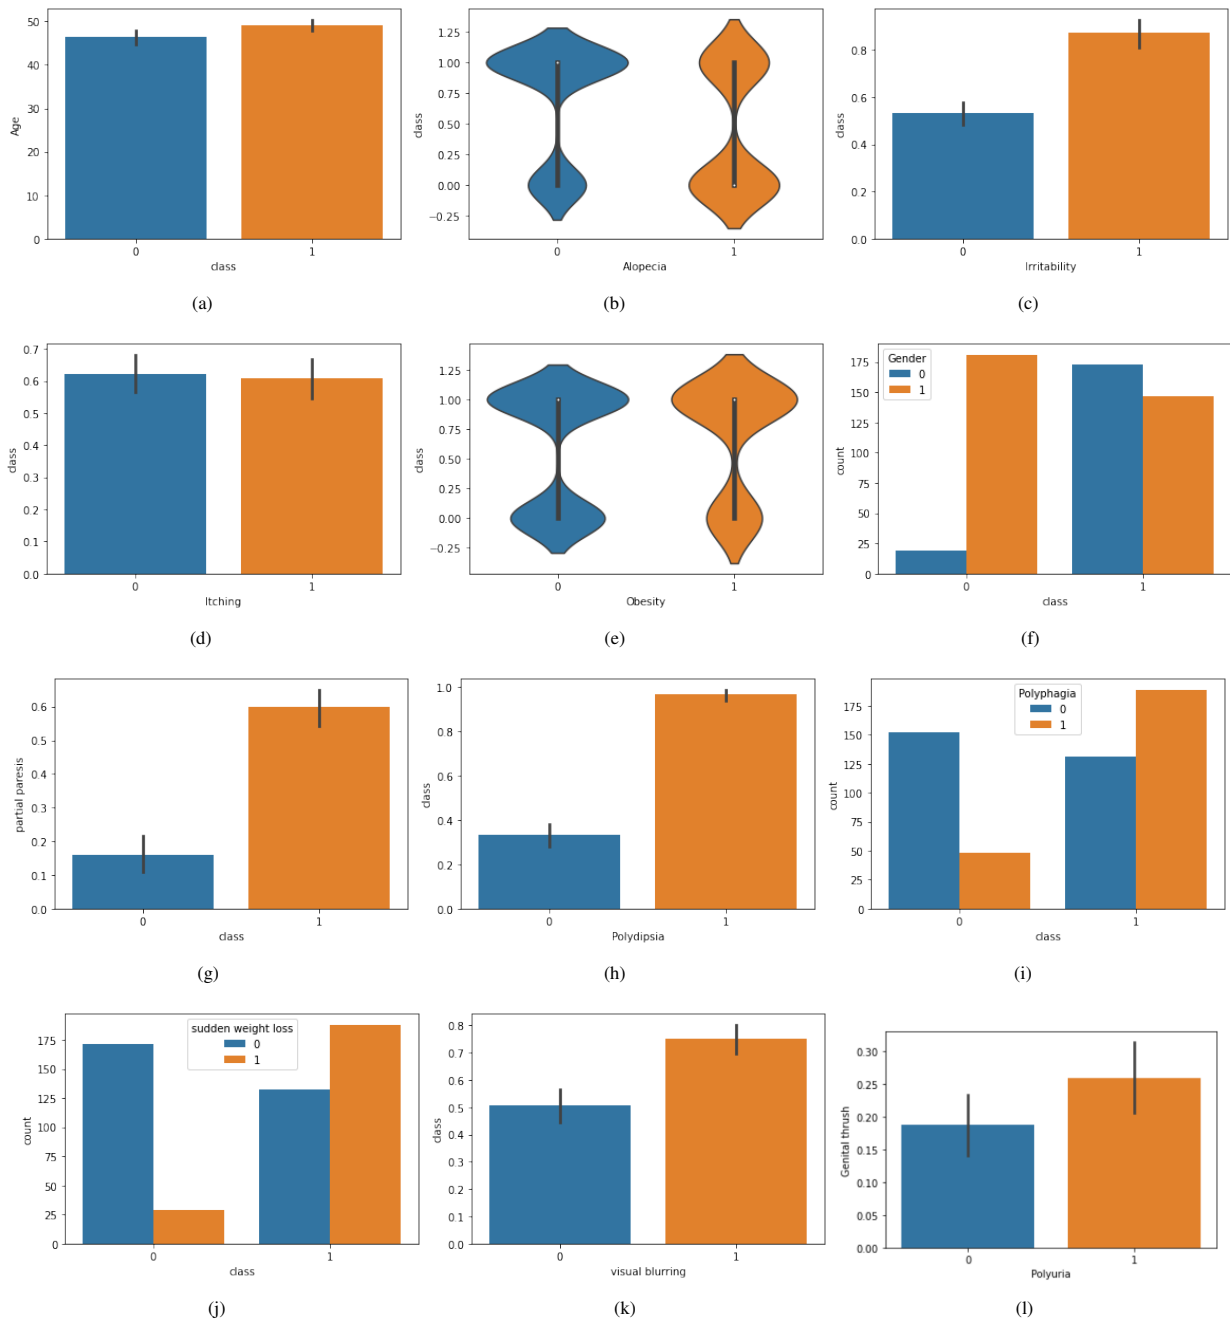

Fig. 3. Exploratory data analysis for the extracted features from the dataset - a)age-class, b)alopecia, c)irritability, d)itching, e)gender, f)obesity, g)partial paresis, h)polydipsia, i)polyphagia, j)sudden weight loss, k)visual blurring, l)polyuria Vs genital thrush.

promising with their results, it is still a challenge to practice these methods in real-time for clinical diagnosis. The main reason is that AI needs a large amount of data to work with, and this requires time. In the case of AI, this is called data transfer learning. And it means that you need a large amount of labeled data to train your algorithm with. Moreover, the results may again vary based on the data collected from a geographic location such as Asia Pacific, USA, and European regions. The datasets available on open-source platforms are outdated and don't meet the expected results as the prediction needs to be dynamic, which means based on the patient's current

reports. Also, the results will vary based on the top features or attributes selected during the process of feature selection. The challenge of building a machine learning model is that it requires extensive data, which is often not available in the medical field. Therefore, there are limitations to building a model based on the available data.

#### IV. RESULTS AND DISCUSSION

Our research presents compelling results on the detection of Type 2 Diabetes (T2D) using feature selection algorithms.

Fig. 4. Confusion matrix depicting true positive, true negative, false positive and false negative to calculate precision, recall, F1-score and accuracy for - a)decision tree, b)support vector machine, c)random forest.

Through the utilization of carefully curated datasets, we employed various algorithms to assess the probability of individuals having T2D. The evaluation of our results was based on performance metrics such as prediction, F1-score, recall, and accuracy, which are presented in Table IV.

Fig. 4 highlights the notable findings of our study, emphasizing the significant improvement in T2D prediction accuracy achieved by addressing imbalanced datasets using feature selection techniques. The Confusion Matrix visually represents the superior performance of our approach, clearly demonstrating the enhanced accuracy obtained through our methodology.

Of particular interest is the remarkable performance of the Random Forest (RF) algorithm, outperforming other algorithms examined in our study. This discovery holds great promise for the healthcare industry, as our proposed model proves to be cost-effective and efficient in terms of implementation time. Unlike traditional diagnostic tests such as Oral Glucose Tolerance Test (OGTT) and Hemoglobin A1c (HbA1c), our model eliminates the need for expensive lab reagents and specialized skills. This breakthrough paves the way for early detection of diabetes, especially in remote areas with limited access to healthcare facilities.

Looking ahead, the integration of 5G and Artificial Intelligence (AI) technologies offers even more potential for improving healthcare outcomes. By leveraging deep learning algorithms, the latency at the edge can be significantly reduced, enabling real-time data analysis and decision-making. This cognitive system architecture represents the inception of a smart healthcare system, empowering remote areas and underserved communities with access to timely and accurate diabetes detection.

Moreover, the potential impact of our research extends beyond the realm of T2D detection. The application of feature selection algorithms and the success of the RF algorithm in this study open avenues for exploring similar approaches in the diagnosis and prediction of other medical conditions. By leveraging the power of data analysis and machine learning, we

can unlock new insights into various diseases and develop efficient and accessible diagnostic models. This not only has the potential to transform healthcare delivery but also contributes to the advancement of personalized medicine, where early detection and targeted interventions can significantly improve patient outcomes and overall population health. Our research lays a solid foundation for future investigations into leveraging feature selection and algorithmic techniques to enhance medical diagnostics across diverse healthcare domains.

TABLE IV. THE ML ALGORITHMS WITH THE KPI AFTER BEING TRAINED WITH THE PROPOSED MODEL

SL No.	Algorithms	Precision	Recall	F1-score	Accuracy
1	Logistic Regression	92%	91%	91%	89%
2	SVM Linear	94%	91%	92%	90%
3	SVM Radial	98%	98%	98%	98%
4	KNN	98%	98%	98%	98%
5	Naive bayes	89%	88%	88%	86%
6	Decision Tree	97%	97%	97%	97%
7	Random Forest	98%	98%	98%	98%

The dataset used in this research was obtained from the Sylhet Diabetes Hospital in Bangladesh. It consists of 520 records with 17 attributes. The data was collected through patient questionnaires, verified by medical professionals. However, the dataset's regional specificity may limit generalizability. The sample size, though substantial, should be considered for its representativeness. Potential limitations include self-reporting bias and missing variables. Despite these considerations, the dataset provides a valuable foundation for studying the relationship between urbanization and diabetes.

In summary, our results demonstrate the effectiveness of feature selection algorithms, with the RF algorithm standing out as a powerful tool for T2D prediction. The cost-effectiveness, efficiency, and accessibility of our proposed model present exciting opportunities for revolutionizing healthcare and fostering the development of smart healthcare systems.

tems.

## V. CONCLUSION

Our research on early detection of Type 2 Diabetes Mellitus (T2DM) using machine learning classification has yielded significant findings. By employing feature selection techniques and effective data management, we have developed an innovative model for diagnosing diabetes at its early stages. The combination of various feature selection methods with machine learning algorithms has proven to be highly effective in predicting the presence of T2DM, with the Random Forest algorithm achieving an impressive accuracy of 98%. This research highlights the importance of early identification of diabetes due to its widespread prevalence and impact on individuals' health. Furthermore, the application of machine learning classification in the healthcare sector not only facilitates more efficient decision-making but also lowers the cost of diagnosis, making it more accessible to a broader population. Our contribution lies in the significance of feature selection and appropriate data management techniques, which greatly improve the predictive power of the model. However, further validation is necessary through larger sample sizes and diverse populations to ensure the model's robustness and generalizability. Future research should explore the impact of variables such as body size, height, and body mass index (BMI) in the early identification of diabetes, potentially enhancing the accuracy of the diagnostic model. Continued advancements in machine learning algorithms and refinement of the feature selection process can further enhance the model's performance and applicability. Overall, our study demonstrates the promising potential of machine learning classification with feature selection in early T2DM detection, aiding in better management and prevention of this prevalent disease.

## ACKNOWLEDGMENT

The authors acknowledge the support from REVA University for the facilities provided to carry out the research.

**Abstract**—Preventing and controlling grape diseases is essential for a good grape harvest. With the help of “single shot multi-box detectors”, “faster region based convolutional neural networks”, & “You only look once-X,” the study improved grape leaf disease detection accuracy with effective attention mechanisms, which includes convolutional block attention module, squeeze & excitation networks, & efficient channel attention. The various attention techniques helped to emphasize important features while reducing the impact of irrelevant ones, which ultimately improved the precision of the models and allowed for real-time performance. As a result of examining the optimal models from the three types, it was found that the Faster (R-CNN) model had a lower precision value, while You only look once-X and SSD with various attention techniques required the fewest parameters with the highest precision, with the best real-time performance. In addition to providing insights into grape diseases & symptoms in automated agricultural production, this study provided valuable insights into grape leaf disease detection.

**Keywords**—Grape leaves; faster region-based convolutional neural networks; you only look once (x); single shot detection attention techniques

## I. INTRODUCTION

Preventing and controlling crop diseases is crucial for producing safe and healthy vegetables, minimizing losses, and reducing the use of pesticides in the production of crops [1]. Thus, early detection & prevention of diseases are crucial. Grape plants can be affected by various diseases, such as powdery mildew, brown blotch, and anthracnose, which can significantly impact the yield and quality of the fruit. Traditional methods of detecting grape diseases rely on the experience of the growers or the guidance of experts, which can be slow, inefficient, and lack real-time performance. Images of grape leaves are used to detect, identify, and provide guidance about diseases infected with grape leaves [2] because disease-infected grape leaves often have visible spots.

Grape leaf disease detection is crucial for several reasons. Firstly, it allows growers to monitor the health of their grapevines and take appropriate actions to prevent or

manage diseases effectively. Early detection enables timely interventions, minimizing potential damage and crop losses. Different grape leaf diseases require specific treatments, and accurate identification helps growers implement targeted control measures. This optimizes the use of pesticides, reduces environmental impact, and ensures effective disease management.

Grape leaf diseases can significantly impact the yield and quality of grapevine production. Some diseases cause defoliation, reducing the vine’s ability to photosynthesize and produce energy, leading to decreased fruit quality, delayed ripening, and reduced yield. Early disease detection enables growers to protect the crop and implement measures to minimize yield losses. Early identification of grape leaf diseases is essential for preventing their spread within vineyards. Prompt isolation and treatment of infected vines help prevent diseases from affecting healthy plants. Additionally, preventive measures such as pruning, canopy management, and cultural practices can be implemented to reduce the likelihood of disease occurrence and spread. Economically, grapevines are valuable crops, and detecting diseases in grape leaves allows growers to make informed decisions on disease management, optimizing resource utilization, and reducing unnecessary costs. This helps preserve the economic viability of vineyards and sustain profitability in grape production.

Efficient disease detection and management practices also contribute to sustainable agriculture. Early identification minimizes the use of broad-spectrum pesticides, reducing their negative impact on the environment and non-target organisms. Targeted treatments based on accurate disease detection help reduce chemical inputs, promote ecological balance, and support sustainable cultivation practices for grapevines. In summary, grape leaf disease detection is vital for crop health monitoring, disease management, yield protection, disease prevention, economic considerations, and sustainable agriculture. Early detection allows for timely interventions, optimization of disease control measures, minimization of crop losses, and the long-term sustainability of grapevine production.

Due to the rapid development of artificial intelligence technologies, a wide variety of vision approaches are utilised in the processing of photos for various crop diseases [3][4][5]. Research into classifying agricultural diseases uses a wide range of approaches, including “genetic algorithms” [6], “support vector machines” [7], “K-means clustering” [8], “ensemble learning” [9], “Bayesian classification” [10], “radial basis functions” [11], & “filter segmentation” techniques [12]. Unfortunately, conventional approaches to crop disease classification and identification rely on labour-intensive, environment-dependent manual feature selection. In particular, the development of deep learning’s Convolutional Neural Network (CNN) has led to vast improvements in the field of autonomous detection and identification of agricultural diseases.

An object detection system that uses a convolutional neural network (CNN) has made great strides recently. Several applications make use of this technique, including recognition of faces [13], navigation [14], detection of road obstacles [15], detection of pedestrians, abnormal activity recognition [16], monitoring of physical activity [17][?], [18] detection of fruits, and detection of weeds [19]. Despite complex backdrops, crop leaf diseases can be detected using object detection algorithms due to CNN’s ability to extract high-dimensional properties from object images.

As a result, scientists in China and others have studied object detection algorithms to develop models for detecting crop diseases. For instance, Some authors have applied various models for object detection to the tomato disease dataset, including the Faster(R-CNN), and the Single Shot Multibox Detector. Faster (R-CNN) as well as VGG16, produced the best disease detection results. Dynamic identification of grape leaf illnesses was accomplished by using Faster (R-CNN) on time-series images of grape leaves. Using an enhanced Faster (R-CNN) model, the authors of [20] detected diseases in bitter melon leaves with excellent results. Using an in-house dataset, The authors of [21] trained the SSD model to identify agricultural diseases with an overall accuracy of 83.90%. An enhanced model based on MobileNetv2 & YOLOv3 was proposed by the authors [22], which allowed for the early detection of grey speck disease in tomatoes. This refined model benefits from a number of desirable characteristics, including a low memory size, outstanding detection accuracy, and lightning-fast identification.

Previous studies have shown that using object detection technology to detect grape leaf diseases is feasible. Existing grape detector models, however, operate slowly and have low detection precision, which severely limits their application. This research included the attention methods of “convolutional block attention module,” “efficient channel attention,” & “squeeze & excitation attention” into the models of “Faster(R-CNN),” “SSD,” & “YOLO-X” to boost their accuracy and speed. The goal was to boost the feature extraction network’s efficiency and put more emphasis on health issues. Experiments were run on a plant village dataset of grape diseases, and the findings revealed that models based on diverse attention mechanisms, such as “Faster(R-CNN),” “SSD,” & “YOLO-X,” significantly improved detection accuracy and operation performance with only little parameter tweaks. The findings of this study can be used as a foundation for future work on grape disease control measures. The main objectives of the

paper are to enhance the accuracy and speed of grape leaf disease detection, improve the efficiency of feature extraction networks, validate the performance improvements on a grape disease dataset, and provide a foundation for future grape disease control measures.

However, the existing literature lacks research on incorporating attention mechanisms, such as the “convolutional block attention module,” “efficient channel attention,” and “squeeze & excitation attention,” into grape detector models like “Faster(R-CNN),” “SSD,” and “YOLO-X.” There is a gap in knowledge regarding the potential impact of attention mechanisms on improving detection accuracy and processing speed for grape leaf diseases. The main objectives of the paper are:

- Enhance the accuracy and speed of grape leaf disease detection: The purpose of this work is to enhance the efficiency of previously developed grape detection models by incorporating attention mechanisms such as “convolutional block attention module,” “efficient channel attention,” and “squeeze & excitation attention” into the models of “Faster(R-CNN),” “SSD,” and “YOLO-X.” The objective is to achieve higher detection accuracy and faster processing speeds, addressing the limitations of slow operation and low detection precision in existing models.
- Improve the efficiency of feature extraction networks: By integrating attention methods into the models, the paper aims to enhance the efficiency of the feature extraction networks. The attention mechanisms help to prioritize relevant features and emphasize health issues related to grape leaf diseases, leading to more effective and accurate detection.
- Validate the performance improvements on a grape disease dataset: The research conducts experiments using a dataset specifically focused on grape diseases. By evaluating the models based on diverse attention mechanisms, such as “Faster(R-CNN),” “SSD,” and “YOLO-X,” the paper aims to demonstrate significant improvements in detection accuracy and operation performance. The experiments involve minimal parameter tweaks, ensuring that the observed enhancements are primarily attributed to integrating attention mechanisms.
- Provide a foundation for future grape disease control measures: The findings of this study serve as a basis for future work on grape disease control measures. By demonstrating the effectiveness of attention mechanisms in improving detection accuracy and speed, the paper offers valuable insights and guidance for the development of advanced and efficient techniques for managing and controlling grape leaf diseases.

## II. RELATED WORK

Detecting plant diseases in a timely manner is crucial for effectively managing plant losses. However, relying on manual diagnosis by humans is a time-consuming process that is prone to errors and can be costly. To address these challenges, researchers have been actively exploring automated

techniques for disease detection and classification in plants. The utilization of automated equipment and methods has emerged as a promising approach for monitoring crop fields. In this section, we will delve into the specifics of computer vision methods employed to identify and diagnose diseases in plant leaves.

The authors of [23] conducted a study focusing on detecting black rot in grape leaves using a YOLOv3-SPP-based deep learning method. The researchers employed a combination of super-resolution image enhancement and convolutional neural network techniques to identify the disease in grape leaves. The initial step involved upsampling the input image through bilinear interpolation. After enhancement, the processed inputs were fed into the YOLOv3-spatial pyramid pooling model, resulting in a remarkable detection accuracy of 95.79%. However, when tested in real field conditions, the precision of this method dropped to 86.69%. In a separate study, The authors of [24] proposed a deep learning approach specifically for accurately detecting black rot spots on grape leaves. They employed the DeepLab V3+ model, which incorporates feature maps from different levels and utilizes ResNet 101 as the backbone network. The test results demonstrated that the improved DeepLab V3+ model outperformed conventional methods.

The authors of [25], [26] developed a novel support vector machine & image processing-enabled technique for identifying and categorizing grape leaf disease. The authors of [27] employed a CNN-SVM-based approach to classifying five different species of grapevine leaves. They utilized the MobileNetv2 CNN model for leaf-type classification. Initially, features were extracted from the pre-trained MobileNet2 logits layer, and classification was performed using SVM with various kernels. The Chi-squares method was applied for feature selection, resulting in an impressive classification accuracy of 97.60%. The use of feature selection techniques significantly contributed to the improved accuracy of classification.

The authors of [28] focused on detecting grape black measles disease. They utilized the ResNet-50-based DeepLabV3 segmentation model in combination with fuzzy logic to determine the severity of the disease. The input image provided region of interest features and the percentage of infections. A fuzzy rule-based reference system was developed based on each feature, which was then used to grade the grape disease. The grading system allowed for the classification of healthy, mild, medium, and severe cases, specifically for measles disease.

### III. MATERIALS AND METHODS

#### A. Image Acquisition

The plant-Village dataset provides 4,062 images of grape leaves displaying common symptoms. In this dataset, 1,180 images were found to be affected by Black Rot, 1,383 by Esca measles, 1,076 by Leaf spot, and 423 by healthy leaves, all with a resolution of  $256 \times 256$  pixels. A leaf with black rot, a leaf with black measles, a leaf with blight, and a healthy leaf is displayed in Fig. 1.

The data set contains varying quantities of images for each category, indicating significant imbalances. Esca is the most

Fig. 1. Sample images from dataset.

TABLE I. LIST OF PARAMETERS USED FOR IMAGE ENHANCEMENT

Enhancement method	Parameters
gaussian filter	sigma-range(0.4,1.3)
mean filter	kernel-size-range(3,5)
median filter	kernel-size-range(2,5)
image acutance	alpha-range(0,0.2)
brightness	gamma(2.0)
contrast	alpha(1.0)

common classification, accounting for roughly 34% of the images, while Black Rot and Leaf Blight make up 29% and 26% respectively. There are also 1076 Healthy images and 10.4% Normal images in the collection.

#### B. Image Pre-processing and Augmentation

The size of the dataset must be increased by using data augmentation techniques in order to prepare grape leaves disease images for disease identification. Training the recognition model in this way ensures that it will be more resilient and can generalize more effectively. Using standard data augmentation methods, the experiment compared the effectiveness of the data augmentation method proposed in this study. The traditional methods included flipping the image horizontally and vertically, rotating the image, applying different types of filtering (Gaussian, mean, and median) with a probability of 0.2, enhancing image contrast, sharpening images with a probability of 0.3, and adjusting image brightness. According to Table I, the parameters used for each image enhancement method are listed. Table II provides more details about the dataset and can be accessed at <https://www.kaggle.com/datasets/rm1000/augmented-grape-disease-detection-dataset>.

#### C. Proposed Methodology for Grape Leaf Disease Detection

This study focuses on the detection of grape leaf diseases using three specific models: faster-rcnn, YOLOx, and SSD. The training process for these models to detect diseases in grape leaves is depicted in Fig. 2. The process begins with inputting

TABLE II. INFORMATION ABOUT THE DATASET

Class	No of images without augmentation	No of images with augmentation
Healthy	423	3000
Esca measles	1383	3000
Leaf spot	1076	3000
Black rot	1180	3000
Total	4062	12000

the selected grape leaf disease images. Next, classification features are extracted from the input images. Output is then derived from the findings of disease identification using the faster-rcnn, YOLOx, and SSD models.

A loss function is used throughout to quantify the degree to which the projected disease species deviates from the true disease species. This enables the models to learn and improve their detection accuracy over time. The optimization of the final output result is achieved through the utilization of the Adam optimizer, a widely used optimization algorithm in deep learning.

By following this approach, the study aims to leverage the capabilities of faster-rcnn, YOLO:x & SSD models to detect grape leaf diseases effectively. The training flow chart provides a systematic framework for the feature extraction and disease detection process, facilitating the accurate identification of different disease species in grape leaves.

#### D. Attention Mechanism Models

The study utilizes three attention mechanisms: “Squeeze & Excitation”, “efficient channel attention”, and “Convolutional Block Attention” spatial attention mechanism. We chose the SE attention mechanism because it is simple and adds only a few new parameters. With ECA attention, models become more accurate without significantly increasing model complexity. It is an enhanced version of the SE attention mechanism. Finally, the CBAM attention mechanism is useful because it connects the spatial domain and the channel domain, leading to more effective improvement in network performance.

1) *Squeeze & Excitation Attention*: In order to extract features, the SE channel attention mechanism employs the CNN channel. It requires re-calibrating features so that the model can pick up and remember relevant details from all of the available feature channels. Fig. 3 depicts the two steps involved in this mechanism: squeezing and excitement. After the feature image has been spatially compressed using the squeeze technique, the feature channel’s relative relevance can be determined using the excitation technique; a model is created based on the correlation between the channels. In doing so, the original feature images are excited into matching channels. The SE mechanism has few additional parameters and is computationally simple.

The “efficient channel attention” attention mechanism is utilized to enhance cross-channel interaction and reduce model complexity, while the Squeeze & Excitation attention mechanism is used to prioritize the most informative channel features for disease identification. For end-to-end training of the grape leaf disease detection model, the “Convolutional Block

Attention Module” attention mechanism is introduced to take into account the importance of pixels in different places. All three attention methods contribute significantly to improving the model’s efficiency and precision.

2) *ECA Attention Module*: It uses local cross channel interaction methods without reducing the magnitude of the dimensionality can be accomplished without using reduced-dimension SE. The functionality of the attention module is enhanced while its complexity is decreased thanks to this mechanism. In Fig. 4 we can observe the construction of the efficient channel attention mechanism.

3) *CBAM Attention Module*: The “CBAM Spatial Attention Module” is made up of 2 modules, first one is the “spatial attention module”, second one is the “channel attention module” and is designed to optimize input feature maps by inferring attention maps on both channel and spatial dimensions. These attention maps are then multiplied with the input feature map, resulting in self-adaptive feature optimization. The CBAM mechanism is effective in enhancing useful features while suppressing those that are not useful, making it a popular tool in practical applications. Fig. 5 illustrates the network structure of CBAM.

#### E. Decton Models for Disease Detection in Grape Leaves with Attention Mechanism

CNN-based object detection can be categorized into two main types. The first type uses a regional proposal to detect objects. This involves identifying candidate regions in the image, which are then divided to detect objects. This two-stage approach is exemplified by methods such as “R-CNN”, “Fast(R-CNN)”, & “Faster(R-CNN)”. The second type of object detection does not use a regional proposal and is referred to as one-stage object detection. An image is analyzed based on a CNN prediction of an object’s position & properties. There are a variety of algorithms available for this type of detection, such as SSDs and YOLOs.

The study used three models, namely the “Faster R-CNN model”, “YOLO-X model”, & “SSD model” for detecting grape leaves disease. The input of the selected grape leaf disease images, extraction of classification features, and use of the three disease detection models were involved in the process. The output was an analysis of the disease detection results. For optimizing the final output, an Adam optimizer was used to predict the difference between reality and the prediction of disease species.

Researchers found that the “Faster(R-CNN)” model boosts high detection accuracy and can detect targets end-to-end. However, its running speed is relatively slow. On the other hand, the “YOLO-X” model runs quickly, but it doesn’t detect small objects. The “SSD” technique has faster running speed and higher detection accuracy than the “YOLO-X” model, but its training process heavily relies on prior experience, and its performance in detecting small targets is not as good as the “Faster(R-CNN)” model. The characteristics of these models are elaborated as follows:

1) *Grape Leaves Disease Detection using Faster (R-CNN) Model*: This model is comprised of three main components: the “Extraction of features”, the “Region Proposal Network”

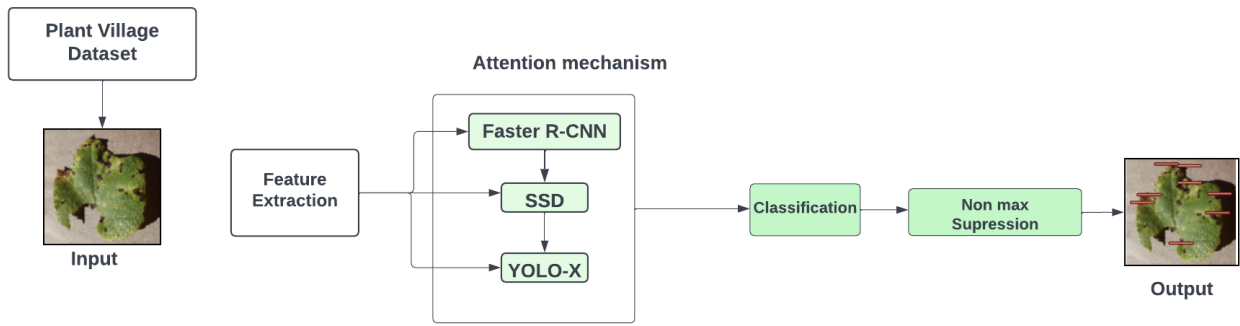

Fig. 2. Proposed attention model for grape disease detection.

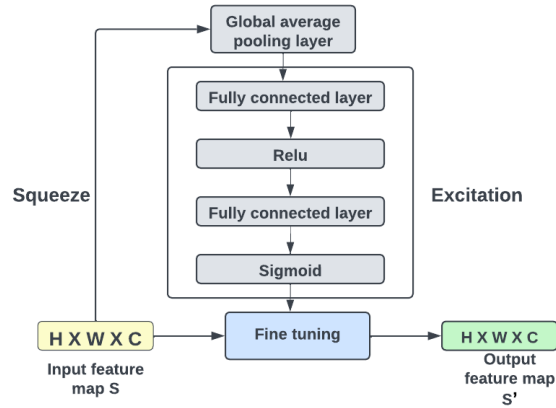

Fig. 3. SE attention mechanism.

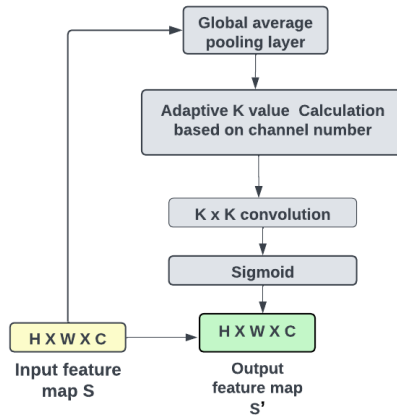

Fig. 4. ECA attention mechanism.

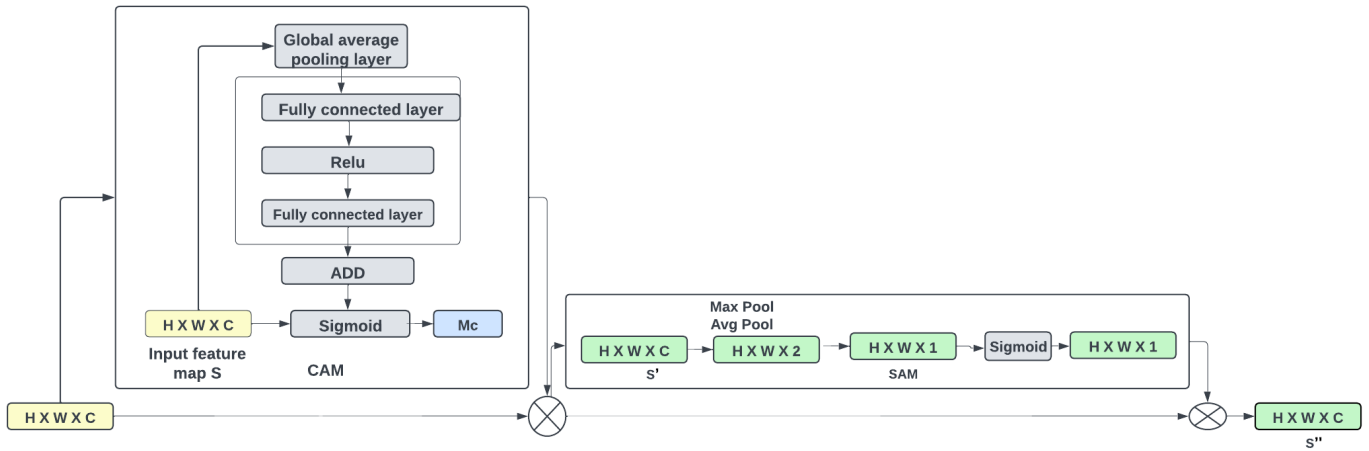

Fig. 5. CBAM attention mechanism.

, and the “Region with Convolutional Neural Network Features”. Fig. 6 depicts the Faster (R-CNN) model with attention techniques. A Faster (R-CNN) method is used to detect grape leaf diseases in four primary steps: generating candidate disease regions, extracting disease characteristics, categorizing the disease, and performing bounding box regression. The Faster (R-CNN) model utilizes convolutional neural networks for the extraction of features and then generates feature maps for corresponding images. However, the convolution kernel’s inherent locality means that only local information of disease images is retained, leading to information loss and reduced detection accuracy. To address this issue, the study introduced attention mechanisms, namely SE, ECA, and CBAM, without changing the feature extraction network’s structure or backbone features. As a result of forward propagation after the last identity block, these mechanisms were introduced to enhance the model.

2) *Grape Leaves Disease Detection using YOLO-X Model::*  
The YOLO-X with Darknet53 network is a model with high operational speed and flexibility. It includes four primary components: the input end, Backbone network, Neck, and Prediction. Fig. 7 illustrates the YOLO-X model based on various attention mechanisms. In the YOLO-X model, the YOLO Head has been changed to a decoupled head in the prediction section, the anchor-based approach has been replaced with an anchor-free method, and the SimOTA method has been introduced for dynamic matching with positive samples. The model’s detection accuracy and speed have both been enhanced by these revisions, and the models’ parameter sizes have been significantly decreased. The YOLO-X model is known for its high detection speed and precision, but it has some limitations when applied directly for disease detection in different environments. For instance, its backbone lacks the ability to extract features and integrate high-quality contextual feature information, leading to a reduction in the model’s detection precision. Therefore, in this study, the Darknet53 network structure of the YOLO-X model remained unchanged, allowing pre-training weights to be directly loaded into model training. The YOLO-X model can selectively strengthen key features while suppressing irrelevant ones based on the branches of the backbone network, namely “Darknet53”, “convolutional block

attention module”, “efficient channel attention” and “squeeze & excitation attention mechanisms.

3) *Grape Leaves Disease Detection using SSD Model::*  
Using a tiny convolution kernel and multi-dimensional feature prediction, the model combines the anchor mechanism of Faster (R-CNN) with the regression mechanism of “YOLO” for fast and accurate detection. Fig. 8 depicts the SSD model that includes attention mechanisms. The first component is an enhanced capability for disease detection based on the deep learning network model used to collect baseline disease features. The multi-scale feature detection network is the second part, and it uses cascaded-neural-networks to categorize features at various scales in order to learn about the disease’s category and location, as well as low-layer convolutional layer features to enhance detection precision and Non-Maximum suppression to generate the final detection results. Using a multi-dimensional prediction strategy, the SSD model is able to distinguish between small and large objects; the front-end deep-learning models are responsible for the former, while at the back-end multi-dimensional feature detection models handle them. Although the front-end network delivers precise coordinates and geometry, it has a limited range of perception and isn’t great at representing abstract concepts. Whereas the frontal network has a narrow receptive field and poor representational capacity for geometric data, the posterior network has a wide receptive field and excellent representational ability for semantic data. Because of this, the SSD model may overlook some diseases or incorrectly identify others. Six feature images of varying sizes were collected from the “SSD” model and supplied into the various attention modules in order to better represent critical feature information and identify disease object features. With this method, the SSD model is better able to recognize diseased items.

#### IV. RESULTS AND EXPERIMENTS

##### A. Evaluation Metrics

Results were evaluated based on standard measures for evaluating target detection. One class of targets will be evaluated using “Precision,” “Recall,” “Average Precision,” and

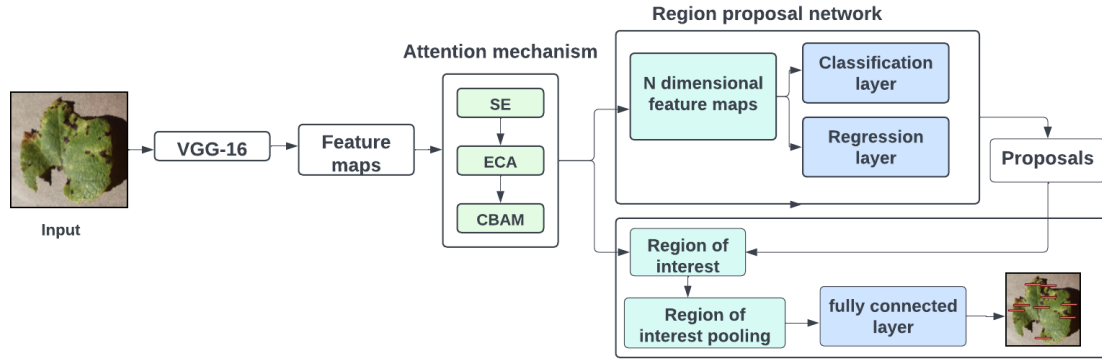

Fig. 6. Faster (R-CNN) model with attention techniques.

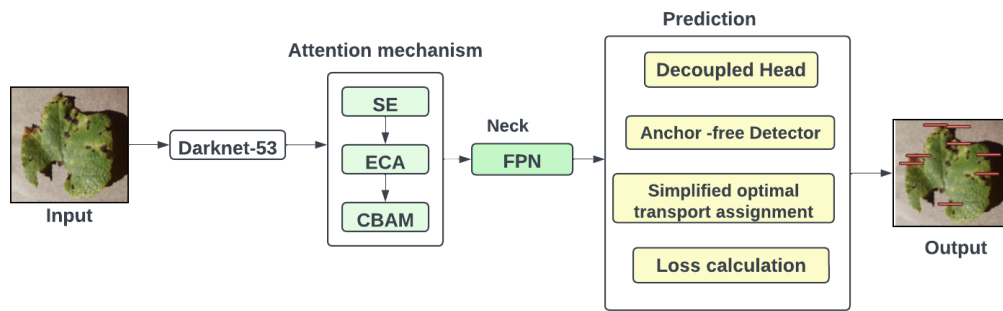

Fig. 7. YOLO-X model with attention mechanism.

Fig. 8. SSD model with attention mechanism.

”Mean Average Precision,” while all targets will be evaluated using ”Mean Average Precision.” However, in this study, we evaluated the grape leaf disease detection model’s performance on a wider set of metrics, including the mean absolute percentage (mAP), the frame rate (FPS), the parameters, and the precision (P) and recall (R) values. The Eq. 1,2 and 3 were used to calculate P, R, and F1.

$$Precision = \frac{TruePositives}{TruePositives + FalsePositives} * 100 \quad (1)$$

$$Recall = \frac{(TruePositives)}{(TruePositives + FalseNegatives)} * 100 \quad (2)$$

$$F1score = \frac{(2 * Precision.Recall)}{(Precision + Recall)} \quad (3)$$

In Eq. 4, the variables P, TP, FP, R, FN, and F1 represent various metrics used to evaluate the performance of a model. P is the precision, which measures the percentage of correct positive predictions. The probability that grape disease leaves are accurately detected is denoted by true positives (’TP’), whereas the probability that they are mistakenly categorised as positive is denoted by false positives (’FP’). Recall, or the proportion of true positives that were correctly detected, is denoted by the letter R. The likelihood of mislabeling a positive sample as negative is known as the ”Fasle negatives” (’FN’) rate. F1 is a measure of accuracy that is the harmonic mean of two other metrics, recall and precision.

$$\int_0^1 PRdR \quad (4)$$

TABLE III. COMPARISON ANALYSIS OF FASTER (R-CNN) MODELS WITH DIFFERENT ATTENTION TECHNIQUES FOR DETECTING GRAPE DISEASES

Model	Precision	Recall	F1-Score	mAP
Faster (R-CNN) model	75.06	74.42	74.74	79.12
Faster (R-CNN) with SE Attention	79.80	84.23	81.96	85.39
Faster (R-CNN) with ECA Attention	76.54	78.71	77.61	81.93
Faster (R-CNN) with CBAM Attention	75.75	75.89	75.82	79.65
Faster (R-CNN) with SE, ECA,CBAM Attention	84.52	86.32	80.79	84.31

A higher value for TP indicates a more accurate prediction & better performance of the model. A model's performance can be measured using mAP, which is a metric that averages the average precision of all diseases. Eq. 5 defines mAP as the average of all AP values. FPS stands for the number of pictures handled each second. The algorithm's ability to recognize items improves as the FPS increases.

$$mAP = \frac{1}{N} \sum_{m=1}^N AP \quad (5)$$

A computer with 16 GB of RAM is used for this research, which runs Windows 10. Model parameters and hardware configuration are considered in Pytorch 1.10.1.

### B. Experiment Results and Analysis

The grape disease dataset was utilized to compare the Faster(R-CNN), YOLO-X, and SSD models with the classical versions based on different attention mechanisms. The models were all trained and detected with the same configuration information and training platform.

1) *Faster (R-CNN) Result Analysis:* The "Faster(R-CNN)" model can be combined with different attention mechanisms to create different versions. Also we have combined the three attention mechanisms i.e. Faster (R-CNN) with SE, ECA,CBAM Attention. To test their performance in detecting grape diseases, all these versions were used in the same experimental setup, and the results are presented in Table III and in Fig. 9. Table III presents a comparison between the Faster (R-CNN) model and four modified versions: "Faster (R-CNN) with SE Attention", "Faster (R-CNN) with ECA Attention", and "Faster (R-CNN) with CBAM Attention". The results indicate that the Faster (R-CNN) with SE Attention model outperformed the original model with an increase in P, R, and F1 values by 4.74%, 9.81%, and 7.22% respectively, and an increase in mAP by 6.27%. Similarly, the Faster (R-CNN) with ECA Attention model showed improvements over the original model with an increase in P, R, and F1 values by 1.48%, 4.29%, and 2.87% respectively, and an increase in mAP by 2.81%. Finally, the "Faster (R-CNN) with CBAM Attention" model showed slight improvements over the original model with an increase in P, R, and F1 values by 0.69%, 1.47%, and 1.08% respectively, and an increase in mAP by 0.53%.

Based on the analysis above, it is evident that the performance of Faster (R-CNN) improved after the inclusion of attention mechanisms, despite a slight increase in parameters for "Faster (R-CNN) with SE Attention and Faster (R-CNN) with CBAM Attention". Enhanced precision and accelerated

TABLE IV. COMPARISON ANALYSIS OF YOLO-X MODELS WITH DIFFERENT ATTENTION TECHNIQUES FOR DETECTING GRAPE DISEASES

Model	Precision	Recall	F1-Score	mAP
YOLO-X model	82.35	74.85	78.42	83.22
YOLO-X with SE Attention	82.46	82.21	82.33	84.02
YOLO-X with ECA Attention	87.77	86.07	86.91	88.66
YOLO-X with CBAM Attention	85.81	77.91	81.67	84.21
YOLO-X with SE, ECA,CBAM Attention	89.77	86.97	85.91	88.96

speed of detection are achieved through the attention mechanism for grape leaves images. Among the various models, "Faster (R-CNN) with SE, ECA, CBAM Attention" displayed the best detection effect when compared with "Faster (R-CNN) with SE Attention". The "Faster (R-CNN) with SE Attention" model demonstrated a 3.26%, 5.52%, and 4.35% increase in P, R, and F1 values, respectively, with an increase of 3.46% in mAP. In comparison with "Faster (R-CNN) with CBAM Attention", "Faster (R-CNN) with SE Attention" increased P, R, and F1 by respectively 4.05%, 8.34%, and 6.14%. When precision is considered, the "Faster (R-CNN) with SE, ECA, and CBAM Attention" model shows optimal results. It focuses on channel features with the most significant information while suppressing un-important features, making it ideal for detecting grape diseases in the dataset.

2) *YOLO-X Result Analysis:* The YOLO-X model has been enhanced with different attention mechanisms: SE, ECA, and CBAM. To compare their performance, all the models (including the original YOLO-X model) were tested on the dataset under the same configuration. The results are shown in Table IV and in Fig. 10. Table IV shows that the "YOLO-X with SE Attention" model has improved performance compared to the YOLO-X model. Specifically, the precision, recall, and F1 values of the "YOLO-X with SE Attention" model increased by 0.11 %, 7.36 %, and 3.91 %, respectively, while the mAP increased by 0.8%. Similarly, the "YOLO-X with ECA Attention" model also outperformed the YOLO-X model, with increases of 5.42%, 11.22%, and 8.49% in precision, recall, and F1 values, respectively. The mAP also increased by 5.44% respectively. The "YOLO-X with CBAM Attention" model also showed improvements, with increases of 3.46%, 3.06%, and 3.25% in precision, recall, and F1 values, respectively, and a 0.99% increase in mAP. Based on the analysis above, it was found that the detection performance of the YOLO-X model was improved with the introduction of attention mechanisms, despite a slight increase in the parameters of the "YOLO-X with SE Attention" and "YOLO-X with ECA Attention" models. Models were able to identify disease objects more accurately due to the attention mechanisms that allowed them to extract more comprehensive and rich features. Out of all the models, the "YOLO-X with SE, ECA,CBAM Attention" model had the best detection performance. Compared to the "YOLO-X with SE Attention" model, the "YOLO-X with ECA Attention" model had a 5.31%, 3.86%, and 4.58% increase in P, R, and F1 values, respectively, a 4.64% increase in mAP, a 4.8 increase in FPS value, and a 0.49 MB expansion in parameters. Compared to the "YOLO-X with CBAM Attention" model, the "YOLO-X with ECA Attention" model had a 1.96%, 8.16%, and 5.24% increase in P, R, and F1 values, respectively, a 4.45% increase in mAP, a 1.8 increase in FPS value, and a 0.66 MB expansion in parameters. Compared to other models YOLO-X with SE, ECA,CBAM Attention

Fig. 9. Comparison analysis of Faster (R-CNN) models with different attention techniques.

Fig. 10. Comparison analysis of YOLO-X models with different attention techniques.

models had outperformed than previous models. In conclusion, even though the “YOLO-X with SE, ECA, CBAM Attention” model had more parameters than the other three models, it achieved the best detection results with fast operation speed on the grape disease dataset, partially due to its ability to achieve cross-channel interaction.

3) *SSD Result Analysis*: Under the same experimental conditions, all the models were utilized to detect diseases on the plant village dataset, & the results of the experiment can be found in Table V and in Fig. 11.

Table V displays the results of various different models. The comparison is based on various metrics, including precision (P), recall (R), and F1 values, mean average precision (mAP).

Compared to the SSD model, the SSD with SE Attention model showed significant improvements in P, R, and F1 values by 2.72%, 15.23%, and 9.45%, respectively.

The SSD with ECA Attention model also showed improvements over the SSD model, but to a lesser degree. A relative increase of 1.35%, 8.77%, and 5.47% in P, R, and F1 values was experienced, while a relative increase of 6.67% was seen in mAP.

The SSD with CBAM Attention model showed the smallest improvements over the SSD model. There is an increase of 0.94 %, 3.61 %, and 2.48 % in P, R, and F1 values, respectively, as well as a 4.91% increase in mAP and a

TABLE V. COMPARISON ANALYSIS OF SSD MODELS WITH DIFFERENT ATTENTION TECHNIQUES FOR DETECTING GRAPE DISEASES

Model	Precision	Recall	F1-Score	mAP
SSD model	80.74	68.87	74.33	76.23
SSD with SE Attention	83.46	84.10	83.78	86.96
SSD with ECA Attention	82.09	77.64	79.80	82.90
SSD with CBAM Attention	81.68	72.48	76.81	81.14
SSD with SE, ECA, CBAM Attention	85.46	84.90	84.78	83.96

3.38 MB increase in the model parameters. "SSD with SE Attention", "SSD with ECA Attention", and "SSD with CBAM Attention" models were all enhanced by the incorporation of attention modules in the network architecture. However, the three models were able to effectively identify important information in feature images while filtering out irrelevant information based on feature importance. As a result, the detection performance of the three attention mechanisms with SSD was superior to that of the SSD model.

We have applied the different attention mechanism but, the "SSD with SE, ECA, CBAM Attention model" demonstrated the best detection performance with significantly faster real-time processing than the other three models. Compared to the "SSD with ECA Attention" model, the "SSD with SE Attention" model showed a 1.37%, 6.46%, and 3.98% improvement in P, R, & F1 values, respectively. Compared to the "SSD with CBAM Attention" model, the "SSD with SE Attention" model showed a 1.78%, 11.62%, and 6.97% improvement in P, R, and F1 values, respectively.

These experimental results demonstrate that the SE attention mechanism optimized feature images, resulting in significantly better detection performance and real-time processing compared to the other three models. Therefore, the "SSD with SE, ECA, CBAM Attention" model can be effectively applied in the detection of various grape diseases with superior comprehensive performance.

4) *Comparison Analysis* : After screening, the three optimal disease detection models were compared to present their disease detection performance. The analysis above showed that "Faster(R-CNN)", "YOLO-X", and "SSD" models when combined with multiple attention mechanisms were the optimal models of their respective detection methods. Fastest R-CNN models exhibited the lowest overall detection accuracy, the slowest operating speed, and the most parameters. The "SSD" models' rapid operation speed and great accuracy made them ideal for near-instantaneous disease diagnosis in vineyards. Strong robustness was demonstrated by the "YOLO-X" models, which achieved the maximum detection precision with the fewest parameters and performed well while identifying both small objects and items hidden by background clutter.

## V. CONCLUSION

After initial screening, three top disease detection models were selected and their performance was compared. The results of the foregoing investigation demonstrated that the "Faster(R-CNN)", "YOLO-X", and "SSD" models, when enhanced with numerous attention mechanisms, provided the most accurate detection results. Overall, "Faster (R-CNN)" models exhibited the lowest detection precision, the slowest operating speed, and the most parameters of the three types of models. Due to its excellent accuracy and quick processing speed, the

"SSD" model was found to be ideal for monitoring field grapes in real time. The "YOLO-X" models demonstrated the highest detection accuracy with the fewest parameters, and they performed well while recognising both small objects and items that were partially obscured.

**Abstract**—It is of great importance for Higher Education (HE) institutions to continuously work on detecting at-risk students based on their performance during their academic journey with the purpose of supporting their success and academic advancement. This is where Learning Analytics (LA) representing learners' behaviour inside the Learning Management Systems (LMS), Educational Data Mining (EDM), and Deep Learning (DL) techniques come into play as an academic sustainable pipeline, which can be used to extract meaningful predictions of the learners' future performance based on their online activity. Thus, the aim of this study is to implement a supervised learning approach which utilizes three artificial neural networks (vRNN, LSTM, and GRU) to develop models that can classify students' final grade as Pass or Fail based on a number of LMS activity indicators; more precisely, detect failed students who are actually the ones susceptible to risk. The three models alongside a baseline MLP classifier have been trained on two datasets (ELIA 101-1, and ELIA 101-2) illustrating the LMS activity and final assessment grade of 3529 students who enrolled in an English Foundation-Year course (ELIA 101) taught at King Abdulaziz University (KAU) during the first and second semesters of 2021. Results indicate that though all of the three DL models performed better than the MLP baseline, the GRU model achieved the highest classification accuracy on both datasets: 93.65% and 98.90%, respectively. As regards predicting at-risk students, all of the three DL models achieved an = 81% Recall values, with notable variation of performance depending on the dataset, the highest being the GRU on the ELIA 101-2.

**Keywords**—Predict at-risk student; artificial neural network; learning management system; and educational data mining

## I. INTRODUCTION

Educational Data Mining (EDM) is currently an exciting field of Data Mining (DM) which deals with investigating Educational Big Data and Learning Analytics (LA) with the purpose of conceptualizing models that can be effectively used in enriching the learners' experiences and augmenting educational institutions' academic offerings and efficiency. Traditionally, EDM applies DM, Machine Learning (ML), and statistical methods to identify patterns in large educational data [1]. Many researchers established the effectiveness of using DM techniques in the educational field, especially, in domains that are crucial to learners' progress, engagement and performance [2] [3].

The previously cited metrics of the students' learning journey, and others, are closely connected to how decision-makers and educators are preoccupied with proactively identifying at-risk students based on their behaviours and performance in educational environments. Currently, EDM, in combination with ML and Deep Learning (DL) techniques have greatly

impacted academic decision-making in terms of robustness, accuracy, and sustainability because mining LA to discover information about students' learning have led to many preemptive measures that support learners' success and advancement [4] [5].

In E-learning environments, LA is oftentimes representative of a user's behaviour inside an institutional Learning Management System (LMS). Theoretically, and in educational contexts, users' behaviour denotes the interactions performed by users inside a website, a mobile app, or a system which can be monitored through analytics tools. The detection of a user's behaviour is often dependent on features which demonstrate the amount, continuation, and emphasis of user activities [6]. These behaviours are significant factors in the evaluation of why a certain user interacts with the system in a specific way, how to proactively predict these behaviours; consequently, detect their impact on the endpoint of the process. In an educational setting, students' behaviour data represent the activities and learning interactions; ideally, within an E-learning platform such an LMS, where there are tools that can help in collecting and storing such data for further analysis. The features of this data can be, for example, course accesses, submissions, clickstream, time-series data, videos, lectures, assessments, discussion forums, and even live video discussions through the internet [7]. The features of this data are usually analysed to predict students' academic achievement, develop recommendation systems, analyse students' behaviour, re-design courses, and identify at-risk students.

Using LA with a combination of EDM, ML and DL to detect at-risk students in Higher Education (HE) Institutions has become the focus of contemporary research, where identifying at-risk learners is often, if not always, associated with demographic, social, psychological, or cultural factors both inside and outside the institution and their impact on final grades in courses and GPAs, or outcomes in programs [8] [9]. Attention to LA is, as well, crucial to a rounded understanding of learners who are susceptible to risk. Since the early 2000s, we discern a change in demarcating the scope of at-risk students, which is motivated by the mainstream use of online environments where LA has become another indicator of learners' behavioural activity in educational settings, as well as the possibility of utilizing ML, generally EDM, techniques to determine risk factors and outcomes [10]. We observe, however, the scarcity of research that addresses practical methods for detecting at-risk students based on DL algorithms in HE contexts.

The current study is primarily motivated by the need for prior discovery of at-risk students through examining their user behaviour in an online learning offering during COVID-

19 in King Abdullaziz University (KAU), which is originally delivered in the same format even before the transformation to Distance Education throughout the pandemic lockdown. The ELIA 101 course is designed and taught in a blended format to Foundation-Year students in KAU including a number of assessments that are submitted via the official LMS, Blackboard. The ultimate aim of at-risk learners' identification is to improve their performance by giving them the opportunity to enhance their achievement and avoid dropout or being academically dismissed from the programs. We assume that, based on the automated predictive modelling of Foundation-Year students' online interactions data, KAU can progressively improve the engagement of low-performing learners, predict students' final grade indicative of their Pass/Fail performance, and prevent their dropout from the course.

Therefore, the aim of this study is to 1) create two datasets which represent the main features of assessment design in ELIA 101 alongside other meaningful online activity attributes, 2) develop three Artificial Neural Networks models that classify students based on their final grade; consequently, detect at-risk students enrolled in the ELIA 101 English course, and 3) evaluate the performance of the models focusing on their accuracy and effectiveness. Generally, we will be investigating answers to the following research questions:

- 1) Which DL network achieves the highest accuracy in detecting students' at-risk status (Fail)?
- 2) Which DL network achieves the highest accuracy in classifying students Pass/ Fail status in the course?

Ideally, this study's contributions can be outlined as follows:

- The collection and pre-processing of two datasets for training the at-risk students prediction models.
- The development of three neural networks, i.e., vanilla Recurrent Neural Network (vRNN), Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), to predict at-risk students in ELIA 101 Foundation-Year English course at KAU.

The rest of this paper is organized as follows: Section II is a literature review of ML and DL methods used in students' performance, and at-risk status prediction. Section III, describes the research methodology. Section IV, presents the findings, discussion and limitations of our research. Section VI, is the conclusion with reference to future work.

## II. REVIEW OF LITERATURE

Predicting students' final grade (including the identification of their at-risk status) is representative of their course performance, and help academic institutions support their students' success, as well as encourage learners to change their study patterns and get better grades.

From an ML perspective, there has been numerous research which experimented with various techniques to predict learners' final grade, and detect their at-risk status using supervised learning methods with a specific implementation of binary classification. Among the studies which considers ML methods is Macarini in which thirteen datasets have been created from 89 students' activity on the Moodle LMS. The

classification algorithms used to classify these datasets are K-Nearest Neighbors (K-NN), Multilayer Perceptron (MLP), Random Forest (RF), AdaBoost, and Naive Bayes. Results show that a combination of the AdaBoost with dataset2 and dataset5 have performed better than the rest of the models [11].

Similarly, Kumari, assessed the behavioural features which could be effective in enhancing students' performance. The data is collected from the LMS for 500 students using the experience API (xAPI). Their model utilized ML algorithms like Iterative Dichotomiser 3 (ID3), K-NN, naive Bayes, Support Vector Machine (SVM). The algorithms have been implemented on the Waikato Environment for Knowledge Analysis (WEKA), where the ID3 achieved a higher accuracy than the other methods (=90%) [12].

Besides, Karthikeyan have assessed students' performance by proposing a Hybrid Educational Data Mining (HEDM) model. This model combines the effectiveness of naive Bayes and the J48 Classifier classification technique. The model has been tested against an online dataset and achieved an 98% accuracy [13].

The investigation of at-risk students' activity metrics and impact on their final grade have been also studied with a combination of ML and basic DL techniques like ANNs. ML and DL algorithms have been developed in Howard, on a dataset consisting of 136 students' LMS activity, the researchers implemented RF; XGBoost; Bayesian Additive Regression Trees (BART); Principal Components Regression (PCR); SVM; Multivariate Adaptive Regression Splines (MARS); neural network; and K-NN. They used the actual final grade as the main variable to which they compared the predicted one. The Mean Absolute Error (MAE) was calculated; and they reported that PCR had the lowest MAE value 6.5. The researchers found that the best time to expect at-risk students was during weeks 5/6 [14].

In Hung the data representing 12,869 students has been collected from a K-12 virtual school in the northern USA. The algorithms used for the model are SVM with the sigmoid kernel, SVM with polynomial kernel, SVM with gaussian radial basis function, RF, and ANN. The DL model achieves better performance than the ML ones by correctly identifying 51% of at-risk students with 86% accuracy [15].

Besides, Altabrawee, utilizes both ML and DL models to predict students' performance in a computer science subject at Al-Muthanna University, which is tested on data representing the user behaviour of 161 students. The researchers design an ANN, Naïve Bayes, decision tree, and logistic regression models. As indicated by results, the ANN model achieved a 77% accuracy, higher than the other models [16].

The early at-risk detection of students' performance enables them to improve their learning strategies. For example, Sultana, develop models to warn learners who have low performance issues based on their cognitive and non-cognitive competences to decrease their dropout. The non-cognitive features include: Time-management, Self-concept, Realistic-Self-appraisal, and Community support. The dataset used in this research represent the user activities of 778 students collected from different universities and online repositories. The researchers have applied logistic regression, decision tree,

naive Bayes, and an ANN. Results indicate that certain combinations of cognitive and non-cognitive features improved the model performance. For example, a combination of cognitive features, Leadership and Realistic-Self-appraisal data trained with a naive Bayes model has resulted in the highest accuracy value, 65%. Similar cognitive, non-cognitive combinations have achieved the same accuracy with the naive Bayes model as well [17].

With a specific focus on DL methods, Aydođdu uses an ANN for student final performance prediction. The dataset, used in this research, comes from the activity stream of 3518 students. The model achieves an accuracy of 80% [18]. In the same manner, the researchers in Hussain, design a method to predict students' results, which is tested on a dataset representing the user behaviour of 10140 students. The results demonstrate the effectiveness of the RNN which achieves an accuracy of 95% [19]. Utilizing an RNN as well, He, proposed a novel joint RNN-GRU neural networks that predicts at-risk students using OULAD. Three algorithms are considered as baseline models: vRNN, GRU, and LSTM. The findings show that simple techniques such as GRU and vRNN have better outcomes than the relatively complex model of LSTM. The joint model successfully predicted at-risk students at the end of the semester and obtained over 80% accuracy [7].

Prior studies examining student behavior mainly on an online or MOOC dataset, this study uses real students' datasets from the Blackboard LMS, the adopted LMS in most Saudi higher education institutions.

Moreover, the extracted LA data in the rest of the studies, which use a real student's dataset, is for a limited number of students except in [19], which has 10,140 learners. This study worked with two datasets created from data values representing 3,529 learners.

Therefore, this study extends previous research by providing an effective solution for predicting students' pass/ fail status and identifying at-risk students (fail) by implementing DL models based on individual student behavior in LMS.

### III. METHODOLOGY

The methodology adopted for this research consists of four key phases: data collection, data pre-processing, development of prediction models, and evaluation (see Fig. 1).

Fig. 1. Methodology pipeline.

More specifically, the process of the proposed models' pipeline could be illustrated in Fig. 2.

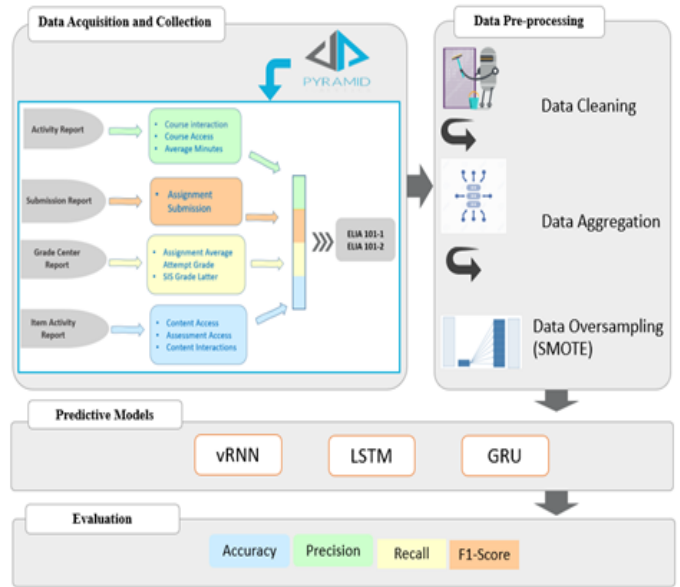

Fig. 2. The proposed models' pipeline.

#### A. Data Collection

The datasets used in this study are retrieved via a collaboration with the Deanship of E-Learning and Distance Education at KAU using the official Learning Analytics system, A4L which supports the Blackboard LMS. This service facilitates the extraction of big educational data; specifically, in our case, detailed reports on students' course activity (overall interactions), submissions, grade centre assessments, and activity on item level alongside their final grade in the course.

The A4L system has two interfaces, one for the institution and the other is user-centric, accessible via the LMS.

1) *The Institution Interface:* A4L records and displays students' LMS behaviour and interactions sliced by multiple data dimensions. Data measures in the form of frequencies, averages, and percentages can be extracted. Examples of dimensions include: Course, Advisor, SIS Major, SIS Student College, SIS Student Level, Student Risk Profile, Term, Time Series, etc. Examples of measures are Items Accessed, Assessments Accessed, Course Accessed, Content Accessed, etc.

2) *The User Interface:* Both instructors and students have a view-only permission to the A4L reports, which allow them to compare their performance to other users and follow their progress.

From the A4L solution described above, two datasets have been extracted. Both datasets are comprised of a total of 3529 students' activity data from an English Foundation-Year course (ELIA 101), which is delivered during the first and second semesters of 2021. The first dataset (ELIA 101-1) is from the Spring term run of (ELIA 101) and consists of 75,971 records representing (2386) students. (2322) of those students passed the course, whereas (64) of them failed. The second dataset (ELIA 101-2) is the Fall run of the (ELIA 101) course and included 26,291 records of 1,143 students. 1,137 of those students passed the course, and 6 of them failed.

TABLE I. DATASETS STRUCTURE

User Id	Assessment Access	Content Access	Course Access	Course Interactions	Course Item Interactions	Avg. Minutes	Assignment Submission Count	Assignment Attempt Grade
STD_1	0	3	2	4	3	117.717	1	100
STD_1	6	1	2	87	7	63.3	1	100
STD_1	3	12	3	96	16	74.367	1	100
STD_1	0	1	1	10	1	209.05	1	100
STD_1	0	0	1	1	0	0.217	1	100

TABLE II. FEATURES DESCRIPTION

Reports	Features	Description
Activity	Course_Access	A count of students' access per the course.
	Course_Interactions	A count of students' interactions per the course.
	Avg_Minutes	Average minutes that the students spent per course
Submission	Assignment_Submission	A count of students' submissions per a specific assignment.
Grade Center	Assignment_Avg_Attempt_Grade	Average students' grade per a specific assignment.
	SIS_Grade_Letter	Corresponding final course grade for the students.
Item Activity	Assessment_Access	A count of students' access per a specific assessment.
	Content_Access	A count of students' access per a specific content.
	Course_Item_Interactions	A count of students' interactions per a specific item.

Ideally, this course is delivered, at least, twice a year. The dataset is basically extracted as a report made up of several online activity indicators. Both datasets included 9 students' activity metrics as shown in Table I. The description of these metrics is listed in Table II.

The following inclusion and exclusion criterion for dataset creation have been observed and implemented:

1) Inclusion criterion:

- The extracted reports included features (measures) representative of 1) the basic elements of instructional design, specifically, assessments and engagement indicators like interaction, as well as, 2) potential risk factors, which might have an impact on the instructional context of ELIA 101 as delivered in the English Language Institute in KAU, where, for example, assignments are delivered weekly via Blackboard as per required by the official Course Specification for this course [20]. Other assessment types like a Final Speaking Exam and a Final Writing Exam are used but are summative assessment tools like the Final Exam, and what we are interested in are formative assessments conducted during the semester. According to the instructional strategy of the course, forums and other collaborative tools are not used as assessment methods, henceforward, data related to them are not included [20].
- Comparability is ensured through extracting data about a definable student cohort (Foundation-year students enrolled in the English Course, ELIA 101).
- The data was extracted from both course and students' perspectives for 3529 students.
- The researchers verified that the course included actual activities so that the extracted reports reflect actual user behaviour.
- Extracted reports coverage is of the first and second semesters of 2021, where KAU migrated to the online learning platform to ensure the continuity of its academic offering during the COVID-19 lockdown.

2) Exclusion criterion:

- Measures which relate to logins were excluded, because they display data representative of all the courses a student is enrolled in, not just ELIA 101.
- Measures which perform complex statistical operations on the data (change rate, moving averages) were as well not considered.

B. Data Pre-processing

1) *Data Cleaning*: Data cleaning is a data pre-processing technique that is used to improve the quality of the data. This process ensures that there is no data nosiness or inconsistency, thus eliminating what researchers consider "garbage" [21]. In this step, the researcher cleans up the data by removing students with undefined grade schemas in the "SIS\_Grade\_Letter" column. For example, values like "NF", "No SIS Match", "W", "XX", and "No Recorded Grade" were removed as they have no relevant reference in the KAU grades schema except for (W) which indicates a student who dropped from the course or the program. Moreover, the grade above the actual (100), reported usually as a percentage mean of assessment grade, is removed from the "Assignment\_Avg\_Attempt\_Grade" and "SIS\_Grade\_Letter" columns, which sometimes reflect an addition of an extra grade by the instructor that disrupts the percentage representation. However, only a few cases of these instances have been found (only 169 grade representations in the two datasets). Similarly, the "SIS\_Grade\_Letter" "DN" and "F" grade marks have been encoded as zeros because these symbols represent students who failed the course either due to their non-attendance or getting a grade lower than 60 out of 100.

2) *Data Aggregation*: The original dataset consisted of 75,971 entries for ELIA 101-1, and 26291 for ELIA 101-2), ranging from two to sixteen rows per student ID indicative of their level of interaction with the course. This necessitates that we find a method by which data representation becomes uniform for all students. So, conditional aggregation of data points based on an index (Student ID) has been performed through computing the mean of all the interaction values per student. The 'mean' value was used for aggregation because, unlike the 'count' and 'median' values, it does not affect the student's final grade, which we have noticed during experimentation with various data aggregation methods.

3) *Data Imbalance*: The number of students who have failed both ELIA 101-1 (64) and ELIA 101-2 (6) is small compared to the number of passing students in both datasets: 2322, 1137, respectively. This indicates (as Fig. 3 and 4 show) that there is a data imbalance problem that needs to be addressed so that the minority class, in this case "Fail", is not misrepresented, or affect the performance of the model. Therefore, data balancing strategies are applied to avoid a lower performance by DL methods which usually expect a balanced class distribution [22].

One method to overcomes data imbalance is Oversampling which increases the instances of the class with fewer numbers. As a first step, Random Oversampling (ROS) has been applied to the ELIA 101-1 and ELIA 101-2 datasets, but it only duplicates the data of the minority class which causes the models to overfit [23].

Fig. 3. ELIA 101-1 Pass/Fail imbalance.

Fig. 4. ELIA 101-2 Pass/Fail imbalance.

To overcome overfitting, the Synthetic Minority Over-sampling Technique (SMOTE) is employed [24]. where it populates the minority class instance (Fail) in the datasets by generating a synthetic sample that selects one of the k nearest neighbours of the feature in the feature space, and in the process, draws a line between the examples in the feature space, while defining a point along that line to generate the sample.

Oversampling the two datasets with SMOTE resulted in balanced datasets. ELIA 101-1, upon oversampling consisted of 4772 samples with equal Pass/Fail count, and ELIA 101-2 included 2286 samples with an equal distribution of the Pass/Fail grading schema.

4) *Data Labelling*: A Target column is added to the oversampled dataset, which translates the “SIS\_Grade\_Letter” grade value into 1 or 0 binary, indicating a Pass/Fail status, respectively. Students who score less than 60 on their final grade are classified as failing students, whereas students scoring 60 or above are recorded as pass.

5) *Training and Testing Split*: The dataset was split into training and testing sets with an 80/20% ratio. The data splits have been stratified by the target column so that neither the training nor testing sets be made completely of either one of the students’ status indicators 0 or 1. Consequently, the proportion of instances of each class (Pass/Fail) in each subset (Train/ Test) is almost equal to that in the original dataset. We assume, as research indicates, that stratification improves the model’s

TABLE III. MODELS’ HYPERPARAMETERS

Models	Layers	Optimizer/ Loss/ Metric	Epochs	Batch Size
<b>vRNN</b>	- Input (128, relu) - Hidden (64, relu) - 2 Hidden (32, relu) - Output (1, sigmoid)	- Adam (learning rate=0.001) - binary_crossentropy - accuracy	100	32
<b>LSTM</b>	- Input (128, relu) - Hidden (64, relu) - 3 Hidden (32, relu) - Output (1, sigmoid)

performance as well as contributes to avoiding both bias issues related to variance.

### C. Building the DL Models

The main objective of this research has been to adopt a supervised learning approach to develop DL models that are capable of predicting the presence of at-risk students depending on their LMS interaction with the various course components that made up the final grade (Pass/Fail). More specifically, we performed a binary classification of the two datasets representing the ELIA 101 Course based on students’ final grade. As we are considering a dataset with multiple predictors, we opted for developing and comparing the performance of classification models that are capable of prediction based on multiple indicators. To achieve this objective, we experimented with three deep learning models (vRNN, LSTM, and GRU).

All deep learning models have been trained and tested using Python 3 and TensorFlow 2.6.0. The three models’ hyperparameters are set to the ones illustrated in Table III. In order to avoid the overfitting problem, early stopping is used for all models [25].

1) *Baseline Model*: An initial implementation of a baseline neural network has been attempted, where the results are later used as a reference point of comparison to the proposed models. The objective is to generally investigate the efficacy of our deep learning approach while using baseline structures that can be improved on.

#### a) Multilayer Perceptron (MLP):

An MLP is one of the simplest representations of neural networks. It is a class of Feedforward ANNs which is composed of multiple layers of neurons that are connected through directed connections to the neurons of each subsequent layer [1]. There are three layers of neurons, including the input, hidden, and output layers. In its hidden and output layers, MLP uses sigmoid functions to predict probabilities. As part of the training process, MLP adjusts the weights iteratively by learning through a backpropagation function to produce good results [9]. An MLP with a hidden layer demonstrates a non-convex loss function which results in multiple local minima [26]. Moreover, the decision process in an MLP is made in relation to the immediate input. It does not have memory of past or future input.

#### 2) Proposed Models:

a) *Vanilla Recurrent Neural Networks (vRNN):*

RNNs are a type of artificial neural network which consists of connected nodes in a directed or undirected graph [27]. In RNNs, the information loops through the middle-hidden layer. The input is passed to the input layer, processes it, then passes it to the middle layer. The middle layer usually consists of multiple hidden layers, each with its own activation functions and weights. Unlike MLP, which is a Feedforward network considering only the current input, RNNs implements a feedback loop that ensures information cycles, which means that unlike feedforward connections, RNNs can also have connections that feed information to the previous or same layer [1]. Vanilla RNN is the standard RNN, it passes input as well as a hidden state through a single tanh layer [7]. In this research, the vRNN model is constructed of one input layer with 128 units, one hidden layer with 64 units, 2 hidden layers with 32 units, and the output fully connected layer. All layers use a Rectified Linear Unit (ReLU) activation function, except for the output layer which uses a 'sigmoid' activation. The model training stopped at 37 epochs on the (ELIA 101-1) dataset, and on 35 on the (ELIA 101-2) dataset.

b) *Long Short-Term Memory (LSTM):*

The main issue with vRNNs is the problem of vanishing gradients, which suffers an exponential decrease as the neural network back-propagates, which slows up the learning process in the final layers of the RNN [1]. Therefore, an LSTM model is developed to counteract the limitation of the vRNNs special architecture. The memory cell concept is introduced in LSTM architecture, which enables long-term dependency learning. As a function of its inputs, the memory cell temporarily holds its value, and is composed of three gates that regulate how information flows. Basically, there is an input gate which regulate when new information accesses the memory cell; a forget gate which manages the time limit for storing information in the cell, thus permitting new information to flow in; and the output gate that manipulates when the stored information is to be utilized by the processor [1]. Ultimately, this speeds the learning process as well as retains its information. Our LSTM model is constructed of an input layer with 128 neurons, a hidden layer contains 64 neurons, two hidden layers that include 32 neurons. Finally, the fully connected layer with one neuron was applied. Whereas all layers make use of a ReLU activation function, the output layer applies a 'sigmoid' activation. The model training stopped at 79 epochs with the (ELIA 101-1) dataset, and on 51 with the (ELIA 101-2) dataset.

c) *Gated Recurrent Unit (GRU):*

LSTM relies on using more training parameters, therefore uses more memory and executes slower than other models. So, for addressing this, we developed a GRU model, which is a simplified version of an LSTM [1]. Its hyperparameters are fewer in comparison to the LSTM as it consists of two gates in place of three, a reset and update gates. The GRU's update gate is a merge up of the LSTM's input and forget gates [7].

In this research, GRU is constructed with 7 layers; the input layer has 256 neurons, one hidden layer made of 128 neurons, five hidden layers including 64 neurons, and the output layer which has 1 neuron. All layers use an activation function, a ReLU, except the output layer which uses a 'sigmoid'. The model training stopped at 88 epochs when trained on the (ELIA

101-1) dataset and on 96 when trained on the (ELIA 101-2).

D. *Evaluation*

To evaluate the performance of the baseline and proposed models, we used the following metrics:

- Accuracy: is a metric that helps determine the percentage of correctly categorized instances in relation to the total of those instances based on the following Eq. 1 [9]:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

- Recall: is a metric that is used to evaluate model overall. It computes the percentage of the correctly classified true positives using the following equation 2 [9]:

$$Recall(TPR) = \frac{TP}{TP + FN} \quad (2)$$

- Precision: is a metric that is used to assess the accuracy of the model. It reflects the percentage of true positives to those instances listed as positive by the classifier employing the following Eq. 3 [9]:

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

- F1-score: is a metric that computes the average of precision and recall, and it is useful in cases where the performance of different classifiers is to be compared. The following Eq. 4 represents the F1-core computation process [9]:

$$F - Measure = \frac{2 * Precision * Recall}{Precision + Recall} \quad (4)$$

#### IV. RESULTS AND DISCUSSION

The aim of this research is set initially to predict at-risk students based on their behaviour inside the ELIA 101 course in two datasets (ELIA 101-1) and (ELIA 101-2), which has been delivered via KAU's official LMS, Blackboard. Therefore, the proposed models' performance (vRNN, LSTM, GRU) are evaluated and compared to each other as well as the baseline model (MLP). Table IV shows the results of the various models' predictions on the datasets.

The MLP, as baseline, achieved an accuracy of 84% on the (ELIA 101-1) and 91.65% when tested on the (ELIA 101-2) dataset, which sets it as the model with the lowest performance in classifying students' Pass/Fail status. The GRU model, on the other hand, achieved an accuracy of 94.40% on the (ELIA 101-1) dataset and 98.02% on the (ELIA 101-2) which is considered the highest set of values among baseline and proposed models. The GRU, as well, achieved the best f1-scores (= 94.25% and 97.99%, respectively).

According to the results outlined above, a comparison of all predicted models is provided in Fig. 5 and 6.

Moreover, Fig. 7, 8, 9, 10, 11, and 12 illustrate the loss and accuracy of training and validation data per each model

TABLE IV. PERFORMANCE RESULTS FOR THE MODELS ON THE TWO DATASETS

Models	Dataset	Accuracy	Precession	Recall	F1_Score
MLP	ELIA 101 -1	83.85	82.98	85.13	84.04
	ELIA 101 -2	91.65	98.96	84.14	90.95
vRNN	ELIA 101 -1	84.50	86.53	81.68	84.04
	ELIA 101 -2	96.92	100	93.83	96.82
LSTM	ELIA 101 -1	93.22	97.62	88.58	92.88
	ELIA 101 -2	89.24	92.72	85.13	88.76
GRU	ELIA 101 -1	93.65	97.87	89.22	93.35
	ELIA 101 -2	98.90	100	97.79	98.89

with the number of epochs. There is no overfitting since the early stopping was used.

vRNN learned faster than the other models by only 37, and 35 epochs for ELIA 101-1, and ELIA 101-2 datasets, in contrast to the LSTM, which learned by 79, and 51 epochs and GRU, which learned by 88, and 96 epochs, respectively. The slow learning of the LSTM and GRU in comparison with vRNN is due to the models' complexity and the extra wights. This begs the question of the feasibility of using the GRU model on huge students' real-time datasets and the expected time-consuming performance on such data, while considering

Fig. 11. GRU loss and accuracy for ELIA 101-1.

Fig. 12. GRU loss and accuracy for ELIA 101-2.

the sensitivity of at-risk students' activity.

The main objective of this research has been the utilization of DL techniques and models to predict at-risk students, who are, in this learning scenario, the failing students. Therefore, it is of importance that we reflect on the results of the prediction accuracy when it comes to identifying at-risk students. The confusion matrices in Fig. 13, 14, 15, 16, 17, 18, 19, 20 and the Precision and Recall values in Table IV, have demonstrated that the GRU's Recall (representing in our case the failing students) on the (ELIA 101-2) dataset (=97.7%) is the highest value indicative of the model's performance in regard to detecting the at-risk factor, which is critical for our study. The vRNN Recall on the (ELIA 101-2) is also high with a value of 93.8%, which is again representative of the model's capability at classifying the students' fail instances. The GRU's accuracy in identifying failing students on the (ELIA 101-1) comes next with a value of 89.22%, then the LSTM's Recall value (=88.5%) on the same dataset.

The previously cited results point out the predictive power of the GRU, vRNN, and LSTM, almost in that order, especially with reference to detecting at-risk students, on both datasets with Recall values ranging from 81.68% to 97.79%. Though the results in this regard are relatively close, yet the slight distinctions are probably suggestive of two main things. Firstly, there is a differentiation of learning patterns among at-risk students, who are subject to various life situations that impact their learning interactions online which could explain the

distinction in the models' performance regarding the detection of their Fail status. Secondly, there is also no uniformity among at-risk students enrolled in different, time-displaced cohorts with regards to their level of expected learning interactions and the impact of those interactions on their academic performance.

It is also significant to reflect on the models' performance with reference to its ability to differentiate passing from failing students. As the confusion matrices in Fig. 13, 14, 15, 16, 19, 20, 17, and 18 show, except of course for the MLP implementation on the (ELIA 101-1) dataset, there is a greater reported accuracy when it comes to predicting passing students in contrast to failing ones. For the GRU, for example, the model has been able to predict 97.8% of passing students and 89.2% of the failing ones on the (ELIA 101-1) dataset in comparison to 100% accuracy of predicting passing students and 97.7% of failing students on the (ELIA 101-2) dataset. As far as the LSTM and vRNN models are concerned, we notice the same trend of the model's ability to predict successful students with a pass indicator. Whereas, the vRNN application to the first dataset, for instance, has resulted in an accurate prediction of 86.5% passing students and 81.6% of the ones with a failing status, its implementation on the second dataset has yielded a 100% accuracy value for predicting passing students and a 93.8% for students with a failure grade. Almost the same results are reported for the LSTM, with accuracy values for predicting successful learners (97.6%, 92.7%) that are higher than the values of classifying unsuccessful ones (88.5%, 85.1%) on both datasets.

This could be attributed to the almost inherent homogenous nature of intermediate to high-performing students' learning activity and behavior which is often intrinsically motivated to the point that their commitment to the learning process manifests in the form of almost uniform patterns across most learning cohorts. DL models, including the ones developed for this study, discover the hidden patterns in learners' data that contribute to an understanding of their learning behaviour, and this reflects positively on the performance of the models.

Fig. 13. MLP confusion matrix for ELIA 101-1.

One has to note that the improved performance of the models on the ELIA 101-2 dataset could be attributed to the relatively small number of records originally found in it (1143) including both pass (1137) and fail (6) students, which upon augmentation reached (2274). This, if compared to the

Fig. 14. MLP confusion matrix for ELIA 101-2.

Fig. 16. vRNN confusion matrix for ELIA 101-2.

Fig. 19. GRU confusion matrix for ELIA 101-1.

4644 augmented records in the ELIA 101-1 dataset can be considered one of the limitations decision-makers encounter in real-life educational scenarios. Unlike the MOOC, for example, learning experience, students in compulsory university education are usually grouped in smaller cohorts and required to complete courses within a specific timeframe. Rarely, if ever, especially in Foundation courses, we encounter high rates of failure or even dropout.

Another limitation we believe is related to the dataset size and representation of one course and student cohort. More testing on differentiated datasets representing students' LMS

behaviour in KAU can lead to a better understanding of what constitutes risk factors for students.

## V. CONCLUSION AND FUTURE WORK

LMS platforms provide useful information about students' interactions, which can be used to identify at-risk students. In this study, we proposed three neural network models (vRNN, LSTM, and GRU) for predicting both students' final grade performance and at-risk standing based on two datasets extracted from the A4L: KAU Blackboard.

The results show that the GRU performs better than

Fig. 20. GRU confusion matrix for ELIA 101-2.

other models in detecting learners' Pass/Fail status because it achieved the highest accuracy 93.65 (on the ELIA 101-1) and 98.90 (on the ELIA 101-2).

As far as predicting the at-risk students (likely to Fail), the previously mentioned results highlight the predictive power of the GRU, vRNN, and LSTM, respectively, on both datasets, with Recall values ranging from 81.68% to 97.79%.

The researchers think the dataset's size and its representation of only one course and student cohort are a drawback. A deeper knowledge of what comprises risk variables for students may result from more testing on differentiated datasets representing students' LMS behaviour in KAU.

For further research, we will use methods to overcome the impact of small size datasets on the realistic performance of DL models by, for example, through implementing advanced data augmentation techniques, considering time-series factors to predict at-risk students half-away through the semester; and, adding other predicators of students' user behaviour inside the LMS and exploring their relation to students' final achievement. More importantly, and while observing the variation among the proposed models in the accuracy of predicting at-risk students on different datasets, we will experiment with ensemble techniques, where the best results of each model might be enhanced by its combination with the others.

#### ACKNOWLEDGMENT

The researchers would like to thank the Deanship of E-Learning and Distance Education at King Abdulaziz University for the provision of datasets.

**Abstract**—Effort estimation in software development (SEE) is a crucial concern within the software engineering domain, as it directly impacts cost estimation, scheduling, staffing, planning, and resource allocation accuracy. In this scientific article, the authors aim to tackle this issue by integrating machine learning (ML) techniques with metaheuristic algorithms in order to raise prediction accuracy. For this purpose, they employ a multilayer perceptron neural network (MLP) to perform the estimation for SEE. Unfortunately, the MLP network has numerous drawbacks as well, including weight dependency, rapid convergence, and accuracy limits. To address these issues, the SSA Algorithm is employed to optimize the MLP weights and biases. Simultaneously, the SSA algorithm has shortcomings in some aspects of the search mechanisms as well, such as rapid convergence and being susceptible to the local optimal trap. As a result, the genetic algorithm (GA) is utilized to address these shortcomings through fine-tuning its parameters. The main objective is to develop a robust and reliable prediction model that can handle a wide range of SEE problems. The developed techniques are tested on twelve benchmark SEE datasets to evaluate their performance. Furthermore, a comparative analysis with state-of-the-art methods is conducted to further validate the effectiveness of the developed techniques. The findings demonstrate that the developed techniques surpass all other methods in all benchmark problems, affirming their superiority.

**Keywords**—Software development effort estimation; machine learning; multilayer perceptron neural network; salp swarm algorithm; genetic algorithm

## I. INTRODUCTION

Software engineering encompasses a systematic, methodical, and quantitative approach to the creation, operation, and maintenance of software systems. In order to ensure the effective and timely production of software products, software engineering management adopts specific actions such as planning, monitoring, measuring, and reporting [1], [2]. Conversely, software development effort estimation (SEE) represents a formidable challenge that holds significant importance in the software development process. SEE can be defined as the process of constructing a model that aids software engineers

in determining the cost of a software project prior to or at the commencement of the software development process [3], [4].

The scholarly literature proposes various methodologies to tackle the SEE problem. Some of these methodologies fall under the non-soft computing category, while others utilize machine learning (ML) techniques. ML techniques have demonstrated their effectiveness and capability to address similar problems encountered in diverse engineering fields. Among these ML techniques, artificial neural networks (ANN) have gained popularity and been extensively adopted in numerous research studies. One common type of ANN is the Multilayer Perceptron Neural Network (MLP), which is widely employed in addressing classification and prediction problems. Additionally, MLP exhibits excellent capability for handling non-linear and complex engineering problems [2], [3].

Motivated by the shortage of accuracy in the available models for estimating software development efforts in the literature, this research study aims to develop a robust and reliable ML model that has the ability to address the problem with high accuracy. However, to overcome limitations in prediction accuracy in the MLP network, the study integrates a metaheuristic algorithm known as the Salp Swarm Algorithm (SSA) into the MLP network. This integration aims to optimize the weights and biases of the MLP network, thereby enhancing its prediction accuracy. Furthermore, considering the SSA algorithm's search restrictions, the research suggests a strategy for using the Genetic Algorithm (GA) to fine-tune the SSA parameters.

Because the optimization procedure is stochastic, the effectiveness of metaheuristic algorithms essentially rests on finding a reasonable balance throughout the exploration and exploitation phases and refining the solutions over generations. The algorithm investigates the search space broadly during the exploration phase in an effort to avoid becoming stuck in local optima. Where, in the exploitation phase, the promising solutions found during the exploration phase are refined to attain the global optimum [5].

The Salp swarm algorithm (SSA) was put out in 2017 by Mirjalili [6] as an effective way for solving optimization issues in the context of metaheuristic methodologies. The swarming behavior of salps in deep waters, which commonly generates a chain of salps, served as the basis for this method. In order to have more control and make coordinated adjustments for quick foraging, this chain advances by pushing water inside its barrel-shaped shells.

The key drawbacks of the SSA algorithm, like those of other metaheuristic algorithms, are delayed convergence and premature convergence toward local optima. The No Free Lunch theorem in optimization states that it must be altered in order to address certain particular problems. This theorem argues that when addressing all optimization issues, all methods function on average equally well. As a result, a particular approach may work effectively for one group of problems but fail miserably for another. In order to enhance algorithms that are acceptable for the majority of issue types, researchers [7], [8], [9] determined that the proper balance between exploration and exploitation needed to be improved.

There are potential benefits to fine-tuning the SSA algorithm parameter settings using the GA algorithm, thus optimizing the MLP network weights. By integrating the SSA's exploration skills with the GA's global search, the SSA optimization capabilities are improved. Therefore, by overcoming local optimum conditions and responding to various scenarios, the developed model becomes adaptable and flexible. The MLP network's estimation error can be reduced, which in turn improves the accuracy of resource planning and project scheduling. The SSA-GA approach makes it easier to facilitate generalization and produce accurate estimates for varied software projects. Overall, this method effectively addresses the issue of estimating the effort required for software development, allowing for good resource management and project planning. The key contributions of this work are as follows:

- 1) Use the MLP network to address the issue of estimating software development effort.
- 2) Use the SSA algorithm to optimize the MLP parameters (Weights and biases).
- 3) Apply the GA algorithm to boost the SSA algorithm's optimization capabilities by fine-tuning its parameters.
- 4) Use several common benchmark SEE datasets to generalize the findings.
- 5) Develop three methods (e.g., MLP, SSA-MLP, and SSA-GA) and conduct statistical comparisons among the methods to determine the most effective one.

The rest of the paper contains the following: Section II provides a brief overview of the SEE problem, the MLP network, and the SSA algorithm. Section III introduces the developed methods. Section IV introduces the research results. Section V introduces a discussion for study finding. Section VI introduces the study conclusion.

## II. BACKGROUND

The research at hand encompasses a variety of tools and topics, including "Software Development Effort Estimation Problem", "Multilayer Perceptron Neural Network", and "Salp Swarm Algorithm." These components form the foundation of

the study and contribute to its overall context and objectives. Below is a brief overview of each of them.

### A. Software Development Effort Estimation Problem

Software development effort estimation (SEE) is a critical procedure that involves utilizing uncertain, noisy, inconsistent, and incomplete data inputs to forecast the optimal and realistic amount of effort required for software development and maintenance. Typically, the level of work accomplished is expressed in units such as man-months, man-hours, or the number of individuals involved in the software development process. Accurate estimations play a pivotal role in effectively planning for software project development. However, underestimation and overestimation are two complex issues that software project managers often face, and these challenges can potentially result in project failure [10], [11].

Robert N. Charette [12] extensively discussed the primary causes of failure in software projects, identifying a range of issues that contribute to project failures. These issues encompass unending system requirements, inadequate communication between developers and customers, the utilization of outdated technologies, ineffective project management practices, commercial pressures, difficulties in handling project complexity, inaccurate project status reports, unrealistic project objectives, uncontrolled risks, and stakeholder conflicts influenced by political factors. However, the ultimate success of a software project heavily relies on the accuracy of work estimation. While precise estimation is essential for both project managers and clients, there is a pressing need to enhance software development effort estimation (SEE). SEE plays a crucial role in supporting efficient software development and maintenance for software developers, while also empowering clients to negotiate contracts, plan project completion timelines, and establish release dates for prototypes, among other aspects. Despite the existence of numerous approaches to software effort estimation, the development of accurate and consistent estimation techniques remains challenging for researchers [13], [1].

### B. Multilayer Perceptron Neural Network

The multilayer perceptron (MLP) neural network, a specific component of the feedforward neural network (FFNN), stands as a unique form of Artificial Neural Network (ANN) capable of effectively approximating and comprehending the characteristics exhibited by computational models [14].

The MLP neural network necessitates a unidirectional arrangement of neurons, where data is transmitted through stacked layers organized into three types: input, hidden, and output layers. The connections between these layers can be established using different weights. Neurons within the MLP perform calculations using summation and activation functions. Summation function responsible for calculating the weighted sum of inputs and their corresponding connection weights. This function aggregates the inputs and weights to generate a weighted sum. The activation function, on the other hand, introduces non-linearity to the output of the summation function. It determines the output of a neuron or an entire layer based on the weighted sum calculated by the summation function. The activation function introduces non-linear transformations,

allowing the network to learn and model complex relationships between inputs and outputs.

The hidden layer neurons in the neural network employ the sigmoid activation function, while the output layer neurons utilize the linear activation function. The linear and sigmoid functions can be mathematically represented by Eq. 1 and 2, respectively.

$$f(x) = x \quad (1)$$

$$f(x) = \frac{1}{1 + e^{-x}} \quad (2)$$

Consequently, by adjusting the biases and weights, the network iteratively minimizes the error in the output and improves the accuracy of predictions. Graphical representations of the linear and sigmoid functions can be observed in Fig. 1 and 2, respectively.

Fig. 1. Linear Activation Function

Fig. 2. Sigmoid Activation Function

### C. Salp Swarm Algorithm

The Salp Swarm Algorithm (SSA) is a recently introduced metaheuristic optimization algorithm developed by Mirjalili et al. in 2017 [6]. This algorithm is inspired by the collective behavior of sea salps found in nature. Sea salps, which are transparent, barrel-shaped invertebrates resembling jellyfish, propel themselves forward by pumping water into the back of their shells [15], [16]. They live and swim together in groups, with one salp acting as the leader while the others are considered “followers” [6]. Fig. 3 illustrates the body shape of a salp in (a) and depicts a group of salp swarms in (b).

The collective swimming behavior of salps in a group or swarm can be mathematically formulated and modeled as an optimization algorithm. The positions of the salps are determined within a search space of dimensions  $n \times N$ , where  $n$  represents the number of variables in a specific problem and  $N$  corresponds to the number of solutions in the population. This search space encompasses a food source ( $F$ ) that represents

the desired target or optimal solution for the salps. The leader of the swarm updates its position using Eq. 3.

$$x_j^1 = \begin{cases} F_j + r_1 * ((ub_j - lb_j) * r_2 + lb_j) & r_3 \geq 0.5 \\ F_j - r_1 * ((ub_j - lb_j) * r_2 + lb_j) & r_3 < 0.5 \end{cases} \quad (3)$$

In the provided equations,  $x_j^1$  represents the position of the swarm leader in the  $j^{th}$  dimension,  $F_j$  represents the position of the food source in the same dimension. The variables  $r_1$ ,  $r_2$ , and  $r_3$  correspond to three random numbers, while  $lb_j$  and  $ub_j$  represent the lower and upper boundaries of the search space in the  $j^{th}$  dimension, respectively.

The movement of the swarm leader is determined by the position of the food source  $F$  in the search space, as indicated in Eq. 3. The value of  $r_1$  is used to achieve a balance between exploration and exploitation during the search process, and its formulation is given in Eq. 4.

$$r_1 = 2 * e^{-\left(\frac{4+l}{L}\right)^2} \quad (4)$$

where  $L$  represents the maximum number of iterations and  $l$  represents the current one.

The values of  $r_2$  and  $r_3$  are randomly generated within the range of 0 to 1. These values play a significant role in determining the magnitude of the movement step taken by the salps and influencing the direction of the search, whether it is positive or negative. Consequently, the position of the salps can be updated using the following expression:

$$x_j^{i+1} = \frac{1}{2} (x_j^i + x_j^{i-1}), \quad i \geq 2 \quad (5)$$

where  $x_j^i$  is the position of the  $i^{th}$  follower.

The SSA’s optimization process starts with the population’s random creation of solutions. The followers then start to update their locations, led by the leader’s location, in an effort to find better locations with greater fitness values. Up until the termination condition is satisfied, which signifies the conclusion of the optimization process, these phases are repeated repeatedly.

### III. DEVELOPED TECHNIQUE

The method that has been developed combines an MLP network with SSA and is called “SSA-MLP.” This integration’s main goal is to use SSA to identify the MLP network’s optimal weights and biases, thereby improving the accuracy of MLP predictions. The Genetic Algorithm (GA) is used to upgrade the SSA algorithm to achieve this modification. The goal of this upgrade is to fine-tune SSA’s settings to increase its capacity for optimization. The GA algorithm is used in each iteration of the SSA algorithm to search for the most appropriate values for the SSA parameters, ensuring their optimal setting, which leads to the creation of a new technology called “SSA-GA”. By applying GA iteratively, it fine-tunes the parameters of SSA, leading to enhanced optimization performance. The working steps of the proposed SSA-GA algorithm may be summed up as follows:

Fig. 3. Salp and Salp Swarm

- **MLP Initialization:** The Multilayer Perceptron (MLP) network's initial state is determined during initialization, and this procedure also provides the groundwork for further training and optimization. The weights and biases of the network are chosen at random during MLP startup. The biases serve as adjustable factors that regulate the activation thresholds of individual neurons, while the weights demonstrate the strength of connections between the neurons in the MLP's various layers. The MLP starts with a diverse collection of values thanks to the random initialization of these parameters, allowing for the exploration of many solutions during the training process. In MLP networks, random initialization is desirable because it lessens biases toward particular patterns or structures that may be present in the training data. The MLP is encouraged to learn a variety of characteristics and patterns by adding randomness, which helps it generalize well to data that has not yet been seen. In addition, initializing the MLP network with random weights and biases stimulates variation among its neurons and allows them to contribute to learning on their own. This variant prevents the network from becoming stale in local optima and enables it to explore diverse regions of the solution space.
- **SSA-Population Initialization:** The approach starts with the SSA-Population Initialization step by running the Multilayer Perceptron (MLP) training phase using the given training data. The number of times this training phase is repeated equals the SSA-population size, or the number of solutions in the population, exactly.

The MLP's updated weights and biases are retrieved and arranged as a vector after each training phase iteration. This vector form includes the precise set of adjusted weights and biases from the training procedure. The SSA-population is then updated with these vectors, which reflect the altered weights and biases. The SSA method treats each vector as an independent solution.

The next step is to evaluate the fitness of each solution inside the population once all the upgraded weights and biases vectors have been introduced to the SSA-population. Based on their individual training-fitness values, which represent how well each solution does in terms of minimizing errors throughout the training phase, an evaluation is made. The training-fitness values provide each solution with a numerical evaluation of its fitness or quality.

The optimal solution within the SSA-population is identified in this assessment by finding the one with the best fitness value. The weights and biases used in this study's best solution are those that produce the most accurate estimates while minimizing the mean squared error (MSE), which acts as the study's objective function. The mean squared difference between the anticipated values and the actual values is quantified by the MSE, an extensively used statistic in machine learning.

The SSA-Population Initialization stage makes it easier to identify the best solution within the population by using the MSE as the objective function. This allows for later optimization and enhancement of the MLP's performance in the estimation assignment.

- **GA-Population Initialization:** The GA-population is generated at random during the population initialization stage. The relevant parameters, indicated as  $p_1$  and  $p_2$ , have discrete values between 1 and 15. The GA-population is formulated as a two-dimensional matrix, where each row represents one GA solution. The number of SSA parameters that need to be tweaked is indicated by the size of each row, which is  $d = 2$ . Two parameters,  $p_1$  and  $p_2$ , make up each GA-solution and contribute to the set of accessible parameters shown in Eq. 6.

$$r_1 = p_1 \cdot e^{-\left(\frac{p_2 l}{L}\right)^2} \quad (6)$$

- **GA-Population Evaluation:** Each GA-solution's fitness value is evaluated in order to ascertain it. This evaluation entails running an SSA algorithm optimization process and introducing each GA solution into the SSA-population. The application of each SSA-solution to the MLP, along with the validation data, aims to determine the optimal SSA-solution. The resulting validation-fitness is then calculated. The SSA algorithm is combined with each GA solution to assess it through run its optimization process. The goal of the optimization is to find the SSA-solution that, when combined with the MLP, produces the best results on the validation data. The validation-fitness is calculated using the MLP and the chosen SSA-solution. Based on the results achieved during the MLP validation phase utilizing the validation data, this validation-fitness measures the caliber or efficacy of the GA solution. By evaluating each GA-solution's performance when it is incorporated into the SSA algorithm and then assessing the validation-fitness attained by the corresponding SSA-solution when combined with the MLP and the validation data, the fitness of each GA-solution is thus determined through this GA-population evaluation step.
- **Parameter Tuning:** The GA-solutions go through mutation and recombination after being encoded into chromosomes. Superior individuals within the population develop as a result of these genetic activities, which alter the encoded parameter values. The favorable parameter values that these superior GA-solutions possess boost their chances of surviving, reproducing, and passing on these enhanced parameter values to their progeny.
- **Selection:** The roulette wheel selection strategy is used in this phase to choose the GA-solution from the population. The fitness function for each solution is calculated using the standard SSA technique in this selection scheme. To do this, the solution is used as an input parameter for the SSA algorithm, and the fitness value that results is taken into account as the objective function value for that specific solution. The roulette wheel selection system ensures that the fittest individuals have a greater chance of being picked for continued breeding and development by favoring individuals with higher fitness ratings.

- **Encoding:** All GA-solutions or individuals are restructured in this stage using a binary format. The solutions are transformed by utilizing binary notation to express them. Each solution is recast in a standardized representation using the binary format, making it easier for genetic processes like crossover and mutation to take place in later iterations of the algorithm. The binary encoding makes it easy to manipulate and modify the GA-solutions, allowing the evolutionary process to explore various genetic material combinations.

- **Crossover:** The crossover operation is performed on the chosen solution in this stage, where two encoded parents are picked at random, the same as in the Selection-Step. Both the single crossover and double crossover approaches were used for this study. The chance of using the crossover operation is determined by the crossover rate, which is defined as  $gamma_r$ , where  $gamma_r$  is a number produced at random between [0, 1].

The amount of crossover applied throughout the population is influenced by the  $gamma_r$  value. A major fraction of the population will experience crossover when  $gamma_r$  is closer to 1, leading to a significant inheritance of genetic material across people. This suggests that during crossover, several genes will be transferred across individuals.

The value of  $gamma_r$  is set at 70% for the provided technique, suggesting a comparatively high crossover rate. This decision guarantees that the population experiences a sizable quantity of genetic recombination, enabling the evolutionary process to explore various genetic combinations.

To prevent similarity or uniformity among the solutions, alterations are made to the chromosomes in the mutation stage. This is accomplished by altering one or more chromosomal genes; the mutation rate ( $mu_r$ ) determines the degree of mutation. In order to ensure regulated exploration of the search space and prevent excessive and disruptive modifications to the solutions, the  $mu_r$  is often given a minimal value.

The  $mu_r$  is set to 0.1 for the proposed approach, which is a quite low mutation rate. In order to promote a certain degree of diversity and exploration among the population, this choice permits modest alterations to the genetic code.

- **Decoding:** The chromosomes' binary representation is converted into a decimal format during the decoding process. The binary-encoded chromosomes are translated into their corresponding decimal values throughout this procedure. The genetic data contained inside the chromosomes is converted during this decoding procedure into a format that is better suited for additional analysis and interpretation during the following phases of the algorithm.

- **Evaluation:** In this stage, each new GA-solution goes through an evaluation using the SSA algorithm. The new values for the SSA parameters  $p_1$  and  $p_2$  are produced from the gene values found in each GA-solution. These gene values serve as the adjusted values for the SSA algorithm's associated parameters.

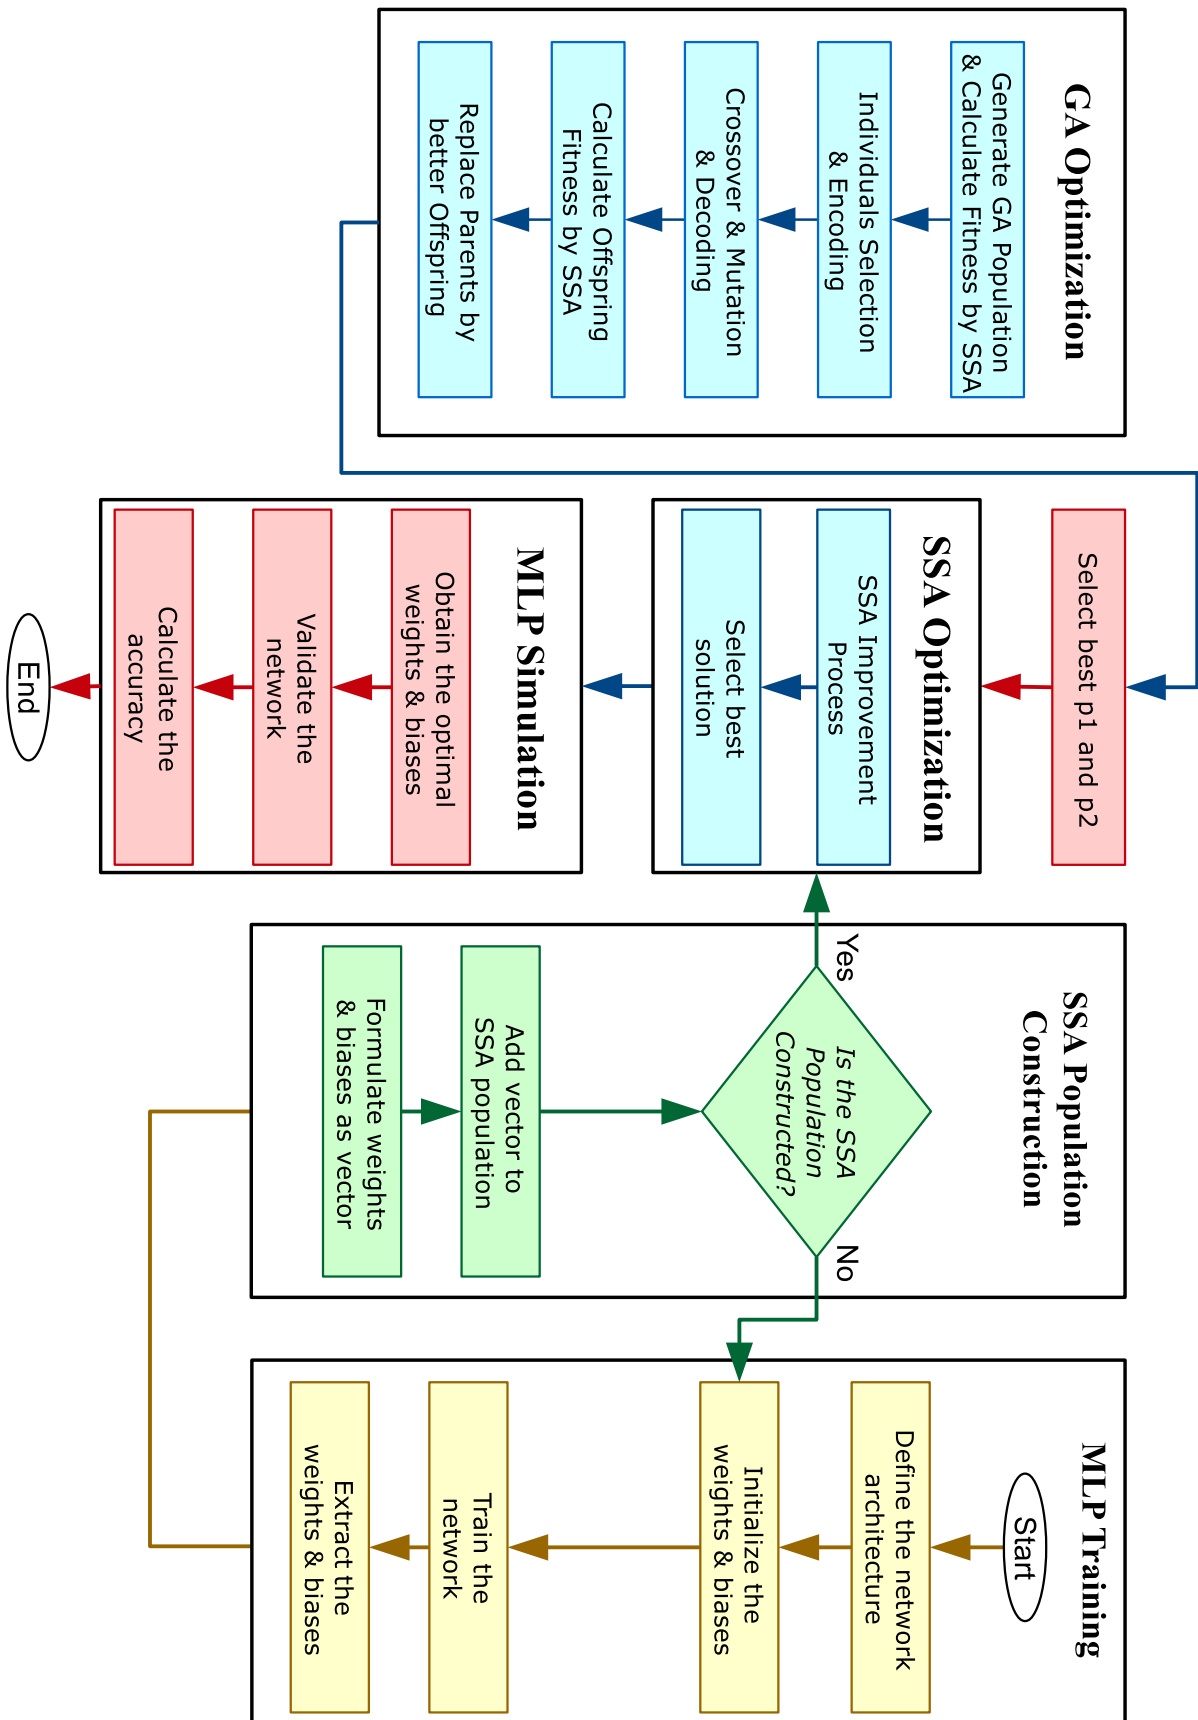

Fig. 4. Developed Technique

The optimal value obtained by using SSA determines the fitness function value for each subsequent GA-solution. The performance or efficacy of any particular solution with regard to the issue at hand is represented by this optimal value. Each solution may be tested for quality or appropriateness within the framework of the optimization process by using SSA to determine its fitness function values.

- **GA Termination Criteria:** To attain the maximum number of generations, repeat the previous procedures (apart from initiation) as many times as necessary. Each generation goes through several procedures like selection, crossover, mutation, and evaluation as the process continues repeatedly. The optimal GA-individual is chosen once the maximum number of generations has been reached. The SSA technique is then used to choose this individual as the candidate for its optimization process. This individual displays the best fitness or performance among all the individuals in the GA-population. The goal of choosing this most optimal GA-solution is to enhance the SSA algorithm's optimization capabilities by enhancing and refining the parameter values linked with it.
- **Select best parameters:** These optimal GA-individuals are chosen when the optimization procedure by the GA is finished and the best individuals have been identified. The SSA algorithm then uses the top candidates that were discovered by the GA optimization as new parameter values. By using these optimal parameters, the SSA algorithm is given the most precise and potent set of parameter values, improving both its performance and its capacity for optimization.
- **Optimization:** Using the optimal parameters discovered in the preceding rounds, the SSA-GA approach is used during optimization. This strategy tries to further optimize the SSA-GA-population and identify the optimal SSA-GA-solution. The MLP's weights and biases are then updated using the best SSA-GA-solution that was chosen. The MLP is provided with better parameters, boosting its prediction accuracy and overall performance by including this new set of perfect weights and biases.
- **Run the MLP simulation phase:** Using recently improved weights and biases, the MLP is run during the simulation phase. The validation data set is used to run this simulation. MLP uses updated weights and biases to produce predictions and estimates based on input data during simulation.
- **Accuracy calculation:** After the simulation, the MLP's estimation accuracy is calculated. Based on the supplied validation data, this accuracy measurement assesses the degree of accuracy and correctness of the MLP's forecasts and estimates. They may be quantitatively assessed by assessing the precision, the efficiency of the optimization procedure, and the influence of the new and optimized weights and biases on the MLP's estimate performance.

The SSA algorithm's parameters are dynamically adjusted

by the GA algorithm by following these formal procedures. As a result, the SSA-GA technique's optimization capabilities are enhanced, increasing the accuracy of MLP predictions. By combining the modeling prowess of MLP and the optimization skills of SSA, this integrated strategy provides an efficient remedy for resolving the SEE problem.

Fig. 4, which shows a flow chart outlining the methodology's several phases, graphically illustrates the suggested and developed process. The proposed methodology is illustrated graphically in the flow chart, which shows the sequence and connections between the numerous parts and steps that make up the method.

#### IV. EXPERIMENT AND RESULTS

This part focuses on the thorough design and construction of an experiment that aims to solve the effort estimation problem, a crucial component of software development. The experiment makes use of MLP embedding together with SSA and GA, two potent metaheuristic techniques. The main goal of this experiment is to build a solid model that can calculate the effort needed for software development projects with accuracy.

The experiment's outcomes will be crucial in determining whether or not the created model is effective. We'll conduct a detailed analysis and comparison of the accuracy and performance of the proposed model with those of currently used effort estimation methods. The outcomes will also give important insights into the model's potential and capabilities for actual software development scenarios.

##### A. Datasets Used

The datasets used in this study are from credible sites like PROMISE and GitHub and are highly recognized benchmark datasets frequently used in research. These datasets illustrate a wide variety of features, traits, and scales, demonstrating their effectiveness. Each dataset is described in full in Table I, including the number of features, dimensions, effort unit, and source repository. Albrecht, Kitchenham, and Kemerer datasets each have seven, seven, and six features, making them the datasets with the lowest feature sizes. On the other hand, Maxwell and COCOMONASA-II have the most characteristics, with twenty-seven and twenty-one, respectively. While the China and Desharnais datasets are gathered from the GitHub and PROMISE repositories and measured in "person-hours," the Maxwell dataset uses "function points" as the measurement unit, in contrast to the other datasets, which all use "man-months" as the measurement unit. The additional datasets, like Albrecht and USPO5, are measured in "man-months" and were downloaded from the PROMISE and GitHub sources, respectively.

##### B. Parameter Setting

A number of careful tests were done to make sure the SSA algorithm worked as intended. Finding the ideal set of parameters—specifically, the population size and maximum iterations—was the main goal. A fair value was found for each parameter: a population size of 30 and a maximum iteration limit of 300, after careful deliberation and thorough investigation. Based on the outcomes of the experiments and how they affected the performance of the algorithm, these

TABLE I. DATASETS

Dataset	Features	Dimension	Unit	Source
Miyazaki-94	048	08	man-months	PROMISE
Kitchenham	145	07	man-months	PROMISE
Desharnais	081	12	man-hours	GitHub
COCOMONASA-I	060	17	man-months	PROMISE
Cosmic	042	11	man-months	PROMISE
Albrecht	024	08	man-months	PROMISE
USP05	203	08	man-months	GitHub
Maxwell	062	27	function points	PROMISE
Kemerer	015	07	man-months	PROMISE
COCOMONASA-II	093	24	man-months	PROMISE
COCOMO-81	063	17	man-months	PROMISE
China	499	16	man-hours	PROMISE

values were determined to be the best ones. Which supports what was used in the original research [6] that developed the SSA algorithm. This study's experiments were all carried out in the environment that was specifically mentioned before.

For the MLP network, this research uses a network with three layers: an input, an output, and a single hidden layer. It is the basic structure of any simple artificial neural network [17], [18]. The trial-and-error method [19], [20] was employed to select the best number of neurons in the hidden layer. Where the number with the best fitness value was considered. Therefore, each dataset has a specific number of neurons in the hidden layer. For instance, the following setting for the number of neurons in the hidden layer for each dataset was found: Miyazaki-94: 12 neurons; Kitchenham: 5 neurons; Desharnais: 15 neurons; COCOMONASA-I: 5 neurons; Cosmic: 10 neurons; Albrecht: 15 neurons; USP05: 12 neurons; Maxwell: 5 neurons; Kemerer: 15 neurons; COCOMONASA-II: 10 neurons; COCOMO-81: 12 neurons; China: 12 neurons. Finally, the activation functions used are as presented in Section II-B, and the learning rate value is 0.05.

Additionally, each experiment was performed 21 times in a row to guarantee accurate findings. As a result of this repetition, a sizable quantity of data was gathered, allowing for the computation of the average performance based on the best results attained over the several runs. In order to conduct the studies, MATLAB 2016a was used. The computing operations were carried out using a device that had 16 GB of RAM and an Intel Core i7 CPU running at a speed of 2.0 GHz. Utilizing this hardware setup gave us plenty of processing power and memory space to support the experimental methods successfully.

### C. Performance Measures

Using six important statistical variables, a thorough assessment of the performance of the developed methodologies was carried out in this study. These metrics were intentionally chosen to offer a comprehensive evaluation of the techniques and cover many facets of error analysis. It's vital to remember that no one measurement can accurately represent all of the performance traits of the developed techniques. As a result, the use of these six metrics enables a flexible and thorough assessment of many elements of the approaches' effectiveness. Researchers can gain a more detailed picture of the benefits and drawbacks of the proposed methodologies by taking into account a variety of measures. The following are the six statistical tests used in this study:

Mean Square Error (MSE): The average of the squared discrepancies between the projected values and the actual values is calculated by the commonly used metric known as MSE. In addition to being very responsive to outliers, it quantifies the overall size of the errors.

$$MSE = \frac{1}{n} \sum_{i=1}^n (A_i - P_i)^2 \quad (7)$$

Root Mean Square Error (RMSE): RMSE is derived from MSE and, by calculating the square root of the MSE value, offers a more understandable measurement. It serves as a representation of the errors' standard deviation and may be used to compare models across various datasets.

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (A_i - P_i)^2} \quad (8)$$

Relative Absolute Error (RAE): RAE quantifies the ratio of an absolute prediction error to an absolute error of a straightforward baseline model. By dividing the error by the total absolute errors in the base model, it normalizes the error.

$$RAE = \frac{\sum_{i=1}^n |A_i - P_i|}{\sum_{i=1}^n |A_i - \hat{A}_i|} \quad (9)$$

Root Relative Squared Error (RRSE): A RAE variant known as RRSE takes the square root of the relative squared error into account. Similar to RAE but including the squared components, it offers a relative estimate of the errors compared to a baseline model.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (A_i - P_i)^2}{\sum_{i=1}^n (A_i - \hat{A}_i)^2}} \quad (10)$$

Mean Absolute Error (MAE): The average of the absolute discrepancies between the expected and actual values is determined by MAE. Regardless of their orientation, it offers a clear indication of the average error magnitude.

$$MAE = \frac{1}{n} \sum_{i=1}^n |A_i - P_i| \quad (11)$$

Mean Magnitude Relative Error (MMRE): The average relative error between the anticipated and actual values is assessed using MMRE. It is the result of dividing the actual values by the average of the absolute differences between the expected and actual values.

$$MMRE = \frac{1}{n} \sum_{i=1}^n \frac{|A_i - P_i|}{A_i} \quad (12)$$

where  $A_i$  is the actual values,  $P_i$  is the predicted values, and  $\hat{A}_i$  is the average of actual values.

These mathematical formulas make it possible to calculate the corresponding statistical measures, providing quantitative numbers for assessing how well the research's methodologies performed.

#### D. The Optimal SSA Parameter Values Found

The authors meticulously looked into many issue scenarios during the considerable testing done for this work in order to determine the best parameter values for the SSA method in each situation. The outcomes of this thorough investigation are shown in Table II, which highlights the precise SSA parameter values that are most successful in resolving the issues under consideration.

The proper values for the SSA parameters, namely  $p_1$  and  $p_2$ , for each problem examined in this research project are clearly outlined in Table II. The fact that each problem requires a different set of parameter values in order to function at its best reveals the individuality of each one.

It is essential to understand that the values shown in Table II are neither constant nor unchangeable. Instead, they are prone to variation since the algorithms used are, by their very nature, probabilistic. There is a chance that the calculated parameter values might vary if the experiments were repeated. This difference might be traced to the algorithms' random features, which provide an element of ambiguity and variety to the optimization procedure.

As a result, the researchers stress how crucial it is to take the algorithms' stochastic character into account when interpreting the findings. The parameter values indicated in Table II are the best options based on the experimentation that was performed; however, they should be viewed as recommendations rather than strict guidelines. Recognizing the potential variations in these variables enables a thorough comprehension of the behavior of the algorithm and promotes a strong optimization procedure.

#### E. Comparison of SSA-GA vs. SSA-MLP and Standard MLP

There were 21 iterations of the experiment. The best findings were therefore averaged, and this was taken into consideration. Table III is a list of the outcomes. The findings of the study for several datasets utilizing MLP (Multi-Layer Perceptron) and two variants of SSA (Salp Swarm Algorithm):

SSA-MLP and SSA-GA, are presented in the supplied data table. For each combination, the average MSE, standard deviation of MSE, worst MSE, and best MSE, as well as MMRE, RMSE, RRSE, MAE, and RAE, were calculated statistically.

The study presented here highlights the results of the recommended approaches and sheds light on two key findings of enormous relevance. First off, it is clear that the efficient optimization of weights and biases made possible by the seamless integration of the Salp Swarm Algorithm (SSA) with the Multi-Layer Perceptron (MLP) network has a significant impact on the predictive capacities of the MLP network. The performance and precision of the MLP predictions are significantly improved as a result of this integration.

The MLP network's training process is improved and made more efficient by using the SSA technique. The SSA algorithm presents a novel method of searching the solution space that is motivated by the organic movement patterns of salp swarms. This technique uses a series of dynamic equations to direct the salps in the direction of the best outcome. The network's predictive capacity is greatly increased as a result of the interaction between the MLP and the SSA algorithm, producing better outcomes and more accurate predictions.

The recommended improvements to the SSA algorithm, which were performed by fine-tuning its parameters with the help of the Genetic Algorithm (GA) have also been shown to significantly improve its optimization performance. The best set of parameters for the SSA may be found using the GA algorithm, which takes its cues from the mechanisms of natural selection and genetics.

The SSA algorithm's efficacy and efficiency in improving the weights and biases are significantly increased by exposing it to the GA's optimization capabilities. Superior optimization results are obtained as a result of the SSA method being able to adapt more precisely to the unique traits and needs of the current issue thanks to this parameter tweaking procedure. The amalgamation the GA algorithm with the SSA algorithm enables the latter to more thoroughly explore the solution space and to converge to optimal solutions in a more effective and efficient way.

In summary, the results obtained using the developed approaches highlight two important facts. First off, by enabling the efficient optimization of weights and biases, the SSA algorithm's integration with the MLP network has a significant positive impact on the performance of MLP predictions. Second, by applying the GA algorithm, the SSA algorithm has been greatly improved in terms of its optimization efficiency, which eventually results in higher-quality results and more precise forecasts. These discoveries open up new opportunities for additional study and application in a variety of fields, enhancing the area of predictive modeling and optimization approaches.

#### F. Comparing the SSA-MLP with State-of-the-Art Methods

A detailed and thorough comparison is made in this phase of the study, contrasting the performance of the recommended approach with leading-edge techniques that have been described in the body of existing literature. The comparison's objective is to show the created technique's effectiveness

and superiority in addressing the Software Effort Estimation (SEE) problem. The comparison study takes into account two different scenarios and thoroughly compares the created strategy to comparable techniques that have been specifically designed to tackle the SEE problem. The state-of-the-art in the field is represented by these chosen approaches, which also act as benchmark models for evaluating the improvements and contributions of the recommended approach.

The first comparison compares the developed technique to the strategy put forward by Kassaymeh et al. (2021), [21], while the second comparison compares the developed methodology to the strategies put forth by Khan et al. (2021), [22]. The benchmark datasets used in each of these comparative assessments are the same ones used in this study, and they use the same two evaluation metrics to assess performance: mean squared error (MSE) and mean magnitude of relative error (MMRE). Tables IV and V include the specific findings of these comparisons, respectively.

The SSA-GA technique clearly outperforms the SSA-BPNN method in terms of Mean Squared Error (MSE) performance metrics across all datasets in the first comparison, as shown by the results of the comparisons that were conducted. This shows that, when compared to the SSA-BPNN approach, the SSA-GA algorithm offers greater accuracy and precision in calculating software effort. This is due to the ability of the developed model that elicits the benefit of GA algorithm in adjusting its parameter according to problem in the hand.

Furthermore, in the second comparison, it is shown that the

- best results in bold

SSA-GA technique outperforms a number of other cutting-edge algorithms. The SSA-GA algorithm stands out as the best performer in terms of predictive abilities when compared to the Straw Berry (SB), Ant Colony Optimization (ACO), Cuckoo Optimization (CO), Genetic Algorithm (GA), Grey Wolf Optimizer (GWO), Particle Swarm Optimization (PSO), and Bat Algorithm (BA) algorithms.

In particular, the SSA-GA method exhibits outstanding results on the COCOMO-81 and Maxwell datasets while taking into account the assessment metrics of mean magnitude of

relative error (MMRE). The SSA-GA method outperformed the other state-of-the-art algorithms analyzed in the study in terms of performance on these datasets, demonstrating the algorithm's greater capacity to estimate software effort precisely and with less relative error.

These superiority results are due to the fact that the SSA algorithm in the SSA-BPNN methods did not obtain parameter tuning, as is the case in the method developed in this paper (SSA-GA). This gives conclusive evidence of the desired benefit of introducing another algorithm (GA here) to adjust the parameters of the main algorithm (SSA) so that the developed algorithm becomes more flexible and effective in handling various prediction problems. In addition, the superior results of the developed algorithm play a pivotal role in proving the need to replace traditional training methods for artificial neural networks with metaheuristic algorithms to enhance prediction accuracy and raise the quality of the results.

- best results in bold

Finally, these results highlight the SSA-GA algorithm's efficiency and competitiveness in the software effort estimation field. The algorithm's use of the Salp Swarm Algorithm and Genetic Algorithm allows it to effectively train the MLP network, improving accuracy and precision in software effort estimation. The SSA-GA method performs better than other advanced techniques, which makes it a promising and reliable alternative for resolving problems related to software work estimates.

## V. DISCUSSION

The SSA-GA framework has the unique capacity to adjust its parameters dependent on the specific problem it is addressing by applying the GA algorithm. This flexibility is critical in improving the overall performance of the algorithm.

The GA method carefully chooses parameter values that are most appropriate for the SSA algorithm. The SSA-GA model assures that the SSA optimizer has optimal parameter values via such a selection procedure. As a consequence, the SSA optimizer becomes extremely trustworthy at avoiding the dangers of local optima, which can stymie exploration of the whole search space. Furthermore, by including the GA method, the SSA-GA model gets the ability to find and explore the most promising parts of the search space.

The ability to avoid local traps and explore the area of search effectively is critical for striking a balance between exploration and exploitation. Exploration entails investigating

different parts of the search space to find possibly optimal solutions, whereas exploitation involves refining and improving the identified solutions. Using the SSA-GA model increases the likelihood of achieving this delicate balance.

On the other hand, the combination of the MLP with the tuned-SSA technique has several advantages, such as enhanced prediction accuracy and higher reusability. The MLP network that results from using the tuned-SSA technique to improve the MLP weights is more reconfigurable. This indicates that the improved MLP may be used with different SEE prediction tasks without requiring substantial adjustments or retraining, saving time and effort.

Additionally, the tuned-SSA technique's improvement of MLP weights results in a decrease in prediction error. The optimized process is successfully guided by the tuned-SSA technique, which enables the MLP to converge towards more precise predictions. This decrease in prediction error results in an improvement in prediction quality, which raises the MLP's dependability and utility.

The addition of the tuned-SSA algorithm also aids in adjusting the MLP network's rate of convergence. The process through which the MLP modifies its weights to reduce estimation error is known as convergence. The MLP weights are optimized using the tuned-SSA method in a way that promotes reasonable convergence. In situations or applications that need critical decisions, this improvement in convergence speed is essential.

A tuned SSA technique further minimizes the MLP's reliance on initial parameter values. Whereas the behavior and performance of MLP convergence can be greatly affected by the values of the initial weights. The MLP becomes less dependent on starting weight values when the Tuned SSA technique is used, which improves the MLP's stability and robustness.

In conclusion, By choosing the best parameter values, the combination of the SSA and GA algorithms improves the performance of the SSA method. With this combination, the algorithm is better able to explore interesting regions of the search space and break out of local optima. An enhanced balance between exploration and exploitation produces more trustworthy optimization results. In addition, using the tuned-SSA method to optimize the weights and biases of MLPs has a number of benefits. When used for various prediction tasks, the improved MLP network becomes more adaptable and requires less alterations. Additionally, it lowers prediction error, raising the accuracy of predictions. A more reliable and stable model is produced thanks to the MLP's faster convergence and decreased reliance on starting weight values.

## VI. CONCLUSION AND FUTURE WORKS

This research explores the integration of the salp swarm algorithm (SSA) and the multilayer perceptron neural network (MLP) in order to tackle the software development effort estimation (SEE) problem. By adjusting the weights and biases of the MLP, the goal is to increase prediction accuracy. Furthermore, a suggested improvement is included by modifying the SSA's parameters using a genetic algorithm (GA). Twelve different SEE datasets with different feature sets are used to comprehensively assess the efficiency of the suggested method.

To evaluate the results of the developed SSA-GA methodology, there are two phases in the assessment process. The outcomes are first contrasted with those attained by traditional MLP and traditional MLP in combination with the original SSA. This comparison research enables a thorough comprehension of the effect of SSA on MLP prediction accuracy. Additionally, the impacts of parameter adjustments on the SSA's optimization performance and the MLP's prediction performance are examined.

In the second evaluation, the results of the developed SSA-GA methodology are contrasted with cutting-edge methods that have been used on datasets related to the SEE problem. The purpose of this comparison is to demonstrate how much better the recommended strategy is than the alternatives. This assessment offers a fair and direct comparison between the proposed methodology and other cutting-edge technologies by using identical datasets.

The main goal of these assessments is to show how SSA affects the precision of MLP predictions as well as how parameter adjustment affects SSA's and MLP's optimization and prediction performance, respectively. The findings of the two assessments consistently show that the proposed methodology is better than the competing techniques. This demonstrates how the SEE problem may be solved by combining SSA and MLP and optimizing the parameters with the GA algorithm, which increases prediction accuracy.

Possible future directions for this work might include expansion to additional software engineering domains and/or exploration of integration with other metaheuristic methods. The suggested approach may be integrated with other metaheuristic optimization methods such as particle swarm optimization (PSO), ant colony optimization (ACO), or differential evolution (DE) in the first potential direction. Investigating hybrid strategies that take advantage of several methods may result in even greater optimization performance and improved software effort estimation accuracy. While In the second scenario, the suggested approach may be investigated further and used in software engineering domains other than effort estimation.

**Abstract**—Alzheimer's disease (AD), a chronic neurodegenerative brain disorder, caused by the accumulation of abnormal proteins called amyloid, is one of the prominent causes of mortality worldwide. Since there is a scarcity of experienced neurologists, manual diagnosis of AD is very time-consuming and error-prone. Hence, automatic diagnosis of AD draws significant attention nowadays. Machine learning (ML) algorithms such as deep learning are widely used to support early diagnosis of AD from magnetic resonance imaging (MRI). However, they provide better accuracy in binary classification, which is not the case with multi-class classification. On the other hand, AD consists of a number of early stages, and accurate detection of them is necessary. Hence, this research focuses on how to support the multi-stage classification of AD particularly in its early stage. After the MRI scans have been preprocessed (through median filtering and watershed segmentation), benchmark pre-trained convolutional neural network (CNN) models (AlexNet, VGG16, VGG19, ResNet18, ResNet50) carry out automatic feature extraction. Then, principal component analysis is used to optimize features. Conventional machine learning classifiers (Decision Tree, K-Nearest Neighbors, Support Vector Machine, Linear Programming Boost, and Total Boost) are deployed using the optimized features for staging AD. We have exploited the Alzheimer's disease Neuroimaging Initiative (ADNI) data set consisting of AD, MCIs (MCI), and cognitive normal (CN) classes of images. In our experiment, the SVM classifier performed better with the extracted ResNet50 features, achieving multi-class classification accuracy of 99.78% during training, 99.52% during validation, and 98.71% during testing. Our approach is distinctive because it combines the advantages of deep feature extractors, conventional classifiers, and feature optimization.

**Keywords**—Alzheimer's disease; brain images; machine learning; deep learning; brain disorder; ADNI dataset

## I. INTRODUCTION

The neurological illness known as Alzheimer's disease (AD) affects the central nervous system and gradually worsens memory and cognitive function over time [1], [2]. Eventually causing the affected person to lose the ability to learn new information and to retain previously learned information [3] which severely impedes people's daily lives such as failing to recognize the family members and performing essential daily activities leaving the patients with anxiety, aggressiveness, or childish behavior [4]–[6]. Studies [7]–[11] shown that the neurological deterioration of this

disease includes the accumulation of abnormal beta-amyloid proteins and phosphorylated tau resulting in depreciation of the hippocampus and cerebral cortex while expanding the ventricles that leads affecting brain regions involved in remembering, thinking, planning, and decision-making.

Usually, AD symptoms appear after the age of 60 with rare exceptions that emerge relatively early at the age of 30 to 50 years in individuals with gene mutation [12]. However, the transition from a healthy state to AD takes several years [13] while going through three different stages, namely, normal controlled (NC), mild cognitive impairment (MCI), and AD. Among the three stages of Alzheimer's, MCI is the symptomatic stage, progressing to its most severe form over time. Since it leads a patient to experience a set of symptoms [14] it incurs huge costs for their proper care and treatment [15]. Therefore, early detection of the disease is essential for initiating treatments, minimizing brain cell damage, and enhancing the quality of life of affected individuals and their families

In the conventional diagnostic system, Alzheimer's patients can be diagnosed the late stages of the disease's progression. In the early stages, the symptoms are similar to those of normal aging. Also, in the conventional system, it is difficult to determine the stages of the disease which may prevent the patient from starting treatment earlier. Besides this, the conventional diagnostic system is limited by the availability of expert physicians and medical tools.

There are studies for automating the diagnosis of this disease. Conventional machine learning and deep learning-based approaches are proposed [16] to classify AD and their stages from different modalities of data. These Machine learning techniques specifically, deep learning techniques are gaining success in the early diagnosis of AD from magnetic resonance imaging (MRI) modality having better accuracy in binary classification while suffering in multiclass classification [2], [17]–[22]. Conventional machine learning leverages handcrafted features while deep learning methods automatically extract features in regression and classification tasks. Studies have shown that the use of conventional machine learning and deep learning techniques combines the strengths of each to create a more accurate and reliable diagnostic tool [3].

Deep Learning models combined with MRI data can give

a high degree of diagnostic accuracy of age-related cognitive decline (ARCD) in dementia patients [4], [21]. It has been argued that deep learning approaches produce the sufficient information necessary to correlate AD sample data [13]. Deep learning enables the characterization of AD in MRI images by generating computational models with multiple processing layers. It automatically retrieves its necessary information from input images, without the intervention of the expert who labels the information, as in a standard Machine Learning model [23]. Besides the conventional machine learning models demonstrated state-of-the-art performance in classification and regression tasks if the feature is provided. Considering the classification performance of conventional machine learning models and the automatic feature extraction capacity of deep learning models, specifically CNN, we utilized the strength of both approaches in our study to get better performance in multi-class classification. In this work, we have selected structured MRI (sMRI) data rather than multimodal or other single modal data considering the benefits mentioned in [21]. The data were collected from Alzheimer's Diseases Neuroimaging Initiatives (ADNI) database (adni.loni.usc.edu). Here, a robust and efficient machine learning model has been proposed for analyzing brain MRI images. There are five main phases in this work: (a) MRI Preprocessing (b) Region clustering (c) feature extraction (d) feature optimization and (e) classification of AD into one of its three stages. At first, preprocessing was performed. Preprocessing was necessary to alleviate the problem of low contrast and enhance image quality. The preprocessing tasks include skull removal, intensity normalization so that the mean is zero and variance is one, and image enhancement with histogram equalizations, and mean and median filtering techniques. For region clustering, we have experimented with otsu, edge-based clustering, k-means, region growing, morphology-based clustering, and fuzzy C-means algorithms and found the watershed algorithm suitable. From the clustered images we have selected 64 three-view patches of size 128 by 128 for further analysis.

To alleviate the problem of low contrast and enhance image quality watershed algorithm has been applied to the MRI image. For clustering, a region-based clustering technique that performs better than other state of art techniques has been chosen. The clustered image is further processed to extract features through the use of multiple deep-learning techniques. The principal component analysis was performed to find fine-tuned optimized features. Finally, these features are then input into a machine learning algorithm to classify the disease into its three major AD phases. The main contribution of our work are: 1) Combining the strength of both conventional and deep machine learning techniques for achieving better accuracy in multi-class classification of AD stages. 2) Improved performance with single modality structural MRI (sMRI) analysis without computing the whole brain. 3) Addressing dataset inconsistency and enhancing contrast quality and visibility through the use of contrast amplification techniques. 4) Selection of region clustering technique to find uniform samples for feature extraction that exhibits improved performance compared to conventional techniques.

The paper is organized as follows: Section II introduces the materials and methods including chosen dataset. Section III includes result analysis. Section IV incorporates the related works and discussion. Finally, the conclusion is drawn in

Section V.

## II. MATERIALS AND METHODS

The workflow for the proposed framework of Alzheimer's detection mechanism has been divided into several steps such as data collection, data preprocessing, region clustering, feature extraction, feature optimization, classification, and evaluation presented in Fig. 1.

First, the brain MR images have been collected from ADNI. The collected images are then preprocessed through several preprocessing techniques such as intensity normalization, image resizing, contrast enhancement techniques, etc. After completing the pre-processing step, the region clustering algorithms such as C-means, threshold-based otsu clustering, K-means, morphology-based, edge-based, watershed, region-growing, and k-means cluster-based methods have been applied to find out the distinct region for analysis.

Several deep learning techniques such as VGG16, VGG19, Alexnet, Resnet18, and Resnet50 have been applied to extract features from the three view samples selected from clustered images. Then features are optimized by using principal component analysis. Finally, the extracted images are then fed into five different ML techniques such as ensemble-based LP-Boost and TotalBoost, tree-based decision tree (DT), distance-based k-nearest neighbor (KNN), and Support Vector Machine (SVM) methods for the classification into three different stages of Alzheimer's.

### A. Dataset

In this study, a subset of the ADNI database has been considered for the experiment. The database was established in 2004 as a result of a public-private partnership with the collaboration of Dr. Michael W. Weiner. The objective of the ADNI dataset was to find the MRI, PET, clinical and neuropsychological assessments, and another biological marker behind the development of MCI and AD. The dataset comprises of 2042 brain MR images representing three different stages of AD such as AD, CN, and MCI. The details of the data are provided in the Table I.

TABLE I. DEMOGRAPHIC INFORMATION OF THE ADNI1:COMPLETE 2YR 1.5T DATASET

Class Label	Number of Scan	Male Subject	Female Subject	Age (Avg. +-std.)
CN	567	271	296	75.12+-8.10
MCI	1206	797	409	76.81+-5.51
AD	269	137	132	75.73+-7.17

The data imbalance problems were avoided by duplicating the MRIs. As we have sampled three view patches from segmented regions to ensure the representation of each significant region the repeated MRIs do not bias the model performance. We have considered total of 1546 MRIs for the experiment (CN-470, MCI-477, AD-599).

### B. Data Preprocessing

In our work, at first, we removed the skull from the MRI images. Then we performed intensity normalization so that the mean intensity is zero while keeping the intensity

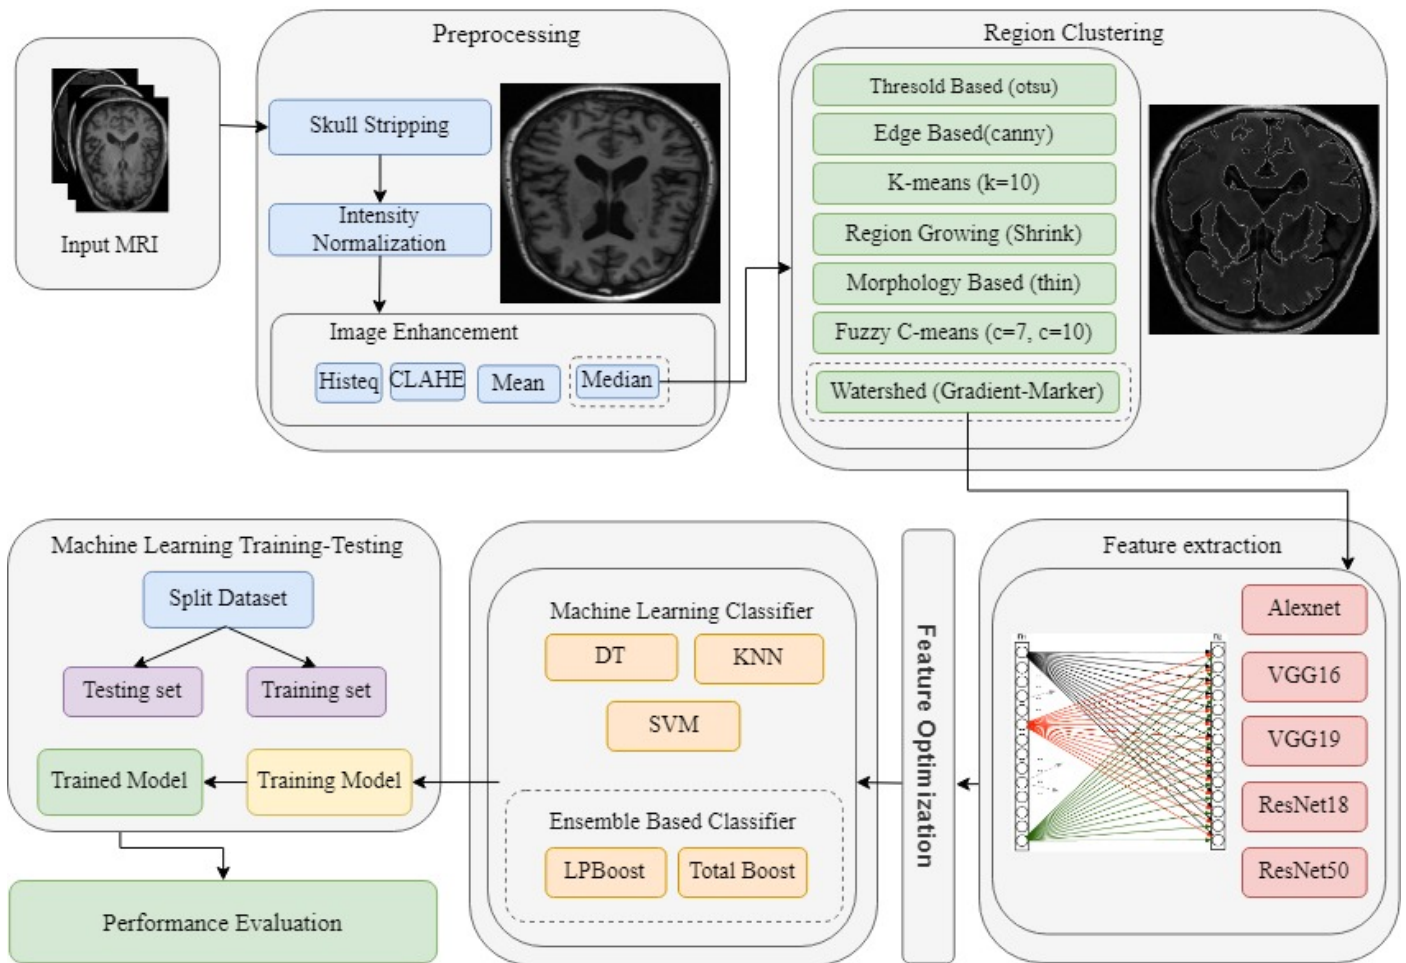

Fig. 1. Conceptual flow of the proposed model.

variance one. We used several pre-processing techniques for contrast enhancement like histogram equalization, contrast limiting adaptive histogram equalization (CLAHE), mean, and median filtering techniques. These techniques are widely used preprocessing methods for medical imaging [24], [25]. The effects of these techniques have been depicted in Fig. 2. Table II represents the comparison of the performance of the preprocessing techniques in terms of mean structural similarity (MSSIM), peak signal-to-noise Ratio (PSNR), and root mean square error (RMSE). It is found that the Median filter outperforms other techniques.

TABLE II. COMPARISON OF VARIOUS PREPROCESSING TECHNIQUES

Preprocessing Technique	MSSIM	PSNR	RMSE
Intensity Transformation	0.9940	12.6433	0.2333
Histogram Equalization	0.9386	3.1293	0.6975
Contrast Limited Adaptive Histogram Equalization (CLAHE)	0.9856	9.1310	0.3495
Mean Filter (3 by 3)	1	32.7397	0.0231
Median Filter (3 by 3)	1	37.5815	0.0132

### C. Region Clustering

In this work, we have applied several region clustering algorithms such as Threshold Based OTSU methods, Edge

Based CANNY filter, region-based region-grow method, Morphological Based THIN filter, K-means Clustering (k=4), Fuzzy Based C-means Clustering (c=4), Watershed with sobel filter considering their wide acceptance in medical imaging [26], [27]. To choose the appropriate method for our system we have calculated the evaluation metrics PSNR, SSIM, and RMSE of these clustering algorithms. In Fig. 3 different output images after using various clustering techniques have been represented. It has been proclaimed here that the Watershed-based clustering technique provides a better image than other techniques. The performance of image enhancement techniques is measured based on evaluation metrics PSNR, MSSIM, and RMSE scores. Table III represents the comparison of different pre-processing techniques. Based on the experimental result it has been found that the watershed algorithm outperforms other algorithms. Here the highest value of MSSIM and PSNR as well as the lowest value of RMSE has been considered to select the method for the system.

### D. Sample three View Patch and Feature Extraction

From the segmented images, we have sampled three view patches as inspired from [2], [21], [22] for further analysis. From each segment of an MRI, we have generated 16 uniformly random three-view patches of size 128 by 128 by 3.

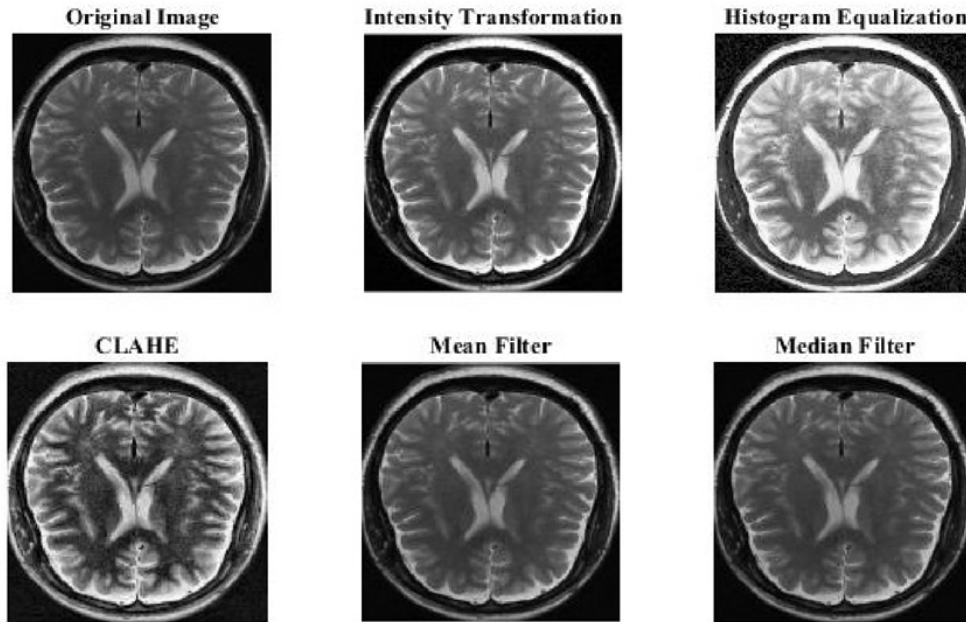

Fig. 2. Effects of various enhancement techniques.

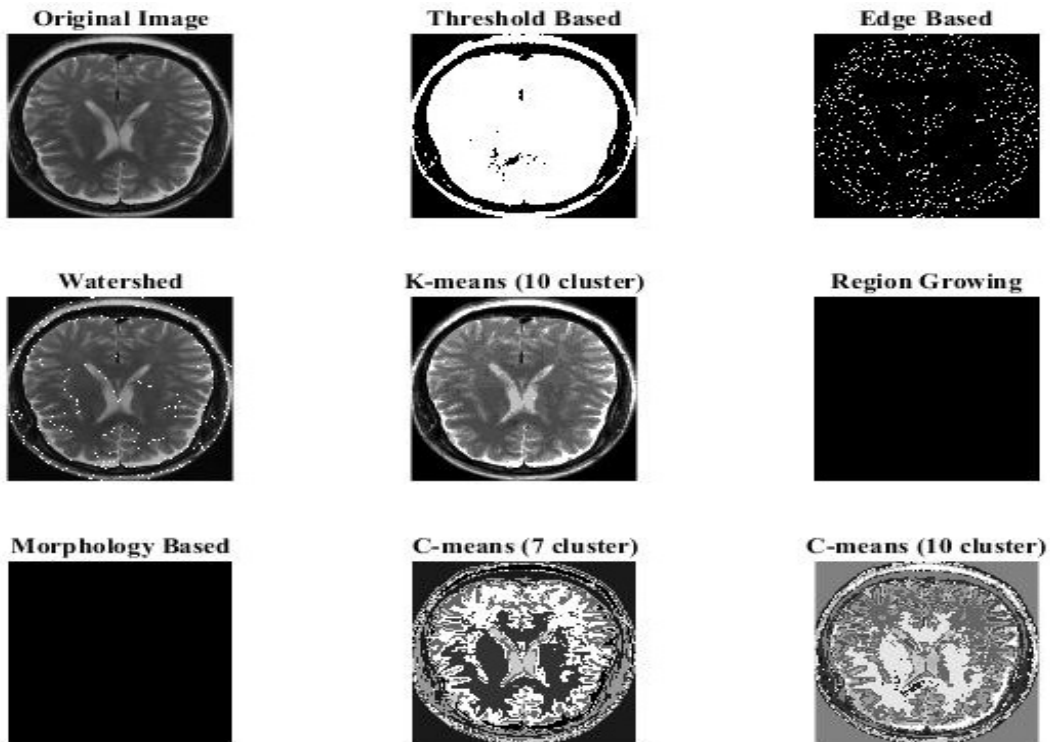

Fig. 3. Images with different clustering techniques.

Then, these are fed to benchmark CNN. In this paper, we have deployed five different benchmark CNN models such as AlexNet, VGG16, VGG19, ResNet18, and ResNet50. We have got the best results using ResNet50. The CNN generated a feature vector of size 262,144. We have applied principal component analysis for selecting optimal 8192 features from 262144 extracted by CNN.

#### E. Classification

In this paper, we have used five different classifiers (considering their classification performance as reputed in [28], [29]) such as DT [30], SVM [31], KNN [32], Linear programming boosting (LPBoost), and TotalBoost [33] after the feature extraction through different techniques.

TABLE III. PERFORMANCE ANALYSIS TABLE FOR IMAGE SEGMENTATION TECHNIQUES

Clustering Technique	MSSIM	PSNR	RMSE
Threshold-based (otsu)	0.9878	9.9152	0.3193
Edge-based (canny)	0.9957	12.1325	0.2474
Watershed (Gradient and Marker)	0.9989	16.3936	0.1515
K-means clustering (4 cluster)	0.9935	12.3958	0.2400
Region growing (shrink)	0.9963	14.5663	0.1869
Morphology based (thin)	0.9959	12.7946	0.2292
Fuzzy C-means clustering (4 clusters)	0.9289	2.5403	0.7464

### III. RESULTS

In this experiment, we have investigated the overall classification accuracy including the individual precision, recall, f1-score, accuracy, and misclassification rate. At first, for each model deep CNN based algorithm such as AlexNet, VGG16, VGG19, ResNet18, ResNet50 were used to extract the enhanced discriminative features. Then ensemble-based TotalBoost, tree-based DT, KNN, and SVM methods were applied for classification. To identify the classification errors of the algorithm, we have calculated the confusion matrix for each method.

#### A. Performance Evaluation

To evaluate the performance of the models we have considered several metrics such as precision, negative predictive value (NPV), sensitivity, efficiency, f1 score, and accuracy. The number of true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) from the confusion matrix are used to define the performance metrics using the following equations from (1) to (6).

$$Accuracy(x, y) = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$PPV(x, y) = \frac{TP}{TP + FP} \quad (2)$$

$$NPV(x, y) = \frac{TN}{TN + FN} \quad (3)$$

$$Recall \text{ or } Sensitivity \text{ or } TPR(x, y) = \frac{TP}{TP + FN} \quad (4)$$

$$Efficiency \text{ or } Specificity \text{ or } TNR(x, y) = \frac{TN}{TN + FP} \quad (5)$$

$$F_1 \text{ Score}(x, y) = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (6)$$

#### B. Deep Feature Extraction using AlexNet

Experiments show that the AlexNet+ML classifier can successfully classify the different phases of AD. The overall classification accuracy for DT classifier achieved 81.5%. SVM, LPBoost, and TotalBoost attained 95.1%, 80.3%, and 81.6% accuracy individually. On the other hand, KNN reached the highest accuracy with 95.8% among the others. This result assures that the classification is performed correctly. Table IV illustrates the performance metrics of ML classifier with AlexNet. The detailed measurements of CN, MCI and AD classes are presented sequentially. Among all the classifier, KNN gained the highest average accuracy with 97.20%. Similarly, it reduced the minimum average error rate with 2.80% compared to the DT, SVM, LPBoost, and TotalBoost.

#### C. Deep Feature Extraction using VGG16

With features extracted by VGG16; DT, KNN, SVM, LPBoost and TotalBoost achieved the overall classification accuracy by 81.2%, 90.9%, 93.5%, 79.0% and 75.4% respectively. On the other hand, SVM reached the highest accuracy with 93.5% among the others. Table V illustrates the performance metrics of the ML classifier with VGG16. The detailed Among all the classifiers, SVM gained the highest average accuracy with 95.69%. Similarly, it reduced the minimum average error rate by 4.31% compared to the DT, KNN, LPBoost, and TotalBoost.

#### D. Deep Feature Extraction using VGG19

It has been found that SVM achieved the highest classification accuracy with 96.1%. DT, KNN, LPBoost, and Total Boost gained 79.9%, 92.6%, 84.8%, and 82.2% classification accuracy respectively. Table VI shows the Illustration of the performance metrics of ML classifier with ResNet50. Among all the classifiers, SVM gained the highest average accuracy with 97.41% minimum average error rate of 2.59%.

#### E. Deep Feature Extraction using ResNet18

The ResNet18+ML classifier model shows the classification of 3 different AD phases. SVM achieved the highest classification accuracy with 91.3%. DT, KNN, LPBoost, and Total Boost gained 75.1%, 90.0%, 79.0%, and 74.4% classification accuracy respectively. An illustration of the performance metrics of the ML classifier with ResNet18 is given in Table VII. Among all the classifiers, SVM gained the highest average accuracy with 94.17% minimum average error rate of 5.83%.

#### F. Deep Feature Extraction using ResNet50

It has been observed that SVM achieved the highest classification accuracy with 98.1%. Other classifiers such as DT, KNN, LPBoost, and Total Boost achieved 81.6%, 91.5%, 85.8%, and 81.6% classification accuracy. From the Table VIII we can observe that SVM gained 98.71% average accuracy. So, the average error rate is 1.29.

In Fig. 4 comparison of different CNN models has been shown. This figure has represented the performance of different CNN models based on accuracy and error rate. Here, ResNet50 with SVM has been provided with a high accuracy rate which is 98.71% and an error rate is 1.29% for the dataset. Based

on this result it can be notified that SVM and KNN perform better than other classifiers. The performance of the ensemble classifier is not that much efficient for AD classification.

#### IV. DISCUSSION

The main objective of this work is to diagnose of AD in the early stages accurately. The comparative study of some of the recent state-of-the-art works in this field with our proposed

Fig. 4. Comparison of the performance of applied techniques consists of CNN feature extractor with ML classifier.

al. [35] exploited OASIS dataset and deployed RESNET18 with SVM classifiers on the whole brain. The method demonstrated a sensitivity of 58.66% and specificity of 80.21% while combining the RESNET 18 features with DenseNet121 features Odusami et al. [36] showed more than 98% in all performance measures. Feng et al. [6] utilized 3DCNN with SVM and showed 92% accuracy with standard deviation of 2. Raju et al. [37] have shown higher performance with the same method and same dataset(97% above in terms of accuracy, precision and recall). Abdulazeem et al. [38] designed a CNN classifier and demonstrated 97.50% accuracy while Hazarika et al. [39] demonstrated 88.66% accuracy with CNN based hybrid model. They have computed the whole brain. In our work, the CNN model ResNet50 along

with SVM classifier has achieved comparable performance with 98.71% accuracy, 97.96% precision, 99.07% NPV, 97.89% recall, 99.04% specificity, and 97.92% f1 score. It is evident from the Table IX that our proposed model outperforms other works such as [6], [34]–[39]. Moreover, in comparison to the whole brain computation of the studies we have computed features from 128 by 128 by 3 slices of MRIs.

## V. CONCLUSIONS

In this paper, we have presented a pipeline for classifying an MRI into one of its three stages(AD, MCI, CN). We have leveraged the benefits of the capacity of deep learning

TABLE IX. COMPARISON WITH STATE-OF-THE ART WORKS

Study	Dataset with stages	Modality	Feature Extraction with Classifier	Performance metrics
Jain et al. [34]	ADNI-150 subjects (AD-50,CN-50, MCI-50)	sMRI	VGG16	Accuracy: 95.73% Precision:96.33% Recall: 96% F1 score: 95.66%
Pueto-Castro et al. [35]	OASIS-416 (AD-2, CN-316, MCI-98); ADNI-1743 (AD-287, CN-525, MCI-921)	MRI	Resnet 18 and SVM	Accuracy: 78.72% Precision: 68.96 % Recall: 58.66% Specificity: 80.21% F1 score: 60.79%
Odusami et al. [36]	ADNI (AD,CN, MCI)	MRI	Resnet18 and DenseNet121 with Randomized weight	Accuracy: 98.21% Precision: 98.14 % Recall: 98.14%
Feng et al. [6]	ADNI-469 subjects (AD-153, MCI-157, CN-159)	MRI	3D-CNN with SVM	Accuracy: 92.11%± 2.31
Raju et al. [37]	ADNI-465 subjects (AD-132, MCI-181, CN-152)	MRI	3D-CNN with SVM	Accuracy: 97.77% Precision: 97.93% Recall: 97.76% F1 score: 97.80
Abdulazeem et al. [38]	ADNI-211,655 (After augmentation)	MRI	CNN	Accuracy: 97.50%
Hazarika et al. [39]	ADNI- 150 subjects (CN:50, MCI: 50, AD: 50)	MRI	Custom CNN based Hybrid Model	Accuracy: 84.66% Precision: 88.33% Recall: 87.66% F1 score: 88.33%
<b>Proposed</b>	<b>ADNI-1546 (CN-470, MCI-477, AD-599)</b>	<b>MRI</b>	<b>Resnet50 +SVM</b>	<b>Accuracy: 98.71%</b> <b>Precision: 97.96 %</b> <b>NPV: 99.07%</b> <b>Sensitivity/Recall: 97.89%</b> <b>Specificity: 99.04%</b> <b>F1 Score: 97.92%</b>

methods in feature extraction and the classification strength of conventional ML methods. In our method, we have optimized benchmark CNN-extracted features from three view patches by PCA that are generated from segmented regions of MRI enabling us to avoid whole-brain computation. We have demonstrated state-of-the-art performance exploited on the ADNI dataset. Our work showed that the RESNET50-PCA-SVM pipeline suits well for this multi-class classification task.

**Abstract**—Traffic congestion has an adverse impact on the economy and quality of life and thus accurate traffic flow forecasting is critical for reducing congestion and enhancing transportation management. Recently, hybrid deep-learning approaches show promising contributions in prediction by handling various dynamic traffic features. Existing methods, however, frequently neglect the uncertainty associated with traffic estimates, resulting in inefficient decision-making and planning. To overcome these issues, this research presents an attention-based deep hybrid network with Bayesian inference. The suggested approach assesses the uncertainty associated with traffic projections and gives probabilistic estimates by applying Bayesian inference. The attention mechanism improves the ability of the model to detect unexpected situations that disrupt traffic flow. The proposed method is tested using real-world traffic data from Dhaka city, and the findings show that it outperforms than other cutting-edge approaches when used with real-world traffic statistics.

**Keywords**—Traffic flow prediction; uncertainty; deep learning; Bayesian inference; Dhaka city

## I. INTRODUCTION

Traffic congestion has a significant negative impact on the global economy as it decreases productivity, and increases waiting time, fuel consumption, air pollution, etc. According to INRIX, a major transportation analytics provider, estimates that the typical commuter in the top 1000 cities in the world will spend 99 hours stuck in traffic congestion in the year 2020 [1]. As a consequence of this, an estimated economic cost of \$1,036 per commuter was incurred as a result of wasted time as well as fuel [2]. More specifically, Dhaka city, the capital of Bangladesh lost Tk56,000 crore (6.5 billion US Dollar) in 2020 due to traffic congestion [3]. Thus for improving the country's economy and for better people's daily life, it is needed to improve the traffic condition. For example, reducing congestion in only Dhaka city gets to benefit from the massive economic growth of 35 percent of the country's GDP [3]. One promising way to mitigate traffic congestion is to accurately predict traffic flow since it helps users to make better route planning and city planners to effectively manage traffic throughout the city.

Extensive research has been conducted on traffic flow prediction, and several strategies have been developed over the years. Among them, deep hybrid approaches have recently gained attention and popularity because of their capacity to capture the complex dynamic nature of traffic data [4]. Traffic flow has complex dynamics as it depends on both space and time dimensions since it has spatiotemporal features. Recent

approaches make use of the power of deep learning algorithms to identify complex spatiotemporal patterns and dependencies in the traffic flow. Besides these, traffic flow is also affected by the many sudden incidents such as accidents, rain, VIP movement, social event, and many more. The attention mechanism is incorporated with a deep hybrid approach to tackle this dynamic and sudden traffic nature. Although the deep hybrid methods can capture the spatiotemporal traffic pattern, it only generates a point prediction and neglects the inherently uncertain nature of the traffic data [5]. Uncertainty is associated with every outcome of any prediction algorithm and most of the existing prediction methods do not consider uncertainty of their predicted outcome. However, uncertainty is accompanied by predicted outcomes due to the overfitting nature of learning, lack of model knowledge, and also the dynamic nature of the traffic flow [6].

Prediction models can generate overly optimistic or gloomy projections when uncertainty is not appropriately addressed in traffic flow prediction. This can lead to poor decision-making and planning since they are providing deterministic predictions. If a forecast model, for instance, does not take into account the uncertainty associated with unexpected traffic events, then it is possible that it would underestimate or overestimate the levels of congestion.

To solve this issue, this paper proposes a prediction approach where Bayesian inference is incorporated with the attention-based deep hybrid network. The proposed method considers the network-traffic flow rather than a single road and considers the connectivity among the links to make better predictions. This method captures the spatiotemporal features of the traffic flow by using a deep hybrid network and handles the sudden incident using an attention mechanism. To handle uncertainty, we mainly incorporate Bayesian inference with attention-based deep hybrid network for prediction. Bayesian inference reduces uncertainty in predicted outcomes made by deep hybrid networks by providing probability. Probabilistic prediction can provide a better outcome to measure the uncertainty and risks of the predicted outcome since it provides an interval consisting of the lower and upper bound in which the future estimation should lie [7]. Thus we have incorporated Bayesian inference in our prediction model. The main contribution of this paper is three folds:

- Proposed model takes into account linked road information, which enables a more comprehensive and precise forecast of traffic flow. The utilization of

this technique allows for the model to effectively apprehend the spatiotemporal interconnections and interdependencies among distinct road segments.

- To handle uncertainty, Bayesian inference is incorporated in the proposed method to measure the probability of the traffic flow propagating to a certain direction. Then, prediction is made by combining the traffic features and reducing uncertainty.
- The proposed approach is validated on the real-life traffic data of Dhaka city collected from Google Maps. To the best of our understanding, this is the first study that uses deep learning with Bayesian estimation to estimate traffic flow in Dhaka. The outcomes indicate that the proposed methodology outperforms all of the standard techniques in terms of prediction accuracy.

The remaining sections of the paper are structured as follows: Section II provides a comprehensive literature review, discussing existing works in the field. In Section III, we present essential background knowledge that underpins our proposed method. Section IV elaborates on our proposed methodology. The results and interpretations of our studies are presented in Section V. In Section VI, we delve into a related discussion surrounding our proposed method. Finally, Section VII offers a concise conclusion summarizing our findings.

## II. LITERATURE REVIEW

Accurate prediction of traffic patterns plays a vital role in mitigating congestion and improving traffic flow. Many existing research has focused on traffic flow prediction, however, only a few of them have taken the uncertainty associated with these projections into account. Traffic flow is naturally unpredictable and it is critical to take this into account when making predictions. In this section, some research works that concentrate on uncertainty within prediction are addressed here.

Researchers aim to improve the precision and dependability of traffic forecast models by including uncertainty quantification. Ying Wu et al. [8], for example, develop a Bayesian deep learning model for traffic speed prediction with uncertainty quantification. This model uses ChebNet to capture the spatial feature and uses gated linear units (GLU) for temporal prediction. The model is designed to be a universal traffic forecasting framework and perform better in traffic flow and speed forecasting tasks both in prediction accuracy and handling uncertainty. However, this model can not be able to capture all the factors that affect traffic speed, such as weather conditions and sudden incidents.

Another recent work proposed by Genwang Liu et. al. [9] focuses on the problem of incident detection on freeways and addresses the challenge of uncertainty quantification. The proposed method utilizes a variant of convolutional neural networks (CNN) within a Bayesian framework. The weight of the model is updated using mechanisms such as Bayes by backpropagation and local reparameterization techniques. By integrating the aleatoric uncertainty (uncertainty in the data) and epistemic uncertainty (uncertainty in the model), the method models the predictive uncertainty comprehensively.

The results of the experiments indicate that the aleatoric uncertainty of the model remains relatively stable under different noise levels.

Mundher Seger et al. [10] presents a Monte Carlo simulation-based method for quantifying uncertainty in traffic assignments, as well as insights into the unpredictability and bias of expected traffic flows. The authors created an approach that utilizes Monte Carlo simulation to evaluate uncertainty in traffic flows. The values of the origin-destination (OD) matrix were handled as stochastic variables with a specified probability distribution. The methodology calculated values for every link by simulating traffic patterns on the transportation network. This work focuses on four scenarios that can occur when uncertainty exists: Case 1: low prediction uncertainty, Case 2: medium prediction uncertainty, Case 3: large prediction uncertainty with ensemble agreement, and Case 4: severe prediction uncertainty with divergence estimates. They also discovered that traffic flow uncertainty occurs on all transportation network links, but to varying degrees, depending on the scenario's specifications and actual traffic flow.

To deal with the issue of low fitting between projected and real values in existing research methodologies, Lingmin Yang [11] proposes a traffic flow uncertainty prediction approach based on the K-nearest neighbor (KNN) algorithm. To generate the necessary database for the prediction process, the suggested method uses numerous databases, comprising the original database, classification center database, k-nearest neighbor database, and intermediate search database. The method employs multivariate linear regression to assign weights to state variables, taking into account the uncertainties of traffic flow. The K-nearest neighbor algorithm and Kalman filter are then utilized to update the weights iteratively, adapting them to the evolving uncertainties of traffic flow. Through this iterative process, the predicted values of traffic flow uncertainties are obtained. In their paper, they mainly handle the uncertainty by considering linked road information. When predicting a road segment they consider the other connected road traffic condition. Their experimental result shows that the model achieves good accuracy but it still suffers from uncertainty and the sudden incident can not be handled by the method.

For traffic prediction, Jun Fu et al. [12] suggests a Bayesian Spatio-Temporal Graph Convolutional Network (BSTGCN). This method learns the graph structure using both the physical road network topology and the traffic data. Graph convolutional networks (GCN) are utilized for expressing traffic data as well as the physical structure of road networks as graphs. This enables a more accurate depiction of the intricate interactions between traffic flows to be captured. Furthermore, they provide a probabilistic generative model for expressing the graph structure, which improves the generalization capability of GCNs and handles uncertainty.

## III. BACKGROUND

In this paper, we use ConvLSTM to handle spatiotemporal data, attention mechanism to handle sudden incidents and Bayesian Inference to handle uncertainty. In the following section, the background of this models is discussed.

### A. Convolutional Long Short-Term Memory

ConvLSTM (Convolutional Long Short-Term Memory) is a type of recurrent neural network (RNN) that is intended to handle spatiotemporal data. It uses the strengths of both convolutional neural networks (CNNs) and long short-term memory (LSTMs) to make a better model. This makes ConvLSTM very good at jobs that involve sequential data with a spatial structure, like analyzing videos, predicting the weather, and predicting traffic.

In ConvLSTM, the input data is in a matrix format, where the measurements are width, height, and time steps.

$$X_t^s = \begin{bmatrix} V_{t-m}^s \\ \vdots \\ V_{t-1}^s \\ V_t^s \end{bmatrix} = \begin{bmatrix} V_{t-m}^1 & V_{t-m}^2 & \cdots & V_{t-m}^n \\ \vdots & \vdots & \ddots & \vdots \\ V_{t-1}^1 & V_{t-1}^2 & \cdots & V_{t-1}^n \\ V_t^1 & V_t^2 & \cdots & V_t^n \end{bmatrix} \quad (1)$$

where  $X_t^s$  represents the road networks state, including  $m+1$  time periods and  $n$  road segments.  $V_t^s = [V_t^1, V_t^2, \dots, V_t^n]$  denotes traffic intensity of all road segments in the road networks at time  $t$ . The convolutional layer and pooling layer of the first CNN takes the input data and convert multi-dimensional data  $V_t^s$  into one-dimensional data for LSTM. The main idea behind ConvLSTM is to record spatial dependencies by using convolutional operations instead of fully connected layers in the LSTM cell. This lets the model take advantage of the local connectedness and parameter-sharing features of CNNs, which are good for dealing with spatial data. The equations for ConvLSTM can be expressed as follows:

Input Gate:

$$i_t = \sigma(W_{xi} * X_t + W_{hi} * H_{t-1} + W_{ci} \circ C_{t-1} + b_i) \quad (2)$$

Forget Gate:

$$f_t = \sigma(W_{gf} * O_t^s + W_{hf} * H_{t-1}^s + W_{cf} \circ C_{t-1} + b_f) \quad (3)$$

Cell Update:

$$C_t = f_t \circ C_{t-1} + i_t \circ \tanh(W_{gc} * O_t^s + W_{hc} * H_{t-1}^s + W_{cc} * H_{t-1}^s + b_c) \quad (4)$$

Output Gate:

$$O_t = \sigma(W_{go} * O_t^s + W_{ho} * H_{t-1}^s + W_{co} \circ C_t + b_o) \quad (5)$$

In these equations,  $X_t$  represents the input tensor at time step  $t$ ,  $H_{t-1}$  represents the hidden state tensor from the previous time step, and  $C_{t-1}$  represents the cell state tensor from the previous time step. The  $*$  operator denotes the convolution operation,  $\circ$  represents the Hadamard product (element-wise multiplication), and  $\sigma$  denotes the sigmoid activation function. The ConvLSTM cell consists of input gates ( $i_t$ ), forget gates ( $f_t$ ), and output gates ( $o_t$ ) that control the flow of information within the cell. The cell state ( $C_t$ ) is updated based on the input, previous cell state, and the gates. The hidden state ( $H_t$ ) is computed by applying the output gate to the cell state passed through the hyperbolic tangent activation function. By using convolutional operations within the LSTM cell, ConvLSTM can describe complex spatiotemporal patterns in the data. It does this by capturing spatial dependencies across different time steps. This makes ConvLSTM a powerful tool for analyzing and predicting spatiotemporal data.

### B. Attention Mechanism

The attention mechanism is crucial for enhancing the performance and effectiveness of traffic flow prediction systems. It enables the model to focus on important spatial and temporal information, focusing on specific regions or time steps that are more useful for the prediction aim [13]. Incorporating attention processes can help collect complicated trends, dependence, and changes in traffic data, leading to more precise and interpretable forecasts. To gain the benefits of the attention mechanism in traffic flow prediction, a combination of two ConvLSTM layers can be used. ConvLSTM layers are RNN layers that combine convolutional layers with LSTM (Long Short-Term Memory) units. These layers are quite helpful in mimicking spatiotemporal dependencies in traffic data. By combining spatial information from the first ConvLSTM layer with temporal information from the second ConvLSTM layer, the model can successfully capture both local spatial patterns and long-term temporal correlations in traffic data. This combination enables the attention mechanism to prioritize important spatial and temporal regions, resulting in more accurate predictions from the model.

### C. Bayesian Inference

Bayesian inference is an approach to statistics that uses Bayes' theorem to revise our assumptions or probabilities depending on observed data. Bayesian inference represents the uncertainty related to predictions in a probabilistic manner [14]. Bayesian inference, rather than offering a single-point projection, provides a posterior probability range that defines the range of alternative outcomes and associated likelihoods. This distribution represents the prediction's uncertainty, providing decision-makers with a full picture of the probable outcomes. The Bayes theorem can be represented mathematically as:

$$P(H|D) = \frac{P(D|H).P(H)}{P(D)} \quad (6)$$

where,  $P(H|D)$  is the posterior probability of hypothesis  $H$  given the observed data  $D$ .

$P(D|H)$  is the likelihood of observing data given hypothesis  $H$ .

$P(H)$  is the prior probability of hypothesis  $H$  before observing the data.

$P(D)$  is the probability of observing the data  $D$ .

The Bayesian inference posterior distribution provides a quantifiable measure of uncertainty. It can be used to compute statistics such as confidence intervals or reasonable intervals, which specify the range of values that the real value of a parameter or variable is expected to fall. These intervals indicate the prediction's uncertainty and serve as a measure of the confidence or dependability associated with the estimations.

## IV. PROPOSED METHOD

In this section we have presented our proposed prediction approach with Bayesian Inference which incorporated linked road traffic information using graph. We start with a linked road network graph  $G(V, E)$ , where  $V$  is the set of  $N$  roads and  $E$  is the set of edges. We also collect historical information about the road segments.  $X_{1:t} = \{X_1, X_2, X_3, \dots, X_t\}$ , where  $X_t$  is a member of  $\mathbb{R}^{N \times n}$  and  $n$  is the size of the traffic data. Our

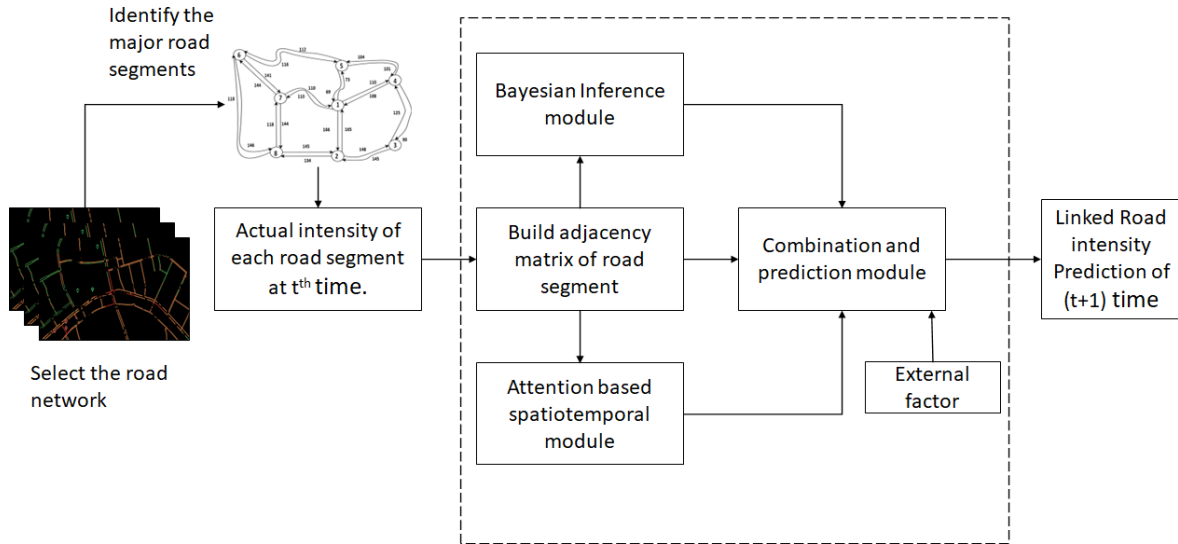

Fig. 1. Overall process of our proposed attention-based deep hybrid network with bayesian inference.

main goal is to predict the traffic flow for the next  $T$  timesteps, from  $X_{t+1}$  to  $X_{t+T}$ , based on collected historical data. For accurate traffic flow prediction, we proposed a technique that incorporates three modules, an attention-based spatiotemporal module, a Bayesian inference module, and a prediction module. An attention-based spatiotemporal module ( $H$ ) can handle the spatiotemporal nature of traffic data and also handle sudden incidents. The Bayesian inference module ( $B$ ) handles the uncertainty of traffic prediction. Lastly, the prediction module ( $P$ ) combines the other modules and produces the next timesteps traffic flow prediction  $X_{t+T}$ . So our objective function is used to minimize the prediction error by reducing uncertainty which can be written as

$$\min(\|Y_i - P(X_{t+1:t+T} : X_{1:t}, G(V, E), H, B, P)\|) \quad (7)$$

Our proposed model's main objective is to produce a more accurate prediction and the difference should be minimized from the actual value. In equation 7  $Y_i$  is the actual value of traffic flow. Fig. 1 represents the proposed attention-based deep hybrid network with Bayesian inference. In the following subsection, we describe the procedures of the modules.

#### A. Attention-based Spatiotemporal Module

The Attention-based spatiotemporal module is a key component of the proposed model, designed to calculate the spatiotemporal weight ( $STW$ ). This module utilizes two ConvLSTM layers to capture the temporal dependencies in the data. The input to the module consists of the data from each road segment, along with external factors such as temperature, holidays, or any other relevant information. These inputs are processed by the ConvLSTM layers, which enable the model to learn and capture the temporal patterns and dependencies in the data. By incorporating the external factors, the module can account for their influence on the spatiotemporal weight calculation. This allows the model to adapt its predictions based on specific contextual information, such as the impact of temperature or holidays on traffic patterns. The internal structure of the module is shown in Fig. 2.

#### B. Bayesian Inference Module

Most existing works only predict traffic flow using spatiotemporal weights without considering the data's uncertainty. Those predictions neglect the diversity and uncertainty of data and network parameters and provide a deterministic forecast. Indeed, traffic conditions can vary between different days and times, such as the difference between a Sunday at 8:00 AM and a Monday or the following Sunday. This variation can lead to differing levels of congestion. However, if a deep learning model overfits the data, it may struggle to capture this uncertainty accurately, resulting in uncertain predictions. To overcome this problem, the proposed framework incorporated Bayesian inference with an attentive spatiotemporal convolutional network to handle uncertainty within the prediction. Bayesian inference determines the probability associated with certain predictions which defines the probability of a particular prediction.

Incorporating Bayesian inference with the transitional probability ( $TP$ ) calculation can help to handle uncertainty and provide a more accurate estimate of the probability of traffic flow propagation. We used the Bayesian theorem to calculate the posterior probability of a particular road segment given the collected traffic data, which is represented as  $P(i|D(t))$ . Then, using the adjacency matrix of the graph, we calculate the prior probability of being on that road segment at the next time step, represented as  $P(i|t+1, D(t))$ . Using the prior and posterior probabilities, the transitional probability of propagating traffic from road segment  $i$  to road segment  $j$  at time  $t$ , represented as  $P(i \rightarrow j|t)$  is calculated.

$$P(i \rightarrow j|t) = P(j|i, t) \cdot P(i|t+1, D(t)) \quad (8)$$

where  $P(j|i, t)$  is the conditional probability of propagating from road segment  $i$  to road segment  $j$  within a given time period, and  $D(t)$  refers to the traffic data collected at a particular time step  $t$ . By combining the Bayesian inference with the transitional probability calculation, we can obtain the Bayesian transitional probability of propagating traffic from road segment  $i$  to road segment  $j$  at time  $t$ , which is

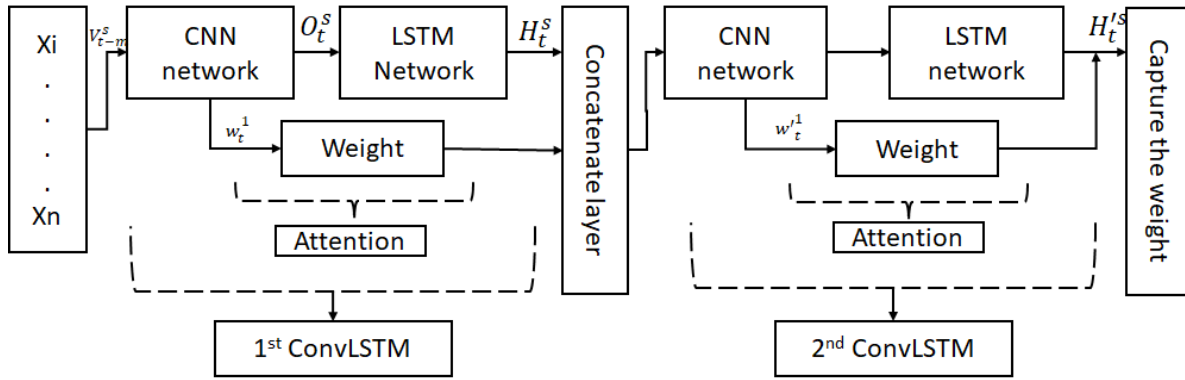

Fig. 2. Internal structure of attention-based spatiotemporal module.

represented as  $P(i \rightarrow j|D(t))$ .

$$P(i \rightarrow j|D(t)) = P(j|i, t) \cdot P(i|D(t)) \quad (9)$$

This probability represents the likelihood of traffic flow transitioning from segment  $i$  to segment  $j$  given the historical traffic data. We calculate the posterior probability of each road segment using the collected traffic data, then calculate the prior probability using the adjacency matrix of the graph. Finally, we use the prior and posterior probabilities to obtain the Bayesian transitional probability of traffic flow transitions between road segments in the network. Bayesian inference with the transitional probability calculation using the last two-time adjacency matrix, we can obtain the Bayesian transitional probability of traffic flow transitions between road segments in the network. This probability takes into account the uncertainty in the data and network parameters, providing a more accurate estimate of the likelihood of traffic flow transitions.

### C. Combination and Prediction Module

After finding the matrices such as the transitional probability matrix represented as  $(TP)$  and the spatiotemporal weight matrix as  $(STW)$ . The process of finding these values is described above. To predict the intensity of the next time step  $(t)$ , we combine spatiotemporal weights  $(STW)$ , transitional probability  $(TP)$ , and actual intensity matrix  $(A)$  of the previous time step  $(t-1)$ . We combine the spatiotemporal and transitional probability of the previous time step  $(t-1)$  using equation 10 and find the combined weight as  $(SPW)$ , which handles spatiotemporal traffic features and uncertainty. Then, the prediction is made by multiplying previous time steps combined weight  $(SPW^{t-1})$  with the actual intensity matrix  $(A^{t-1})$  as shown in equation 11. Where  $(A^t)$  represents the next timesteps prediction outcomes. Algorithm 1 shows the overall process of the proposed prediction architecture where three dynamic characteristics of traffic flow are incorporated.

$$P^{t-1} = STW^{t-1} + TP^{t-1} \quad (10)$$

$$A^t = A^{t-1} \times P^{t-1} \quad (11)$$

## V. SIMULATION AND RESULT ANALYSIS

To evaluate our proposed approach we have compared it with that of the states of the art method and this section provides the details of the simulation setup and result analysis.

### A. Data Description

To evaluate our proposed model we have chosen Dhaka city's traffic data as a case study since it is the fifth most congested city in the world. The real-life traffic data of Dhaka city is collected from Google map images using the tool [15, 16] available at [17].

We have worked on road network topology rather than a single road, thus it is needed to collect traffic data from individual road segments. To achieve this, we first select a zone and identify the major road segments. Then collect the

starting and ending latitude and longitude of each road segment and collect traffic data from every road segment. For our simulation, we have selected the Shahbag region of Dhaka city and selected twelve main road segments, each with two lanes thus a total of twenty-four roads. Fig. 3(a) represents the Shahbag region road network with eight-road intersections and Fig. 3 (b) represents the graph that is built considering the selected road network. We need to collect each road segment data separately and then combine it according to the graph network. For simulation, we collect one-month data. One month of data provides a sufficient amount of data for short-term traffic flow modeling and analysis [18]. Our collected data set comprises a total of 3720 data instances for each road segment. Thus we have a total of  $3720 \times 24 = 89280$  instances for twenty-four road segments. Since we considered a total of eight intersections (nodes), thus the size of the adjacency matrix is  $8 \times 8$ . We split the collected data into two sets: 80% for training and 20% for testing our model. Table I represent the learning parameter of the Attention-based Spatiotemporal Module.

TABLE I. ATTENTION-BASED SPATIOTEMPORAL MODULE LEARNING PARAMETER

Parameter	Value
Learning Rate	0.01
Number of Epochs	1000
Batch Size	32
Loss Function	RMSE
Optimizer	Adam
Regularization Techniques	L2 regularization

### B. Performance Metrics

Three performance indices the mean absolute error (MAE), the mean absolute percentage error (MAPE), and the root mean square error (RMSE) are used to evaluate the effectiveness of the proposed model. This is carried out to assess how accurately the model's predictions were made. The suggested model's efficacy is evaluated using three performance indices: MAE, MAPE, and RMSE. RMSE is frequently used to assess the effectiveness of traffic forecast models [19, 20]. The RMSE gives a general notion of the typical discrepancy between the values of the observed and forecasted data. The model and its predictions are better when the RMSE value is lower. We can calculate the value of RMSE by using equation 12, where  $f_i$  is the predicted value and  $\hat{f}_i$  is the observed value.

$$RMSE = \left[ \frac{1}{n} \sum_{i=1}^n (|f_i - \hat{f}_i|)^2 \right]^{\frac{1}{2}} \quad (12)$$

A statistical indicator of a forecast system's accuracy is the MAPE. It is easy to understand since it measures as a percentage. MAPE calculation is represented in equation 13, where  $f_i$  is the predicted value and  $\hat{f}_i$  is the observed value.

$$MAPE = \frac{1}{n} \sum_{i=1}^n \frac{|f_i - \hat{f}_i|}{f_i} \quad (13)$$

A negative number becomes positive through a mathematical operation known as the absolute. As a result, when calculating the MAE, the difference between an expected value and a

predicted value is always positive. We can use equation 14 for calculating MAE, where  $f_i$  is the predicted value and  $\hat{f}_i$  is the observed value.

$$MAE = \frac{1}{n} \sum_{i=1}^n |f_i - \hat{f}_i| \quad (14)$$

MAE is calculate using equation (14) where  $f_i$  is the actual traffic flow and  $\hat{f}_i$  is the predicted traffic flow. In general, a good prediction model should have lower values of MAE, MAPE, and RMSE, indicating that the predicted values are closer to the actual values. On the other hand, a bad prediction model will have higher values of these metrics, indicating that the model's predictions are further from the actual values. It is essential to consider these metrics when evaluating the effectiveness of a prediction model as they provide insights into the accuracy and reliability of the model's predictions.

### C. Compared Methods

We evaluated our proposed model's performance against the following widely used models for traffic flow prediction. Here we choose five widely used methods from deep learning, and conventional time-series prediction techniques which include ARIMA, SVR, LSTM, GRU, and DNN.

*a) ARIMA (Autoregressive Integrated Moving Average):* is a conventional statistical method that models the temporal dependence in the data using autoregression, differencing, and moving average techniques. Several research has made use of modeling that is based on ARIMA for the purpose of predicting traffic flow [24, 26, 27]. For instance, an ARIMA model was proposed to develop a short-term time series traffic flow forecast model[26].

*b) SVR (Support Vector Regression):* makes use of a hyperplane to capture the relationships that exist between the input variables and the output variables. It is efficient in dealing with nonlinear relationships present in the data and has been applied in a number of studies for the purpose of predicting traffic flow [25]. For instance, SVR was applied to the problem of predicting trip times, and it was found to be applicable and to perform well when applied to the study of traffic data [28]. For the purpose of traffic forecasting, LS-SVMs, also known as Least Squares Support Vector Machines, were used. These machines demonstrated benefits such as rapid convergence, high accuracy, and little computational effort [29]. When used in conjunction with other methodologies, SVR can accurately forecast changes in traffic flow as well as accidents. The capability of SVR to handle high-dimensional data, its resistance to noise, and its adaptability to non-linear relationships in the data are just some of its many advantages. SVR, on the other hand, has a number of drawbacks, including the fact that it is very dependent on the kernel function that is used and that it has difficulties managing huge datasets [30].

*c) LSTM (Long Short-Term Memory):* has been successful at identifying long-term dependencies in sequential data. Due to its capacity for handling input and output of varying lengths, it is frequently employed in time series prediction problems. LSTM is frequently used to estimate traffic flow and has been demonstrated to perform better than other machine learning techniques [23, 31, 32]. An example

Fig. 3. Road network selection from Google map and graph representation of the selected road network.

of a Recurrent Neural Network (RNN) that uses memory cells to preserve significant information over time is the LSTM. Long-term memory storage technology (LSTM) is capable of learning long-term dependencies and non-linear traffic flow data. To increase the accuracy of traffic flow prediction [23], LSTM has also been integrated with other techniques, such as multiple linear regression (MLR) [31].

d) *GRU (Gated Recurrent Unit)*: deep learning model, has been effective at identifying dependencies in sequential data. Its capacity to accommodate variable-length inputs and outputs makes it a popular choice for time series prediction jobs. In contrast to the assertion, GRU is frequently employed in traffic flow prediction and has been proven to be successful in doing so [22]. GRU is a variant of recurrent neural networks that work well for predicting traffic flow and can memorize data from the prior sequence [33]. To increase the accuracy of traffic flow prediction, GRU has also been integrated with other approaches like graph convolution networks [34].

e) *DNN (Deep Neural Network)*: is a class of machine learning models that use multiple layers of artificial neurons to make predictions. DNNs have been widely used in various applications, including regression and classification tasks, due to their capacity to learn complex nonlinear correlations in

data. Keras is a popular Python library for building DNNs and CNNs (Convolutional Neural Networks) [21]. Keras provides a high-level API for building and training DNNs, making it easy to create and experiment with different architectures [35]. Keras also supports various optimization algorithms, activation functions, and loss functions, making it a versatile tool for building and training DNNs.

#### D. Performance Evaluation

The simulation result of our proposed traffic flow prediction models is presented in this section. Table II presents the forecasting performance comparison of the proposed model and other baseline methods for different forecasting horizons ranging from 15 minutes to 120 minutes on our collected data set. The findings demonstrate that over the majority of the forecasting horizons, the proposed model performs better than other models in terms of several evaluation measures. Due to its inability to handle complicated spatiotemporal data, the ARIMA model scores the lowest. Because models based on LSTM have the ability to capture dependence over time and nonlinear interactions in the data, LSTM forecasts are sometimes better. In comparison to previous models, the DNN model performs substantially better when predicting traffic

flow for 75 minutes, but it performs poorly in all other situations.

Further, we try to measure the statistical significance of our result. We perform a one-way ANOVA test to determine the statistical significance of the differences in the RMSE values among the models. F-statistic is 8.055 and the p-value is  $4.496 \times 10^{-6}$ , which is very small. This indicates that there is a significant difference in the RMSE values among the models. The confidence interval for the proposed method, which is the model of interest, is 15.04 to 21.75. This means that with 95% confidence, the true population means of RMSE values for the proposed method is between 15.04 and 21.75. For measurement of uncertainty we calculate the confidence interval, Table III represents the confidence interval range for different models. Comparing the proposed method's confidence interval to the other models' confidence intervals, it can indeed measure the uncertainty associated with a prediction [36]. A wider confidence level suggests greater uncertainty since it contains a wider spectrum of possible values. A narrower confidence interval, on the other hand, indicates less uncertainty because it gives an estimate that is more accurate [37]. We can see that the proposed method's interval does not overlap with some of the other models, such as ARIMA, SVR, LSTM, the proposed method without BI, and the proposed method. This means that the proposed method has significantly different RMSE values compared to these models. Additionally, the proposed method's confidence interval is narrower than some of the other models, such as DNN and GRU, indicating that the proposed method has less uncertainty in its predictions. Results suggest that the proposed method performs better in handling the uncertainty in traffic flow prediction compared to other models. The narrower confidence interval for the proposed method suggests that it provides more accurate predictions with less uncertainty.

TABLE III. CONFIDENCE INTERVAL OF RMSE OF DIFFERENT MODEL

Model	Start	End	Difference
<b>Proposed method</b>	15.0437	21.746	6.702
<b>Proposed method without BI</b>	14.446	30.333	15.887
<b>DNN</b>	16.050	27.607	11.557
<b>SVR</b>	16.874	27.236	10.362
<b>ARIMA</b>	17.339	30.313	12.974
<b>GRU</b>	17.233	26.621	9.388
<b>LSTM</b>	14.690	23.454	8.764

## VI. PERFORMANCE ANALYSIS

Our suggested model takes into account the effect of linked roads on traffic flow forecast. This model captures the influence of neighboring roads on the target road segment by including the road network topology and analyzing the dependencies between road segments. This allows for more precise predictions by accounting for traffic dynamics and flow patterns over the whole road network. It employs Bayesian interference for addressing prediction uncertainty. It can calculate the uncertainty related to its predictions by adding probabilistic modeling. This is especially useful when the prediction outcomes may fall outside of a given range or demonstrate greater variability. This model uses Bayesian inference to assist measure and managing uncertainty, resulting in more trustworthy and robust predictions. It also handles the spatiotemporal patterns and relationships in the traffic flow data

like other deep learning models. By giving more importance to relevant spatial and temporal features, this model can make more precise predictions. This model also used an attention mechanism that allows it to focus on the most informative features and road segments.

## VII. CONCLUSION

We proposed an attention-based deep hybrid network with Bayesian inference for traffic flow forecasting to address the problem of uncertainty. The attention mechanism in our suggested methodology enhanced the model's ability to recognize unexpected scenarios that impede traffic flow. By collecting complicated spatiotemporal trends in traffic data, our deep hybrid network effectively identified patterns and dependencies, improving the accuracy of traffic flow predictions. Most significantly, by applying Bayesian inference, we successfully evaluated and minimized uncertainty in the projected outcomes. In future, the suggested method's transferability and scalability will be evaluated by testing it in various parts of cities or regions with diverse traffic patterns and features. To prove its generalizability, it would be beneficial to assess its performance in other metropolitan areas also.

**Abstract**—Automated License Plate Detection and Recognition (ALPDR) is a well-studied area of computer vision and a crucial activity in a variety of applications, including surveillance, law enforcement, and traffic management. Such a system plays a crucial role in the investigation of vehicle-related offensive activities. When an input image or video frame travels through an ALPDR system for license plate detection, the detected license plate is frequently blurry due to the fast motion of the vehicle or low-resolution input. Images of license plates that are blurred or distorted can reduce the accuracy of ALPDR systems. In this paper, a novel Variational AutoEncoder(VAE) architecture is proposed for deblurring license plates. In addition, a dataset of obscured license plate images and corresponding ground truth images is proposed and used to train the novel VAE model. This dataset comprises 3788 image pairs, in which the train, test, and validation set contains 2841, 568, and 379 pairs of images respectively. Upon completion of the training process, the model undergoes an evaluation procedure utilizing the validation set, where it achieved an SSIM value of 0.934 and a PSNR value of 32.41. In order to assess the efficacy of our proposed VAE model, a comparison with contemporary deblurring techniques is presented in the results section. In terms of both quantitative metrics and the visual quality of the deblurred images, the experimental results indicate that our proposed method outperforms the other state-of-the-art deblurring methods. Therefore, it enhances the precision and dependability of an ALPDR system.

**Keywords**—Image blur; bangla license plate blur; Variational AutoEncoder (VAE); computer vision

## I. INTRODUCTION

With the increase in the number of vehicles on the road, violations of traffic laws such as racing through red lights, leaving the scene of an accident, and kidnapping escalated. As a result, ALPDR systems have been extensively developed and applied to a variety of intelligent traffic systems [1]–[4]. Unfortunately, despite the fact that drive recorders and surveillance cameras perform significantly better than in the past, license plates of vehicles are frequently blurred due to fast-moving vehicles, camera shakes during the exposure period, and other factors. Multiple variables contribute to the blurring and distortion of license plate images. The initial variable is the local environment. For instance, the impacts of intense illumination, precipitation, and weather may increase the likelihood of blurring. The second variable consists of the vehicle's motions. For instance, when vehicles run red lights, they are frequently traveling at a very high rate of speed; consequently, the pictures taken tend to be blurry. The

surveillance system serves as the final variable. Due to the fact that surveillance cameras are frequently positioned at higher elevations, far from the car, the captured image has a reduced resolution, leading to poor image quality. Blurred license plate images can significantly reduce the accuracy of ALPDR systems. Therefore, deblurring of the license plate images is a crucial step towards achieving reliable ALPDR systems.

Starting from deblurring images using methods such as dihedral group [5], image deblurring techniques have significantly advanced [6] in recent years. On the basis of high-frequency residual image learning, the authors of [7] proposed a two-phase deblurring algorithm for restoring blurred images of dynamic scenes. The method proposed in [8] defines a new regularization term that incorporates both intensity and gradient assumptions and provides an efficient and convergent solution for deblurring license plate images. Convolutional Neural Networks (CNNs) have been extensively utilized [9]–[11] alongside Generative Adversarial Networks (GANs) [8], [12] to generate sharp license plate images. However, these approaches demand a large amount of training data, as with a small dataset the model may not converge and can lead to a less generalized model. To our knowledge, there are a handful of works related to Bangla license plate deblurring.

The purpose of this study is to develop and establish a state-of-the-art Bangla license plate deblurring system that can work in real-time. In order to accomplish this we propose a novel VAE architecture with a custom loss function for Bengali license plate image deblurring. The proposed VAE network is a generative model capable of learning the underlying distribution of training data and producing new samples based on the learned distribution. Thus, it can perform well even if it is trained on a small dataset. However, there's a lack of publicly available Bangla license plate dataset for deblurring. Thus, we created a new balanced and generalized dataset consisting of 3788 pairs of images that were used to train, test and validate the model. 75% of the data belong to the train set, whereas 15% and 10% data belong to the test and validation sets, respectively. The proposed VAE model achieved an SSIM score of 0.934 and a PSNR score of 32.41. To assess the efficacy, we recreated state-of-the-art deblurring models [13], [14] and trained them on our dataset. The evaluation demonstrates that our method outperforms state-of-the-art deblurring techniques in terms of both quantitative metrics and image quality. In addition, we demonstrate the

efficacy of our procedure using actual blurred license plate images in this paper.

**The most significant contributions of this study are as follows:**

- Established a novel VAE network for the deblurring of Bangla license plate images.
- Created a new dataset for Bangla license plate deblurring.
- Provided quantitative and visual performance analysis of the proposed model with other available image deblurring models.

The subsequent sections of the paper are structured in the following manner: Section II encompasses the literature review. The following Section III, provides a comprehensive summary of the dataset. Section IV presents a detailed description of the proposed methodology. Section V presents the results and comparisons of this research. The conclusive remarks can be found in Section VI. The residual content comprises references.

## II. LITERATURE REVIEW

The field of deblurring license plate images is a highly intriguing area of research. Despite the limited amount of research on the deblurring of Bangla license plate images, a small number of studies have successfully developed methods that can be applied in real-world scenarios. Nevertheless, this area of research remains largely unexplored. The following segment delineates the progression of scholarly inquiry pertaining to the restoration of clarity in license plate images.

Fang *et al.* [8] introduced a deblurring methodology that integrates gradient priors and intensity through a novel regularization technique. In addition, the authors determined that the binarization threshold of the image is a significant factor in distinguishing between blurred and clear images. CNNs have been employed in the past for the purpose of image denoising [9]–[11], as well as for super-resolution [15], [16]. The study conducted by the author of [9] aimed to address the issue of image blurring in traffic surveillance. To achieve this objective, the author developed a customized CNN model. This model was designed to take a blurry image as input and generate a clear image as output, with the license plate content being easily discernible. While the methods proposed by [8], [9] were deemed partially satisfactory, they were found to be lacking in terms of accuracy measures and evaluations.

Qingbo *et al.* [17] introduced a new approach for estimating blur kernels by integrating linear uniform convolution and the angle of the image. A scheme was proposed utilizing sparse representation to detect the blur kernel resulting from rapid vehicular movement. The authors analyze the coefficients of the sparse representation of the reconstructed image to ascertain the orientation of the kernel. They estimate the length of the motion kernel using the Radon transform in the Fourier domain. However, the dataset that the authors used only had 240 images, which limited its ability to include all aspects of real-world scenarios.

Orest *et al.* [6] proposed an innovative approach for image deblurring that employs a Generative Adversarial Network

(GAN) architecture. The researchers utilized the GoPro and Kohler datasets in order to train their model. Despite the fact that the dataset consists of arbitrary blurred images, the proposed approach demonstrates the ability to deblur, blurry vehicle images. The model proposed by the author attained a Peak signal-to-noise ratio (PSNR) score of 26.10 and a structural similarity index measure (SSIM) score of 0.816. The proposed model's inference time is 0.85 seconds. Subsequently, the author introduced an enhanced approach in [14]. The authors put forth a sophisticated GAN framework, which achieved a PSNR score of 29.55 and an SSIM score of 0.93. They concluded that the novel architecture outperformed their previous model. Furthermore, the inference time of the model under consideration is a mere 0.35 seconds. In any case, the duration required for inference in both of the aforementioned studies can be considered unsuitable for the practical application of ALDPR systems.

The researchers of [18] proposed a GAN architecture to address the task of image deblurring. The authors additionally employed the GoPro and Kohler dataset for the purposes of training and assessing their model. A PSNR score of 29.32 and an SSIM score of 0.93 show that the network the authors propose is significantly effective in the task of deblurring vehicle images. However, it is worth noting that the inference time associated with this network is relatively high, at 0.64s. A sparse regularization model for vehicle image deblurring was proposed by the author of [19], utilizing the statistical distribution characteristics of the image. The author presents a concise analysis of the statistical distributions of vehicle images and concludes that the gradient histogram of the ground truth follows the Hyper-Laplacian distribution. The model exhibited exceptional performance in comparison to contemporary techniques for deblurring vehicle images. The PSNR and SSIM values are 28.2 and 0.99 respectively. However, the impact of the model parameter  $p$  on the deblurring quality is not extensively discussed in the paper. Hence, additional research may be necessary to explore the optimal value of  $p$  for diverse license plate images.

Hiroki *et al.* [12] presented a technique for achieving high-quality image deblurring. The method employs a Discrete Cosine Transform (DCT)-based loss function to maintain texture and mitigate ringing artifacts in the resulting image. The authors' proposed model exhibits reduced computational complexity in comparison to alternative methods that employ multi-scale architecture. The proposed method involves a comparison of the frequency domain of the deblurred image with the ground truth image via DCT. This approach effectively mitigates block noise and ringing artifacts, while simultaneously preserving the deblurring performance. The empirical findings indicate that DeblurDCTGAN exhibits better results compared to conventional techniques. Their proposed model achieved PSNR and SSIM values of 28.84 and 0.93, respectively. Moreover, DeblurDCTGAN exhibits a comparatively quicker runtime of 0.28s per pair in contrast to alternative techniques, rendering it a more efficient alternative for the purpose of image deblurring. The Enhanced Super Resolution Generative Adversarial Network (ESRGAN) was employed by the authors of [20] to enhance the quality of license plate images that were originally of low quality. ESRGAN has undergone training using a dataset comprising license plate images, with the aim of acquiring the ability to perform image deblurring and

upsampling. Subsequently, the generated high-resolution images are employed to achieve precise recognition of license plates. However, The size of the dataset utilized in the training of ESRGAN is comparatively limited, potentially impeding the model's ability to generalize to license plate images beyond those included in the dataset. Additionally, the optical character recognition accuracy for the reconstructed images is lower than that of the ground truth images, indicating that there is still room for improvement for the generator model. Finally, the paper did not provide a detailed description of the results obtained using the ESRGAN.

Despite notable progress made in the domain of image deblurring in recent years, a number of constraints remain prevalent in previous research endeavors, as indicated earlier. A significant constraint lies in the challenge of precisely simulating the blurring mechanism, which can exhibit substantial variability contingent upon factors such as vehicle motion, lens, and scene attributes. Furthermore, the majority of previous studies concerning license plate deblurring or image deblurring have concentrated on restoring clarity to comparatively uncomplicated scenes or images, and may not possess the capability to address more intricate or demanding scenarios. One additional constraint pertains to the computational cost linked with deblurring techniques, which may pose a significant hindrance for real-time implementations. In general, although previous studies on the deblurring of license plates or images have made noteworthy advancements in enhancing the quality of deblurred images, there remain various obstacles that require attention to enhance the robustness, efficiency, and efficacy of these approaches.

### III. DATASET DESCRIPTION

This section discusses the dataset's curation and preprocessing. There is a scarcity of publicly accessible datasets for deblurring purposes, as very little research has been conducted on the deblurring of Bangla license plates. Therefore, a new dataset is proposed for this investigation. Initially, a license plate-related dataset was proposed in [4]. As shown in Fig. 2, their proposed dataset was for license plate detection and recognition. Therefore, we accumulated and expanded this dataset. Afterward, the license plate was extracted from these images, and a dataset containing 3788 image pairs of license plates was created, samples of which are depicted in Fig. 3. Each image of a clear license plate  $I_i$  is passed through a blur function, resulting in a blurred license plate  $B_i$ . The blur function is denoted by the Eq 1.

$$B_i = I_i \otimes F + N + R + S \quad (1)$$

A dataset that is unbalanced and insufficient can cause the VAE network to produce low-quality images, which can hinder its ability to generalize to new data. A balanced dataset is crucial for training VAE since it helps to ensure that the network is trained properly and is capable of generalizing adequately to new data. The distribution of the dataset among the train, test, and validation set is shown in Fig. 1, where the train, test, and validation sets, respectively, include 2841, 568, and 379 pairs of images. The validation set is used to assess the model post-training but is concealed from the model during training.

Fig. 1. Data distribution.

Fig. 2. Sample images from the dataset of [4].

### IV. PROPOSED METHOD

Traditional approaches for deblurring license plate images [8], [12], [20], function well. However, issues with compute power, inference time, loss of details in the generated image, and the likelihood that noise may recur in the resulting image continue to exist. In this paper, a novel approach is proposed to address the issue of license plate image blurring. The proposed method utilizes the capabilities of a Variational AutoEncoder (VAE) to achieve this objective. The proposed approach involves developing a novel VAE network that has the capability to acquire a low-dimensional representation of the underlying image data. This representation can be leveraged to effectively eliminate blur and distortion from license plate images, while simultaneously preserving the texture and details of the input image. The objective of the model is to restore a clear image of a license plate denoted as  $I_i$ , given a blurred image  $B_i$  as the input. It is noteworthy that no information pertaining to the blur kernel is unseen by the model in the training, testing, and validating phases.

Fig. 3. Sample images of the proposed dataset.

#### A. VAE Architecture

The proposed VAE network incorporates a prior distribution on the latent vector  $Z$ , which follows a Multi-Variate Gaussian distribution. In contrast to mapping the image onto a point space, the encoder of VAE maps the image onto a normal distribution. The encoder employs a Convolutional Neural Network (CNN) as a dimensionality reduction model to effectively map intricate training data onto the latent space  $Z$  while maintaining appropriate statistically significant attributes.

Fig. 4 depicts the comprehensive structure of the proposed VAE network. The encoder receives a visually blurred input image denoted as  $X$ , from which it generates two latent vectors,  $ZU$  (mean) and  $ZS$  (variance), that serve as the distribution parameters learned during the training process. The ultimate latent vector  $Z$  is obtained through the utilization of a Multi-Variate Gaussian distribution, which samples from  $ZU$  and  $ZS$ . Subsequently, the vector  $Z$  is transmitted to the decoder module, where it is subjected to the inverse transformation of the encoding process. This results in the generation of the predicted image  $Y$ , which represents a restored and clear version of the original blurry input image. The proposed VAE network encompasses a specific region that is centered on the mean and has a magnitude equivalent to the standard deviation. This provides the decoder with a greater amount of data, enabling it to generate an image that closely resembles the ground truth image.

#### B. Encoder-Decoder

This section outlines the definition of the Encoder and Decoder components of the network. The encoder-decoder model is presented in Fig. 6 for a comprehensive understanding. The input image's dimensions for the encoder are (None, 128, 128, 3). The encoder architecture comprises three convolutional blocks, each of which incorporates Conv2D alongside the ReLu activation function and Batchnormalization. The final layer employs a Flatten operation to transform the feature matrix, which has dimensions of (16, 16, 256), into a vector with a size of 65536. Subsequently, the Flatten layer's outcome is transmitted to two distinct dense layers with the aim of obtaining latent vectors  $ZU$  and  $ZS$ . The encoder network acquires the ability to establish a mapping between the input data and  $ZU$  and  $ZS$ , which are anticipated to conform to a normal distribution. Subsequently, the  $ZU$  and  $ZS$  vectors are transmitted to a sampling block that employs a Lambda layer. The utilization of the lambda layer proves to be advantageous in the implementation of bespoke functions that are not inherently incorporated as standard functions within TensorFlow<sup>1</sup>. Equation 2 presents a bespoke Lambda layer function that accepts  $ZU$  and  $ZS$  as input and generates the  $Z$  vector as output during the training stage. The utilization of a basic sampling technique may result in a bottleneck within the backpropagation process. To address this concern, a reparameterization technique<sup>2</sup> is employed. This technique enables the loss to propagate backward through the mean and variance nodes, which are deterministic while segregating the sampling node by introducing a non-deterministic parameter  $\epsilon$ , which is drawn from a standard normal distribution. This property ensures that  $Z$  is deterministic.

$$Z = ZU + ZS^2 * \epsilon \quad (2)$$

The two computation graphs depicted in Fig. 5 illustrate the original sampling block in (a) and its reparameterized form in (b). The blue nodes in the diagram depict the deterministic nodes, specifically the input, and weights, whereas the red nodes represent the stochastic nodes. Throughout the training process, the input image undergoes a mapping procedure resulting in the derivation of two latent variables, namely  $ZU$  and  $ZS$ . Subsequently, a vector  $Z$  is sampled from the aforementioned variables. The stochastic sampling process employed in this operation renders  $Z$  a random node, thereby creating an obstacle due to the inability of gradients to backpropagate through the sampling layer, owing to its stochastic nature. Consequently, the parameters  $ZU$  and  $ZS$  are unable to acquire knowledge. The process of backpropagation necessitates that the nodes exhibit determinism in order to facilitate the iterative propagation of gradients. The proposed VAE network introduces a reparameterization technique to tackle the aforementioned concern, whereby the stochastic node  $Z$  is transformed into a deterministic node. The utilization of  $\epsilon$  enabled the preservation of the stochasticity of the entire system while allowing the  $ZU$  and  $ZS$  vectors to function as the learnable parameters of the network.

The decoder network receives the output of the encoder (vector  $Z$ ), which has a dimension of (None, 2). The initial

<sup>2</sup><https://gregorygundersen.com/blog/2018/04/29/reparameterization/>

Fig. 4. Overview of the proposed VAE network.

Fig. 5. Reparameterized form of custom sampling block.

dense layer is assigned a filter value of 65536, which corresponds to the product of 16, 16, and 256. Thus to make the vector into a 2D matrix a reshape layer is utilized with the shape value of (16,16,256). This value is derived from the flattened output of the preceding encoder. The architecture consists of four inverse convolutional blocks, each of which incorporates Conv2DTranspose with Relu activation function and Batchnormalization. The final convolutional block within the decoder exhibits a filter value of 3, resulting in an output image shape of (None, 128, 128, 3). Therefore, a clear image of the license plate is obtained.

### C. Loss Function

The latent vector  $Z$  conforms to a Gaussian distribution with unit variance and is accountable for the minimization of the reconstruction loss denoted as  $L_r$ . The final loss function of the VAE that has been suggested is a combination of the reconstruction loss and Kullback–Leibler Divergence (KLD) loss, which is represented as a weighted sum in Equation 3. Both loss functions are optimized in this context. The reconstruction loss serves to guarantee that the resulting image is comparable to the ground truth image, while the KLD loss ensures that the latent variables are in proximity to the standard normal distribution. The KLD metric quantifies the divergence between the latent vector  $Z$  (sampled from  $ZU$ , and  $ZS$ ) and the unit normal distribution  $\gamma$ . The parameters of the encoder and decoder are represented by  $\sigma$  and  $\eta$  in Equation 3.

$$L_{total}(\sigma, \eta, y) = L_r(\sigma, \eta, \hat{y}) + KLD[ZU, ZS, \gamma] \quad (3)$$

Equation 4 refers to the calculation of  $L_r$ , where  $P$  refers to the total number of pictures in a training batch,  $y$  is the ground truth image, and  $f_\sigma(g_\eta(y))$  is the reconstructed image. The reconstruction loss is calculated by determining the difference between each pixel of the ground truth image and the corresponding pixel of the reconstructed output image. This difference is then squared and averaged across the entire batch of the data.

$$L_r(\sigma, \eta, y) = \frac{1}{P} \sum_{j=1}^P (y_j - f_\sigma(g_\eta(y_j)))^2 \quad (4)$$

The Variational Autoencoder (VAE) is trained with the objective of minimizing the Kullback-Leibler Divergence (KLD) between the latent vectors and  $\gamma$ . In the event that the encoder produces a vector  $Z$  that deviates significantly from a standard normal distribution, the KLD loss function will impose a greater penalty. The KLD serves as a regularization technique to ensure adequate diversity within vector  $Z$ . During the computation of the KLD, it is customary to assign the parameter  $ZS$  to the natural logarithm of the variance. The mathematical expression for KLD is represented by Equation 5. Through the application of the logarithmic function to the  $ZS$ , the network is constrained to produce output values within the domain of natural numbers, as opposed to solely positive values. This facilitates more seamless illustrations of the underlying space.

$$KLD[ZU, ZS, \gamma] = -0.5 * \sum_{j=1}^P (1 + \log(ZS_j^2) - ZU_j^2 - e^{\log(ZS_j^2)}) \quad (5)$$

## V. RESULT AND ANALYSIS

The objective of this research is to design a Variational Autoencoder (VAE) architecture that exhibits high performance in the task of restoring clarity to the input image of license plates. The images in the dataset represent a variety of perspectives and environmental conditions. In addition to images of average to excellent quality, the dataset also contains rotated, tilted, pixelated, and occluded images. Therefore, this dataset is highly suitable for extrapolating the deblurring issue. This section provides an analysis of the results obtained from the proposed VAE model. Furthermore, a comparative analysis is presented between the proposed VAE model and prominent deblurring models such as DeblurGan [13] and DeblurGanV2 [14].

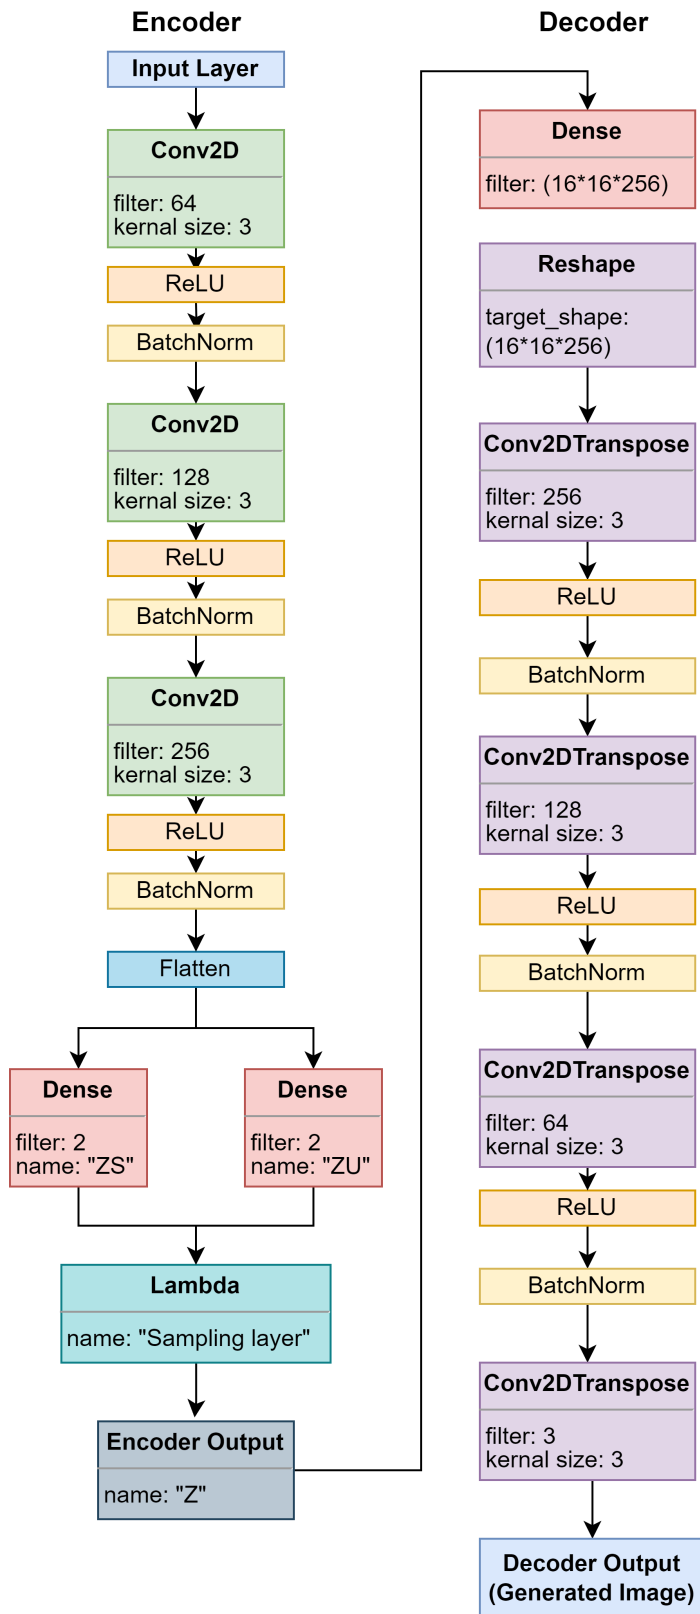

Fig. 6. Proposed encoder and decoder in the VAE network.

### A. Experimental Setup

Throughout the model training and testing process, the hardware setup consisted of an Intel Core i7 10700K Central Processing Unit (CPU), a total of 32 GB of DDR4 RAM, and an Nvidia GTX 1070 GPU with 8 GB of memory. The VAE model was developed utilizing the Tensorflow 2.11 deep learning framework in conjunction with the Python 3.9 programming language.

### B. Evaluation Metrics

1) **PSNR**: The Peak Signal-to-Noise Ratio (PSNR) is a metric employed to assess the fidelity of an image that has been restored. The process involves a comparison between the initial image and the restored image, followed by the computation of the ratio between the highest attainable value of the original signal and the value of the interference that impacts the quality of the restoration. The quality of a restoration of an image is positively correlated with the PSNR value, such that a higher PSNR value indicates superior image quality. Due to the broad dynamic range of signals, the PSNR is often expressed in decibels, a logarithmic scale. The PSNR is calculated using Equation 7. In Equations 6 and 7, the symbols  $p$  and  $q$  respectively denote the matrix values of the ground truth image and the restored image. The indices  $i$  and  $j$  represent the row and column of the matrices, while  $MAX_g$  represents the maximum value present in the original data. The primary constraint of this metric pertains to its exclusive reliance on numerical comparison, without considering any other factors of the human vision system, such as the structural similarity index (SSIM).

$$MSE = \frac{\sum_0^{i-1} \sum_0^{j-1} \|p(i,j) - q(i,j)\|^2}{i * j} \quad (6)$$

$$PSNR = 20 \log_{10} \left( \frac{MAX_g}{\sqrt{MSE}} \right) \quad (7)$$

2) **SSIM**: The Structural Similarity Index Measure (SSIM) is a prominent metric employed to evaluate the degree of similarity between two images. In contrast to conventional metrics such as MSE or PSNR, which concentrate exclusively on discrepancies at the pixel level, SSIM incorporates both the structural characteristics and perceptual attributes of images. The Structural Similarity Index (SSIM) assesses three fundamental elements of image similarity, namely luminance ( $L$ ), contrast ( $C$ ), and structure ( $S$ ).  $L$ ,  $C$ , and  $S$  are calculated using Equation 8, Equation 9, and Equation 10 respectively. The method operates by evaluating the resemblance of matching localized image patches and subsequently calculating a weighted mean over the entire image. The SSIM value obtained falls within the range of 0 to 1, where a value of 1 denotes a high degree of similarity. The SSIM metric shown in Equation 11 is designed to overcome certain drawbacks of conventional metrics, including susceptibility to noise and variations in image resolution. The incorporation of human visual perception and structural information renders it more perceptually significant. The SSIM metric is highly advantageous in applications that involve image quality evaluation, image recovery, and image compression, as it is imperative to maintain perceptual quality in these tasks.

Fig. 7. Sample output of the proposed VAE network; where a) input, b) ground truth, and c) generated image by the proposed model.

$$L(n, m) = \frac{(2\mu_n\mu_m + v1)}{(\mu_n^2 + \mu_m^2 + v1)} \quad (8)$$

$$C(n, m) = \frac{2\sigma_n\sigma_m + v2}{\sigma_n^2 + \sigma_m^2 + v2} \quad (9)$$

$$S(n, m) = \frac{\sigma_{nm} + v3}{\sigma_n\sigma_m + v3} \quad (10)$$

$$SSIM(n, m) = L(n, m)^\delta * C(n, m)^\lambda * S(n, m)^\omega \quad (11)$$

The variables  $n$  and  $m$  represent the deblurred image and its corresponding ground truth image, respectively. The variables  $\mu_n$  and  $\mu_m$  represent the arithmetic means of the values of  $n$  and  $m$ , respectively. The variables  $\sigma_n^2$  and  $\sigma_m^2$  denote the variances of  $n$  and  $m$ , respectively, while  $\sigma_{nm}$  represents the covariance between  $n$  and  $m$ . The variables  $\sigma_n$  and  $\sigma_m$  represent the standard deviation of  $n$  and  $m$  respectively. The stabilization of the division with a weak denominator is achieved through the utilization of three parameters, namely  $v1 = (U1 * L)^2$ ,  $v2 = (U2 * L)^2$ , and  $v3 = v2/2$ . Here,  $L$  denotes the dynamic range of the pixel values, while the values of  $U1$  and  $U2$  are assigned as 0.01 and 0.03, respectively.

### C. Analysis of the VAE's Performance

Here Fig. 7 illustrates a) the input blurred image of the license plate, b) ground truth in other words sharp image, and c) the output image of the proposed VAE model. From Fig. 7, it is evident that the proposed model is better able to retain and restore the texture in the deblurred image. It shows superior results in terms of visual representation. The images depicted in Fig. 7(a) exhibit a significant degree of blurriness, rendering the license plate information indiscernible. However, the model performs well in restoring the image and the informations are clearly visible. Along with restoring private vehicle license plate images (with white license plate background), the model is also capable of restoring public vehicle license plate images (with green license plate background). The 6<sup>th</sup> image of Fig. 7(b) has a noise and ringing effect. However, the generated image is very clear and there is no existence of noise in it. Thus, in accordance with image deblurring the proposed model can also reduce noise in the input image. After training the model for 100 epochs we achieved such results due to a generalized dataset and careful tuning of the hyperparameters and loss function tuning of the proposed model.

To conduct a comparative analysis, we replicated the structural design of DeblurGan [13] and DeblurGanV2 [14], and subsequently subjected them to training using our suggested dataset. The visual comparison between the two models and the proposed VAE network is depicted in Fig. 8. The analysis reveals that the DeblurGan [13] and DeblurGanV2 [14] models exhibit unsatisfactory performance, as evidenced

by their inability to produce output images of comparable quality and texture to the original ground truth image. The VAE network proposed in the majority of cases exhibits superior performance in deblurring and effectively enhances the legibility of license plates, resulting in the identification of information contained within the plate image. The results depicted in Fig. 8 demonstrate that the model proposed in this study exhibits superior performance in generating license plate images that are deblurred, noise-free, and the semantic characteristics of the image are preserved.

Fig. 8. Comparison with state-of-the-art-models; where a) input blurred image, b) Output of DeblurGan [13], c) Output of DeblurGanV2 [14], d) generated image by the proposed VAE model and (e) is the ground truth image.

The assessment of performance with respect to three primary metrics, namely Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and Inference Time, is presented in Table I. The validation set of our proposed datasets is employed for the purpose of validating these models. Table I demonstrates that the PSNR and SSIM metrics of our model are significantly higher than those of the previous state-of-the-art models. The model under consideration attained a PSNR score of 32.41 and an SSIM score of 0.934. The VAE network proposed exhibits superior performance in terms of producing visually, semantically correct, and readable outcomes. Unlike alternative neural models, our model is not dependent on L2 distance within the pixel area, and therefore, it is not inherently optimized for the PSNR metric. The output, as depicted in Fig. 7, demonstrates the capability of the method to effectively mitigate the effects of camera shake and object movement-induced blur. Furthermore, the approach does not exhibit the typical artifacts that are commonly observed in kernel estimation techniques. Simultaneously, it exhibits the shortest inference time.

TABLE I. PERFORMANCE EVALUATION WITH RESPECT TO PSNR, SSIM, AND INFERENCE TIME

Performance Metrics	DeblurGan [13]	DeblurGanV2 [14]	Proposed Network	VAE
PNSR	20.99	24.15	32.41	
SSIM	0.504	0.563	0.934	
Inference Time	0.85s	0.28s	0.16s	

## VI. CONCLUSION

This research introduces a new approach for enhancing the clarity of license plate images through the utilization of a novel Variational AutoEncoder(VAE) network. The experimental findings indicate that the proposed model surpasses the current state-of-the-art deblurring techniques, exhibiting a higher peak signal-to-noise ratio (PSNR) score of 32.41 and a structural similarity index measure (SSIM) score of 0.934. The proposed approach utilizes VAE to acquire a reduced-dimensional depiction of the image data, thereby facilitating the efficient elimination of blurriness and noise from license plate images. In future research, our suggested model may be further refined to minimize the duration of execution and enhance its efficacy, rendering it appropriate for real-time implementations. Despite the absence of a publicly accessible dataset for Bangla license plate deblurring, the model can be effectively trained on license plates from other countries to enhance its applicability. Furthermore, the model has the potential to be deployed on edge devices, such as smartphones or embedded systems, thereby facilitating license plate recognition applications in resource-constrained or remote settings.

**Abstract**—The synthesis of facial images from textual descriptions is a relatively difficult subfield of text-to-image synthesis. It is applicable in various domains like Forensic Science, Game Development, Animation, Digital Marketing, and Metaverse. However, no work was found that generates facial images from textual descriptions in Bangla; the 5th most spoken language in the world. This research introduces the first-ever system to generate facial images from Bangla textual descriptions. The proposed model comprises two fundamental constituents, namely a textual encoder, and a Generative Adversarial Network (GAN). The text encoder is a pre-trained Bangla text encoder named Bangla FastText which is employed to transform Bangla text into a latent vector representation. The utilization of Deep Convolutional GAN (DCGAN) allows for the generation of face images that correspond to text embedding. Furthermore, a Bangla version of the CelebA dataset, CelebA Bangla is created for this study to develop the proposed system. CelebA Bangla contains images of celebrities, their corresponding annotated Bangla facial attributes and Bangla Textual Descriptions generated using a novel description generation algorithm. The proposed system attained a Fréchet Inception Distance (FID) score of 126.708, Inception Score (IS) of 12.361, and Face Semantic Distance (FSD) of 20.23. The novel text embedding strategy used in this study outperforms prior work. A thorough qualitative and quantitative analysis demonstrates the superior performance of the proposed system over other experimental systems.

**Keywords**—Bangla text-to-face synthesis; Natural Language Processing (NLP); Computer Vision (CV); GAN; text encoders

## I. INTRODUCTION

Generative Adversarial Networks (GANs) have been identified as an effective tool for producing lifelike images in diverse domains, encompassing natural landscapes and human countenances. The capacity to produce superior images from textual depictions has garnered considerable interest owing to its potential implications in virtual avatars, content creation, and tailored advertising.

The generation of an image from a given textual input is referred to as text-to-image generation. The Text-To-Face (TTF) technique is a subfield of the Text-To-Image (TTI) generation field, wherein a depiction of a human face is furnished, and a facial image is produced by utilizing the description. Generating images of faces is a more challenging task compared to text-to-image generation, primarily due to the intricate nature of facial attributes. The utilization of text-to-face synthesis holds significant potential in various practical domains, such as Forensic Science, Game Development, Animation, Digital Marketing, and the Metaverse. The generation

of images and faces from text has emerged as a prominent area of research in recent times, resulting in a substantial body of literature on the subject. Notably, a majority of scholars have directed their attention towards image generation in the English language [1]. Although significant advancements have been achieved in the field of English-based text-to-image synthesis, there has been a dearth of research pertaining to non-English languages, specifically the Bangla language. The Bangla language possesses distinct linguistic and cultural subtleties, thereby posing distinctive obstacles to the synthesis of text-to-face. The process of generating facial images from Bangla text necessitates a profound comprehension of the language's phonological, syntactic, and semantic frameworks. The accurate representation of the visual heterogeneity and distinctive facial attributes of Bangla-speaking individuals is imperative in producing genuine and culturally appropriate facial depictions.

To mitigate this gap, in this paper, a novel GAN-based system, specifically for generating face images from Bangla textual input is proposed. The objective of the proposed system is to mitigate the challenges related to Bangla text and cultural diversity in multimodal synthesis research, thereby filling an existing gap in this field. The proposed model consists of two primary components, namely a text encoder and an image generator. The utilization of Bangla FastText [2] by the text encoder serves the purpose of encoding Bangla text into a latent vector representation that adeptly captures the semantic information that is intrinsic to the text. Subsequently, the image generator utilizes a Deep Convolutional Generative Adversarial Network (DCGAN) architecture to produce facial images that align with the encoded textual depiction. Modifications have been made to the CelebA dataset [3] to enhance the efficiency of our model's training and evaluation processes. Labels have been meticulously assigned to 40 distinct facial attributes using semantically accurate Bangla vocabulary. This has led to the creation of a novel dataset named CelebA Bangla. The CelebA Bangla dataset is a compilation of face images showcasing celebrities, accompanied by 40 facial attribute annotations in the Bangla language. Utilizing these attributes, textual depictions of Bangla faces are generated through our novel algorithm for Bangla facial description generation. By conducting thorough experimentation and utilizing both quantitative and qualitative evaluation metrics, the quality, diversity, and fidelity of the produced facial images are evaluated. Then, the performance of our proposed model is compared to that of the current leading models. The proposed system attained a Fréchet Inception Distance (FID) score of 126.708, Inception Score (IS) of 12.361, and Face Semantic Distance (FSD) of 20.23.

\*Corresponding authors

**The major contributions of this paper are:**

- A novel version of the CelebA dataset has been proposed entitled CelebA Bangla.
- A novel system for generating facial images from Bangla text descriptions has been developed, whereby meaningful images are produced in response to input in the Bangla language. The system under consideration attained an FID score of 126.708.

The subsequent segments of the document are structured in the following manner: Section II discusses the related works. The dataset is elaborated upon in Section III, while Section IV provides an overview of the methodology employed. Section V presents a thorough analysis of the qualitative and quantitative outcomes. Section VI establishes the limitations or constraints of the study followed by Section VIII containing the conclusion. The remaining portion comprises references.

## II. RELATED WORK

In this section, significant works of state-of-the-art Generative Adversarial Networks, text encoders, text-to-image, and face synthesis architectures are analyzed.

### A. GANs

Generative Adversarial Network (GAN) [4] is an exceptional framework that can learn to generate new data based on the data of a specified training set. GANs are composed of two parts, the Generator and Discriminator respectively. There is a constant competition between these two parts where the generative network generates new data learning to map from a latent space of data distribution while the discriminative network differentiates the data produced by the generator from the actual data distribution. Deep Convolutional Generative Adversarial Network (DCGAN) [5] is an extension of GAN that incorporates convolutional and convolutional-transpose layers in the generator and discriminator accordingly. Self-Attention Generative Adversarial Network (SAGAN) [6] provides attention-driven modeling of long-range dependencies for image generation activities where its discriminator can verify the consistency of highly detailed features in distant portions of the image and attention mechanism can provide the generator and discriminator with more power to directly model the long-range dependencies in the feature maps and better approximate the original image's distribution.

Attentional Generative Adversarial Network (AttnGAN) enables multi-stage, attention-driven image generation from textual description [7], [8]. AttnGAN begins with a rudimentary low-resolution image which it then refines in multiple phases to produce a final image from the natural language description. StyleGAN [9]–[11] is another extension of the progressive GANs that enables generation of high-quality photorealistic images by means of the incremental development of discriminator and generator models beginning with a low resolution and expanding to a high resolution of 1024x1024 pixels. GigaGAN\* synthesizes high-resolution images, such as ultra-high 4k resolution images in 3.66 seconds, and supports a variety of latent space editing options including latent interpolation, style blending, and vector arithmetic operations.

### B. Text to Image Synthesis

In paper [12], they proposed an efficient deep GAN architecture-based text-to-image synthesis of birds and flowers images from human-written descriptions. They utilized the Caltech-UCSD Birds dataset (CUB), Oxford-102, and MS COCO dataset to train and evaluate their model. Their proposed model showed substantial improvements in Text-to-image synthesis. Later on, the paper [7] suggested the first Bangla language-based Text-to-image generation method AttnGAN that analyzed Deep Attentional Multimodal Similarity Model and Attentional GAN to generate improved and realistic high-resolution images from Bangla text description surpassing the state-of-the-art (SOTA) image synthesis GAN models by an ideal inception score of  $3.58 \pm .06$ .

The author of [8], presented AttnGANTRANS which consists of Attentional GAN and transformer models such as Bidirectional Encoder Representations from Transformers (BERT), GPT2, and XLNet that were capable of extracting semantic information from text descriptions more accurately than the conventional AttnGAN. Gao *et al.* [13] proposed LD-CGAN comprised of one generator and two independent discriminators to regularize and generate 64x64 and 128x128 images. The generator includes three major components- Conditional Embedding (CE) which disentangles integrated semantic attributes in the text, Conditional Manipulating Modular (CM-M) used to continuously provide image features with compensation information and Pyramid Attention Refine Block (PAR-B) to enrich multi-scale features. The experiments were evaluated on CUB and Oxford-102 datasets achieving an Inception score of  $3.64 \pm 0.04$  and  $4.18 \pm 0.06$  on 64x64 and 128x128 images.

Zhang *et al.* [14], presented XMC-GAN comprised of several contrastive losses, an attentional self-modulation generator, and a contrastive discriminator to generate images of higher quality and closer correspondence to the input descriptions which was evaluated on three datasets demonstrating SOTA FID score of 9.33 on the MS-COCO dataset and an impressive benchmark FID score of 26.91 on the Open Image Data. Siddharth *et al.* [15] proposed AttnGAN with pre-trained text encoder RoBERTa using the Caltech-UCSD birds dataset for textual descriptions obtaining an FID score of 20.77.

The authors of [1], [16], [17] suggested DF-GAN that can directly synthesize high-resolution images without entanglements between different generators, improve TTI semantic coherence and make complete integration between text and synthesized features that was evaluated on the CUB and COCO datasets where yielded results surpassed SOTA models.

### C. Text to Face Synthesis

It is a very challenging task to convert human-written descriptions into human faces. But many types of research [1], [9], [18]–[22] have been conducted in this field of Text-to-face synthesis.

Deorukhkar *et al.* [1], proposed to use Sentence Bidirectional Encoder Representations from Transformers (SBERT) to convert the textual descriptions (from their own dataset based on CelebA dataset) into embeddings and generated 128x128 sized images using DCGAN, SAGAN and DFGAN models. Recently, StyleGAN-based models [9], [19] have

advanced Text-to-face synthesis in terms of image quality and diversity. The author of [9] introduced a Multi-Modal CelebA-HQ dataset. They also introduced a framework containing the GAN inversion technique based on the multi-modal inputs. Finally, evaluating the model on the Multi-Modal CelebA-HQ dataset, they achieved an FID score of 106.37 and generated 1024x1024 sized images. The authors of [19] presented a two-stream framework combining CLIP visual concepts and StyleGAN using Multi-Modal CelebA-HQ and CelebAText-HQ [23] datasets for high-fidelity Text-to-face synthesis. Later, they evaluated the model on two datasets including the Multimodal CelebA-HQ dataset and the CelebAText-HQ dataset, and finally, achieved an FID score of 50.56 and 56.75, respectively.

Recently, StyleGAN2-based models [18], [20] have been introduced in the field of Text-to-face synthesis. The authors of [18], used a Text-to-face framework with StyleGAN2 and a sentence encoder named BERT and generated 1024x1024-shaped high-quality images. In the paper [20], they proposed a TTF-HD framework with StyleGAN2 using the CelebA dataset in order to generate high-quality facial images with a wide range of variations leading to generating 1024x1024 sized images.

Peng *et al.* [21] introduced a dynamic pixel synthesis network that can transform text features into dynamic knowledge embeddings and generate accurate Text-to-face images that were trained and evaluated on the Multi-Modal CelebA-HQ dataset achieving an excellent FID score of 13.48. The authors of [22], proposed a GAN model which can directly convert the text descriptions into pixel values. They conducted zero-shot experiments on Face2Text [24] then trained and evaluated their proposed model on Multi-Modal CelebA-HQ and managed to achieve an FID score of 14.45.

There are many existing works on English text-to-face synthesis, as discussed in this sub-section. However, there is no research work done on Bangla text-to-face synthesis. There are also some limitations in the prior English text-to-face synthesis works. For instance, when the textual descriptions of faces are long, some of the works failed in handling those long descriptions of faces. As a result, the models could not generate accurate facial images. In some other works the models are not robust enough, so the generated images do not match with the input text descriptions.

### III. DATASET

The present study employs the CelebA dataset, which was introduced by the authors of [3]. The dataset comprises in excess of 200,000 images of celebrities' faces, each with a resolution of 128x128 pixels. Additionally, it contains annotations (in English) of 40 facial attributes for each image.

Nonetheless, the CelebA dataset is inadequate for creating a system that utilizes Bangla facial description as input and produces the corresponding image. Consequently, a novel iteration of the CelebA dataset, titled CelebA Bangla, has been created and presented in this paper. The proposed dataset consists of three distinct segments. The initial segment depicts a collection of images of notable celebrities, followed by a list of 40 attributes that have been manually annotated in the Bengali language. The third segment pertains to the Bangla

TABLE I. FACIAL ATTRIBUTE SAMPLE OF THE PROPOSED CELEBA BANGLA DATASET

image_file_name	হালকা দাড়ি (5_o_Clock Shadow)	কুঁচকানো ঝুঁক (arched eyebrows)	আকর্ষণীয় (attractive)	.....	অল্পবয়স্ক (young)

.....					
 202599.jpg	-1	1	1	.....	1

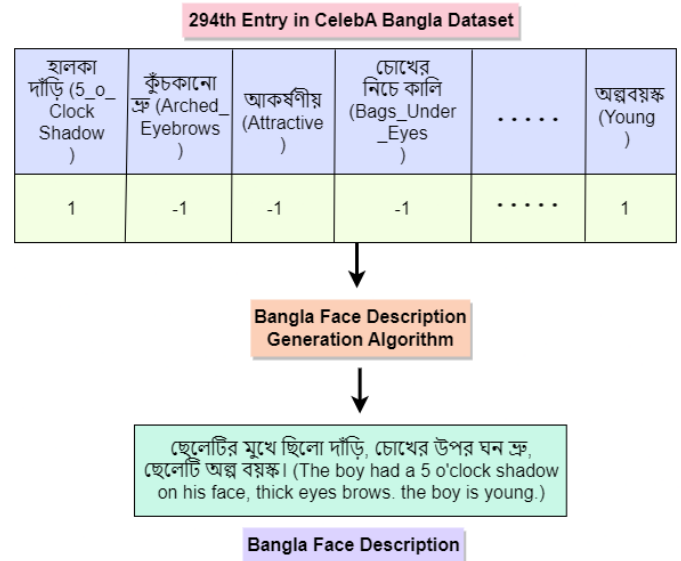

Fig. 1. Proposed Facial Description Generation Process.

descriptions, which are obtained from the second segment. Therefore, it can be observed that every image is associated with 40 distinct Bangla facial attributes and a corresponding Bangla facial description.

Table I represents 40 facial attributes corresponding to a single image. Here, the first column shows the image of celebrities and each of the following columns is facial attributes in Bangla. Considering  $i$  as row and  $j$  as the column

of Table I, if  $TableI[i][j] = 1$ , it implies that attribute  $j$  is present in image  $i$ . Otherwise,  $TableI[i][j] = -1$  means attribute  $j$  is absent in image  $i$ . Face attributes were manually annotated into the most suitable Bangla attributes.

Algorithm 1 is utilized to generate a Bangla description for each image based on its facial attributes. Algorithm 1 depicts a partial segment of the comprehensive algorithm for generating Bangla facial descriptions. This particular segment outlines the process for generating textual descriptions pertaining to males and females of varying ages. The gender and age attributes of the dataset are represented by row[22] and row[41], respectively. The Bangla text descriptions in Table II have been generated through the utilization of the suggested description generation algorithm. In order to produce significant textual depictions in Bangla, the algorithm receives annotated Bangla attributes. Subsequently, the Bangla text description generation algorithm generates semantically accurate Bangla text descriptions that correspond to the images of faces. The aforementioned procedure is depicted in Fig. 1.

#### IV. METHODOLOGY

The proposed system utilized DCGAN+Bangla Fasttext to generate face images from the corresponding Bangla descriptions. Firstly the Bangla text description is fed to Bangla Fasttext [2] which returns a  $[300 \times 1]$  shaped text embedding. A random noise vector with a shape of  $[100 \times 1]$  along with the achieved text embedding is passed to the generator. The generator generates images with a resolution of 128x128, then the discriminator detects whether the generated images are real or fake by comparing the generated images with ground truth images. Based on the difference between generated and ground truth images the loss is calculated and is back-propagated through the generator and discriminator as shown in Fig. 2.

#### Algorithm 1 Bangla Face Description Generation Algorithm

```

#### A. Embedding Strategy

The proposed dataset comprises image-text pairs, where a single pair contains textual description  $T$  of the facial image  $I$ . In this study, a text encoder denoted as  $TE$  was employed in conjunction with a Deep Convolutional Generative Adversarial Network (DCGAN). The text  $T$  is passed through  $TE$  in order to obtain the corresponding text embedding  $E$ . Ultimately, the DCGAN was trained through the utilization of  $I$  and  $E$ .

$$E = TE(T) \quad (1)$$

In FGTD [1], text embeddings were generated for a given text description  $T$  consisting of a series of sentences  $S_i$ , and embeddings  $E_{S_i}$  were computed, where  $i \in \mathbb{N}$  and  $\mathbb{N}$  is the set of all natural numbers. The arithmetic average of the embedding vectors was utilized as input for the conditional GAN, as depicted in Fig. 3(a). However, it was anticipated that the process of obtaining the mean of embeddings results in a reduction of significant semantic information that is initially present in the sentence embeddings,  $E_{S_i}$ . In order to mitigate the loss of information, our proposed embedding strategy (as depicted in Fig. 3(b)) which involves the utilization of a text encoder to generate a text embedding,  $E$ , by processing the complete textual description  $T$  as shown in Equation 1. Thus a text embedding is obtained without losing semantic information caused by the mean operation. Since  $E_T$  is an

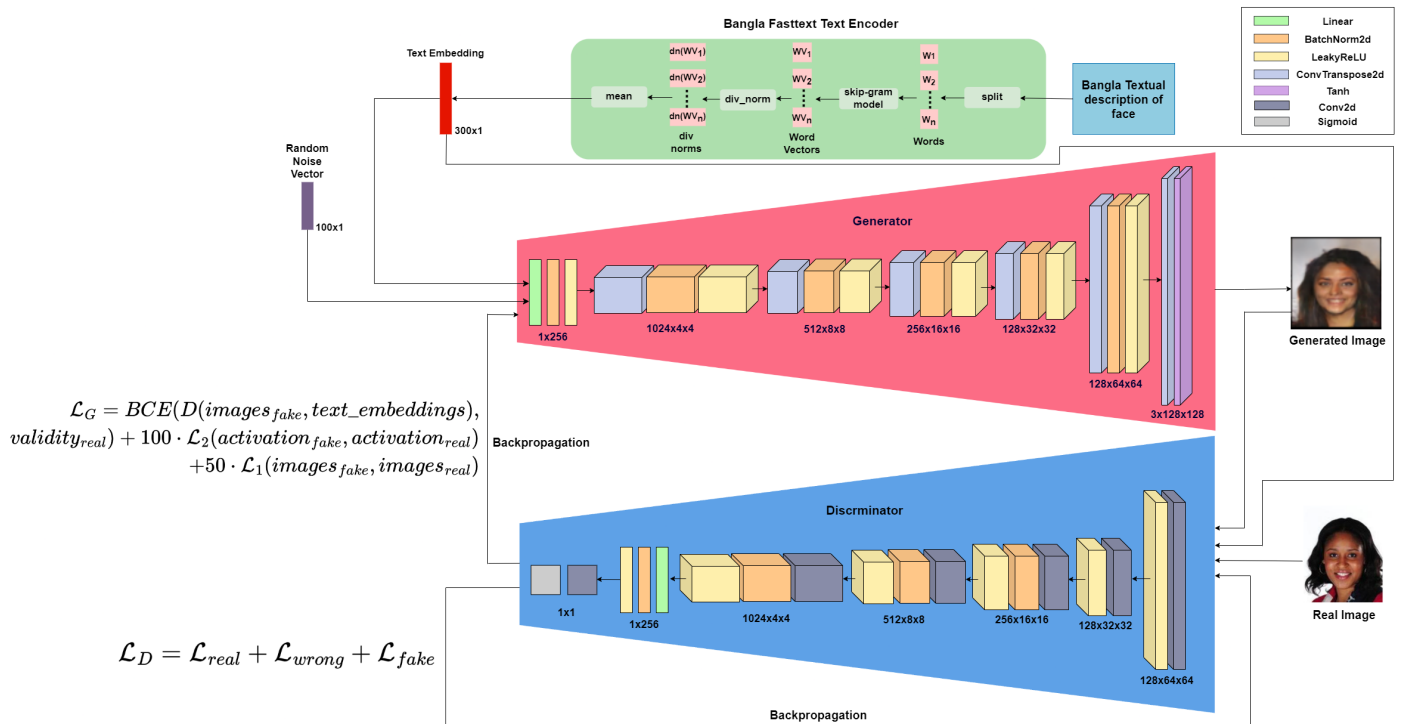

Fig. 2. Neural architecture of the proposed system: Bangla Fasttext + DCGAN.

embedding of the entire textual description  $T$ , it has a better one-to-one correlation between the text description and the final embedding.  $E_T$  is directly passed to DCGAN. Within the section pertaining to quantitative results, it is demonstrated that the proposed text embedding strategy exhibits superior performance in comparison to the strategy employed in FGTD [1].

### B. Text Encoder

A work [8] from 2021 suggested that using a pre-trained text encoder enhances the performance of text-to-image synthesis. The proposed system employs Bangla FastText [2] as pretrained text encoder. Bangla FastText is trained using 20 million Bangla data. As demonstrated in Fig. 4(a), the Bangla Fasttext sentence encoder first splits the facial descriptions into words. It then computes word embeddings using a skip-gram model. Afterwards, the word embedding vectors go through an operation  $div\_norm$  defined by Equation 2.  $div\_norm$  essentially prevents a distribution from being dispersed by dividing a vector by its euclidian norm if the euclidian norm is greater than zero. Finally, the mean of  $div\_norms$  is passed on as a  $[300 \times 1]$  sentence embedding vector.

$$div\_norm(x) = \begin{cases} \frac{x}{\sqrt{\sum_{i=0}^n x_i^2}} & \text{if } \sqrt{\sum_{i=0}^n x_i^2} > 0 \\ x & \text{if } \sqrt{\sum_{i=0}^n x_i^2} \leq 0 \end{cases} \quad (2)$$

In our experimental models, two other pretrained Bangla

text encoders were also used provided by sbnltk<sup>†</sup>: sbnltk sentence transformer hd (trained on 3,00,000+ human data) and sbnltk sentence transformer gd (trained on 3,00,000+ google translated data). Both of these models have the same neural architecture but were trained on different datasets. As depicted in Fig. 4(b), the sbnltk sentence transformer first generates tokens from sentences. The tokens are passed on to a pretrained multilingual model, XLM-RoBERTa [25] which has 12 hidden encoder layers. Finally, a pooling layer gives us the sentence embedding vector of length 768. Despite the superior neural architecture of XLM-RoBERTa, sbnltk sentence transformer is trained on lesser amount of Bangla text corpus, which may have led it to have learned an inadequate probabilistic distribution of text written in Bangla; compared to Bangla FastText. For this reason, Bangla FastText have been incorporated in our proposed system.

### C. GAN Architecture

Our proposed method has DCGAN [5] as its GAN architecture. The generator of DCGAN has a sequence of transpose convolution, batch normalization, and LeakyReLU layers. In the end, a Tanh activation function gives us generated or fake images. Strided convolutions used in the generator allows the network to learn its own spatial upsampling. The Discriminator mainly has a sequence of blocks containing convolution, batch normalization, LeakyReLU layers, and a sigmoid activation in the end to classify real/fake images. The discriminator uses strided convolution to learn its own spatial downsampling. Batch normalization employed in both generator and discriminator normalizes the input to each unit to have zero mean and unit variance to stabilize the training process. The use

<sup>†</sup><https://github.com/Foysal87/sbnltk>

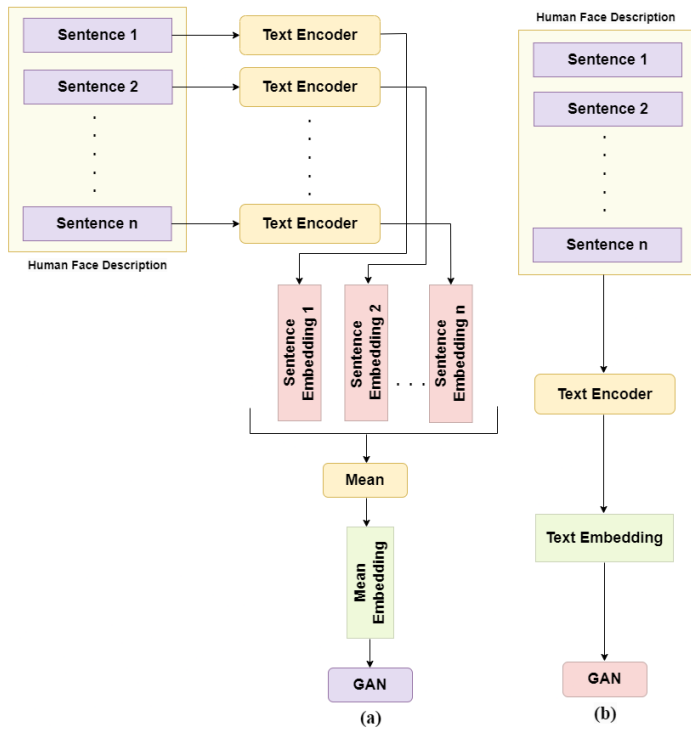

Fig. 3. (a) Text embedding strategy used in FGTD [1], (b) Proposed embedding strategy.

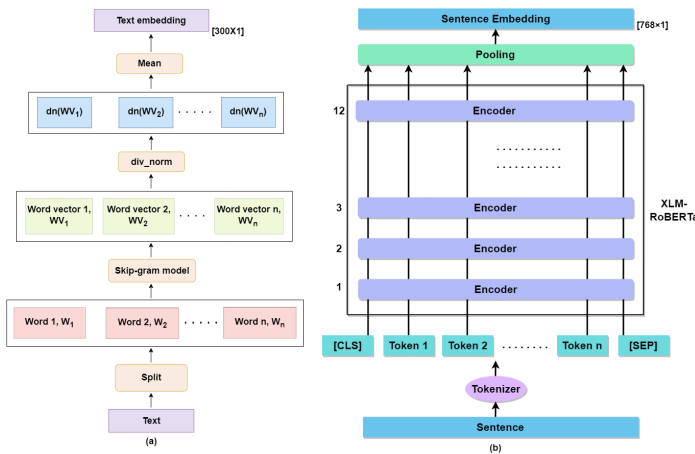

Fig. 4. (a) Bangla FastText architecture, (b) Sbnltk Sentence Transformer neural model.

of an unbounded activation, Leaky ReLU allows DCGAN to converge fast and learn the color space of the distribution of training images.

To train the Generator of DCGAN, Adam optimizer was utilized with learning rate,  $\alpha = 0.0002$  and  $\beta_1 = \beta_2 = 0.5$ . For training the Discriminator of DCGAN, Adam optimizer was utilized with learning rate,  $\alpha = 0.0001$  and  $\beta_1 = \beta_2 = 0.5$ .

#### D. Loss Functions

The loss function of the generator of our proposed DCGAN+Bangla FastText method is shown in Equation 3.

$$\mathcal{L}_G = BCE(D(images_{fake}, text\_embeddings), validity_{real}) + 100 * \mathcal{L}_2(activation_{fake}, activation_{real}) + 50 * \mathcal{L}_1(images_{fake}, images_{real}) \quad (3)$$

Here  $BCE$  in Equation 3 is the Binary Cross Entropy Error.  $images_{fake}$  are images generated from input noise and text embeddings passing through the Generator of DCGAN.  $input\_noise$  is a 100-dimensional vector which comes from a standard normal distribution with mean 0 and variance 1.  $text\_embeddings$  are generated from textual descriptions of faces which went through a text encoder (Equation 4). The dimensions of  $text\_embeddings$  are  $[300 \times 1]$ .  $validity_{real}$  is a vector where each element equals 1 (Equation 5). The dimensions of  $validity_{real}$  are  $[batch\_size \times 1]$ . The  $BCE$  loss mentioned here uses discriminator  $D$  to assess how realistic the generated images are in response to text embeddings. Higher BCE loss penalizes the generator network more.

$$images_{fake} = Generator(input\_noise, text\_embeddings) \quad (4)$$

$$validity_{real} = \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}_{[batch\_size \times 1]} \quad (5)$$

$\mathcal{L}_2$  loss is the Mean Square Error (MSE). By passing  $images_{fake}$  and  $text\_embeddings$  through the Discriminator of DCGAN in Equation 6,  $activation_{fake}$  was obtained. By passing  $images_{real}$  and  $text\_embeddings$  through the Discriminator of DCGAN,  $activation_{real}$  was obtained in Equation 7. The  $\mathcal{L}_2$  loss is a comparison of how different the activations are from the discriminator with regards to real and fake images. Since this loss can potentially prove to be crucial in the training process, it is multiplied by 100 in Equation 3.

$$activation_{fake} = Discriminator(images_{fake}, text\_embeddings) \quad (6)$$

$$activation_{real} = Discriminator(images_{real}, text\_embeddings) \quad (7)$$

$\mathcal{L}_1$  loss is defined as the mean absolute error. in Equation 3,  $\mathcal{L}_1$  loss measures how different the generated images are compared to real images. Since this loss has lower relevance than  $\mathcal{L}_2$  loss and higher significance than  $BCE$  loss, it is given a multiplier 50 in Equation 3.

Performing a weighted sum of  $BCE$  loss,  $\mathcal{L}_2$  loss and  $\mathcal{L}_1$  loss in Equation 3 equips the generator of DCGAN with a

robust loss function to help it generate more realistic images which are semantically aligned with textual descriptions.

The loss function illustrated in Equation 8 was used to train the discriminator network of DCGAN.

$$\mathcal{L}_D = \mathcal{L}_{real} + \mathcal{L}_{wrong} + \mathcal{L}_{fake} \quad (8)$$

Where, For computing  $\mathcal{L}_{real}$ ,  $images_{real}$  and  $text\_embeddings$  were passed through the Discriminator of DCGAN to get  $output_{real}$  and  $activation_{real}$  in Equation 9.  $output_{real}$  is compared with  $labels_{real}$  to compute *BCE* loss, which is our  $\mathcal{L}_{real}$  loss(Equation 10).  $labels_{real}$  are textual descriptions of faces corresponding to a batch of facial images.  $\mathcal{L}_{real}$  loss essentially determines how close the outputs of the discriminator are compared to true labels.

$$output_{real}, activation_{real} = Discriminator(images_{real}, text\_embeddings) \quad (9)$$

$$\mathcal{L}_{real} = BCE(output_{real}, labels_{real}) \quad (10)$$

When calculating  $\mathcal{L}_{wrong}$  in Equation 11,  $validity_{fake}$ , a vector of 1s and dimensions  $[batch\_size \times 1]$  are taken.  $output_{wrong}$  is obtained by passing  $images_{wrong}$  and  $text\_embeddings$  through the Discriminator of DCGAN.  $images_{wrong}$  are images which are different from  $images_{real}$  and do not correspond to  $text\_embeddings$ . *BCE* loss between  $output_{wrong}$  and  $validity_{fake}$  are calculated to acquire  $\mathcal{L}_{wrong}$ (Equation 12). The task of  $\mathcal{L}_{wrong}$  is to ensure that the discriminator is classifying the wrong images correctly.

$$output_{wrong} = Discriminator(images_{wrong}, text\_embeddings) \quad (11)$$

$$\mathcal{L}_{wrong} = BCE(output_{wrong}, validity_{fake}) \quad (12)$$

For the purpose of determining  $\mathcal{L}_{fake}$ , first  $output_{fake}$  is obtained by passing  $images_{fake}$  and  $text\_embeddings$  through the Discriminator of DCGAN in Equation 13. In Equation 14, *BCE* loss between  $output_{fake}$  and  $validity_{fake}$  is calculated to get  $\mathcal{L}_{fake}$ .  $\mathcal{L}_{fake}$  instructs the discriminator to classify fake images correctly.

$$output_{fake} = Discriminator(images_{fake}, text\_embeddings) \quad (13)$$

$$\mathcal{L}_{fake} = BCE(output_{fake}, validity_{fake}) \quad (14)$$

A linear combination of  $\mathcal{L}_{real}$ ,  $\mathcal{L}_{wrong}$  and  $\mathcal{L}_{fake}$  in Equation 8 form a strong loss function to assist the discriminator of DCGAN to adjust its parameters to attain superior classification performance.

## V. RESULT ANALYSIS

In this section, a comprehensive discussion of the experimental details during training and validation of the proposed model is provided.

### A. Experimental Setup

During the process of training and testing the model, the hardware configuration utilized comprised an Intel Core i7 7700K CPU, 16 GB of DDR4 RAM, and an Nvidia RTX 3060 GPU equipped with 12 GB of VRAM. The proposed system is implemented and developed using the Anaconda 22.11.1 environment, which runs on Windows 10 and has Python 3.9.15 installed.

Prior work related to text-to-face synthesis utilizes English text descriptions where they employ sBERT [1], Roberta [15], GPT2 and XLNet [8] etc. as text encoders. However, these text encoders are not usable when considering Bangla text description. Thus, in this study, Bangla FastText and sbnltk text encoders are used in combination with several GAN architectures to provide a comprehensive analysis of performance between our proposed system and other systems. Some details about the models used for comparison are presented in Table III where Model-1 is the proposed model. Keeping limited computational resources in mind, DCGAN [5] (30 Million Parameters), SAGAN [6] (18M Parameters) and DFGAN [16] (110M Parameters) architectures were chosen to perform the experiments. FGTD [1]'s implementation of DCGAN, SAGAN, and DFGAN were used in this research endeavor and sbnltk and Bangla FastText replaces the text encoder of FGTD to take Bangla text descriptions as input.

TABLE III. CONFIGURATION OF DIFFERENT EXPERIMENTAL MODELS

Experimental Models	Text encoder and GAN utilized	Batch size	VRAM consumption while training
Model-1 (Proposed system)	DCGAN + Bangla FastText	64	4.5 GB
Model-2	DCGAN + sbnltk HD	64	4.7 GB
Model-3	DCGAN + sbnltk GD	64	4.7 GB
Model-4	SAGAN + Bangla FastText	16	7.8 GB
Model-5	SAGAN + sbnltk HD	16	9 GB
Model-6	SAGAN + sbnltk GD	16	9 GB
Model-7	DFGAN + sbnltk GD	8	10 GB

To train the Generator of SAGAN, Adam optimizer was used with learning rate,  $\alpha = 0.0001$  and  $\beta_1 = 0$ ,  $\beta_2 = 0.9$ . For training the Discriminator of SAGAN, Adam optimizer was utilised with learning rate,  $\alpha = 0.0004$  and  $\beta_1 = 0$ ,  $\beta_2 = 0.9$ . For training the Generator of DFGAN, Adam optimizer was utilised with learning rate,  $\alpha = 0.0001$  and  $\beta_1 = 0$ ,  $\beta_2 = 0.9$ . For training the Discriminator of DFGAN, Adam optimizer was utilised with learning rate,  $\alpha = 0.0004$  and  $\beta_1 = 0$ ,  $\beta_2 = 0.9$ .

The aforementioned GAN architectures were paired with Bangla FastText [2], sbnltk sentence transformer HumanTranslated Data (HD), and sbnltk sentence transformer GoogleTranslated Data (GD) text encoders.

## B. Evaluation Metrics

To evaluate our models, 5 different conventional evaluation metrics were utilised including Inception score (IS), Fréchet Inception distance (FID), Learned Perceptual Image Patch Similarity (LPIPS), Face Semantic Similarity (FSS) and Face Semantic Distance (FSD).

1) *Inception score (IS)*: IS is used to measure the quality and diversity of the generated images where a higher score of IS suggests that the generated images are of high quality and diverse. IS is calculated using Equation 15.

$$\text{Inception Score} = \exp(\mathbb{E}_x \text{KL}(p(y|x)||p(y))) \quad (15)$$

Here,  $p(y|x)$  is the conditional class distribution of the generated images,  $p(y)$  is the marginal class distribution of the generated images, and KL is the Kullback-Leibler Divergence. PyTorch ignite's implementation<sup>‡</sup> of inception score was used.

2) *Fréchet Inception Distance (FID)*: FID compares the similarity of generated images to the real ones. FID is a more accurate performance metric compared to IS and unlike IS, a lower FID score means that the generated images are more similar to the real images. FID is calculated using Equation 16.

$$d^2 = \|\mu_X - \mu_Y\|^2 + \text{Tr}(\Sigma_X + \Sigma_Y - 2\sqrt{\Sigma_X \Sigma_Y}) \quad (16)$$

Where  $d^2$  indicates the distance has squared units.  $\mu_X$  is the feature-wise mean of the real image.  $\mu_Y$  indicates the feature-wise mean of the generated image.  $\Sigma_X$  is the covariance matrix of the feature vector of the real image.  $\Sigma_Y$  is the covariance matrix of the feature vector of the generated image. Trace linear algebra operation is indicated by  $Tr$ .

3) *Learned Perceptual Image Patch Similarity (LPIPS)*: LPIPS essentially measures the similarity between the activations of two image patches where the two images are the real image and the generated image, respectively. Like FID [26] score, a lower LPIPS score indicates that image patches are perceptually similar. The formula used to calculate LPIPS is in equation 17.

$$d(x, x_0) = \sum_l \frac{1}{H_l W_l} \sum_{h,w} \left\| \omega_l \odot (\hat{y}_{hw}^l - \hat{y}_{0hw}^l) \right\|_2^2 \quad (17)$$

Where  $d$  is the LPIPS distance between real image  $x$  and generated image  $x_0$ . Features are extracted from layer  $l$  of Alexnet. In the channel dimension, unit normalization is applied.  $\odot$  indicates the Hadamard product. The number of activated channels are scaled by the vector  $\omega_1$ . For calculating LPIPS, `lpips-pytorch`<sup>§</sup> was used to evaluate the generated images using a pre-trained Alexnet model.

4) *Face Semantic Similarity (FSS)*: FSS measures the similarity between the generated face and the real face with regard to their facial features. In the case of FSS, a higher score of FSS means that the images are more similar. Equation 18 is utilized to compute FSS.

$$\text{FSS} = \frac{1}{N} \sum_{i=0}^N \cos(\text{Facenet}(F_{G_i}) - \text{Facenet}(F_{GT_i})) \quad (18)$$

5) *Face Semantic Distance (FSD)*: FSD is used to measure the dissimilarity between the generated face and the real face with respect to their facial features. Regarding FSD, a lower score implies that images are more similar. The formula for determining FSD is presented in Equation 19.

$$\text{FSD} = \frac{1}{N} \sum_{i=0}^N |\text{Facenet}(F_{G_i}) - \text{Facenet}(F_{GT_i})| \quad (19)$$

Here,  $\text{Facenet}()$  indicates using a pre-trained Facenet model to extract a semantic vector of the input face.  $F_{G_i}$  is one of the generated faces,  $F_{GT_i}$  is the ground truth of the synthesized face image.  $\cos()$  indicates calculating the cosine similarity of two vectors. For calculating FSS and FSD, a pretrained VGGFace2 model provided by `facenet-pytorch`<sup>¶</sup> was used.

## C. Qualitative Results

Fig. 5 comprises images synthesized using the proposed system. The initial column denotes the input Bangla text descriptions, while the fourth column represents the corresponding translation of the stated Bangla descriptions. The images presented in the second column were produced through the utilization of the mean embedding approach of FGTD. On the other hand, the images displayed in the third column were generated by employing our proposed embedding strategy, which is elaborated in subsection IV-A. The figure presented provides clear evidence that the utilization of our proposed embedding strategy yields superior outcomes in generating accurate images that correspond to the input text. Specifically, the first, second, and fourth images of the third column accurately depict the gender as specified in the input text.

The visual representation in Fig. 6 illustrates that model-2 and model-3 have generated facial images that exhibit a degree of realism. The images generated by models 4, 5, and 6 exhibit noise and lack realism, which can be attributed to non-convergence, as noted in [27]. The potential reason for the absence of intricate features in almost all of the produced images may be attributed to the utilization of low-resolution images (solely 128x128) during the training process, coupled with the intricate structural composition of Bangla facial descriptions. Based on a visual assessment, it can be concluded that the proposed model, namely model-1, generated the most authentic and precise images. The model configuration details are presented in Table III, while their corresponding explanation can be found in subsection V-A.

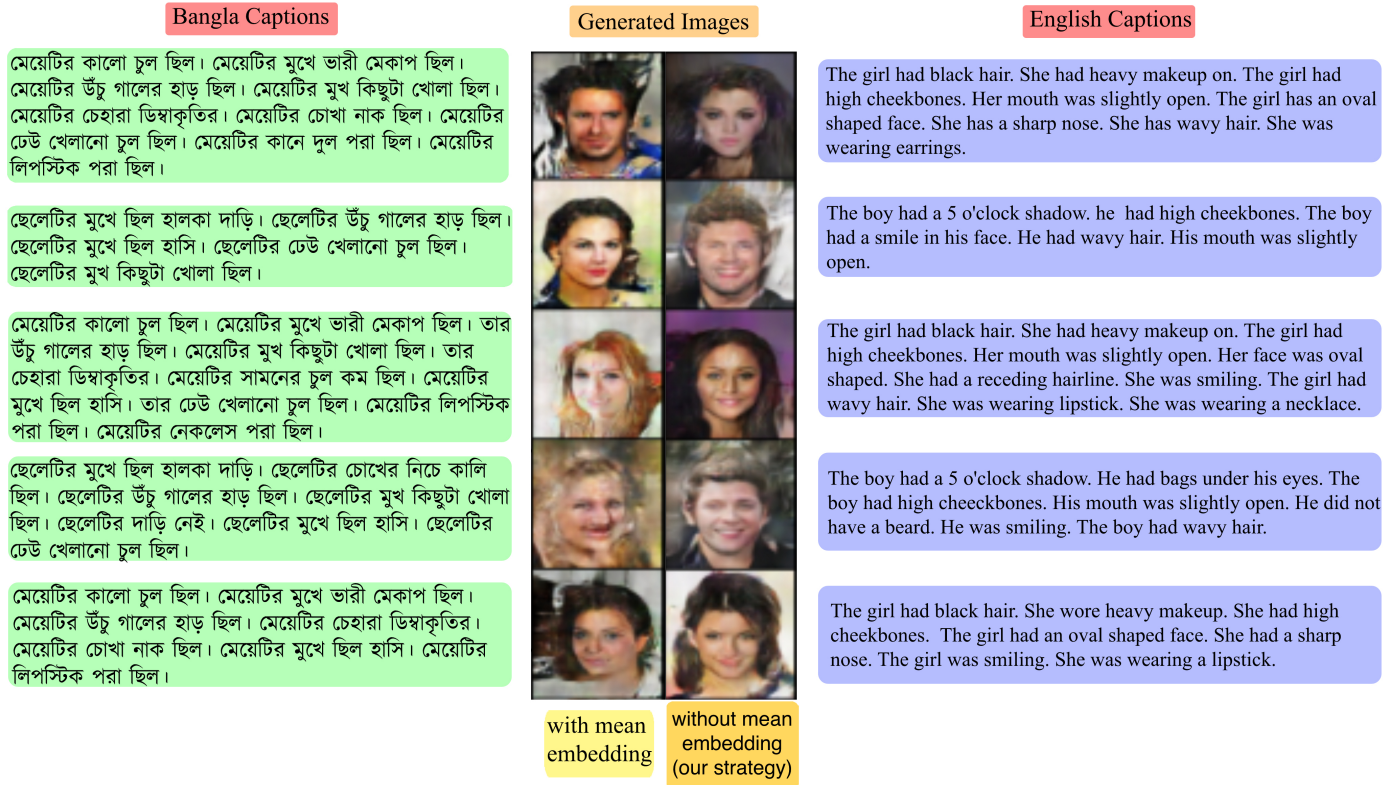

Fig. 5. Comparison of generated images between FGTD and proposed embedding strategies.

#### D. Quantitative Results

Table IV demonstrates that Model-1, which is proposed in this research, surpassed the other models in FID, Inception Score, and FSD metrics. This can be attributed to the stable training of DCGAN and the rich sentence embeddings of Bangla FastText. However, Model-7 shows moderate improvement in LPIPS and FSS performance metrics due to its matching-aware gradient penalty policy [16]. Nonetheless, the proposed model has a better overall performance.

TABLE IV. PERFORMANCE ANALYSIS AMONG DIFFERENT MODELS AND OUR PROPOSED MODEL

Experimental Models	FID ↓	IS ↑	LPIPS ↓	FSD ↓	FSS ↑
<b>Model-1 (Proposed system)</b>	<b>126.71</b>	<b>12.361</b>	21.8291	<b>20.23</b>	0.343
Model-2	165.87	11.676	21.6	20.35	0.34
Model-3	145.36	7.82	26.6	22.3	0.25
Model-4	184.17	9.05	6.25	21.81	0.303
Model-5	191.26	8.76	7.11	20.28	0.272
Model-6	210.93	8.28	6.6	21.93	0.233
Model-7	155.16	4.78	<b>3.22</b>	20.37	<b>0.42</b>

Bangla FastText performed better compared to sbnltk sentence transformer likely due to its robust pretraining procedure. Furthermore, it can be observed from Fig. 8 that the utilization of the proposed embedding strategy results in a superior FID score. The performance of our models is less significant in comparison to the state-of-the-art English text-to-face models,

which can be caused by the intricate nature of Bangla textual descriptions. The FID score graph presented in Fig. 7 indicates that the proposed DCGAN+Bangla FastText method exhibits superior performance.

## VI. DISCUSSION

It is clear from Fig. 9 that Both DCGAN and SAGAN suffered from non-convergence [27]. After about 47 epochs, DFGAN fell into mode collapse. Moreover, None of our models reached Nash equilibrium [27]. The last blocks of both generator and discriminator were omitted in the implementation of DFGAN in FGTD [1]; which may have made DFGAN more prone to mode collapse [27] and unstable training [27]. Although Transformer based models generally perform better than FastText-based models, Bangla FastText [2] performs better than sbnltk sentence transformer due to the superior training dataset, hyperparameter tuning, and preprocessing strategy used in Bangla FastText.

## VII. LIMITATIONS OF OUR WORK

The quality of the generated images is low due to the proposed system's inability to map the text space to the generated facial image space accurately. Larger GAN architectures are relatively more capable of generating more realistic images. Further research can be done by employing such architectures to enhance the results of Bangla text-to-face synthesis.

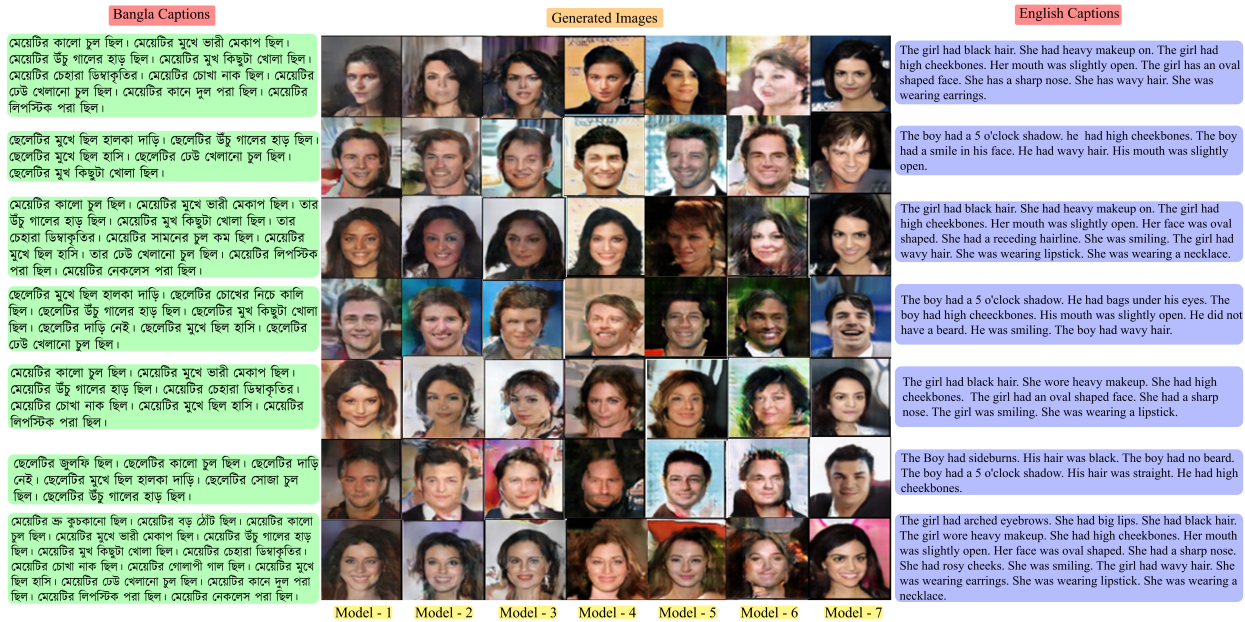

Fig. 6. Comparison of generated images among various experimental models.

Fig. 7. Comparison of FID between our proposed model and other models considering FID.

Fig. 8. Comparison of FID scores between FGTD [1] and our proposed embedding strategies.

### VIII. CONCLUSION

This study presents a new approach that employs DCGAN + Bangla FastText to produce facial images based on textual descriptions in the Bangla language. A comprehensive performance comparison is provided between our proposed model and various utilizations of DCGAN, SAGAN, and DFGAN models in conjunction with Bangla FastText, sbnlk sentence transformer hd and sbnlk sentence transformer gd pre-trained Bangla text encoders. Furthermore, a new textual embedding approach is suggested. The superiority of the suggested embedding approach is established through both qualitative and quantitative results. The models presented in

Table III were trained and evaluated using the CelebA Bangla dataset that is proposed in this research. The evaluation of generated face images involves the utilization of five distinct performance metrics, specifically FID, IS, LPIPS, FSS, and FSD. The study revealed that among all the models tested, the proposed model (DCGAN + Bangla FastText) exhibited the highest performance, attaining a FID, IS and FSD score of 126.71, 12.361 and 20.23 respectively. The proposed system's performance is moderate, likely due to the intricate structure of textual descriptions in the Bangla language. The use of diffusion models, variational autoencoders, pre-trained GANs, generating higher resolution images (256x256, 512x512, or

Fig. 9. Losses at different epochs of our experimental models.

1024x1024) in conjunction with large pre-trained language models can be investigated in future research for the task of Bangla text-to-face synthesis.

#### ACKNOWLEDGMENT

We are grateful to the Institute of Energy, Environment, Research, and Development (IEERD, UAP) and the University of Asia Pacific for their financial support.

# Microbial Biomarkers Identification for Human Gut Disease Prediction using Microbial Interaction Network Embedded Deep Learning

Anushka Sivakumar, Syama K, J. Angel Arul Jothi  
Department of Computer Science, Birla Institute of Technology  
and Science Pilani, Dubai Campus, Dubai, UAE

**Abstract**—Human gut microorganisms are crucial in regulating the immune system. Disruption of the healthy relationship between the gut microbiota and gut epithelial cells leads to the development of diseases. Inflammatory Bowel Disease (IBD) and Colorectal Cancer (CRC) are gut-related disorders with complex pathophysiological mechanisms. With the massive availability of microbiome data, computer-aided microbial biomarker discovery for IBD and CRC is becoming common. However, microbial interactions were not considered by many of the existing biomarker identification methods. Hence, in this study, we aim to construct a microbial interaction network (MIN). The MIN accounts for the associations formed and interactions among microbes and hosts. This work explores graph embedding feature selection through the construction of a sparse MIN using MAGMA embedded into a deep feedforward neural network (DFNN). This aims to reduce dimensionality and select prominent features that form the disease biomarkers. The selected features are passed through a deep forest classifier for disease prediction. The proposed methodology is experimentally cross-validated (5-fold) with different classifiers, existing works, and different models of MIN embedded in DFNN for the IBD and CRC datasets. Also, the selected biomarkers are verified against biological studies for the IBD and CRC datasets. The highest achieved AUC, accuracy, and f1-score are 0.863, 0.839, and 0.897, respectively, for the IBD dataset and 0.837, 0.768, and 0.757, respectively, for the CRC dataset. As observed, the proposed method is successful in selecting a subset of informative and prominent biomarkers for IBD and CRC.

**Keywords**—Biomarker discovery; microbial interaction network; graph embedding feature selection; inflammatory bowel disease; colorectal cancer

## I. INTRODUCTION

The human gut microbiome represents a complex community of trillions of microorganisms, some of which are well known to affect general health. With rapid mutations and a rise in resistance, there is a disruption in the steady relationship between the microbiome and body cells, which can be linked to several diseases [1]. Metagenomics, broadly, is the study of the structure and function of the genetic material of organisms extracted from multiple environmental samples. The metagenomic data presents each sample with its microbial taxonomic composition. Microbiome-wide association studies (MWAS) on the metagenomic data help identify the disease-associated microbial biomarkers. These biomarkers assist in the early diagnosis of diseases, and the development of treatment.

While there is a steady increase in the available and accessible data, the interpretation of the biological data is becoming considerably slower. Machine Learning (ML) tools can be used

to handle, organize and extract meaningful information from unorganized biological data in an efficient manner. Recently, even deep learning methodologies have garnered attention especially due to their learning capabilities and abilities to identify specific patterns directly from the data, thus avoiding manual feature engineering.

As ML continues to be widely used for biomarker identification and classification of disease; a higher accuracy of identified biomarkers will lead to higher accuracy of disease prediction. But, the biggest challenge faced is the high dimensionality of the metagenomics data, coupled with low sample size. The high dimensionality in the metagenomics dataset is represented by the large number of features which are the taxa of microbes.

Feature selection is the process of reducing the number of input variables by selecting informative features. This benefits classification models to predict more accurately since there exist fewer misleading features. It helps in improving performance, and reducing the computational load and cost of the model. It also helps by minimizing training time, and overfitting due to the reduction in noisy data. Above all, feature selection methods play an important role in identifying the subset taxa in the metagenomics dataset that form the set of potential biomarkers.

The main drawback of some of the well-known feature selection mechanisms is the fact that they do not take into consideration the interaction and the effect of interaction between the features (taxa) [2]. However, in the case of microbial communities, their structure and functions are heavily dependent on ecological interactions and microbial relationships (such as mutual, competition, synergism, etc.) in various environments making it a crucial factor to be taken into account when dealing with selecting appropriate features (biomarkers) with highest predictive influence [3]. By understanding microbial interactions, an insight into the dynamic properties of microbes and their functions are obtained [4]. Microbial Interaction Networks (MIN) are graph-based interaction networks that map the relationship and association between the gut microbes (features). Studies have shown that by embedding the resultant MIN into a neural network, the high-dimensionality vector can be mapped to a low-dimensionality vector. Moreover, this retains relevant information about the topology thereby improving the reliability of the network and facilitating the extraction of prominent biomarkers [5].

Inflammatory Bowel Disease (IBD) results from the interaction between environmental and genetic factors that influence immune response [6]. There are two major diseases that come under the umbrella of IBD namely, Ulcerative Colitis (UC) and Crohn's Disease (CD). Colorectal Cancer (CRC) is the second deadliest form of cancer arising from the mutation of specific genes [7]. Both IBD and CRC cause disruption and inflammation of the digestive system, and can lead to multiple symptoms. Since the etiology of IBD and CRC is not fully understood and symptoms are complex, the design of new tools that make use of the available human gut metagenome data is essential for their diagnosis [8], [9]. Hence, the metagenomic analysis of the human gut microbiome helps to illuminate disease development mechanisms [9].

The objective of this paper is to extract and identify the biomarkers for IBD and CRC by constructing an MIN. The feature selection is done by embedding the MIN into a graph using a graph embedding technique in conjunction with a Deep Feedforward Neural Network (DFNN) model to calculate feature importance scores. This feature importance score is used to rank the features on the basis of how informative it is for the prediction of the presence of the disease. The proposed method for feature selection allows for capturing the ecological topology of the microbial community and generating a subset of the top features which form the set of meaningful biomarkers for the disease dataset.

All things considered, the proposed framework puts forward the following contributions.

- 1) Construction of an MIN using MAGMA to capture the interactions and associations between microbes in a microbial community.
- 2) A graph-embedding neural network architecture with a MIN embedded in the neural network forms a sparsely connected first hidden layer. The model performs feature scoring to rank the features (taxa) during training.
- 3) The efficiency of the proposed framework is studied by applying it to two different real disease datasets of IBD, and CRC and classifying using Deep Forest (DF) classifier. The results of the proposed method are compared against other embedded MIN construction models and existing works with various classifiers.
- 4) Also, the biomarkers obtained as a result of the model training and feature scoring from MAGMA+DFNN feature selection technique is cross validated with biological studies on IBD and CRC.

The paper has been organized as follows. Section II performs a literary review of various proposed works that focus on feature selection algorithms and biomarker identification techniques. The proposed methodology, and the dataset used is elaborated upon in Section III. Section IV elucidates the details of the implementation, and the evaluation criteria of the experiments. Section V details the findings of the experiment and Section VI includes a discussion segment. Finally, Section VII concludes the paper with the closing remarks.

## II. RELATED WORKS

The MWAS are not only required to conduct metagenomic sample classification tasks but also feature selection tasks. Numerous studies have been conducted on effective and efficient feature selection, and biomarker identification techniques.

This review aims to analyze the various feature selection algorithms and methodologies for biomarker identification implemented on different datasets, and identify the advantages and disadvantages of each which help to guide this work. Based on the objective of this work the literature review is divided into two sections: feature selection algorithms, and biomarker identification for human diseases.

### A. Feature Selection Algorithms

Fleuret proposed "Fast Conditional Mutual Information Maximization (CMIM)", an algorithm for a fast and reliable feature selection technique based on conditional mutual information. The algorithm reduced computational overhead by computing CMIM between the feature and class given the most recently picked feature. This method calculated the entropy based on probabilistic and histogram methods. It made use of a partial score and updated the score only if the best one found so far in the iteration was not better. This feature selection method outperformed other classical algorithms and had a decently low error rate, working well for noisy data. In combination with well-known classifiers, this feature selection method ranked high in terms of low error rates and high speed [10].

Yu and Liu proposed a novel concept of predominant correlation and introduced a fast feature selection algorithm Fast Correlation Based Filter (FCBF). The aim was to select features by using information gain to calculate the symmetric uncertainty as its main selection criterion. A feature was selected and considered good only if it was predominant in predicting class and not redundant among the relevant selected features. The algorithm was put through C4.5 and Naïve Bayes Classifier (NBC) and reported high average accuracy when compared with other feature selection techniques. It was computationally efficient and fast, with less computational time complexity, and achieved high levels of dimensionality reduction [11].

Ding and Peng proposed a feature selection method that can reduce redundancy in chosen features, while selecting features having a more balanced coverage of the feature characteristics. A basic heuristic algorithm was used. For discrete variables, it was based on mutual information while for continuous variables, it was based on F-statistic. The selected features were put through classifiers such as NBC, Linear Discriminant Analysis (LDA), and Support Vector Machine (SVM), Logistic regression was used for the comparison in terms of error reduction between the baseline features and features selected by Minimum Redundancy Maximum Relevance (MRMR) [12].

Alshawaqfeh et al. created a novel hybrid feature selection method that combined the speed of filter methods with the accuracy of wrapper methods. The hybrid method performed feature importance scoring using a filter method i.e. ratio of Between group Sum-of-Squares (BSS) and Within group Sum-of-Squares (WSS). On the selected features, a wrapper method was applied by employing an embedded Nearest

Centroid Classifier (NCC) with a forward sequential search. The resulting model showed improved performance in terms of execution time as well as classifier accuracy in comparison with other feature selection techniques [13].

### B. Biomarker Identification Techniques

Zhu et al. proposed a method for the identification of microbial biomarkers via the use of Graph Embedding Feed Forward Neural Networks (GEDFN). The aim was to reduce overfitting and noise, and to construct a reliable neural network with the ability to simultaneously assign feature importance scores for feature selection while performing accurate classification. The model made use of a modified weights initializer to perform graph embedding in the first hidden layer of the network. The dot product of the weights was done with the adjacency matrix created by the amalgamation of the resulting matrix from the Maximal Information Coefficient (MIC), MINs: SparCC, and Spiec-Easi. MIC is a statistic method that identifies relationships between pairs of variables by measuring the dependence for two-variable relationships [14]. The resulting model showed improved performance in terms of Area Under Curve (AUC) score, and classifier accuracy, when compared with state-of-the-art classifiers [4].

Abbas et al. proposed a method to identify reliable microbial biomarkers from metagenomics data for IBD using network-based feature selection. The solution was based on hybrid feature selection and incorporated ecological microbial network construction of healthy samples and IBD samples. The tools used for network construction included SparCC, Meinshausen and Bühlmann (MB), CoNet, Proxi, and Random Matrix Theory (RMT). The importance scores were calculated based on network topology and a node resilience clustering algorithm. The hybrid solution suggested combining the features selected by Random Forest Feature Importance (RFFI) and instances of the best-performing network-based feature selection framework. The selected features were fed to a Random Forest (RF) classifier, and evaluation was done based on a comparison of the AUC scores obtained. Overall, the RF classifiers using the hybrid feature selection network outperformed its counterparts [15].

Bakir-Gungor et al. aimed to increase Type 2 Diabetes (T2D) diagnostic accuracy by developing a classification model using metagenomics data. Additionally, the goal was to discover T2D biomarkers. Feature selection was done using well-known variable selection techniques such as CMIM, MRMR, Correlation Based Filter (CBF), and SelectKBest. These features were then fed to RF classifiers which yielded highly promising performances. Further, K-means clustering was applied to the selected features to generate subgroups for visualization and outputs. 15 features were commonly identified by all feature selection methods and were able to cover a large portion of important features from the samples with comparable performance with respect to the best results [16].

Acharjee et al. aimed at analyzing stable RF based feature selection methods for the identification of biomarkers and power analysis. A number of RF based feature selection methods were compared against one another and the resulting features were tested in a regression, as well as a classification

model for power analysis of the models. Overall, the Boruta method yielded the best stability with high specificity and best prediction ability among all the methods [17].

Bakir-Gungor et al. made use of ML algorithms to be able to generate a classification model to aid IBD diagnosis, discover the potential biomarkers for IBD, and identify IBD patient subgroups. First, feature selection was conducted using well-known feature selection techniques, namely FCBF, CMIM, MRMR, and XGBoost. Their performance was verified using classifiers such as RF, Decision trees, Logiboost, AdaBoost, K-means + Logiboost, and SVM. Finally, using unsupervised learning methods such as K-means clustering, hierarchical clustering, and Principal Component Analysis (PCA), visualizations, and outputs were achieved. Promising results were seen in terms of performance and predictive power, especially by the union of feature selection methods and K-means + logiboost classifier, as well as, XGBoost feature selection and K-means + logiboost classifier [8].

Zhu et al. aimed at creating a stable and robust model, Deep-Forest, for MWAS along with ensemble feature selection for biomarker identification. The ensemble feature selection method aggregated multiple different feature selectors through linear combinations of the subsets to form the final result. The features were put through Deep-Forest which is an ensemble learning model consisting of 8 random forests. The proposed model was compared against other feature selection methods and classifiers and achieved the best results among all three datasets [18].

From the literature review, it could be noted that the methods reviewed either fail to capture the ecological interaction between the microbial community for an MWAS dataset or are computationally expensive. The proposed methodology in this work emphasizes the underlying biological process, especially through the inclusion of covariates during feature selection which enables the identification of a subset of meaningful biomarkers for disease diagnosis.

Table I provides a summary of various feature selection algorithms and Table II summarizes the previous work on biomarker identification for human diseases.

## III. METHODOLOGY

Fig. 1 illustrates the overall workflow of the methodology for the extraction and validation of potential biomarkers. Firstly, prevalence measure is applied on the original dataset to generate a reduced dataset. Secondly, the MIN is constructed using the network construction tool MAGMA [19]. Thirdly, the resulting network (adjacency matrix) is embedded into a deep neural network using graph embedding (DFNN). Then, feature importance scoring is done via the DFNN model resulting in the selection of the subset of the top-scoring features which form the set of disease biomarkers. Finally, the top features are classified using DF for performance evaluation.

### A. Dataset

This paper has focused on the use of two real datasets, one on IBD and the other on CRC. For both datasets, the taxonomy classification is done against the Greengenes database and the

TABLE II. SUMMARY OF WORKS ON BIOMARKER IDENTIFICATION

Ref	Dataset	Methodology	Advantage	Disadvantage	Results
[4]	IBD QITA (study id: 1939) dataset with a total of 1,359 metagenomic samples. Final dataset consisted of 657 IBD samples and 316 normal samples.	Network construction: SparCC + Spiece-Easi Feature selection: MIN + MIC Feature Importance+classification: GEDFN	Improve the reliability of the network by embedding prior knowledge Effectively reducing noise and overfitting and dodging compositionality bias.	SparCC is computationally expensive. There were no relevant guidance suggestions for the threshold of the association networks.No neuron threshold was considered.	AUC: 0.843, Accuracy: 79.52%
[15]	IBD QITA (study id: 1939) dataset with a total of 1,359 metagenomic samples. The final dataset consisted of 657 IBD samples and 316 normal samples.	Network construction: SparCC, MB (Spiece-Easi), RMT, CoNet, and Proxi. Feature Selection: Betweenness Centrality, Closeness Centrality, Average Neighbor Degree, Clustering Coefficient, Node Clique Number, Core Number, and critical attack set- NBR-Clust. Classification: RF	Chosen feature selection method: RFFI + best instances of NBBB framework. Optimal number of features required to specify a biomarker need not be specified as fixed information. Able to achieve the best performance using a small number of samples.	The algorithm's performance on larger problems are not defined in the study.	RFFI+MB (20 features): AUC= 0.82, Accuracy=73%, Specificity=0.76, Sensitivity=0.72
[16]	T2D microbiome data from the NCBI Sequence read Archive (accession numbers SRA045646, and SRA050230). The dataset contained 290 samples with 1,455 species.	Feature selection: CMIM, MRMR,CBF,SelectKBest. K-means to generate subgroups. Classification: RF	The combined feature selection method was able to cover a large portion of important features from the samples.	Compositionality bias.	(199 common features out of 500 features) Accuracy = 73%, F1 score = 0.79, AUC = 0.73
[17]	Use of simulated dataset and 6 published datasets - lipid metabolites,lipidomic, and colorectal cancer, IBD, and adipose tissue transcriptomics- obtained from PubMed.	RF based Feature selection: Boruta, Recursive feature elimination, permutation based feature selection with and without correction, and backward elimination based feature selection. Classification: RF	Boruta has good stability in detecting potential biomarkers Power prediction while capturing complex dependencies between the covariates and the outcome.	Boruta method tends to have a higher time complexity, especially with larger, high dimensional datasets.	Minimum Classification Error rates - Boruta Simulated dataset: 3%, metabolics dataset: 2%, colorectal cancer: 4.23%, IBD: 5%, adipose tissue:10%
[8]	Raw microbiome DNA sequencing data of 148 IBD patients, 234 control patients were obtained from the MetaHit project.	i) Feature selection: FCBF, CMIM, mRMR, and XGBoost. Subgroups: K-means, PCA, hierarchical clustering. ii) Classification: RF, Decision trees, Logitboost, AdaBoost, K-means + Logitboost, and SVM.	XGBoost feature selection achieves minimal diagnostic markers with large effect size	Compositionality bias	The union of the features with K-means and logitboost : Accuracy=91.623%, AUC=0.933, F1-score 0.89
[18]	Three different datasets for Cirrhosis of 144 patients and 118 healthy subjects, Type 2 Diabetes of 170 patients and 174 healthy samples, and Obesity of 89 patients and 164 healthy samples are obtained from MetAML package.	Feature selection + Classification: Deep Forest (data perturbation method for feature selection)	Good stability in detecting potential biomarkers Power prediction while capturing complex dependencies between the covariates and the outcome.	The prediction using layers of RF can be time-consuming due to the nature of RF.	Cirrhosis: accuracy=82.57%, AUC=0.939 Obesity: Accuracy= 67.09%, AUC=0.749 T2D: Accuracy=64.71%, AUC=0.623

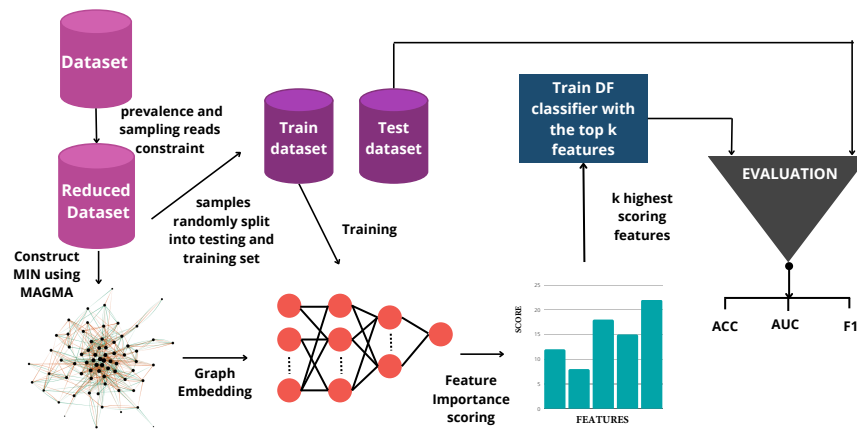

Fig. 1. Flowchart of the methodology.

comprehensive dataset is simplified in the form of an OTU table. The common structure of the OTU table consists of the number of samples in rows and the corresponding species-specific taxa that are found in the sample in the columns in a matrix format.

The IBD dataset has been procured from an online repository [20]. The original data for the IBD dataset is derived from the QIIME database under Study ID 2516 for all the proposed techniques. The dataset consisted of a total of 1359 samples out of which 336 are healthy, and 1023 are infected samples with a total of 9511 species.

The CRC dataset has been procured from an online repository [21]. The original data for the CRC (CRC1) dataset is derived from Zeller et al.'s [22] study. The dataset consisted of 182 samples out of which 90 are cancer samples and 92 are normal samples with a total of 18,170 species.

### B. Reduced Dataset

The number of taxa in the data set was reduced according to the percentage prevalence of the microbe in the samples. The number of samples is reduced by removing the samples whose sequencing depth is less than 500 reads on the remaining OTUs (sampling reads threshold). The reduced dataset is generated to reduce feature dimension and remove features that may be redundant, irrelevant, or have low impact on the sample.

For the IBD dataset, upon setting a 10% prevalence threshold and 500 sampling reads threshold, the resulting dataset contains 1359 samples and 1032 features. For the CRC dataset, upon setting a 15% prevalence threshold and 500 sampling reads threshold, the resulting dataset contains 182 samples and 1260 features. The reduced datasets are then split into an 80% training set and a 20% testing set.

### C. Construction of MIN

1) *Microbial interaction networks*: Most microorganisms do not live in isolation and thrive in communities while forming interactions and establishing ecological relationships. These ecological interactions and relationships shape microbial abundances [3]. Detection of significant undirected associations between sample populations enables the inference of

their interactions. By constructing MINs, the use of statistical methods that utilize relative data which are not independent and reflect the compositional nature of the data rather than the underlying biological process [23], is avoided. Thereby, by making use of absolute abundance data, compositionality bias is addressed. By exploring the structure and diversity, comprehensive and statistically significant associations between taxa can be achieved. Using this information, the interplay between the environment and microbial populations can be predictively modeled as a network. The edge between two nodes, which represent taxa, denotes that the connected nodes provide some type of relational additional information about the state of the other and that they are not conditionally independent [24].

Some popular MIN construction methods include SparCC [23], Spiec-Easi [24], CoNet [25], MAGMA [19], and Proxi [26]. SparCC enables the estimation of correlation values by having a mathematical model based on the calculation of log ratios. The dependencies are described using the variance between the variables [23]. Spiec-Easi makes use of the statistical method of conditional independence and covariance matrix for inference of graph-based MIN [24]. CoNet combines an ensemble method of similarity or dissimilarity measures with a permutation-renormalization bootstrap method to generate an association network [25]. MAGMA constructs the MIN based on a Gaussian copula mathematical model to graph the interaction between variables [19]. Proxi makes use of nearest-neighbor distances based on Pearson's Correlation to generate proximity graphs [26]. Among these methods, this work uses MAGMA to construct the MIN.

2) *MAGMA*: Cougal et al. proposed a method Microbial Association Graphical Model Analysis (MAGMA) for the construction of MIN.

MAGMA is able to account for data flaws such as noisy structure, overdispersion, and zero-count values, and can also handle compositionality bias. Its main working principle is based on the Gaussian copula model coupled with a generalized linear model to achieve mapping of the estimation of latent data by median values. The data is filtered to ensure that sample reads and the prevalence measure of each feature are above a particular threshold. The zero values in the data are handled by the use of a zero-inflated distribution executed

by the parametric mapping function and the overdispersion is tackled by modeling a negative binomial distribution. Additionally, the sequencing depth is modeled as a variable number by accounting for compositionality by an offset. The main feature of MAGMA is that it integrates covariates (characteristics of the participating variable) which improves the quality of inference of the categorical variables. The covariates are modeled over the mean of microbial abundances.

In this work, the dataset (Section 3.1) in the form of an Operational Taxonomic Unit (OTU) table containing  $f$  features and  $N$  samples, is presented as input to the MAGMA algorithm and the sparse precision matrix is estimated. The resulting precision matrix or inverse covariance matrix is the resulting network in the form of an adjacency matrix and is given by equation 1.

$$A = \begin{cases} 1 & \text{if, edge between nodes } n_i \text{ and } n_j \forall i, j \in \{1, \dots, f\} \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

The main advantages of this network construction method are that the graphical models have minimum bias, and the model takes covariates into consideration which are important to account for any confounding in inference and beneficial in recovering the network structure. Additionally, the inference quality improves leading to fewer spurious correlations. More details on the algorithm can be found in [19].

#### D. Graph Embedding using Deep Feedforward Neural Network

1) *Overview*: Zhu et al. proposed a method to perform graph embedding feature selection by constructing a neural network that would simultaneously assign feature importance scores to the input variables while training to classify. Wrapper methods lack the capability of good generalization over classifiers and filter methods, since they are based on a discriminative methodology of eliminating features, and are independent of any ML algorithms, they are unable to find a truly optimal subset [27]. Graph embedding techniques, on the other hand, aptly represent the high dimensional vector representation of discrete variables in low dimensions while preserving relevant information like the topology of the graph and the relationship between nodes [28]. It combines the method of feature selection by importance and also feature extraction - mapping higher dimensions to lower dimension vectors - into the optimizing training step of the ML model [29]. Using this method, this paper aims to reduce overfitting, and noise and to embed priori knowledge into the neural network which would help improve the reliability of the network [4].

2) *Deep feedforward neural network architecture*: Fig. 2 depicts the model architecture of the neural network composed of an input layer, four hidden layers, and an output layer. Each neuron in the input layer corresponds to every feature or taxa, the first hidden layer corresponds to the graph embedding layer, and the output layer corresponds to the class label for the sample after prediction. The second hidden layer is composed of 128 neurons, the third layer is composed of 32 neurons and the fourth layer is composed of 8 neurons. The model has a learning rate of 0.0001 and utilizes the Adam optimizer for gradient descent. Other model hyperparameters include

Rectified Linear Unit (ReLU) activation function applied to the hidden layers and the Sigmoid activation function applied to the output layer, and a dropout of 0.5 applied to all the hidden layers except the first graph embedding hidden layer.

3) *Graph embedding*: After the MIN is constructed, the network is represented in the form of an adjacency matrix where an edge between two nodes is depicted with 1 if exists, else 0. The resulting matrix is then used as input to the graph embedding layer, the first hidden layer in the neural network. It generates a sparsely connected layer in contrast to the traditionally fully connected layers. The sparse layer is generated by performing element-wise dot product between the calculated weights and the adjacency matrix received from network construction as seen in equation 2. The dot product is used as the kernel constraint.

$$\begin{bmatrix} w_1 & w_2 & \dots & w_i \\ \vdots & \vdots & \vdots & \vdots \\ w_{i(i-1)} & \dots & \dots & w_{i*i} \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \dots & \dots & 1 \end{bmatrix} = \begin{bmatrix} w_1 & w_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \dots & \dots & w_{i*i} \end{bmatrix} \quad (2)$$

$i$  = number of features

Input: weights matrix  $w$ , and adjacency matrix  $a$

Output: modified weights matrix  $w'(w_{in})$

The neurons in the first layer ( $L_1$ ) can be represented as given in equation 3 where  $X$  is the input matrix ( $n\_samples \times i\_features$ ),  $b$  denotes the initialized bias parameter, and  $\sigma$  is the activation function.

$$L_1 = \sigma(w'X + b) \quad (3)$$

#### E. Feature Importance Scoring

The feature importance score is given on the basis of the graphical connect weight method. The relative importance of each feature is scored on the basis of the sum of absolute values of the weights directly related to that feature or neuron as represented in equation 4, and 5 [4].

$$s_j = \gamma_j \sum_{k=1}^i |w_{kj}^{(in)} I(a_{kj} = 1)| + \sum_{l=1}^{h_1} |w_{jl}^{(1)}| \quad (4)$$

$$\gamma_j = \min \left( \frac{c}{\sum_{k=1}^i (a_{kj} = 1)}, 1 \right), j = 1, \dots, i \quad (5)$$

where  $s_j$  is the score of the  $j_{th}$  feature and  $w$  denotes the weight of the layer,  $w_{(in)}$  for the input layer,  $w_{(1)}$  for the weight between the first and second layer, and  $c$  denotes the penalty score for vertices with many edges. The weights are updated using a backpropagation algorithm that calculates the gradient based on the backward flow of the static cost function that was calculated by the feedforward network [4].

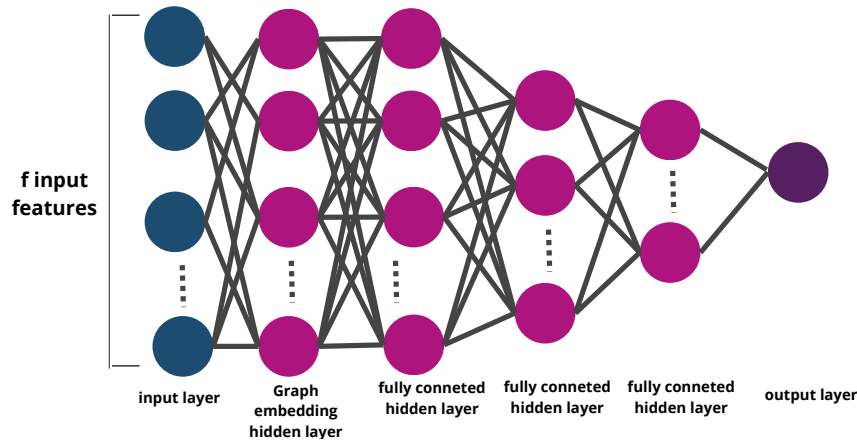

Fig. 2. DFNN architecture model.

### F. Deep Forest Classifier

Deep Forest is an ensemble learning model based on a cascading structure of decision trees. The ensemble model can generally achieve better generalization performance than single classifiers and the cascading structure enables the representation learning by the forests [18]. The DF's performance is quite robust to hyper-parameter settings and it can reach a deeper layer through layer-wise learning in the classification task compared to other traditional ML models [30].

## IV. IMPLEMENTATION, EVALUATION, AND EXPERIMENTS

### A. Implementation

The microbial network construction tool was implemented using the MAGMA package [31] in R. The neural network was modeled in Python v3.7 with the help of additional frameworks and libraries such as keras v2.8.0 and tensorflow v2.8.2, numpy, pandas, and Scikit-learn. All codes were run on Intel(R) Xeon(R) CPU @ 2.20GHz in Google Colab. The Python 3 Google Compute Engine backend was used for the Python codes and the ir Google Compute Engine backend was used for R codes. 12.7GB System RAM and 107.7GB disk space was allocated on Google colab.

### B. Evaluation

To evaluate model efficiency, statistical measures such as Accuracy, F1 score, and AUC were measured. True Positive (TP) represents the number of positive samples predicted correctly, True Negative (TN) represents the number of negative samples predicted correctly, False Positive (FP) represents the number of negative samples predicted incorrectly, and False Negative (FN) represents the number of negative samples predicted incorrectly.

Accuracy (equation 6) is used to measure the total number of correct predictions out of all observations.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

The F1 score (equation 9) is the harmonic mean of Recall (equation 7) and Precision (equation 8) and is used as a statistical measure to rate the overall performance of classification.

$$Recall(Sensitivity) = \frac{TP}{TP + FN} \quad (7)$$

$$Precision = \frac{TP}{TP + FP} \quad (8)$$

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall} \quad (9)$$

AUC is used to quantify the capability a model has in distinguishing between classes. It calculates the area under the curve made of points formed by calculating the True Positive vs the False Positive value at different thresholds. The higher the AUC score, the better the model is at accurate prediction.

### C. Experiments

In order to evaluate and establish the superiority of the proposed model in terms of feature selection, the following different models of MIN embedded in DFNN were developed.

- 1) The proposed method: Constructing the MIN using MAGMA, embedding it using DFNN to obtain the reduced features (MAGMA+DFNN), and classifying the reduced features using DF.
- 2) Constructing the MIN using SparCC, embedding it using DFNN to obtain the reduced features (SparCC+DFNN).
- 3) Constructing the MIN using Spiec-Easi, embedding it using DFNN to obtain the reduced features (Spiec-Easi+DFNN).
- 4) Constructing the MIN using SparCC and Spiec-Easi, and combining that with the network constructed using MIC, embedding it using DFNN to obtain the reduced features ((SparCC+Spiec-Easi+MIC)+DFNN).

The top k features were chosen from each of the above methods. In this work, we experimented by varying the value of k in [100, 200, 300, 400, 500]. The selected features were then put through selected classifiers like Support Vector Machine (SVM), DF, Random Forest (RF), Multi-Layer Perceptron (MLP), and XGBoost (XGB) for evaluation. Python's scikitlearn package with default settings was applied for the implementation of all the classifiers.

A baseline model with no feature selection was also experimented. The baseline model experiment was conducted by subjecting all the features of the IBD and CRC dataset through the classifiers for classification. The proposed methodology was experimentally analyzed against existing works on IBD and CRC datasets. Finally, the biomarkers obtained by the proposed method was verified against biological studies of IBD and CRC datasets. All the experiments were performed using 5-fold cross validation.

## V. RESULTS

### A. Comparative Results

In this section, the classification performance of the proposed model and other MIN construction models for feature selection over different classifiers such as RF, DF, SVM, MLP, and XGB is compared. The results are presented in terms of the evaluation metrics AUC, Accuracy, and F1 scores across all the five classifiers.

1) *IBD*: Table III presents the findings for the result obtained after the experiments for the IBD dataset. Table IIIa presents the performance across classifiers for the baseline with no feature selection applied on the dataset. As noted from the table, the maximum AUC of 0.855, highest accuracy of 0.829, and F1 score of 0.89 were resulted with the DF classifier. Table IIIb presents the results for MAGMA+DFNN feature selection technique. As noted from the table, the highest AUC, accuracy, and F1 score is 0.863, 0.839, and 0.897, respectively when classified using the DF classifier with the top 300 features. Table IIIc tabulates the results for (SparCC+Spiec-Easi+MIC)+DFNN feature selection technique. As noted from the table, the best AUC score of 0.85 was obtained using XGB with 300 features, accuracy of 0.832 using DF with 300 features, and an F1 score of 0.892 using DF with 400 features. Table III d presents the results for Spiec-Easi+DFNN feature selection method. The feature selection and classification method resulted in an AUC of 0.849 using RF with 400 features, an accuracy of 0.819, and an F1 score of 0.884 when using DF with 200 features. Table IIIe shows the results for SparCC+DFNN feature selection method. As seen from the table, the maximum values for AUC is 0.858 for 300 features, for accuracy is 0.824 for 100 features, and for F1-score is 0.889 for 500 features all with the DF classifier.

The results obtained by the proposed method (MAGMA+DFNN), put through all the classifiers (SVM, RF, MLP, DF, XGB) for different numbers of features are illustrated in Fig. 3. Additionally, the final results comparing the feature selection techniques tested using the different classifiers in terms of AUC, accuracy, and F1-score as detailed in Table III is illustrated by Fig. 4.

2) *CRC*: Table IV presents the findings for the result obtained after the experiments. Table IVa presents the evaluation metrics AUC, accuracy, and F1 scores across classifiers for the baseline with no feature selection applied. As noted from the table, the maximum AUC is 0.801 with RF, and highest accuracy is 0.746 and F1 score is 0.89 with the DF classifier. Table IVb presents the results for MAGMA+DFNN feature selection technique. It achieved the highest AUC, accuracy, and F1 score of all findings of 0.837, 0.768, and 0.757, respectively when classified using the DF classifier with the

top 400 features selected as highlighted in bold. Table IVc tabulates the results for (SparCC+Spiec-Easi+MIC)+DFNN feature selection technique. It achieved an AUC of 0.808 with RF for 300 features, an accuracy of 0.735 and F1 score of 0.742 with RF for 200 features. Table IVd presents the results for Spiec-Easi+DFNN feature selection method. The feature selection and classification method achieved an AUC of 0.803, an accuracy of 0.735, and an F1 score of 0.729 with RF for 500 features, 400 features and 400 features respectively. Table IVe shows the results for SparCC+DFNN feature selection method. It resulted in an AUC of 0.815 with DF for 400 features, an accuracy of 0.724 and an F1-score of 0.752 with SVM for 200 features.

The results obtained by the proposed method (MAGMA+DFNN), put through all the classifiers (SVM, RF, MLP, DF, XGB) for different numbers of features are illustrated in Fig. 5. Additionally, the final results comparing the feature selection techniques tested using the different classifiers in terms of AUC, accuracy, and F1-score as detailed in Table IV is illustrated in Fig. 6.

### B. Comparison Against Existing Model

The proposed methodology ((MAGMA+DFNN)+DF) is compared against the model proposed in Zhu et al.s' study [4] which makes use of a combination of SparCC, and Spiec-Easi for MIN construction along with MIC for the graph network construction, and a graph embedding deep model (GEDFN) for feature extraction from both IBD and CRC datasets. The top k features, where  $k \in 100, 200, 300, 400, 500$ , were chosen and put through selected classifiers, SVM, RF, DF, MLP, and XGB. The best results were achieved by the DF classifier for both datasets and both models. The results are presented in Table V. From the table, it could be observed that, the proposed model obtained the best classification performance.

### C. Biomarker Analysis

The top features selected by the MAGMA+DFNN model were cross-validated with biological studies to determine the reliability and accuracy of the biomarkers(features) suggested for the respective disease datasets.

1) *IBD*: Upon analyzing the top 300 features selected by MAGMA+DFNN, the top-scoring taxa were found to be related to the IBD development mechanisms. The selected taxa as seen in Fig. 7 could be suggested as potential IBD-biomarkers of human gut microbiota.

The results were cross-validated with the results from two biological studies presented by Paljetak et al. [32], and Gevers et al. [33].

The biomarkers identified by MAGMA+DFNN match with the majority of the informative biomarkers identified by Gevers et al., and Paljetak et al. in their respective studies as seen from Table VI. The biomarkers highlighted in bold denote the common subset of biomarkers from the study and the top 300 features selected by the proposed model for IBD. The top and most common IBD biomarkers identified in this study include *Bacteroides*, *Bifidobacterium*, *Lachnospiraceae*, *Ruminococcaceae*, *Enterobacteriaceae*, and *Streptococcaceae* among others.

TABLE III. IBD EVALUATION RESULTS. THE MAXIMUM VALUES ARE HIGHLIGHTED IN BOLD.

## VI. DISCUSSION

Overall, the proposed solution ((MAGMA+DFNN)+DF) can capture a large characteristic space using a limited number of features and is able to identify the core potential IBD and CRC biomarkers. The downsides of this methodology include the fact that MAGMA is not extremely good at predicting very sparse networks with high accuracy. It is also

uncertain if the model can detect both linear and non-linear relationships. Moreover, the Gaussian copula model cannot model tail dependence which is the stronger dependence on extreme events [35].

But, in contrast to network construction tools like SparCC, MAGMA is centered around multivariate normal and does not perform pairwise associations, thereby allowing it to consider multivariate associations. It is also able to work to measure partial correlations between nodes. In comparison to state-of-the-art tools SparCC and Spiec-Easi, MAGMA showed the most tempered output and the least negative links. The spurious negative links were eliminated by taking the covariate measure into account. Embedding the suitable MIN enabled in retaining the topological structure of the network while mapping it to a low dimension and also helped to deal with overdispersion and high levels of noise in the dataset. The feature selection performance was also verified by the results of the DF classifier and comparison with biological studies. Thereby, MAGMA+DFNN can be considered as a reliable feature selection technique.

The future work, inspired by the learnings of the literature review and conducted experiments, can focus on a more thorough analysis of the construction of the MINs, and feature selection methods. The model can be improved by overcoming the aforementioned limitations of MAGMA, and incorporating and leveraging more biological information into the construction of the MIN. Additionally, the future scope includes improving the design of the neural network architecture to create a better, more precise model while dealing with the previously mentioned shortcomings for improved feature importance scoring techniques, accurate classification, and efficient and meaningful biomarker identification. Finally, as this work focuses its evaluation on smaller datasets, further efforts can be made to ensure the analysis of the methodologies on a larger, comprehensive data set.

## VII. CONCLUSION

IBD and CRC are global diseases affecting millions of humans around the world with IBD being on a steady rise and CRC being one of the most frequently maligned cancer in the world. The accurate diagnosis of these is crucial for

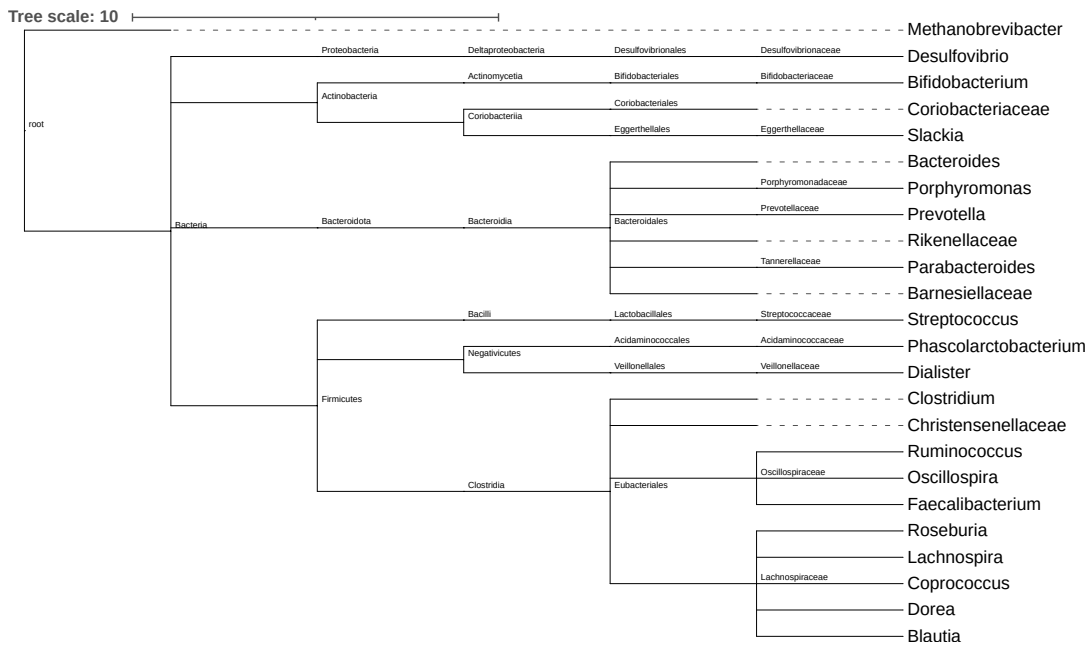

Fig. 9. Phylogenetic tree of the top 400 biomarkers selected by MAGMA+DFNN feature selection method for CRC.

Fig. 10. Venn diagram depicting the top 400 features of CRC dataset selected by each of the feature selection algorithms.

effective treatment, creating a need to identify the informative subset of microbiota by applying fitting feature selection techniques. This work utilizes the method of embedding the MIN constructed using MAMGA+DFNN as a feature selection technique to extract prominent features for the identification of potential biomarkers. Across all of the feature selection methods considered, the proposed methodology achieved the highest AUC, accuracy, and F1-score when classified using DF across both the IBD and CRC datasets. Further, upon inspecting the resulting biomarkers identified

by the proposed approach against relevant biological studies, it is validated that these microbial biomarkers have a relationship with the diagnosis of the disease. Therefore, these results could guide further experimental investigation and contribute to the diagnosis of microbiome-related diseases.

**Abstract**—Over the years, digital traces have proven to be significant for analyzing IT systems, including applications. With the persistent threats arising from the widespread proliferation of malware and the evasive techniques employed by cybercriminals, researchers and application vendors alike are concerned about finding effective solutions. In this article, we assess a hybrid approach to detecting software vulnerabilities based on analyzing traces of application execution. To accomplish this, we initially extract permissions and features from manifest files. Subsequently, we employ a tracer to extract events from each running application, utilizing a set of elements that indicate the behavior of the application. These events are then recorded in a trace. We convert these traces into features that can be utilized by machine learning algorithms. Finally, to identify vulnerable applications, we train these features using six machine learning algorithms (KNN, Random Forest, SVM, Naive Bayes, Decision Tree-CART, and MLP). The selection of these algorithms is based on the outcomes of several preliminary experiments. Our results indicate that the SVM algorithm produces the best performance, followed by Random Forest, achieving an accuracy of 98% for malware detection and 96% for benign applications. These findings demonstrate the relevance and utility of analyzing real application behavior through event analysis.

**Keywords**—Execution traces; events; vulnerability detection; malware; applications

## I. INTRODUCTION

The prevalence of malicious applications has significantly increased in recent years. Unfortunately, as digital technology continues to advance, the number of vulnerabilities in applications is also growing exponentially, thereby leaving users even more vulnerable. Since these applications handle highly personal and sensitive data, it remains a significant challenge for researchers and application providers to find effective and efficient solutions. Despite the efforts described in the existing literature to safeguard data, the threat remains very real. Moreover, in recent years, it has become even more severe as cybercriminals increasingly employ evasion techniques to bypass existing protection measures [1], [2]. Not only are the majority of available solutions limited or inadequate against the sophisticated tactics of cybercriminals, but these malicious actors are also becoming more organized and motivated [2], [3], [4], [5]. Consequently, ensuring data security and protection has become an essential and urgent concern. It is crucial, therefore, to urgently discover solutions that can minimize the exploitation of software vulnerabilities and mitigate the risk of attacks targeting user data [3], [6].

Among the techniques employed to detect malware in

recent years, machine learning has been utilized [7]. This is associated with the static approach ([8], [9]) or the dynamic approach ([1], [10], [11]), depending on the methods employed. In the literature, the hybrid approach is increasingly being utilized to leverage the advantages of both the static and dynamic approaches, thus partially mitigating the limitations inherent in each of these two approaches. As our approach involves utilizing data from the Android's manifest file for static analysis and execution traces for dynamic analysis, it can be categorized as a hybrid approach. By combining the analysis of application execution traces with machine learning techniques, we aim to enhance malware detection. Previous studies have emphasized the significance and utility of traces in monitoring computer system behavior [11], [12], [13], [14], [15].

The collected traces enable us to comprehend the functioning of a system and identify anomalies, deviations in operation, suspicious behavior, and more. Hence, traces contain pertinent and valuable information for analyzing the behavior of systems in general, as well as applications specifically during their execution. Although traces are beneficial, they are less commonly utilized for identifying malicious applications. Instead, they are typically employed for debugging, profiling, or logging purposes. This study aims to assess the hypothesis that traces of application execution are high-quality data that can be used to analyze and detect malicious applications [16]. Consequently, the solution proposed in this study is founded on capturing relevant behavioral elements (events) during application execution, based on pertinent characteristics. These events are recorded in the traces. Subsequently, the values of the behavioral features are extracted in the form of dictionary objects or converted into eigenvectors using appropriate tools for analysis with machine learning algorithms. The primary objective of this study is to effectively detect malware in order to enhance the safeguarding of private data transmitted through applications. Therefore, it presents a proactive solution that diminishes cybercriminals' attack vectors. The experimental results demonstrate the significance of execution traces in identifying software vulnerabilities. This study contributes to malware detection in the following ways:

- We present a model that effectively and efficiently identifies malware by utilizing a blend of static features (permissions and characteristics) and behavioral features (traces). The features we have selected allow us to describe the dynamic behavior of applications. Furthermore, these features are comprehensive, en-

compassing attributes extracted from the Android-Manifest file as well as features extracted during application execution.

- We have extracted five (05) relevant features to characterise the behaviour of Android applications. The numerical values of these features vary from one application to another. We use six (06) classifiers, namely Support Vector Machine (SVM), k-Nearest Neighbor (kNN), Random Forest (RF), NB, MLP and DTREE-CART, to identify malware. We compare the detection performance of these different classifiers.
- We conducted analyses on a dataset containing 8014 traces from benign and malware applications collected from Google Play (15%) and Drebin (85%). Experimental results show the effectiveness of the model with a detection accuracy of more than 98% with the SVM algorithm.

The rest of the document is structured as follows: the Section II deals with some previous studies and research into traces and vulnerability detection methods. In Section III we detail the process of collecting traces and converting them into features through trace generation, data pre-processing and feature vector formation. Section IV presents the construction of the data set and experimental setup. In addition, the results obtained will be presented in this section. We conclude the work in Section V.

## II. RELATED WORK

Over the last few years, the digital world has seen an impressive development in malicious software, which represents a major threat [3], [4]. The consequences of this malware for users are enormous. On an ongoing basis, a number of researchers have proposed methods and techniques for detecting malware in applications [7], [8], [17], [18], [10]. The aim is to improve data protection methods by reducing threats and attacks against private data. Unfortunately, their efforts are coming up against determined cybercriminals who are more innovative in their malicious behaviour [3], [2], [19], [5], [17]. They are increasingly using sophisticated techniques to bypass security solutions or evade the control systems in place. It is therefore crucial and urgent to find effective solutions to protect data. Several methods and techniques based on static and dynamic approaches are proposed [7], [19], [13], [16]. Previous works [4], [19], [16] have proposed literature reviews on both analysis approaches and their weaknesses [3], [17], on analysis techniques, [7], [20], on the use of machine learning techniques [7], [8], [17], on digital traces [11], [16]. Nevertheless, we will mention some of the work related to traces, especially as our approach is a hybrid one.

In static analysis, the source code is examined and representative features (libraries, opcodes, API calls, permissions, function calls, etc.) are extracted. In contrast to the static approach, for dynamic analysis, representative features are extracted during the execution of the application by monitoring its behaviour. Features such as system calls, file behaviour (access, create, read, modify, delete), registry access (create and modify), network traffic, are relevant data used by some authors to study application behaviour and detect malicious actions.

The authors of the works [8], [9], [10], [20], combined machine learning techniques with one or other of these approaches, depending on their methodology to improve detection. The authors Al-Hashmi et al. [10] selected several features from the extracted features and combined them with different machine learning techniques to train a model. The results obtained are encouraging with their DeepEnsemble model. Numerous other works on detecting malware in Android applications extract certain information to distinguish malicious applications from benign ones. This is the case of the work by Bassole et al. [18] and the authors [8] and [9]. These authors extracted authorisations and other functionalities as features, and combined them with machine learning methods to detect malware.

As for traces, they were used by the authors [13], [15], [14], [21], [22] and [23] in their work. The authors of the references [24], [25] [26] and [27] used traces to detect their code errors through debugging. In the studies [24] and [26], traces are used for profiling while the authors [28], [29] and [30] use them as a means of studying logging. All these techniques using traces (debugging, profiling and logging) do not provide enough information for optimal diagnosis of flaws in applications. It was in the web and network domain that the first uses of traces were useful. Hassan et al. [21] used traces to detect vulnerabilities in web sites and Zhou et al. [22], used them to analyse anomalies in TCP/IP networks. Several other studies show that traces provide more relevant results when combined with machine learning techniques [31], [32]. Studies such as that carried out by Razagallah et al. [11] show us that traces are an invaluable source of information on the execution behaviour of a program. This information can be used to detect malicious software in Android applications. The authors have therefore built up a dataset based on traces that can be exploited according to research needs.

Despite all these malware detection methods and protection measures, cybercriminals often manage to escape and exploit vulnerabilities with more sophisticated attacks. Between the repackaging of certain benign applications for malicious purposes, new families of malware, vulnerabilities (known and unknown) and inadequacies in data protection, there is a need to explore possible solutions to limit the risk of attacks.

With the ever-changing and innovative nature of malware, detection based solely on one approach or type of functionality cannot meet data protection needs. In this study, we therefore evaluate an analysis model that uses events collected during application execution to analyse the malicious behaviour of these applications (Fig. 1). This is a hybrid approach that takes advantage of both static and dynamic approaches and combines machine learning techniques. The traces generated contain sensitive information extracted and trained by the algorithms for detecting software vulnerabilities. In this way, static characteristics (permissions and features) are extracted and dynamic characteristics are captured in order to obtain data that is more relevant and better suited to improving malware detection performance.

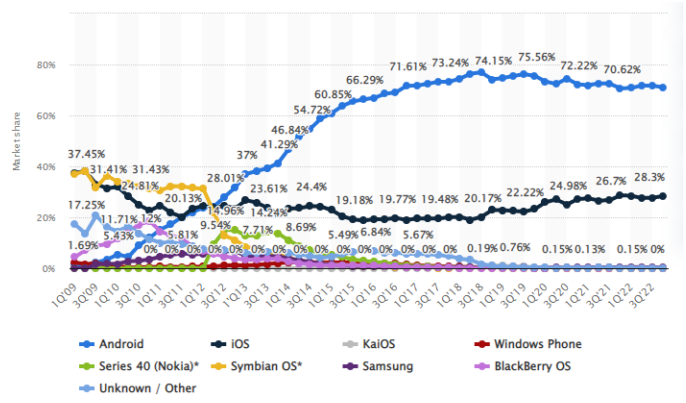

Fig. 2. Growth rate of android applications compared with other applications from 2009 to 2022.

### III. TRACE COLLECTION AND PROCESSING

In this section, we present the process for extracting features and events, the construction of our dataset, and the features selected for training the machine learning algorithms. We also present the tools and equipment used to collect the events.

#### A. Choice of Android Applications

To evaluate our model, we used execution traces generated from Android applications. Our choice is motivated by the fact that the high number of these applications with a share of over 82% of mobile applications, according to Gartner’s 2021 report<sup>1</sup>. According to this report more than 2 billion will be delivered in 2021. All this popularity (see Fig. 2) combined with Android’s security model makes users of these applications a prime target for malware writers. The scale of attacks targeting Android users is considerable [1].

#### B. Behavioural Data Extraction (Events)

Application behaviour, operations performed and system performance are among the essential and useful data provided by application execution traces. This data can be used for analysis, debugging, performance optimisation, problem detection and many other tasks related to application monitoring and diagnosis. For analysis, the features to be extracted from the events depend on the context of the application and the information you wish to use to construct the eigenvectors. In this study we have specified the behavioural features to be extracted in the features\_to\_extract list (Table I). These features are relevant, we believe, to understanding the actual behaviour of the application being run. Several events are captured and recorded in a file (the trace). All events are generated with the LTTng tracer. Also, to extract characteristics during the execution of each application, we created a dynamic environment with the Genymotion emulator version 3.3.3 with a Google Nexus 5 API 11 device. Each of the applications is installed and then run. In the Algorithm 1, we describe the process of collecting events, the building blocks of traces.

<sup>1</sup><https://www.gartner.com/en/information-technology/insights/top-technology-trends/top-technology-trends-ebook>

TABLE I. LIST OF BEHAVIOURAL DATA TO BE EXTRACTED

Event data	Type of data	Description
Timestamp	Numeric	This is the timestamp that indicates the precise moment when each event occurred. It is useful for temporal analysis of events and for understanding the chronological order in which they occurred
"Name"	String	This is the name of the event, representing the type or category of the event. It can indicate a specific action performed by the application, a function call or a system operation
PID (Process ID)	Numeric	This is the process identifier (PID), which is a unique number assigned to each process running on the system. It identifies the process that caused the event
TID (Thread ID)	Numeric	This is the thread identifier (TID), which is a unique number assigned to each thread in a process. It identifies the specific thread at the origin of the event
"Syscall" (System Call)	String	This is the set of data that represents a request from the running program to the operating system kernel to perform a specific operation. For example, read or write data, access external resources, create files, allocate memory, etc. The "syscall" field indicates the specific system call associated with the event
Retval (Return Value)	Numeric	This represents the return value of the system call (syscall). It is a numerical value that indicates the result of the operation performed by the system call, such as the success of an operation or the occurrence of an error
Duration	Numeric	Duration represents the time elapsed between the start and end of an event. It is used to measure the execution time of each specific operation

#### C. Data Pre-processing

Once the traces have been generated, the data collected must be made useful for the rest of the process. This stage is essential and requires appropriate tools to transform behavioural data into features. It is this phase that produces data that can be used by machine learning algorithms. During the pre-processing phase, only data that can contribute to improving detection or classification is retained from the data collected. This data should maximise the accuracy of the results obtained. Unnecessary data is therefore ignored. Given that the data we collected in the previous stage is unstructured data, it comes in different formats and is sometimes unreadable. Also, they generally contain redundant and unnecessary features, with missing values, symbols, punctuation and spaces. To prevent unnecessary data from negatively influencing the results, we converted the traces into Python dictionary objects. The Algo-

---

**Algorithm 1: Extracting Events from an Application**

---

**Entry :**  
Application : .apk  
events\_to\_extract[]: contains the list of elements to be extracted

**Output:**  
T: list of traces (content and metadata)

```
1 Load application into memory //Specify application package name
2 package_name = "MyApp"
3 source_code = decompile(app.apk)//Decompile the apk to obtain the source code
4 trace_code = insert_tracepoints(source_code)
5 //Insert tracepoints in the source code to capture the desired events (calls to special functions or macros that record events)
6 Run the application several times //(2 to 5 times)
7 Run Tracer //Configure the lttng-ust tracing tool to collect events
8 events = extract(trace_code) // collect events generated on the state of variables, function calls, errors, system events, etc.
9 T=[] // Initialise the list of traces
10 foreach event ∈ events do
11   if event ∈ events_to_extract then
12     // for an event element in the list
13     events_to_extract
14     trace = event // Create a new trace with the event
15     T.append(trace) // Add the track to the list of tracks
16   end
17   else
18     Continue with the next event
19   end
20 end
21 Return T
```

---

Algorithm 2 presents this transformation process. Once converted, machine learning algorithms use these dictionaries to identify malware from benign software. We also use the Trace compass visualisation tool to convert the traces into CTF files. As the contents of these files are readable, they are used to construct feature vectors, as indicated by the algorithm 3. In this way, machine learning algorithms can use these feature vectors to detect vulnerable applications, and therefore behaviours that are precursors to possible attacks.

#### D. Features Representation

Feature extraction creates new feature sets in which the typical malware example is better represented than the use of the original features. This feature-derived data extracted from software behavioural data improves the accuracy of malware detection. Before extracting these characteristics from the traces, we statically extracted the permissions and features of each application. This brings the total number of feature fields to five (05) for vulnerability analysis. For the detection of a vulnerable or malicious application by the machine learning model, the analysis focuses on the features taken from the

**Algorithm 2: Convert Generated Traces into Python Dictionary Objects**

---

**Entry :**  
trace\_file : events file

**Output:**  
event\_dicts : events converted into dictionary objects

```
1 Define the path to the directory containing the traces
2 Define the name of the traces session
3 events_to_extract = [timestamp, "name", pid,tid,"syscall", retval,duration, cpu]
4 Run TraceCompass // to convert evenements
5 Load the file containing extracted events
6 events = open("trace_file", "read") //Storing events in an event variable
7 event_dicts = { } // Initialise the object dictionary
8 foreach event ∈ events do
9   if event["name"] ∈ events_to_extract then
10    //If the event name is in the list
11    events_to_extract
12    event_dict = { //create a dictionary event_dict with the variables
13      timestamp: event[timestamp],
14      "name": event["name"],
15      pid: event["fields"][pid],
16      tid: event["fields"][tid],
17      "syscall": event["fields"]["syscall"],
18      retval: event["fields"][retval],
19      duration: event[duration],
20      cpu: event[cpu]
21    }
22  end
23  else
24    continue with the next event
25  end
26  event_dicts.append(event_dict) //Adding the dictionary to the list
27 end
28 return event_dicts
```

---

execution traces and the AndroidManifest file. These fields include all the important information from the traces. These features are based on:

- C1(Searching for abnormal activity): The aim is to analyse the values in this field to identify any activity that does not conform to the expected behaviour of the application. This includes inappropriate access to system resources, attempts to modify critical files and suspicious communications with external servers. The application will be detected as vulnerable.
- C2 (Error and exception detection): This involves identifying errors and exceptions reported in the execution trace and contained in this field. If there are frequent errors in the traces, such as access violations or security exceptions, this indicates potential vulnerabilities in the application.
- C3(Verification of privileges): this field contains the values of the analysis of system calls made in the trace

---

**Algorithm 3:** Transformation of Events into CTF Files to Construct Eigenvectors

---

**Entry :**  
    trace\_file : input trace file  
    features\_to\_extract : list of characteristics to be extracted from events

**Output:**  
    feature\_vectors: list of eigenvectors constructed from events

- 1 Load traces // with Trace Compass from the file trace\_file
- 2 Configuring CTF conversion parameters
- 3 Convert tracks to CTF // format using Trace Compass
- 4 Loading converted CTF files
- 5 Initialise feature\_vectors as an empty list
- 6 **foreach** event belonging to the converted CTF files **do**
- 7 |     Extract the characteristics specified in features\_to\_extract to converted CTF files
- 8 |     Construct a feature vector for the event using the extracted values
- 9 |     Add the feature vector to the list feature\_vectors
- 10 **end**
- 11 Return feature\_vectors

---

and checks whether they are appropriate for the application in question. For example, system calls relating to access to files, processes or network resources may reveal unauthorised access attempts.

- C4(Searching for suspicious network behaviour): This involves examining the values in this field, which represent network communication activities in the trace. If there are suspicious outgoing connections to unknown IP addresses or domains, unauthorised protocols or unencrypted transmissions of sensitive data, then the application is considered vulnerable.
- C5(Detecting malicious behaviour): This involves comparing the permissions and features fields in the Android's manifest file with the *authorisations.txt* and *features.txt* lists. These lists contain all the permissions and features declared in the official Android documentation.

Representing the functionalities represented by each field (C1, C2, C3, C4, C5) in figures means that the counter values can be incremented if a suspect element is present. These values are used to create the data set. The final value of the counter is compared with its initial value. If the final value is equal to the initial value, this implies normal behaviour and therefore a benign application. Otherwise, for any other value different from the initial value, the model assumes that the application is vulnerable.

#### IV. IMPLEMENTATION AND RESULTS

##### A. Dataset and Experimental Setup

1) *Dataset:* To experiment with our approach, we collected a number of Android applications that included both benign and malicious apps. We acquired benign apps from Google

Play<sup>2</sup> and malicious apps from Drebin<sup>3</sup> and built a dataset of 8014 traces (benign apps and malicious apps). This approach gives us apk's that have undergone Google's verification tests before being published on its site. Nevertheless, all applications are downloaded and then analysed on VirusTotal<sup>4</sup> with a considerable number of antivirus software for detection. The results of these scans are used to group the applications into benign and malware. Applications are selected according to several criteria. For benign applications, almost all sectors of activity are taken into account (tourism, news, health, education, financial transactions, justice, culture, religion, job search, history, geolocation and entertainment, etc). Several types of malware were collected (repackaging, privileges, sending sms, stealing information, advertising, etc.). We formed a set of 8014 traces for analysis.

2) *Experimental setup:* We conducted our experiments on a computer Inter(R), Core(TM) i3-4160, CPU @ 3.60GHzx4 with with 12GB RAM running on Ubuntu 22.04.2 LTS 64 bits and GNOME 42.5. We have installed the LTTng 2.13 plotter including LTTng-tools<sup>5</sup>2.13.9, LTTng-UST<sup>6</sup>2.13.5 and LTTng-modules<sup>7</sup>2.13.9. The models are built with Python 3.10.6 and GCC 11.3.0.

*Evaluation metric:* The metrics precision (P), recall (R) and F-measure (F1), Accuracy are proposed to evaluate our method. The precision, recall and F1 for example are defined as:

$$P(\text{precision}) = \frac{TP}{TP + FP} \quad R(\text{recall}) = \frac{TP}{TP + FN}$$

$$F1 = \frac{2 * P * R}{P + R} \quad \text{Accuracy} = \frac{TP + TN}{TP + FP + FN + TN}$$

Where :

- TP (True Positive): when the actual class and the predicted class are all yes.
- TN(True Negative): when the actual class and the predicted class are all no.
- FP(False Positive): when the actual class is no and the predicted class is yes.
- FN(False Negative): when the actual class is yes and the predicted class is no.

##### B. Results

To analyse the performance of our model, we used six (06) machine learning algorithms including the K-Nearest Neighbors classifier(KNN), the Decision Tree Classifier (DTREE-CART), Naive Bayes (NB), MLP classifier, Random Forest (RFORREST) classifier, Support Vector Machine (SVM) which were selected on the basis of the results of several preliminary experiments carried out.

<sup>7</sup>[git://git.lttng.org/lttng-modules.git](https://git.lttng.org/lttng-modules.git)

Fig. 3. The results obtained with each algorithm.

The Table II presents a comparison of the performance of the proposed approach with the precision, recall and F1 score measures for detecting software vulnerabilities on Android. The results show good performance for all the machine learning algorithms used. The best performance is given by the SVM algorithm with an F-score of 0.99 for malware detection and 0.89 for benign software detection.

TABLE II. COMPARISON OF ML ALGORITHMS

	Malware			Benign apps		
	Precision	Recall	F1-score	Precision	Recall	F1-score
KNN	0.98	0.99	0.99	0.96	0.75	0.84
DTREE-CART	0.98	0.99	0.99	0.93	0.80	0.86
NB	0.91	0.96	0.95	0.31	0.24	0.27
MLP	0.98	0.99	0.99	0.96	0.77	0.85

TABLE III. IMPLEMENTATION FOR ALL ML ALGORITHMS

	Macro Precision	Macro Recall	Macro F1-score	Accuracy
KNN	0.97	0.87	0.91	0.98
DTREE-CART	0.96	0.90	0.93	0.98
NB	0.73	0.70	0.71	0.91
MLP	0.96	0.89	0.92	0.98
SVM	<b>0.97</b>	<b>0.90</b>	<b>0.93</b>	<b>0.98</b>
RFOREST	0.97	0.88	0.92	0.98

The Table III shows the implementation results for all the machine learning algorithms with precision and the F1 macro score. The best performing algorithm obtained an accuracy of 0.98 and a score of 0.93 for the F1 macro. Fig. 3 shows that the SVM algorithm is better than the others. We can therefore conclude that the proposed model obtains results that show its good performance in detecting vulnerabilities. It is effective and can therefore be used to improve the protection of data passing through Android applications.

### V. CONCLUSION

Although identifying malware is a difficult and tedious task, it remains an imperative when it comes to protecting data. Our solution, based on application execution traces and machine learning techniques, meets this challenge. On the one hand, the results obtained enable us to confirm the relevance

of execution traces in analysing unexpected and unhealthy application behaviour. On the other hand, these experimental results also show that static and behavioural characteristics are more effective and efficient for detecting malware. The use of behavioural features can enable the detection of malware that escapes the control of solutions based on signatures or static approaches. This compensates for the shortcomings of static feature-based approaches.

In this way, the combination of behavioural and static features improves the level of detection of software vulnerabilities. Our model will make it possible to reduce new threats targeting Android applications. Unfortunately, there are a few limitations to our study, the future objective of which is to generalise this solution to all emerging applications and technologies. Also, to increase the number of applications and consequently the number of traces. The second objective is to have a real environment and not an emulated environment for a better user experience of this solution. We will continue to improve this approach in order to have a vulnerability detection system that is accessible to users.

**Abstract**—Network security has gained importance in recent years. Information system security is greatly aided by the development of encryption as a solution. To safeguard the shared information, several strategies are required. Thanks to the cutting-edge Internet, networking corporations, health information, and cloud applications, our data is growing exponentially every minute. In order to handle enormous amounts of data efficiently, a new application called Hadoop distributed file system (HDFS) was created. However, HDFS doesn't come with any built-in data encryption tools, which poses serious security risks. In order to increase data security, encryption techniques are established; nevertheless, standard algorithms fall short when dealing with bigger files. In this study, huge data will be secured using a novel hybrid encryption algorithm that combines CP-ABE (encryption based on the features of the encryption policy), AES (advanced standard encryption), and RSA (Rivest-Shamir-Adleman). The suggested model's performance is compared against that of traditional encryption algorithms like DES, 3DES, and Blowfish in order to demonstrate improved performance as it relates to decryption time, encryption time, and throughput. The results of the studies demonstrate that our suggested method's algorithm is more secure.

**Keywords**—Hadoop distributed file system (HDFS); big data security; data encryption; data decryption

## I. INTRODUCTION

Megadata is typically believed to be a collection of data whose structure is too huge or too diverse and complicated to be handled by standard data processing tools [1]. The problems of Big data include acquiring, storing, analyzing, transporting, sharing and displaying the information it contains [1]. Scientists, entrepreneurs and healthcare professionals are frequently needed to utilize data from a range of sources, including megadata from worldwide literature, the Internet, medical records, patient registries and even "smart" gadgets [1]. Smart phones increased use in recent years has resulted in a sharp rise in the amount of data created by social networking services (SNS). Data including multimedia material in a variety of formats has expanded to big data scale. Big data is a contemporary industrial research hotspot. Big data started to take off and get more and more attention as the cloud age came into being. Numerous apps, sensor networks, social networking sites and enterprises big and small handle this massive volume of data [2], [3]. Big Data challenges may be described in a number of ways, not least by reference to the 4 Vs [4]: volume, velocity, variety and veracity. The work of living with large data is different for every situation.

- Volume: Data with a size of many terabytes or petabytes.

- Variety: There are several types of data. organized, semiorganized, and unorganized.
- Velocity is an abstraction layer that allows Big Data systems to store data independent of the incoming or departing flow by specifying the different speeds at which data streams might enter or exit the system.
- Veracity: The information is under question. relates to the data's credibility, taking into account data availability, confidentiality, and integrity. Companies must guarantee that the data are accurate, as well as any analysis that are done on the data.

Using a distributed, trustworthy, and scalable computing infrastructure, big data sets may be handled and stored using the open-source Hadoop framework [5]. Because of Hadoop's cheap cost, quick processing, fault tolerance, and flexibility, large clusters or public cloud services often employ it. Hadoop [6] is an open source Java-based distributed computing framework consisting of two modules: MapReduce and Hadoop Distributed File System. It is used as a framework for cloud storage (HDFS). By simply defining the map and reduce functions, users can process large amounts of data using MapReduce, enabling them to efficiently use thousands of commodity computers in parallel [7], [8], [9]. HDFS is used to store data on distributed clusters of machines. Large clusters or public cloud services such as Yahoo!, Facebook, Twitter and Amazon are the places where Hadoop is most often used [10]. The popularity of these applications has shown Hadoop's scalability, but it lacks security for data storage by design. Hadoop has weaknesses in its security features even if its processing capacity is far more than that of traditional data processing systems. As the Hadoop design is not meant to be safe, it offers no security mechanisms to protect data while it is being stored or transferred. Currently, corporations are analyzing consumer information and location data obtained in numerous areas and utilizing it for marketing activities. As a consequence, sensitive personal data may be revealed when consumer data is evaluated. There would be significant reputational harm and legal implications as a result of the data breach. In addition, businesses store and process a large amount of data, all of which has to be protected in HDFS storage using encryption, threat detection, and logging systems. These methods let systems quickly detect vulnerabilities and protect user data. To safeguard data from the generating phase through the storage phase, several solutions have developed recently. Using data fabrication methods and limiting access during data production improves data privacy. Data security and privacy are mostly ensured during the storage phase via encryption methods [11].

The structure of simple file authorization and access control techniques constitutes the security service of the Hadoop project. To protect HDFS files stored in data nodes and to move files between data nodes when performing MapReduce operations, encryption is the best option. The process of converting plain text into ciphertext is known as encryption. By allowing users to be properly authenticated and prohibiting others, the transformation of explicable data into an incomprehensible form protects data confidentiality [12]. Data confidentiality and integrity are two objectives that can be achieved in Hadoop when using encryption. There are two different types of cryptographic keys: symmetric key cryptography, sometimes called secret key cryptography. Asymmetric key cryptography, sometimes called public key cryptography [13]. Stream ciphers, such as RC4 and OTP, and block ciphers, such as the AES, DES, 3DES and BLOWFISH algorithms, are generally used in secret key cryptography methods [14]. Using encryption techniques, several researches [15], [16], [17] indicated that the file size was 1.5 times larger than the original file and that download time also increased.

#### A. The Scope of this Paper

In order to protect data on Hadoop, the main objective of this research is to solve the problem of data security in Hadoop. This was solved by recommending the implementation of a new strategy that combines HDFS files with the CP-ABE (attribute-based encryption) technique with RSA (Rivest-Shamir-Adleman) and AES (Advanced Encryption Standard) algorithms to speed up the upload and download of the encrypted file. The main contributions of this paper are summarized below:

- We present a thorough related works on encrypting data in HDFS.
- We describe the architecture of big data encryption system.
- We present a hybrid encryption technique in HDFS for Big Data security.

In the subsequent sections, we present a structured outline of the remaining content. Section 2 delves into a brief literature review, examining key studies and their findings in the field. Section 3 introduces our suggested hybrid encryption approach, providing insights into its design and implementation. The experimental results obtained from applying this approach on a substantial dataset are presented in Section 4, along with a thorough analysis. Finally, Section 5 concludes the paper by summarizing the main findings and discussing potential avenues for future research.

## II. RELATED WORKS

This section includes short appraisals of the literature on Big Data security and encryption approaches. The security and privacy aspects of Big Data applications are considerably strengthened by researchers utilizing a range of encryption technologies [18], [19], [20]. A privacy-preserving auction mechanism is utilized in the homomorphic cryptography and secure network protocol architecture proposed by W. Gao et al. [21] to increase user and third-party service provider confidence and data privacy. Data communication between the

user and third-party service providers is safeguarded by the homomorphic encryption technique. For better data security, the revised approach leverages signature-based verification. However, as the user base and file size rise, system performance declines.

The completely homomorphic encryption system presented by A. Alabdullatif et al. [22] avoids dangers and data privacy breaches in the Big Data environment from both inside and outside. The resilient cryptosystem splits computation and data into two different portions following task analysis. The system's capacity to digest data is substantially sped by this technique, which also achieves a high degree of accuracy. C. Xiao et al. [23] proposes an accelerated approach for solving a range of complicated data encryption and computing challenges. A secure data storage system with adaptive cryptographic acceleration that dynamically enhances the working modes of huge data files is given for big data encryption. Compared with comparable software and hardware gas pedals, the design work achieves a better compromise.

By the use of an encryption technique, the data analysis model described by K. Sharma et al. [24] effectively addresses the privacy concerns in the interchange of health information. The patient-centric data access control mode addresses the privacy concerns with regard to health information and the need for data encryption. The patient file is encrypted and sent utilizing a variety of domains when employing the suggested RSA-based encryption. Even if the encryption paradigm successfully addresses the security and privacy concerns, data transmission across many domains is required. Comparatively to other data transmission techniques, this raises the system cost.

The results in [25] describe the challenges the user encounters when the data is outsourced. The main goals of the research project are data privacy and secrecy, and multi-keyword searchable encryption helps to achieve these goals. The formation of the probabilistic trapdoors enhances data security and resistance to assaults. Data secrecy in huge data streams is guaranteed by the selective encryption technique described by D. Puthal et al. [26]. Data integrity and confidentiality are security factors that affect how reliable the obtained data is. To increase the efficiency of encrypting and decrypting data streams while retaining data integrity and privacy, the authors employ the selective encryption technique.

The challenges connected with employing standard cryptographic techniques have been overcome in the attribute-based encryption stated by P. Perazzo et al. [27]. The encryption paradigm addresses the need for accurate access control in a vast data environment. Flexible rules improve access control to encrypted data while simplifying the management of large data volumes. Ten unique criteria are utilized to measure performance, and cryptographic acceleration is employed to boost performance. The key benefits of this encryption system are its minimal memory and energy needs. The shortcoming of standard attribute-based encryption (ABE) approaches is overcome by the hybrid attribute-based encryption (ABE) model described by H. Deng et al. [28]. The hybrid model provided adds a new proxy encryption to turn ABE ciphertext into IDE (identity-based encryption) ciphertext, since the rules stated by standard models become outdated after a specific length of time. Data collisions are prevented and security is promoted

by using identity-based encryption and key randomization properly.

Using the CP-ABE approach, P.S. Challagidad et al. [29] investigated the difficulties of unauthorized data access and confidentiality concerns in enormous data clouds. The encryption technology addressed the demand for multi-authority access control and data secrecy. Users get precise data and access thanks to the role hierarchy algorithm and hierarchical access structure. The two key benefits of hierarchy algorithms are computation speed and minimum storage needs.

Attack detection and intrusion detection are crucial concepts to take into account while researching Big Data security due to their impact on data privacy and confidentiality. To boost data security, several attack detection models and intrusion detection methodologies have been created. Using instruction sequences, a two-stage attack detection system presented by S. Aditham et al. [30] defends communication protocols. To assess system needs, these instruction sequences are further mapped to nodes. The encryption and decryption method presented by J. S. Raj et al. [31] takes into consideration the shortcomings of attribute-based encryption matching techniques, which impair the performance of the encryption system. For outsourced data operations, a lightweight, fine-grained data sharing strategy is employed to bypass this challenge. This increases overall data security and avoids the leakage of decryption keys.

Abd al wahid, S. M. J. et al. [32] suggested a solution for encrypting all files stored in HDFS utilizing public-key cryptography to safeguard them all. Acquired data is encrypted in HDFS during the data collecting process using the suggested data encryption technique (Rabin RZ). The suggested technique is contrasted with the Paillier method and the default Rivest-Shamir-Adleman (RSA) cryptosystem, respectively. Compared with previous cryptosystems, the suggested technique provides more powerful computational complexity and lower latency than the alternatives.

In order to strengthen transaction security against unauthorized access and to verify the speedy data transaction with minimal encryption and decryption time, Motupalli, R. K. et al. [33] presented an effective mixed algorithm design utilizing the Salsa20 and AES algorithm. The impressive throughput achieved in this hybrid framework shows how effective the recommended algorithmic structure is on current platforms.

### III. BIG DATA ENCRYPTION SYSTEM ARCHITECTURE

With the user interface the system offers, the client may communicate with the large data storage system. The major functionalities of the user interface include identity authentication, which provides users with login authentication and operation authority authentication, big data management, which offers authorized users services like browsing and replicating huge data, and other interfaces. Storage cluster and metadata cluster are the two primary components of the big data storage system. Storage cluster is used to store user files and other non-metadata data, whilst metadata cluster is used to store metadata like user and file information. The hierarchical structure of the system is analogous to the large data storage system as a whole, which consists of four layers: the access layer, the application interface layer, the data management

layer and the storage layer. Users may access cloud storage systems via sites like login and data operations, which are part of the direct user-system interface provided by the access layer. To access HDFS, HBase, and MySQL, the application interface layer offers web services and APIs. In response to user requests, the application server may call the appropriate routines to perform a particular data activity or user identity authentication. The data storage systems HDFS, HBase, and MySQL that can perform the operations of adding, removing, editing, and verifying data are included in the management layer. The physical storage devices that make up the bulk of the storage layer are virtualized into a single entity that offers storage services to the outside world. It also performs status monitoring and centralized management of storage resources concurrently. The system's basic four modules for module and function design are user file systems, file sharing, user information management, and personnel management. File browsing, file uploading, download, sharing, file inquiry, file management, shared file browsing, shared file downloading and retrieving, removing sharing files, changing passwords, adding users, deleting users, resetting passwords, etc. are some of the specific features.

Fig. 1 depicts the system's general design.

Fig. 1. Overall structure of system.

## IV. PROPOSED WORK

### A. Overview

One potential strategy to combine HDFS files with CP-ABE, RSA, and AES algorithms to speed up uploading and downloading while minimizing the size of the encrypted file could involve the following steps:

- Partitioning data into smaller chunks: Let's assume that we have a large file of size  $L$  that we want to upload or download. Instead of uploading or downloading the entire file at once, we can partition the file into  $n$  smaller chunks, each of size  $L/n$ . By doing this, we can distribute the load across multiple machines, which can significantly speed up the process. Mathematically, we can represent this as:

$$L = n(L/n)$$

- The hybrid CP-ABE, AES, and RSA encryption scheme is a secure data communication approach that utilizes three encryption methods to provide confidentiality, integrity, and access control. The scheme involves the use of a cyclic group  $G$ , a hash function  $H$ , and a bilinear pairing  $e: G \times G \rightarrow GT$  for cpABE encryption. The master key  $mk$  and user secret keys  $sk_i$  are generated using a set of equations and algorithms. The  $mk$  consists of  $(s, t, T)$  where  $s$  is a random element of  $Z_p$ ,  $t$  is a random element of  $Z_p$ , and  $T$  is a bilinear map from  $G$  to  $GT$ . The user secret key  $sk_i$  consists of  $(D_i, T^i)$  where  $D_i$  is an element of  $G$  and  $T^i$  is  $T$  raised to the power of the attribute vector of  $i$ . To encrypt a message  $M$ , a random symmetric key  $K$  is generated, and the message is encrypted using AES. The symmetric key  $K$  is then encrypted using RSA with the recipient's public key, and both ciphertexts are encrypted using cpABE with a given access policy  $\omega$ . To decrypt the message, the recipient uses their RSA private key to decrypt the encrypted symmetric key  $K$ , and the message is decrypted using the decrypted symmetric key. The security of the proposed scheme is analyzed using formal security definitions and proofs. The performance evaluation of the scheme is conducted in terms of computation time and communication overhead, and the results demonstrate that the scheme is efficient and practical for real-world applications.

For more Mathematical explanation in the hybrid cpABE, AES, and RSA encryption scheme we found four step:

- Setup:
  - Let  $p$  and  $q$  be two large prime numbers. The product of these primes,  $n = pq$ , is used as the modulus for RSA encryption:
 
$$n = pq$$
  - The totient of  $n$ ,  $\phi = (p - 1)(q - 1)$ , is used to compute the RSA public and private exponents,  $e$  and  $d$ , respectively:
 
$$\phi = (p - 1)(q - 1)$$

$e, d$  are such that  $e \cdot d \equiv 1 \pmod{\phi}$  and  $1 \leq e < \phi$ , where  $e$  is the public exponent and  $d$  is the private exponent.
  - A cyclic group  $G$  is chosen with order  $n$ , and a generator  $g$  is selected from this group. This group is used for cpABE encryption:
 
$$G = g^x \pmod{n} : x \in Z_{n^*}$$
  - A hash function  $H$  is chosen that maps a bit string of arbitrary length to an element of the group  $G$ :
 
$$H : 0, 1^* \rightarrow G$$
- Key Generation:
  - The authority generates a master key (MK) consisting of  $(p, q, n, \phi, e, d, G, g, H)$ .
  - For each user  $i$ , the authority generates a secret key SK $_i$  consisting of a set of attributes  $A_i$  and a private key  $s_i$ . These secret keys allow users

to decrypt messages that are encrypted with CP-ABE.

- Encryption:
  - To encrypt a message  $M$  for a set of attributes  $S$ , the encryptor first generates a random symmetric key  $K$  that will be used to encrypt the message with AES:

$$K = Random()$$

- The encryptor encrypts the message  $M$  using AES with the symmetric key  $K$ , producing the ciphertext  $C1$ :

$$C1 = AES\_Encrypt(M, K)$$

- The encryptor encrypts the symmetric key  $K$  using RSA with the public key  $(n, e)$ , producing the ciphertext  $C2$ :

$$C2 = RSA\_Encrypt(K, (n, e))$$

- The encryptor encrypts both  $C1$  and  $C2$  using cpABE with the policy  $P(S)$ , resulting in the final ciphertext  $C$ :

$$C = cpABE\_Encrypt(P(S), (C1, C2))$$

- Decryption:
  - To decrypt the ciphertext  $C$  for a user  $i$  with attributes  $A_i$ , the user first decrypts  $C2$  using their private key  $s_i$  to obtain the symmetric key  $K$ :

$$K = RSA\_Decrypt(C2, s_i)$$

- The user then decrypts  $C1$  using the symmetric key  $K$  to obtain the plaintext  $M$ :

$$M = AES\_Decrypt(C1, K)$$

The triple encryption approach provides better data protection when compared to traditional encryption techniques. ABE has recently attracted a lot of attention because of its decentralized access control and secure communication skills in dynamic environments. However, user-defined rules or processes cannot define the encryption process. To provide users more influence over the encryption process, access control rules are specified as ciphertext policies. Along with setting the properties, users may also control the encryption and decryption policies. These access control restrictions also provide cryptographic protection for data during transmission and storage. Only the properties are encrypted in CP-ABE; the whole block is not.

The hybrid encryption algorithms model for encrypting /decrypting files is seen in Fig. 2. The selection of input file properties is where the operation starts. Qualities are picked utilizing logical combinations and user preferences. Once the criteria have been determined, a set of rules is built expressly for these traits and encryption is executed. The AES algorithm creates a key that is used to safeguard the file after it has been encrypted for two-level security. Then, to safeguard the encrypted file, the AES key produced using the RSA process is applied. RSA AES key encryption is used to offer authentication while decrypting the encrypted file. If they do, it goes to the next stage; if not, the decryption process pauses and

records the endeavor as an intrusion. Once the characteristics of the cipher match those of the key, if the key is the same as the actual key, attributes are applied and the file is then decrypted. If not, it is likewise categorized as an incursion at this level. The final file that has been encrypted will be plain text and useable in the appropriate program.

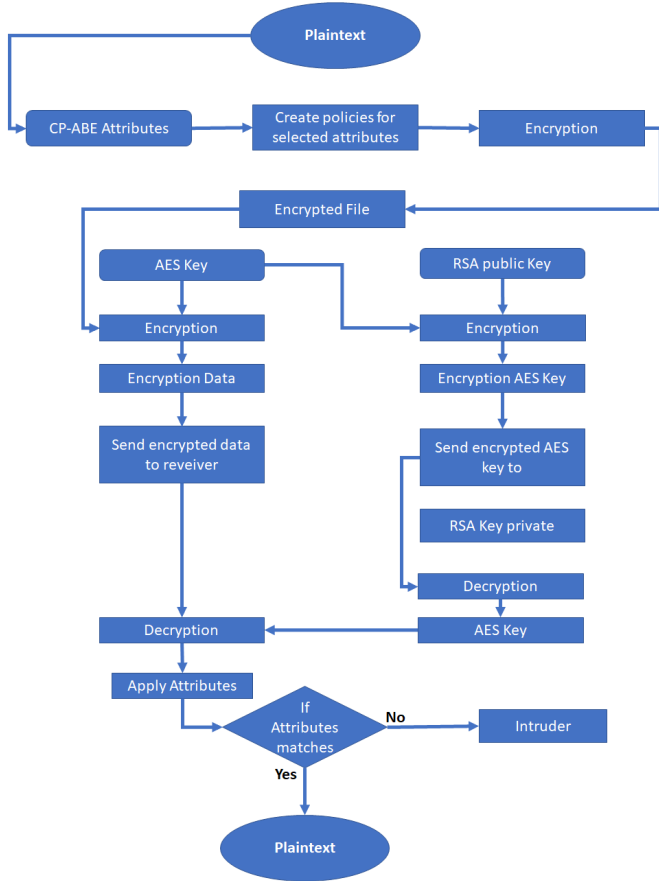

Fig. 2. Overview of the proposed hybrid encryption model.

### B. Encrypting Files in HDFS

When submitting files to the HDFS system, the encryption operation is carried out. When files are successfully encrypted, data security is increased. Fig. 3 depicts the HDFS system’s encryption process.

The actions taken during the encryption process are listed below in brief:

Step 1 : The system of distributed files is utilized in the first stage to simplify interaction between the HDFS user and the master node.

Step 2: The system of distributed files forwards the request containing the demand to create a new file to the master node.

Step 3: The master node analyzes the data node’s availability of space and picks the right data node.

Step 4: Data node information is exchanged with the distributed file system and subsequently transmitted to the HDFS client.

Step 5: Before encrypting the file, the client transmits the attributes . The file is encrypted in the data node when the characteristics are specified.

Step 6: A key is generated using the AES approach

Step 7: The AES key generated encrypted using RSA Algorithm and applied to the encrypted file in order to safeguard it.

Step 8: Using output data streams from a distributed file system, a writing process begins from a client to a particular data node.

Step 9: Data from the current data node is relocated to another data node if the write operation is complete.

Step 10: The master node stores information about the current data node and replication data node throughout the replication operation.

Step 11: Using the distributed file system, an acknowledgment is sent to the HDFS client once the data has been correctly duplicated on the secondary data node.

Step 12: After receiving the acknowledgment, the HDFS client pauses the writing process.

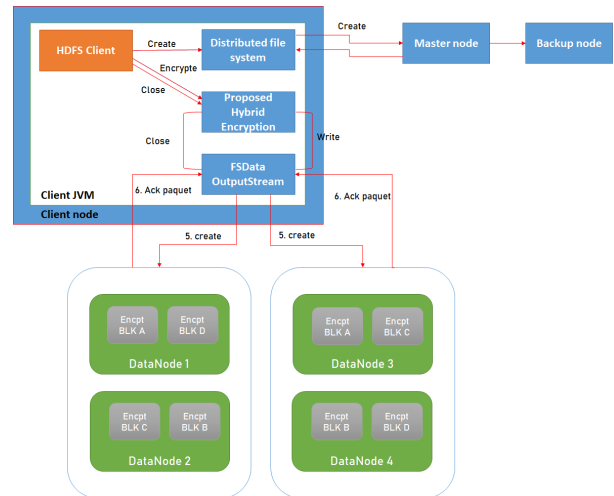

Fig. 3. Encryption process in HDFS.

### C. Decryption Files in HDFS

When reading the files from the HDFS system, the decryption phase is carried out. Before reading the operation, the file must be decrypted, and using this technique may assist identify any illegal access or intruders. Fig. 4 depicts the HDFS system’s decryption process.

The activities followed during the decryption method are explained as follows:

Step 1: The HDFS client talks with the master node across the distributed file system to begin the decryption process.

Step 2: A distributed file system sends a request comprising a request to read a file to the master node.

Step 3: The master node gives info about the data node that holds the encrypted files.

Step 4: The HDFS client begins the operation by picking data from the chosen block using the file system data input stream.

In Step 5: The client inputs the attributes to decrypt the file if the password provided for authentication matches.

Step 6: Access is regarded as an invasion or illegal access if the matching procedure is failed.

Step 7: After getting the acknowledgment, the HDFS client pauses the reading operation.

Step 8: After getting the HDFS client acknowledgment, the reading process is fully complete.

Fig. 4. Decryption process in HDFS.

#### D. Proposed Approach Pseudo Code

##### Initialization

**Data:** Plaintext to encrypt

**Result:** Encrypted cipher-text

##### Begin Algorithm

- 1: Initialize characteristics
- 2: Create a set of guidelines based on the characteristics and logical pairings
- 3: Apply characteristics to the file and use a set of rules to encrypt it.
- 4: Using the AES-generated key encrypted by RSA, secure the file. =0

#### V. EXPERIMENTS AND RESULTS

The suggested hybrid encryption technique for large data security in the HDFS environment is confirmed by tests done in the Hadoop system installed in the CPU Intel® core i5 2.40GHz, 8 processors, 16 GB memory, 128G Solid state drive and operating system CentOS release 7.5.1804. The master node is chosen as one of the nodes, while the data nodes are the other nodes. Performance evaluation of encryption and decryption is done on files of various sizes. Throughput, encryption and decryption times, efficiency, and other factors are compared to the conventional DES, 3DES, and Blowfish

algorithms. We also contrasted it with a different hybrid approach, that consists of AES and OTP algorithms. The parameters used in the proposed work on five CVs files with different sizes (64 MB, 128 MB, 256 MB, 512 MB , 1024 MB) depicted in Table I.

TABLE I. PARAMETERS

Simulation No.	Parameter	Range/Value
1	Input file size	64 MB to 1024 MB
2	Memory	16
3	Key length	128, 256 bit

#### A. Data Security

Five algorithms are employed in this experiment to encrypt and decode the same data. The results show that the best algorithm is our hybrid approach, which provides the highest reliability and security for the data sent when the DES, 3DES , Blowfish hybrid algorithm (OTP and AES) and our approach algorithms are compared, the differences in encryption and decryption times evaluated in Fig. 5. The encryption-decryption timing for the five is provided in Tables III and IV with varying file sizes. Table V displays the entire processing time in minutes. From the findings shown in Table V, it's evident that our technique is superior than the other algorithms (DES 3DES, Blowfish and Hybrid) after evaluating all five algorithms and calculating the time required to finish processing on many files of varying sizes. Our hybrid approach encryption method gives the best degree of data security of the other algorithms, and its performance is substantially quicker than the DES,3DES, Blowfish and hybrid algorithms. Comparison of Encryption Algorithm is given in Table II.

Calculating how long it takes to convert plain text into ciphertext gives us the encryption time. The Table III shows that the suggested model takes the fewest amount of time for each file. A maximum file size of 1 GB of data takes around 5 minutes to encrypt, compared to 13 minutes for DES, 12.5 minutes for 3DES, 11.8 minutes for Blowfish, and 6.2 minutes for hybrid. The encryption time grows progressively as the file size increases.

TABLE II. COMPARISON OF ENCRYPTION ALGORITHM

Factors	AES	DES	3DES	RSA	Blowfish
Created by	Dr. Joan Daemen and Dr. Vincent Rijmen	IBM	Dr. Walter Tuchman	Ron Rivest, Adi Shamir, and Leonard Adleman	Dr. Bruce Schneier
Published year	2000	1977	1998	1978	1993
Structure / Scheme	Substitution-Permutation	Feistel	Feistel	Factoring prime numbers	Feistel
Key length	128, 192, or 256 bits	56 bits	112 or 168 bits	>1024 bits	32-448 bits
Rounds	10, 12, or 14	16	48 DES-equivalent	1	16
Block size	128 bits	64 bits	64 bits	Variable	64 bits
Cipher Type	Symmetric	Symmetric	Symmetric	Asymmetric	Symmetric
Key used	Same key	Same key	Same key	Different key	Same key

TABLE III. ENCRYPTION TIME TAKEN FOR EACH ALGORITHM IN MINUTES

Files size (MB)	DES ENCR	3DES ENCR	Blowfish ENCR	Hybrid ENCR	Proposed ENCR
64	0.9	0.95	0.92	0.09	0.01
128	1.9	1.95	1.92	0.6	0.1
256	2.9	2.7	2.5	1.6	0.5
512	7.5	6.8	6.1	3.5	1.3
1024	13	12.5	11.8	6.2	5

TABLE IV. DECRYPTION TIME TAKEN FOR EACH ALGORITHM IN MINUTES

Files size (MB)	DES DECR	3DES DECR	Blowfish DECR	Hybrid DECR	Proposed DECR
64	1.4	1.2	0.7	0.07	0.04
128	2.3	3.2	1.7	0.3	0.1
256	3	3.2	2.9	1.5	0.4
512	8.4	7.1	5.1	2.8	1
1024	16.4	15.4	12.6	5.7	4.5

The time required to translate ciphertext into plain text is used to compute the decryption time (Table IV). According to the investigation, the suggested model's decryption time is less than that of existing encryption techniques. To decode 1 GB of data, the decryption process takes around 4.5 minutes. DES decrypts a file of the same size in 16.4 minutes, 3DES in 15.4 minutes, Blowfish in 12.6, and hybrid in 5.7 minutes.

TABLE V. TOTAL TIME FOR EACH ALGORITHM IN MINUTES

Files size (MB)	DES	3DES	Blowfish	Hybrid	Proposed
64	2.3	2.15	2.84	0.16	0.05
128	4.2	5.15	3.62	0.9	0.2
256	5.9	5.9	5.4	3.1	0.9
512	15.9	13.9	11.2	6.3	2.3
1024	29.2	27.9	24.4	11.9	9.5

The Total time is obtained by calculating the time taken to generate a ciphertext from plain text and the time taken to convert ciphertext into plain text. It is observed in Table IV and Fig. 5 that the time taken for the proposed model is minimum for all the file size. The total time increases gradually from small to large file size, and for a maximum file size of 1 GB of data, The total time of the proposed hybrid encryption algorithm is 9.5 min, which is 2.4 min less than the hybrid

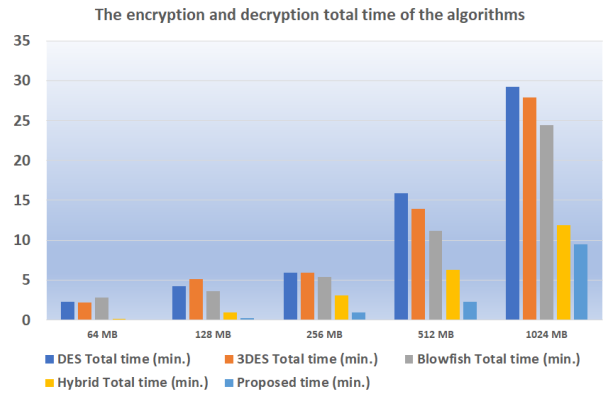

Fig. 5. The encryption and decryption total time of the five algorithms.

algorithm (OTP and AES), 14.9 min less than the Blowfish algorithm, 18.4 min less than the 3DES algorithm, and 19.7 min less than the DES algorithm.

B. Throughput

Throughput is characterized as the quantity of data traveling through a network system. It is the result of dividing all the data delivered in megabytes by the average time required to transfer all the data in minutes. Throughput value in (MB / min) for each algorithm as indicated in Table VI. The throughput study is given in Fig. 6.

TABLE VI. THROUGHPUT VALUE OF THE ALGORITHMS

Algorithm	DES	3DES	Blowfish	Hybrid	Proposed
Throughput value	34.50	36.07	41.80	88.72	153.20

According to the tests done in this article, the hybrid encryption algorithm may be utilized in software applications, system design and other fields essential for data security exchange, which can effectively safeguard data, in addition to quick performance and execution time, as the results showed that the our approach encryption is 77.48% faster than the DES algorithm, 76.84% faster than 3DES algorithm, 72.71% faster than Blowfish and 42.08% faster than hybrid algorithm.

Fig. 6. Throughput value of the algorithms.

## VI. CONCLUSION

In this work, a hybrid encryption method for the Hadoop distributed file system environment's megadata security was presented. When publishing files to the HDFS data node, three-level encryption using the CP-ABE, AES, and RSA algorithms was made possible. The properties supplied for the input file were encrypted using CP-ABE. Additionally, a Rsa key was used to encrypt the key generated using the standard Advanced encryption method. By using this AES key as the password for the encrypted file, data security is increased, and the intruder may be located throughout the decryption process. The effectiveness of the proposed approach has been confirmed in terms of throughput, decryption time, and encryption time. The proposed hybrid encryption model outperformed DES, 3DES, Blowfish, and other conventional Hybrid techniques. The tiny limitation noted in the proposed research is that the CP-ABE approach relies on policies and characteristics, and if the attributes are not selected properly, there may be discrepancies in performance on different runs. Additionally, using optimization techniques to raise other performance metrics may improve the research effort. However, there are promising avenues for future research in this field. Integrating advanced machine learning techniques, exploring post-quantum cryptography, evaluating the impact of blockchain, and addressing scalability challenges are key directions for further investigation. By pursuing these future endeavors, we can strengthen the security of data stored in Hadoop clusters, mitigating emerging threats and ensuring the confidentiality and integrity of sensitive information.

# Review of Unsupervised Segmentation Techniques on Long Wave Infrared Images

Mohammed Abuhussein, Aaron L. Robinson, Iyad Almadani  
School of Electrical and Computer Engineering,  
University of Memphis, Memphis, TN, 38111, USA

**Abstract**—This paper studies the different unsupervised segmentation algorithms that have been proposed and their efficacy on thermal images. The scope of this research is to develop a generalized approach to blindly segment urban thermal imagery to assist the system in identifying regions by shape instead of pixel values. Most methods can be classified as thresholding, edge-based, region-based, clustering, or texture analysis. We explained methods, worked before applying the methods of interest on thermal images of 8-bit and 16-bit resolution, and evaluated the performance. The evaluation section discusses where each method succeeded, where it failed, and how the performance can be enhanced. Finally, we study the time complexity of each method to assess the feasibility of implementing a fast, and generalized method of pixel labeling.

**Keywords**—Unsupervised segmentation; thermal images; texture analysis; pixel labeling; Gabor; GMM; image analysis; K-Means; MRF; Otsu's; DNN; region-based clustering

## I. INTRODUCTION

Image segmentation [1] is an area of focus primarily due to its potential usefulness in numerous fields of application. Given that images allow for the transfer of information, understanding them and the associated methods of extracting information is essential. Image segmentation often serves as the first step in the process of image interpretation. It aims to change, simplify, or partition the representation of an image into a more meaningful collection of segments for enhanced analysis [2], [3]. The importance and applicability of image processing cannot be overemphasized. In practice, many image processing algorithms do not focus on the entire image but only require information from the image regions that share certain features. For example, consider an application such as medical imaging where surgery decisions need accurate information about the images to either initiate or speed up patient recovery [4], [5]. Image segmentation supplies the critical image processing function of aiding object location and boundaries in patient imagery in these situations. It effectively assigns labels to every image pixel and enables necessary identifications such as foreground and background regions and other objects of interest in the scene [6].

As implied by the name, the outcome of an image segmentation procedure is a set segment that, when combined, covers the whole image. Each one of these individual segments is called a mask [7]. Masks are pixels in a particular region that share certain texture, color, and intensity characteristics. Image segmentation converts images into sets of masks which can then be interpreted as labeled images. Consequently, the labeled regions produced by the segmentation allow one the

capability of only processing the important parts of an image rather than processing the whole image [5].

So far, there has been a plethora of effective segmentation techniques developed for multiple applications and platforms. These techniques include threshold segmentation [8], region [9], and edge-based segmentation [10], clustering, texture-based segmentation [11], and Partial Differential Equation (PDE) based segmentation [12]. There are a plethora of segmentation approaches. However, the underlying question becomes how does one identify the technique that offers the best image analysis results and performance?

This paper will apply the aforementioned methods to long-wave infrared images (LWIR) and analyze the results. We will discuss each of these methods in general and provide variation details concerning implementation, effect on accuracy, the difference in performance on eight vs. 16-bit data, number of tunable parameters, response to texture and uniform surfaces, and lastly, their time complexities.

In this paper, we present a comprehensive review of unsupervised segmentation techniques applied to long-wave infrared (LWIR) images. The paper has main six sections, starting with the motivation section and ending with the conclusion. The motivation for this study arises from the growing need for effective image analysis in LWIR applications. The literature review section provides an overview of the existing research, highlighting unsupervised segmentation techniques specifically designed for LWIR images. The evaluation section presents the comparative analysis results, showcasing the effectiveness of each technique. The discussion section offers insights into the findings, identifying trends and potential areas for improvement. The conclusion summarizes the key takeaways from the review, emphasizing the most promising techniques. This review serves as a valuable resource for researchers and practitioners in LWIR image segmentation, facilitating the development of accurate and efficient segmentation methods.

## II. MOTIVATION

LWIR is one of the three commonly defined wavelength bands in which infrared imaging operates. The other two are Medium Wavelength Infrared (MWIR) and Very Long Wavelength Infrared (VLIR). LWIR infrared is commonly defined as covering the wavelengths that range from 8,000nm to 14,000nm ( $8\mu\text{m}$  to  $14\mu\text{m}$ ) [13]. Generally, LWIR cameras detect the thermal emissions of animals, vehicles, and people as they stand out when the environment's temperature differs by an amount greater than the camera's sensitivity. LWIR imaging is commonly utilized as a solution for night vision,

thermal imaging, and in degraded visual environments because the longer wavelengths make it less susceptible to scattering from obscurants, such as fog, rain, smoke, dust, and sand. LWIR imaging is instrumental in distinguishing targets at night since traditional imaging employs visible light and cannot reveal sufficient information in these scenarios due to a lack of signal.

The fields of computer vision and image processing are responsible for developing many methods designed to resolve the problems arising in the image segmentation process. However, for infrared/thermal images, the traditional techniques face some additional restrictions, which result in the segmentation being a more challenging problem. For example, when attempting to apply pixel-based segmentation methods to infrared images, the lack of disparity in pixel intensities poses a challenge in grouping/defining the objects' pixels with respect to their background. That can mainly be due to insufficient temperature differences between the object and the background. Another example occurs when utilizing image gradients as edge indicators. In these cases, the LWIR segmentation may fail to accurately identify appropriate object boundaries within the scene due to the non-uniform nature of the pixel intensities and the resulting the poor edge identification.

In this study, we focus on evaluating traditional segmentation algorithms and their feasibility in segmenting thermal images. The challenges mentioned above will be the main scope of this work to create a user-friendly tool to provide labeled data with minimal human input. For some algorithms, the human input will be selecting the number of thresholds, clusters, or objects. Meanwhile, other methods, such as region-growing, will take starting seeds as inputs. Texture segmentation takes sample texture patches as inputs. Ideally, the tool will include a standalone method that will only require the semantic labels from the user.

### III. LITERATURE REVIEW

In this treatment, we have reviewed publications from the last 20 years addressing image segmentation. This period can be divided into the pre-popularization and post-popularization of the deep learning era. The authors note that the deep-learning methods are very efficient with RGB representations of visible light images and are widely used due to this fact. More importantly, the authors note that very few deep-learning algorithms are applied to segment infrared images. This is most likely due to the difficulties mentioned above associated with infrared image segmentation.

The next sections present common methods used in unsupervised segmentation. We discuss thresholding as the first and most common pre-processing step, then discuss other prevalent and promising segmentation techniques. Lastly, we evaluate these techniques by visually analyzing the results and providing quantitative performance evaluation, and discussing scenarios where each method fails in the results sections.

This section explains the methods examined in this study, including the different variations of the same general approach. We begin with thresholding since it is an essential step in most segmentation approaches. Section III-B discusses the various edge detection approaches. Sections III-C, III-D, and III-F

delve into region growing, clustering, and texture analysis, respectively.

#### A. Thresholding

Thresholding image segmentation techniques have gained significant attention due to their simplicity and effectiveness. They are especially useful when dealing with images that have distinct foreground and background intensities. The basic idea behind thresholding [14] is to select a threshold value that separates the desired objects or regions from the rest of the image. Thresholding is the simplest and probably the most common image segmentation technique. The underlying principle relies upon setting a number of pixel intensity thresholds to divide the image pixels into multiple categories. Each category or mask is intended to represent a region of the input image with common features. Common features include color/grayscale characteristics or other common transformation characteristics. If the technique is based on a single threshold value, the effective result is to change a grayscale image into a binary one. If more than one threshold is desired, the thresholding is referred to as multi-level. Binary segmentation and other multi-level thresholding techniques all share the same core issue of effectively selecting optimal thresholds based on certain criteria [1]. Thresholding techniques can be categorized based on global, local, or image histograms. Global Thresholding is the simplest form of thresholding, where a single threshold value is applied to the entire image. Pixels with intensities above the threshold are classified as foreground, while those below the threshold are classified as background. Local thresholding, also known as adaptive thresholding, is a technique used for image segmentation where different threshold values are determined for different regions or pixels of an image. Unlike global thresholding, which applies a single threshold value to the entire image, local thresholding takes into account the local characteristics of the image to handle variations in illumination, contrast, and noise. In local thresholding, the threshold value for each pixel is computed based on the neighborhood around that pixel. The neighborhood can be defined as a fixed window size or a variable size depending on the algorithm or application. The threshold is calculated using statistical measures such as the mean, median, or standard deviation of the pixel intensities within the neighborhood. The main advantage of local thresholding is its ability to adapt to local variations in image properties. This makes it particularly useful in situations where the lighting conditions or intensity characteristics change across different regions of the image. By adjusting the threshold values locally, local thresholding can effectively segment objects or regions with varying illumination or contrast levels. Image histogram thresholding techniques analyze the histogram of the image to determine the threshold values. These techniques can be either global or local. They involve examining the distribution of pixel intensities in the histogram and selecting appropriate threshold values based on certain criteria or statistical measures. Examples of image histogram thresholding methods include Otsu's method, which finds an optimal threshold by maximizing the between-class variance, and the Maximum Entropy method, which selects the threshold that maximizes the entropy of the image.

The most popular variable thresholding method is Otsu's maximum variance approach. Formulated by Nobuyuki Otsu,

the Otsu method is also known as the variance threshold and is a popular algorithm in image segmentation. The optimal threshold is obtained by maximizing class variance functions [5]. It partitions the input image grayscale levels into foreground and background regions. The maximum inter-class variance difference between the two is obtained when the threshold is set to the “optimal” value. It is the preferred method for real-world images based on shape measures and uniformity. However, if the variances among classes differ significantly, the Otsu method cannot offer suitable thresholds for separating the classes [1]. Despite these shortcomings, the Otsu method has a simple algorithm that makes it feasible, convenient, and widely implemented. We will briefly summarize the implementation steps. The first step is to determine the highest grayscale intensity value in the image and denote that level as  $L - 1$ . The threshold  $K$  is then calculated by considering each gray level from 0 to  $L-1$ . Then the threshold probability is calculated and summed by the weight.

The average gray level of the pixel  $\mu_i$  is then calculated as the following:

$$\begin{aligned}\omega_2 &= \sum_{i=k+1}^{l-1} p_i \\ \mu_1 &= \frac{1}{\omega_1} \sum_{i=k}^{L-1} ip_i \\ \mu_2 &= \frac{1}{\omega_2} \sum_{i=k}^{L-1} ip_i\end{aligned}\quad (1)$$

The overall gray value of the image  $\mu$  is given by  $\mu = \sum_{j=0}^{i-1} ip_i$ . Follow-on stages calculate the variance  $\sigma_B$  and finally the maximum threshold  $T$ .

$$\sigma^2 = \omega_1(\mu_1 - \mu)^2 + \omega_2(\mu_2 - \mu)^2 \quad (2)$$

The optimal threshold is obtained by maximizing  $\sigma^2$ .

In multiple/bi-modal thresholding, multiple threshold values such as  $T_0$ ,  $T_1$ ,  $T_2$ , and  $T_3$  exist. Calculation of these levels permits the subsequent multiple category image representation. For example, if a segmented image containing three levels is desired, the output image  $B(x, y)$  can be obtained from the pixels of an input image  $A(x, y)$  using the following formula:

$$B(x, y) = \begin{cases} m & \text{if } A(x, y) > T_1 \\ n & \text{if } T_0 < A(x, y) \leq T_1 \\ 0 & \text{if } A(x, y) \leq T_0 \end{cases} \quad (3)$$

Threshold values can be calculated from the peak values of the image histogram when obvious differences exist in the gray levels of the background and foreground. Both the object and the background contribute to peaks in the histogram. The boundary between them produces a valley. Image segmentation yields perfect results when the segment threshold is at the valley. The threshold method is advantageous because of its simplicity and faster-operating speed. When both the target and the background have high contrast, one can easily obtain the

segmentation effect [5]. However, the technique is not without limitations. First, this technique does not provide accurate results for image segmentation when grayscale differences are insignificant. The underlying reason is that it only considers the pixel intensity information and ignores the spatial information contained in the image. Its sensitivity to grayscale unevenness and noise explains why it is fused with other methods to process images [1]. Additionally, in cases requiring more than two segments, the multiple threshold method is not applicable for images with low cluster variances.

Although both the maximum variance and bi-modal method take a short time, the former offers a more robust algorithm because it can segment the foreground from the background faster and more accurately when dealing with images where image contrast is not obvious.

As mentioned above, another limitation of threshold-based methods is that they tend to focus on intensity alone and ignore the relationship among pixels. This is especially problematic in cases where it is not immediately obvious that the identified pixels are contiguous. There is also the possibility of including extraneous pixels which are not part of the target region. Similarly, one can easily miss isolated pixels in the target region. The effects worsen as noise increases because the intensity of the pixel does not necessarily depict normal intensity [15]. Thus, thresholding can lead to too much information loss or the inclusion of an excess number of extraneous pixels. Over and above, in global thresholding, changes in the illumination may make some parts darker and others brighter in ways unrelated to the objects within the image [16]. This challenge is addressed by the inclusion of a variable threshold applied across the image.

## B. Edge-based Segmentation

Edge-based segmentation is an image processing method based on identifying object boundaries or edges in an input image. In almost all cases, this technique works by detecting discontinuities in brightness [17]. The method effectively detects and links edge pixels to form contours.

A major feature of an image is its edges. Edges are a crucial aspect of many computer vision and pattern recognition algorithms. As such, the detection of edges is an essential step in image processing [15]. The process may be enumerated as follows:

(1) The primary stage involves identifying edges present in the thermal image. To achieve this, different algorithms designed for edge detection, like the Canny edge detector, Sobel operator, or Laplacian of Gaussian (LoG), can be employed. However, when it comes to thermal images, only a limited number of these algorithms produce satisfactory outcomes. One such effective combination is the utilization of Gabor with Histogram of Oriented Gradients (HOG) technique [18]. This algorithm analyzes the gradients and extracts features of the image to identify regions of rapid intensity changes, which are indicative of edges.

(2) Edge Linking: Once the edges are detected, the next step is to link or connect the individual edge segments to form continuous boundaries. This can be done using techniques like edge linking by Hough transform, region growing, or contour

tracing algorithms. The goal is to create closed curves or contours that represent the boundaries of the objects or regions of interest.

(3) Edge Refinement: In some cases, the detected edges may contain noise or artifacts. Therefore, edge refinement techniques can be applied to enhance the quality and accuracy of the edges. These techniques may involve smoothing or filtering the edges, filling gaps, or removing small or spurious edge segments.

(4) Region Segmentation: Once the edges are obtained and refined, they can be used to segment the image into different regions or objects. This can be achieved by performing operations such as region growing, active contours (snakes), or graph cuts, which utilize the information provided by the detected edges to partition the image into meaningful segments.

Given that images have many redundant data, Kaganami and Beiji pointed in [19] out that the essential information is on the edges of an image. They correspond to texture, object boundaries, as well as changes in surface orientation [15]. In essence, an edge usually corresponds to points in the image wherein the grayscale values differ considerably from pixel to pixel. For this reason, detecting edges helps to extract valuable image feature information in regions in which there are sudden and rapid alterations [20].

Finally, edge detection is an integral step toward understanding the characteristics of an image. Edges have important features and contain information that is meaningful for determining the spatial relationship of neighboring pixels. They can be used to decrease significantly the amount of memory required to store the image, filter out less pertinent information, and preserve the vital structural properties of the image. We will explore some edge detection methods in the following sections.

1) *Gradient Edge Detection Method*: Various methods in the literature use convolutional kernels to extract edge features from images. However, most of them belong to two groups: gradient-based methods and Laplacian-based methods. Gradient-based methods, as Jahne mentioned in [15], detect the edges of an image by searching for both the minimum and the maximum values in the image's first derivative. For instance, the popular Sobel, Prewitt, and Roberts operators detect horizontal and vertical edges of an image based on the value of this derivative. Appropriate thresholding can be used in separating sharp edges [19]. As an edge-detection method, the Sobel edge operator shown in equation 4 carries out a two-dimensional spatial gradient measurement on a particular image and hence emphasizes regions of high spatial frequency, which correspond to the image edges. This operator finds the estimated absolute gradient magnitude at every point in an input grayscale image [21]. Theoretically, the Sobel operators are two  $3 \times 3$  convolution kernels. One kernel is essentially the other kernel rotated by ninety degrees. The Sobel operator is illustrated in the following kernels:

$$G_x = \begin{bmatrix} +1 & 0 & -1 \\ +2 & 0 & -2 \\ +1 & 0 & -1 \end{bmatrix} \text{ and } G_y = \begin{bmatrix} +1 & +2 & +1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} \quad (4)$$

The Prewitt operator computes the maximum response of a set of convolution kernels to find the local edge orientations for every pixel. It is suitable for estimating both the orientation and magnitude of the edge of an image [20]. For this operator, one kernel is sensitive to image edges in the horizontal direction and the other to the vertical direction. The directional kernels are illustrated below:

$$G_x = \begin{bmatrix} +1 & 0 & -1 \\ +1 & 0 & -1 \\ +1 & 0 & -1 \end{bmatrix} \text{ and } G_y = \begin{bmatrix} +1 & +1 & +1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix} \quad (5)$$

The Kirsch edge detector uses four filters to detect edges. These filters are essentially a rotation of a basic compass convolution filter [20]. Kirsch convolution kernels are shown below:

$$N = \begin{bmatrix} +5 & +5 & +5 \\ -3 & 0 & -3 \\ -3 & -3 & -3 \end{bmatrix}, W = \begin{bmatrix} +5 & -3 & -3 \\ +5 & 0 & -3 \\ +5 & -3 & -3 \end{bmatrix} \quad (6)$$

$$S = \begin{bmatrix} -3 & -3 & -3 \\ -3 & 0 & -3 \\ +5 & +5 & +5 \end{bmatrix} \text{ and } E = \begin{bmatrix} -3 & -3 & +5 \\ -3 & 0 & +5 \\ -3 & -3 & +5 \end{bmatrix}$$

The direction of the edge operator is defined by the mask that produces the maximum edge results.

2) *Laplacian Edge Detection Method*: The Laplacian method detects the edges by looking for zero crossings in the second derivative of the image's pixel intensity values. Common approaches include the Laplacian-of-Gaussian (LoG) and Marr-Hildreth [22].

To find the edges of an image, the Marr-Hildreth method of edge detection will first filter the image with the LoG filter matrix, which is calculated using the input value of the standard deviation [19]. The standard deviation value determines the filter matrix's width. It also controls the amount of smoothing that the Gaussian component produces. The LoG filtering then smooths the image and enhances all of its edges. The Laplacian of Gaussians response can be estimated by convolving the image with the kernel 7.

$$\begin{bmatrix} 0 & -1 & 0 \\ -1 & 4 & -1 \\ 0 & -1 & 0 \end{bmatrix} \text{ and } \begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix} \quad (7)$$

As soon as filtering is completed, edge localization is processed by finding zero crossings at every pixel for every direction [21]. Overall, Marr-Hildreth edge detection is used in finding edges through second-order differentiation. In most edge-detection approaches, the main idea is to compute local image change indicators, which include both first-order and second-order derivatives. In image processing, the gradient is the first-order derivative of choice, and it could be utilized in detecting the presence of an edge in an image [21]. Conversely, second-order derivatives are usually calculated with the use of the Laplacian. Notably, the second derivative's sign determines if the pixel of an image is on the light or dark side of an edge [22].

3) *Canny Edge Detection*: Canny edge detection, which was introduced by J Canny in [23] is a multi-stage approach to detect edges in images using the gradient calculated by the Sobel operator in the X and Y direction followed by non-max suppression, double thresholds, and edge tracking by hysteresis. As the case for any gradient operation, Gaussian smoothing is a critical preprocessing step since all gradients are sensitive to noise. Then the intensity of the edges is calculated by finding the gradient in the image by convolving the Sobel kernel in (4) in the x and y directions. The magnitude matrix  $G$  and the gradient slope  $\theta$  is calculated as the following:

$$\|G\| = \sqrt{I_x^2 + I_y^2} \quad (8)$$

$$\theta = \arctan\left(\frac{I_y}{I_x}\right) \quad (9)$$

In the next step, non-maximum suppression uses the pair of magnitude and direction of the gradient to find the most intense pixel in the direction of the gradient  $\theta$ , and the rest of the less-intense pixels are removed or set to zero. This will result in thinner edges with varying edge intensities. The double-threshold stage suppresses false-edge pixels, and eliminates variations in edge intensities. In the final step, the edges pixels are connected by applying hysteresis. Low intensity pixels that fall between string edges are considered strong while the ones with no neighboring edge-pixels are set to zero. This will result in final edge array. Canny edges operate on grayscale images. In the results section, we demonstrate how Canny edges are highly sensitive to noise and shadowing effects in thermal images.

### C. Region-based Segmentation

An image is partitioned into regions based upon the similarity of the pixels. In essence, this technique groups sub-regions or pixels into more prominent regions based on pre-set criteria. The procedure usually begins with a set of seed points. New regions are grown from these points by attaching to every seed those adjacent pixels that have properties comparable to the seed, for instance, particular ranges of gray level or intensity. In other words, the region growing image segmentation approach entails growing regions by recursively including nearby pixels which are similar and linked to the seed pixel [24]. Notably, connectivity is required to ensure that pixels do not connect in different parts of the image.

In region growing, homogeneity of regions is the main criterion for segmentation. The homogeneity criteria are as follows: shape, texture, color, gray level, and model. Pixel aggregation is the simplest of all the region growing approaches. After one region has been fully grown by appending adjacent pixels, another seed pixel that does not yet belong to any region will be chosen and then begins the process once more. The entire process continues until every pixel belongs to some particular region [21]. It is a bottom-up approach. Region growing approach requires human interference in choosing the starting seeds.

1) *Split-and-Merge Segmentation*: The split-and-merge approach is the opposite of the region growing technique. This approach entails separating the image into regions based on

a particular similarity measure. The regions are then merged based upon a different or the same similarity measure [25]. Another name of this technique is quadtree division. Initially, some criteria for what is a uniform area are set. Then, the whole image is split into four sub-images. Every sub-image is checked, and if they are not uniform, they are divided into four new sub-images. After every iteration, the adjacent regions are compared. They are then merged if they are uniform as per the similarity measure. The split-and-merge approach entails splitting an image recursively into smaller and smaller parts until every individual region is coherent and then merging them recursively to produce more significant coherent regions [26].

When merging the regions, the approach can begin with small regions, such as 4 x 4 or 2 x 2 regions, and regions which have similar characteristics, for instance, variance or gray level is then merged [24]. Splitting and merging are usually utilized iteratively.

2) *Watershed Segmentation*: The term watershed is broadly understood as a ridge that divides areas drained by a variety of river systems. The geographical area that drains into a reservoir or river is known as a catchment basin. Catchment basins and watersheds have a connection to image processing [27]. A watershed transform is a crucial tool that can be used to solve image segmentation problems. The watershed transform method grows regions of pixels around an image's local minima. It ensures that the boundaries of nearby areas lie by the side of the crest lines of the gradient image. This method of image segmentation combines features of both the region-based and edge-based segmentation methods. An image in watershed segmentation is considered as a topographic landscape that has valleys and ridges. The landscape's elevation values are defined by their gradient magnitude or gray levels of the respective pixels. The watershed transform decomposes a given image into catchment basins. A catchment basin, for every local minimum, consists of all the points whose path of steepest descent ends at this minimum [28] similar to the previous example. Basins are separated from each other by watersheds. The watershed transform decomposes an image; hence it allocates every pixel to a watershed or a region. Numerous small regions come up with noisy medical image data, and this is typically referred to as the over-segmentation problem [27]. It is the main drawback of the watershed segmentation approach.

The advantage of region-based image segmentation is that region-based methods are usually better in noisy images, where detecting borders is complex. Moreover, region-based image segmentation approaches tend to be more robust than edge-based approaches because regions typically cover more pixels than edges. Hence the scientist has more information available to characterize his/her image. Furthermore, when detecting a particular region, the scientist can utilize texture which is difficult whenever one deals with edges [26]. In addition, region growing techniques usually give good image segmentation, which matches well with the observed edges. However, the disadvantage is that the output of region-growing methods is either too few regions (under-segmented), or too many regions (over-segmented) [25]. Objects such as quantum semiconductor dots, DNA micro-array elements, blood cells, toner spots on a printed page, or any other type of object that may span several disconnected regions cannot be found.

Also, region-based segmentation algorithms are generally more complex than edge-based approaches and multiple other image segmentation methods [26]. The other shortcoming is that the regions obtained in region-based segmentation strongly depend on the initial pixel chosen and the order in which the border pixels are examined. Furthermore, the results are susceptible to the threshold value.

Visualizing the watershed: the image on the left can be topographically represented as the image on the right.

#### D. Clustering-based Segmentation

Clustering is another powerful image segmentation technique. It is an unsupervised learning task that involves identifying a finite set of clusters to classify the pixels in a digital image. Cluster analysis entails partitioning an image data set into several disjoint clusters or groupings [29]. During the partitioning, two criteria must be maintained, namely low coupling property and high cohesive property. When processing an image, its features are first extracted and then put together into properly-separated clusters based on each class of an image [30]. Notably, the clustering algorithm aims at developing the partitioning decisions based upon the first set of clusters updated following every iteration [31]. The number of clusters in these clustering-based approaches is referred to as priors, and image pixels are classified into suitable clusters based upon the principle of inter-cluster similarity minimization or intra-cluster similarity maximization. There are two main categories of clustering-based segmentation algorithms, namely soft or fuzzy clustering and hard clustering.

#### E. Fuzzy C-Means

The Fuzzy C-Means (FCM) clustering algorithm was conceptualized in the year 1981 by Jim Bezdek. It is undoubtedly the most common soft clustering approach. It is a clustering method that allows one piece of data to belong to at least two clusters. It is an unsupervised clustering algorithm. Through FCM, an image is segmented by grouping pixels with identical or almost identical values into one cluster, in which every group of pixel's values belonging to one cluster are similar to each other and differ from pixel's values belonging to other clusters [32]. The clusters represent the segments of the image that has been segmented to indicate group membership. Notably, the FCM algorithm is an iterative method of clustering which yields an optimal  $c$  partition by reducing the weighted within-group sum of squared error objective function [33]. The algorithm is based upon minimization of the objective function shown below:

$$J = \sum_{i=1}^N \sum_{j=1}^C u_{ij}^m \|x_i - c_j\|^2 \text{ for } 1 \leq m < \infty \quad (10)$$

In equation 10,  $m$  is a real number greater than 1,  $u_{ij}$  is the member of the pixel value  $x_i$  in the cluster  $j$ . While  $c_j$  is the center of the cluster and  $x_i$  is the pixel intensity measured data. We use  $\| * \|_p$  to denote the  $p$ -th norm used to express the similarity between the pixel intensity and the center of the clusters [34]. The pixel intensity memberships  $u_{ij}$  are calculated as follows:

$$u_{ij} = \frac{1}{\sum_{k=1}^C \left( \frac{\|x_i - c_j\|}{\|x_i - c_k\|} \right)^{\frac{2}{m-1}}} \quad (11)$$

While the centers of cluster values are calculated as the following:

$$c_j = \frac{\sum_{i=1}^N u_{ij}^m \cdot x_i}{\sum_{i=1}^N u_{ij}^m} \quad (12)$$

In equation 11,  $k$  is the steps in the iteration. The procedure will converge when the stopping criteria  $\sigma$  is reached [33].

$$\sigma < \| U^{(k+1)} - U^{(k)} \| \quad (13)$$

To summarize, the FCM algorithm starts by initializing membership matrix  $U^{(0)}$ , then calculates the cluster centers vectors  $c_j$ . It then updates the values of the membership based on the new cluster centers using equation 11. The algorithm then makes the decision stop if the stopping criteria are met, otherwise calculate the new cluster centers, and begin the process again.

The main advantage of the FCM algorithm is that it is capable of preserving a lot more information than other clustering algorithms. Consequently, it also provides better results than other algorithms such as K-Means.

algorithm and k-nearest neighbors (KNN) algorithm [32]. In addition, the algorithm is renowned for giving the best result for overlapped data sets. Unlike the KM algorithm in which a data point has to belong only to a single cluster center, a data point in FCM clustering is allocated membership to every cluster center, and hence data point can belong to multiple cluster centers [33]. Finally, we mention that another major advantage of the FCM algorithm is computational efficiency. It is widely utilized in the medical field for soft segmentation, such as brain tissue models.

We end this section by mentioning a few shortcomings of the FCM method. First, the algorithm can be sensitive to image noise. It does not consider the pixels' spatial information and therefore can produce excessive output result variance in the presence of noise. The result is somewhat inaccurate image segmentation [34]. Another shortcoming is that the FCM algorithm is time-consuming due in large part to its iterative nature. Moreover, Euclidean distance measures with the Fuzzy c-means algorithm could unequally weigh underlying factors [35]. Besides, although better results can be obtained with lower values of  $\sigma$ , these are obtained to the detriment of more iterations [33]. A priori specification of the number of clusters is also listed as a limitation of the method, so we repeat it here to inform the reader.

#### F. Texture Based

A texture is broadly understood as the regular repetition of a particular pattern or element on a surface. It represents aspects of the surface pattern, including regularity, directionality, color, brightness, and coarseness[36]. It is utilized in identifying dissimilar non-textured and textured areas in an image, segmenting/classifying distinct texture areas in an image, and extracting boundaries between major texture

regions [37]. An image is partitioned into several regions with dissimilar textures containing a comparable group of pixels during texture segmentation. In essence, a textured image is segmented into various regions that have similar patterns. Segmentation of textures necessitates the choice of good texture-specific features with excellent discriminating power. In general, techniques for extracting texture features could be categorized into three main classifications: spectral, structural, and statistical. In spectral techniques, the textured image, as Madasu and Yarlagadda pointed out in [38], is changed into the frequency domain. After that, extract the texture features can be carried out by assessing the power spectrum. In structural-based feature extraction techniques, the fundamental facet of texture, known as texture primitive, is utilized in forming more intricate patterns of texture through the application of grammar rules that stipulate how texture patterns are generated. Lastly, in statistical techniques, texture statistics, for instance, the moments of the gray-level histogram, are founded upon gray-level co-occurrence matrix and are calculated for discriminating different textures [38]. Over the years, many different methods have been developed for texture-based segmentation. The main ones include Gabor filters, Markov random fields, and wavelets.

1) *Gabor Filter*: A Gabor filter essentially refers to a combination of a sinusoidal term and a Gaussian filter. Dennis Gabor conceptualized this method, and it is a linear filter. It is notable that frequency and orientation representations of Gabor filters are comparable to those of the human visual system and are suitable for texture discrimination and representation [39]. A two-dimensional (2D) Gabor filter in the spatial domain is a Gaussian kernel function modulated by a sinusoidal plane wave. In 2D, a Gabor filter is as illustrated in equation 14.

$$g_{\lambda, \theta, \psi, \sigma, \gamma}(x, y) = \exp\left(-\frac{x^2 + \gamma^2 y^2}{2\sigma^2}\right) \cos\left(2\pi \frac{x}{\lambda} + \psi\right) \quad (14)$$

In this equation,  $\lambda$  represents the wavelength of the cosine factor,  $\theta$  represents the orientation of the normal to the parallel stripes of a Gabor function in degrees,  $\psi$  is the phase offset in degrees, and  $\gamma$  is the spatial aspect ratio indicating the elliptical nature of the Gabor function support, and  $\sigma$  is the standard deviation of the Gaussian that determines the (linear) size of the receptive field.

While the sinusoidal component of the Gabor filter provides the directionality, the Gaussian provides the weights. The impulse response of the Gabor filter, as Haralick pointed out in [36], is defined by a harmonic function multiplied by a Gaussian function. A Gabor filter applies to a wide range of image-processing applications. Aside from texture segmentation, it can also be applied to image representation, retina identification, edge detection, and document analysis [36]. One of the advantages of Gabor filters is that they satisfy the minimum space-bandwidth product according to the uncertainty principle. As such, these filters provide simultaneous optimum resolution in both the spatial-frequency and space domains. They are utilized in solving problems that involve intricate images comprising textured regions [36]. Texture segmentation with the use of Gabor filters involves three steps. In the first step, a filter bank is used to decompose the input image, using the equation 14.

The second step is feature extraction. The following non-linear sigmoidal function that saturates the output of the filters is used in this step:

$$\tanh(\alpha t) = \left(\frac{1 - e^{-2\alpha t}}{1 + e^{-2\alpha t}}\right) \quad (15)$$

Where  $\sigma$  is the standard deviation that determines the receptive window size.

Lastly, the pixels in the Gabor responses are grouped together using a clustering algorithm such as K-Means.

2) *Markov Random Fields (MRF)*: Markov Random Fields (MRF) is a highly sophisticated texture-based segmentation method. It is a probabilistic model. Regions in natural images are usually homogeneous. Pixel homogeneity means that adjacent pixels often have similar properties. For instance, these properties include common characteristics such as texture, color, and intensity. MRF captures such contextual constraints. MRF-based segmentation approaches have been extensively utilized for classification and segmentation in remote sensing applications [40]. MRF is extensively studied and also has a solid theoretical background. According to [40], the MRF segmentation can only be applied to a Markovian image. A Markovian image is an image where the probability distribution of gray levels depends on the neighboring pixels' gray levels, and it is represented by Gibbs fields. The conditional probability for the pixel  $Z_i$  with a grey value of  $g_i$  belonging to a cluster of pixel values depends on the neighboring pixels  $Z^i$  with pixel values of  $g^i$ . It is denoted as the following:

$$P(Z_i = g_i | Z^i = g^i) = \frac{1}{S} e^{-H(g_i, G^i)} \quad (16)$$

and

$$S = \sum_{g=0}^G e^{-H(g_i, G^i)} \quad (17)$$

The partition sum  $S$  is calculated by summing the energy function of the Markov random fields for the partition. This characterization of the energy function is defined by the parameter vector  $\theta = [b_0, b_1, \dots]^T$ . The parameter vector  $\theta$  is used for the segmentation and characterization of texture.

### G. Deep Unsupervised Segmentation Models

In recent years, image segmentation has attracted interest in computer vision research. Object detection, texture recognition, and image compression are some applications of image segmentation. A set consisting of pairs of images and pixel-level semantic labels, such as street or car, is used to train supervised image segmentation. In contrast, unsupervised image segmentation is used to predict more general labels. However, there are no training images or ground truth labels for pixels in unsupervised image segmentation. Therefore, once a target image is input, the pixel labels and feature representations are jointly optimized, and the gradient descent updates their parameters. In [41], the proposed approach, label prediction

and network parameter learning are alternately iterated to meet the following criteria:

- 1) Pixels of similar features should be assigned the same label.
- 2) Spatially continuous pixels should be assigned the same label.
- 3) The number of unique cluster labels should be large.

In order to satisfy these criteria, Wonjik et al. present a CNN-based approach that optimizes both feature extraction and clustering functions at the same time [41]. They proposed a novel end-to-end differentiable network of unsupervised image segmentation, and in order to enable end-to-end learning of a CNN, an iterative approach to predict cluster labels using differentiable functions has been proposed. This study extends the previous research published (ICASSP) [42]. In the previous work, superpixel extraction using simple linear iterative clustering was employed for criterion (2) from the criteria mentioned above. However, the previous algorithm had a limitation that the boundaries of the segments were fixed in the superpixel extraction process. In this study, a spatial continuity loss is proposed as an alternative to mitigate the limitation mentioned above. Moreover, they presented an extension of the proposed method for segmentation with scribbles as user input, which showed better accuracy than existing methods while maintaining efficiency. In addition, they introduced another extension of the proposed method: unseen image segmentation by using networks pre-trained with a few reference images without re-training the networks.

1) *Differentiable Feature Clustering*: The following is a description of the picture segmentation problem that has been solved. For the sake of simplicity, let  $(\{\})$  denote  $(\{\}_n^N = 1)$  Unless otherwise stated, where  $N$  is the number of pixels in input color image  $I = V_n \in R^3$ . Consider  $(f : R^3 \rightarrow R_p)$  be a function for extracting features. And  $(X_n \in R_p)$  group of  $p$ -dimensional feature vectors of image pixels. By using  $C_n = G(X_n)$ , cluster labels  $C_n \in Z$  has been assigned to all of the pixels, where  $g : R_p \rightarrow Z$  is a mapping function.  $G$  can be an assignment function that returns the label of the cluster centroid that is closest to  $X_n$  in this case. The equation mentioned above is used to derive  $C_n$  in the scenario when  $f$  and  $g$  are fixed. In contrast, if  $f$  and  $g$  are trainable but  $C_n$  is fixed, the equation, as mentioned earlier, can be considered a conventional supervised classification issue. If  $f$  and  $g$  are differentiable, the parameters for  $f$  and  $g$  can be optimized using gradient descent. Unknown  $C_n$  are predicted in this work while training the parameters of  $f$  and  $g$  in an entirely unsupervised way. The following two sub-problems were addressed to put this into practice: prediction of the optimal  $C_n$  with fixed  $f$  and  $g$ , and training of the parameters of  $f$  and  $g$  with fixed  $C_n$ . In particular, the three criteria presented in Section I are mutually exclusive and can never be ultimately achieved. Applying K-means clustering to  $X_n$  for criterion (a), performing graph cut algorithm using distances to centroids for (b), and finding  $k$  in K-means clustering using a non-parametric technique for (c) is one feasible solution for tackling this problem utilizing a traditional method (c). However, because these traditional approaches are only applicable to fixed  $X_n$ , the solution may be suboptimal. As a result, a CNN-based algorithm is presented as a solution. All of the requirements above are satisfied by jointly optimizing the feature extraction functions for  $X_n$  and  $C_n$ . An

iterative strategy to forecast  $C_n$  using differentiable functions is suggested to enable end-to-end learning of a CNN. The input image  $I$  was fed into the CNN to extract deep features  $X_n$  using a feature-extraction module. The response vectors  $R_n$  of the features in  $q$ -dimensional cluster space were then calculated using a one-dimensional  $1D$  convolutional layer, where  $q = 3$  in this example. The three axes of the cluster space were represented by  $z_1$ ,  $z_2$ , and  $z_3$ . The response vectors were then standardized across the cluster space's axes using a batch normalization method. Furthermore, cluster labels  $C_n$  have been established by utilizing an *argmax* function to give cluster IDs to response vectors. The feature similarity loss was then computed using the cluster labels as pseudo targets. Finally, the spatial continuity loss and the feature similarity loss have been computed and backpropagated.

2) *Superpixel Learning*: Ilyas et al. propose a novel approach for unsupervised segmentation in using superpixels within a CNN framework in [43]. Superpixels are the outcome of perceptual pixel grouping, or, to put it another way, the effect of image over-segmentation. Superpixels contain more information than pixels and match with image borders better than rectangular image patches. The local contrast and distance between pixels in the image's RGB color space are used by superpixel extraction methods. In [43] the authors we extract  $P$  superpixels that are more detailed and unique in the input image. After that, each pixel in each superpixel is given the same semantic name. The fewer iterations the CNN must do to produce the final segmented image, the finer the pixels generated by the technique. Too many generated categories (superpixels) will cause the CNN to produce more iterations. To avoid similar situations, input images are pre-processed image by applying contrast enhancement and blurring. Many structures use the simple linear iterative clustering (SLIC) methodology to produce superpixels. However, Ilyas et al. chose the Felzenswalb algorithm because it utilizes a graph-based image segmentation method. In comparison to the other algorithms, this one does an excellent job with image details. Moreover, its time complexity is linear, and it is quicker than the other available methods.

In their approach, Ilyas et al. computed the  $n$ -dimensional feature vector from this RGB image through their network's  $N$  convolutional blocks. SE-ResNet (detailed later) is the first block, followed by batch normalization and ReLu activation. The dimensions with the highest value were then taken from the feature vector output of the last convolutional block. As a result, we were able to extract the labels from the resulting feature vector. To achieve feature recalibration, we used the bespoke squeeze and excitation networks (SE-Net) initially developed by Jie Hu et al. In order to obtain a SE-ResNet block. We chose to combine SE-Net with ResNet because of its increased representational power. Moreover, we name it SE-Block for simplicity of notation. CNN's extract hierarchical information from images using convolutional filters. Deeper layers detect more abstract features and geometry of the objects present in the images, whereas shallow layers find trivial features from contexts such as edges or high frequencies. Each phase extracts more and more critical information to complete the work at hand at each phase efficiently. In SE-Net, each output channel is weighted adaptively, which is the significant difference between SE-Net and Normal convolutional networks. We add a single parameter to each channel and shift it

linearly based on how relevant each channel is. This is done by obtaining a global understanding of each channel by squeezing the feature maps to a single numeric value using global average pooling (GAP). The results go through the neural network's two fully connected (FC) layers, which produce a vector of the same size as the input. Each original output channel may now be scaled based on its relevance using this n-dimensional vector. As the last step, we utilized K-means to eliminate noise from the final segmented image. In order to apply K-means, we have to find the number of K, which represents the number of clusters. Because of the unsupervised scenario, we do not know how many segmented areas will be in the final segmented image. So, in order to solve this issue, we count the number of disjointed segmented regions in the final segmented image and assign that value to K.

#### IV. PRE-EVALUATION

##### A. Dataset

For this study, we will be using the ADAS dataset provided by FLIR. This dataset contains 8-bit and 14-bit LWIR images and non-annotated RGB images of the same scenes for reference. The dataset was collected by mounting an infrared camera next to a true color camera with center lines approximately 2 inches apart [44]. The two cameras were mounted on a vehicle driving around, collecting synced segments of video and images in Santa Barbra, CA streets and highways. The image capture rate is two frames per second, and the rate of the video is at 30 fps. The infrared frames have a resolution of  $640 \times 512$  with a 45-degree horizontal field of view and a 37 vertical field of view. The RGB images have  $1280 \times 1024$  with a field of view set to match the infrared camera. The dataset contains 10,228 synced frames and includes a variety of categories/labels, such as, persons, cars, bicycles, dogs. The demonstrated test cases in the results table are selected by the dynamic pixel value range. for example, the road image has very low dynamic range i.e. all pixel values are limited to a very small number of bins in the histogram while other images have wider ranges. The FLIR dataset contains labels of bounding boxes of several object used for training object detection models. However, we do not employ any of the bounding box labels or details. the dataset is merely chosen since it provides pairs of RGB and thermal images with relatively high resolution. to that point there is also the KIAST dataset and several other face datasets.

##### B. Preprocessing

First, the image was sharpened to give each item in the image a clear border in order to make a higher-quality image. The image then applied to bilateral filter which reduced unnecessary noise while maintaining the sharpness of the object edges. The filter can be applied in a variety of sizes  $n \times n$ . We avoid using a values higher than  $n = 5$ , since this would result in extreme smoothing and leads to lose a lot of useful information.

##### C. Evaluation Methods

In the field of image processing, evaluating the performance of a segmentation algorithm is a crucial step. The primary key in evaluating segmentation algorithms is how each

method performs in a system or a specific application. For example, in some object detection and tracking applications, the evaluation of how well the segmentation algorithm performs is determined by how well the approach can distinguish the target object from the rest image being considered the background. After extracting the object from the image, the image is furtherly processed . In this case, the target is measured and compared with the ground truth, and the result is evaluated. In their paper, Zhang et al. classify and discuss assessment methods of image segmentation [45]. Additionally, the difference between supervised and unsupervised evaluation methods is examined in detail. In [46], a thorough study about the evaluation approaches in different applications is provided. In this paper, we will provide a qualitative evaluation of the segmentation results for each algorithm and visually compare the results. Furthermore, we will provide a quantitative and analytical evaluation of each algorithm using a semi-supervised approach.

The results reported in this study are calculated using the Dice index, Specificity, Sensitivity, and the Jaccard index as demonstrated in equations Equations (18) to (21).

$$Dice = 2 \times TP / (2 \times TP + FP + FN) \quad (18)$$

$$Specificity = TN / (TN + FP) \quad (19)$$

$$Sensitivity = TP / (TP + FN) \quad (20)$$

$$Jacc = TP / (TP + FN + FP) \quad (21)$$

The Dice index is the intersection between the generated segmentation and the ground truth given in 18. The specificity 19 is the correctly assigned pixels in the image. The sensitivity is the number of uniformly distributed pixels object pixels can be calculated as shown in equation 20. Equation 21 is the Jaccard index which is the relation between the two segmentations, the predicted and the ground truth.

#### V. EVALUATION

##### A. Threshold

Even though we already know that threshold or image "binarization" does not make sense for this application, we have implemented it as an essential step compared to the other segmentation techniques investigated in this study. The optimal number of thresholds for each image is determined by counting the number of peaks in the histogram. Here, we assumed that our objects have uniform temperatures and that this results in constant pixel values across a single object. This assumption means that the significant peaks will determine the optimal number of thresholds in the image. In order to standardize the peak finding process, a median filter was applied to the frames to provide a uniform range of pixel values. Since all the different techniques of locating the thresholds in the histogram returned close results, we will discuss and calculate the accuracy Otsu's approach since it is the commonly used approach and the most robust.

While determining the optimal number of thresholds, we assumed that objects with uniform temperatures create homogeneous regions or segments. Realistically, objects normally do not have consistent surface temperatures. This temperature discrepancy and environmental and sensor noise lead to the common characteristic of thermal images not containing well-defined regions. Therefore, it causes the thresholding process to often fail when dealing with a histogram with a small variance or a histogram with its peaks concentrated in a small portion. sample result is demonstrated in Fig. 1.

Fig. 1. This histogram has two major peaks and several local peaks which will cause the thresholding process to fail.

In Table I, we demonstrate more examples of the binarized images using Otsu's thresholds.

### B. Region and Edge-based Segmentation

When applying edge detectors to thermal images, we notice the overlapping objects, although not at the same depth, with the same pixel values are grouped and have no separating edges between them, as demonstrated in the Fig. 2.

Fig. 2. Over-lapping objects of different depths.

In the case of applying the Canny edge detector, in the active regions of the image, the detector returns many false

positives due to the variation in pixel intensities. In Fig. 3, the brick road forms multiple closed regions where it could be mistaken for multiple local regions when in reality, they belong to the same object.

Fig. 3. Over-segmentation of the brick road due to visible gradient in the temperatures.

Watershed segmentation relies on finding the topographic elevation in the image intensities. We notice that watershed segmentation provides the best results when there is a significant disparity within a region that contains two objects of similar pixel intensities. But it also causes over-segmentation in other cases where the same object contains prominent edges. As shown in Table I, watershed generates qualitatively best results in terms of assigning a uniform labels to objects with respect to their edges and their local maxima.

### C. Clustering

Both  $K$ -means and Gaussian mixtures play an essential role in unsupervised machine learning. They offer simple and intuitive approaches to clustering and are straightforward to implement. Typically, they are included in any significant machine learning software package. When  $K$ -means was applied to the set of test images, it returned results similar to those achieved by multi-modal thresholds. When  $K$ -means fails, GMM comes in. Since  $K$ -means can do good enough on most images, we use GMM only for those cases where  $K$ -means cannot detect good boundaries. We use all the cluster centers calculated by  $K$ -means to initiate the GMM model for the same number of mixtures. Then for each given image, we calculate the probability. We then threshold and normalize them to create a black and white image similar to what we get from  $K$ -means. FCM has the disadvantages of sensitivity to initial cluster values, sensitivity to noise, and the solution provided does not consider any relevant spatial information from neighboring pixels. Applying fuzzy clustering on pixel values without any additional features will result in better segmentation when compared to the results from  $K$ -Means and multi-modal thresholds, as demonstrated in Fig. 4.

### D. Texture Analysis

The results shown provide some insight into how these texture-based feature extraction techniques are performed. The Gabor method performed decently in the given segmentation tasks, although more processing was required to achieve accuracy. Additionally, the Gabor method takes several parameters as initial input to the program, and these parameters require a lot of experimentation and errors. However, the Gabor parameters that have always made the most significant contribution to the method's output were the window sizes. Whether it was the size of the moment mask, the size of the Gabor filter, or the smoothing window after the activation function had been applied, these window sizes caused drastic changes in the results of the segmentation results.

TABLE I. SEGMENTATION RESULTS

Input image	Otsu's	Watershed	K-Means	FCM	Gabor	MRF	DFC	Superpixel

Fig. 4. Comparison between clustering methods K-means, GMM, and FCM.

The MRF model did not segment the image properly. Possibly, because exploiting only pixel values does not give enough segmentation power to the model. However, incorporating complex labels of each class's mean and variance provided more accurate segmentation for the labeled classes. Therefore, the aggregate four features: pixel intensity, mean, variance, and the sum of the log of the intensities of neighboring pixels, are used on the MRF model satisfying segmentation. Fig. 5 demonstrates the difference in the performance between the unsupervised segmentation and the hard-labeled segmentation.

### E. Unsupervised Deep Learning Models

As shown in the qualitative and quantitative results, unsupervised deep learning models provide similar results to the classical clustering algorithms. This poor performance can be due to the lack of feature representation in the images. If the feature representation is not well-suited to the task or

Fig. 5. The difference in the performance after providing hard labels for MRF segmentation. The left image is the blind segmentation result without providing labels while the right image is the result when providing sample segments for each label.

too limited in scope, the model may struggle to accurately segment the image. Another reason would be due to having these models need to be fine-tuned to the dataset used in this study. Also, the choice of hyperparameters would affect the overall performance of these models. There are several hyperparameters involved in unsupervised segmentation models, such as the learning rate, regularization, and optimization method. If the hyperparameters are not chosen correctly, the model's performance can suffer (Table II).

## VI. DISCUSSION

This paper reviewed the most common approaches for providing labels for training purposes using unsupervised segmentation algorithms. The first three sections covered the theory behind each approach. In the results section, we quantitatively and visually analyzed each approach and discussed cases where the method failed and the reasoning for the failure. The results indicated that we could not rely solely on pixel values for segmentation, even for such low-rank images as thermal images. Segmentation methods such as thresholds or clustering performed poorly in more complicated scenes with several objects of the same temperature in the scene. Therefore, extra information must be incorporated in the segmentation approach to producing a more accurate result. Approaches that rely on edges to separate different objects fail due to the

TABLE II. QUALITATIVE AND QUANTITATIVE RESULTS

	8-bit Images				16-bit Images				RGB Images			
	Dice	Spe	Sens	Jacc	Dice	Spec	Sens	Jacc	Dice	Spe	Sens	Jacc
Otsu's	0.33	0.80	0.79	0.20	0.68	0.43	0.24	0.63	0.61	0.52	0.55	0.41

Superpixel	0.35	0.96	0.88	0.21	0.26	0.88	0.21	0.86	0.58	0.19	0.86	0.47

TABLE III. PERFORMANCE EVALUATION OF STUDIED METHODS FOR ALL THREE TYPES OF INPUT IMAGES

Approach	Time complexity
Otsus	$O(N + L^2)$
Watershed	$O(K \times N)$
K-Means	$O(K \times N \times T)$
FCM	$O(K \times N \times T)$
GMM	$O(N \times K \times D^3)$
Gabor	$O(M^2 \times N^2)$
MRF	$O(N \times M \times K \times T)$

lack of depth information. This issue comes in when there are several overlapping objects with the same temperature in the scene. Finally, we see that texture analysis often delivers the best performance since they consider the spatial relations between neighboring pixels. In the case of Gabor segmentation, this approach requires empirical determination of several parameters to return better results. It is worth mentioning that the enhanced results produced by these texture-based methods are not without significant increases in computational requirements, algorithmic complexity, and significant barriers to real-time implementation.

#### A. Time Complexity

Table III lists the time complexities for each of the studies algorithms. Where  $N$  is number of pixels in the image,  $L$  is histogram length,  $K$  number of clusters,  $T$  is the time to calculate the distance between two objects,  $D$  is the problem dimension, and  $M$  is the window size. We notice that texture analysis is more complex and require more analysis than thresholding or clustering. It is evident that in order to build a labeling GUI using any of those algorithms, it would need high computing capabilities to make the GUI easy to use and provide results quickly.

### VII. CONCLUSION AND FUTURE WORK

In conclusion, this paper has provided a comprehensive review of unsupervised segmentation techniques for long wave infrared (LWIR) images. Through the evaluation and analysis of various methods, several key findings have emerged. Firstly, it is evident that unsupervised segmentation techniques play a crucial role in extracting meaningful information from LWIR images, despite the challenges posed by noise, low contrast, and temperature variations. The reviewed techniques have shown varying degrees of effectiveness in segmenting LWIR images, with some demonstrating superior performance in specific scenarios.

Moving forward, there are several avenues for future research in this domain. Firstly, further investigation is needed to explore the combination of multiple unsupervised segmentation techniques to enhance the overall segmentation accuracy in LWIR images. Fusion methods that leverage the strengths of different algorithms could potentially yield superior results. Additionally, incorporating domain-specific knowledge and priors, such as thermal physics, object characteristics, and context information, may further improve segmentation accuracy and robustness. Furthermore, the evaluation of unsupervised segmentation techniques on LWIR video sequences warrants attention. Temporal consistency and motion information can be leveraged to improve the accuracy of segmentation results over time. Investigating the use of unsupervised segmentation techniques for real-time applications, such as tracking and object recognition, is another area of interest.

In conclusion, this review has shed light on the current landscape of unsupervised segmentation techniques for LWIR images. While notable progress has been made, there is ample room for further exploration and improvement. By addressing the identified research gaps and leveraging emerging technologies, we can advance the state-of-the-art in LWIR image segmentation, ultimately facilitating more effective and reliable analysis in LWIR applications such as surveillance, target detection, and autonomous systems.

#### ACKNOWLEDGMENT

The authors express their gratitude to themselves for their dedicated efforts in conducting and presenting this remarkable research.

# The Application of Intelligent Evaluation Method with Deep Learning in Calligraphy Teaching

Yu Wang

School of Humanities, Weinan Normal University, Weinan, 714099, China

**Abstract**—Scientific and effective teaching quality evaluation (QE) is helpful to improve teaching mode and improve teaching quality. At present, calligraphy teaching (CT) QE methods are few in number and have poor evaluation effect. Aiming at these problems, deep learning (DL) is introduced to realize intelligent evaluation of CT quality. First, based on relevant research, the CTQE indicator system is constructed. Secondly, rough set and the principal component analysis (PCA) are used to reduce the dimension of the CTQE index system and extract four common factors. Then, the corresponding index data is input into the BP neural network (BPNN) model optimized by the improved sparrow search algorithm for fitting. Finally, combining the above contents, the improved sparrow search algorithm (ISSA) BPNN model is built to realize the intelligent evaluation of CT quality. The experimental results show that the loss value of ISSA-BPNN model is 0.21, and the fitting degree of CT data is 0.953. The evaluation Accuracy is 95%, Precision is 0.945, Recall is 0.923, F1 is 0.942, and AUC is 0.967. These values are superior to the most advanced teaching QE model available. The SSA-BPNNCTQE model proposed in the study has excellent performance in CTQE. This is of positive significance to the improvement of teaching quality and students' calligraphy level.

**Keywords**—Deep learning; calligraphy teaching; BPNN; intelligent evaluation; sparrow search algorithm

## I. INTRODUCTION

In recent years, China has paid more and more attention to the inheritance and development of traditional culture. Chinese calligraphy has been handed down for a long time and is an important part of Chinese traditional culture [1]. In addition, calligraphy is also an art form that can fully display the meaning and beauty of Chinese characters, and can give people a beautiful feeling. In China, calligraphy is also known as wordless poetry and pictureless painting. It is an important way to cultivate sentiment, cultivate character and enhance aesthetic taste. Therefore, CT has received extensive attention in China, and relevant courses have been offered at different stages [2,3]. In this context, CTQE has also become a hot research topic. It provides theoretical support and implementation approaches for the improvement of CT mode and the improvement of students' calligraphy performance. At present, the main evaluation method of CTQE is based on expert opinions and student feedback, which has problems such as extremely low efficiency and objective evaluation results. Therefore, the problem of research is to find suitable CTQE methods to improve the efficiency and objectivity of CTQE. The reason for these problems is not only the ideal selection method, but also the unique characteristics of calligraphy Chinese characters, such as a large number of

Chinese characters and similar characters. The large number of Chinese characters makes the traditional CTQE method very effective, but due to the development of technology, the CTQE method has not been improved in a timely manner. Scientific and effective CTQE can promote the improvement of calligraphy teaching mode and improve the quality of calligraphy teaching. Therefore, research needs to design effective CTQE methods. DL is one of the important technologies to realize industry intelligence and automation, and has achieved remarkable results in data mining, machine learning, artificial intelligence and other fields [4,5]. Therefore, DL is introduced to realize the intelligent evaluation of CT quality, so as to help calligraphy teachers understand the defects in the teaching process more intuitively. Thus, the teaching quality and students' calligraphy level have been improved, which has positive significance for the inheritance and promotion of Chinese calligraphy culture.

The key components of the study include the construction of a CTQE indicator system, PCA based common factor extraction, improved BPNN based CTQE model, ISSA-BPNNCT quality intelligent evaluation model, and research results. The main research results are the comparison results between the ISSA-BPNN model and other models under different model evaluation values. There are two main innovations in the research. The first point is to use the improved sparrow search algorithm (ISSA) to optimize the BP neural network (BPNN), so as to build ISSA-BPNN and improve the performance of the model. The second point is to use ISSA-BPNN to realize intelligent evaluation of CT quality to improve the efficiency and objectivity of CT evaluation. Scientific and effective CTQE can help improve the quality of calligraphy teaching and also improve the efficiency of students' learning calligraphy. In order to find a suitable CTQE method, an improved sparrow search algorithm was introduced based on the BPNN algorithm.

## II. RELATED WORKS

China's traditional culture has a long history of inheritance and profound heritage, and is loved and yearned for by people all over the world. Calligraphy is an important part of China's traditional culture, which contains rich artistic aesthetic value. CT is an important course to carry forward our traditional culture, which can improve students' aesthetic taste, cultivate students' sentiment, and cultivate students' artistic aesthetics. Therefore, it has attracted the attention of many scholars. Fang et al. conducted a comprehensive discussion and analysis on the curriculum of calligraphy in Chinese universities. And they have studied the improvement and perfection of calligraphy curriculum, providing theoretical support for the

reform of calligraphy curriculum in China [6]. Under the background of journalism, Liu and others conducted a questionnaire survey on students and teachers of calligraphy in colleges and universities. Thus, the effect of CT reform is analyzed, and the reform strategy is given according to the results of the questionnaire [7]. Huda et al. analyzed the effect of students' calligraphy learning based on Bloom's revised classification to improve CT quality [8]. Sun takes Anhui University of Finance and Economics as an example to explore the auxiliary role of calligraphy learning in the training of environmental design talents. It provides ideas for the development of environmental design industry [9]. Liu discussed the frequency of calligraphic elements in classic films released in China in recent years, and the effects in films. It provides ideas for the inheritance and promotion of Chinese calligraphy aesthetics [10]. Huda S proposed a calligraphy learning assistant system based on projection mapping to improve students' calligraphy learning efficiency and improve their calligraphy level [11]. Kobayashi et al. based on DL, combined with image and human motion, then proposed a calligraphy generation method to realize automatic calligraphy writing [12]. Based on aesthetic psychology, Jin and others combined calligraphy and painting elements with cultural and creative products. It has achieved innovation in the design of cultural and creative products and contributed to the inheritance of calligraphy and painting culture [13].

Xi et al. evaluated the sorting capacity of urban domestic waste in China in combination with analytic hierarchy process (AHP) and BPNN to help cities improve their waste treatment level [14]. Liao et al. used genetic algorithm (GA) to optimize BPNN. Thus, the viscosity model of aluminum alloy is established, which provides a new method for the production and optimization of aluminum alloy [15]. Wen et al. combined random forest (RF) and particle swarm optimization (PSO) to optimize BPNN. Based on the optimized BPNN, the carbon dioxide emissions of China's commercial sector are predicted. It provides data support for China's environmental protection [16]. Chang et al. proposed a back-propagation neural network optimized by thought evolution algorithm to realize the prediction of the penetration quality of asymmetric fillet weld [17]. Li et al. used Levenberg-Marquardt algorithm to optimize BP neural network, and thus proposed a new approximate response model of quadrant detector. The model has good application prospects in beam position measurement [18]. Song et al. conducted mathematical modeling of solid oxide fuel cell (SOFC) through BPNN to evaluate and predict the performance of SOFC at different furnace temperatures. The error of the prediction method is less than 5%, and it is better than the traditional method [19]. In order to make up for the defects of BPNN, Han et al. selected Genetic Algorithm (GA) to obtain network parameters, optimize BPNN, and evaluate the effect of UAV shape product design scheme based on optimized BPNN. The relative error of this evaluation method is less than 4%, and it can evaluate the design scheme quickly and scientifically [20]. Li and others believe that the current motion management system has many defects, such as low accuracy of output results and poor efficiency. To solve these problems, they proposed an optimization method based on BPNN to optimize the motion management system. The effect of this optimization method is ideal and can

significantly improve the performance of the system [21].

In summary, CT accounts for a significant proportion in China's education system, while BPNN is also relatively mature and widely used in various fields. However, there is currently limited research on the combination of BPNN and CT, and the current CTQE method has significant shortcomings. Therefore, this study proposes an improved BPNN and utilizes it to achieve intelligent evaluation of CT, improving the accuracy and objectivity of CTQE. By introducing an improved BPNN into CT, the research has to some extent enriched the research results in this field and also made up for the shortcomings of weak objectivity in current CTQE methods. Therefore, it can provide data and theoretical support for CT reform.

### III. DL-BASED CTQE METHOD

#### A. Construction and Reduction of CTQE System

In CT, teaching QE can help teachers to more intuitively understand the problems in the teaching process, so as to urge teachers to take measures to improve the teaching mode and improve the teaching quality. Therefore, it is very necessary to evaluate the quality of CT. To conduct CTQE, first of all, we should select indicators and build a CTQE indicator system. Combined with the previous research results and the current situation of CT in China, the study evaluated the teaching quality from five dimensions. It includes CT content, teaching methods, teaching environment, teaching process and teaching effect. The research and construction of the CTQE indicator system is shown in Table I.

TABLE I. EVALUATION INDEX SYSTEM OF CALLIGRAPHY TEACHING QUALITY

First-Level Indicators	Code	Secondary Indicators	Code
Content of courses	X <sub>1</sub>	Professors' etymology	Y <sub>1</sub>
		Professor's font	Y <sub>2</sub>
		Calligraphy knowledge	Y <sub>3</sub>
		Calligraphy skills	Y <sub>4</sub>
		Cultural knowledge	Y <sub>5</sub>
		Related activities	Y <sub>6</sub>
Teaching method	X <sub>2</sub>	Teaching language	Y <sub>7</sub>
		Auxiliary teaching	Y <sub>8</sub>
Teaching environment	X <sub>3</sub>	Classroom layout	Y <sub>9</sub>
		Background music	Y <sub>10</sub>
Teaching process	X <sub>4</sub>	Classroom power	Y <sub>11</sub>
		Teacher role	Y <sub>12</sub>
		Student role	Y <sub>13</sub>
		Control of learning process	Y <sub>14</sub>
		Teacher's calligraphy ability	Y <sub>15</sub>
Teaching effectiveness	X <sub>5</sub>	Learner satisfaction	Y <sub>16</sub>
		Learner self-assessment	Y <sub>17</sub>
		Other comments of learners	Y <sub>18</sub>

CT content should be mainly from two aspects, namely, the teaching of calligraphy knowledge and calligraphy skills. To this end, in this dimension, the study includes the teaching of character sources, fonts, calligraphy knowledge, calligraphy skills, cultural knowledge, and related activities. In the dimension of teaching methods, the study includes two

indicators that can evaluate teaching innovation: teaching language and auxiliary teaching methods. In the dimension of teaching environment, the study selected two indicators: classroom layout and classroom background music. In the dimension of teaching process, the study selected five indicators. They include teacher's classroom power, whether the teacher's role is successfully played, whether the student's role is successfully played, whether the teacher has sufficient control in the process of student learning, and the teacher's calligraphy level and ability. In the dimension of teaching effect, the study selected three dimensions: student satisfaction, student self-evaluation score and others' score on students. The weight data corresponding to each index in Table I is input into the BPNN model for fitting learning. Then the intelligent evaluation of CT quality can be realized according to the predicted output results of the BPNN model. In Table I, KMO and Bartlett test are used to test various indicators, so as to analyze the correlation between indicators. Then the effectiveness of the CTQE indicator system built in the study is verified. KMO and Bartlett test results are shown in Table II.

TABLE II. KMO AND BARTLETT TEST

Project		P
KMO inspection		0.638
Bartlett sphericity test	Approximate chi-square	7604.358
	DF	0.74
	Significance	0.000

In Table II, KMP test and Bartlett test of all indicators have passed, and P value is less than 0.05. It means the indicators of the CTQE indicator system built in the study have significant correlation. The validity of the CTQE index system built in the study is further verified. However, KMO test is only 0.638, which indicates that in the CTQE indicator system shown in Table I, some indicators have weak correlation. But, the CTQE indicator system shown in Table I contains a large number of indicators, some of which cannot effectively reflect the CT quality. And the calculation amount in the subsequent calculation will be increased. Therefore, the reduction of rough sets is studied. Rough set has a good effect in dealing with uncertain data, so it is often used to deal with uncertain problems. The attribute reduction function of rough set is used to deal with the CTQE indicator system shown in Table I, so as to eliminate the invalid or weak correlation indicators. The index system was simplified to improve the accuracy of teaching quality evaluation. After reduction, a simplified CTQE indicator system is obtained, as shown in Table III.

In Table III, after rough set reduction, eight redundant indicators are deleted, so that the number of indicators included in the CTQE indicator system is reduced from 18 to 10. This method can effectively improve the efficiency and accuracy of CT quality evaluation.

**B. Common Factor Extraction based on PCA**

After using rough set to reduce the CTQE index system, a simplified CTQE index system containing 10 evaluation indicators is obtained. It reduces the amount of calculation for

subsequent teaching quality evaluation and improves the efficiency and accuracy of teaching quality evaluation. However, the simplified CTQE indicator system still contains a large number of indicators. If these indicator data are input into the BPNN model, 10 input layer nodes need to be constructed. This will cause the network structure of the model to be too complex, and the prediction performance of the model will also be significantly reduced. Therefore, the principal component analysis (PCA) is used to extract common factors to further reduce the dimension of indicators. First of all, the deviation standardization method is used to standardize all indicators. It can avoid the performance degradation of the model due to the inconsistency of the unit and magnitude between different indicators. The standardization process is shown in Equation (1).

$$X' = \frac{x_{ij} - x_{\min}}{x_{\max} - x_{\min}} \tag{1}$$

$X'$  is the index data value obtained after standardization;  $x_{ij}$  is the data value corresponding to the  $j$  index in the  $i$  calligraphy lesson;  $x_{\max}, x_{\min}$  represent the maximum and minimum values of  $x_{ij}$  in Equation (1). The maximum variance method is used for factor analysis of the indicator system to obtain the factor contribution rate in Table IV.

In Table IV, four common factors are extracted, and the cumulative variance of these four common factors exceeds 84%. This data can show that the four common factors extracted can effectively and objectively reflect the teaching situation of calligraphy class, so as to evaluate the teaching quality of calligraphy class. The factors in Table IV are descriptive statistics, and then the factor component matrix is obtained to analyze the correlation between each index and each common factor, so as to find the index of common factor mapping. The factor component matrix is shown in Table V.

From Table V, corresponding indicators that can reflect four common factors are extracted, namely  $Y_4, Y_8, Y_{15}$  and  $Y_{18}$ . This shows the four indicators of calligraphy skill teaching, auxiliary teaching methods, teachers' calligraphy level and others' evaluation of students. It can effectively and comprehensively reflect the effect of CT. Therefore, these four indicators are selected to evaluate CT quality.

TABLE III. SIMPLIFIED EVALUATION INDEX SYSTEM OF CALLIGRAPHY TEACHING QUALITY

C. CTQE Model based on Improved BPNN

Based on the CTQE index system constructed by the research, combined with AHP and expert evaluation method, the teaching quality of calligraphy can be analyzed and evaluated. However, this CT quality evaluation method is easily affected by subjective factors, so it lacks objectivity, scientificity and effectiveness. To solve this problem, DL is introduced to realize the intelligent evaluation of CT quality, so as to eliminate the negative impact of subjective factors on the evaluation results of teaching quality. The realization way is to determine the weight of Y<sub>4</sub>, Y<sub>8</sub>, Y<sub>15</sub> and Y<sub>18</sub> by using expert scoring method combined with AHP and fuzzy comprehensive evaluation. In the experiment, the data related to these four indicators are input into the BPNN model for fitting and learning, and the prediction score is obtained. CT quality was evaluated according to the predicted score. However, the traditional BPNN has some defects, and its performance is greatly affected by the initial parameter value. Therefore, SSA is studied to obtain the optimal parameters of BPNN model, so as to improve the performance of BPNN model. The algorithm of SSA is simple to implement and has good robustness and optimization effect, but it also has the defects of poor convergence performance and weak global optimization ability. To solve this problem, research and propose strategies to optimize it. First, the sparrow population in the algorithm is initialized using the idea of reverse learning. A sparrow population  $X_{i,j}$  is randomly generated, and the inverse solution  $X_{i,j}^*$  of  $X_{i,j}$  is calculated, as shown in Equation (2).

$$X_{i,j}^* = ub_{i,j} + lb_{i,j} - X_{i,j} \quad (2)$$

$ub_{i,j}, lb_{i,j}$  are the upper and lower limit of the  $j$  dimension of individual  $i$  in the initial sparrow population in Equation (1). The fitness value of the individual in the reverse population is calculated. If there is Equation (2), the individual is regarded as the initial population.

$$fit(X_{i,j}^*) < fit(X_{i,j}) \quad (3)$$

The strategy of Equation (1) and (2) can improve the population diversity of SSA, thus optimizing the global optimization ability of SSA. In SSA, the location update of the individual discoverer in the next iteration will refer to its current location information. This characteristic makes the convergence performance and search performance of SSA not ideal at the beginning of the iteration. The global search ability of SSA is poor at the end of the iteration, and it is easy to fall into local extremum. In view of this defect, a nonlinear weighting factor  $\lambda$  is proposed to improve the location update strategy of the individual discoverer in SSA, as shown in Equation (4).

$$\lambda = (t / T_{max})^2 \quad (4)$$

$t$  is the current iteration number;  $T_{max}$  is the maximum number of iterations in Equation (4). The strategy of Equation (5) is used to update the discoverer position.

$$X_{i,j}^{t+1} = \begin{cases} \lambda X_{i,j}^t & \text{if } R_2 < ST \\ X_{i,j}^t + Q & \text{if } R_2 \geq ST \end{cases} \quad (5)$$

$X_{i,j}^t$  is the position of the  $j$  dimension of individual  $i$  in the current iteration in Equation (5);  $Q$  is a normal distribution random number;  $R_2, ST$  are the early warning value and the early warning threshold. For the vigilance, the strategy of Equation (6) is used to update.

$$X_{i,j}^{t+1} = \begin{cases} X_{best}^t + \beta |X_{i,j}^t - X_{best}^t| & \text{if } f_i > f_g \\ X_{i,j}^t + \beta (X_{worst}^t - X_{best}^t) & \text{if } f_i = f_g \end{cases} \quad (6)$$

In Equation (6),  $X_{worst}^t, X_{best}^t$  are the worst individual and the best individual in the current iteration;  $\beta$  is a normal

distribution random number;  $f_i$  is the fitness value of individual  $i$ ;  $f_g$  is the fitness value of the worst individual in all iterations. Using Equation (4), (5) and (6) can effectively reduce the dependence of individual location updates on their current location information, thus improving the convergence and optimization performance of SSA. ISSA is used to optimize the parameters of BPNN, and the ISSA-BPNN model is constructed. Based on the ISSA-BPNN model, the intelligent evaluation of CT quality is realized. The ISSA-BPNNCT quality intelligent evaluation model is shown in Fig. 1.

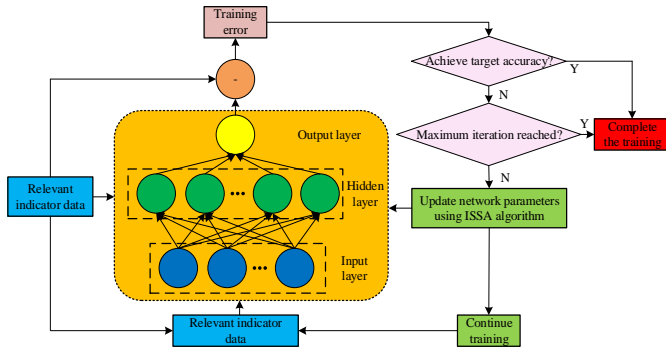

Fig. 1. ISSA-BPNN intelligent evaluation model of calligraphy teaching quality.

#### IV. ISSA-BPNNCT QUALITY INTELLIGENT EVALUATION MODEL

Calligraphy is an important part of China's traditional culture, which contains rich artistic aesthetic value. CT is to promote our traditional culture. It is an important course that can improve students' aesthetic taste, cultivate students' sentiment, and cultivate students' artistic aesthetics, so it has attracted the attention of many scholars. To realize the

intelligent and automatic evaluation of CT quality, the intelligent evaluation model of CT quality is built based on ISSA-BPNN. Relevant data were collected in the teaching system of calligraphy major in a university, and the experimental data set was constructed to test the performance of ISSA-BPNNCT quality intelligent evaluation model. 70% of the data in the experimental data set is randomly divided to train the model, which is recorded as the training sample set, and the other 30% of the data is used to test the model. At present, the common intelligent evaluation models of teaching quality include BPNN (GA-BPNN) model optimized by GA and radial basis function neural network (PSO-RBFNN) model optimized by PSO. The ISSA-BPNN model, GA-BPNN model and PSO-RBFNN model are trained by using the training sample set. During the training, the changes of the loss value and error value of the above models are shown in Fig. 2. In Fig. 2, when the minimum error and the minimum loss value are reached, the ISSA-BPNN model only needs 71 iterations, 42 and 71 times less than GA-BPNN model and PSO-RBFNN model, respectively. In Fig. 2(b), the loss value of ISSA-BPNN model is 0.21, which is 0.23 and 0.30 lower than GA-BPNN model and PSO-RBFNN model, respectively. In the above results, it is proved that the convergence of ISSA-BPNN model is better than GA-BPNN model and PSO-RBFNN model.

In the process of fitting the model to CT data, the fitting degree of several models and CT data is calculated and recorded in the experiment, as shown in Fig. 3. In Fig. 3(a), the fitting degree of ISSA-BPNN model reaches 0.953. In Fig. 3(b), the fitting degree of GA-BPNN model reaches 0.933, 0.020 lower than ISSA-BPNN model. In Fig. 3(c), the fitting degree of PSO-RBFNN model reaches 0.902, 0.051 lower than ISSA-BPNN model. The ISSA-BPNN model has a higher fitting degree with the data and better performance in CTQE.

Fig. 2. Change of loss value and error value of the model.

Fig. 3. Fitting degree of model and calligraphy teaching data.

20 samples were used to analyze the accuracy of ISSA-BPN model, GA-BPNN model and PSO-RBFNN model in CTQE. In the study, according to the evaluation score, the CT quality was divided into four grades, namely 4: excellent; 3: good; 2: general; 1: poor. Among the 20 samples, the difference between the predicted output of ISSA-BPN model, GA-BPNN model and PSO-RBFNN model and the actual sample value is shown in Fig. 4. In Fig. 4(a), in the evaluation of 20 samples, the ISSA-BPN model only evaluated the value of the sample with the number of 18, which was inconsistent with the actual value. However, the evaluation value is quite close to the actual value, and the evaluation accuracy rate reaches 95%. In Fig. 4(b), in the evaluation of 20 samples by GA-BPNN model, the evaluation values of samples numbered 12 and 17 are inconsistent with the actual values. Moreover, the evaluation value of the two samples is quite close to the actual value grade, and the evaluation accuracy rate is 90%, which is 5% lower than the ISSA-BPN model. In Fig. 4(c), PSO-RBFNN model evaluated 20 samples, and the evaluation values of samples numbered 4, 7 and 18 were inconsistent with the actual values. In the evaluation of the sample numbered 4, the evaluation value differs greatly from the actual value. In the evaluation of samples numbered 7 and 18, the difference between the evaluation value and the actual

value is small, and the evaluation accuracy is 85%, which is 10% lower than the ISSA-BPN model. The above results can show that the ISSA-BPN model is more accurate in the evaluation of CT quality, and even if there is an evaluation error, the evaluation error is also within the acceptable range.

The performance of ISSA-BPN, GA-BPNN and PSO-RBFNN are tested by using Precision and Recall indicators. The Precision and Recall of SSA-BPN, GA-BPNN and PSO-RBFNN are shown in Fig. 5. In Fig. 5(a), the precision value of ISSA-BPN is 0.945, 0.142 higher than GA-BPNN and 0.208 higher than PSO-RBFNN. In Fig. 5(b), the Recall value of ISSA-BPN is 0.923, 0.213 higher than GA-BPNN and 0.230 higher than PSO-RBFNN.

Fig. 6 shows the F1 value changes of ISSA-BPN, GA-BPNN and PSO-RBFNN during the iteration process. The F1 value of ISSA-BPN reaches 0.942. The F1 value of GA-BPNN is 0.908, 0.034 lower than ISSA-BPN. F1 value of PSO-RBFNN is 0.896, 0.048 lower than ISSA-BPN. The above data can show that the performance of ISSA-BPN proposed in the study is better than GA-BPNN and PSO-RBFNN in CTQE.

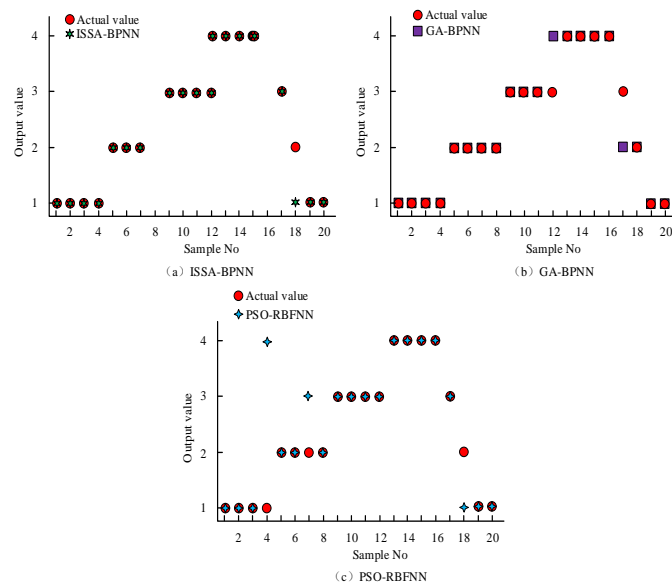

Fig. 4. Difference between model output forecast result and sample actual value.

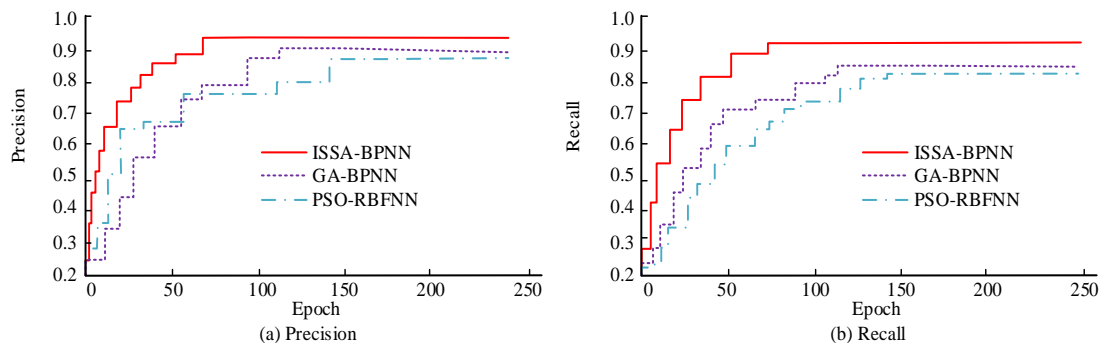

Fig. 5. Precision and recall of the model.

Fig. 6. F1 of the model.

The performance of ISSA-BPNN, GA-BPNN and PSO-RBFNN is evaluated by ROC curve. The AUC values of each are shown in Fig. 7. The AUC value of ISSA-BPNN is 0.967, 0.014 and 0.025 higher than GA-BPNN and PSO-RBFNN respectively. To sum up, the ISSA-BPNNCTQE proposed in the study has good performance and can achieve intelligent evaluation of CT quality with high efficiency and accuracy, thus providing a basis for CT improvement. It has positive significance for the improvement of students' calligraphy level and the inheritance and development of Chinese calligraphy culture.

Fig. 7. AUC value of the model.

## V. DISCUSSION

Calligraphy teaching plays an important role in the development of traditional Chinese culture. In order to overcome the problems of low efficiency and non-objectivity in traditional CTQE methods, an optimized BPNN model was introduced based on the self-developed CTQE evaluation system, aiming to improve the quality of calligraphy teaching and learning efficiency. In order to verify the performance of the optimized BPNN model, the Rate of convergence, fitness, accuracy, recall, F1 value and AUG value of the model are compared and analyzed in the result analysis part. The application of research methods involves rough sets, principal component analysis, sparrow search algorithm, and BPNN algorithm. Research can be applied not only to the quality evaluation of calligraphy teaching, but also to the quality evaluation of teaching in other disciplines. The method chosen by the research institute can greatly improve the efficiency of evaluating the quality of calligraphy teaching and enhance the objectivity of the evaluation results. The author believes that the development of algorithm technology has brought convenience to people's daily work, and people should

effectively utilize it and continuously empower traditional work.

## VI. CONCLUSIONS

At present, the main method of CTQE is based on expert opinions and student feedback, which is extremely inefficient and the evaluation results are often not objective. To solve this problem, DL is introduced and an intelligent evaluation of CT quality based on ISSA-BPNN is constructed. The performance of ISSA-BPNN is tested using the relevant data of calligraphy major in a university. ISSA-BPNN only needs 71 iterations to achieve the best performance, 42 and 71 times less than GA-BPNN and PSO-RBFNN respectively. The loss value of ISSA-BPNN is 0.21, which is 0.23 and 0.30 lower than GA-BPNN and PSO-RBFNN respectively. The fitting degree of ISSA-BPNN reached 0.953, 0.020 higher than GA-BPNN and 0.051 higher than PSO-RBFNN. Its evaluation accuracy is 95%, 5% higher than GA-BPNN and 10% higher than PSO-RBFNN. Its Precision value is 0.945, 0.142 higher than GA-BPNN and 0.208 higher than PSO-RBFNN. The Recall value of ISSA-BPNN is 0.923, 0.213 higher than GA-BPNN and 0.230 higher than PSO-RBFNN. Its F1 value reaches 0.942, 0.034 higher than GA-BPNN and 0.048 higher than PSO-RBFNN. Its AUC value is 0.967, 0.014 and 0.025 higher than GA-BPNN and PSO-RBFNN respectively. To sum up, the ISSA-BPNNCTQE proposed in the study has good performance and can achieve intelligent evaluation of CT quality with high efficiency and accuracy, thus providing a basis for CT improvement. It has positive significance for the improvement of students' calligraphy level and the inheritance and development of Chinese calligraphy culture. However, there are also certain shortcomings in the research. During the experimental process, this study only used relevant calligraphy historical data from one university. This may lead to some randomness in the experimental results. Therefore, it is necessary to expand the research scope and include more universities in subsequent research to eliminate this randomness.

**Abstract**—Two key technologies in robotic object grasping are target object localization and pose estimation (PE), respectively, and the addition of a robotic vision system can dramatically enhance the flexibility and accuracy of robotic object grasping. The study optimizes the classical convolutional structure in the target detection network considering the limited computing power and memory resources of the embedded platform, and replaces the original anchor frame mechanism using an adaptive anchor frame mechanism in combination with the fused depth map. For evaluating the target's pose, the smooth plane of its surface is identified using the semantic segmentation network, and the target's pose information is obtained by solving the normal vector of the plane, so that the robotic arm can absorb the object surface along the direction of the plane normal vector to achieve the target's grasping. The adaptive anchor frame can maintain an average accuracy of 85.75% even when the number of anchor frames is increased, which proves its anti-interference ability to the over fitting problem. The detection accuracy of the target localization algorithm is 98.8%; the accuracy of the PE algorithm is 74.32%; the operation speed could be 25 frames/s. It could satisfy the requirements of real-time physical grasping. In view of the vision algorithm in the study, physical grasping experiments were carried on. Then the success rate of object grasping in the experiments was above 75%, which effectively verified the practicability.

**Keywords**—Mobile robot; target object localization; pose estimation; YOLOv2 network; FCN semantic segmentation network

## I. INTRODUCTION

There are many high-intensity and dangerous delicate operations in the actual industrial production process, and with the significant increase of labor costs in recent years, the industrial production environment requires a lot of human capital to perform these operations. For enhancing the industrial productivity and control labor costs, a lot of industrial robots are introduced in industrial environments to perform daily industrial operations [1]. The ability of robots to perform a range of complex tasks in industrial production quickly and efficiently, and with lower input costs compared to manual labor, has made them the primary choice for real-world industrial operations [2]. However, mobile robots are still very difficult to fully automate in a real-world industrial production environment, and workers are often needed to assist in the process, resulting in limited efficiency gains for the entire industrial process [3-4]. To achieve fully automated robotic operations, vision systems need to be introduced on mobile robots equipped with robotic arms [5]. The introduction of

vision systems in robotics can on the one hand increase the reliability of robotic arms working in real complex industrial environments and on the other hand reduce the need for manual assistance in industrial operations [6-7]. Although a large number of mobile robots have been introduced into actual industrial production environments, they cannot fully automate actual industrial operations. Therefore, a mobile robot equipped with a robotic arm with visual feedback is needed to carry out transportation, sorting and other work in the industrial environment. To achieve this process, mobile robots first need to detect the target, locate the target position, estimate the object's posture, and determine the grasping point. The research mainly focuses on the vision algorithm of the sucking robot arm when grasping objects. The problems to be solved are target location and pose estimation. Research on combining depth information and image color information for pose estimation, and propose an adaptive anchor frame mechanism based on the characteristics of depth images. Then, the semantic segmentation network and principal component analysis are used to determine the surface normal vector of the object, in order to estimate the target pose. The purpose of the research is to make the Robotic arm adjust the pose direction of the robot arm and grasp the object more efficiently and accurately by determining the spatial position and pose of the target object.

## II. RELATED WORK

Target detection is the key and prerequisite for automated object grasping by robotic arms in industrial production environments, and is therefore a research focus in machine vision. Dai Y et al. present a discriminative network for infrared small target detection to address the problem of few features inherent in purely data-driven methods, which fully utilizes labeled data and domain knowledge, and validates its performance on the open SIRST dataset, verifying that the network has some enhancement performance [8]. Scholars Szemenyei M and Estivill-Castro V present two new neural network results for the target detection problem of rescue robots in soccer tournaments, both structures use environmental attributes for enhancing the semantic segmentation and target detection, and use synthetic transfer learning to complete the learning in a small number of manually labeled images, and finally validate the models in experiments low cost and advanced [9]. Three aspects of vision-based robot grasping were investigated by Du et al. A review of traditional methods based on RGB-D image input and new methods of deep learning (DL) was mainly conducted

to provide theoretical help for the challenges and solutions of robot grasping [10]. Ravindran et al. addressed the multi-target detection and multi-target tracking in vehicle driving and proposed the solution of combining sensing modalities with Deep Neural Network (DNN), which includes three sensors and fusion of sensor data with DNN, was proposed for multi-target detection and multi-target tracking problem in vehicle driving [11]. Afif et al. proposed a detection framework for specific indoor category, which is based on "RetinaNet" built and evaluated using ResNet, DenseNet and VGGNet, achieving up to 84.61% detection accuracy in the experiment [12].

After obtaining the target's position in the camera, in order to use the robotic arm to grasp the object, it is also necessary to obtain the object's pose information. Vision-based PE can be divided into two categories: learning-based PE and model-based PE. Wu et al. used linear complementary filters to deal with and depersonalize the multi-sensor PE problem in a device, specifically by obtaining a quadratic observation model through a gradient descent algorithm, and then building an additive measurement model based on the derived results, achieving a reduction in space without loss of estimation accuracy consumption and computational burden without loss of estimation accuracy [13]. Scholars Al-Sharman et al. train DNNs based on DL techniques for identifying related measurement models and filter them out, and use loss techniques to reduce computational sophistication [14]. Scholars Billings G and Johnson-Roberson M proposed SilhoNet, a new way for predicting 6D object pose in monocular camera data, which is to predict the intermediate contours of the objects with associated occlusion masks and 3D translation vectors, and then regress 3D orientation from the contours, obtaining better experimental performance than two networks Estimation performance [15]. Wang et al. presented a DL-based grasping pose estimation method for a SCARA loading and unloading robot, which fuses point clouds with category numbers into a point category vector and uses multi-point mesh networks for evaluating the robot's grasping pose, getting success rates of 98.89%, 98.89%, and 94.44% on three homemade sub-datasets [16]. Liu et al. proposed a grasping posture determination method related to shape analysis for target object shape analysis in robotic grasping, which reduces complicated objects to basic shapes and then simplifies the grasping of objects based on force closure [17].

Comprehensive domestic and international research on mobile robot target detection and PE reveals that most of the detection algorithms are related to DL, which is computationally intensive, while the learning-based PE

methods also rely heavily on the diversity of training data sets, which requires high data collection and calibration. Therefore, the study reduces the computational effort of target detection in the embedded platform by optimizing the original convolution process, and then performs PE by the Fully Convolution Network (FCN) semantic segmentation and (Principal Component Analysis (PCA) algorithm, aiming to provide a more concise and practical mobile robot vision algorithm.

### III. TARGET OBJECT LOCALIZATION ALGORITHM AND POSE ESTIMATION ALGORITHM FOR MOBILE ROBOT

#### A. Target Localization Algorithm and Optimization Based on YOLOv2 Network

Based on the progress of computer technology and artificial intelligence technology, the robotics industry has also developed rapidly, and robots have been applied to more fields, especially in tasks with harsh working conditions and strong repeatability. Using robots to perform these tasks can liberate workers from harsh working environments and also improve work efficiency. In many robot work scenarios, the most common action performed by robots is grasping. Robots perceive the surrounding environment through sensors and then perform grasping operations. When a mobile robot performs grasping of a target object, it must obtain the correct object position and pose to ensure that the robot arm accurately grasps the target from a suitable position and with the correct grasping pose. That is, there are two important problems to be solved in the whole grasping process: localization of the target object and estimation of the spatial pose of the target. The study uses computer vision algorithms to solve the problems faced by mobile robots performing industrial production operations, and the specific process is shown in Fig. 1.

Neural networks have powerful feature extraction capabilities, and with a sufficient number of training datasets with labels, the gradient back-propagation algorithm can be used to renew the weights of the neural network to achieve the coordinate position detection of different target objects. The YOLOv2 network is in view of the Darknet network. It has a powerful feature extraction capability and uses the anchor frame mechanism instead of the direct regression of the target frame coordinates in YOLOv1. However, although the YOLOv2 network has a relatively small model structure and fast localization detection speed, it is still difficult to be arranged in related platforms with very limited resources, so the network structure needs to be further optimized for decreasing the model's size. Fig. 2 indicates the structure of the convolutional layer.

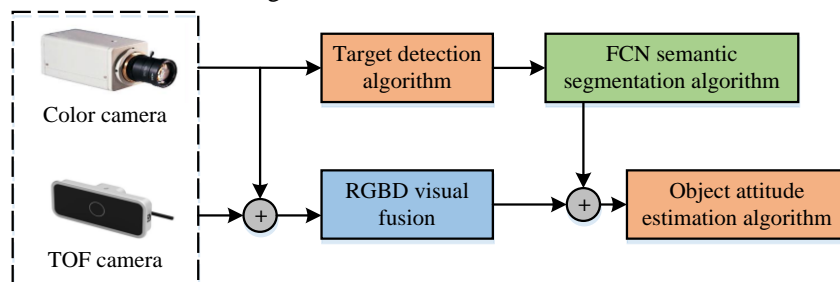

Fig. 1. Computer vision algorithm flowchart.

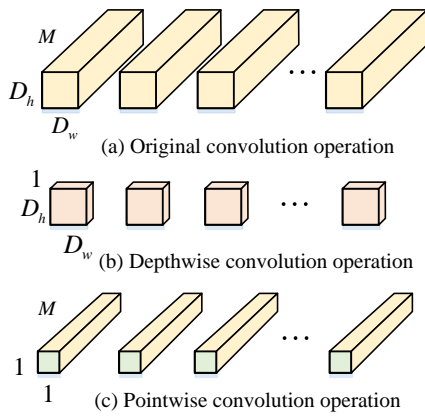

Fig. 2. Structure diagram of convolution layer.

It supposes that a feature map (FM) of  $D_w \times D_H \times M$  is input and a feature map of  $D_w \times D_H \times N$  is output in the standard convolution operation (CO) as in Fig. 2(a), where  $D_H$  and  $D_w$  are the length and width of the FM, respectively, and  $M$  serves as the channels' quantity of the input FM and  $N$  serves as the channels' quantity of the output FM. Assuming that the convolution kernel's (CK) size is  $D_k$  and the step size is 1, the parameters quantity of the CK is  $D_k \times D_k \times M \times N$ , then the amount of computation generated by one CO is shown in Equation (1).

$$D_k \times D_k \times M \times N \times D_w \times D_H \quad (1)$$

The standard CO is divided into two processes: filtering and combining. For decreasing the size of the network, the standard CO is split into depthwise convolution, which is only responsible for filtering, and pointwise convolution, which is only responsible for combining. The depth wise convolution in Fig. 2(b) uses a single-channel CK on each channel of the input FM to generate corresponding feature values at each position on each channel of the input FM. Then the point wise CO is used, i.e., a  $1 \times 1$  CK is used to combine the feature values on different channels at the same position to produce the corresponding feature vectors. Compared with the standard CO, the parameters quantity for depth wise convolution is  $D_w \times D_H \times M$  and the parameters quantity for point wise

convolution is  $1 \times 1 \times M \times N$ . Equation (2) demonstrates the parameters quantity for the two-step CO.

$$D_k \times D_k \times M + M \times N \quad (2)$$

And the two-step CO produces the computation as shown in Equation (3).

$$D_k \times D_k \times M \times D_w \times D_H + M \times N \times D_w \times D_H \quad (3)$$

Compare the transport arithmetic before and after splitting the standard CO into two parts, depth wise CK and point wise convolution, as shown in Equation (4).

$$\frac{D_k \times D_k \times M \times D_w \times D_H + M \times N \times D_w \times D_H}{D_k \times D_k \times M \times N \times D_w \times D_H} = \frac{1}{N} + \frac{1}{D_k^2} \quad (4)$$

The size of CK is usually assumed to be 3, so the former term in Equation (4) can be neglected, i.e., by splitting the standard CO, the number of CK parameters can be reduced while the computation is reduced to one-ninth of the standard CO. In order to facilitate more accurate target detection and localization by the machine, an adaptive anchor frame mechanism is presented to obtain the 3D position of the object by using additional depth pictures to complement the information of the color pictures. The adaptive anchor frame mechanism only requires pre-setting  $n$  anchor frames with different aspect ratios of 1. The width and height of the anchor frames are multiplied by the scale factor calculated from the depth image to obtain the effect of the original anchor frame. The YOLOv2 network framework after adding the adaptive anchor frames is shown in Fig. 3.

Fig. 3 illustrates that the input image is subjected to the YOLOv2 network to generate the prediction parameter, which is used to improve the shape of the anchor frame and produce the normalized prediction frame. The depth image is processed to obtain the scale factor map, and the final detection result is obtained by multiplying the scale factor corresponding to each pixel to the prediction frame. When the camera captures an object, the same object has different distances from the camera and has different sizes in the computer's field of view, thus the object size can be obtained by combining the depth fusion map. The correspondence between depth distance and object size is shown in Fig. 4.

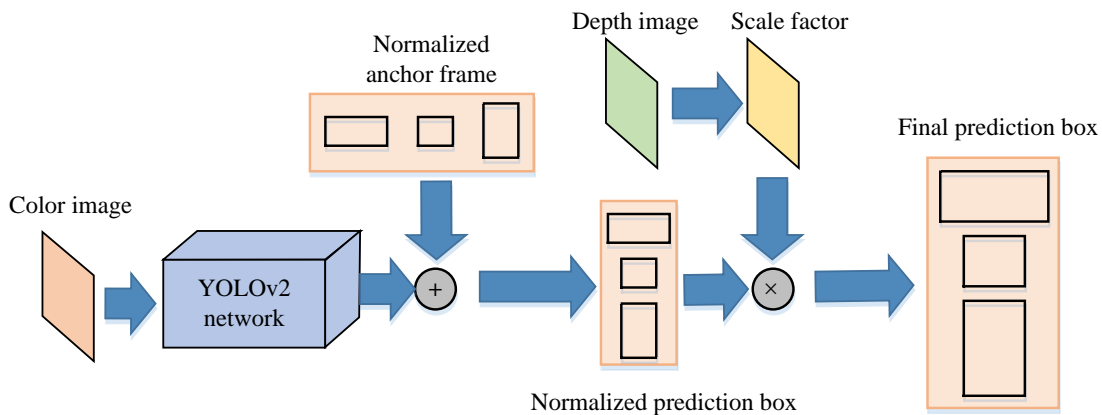

Fig. 3. YOLOv2 network combined with adaptive anchor frame mechanism network block diagram.

Fig. 4. Correspondence between depth distance and object size.

Fig. 4(a) indicates that the size of the object imaged on the imaging plane of the camera is  $s$  can be calculated based on the principle of similar triangles, as shown in Equation (5).

$$s = \frac{f \times l}{h} \quad (5)$$

In Equation (5),  $l$  is the actual length of the object,  $h$  serves as the distance between the object and the camera, and  $f$  serves as the focal length of the camera. In Fig. 4(b), the image size can also be calculated as shown in Equation (6).

$$s = \frac{f \times (l + x)}{h} - \frac{f \times x}{h} = \frac{f \times l}{h} \quad (6)$$

The size factor can be approximated based on this model of the relationship between the object-to-camera distance and the imaging size on the imaging plane, and multiplied by the normalized anchor frame to achieve the original anchor frame effect and get a relatively accurate prediction frame. For fully utilizing the information of all the prediction frames generated on the same object, a soft NMS is used in the study specifically by doing a weighted average of the coordinate information of all the frames to get the final prediction frame  $Box_i$ , as shown in Equation (7).

$$Box_i = \frac{\sum_j conf_{ij} \times box_{ij}}{\sum_i conf_{ij}} \quad (7)$$

In Equation (7),  $box_{ij}$  is the  $j$  th predictor box output on the  $i$  th object, and  $conf_{ij}$  is the confidence score of the predictor box. Finally, the overfitting phenomenon caused by limited training samples is solved by training the anchor frame parameters in steps. When training the anchor frames individually, the training data assigned to each anchor frame almost doubles, thus overcoming the over fitting phenomenon of a single anchor frame due to insufficient training samples.

### B. Target Object Pose Estimation Algorithm

In actual industry and life, mobile robots often need to grasp objects with various shapes, uncertain postures, and possible occlusion between objects. Therefore, it is necessary to obtain the position and attitude information of the target object through appropriate methods, and then use a robotic arm

to grasp the target object. After the position of the object in the camera is determined by the target detection and localization algorithm, the spatial coordinate values of the object can be obtained by using the camera's internal reference and related fused depth maps. However, the robotic arm also needs to know whether there is a plane on the object surface that can be absorbed when it grasps the object. This process can be done by semantic segmentation network to do pixel-level classification of the pixel points on the object surface and extract the points on the object surface that can be grasped, and the maximum connected domain (CD) consisting of these points is the absorbable plane (AP). The plane normal vector (PNV) of the plane equation in the 3D space established by these points is the pose direction of the target object, while the center on the CD is chosen as the target's 3D spatial location. The flow of the PE algorithm in the study is shown in Fig. 5.

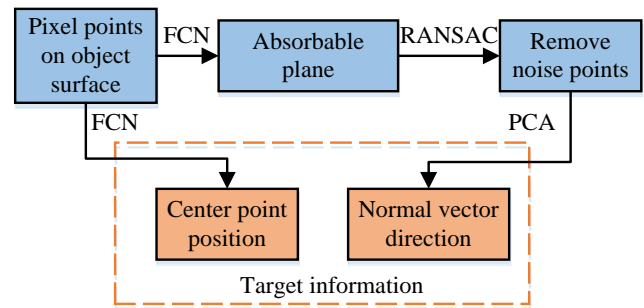

Fig. 5. Flow chart of attitude estimation algorithm.

In Fig. 5, the PE first extracts its AP using the FCN neural network algorithm, then removes the noisy points of the plane using the Random Sampling Consensus (RANDOM Sample Consensus, RANSAC), and finally solves the parameters of the object surface model using PCA for getting the target's pose message. Since there is noise in the depth map by the camera, after using FCN to determine the joint area on the AP of the target, RANSAC is used for removing the noise with large errors before getting a more accurate plane model. The processing flow is shown in Fig. 6.

The planar model used in the study has four parameters. Therefore, four data points (DP) are required for addressing the model. In Fig. 6, the RANSAC algorithm randomly selects four DP in the data set generated from the FCN results for solving the model parameters. All DP are included in the solved model, and the statistical error is less than the internal points' quantity. The model is considered accurate only when the internal points' quantity exceeds the set threshold, and then the PCA algorithm is used for addressing the related model parameters, and if the error of the current optimal model is greater than that of the obtained model, the optimal model is renewed.

The PCA algorithm is used to compress the data in the original feature space into a lower dimensional space. A schematic diagram of the PCA algorithm and its solution to the PNV is shown in Fig. 7.

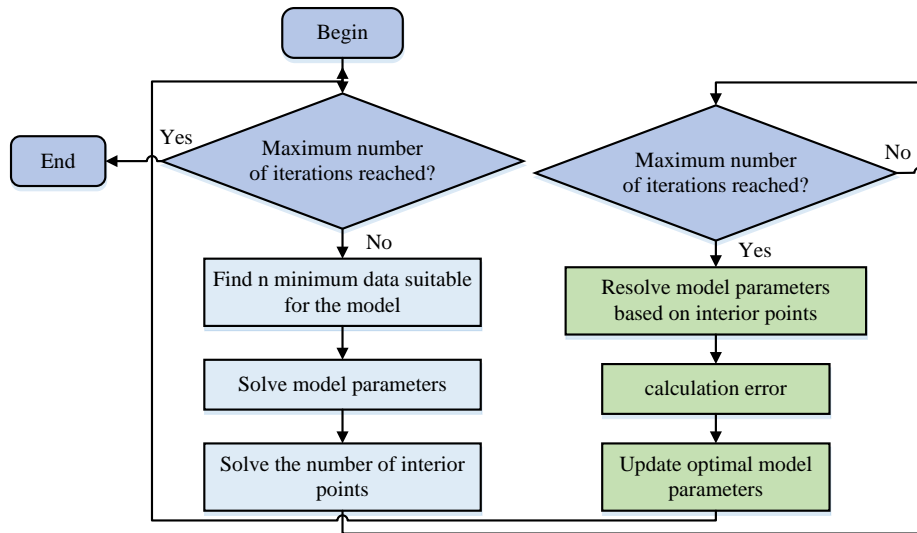

Fig. 6. Flow chart of RANSAC algorithm.

(a) Schematic diagram of PCA algorithm principle

(b) Schematic Diagram of PCA Algorithm for Solving Plane Normal Vector

Fig. 7. PCA algorithm and its schematic diagram for solving plane normal vector.

In Fig. 7(a), PCA transforms the data in the original feature space into the new orthogonal feature space by linear transformation, and then removes the dimensional information that is less informative, leaving a number of dimensions with more informative information to express the original data. The amount of information in a dimension can be expressed by the variance of the data in that dimension; the larger the variance, the greater the amount of information. The projection transformation is shown in Equation (8).

$$\begin{cases} \delta = A^T x \\ A = [\alpha_1, \alpha_2, \dots, \alpha_n] \end{cases} \quad (8)$$

In Equation (8),  $x$  is the data in the dataset,  $A$  is the change transformation matrix, the projected data is  $\delta$ , and the feature space formed by  $\alpha$  as the feature vector is the projected space where the vectors have the relationship shown in Equation (9).

$$\begin{cases} \alpha_i \alpha_i = 1 \\ \alpha_i \alpha_j = 0, i \neq j \end{cases} \quad (9)$$

The data in the original feature space is projected into the feature space consisting of  $\alpha$  as the feature vector by the projection transformation, and the projection value of the vector  $x$  in  $\alpha_i$   $\delta_i$  is shown in Equation (10).

$$\delta_i = \alpha_i^T x \quad (10)$$

The principle of PCA is to let the information in the dataset fall into the feature space as much as possible, so the variance of the projection on the new feature vector should also be as large as possible. The data variance of the projected data in one dimension is shown in Equation (11).

$$\begin{aligned} D(\delta_i^2) &= E(\delta_i^2) - E^2(\delta_i) \\ &= E(\alpha_i^T x x^T \alpha_i) - E(\alpha_i^T x) E(x^T \alpha_i) \\ &= \alpha_i^T \sum \alpha_i \end{aligned} \quad (11)$$

In Equation (11),  $D(\delta_i^2)$  is the variance after projection. To maximize it and to satisfy the relation, it is solved using the Lagrange multiplier method as shown in Equation (12).

$$f(x) = \alpha_i^T \sum \alpha_i - \lambda (\alpha_i^T \alpha_i - 1) \quad (12)$$

In Equation (12),  $\lambda$  serves as the eigenvalue of the matrix  $\Sigma$  and  $\alpha_i$  serves as the corresponding eigenvector. The derivative of  $\alpha_i$  is obtained when the derivative is 0. The maximum value of  $D(\delta_i^2)$  is obtained when the derivative is 0, as shown in Equation (13).

$$\begin{cases} \frac{\partial f(x)}{\partial \alpha_i} = \Sigma \alpha_i - \lambda \alpha_i \\ \Sigma \alpha_i = \lambda \alpha_i \end{cases} \quad (13)$$

Since the points on the AP of the target object are distributed in the whole plane space, the two eigenvectors along the plane direction have the largest variance, and the eigenvector normal to the plane direction corresponds to the smallest eigenvalue, so the eigenvector corresponding to the smallest eigenvalue found by PCA is the normal vector of the AP. With the obtained PNV as the target's pose direction, the grasping of the robot arm for the target can be realized. As shown in Fig. 6(b), PCA first determines the two feature vectors with the largest variance  $x$  and  $y$ , and determines the  $z$  axis direction in view of certain premises. Due to the small impact of sensor noise on the  $z$  axis direction, a portion of the sensor noise is successfully filtered out using the PCA method. The evaluation metric for the target PE is the 2D projection metric, and the PE is considered accurate if the average distance between the projection of the predicted corner point and the real labeled corner point  $e_{REF}$  is less than 5 pixels. 2D projection metric is defined as shown in Equation (14).

$$e_{REF} = \|P_i - TM\mu\|_2 \quad (14)$$

In Equation (14),  $M_c$  is the camera matrix,  $G$  is the target pose to be estimated,  $P_i$  is the position of the  $i$  th pixel, and  $\mu$  is the average of the pixel distribution with the maximum blending weight.

#### IV. ANALYSIS OF THE EFFECT OF TARGET OBJECT LOCALIZATION AND POSE ESTIMATION FOR MOBILE ROBOTS

##### A. Performance of Target Object Localization Algorithm for Mobile Robots

The study is based on a mobile robot platform to test the visual perception algorithm, including the performance analysis of target localization algorithm, PE algorithm and the effect analysis of the robot arm's grasping for the target. The mobile robot platform is equipped with a robot arm system, a color depth binocular vision system, a TX2 DL IPC and an image acquisition IPC for completing the grasping process of the target. The initial Learning rate of network training is 0.001, and the Learning rate of every 100 epochs is divided by 10. The configuration parameters of the experimental hardware are shown in Table I.

The public dataset used in the object detection and positioning experiment is from LineMod, which is a standard dataset for attitude estimation. There are 1200 instances of 13 objects, and the data includes color maps, depth maps, and corresponding camera coordinate information from different

perspectives. In order to improve operational efficiency, the study selected 200 images of each of the four types of objects for comparative analysis of different anchor box mechanisms and to compare the performance of the algorithms before and after the improvement. The mean Average Precision (mAP) results of the original anchor frame mechanism and the adaptive anchor frame mechanism in YOLOv2 are shown in Fig. 8.

In Fig. 8, the accuracy of the adaptive anchor frame mechanism improves by 1.55% when there are only 1 or 2 anchor frames, and the improvement is more obvious. When the number of anchor frames is three or more, the original anchor frame mechanism shows a serious over fitting phenomenon, and the detection accuracy decreases by 3.65%~3.77%. The adaptive anchor frame mechanism can still maintain a high detection accuracy when the number of anchor frames is three and four, which indicates that it has some improvement effect on the over fitting problem. The detection accuracies of different target detection and localization algorithms are shown in Fig. 9.

TABLE I. CONFIGURATION OF EXPERIMENTAL HARDWARE PARAMETERS

Configuration	TX2 Deep Learning Industrial Control Board	Image acquisition industrial control board
CPU	ARM Contex-A57	Intel Bay Trail J1900
Memory	8GB LPDDR4	8G DDR3L 1333MHz
Hard disk	32GB eMMC5.1	64GB Solid-state drive
interface	Wireless, Bluetooth, Ethernet	Network interface, serial port, USB

Fig. 8. Comparison of mAP results between the original anchor frame mechanism and the adaptive anchor frame mechanism under different number of anchor frames frames.

Fig. 9. Detection accuracy of target detection and location algorithm before and after improvement.

In Fig. 9, the improved algorithm detects objects 01, 02, and 03 significantly better than the Support Vector Machine (SVM) algorithm and the Single Shot multiBox Detector (SSD) algorithm, and the detection accuracy for object 04 is lower than the other two algorithms, but still above 95%. The SSD algorithm has good detection speed and accuracy compared to the SVM algorithm, but it is still weak in detecting small object 02. The average detection accuracies of the improved algorithm, SVM algorithm and SSD algorithm for objects are 98.8%, 96.65% and 96.78%, respectively. Taken together, the YOLOv2 network used in the study has high detection accuracy, good small object detection ability, and the optimized model size can be applied to embedded platforms, which is the optimal choice.

**B. Performance of Target Object Pose Estimation Algorithm for Mobile Robots**

The training samples for the pose estimation network model for mobile robots are taken from the LineMod dataset. In order to better simulate the real work environment and verify the stability of the algorithm, the dataset used during the testing was the Occlusion LineMod dataset, which was reannotated and generated from the LineMod dataset, was used during testing. This dataset contains 1435 images of eight objects with complex backgrounds and occlusions. For testing the PE algorithm in the study, it is compared with several commonly used PE algorithms for experiments. The PE results of different algorithms for seven target objects are shown in Fig. 10.

In Fig. 10(a), the BB8 algorithm has the highest PE accuracy for seven types of targets, followed by the PoseCNN algorithm, and the detection accuracy of the proposed PE algorithm is close to that of PoseCNN. However, according to the average detection accuracy and detection speed in Fig. 10(b), although the detection accuracy of BB8 is 92.78%, its detection speed is only 2 frames/s.

The detection accuracy of PoseCNN is 75.91% and the detection speed is 7 frames/s, which is slightly higher than that of BB8. The detection accuracy of PoseCNN is 75.91% and the detection speed is 7 frames/s, which is slightly higher than that

of BB8. The Tekin algorithm runs the fastest at 26 frames/s, but its estimation accuracy is only 63.14%. The accuracy of the PE algorithm is 74.32%, which is a big improvement over Tekin's algorithm, and it runs at 25 fps, which seems to satisfy the needs of real-time operation. Table II depicts the experimental results of the visual perception algorithm for different objects in the real object grasping experiments.

(a) Comparison results of detection accuracy for different target objects

(b) Comparison results of detection accuracy and speed of different algorithms

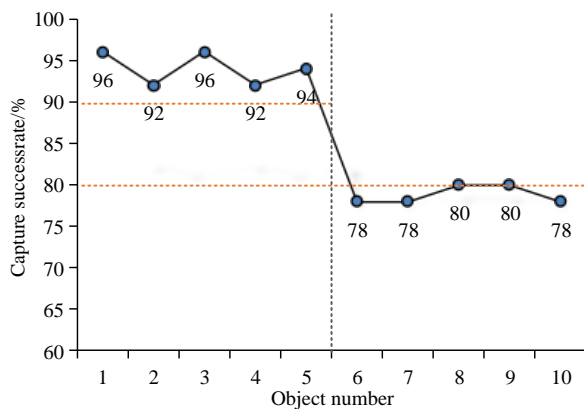

Fig. 10. Comparison of results of common object attitude estimation algorithms.

TABLE II. RESULTS OF VISUAL PERCEPTION ALGORITHM ON DIFFERENT OBJECTS

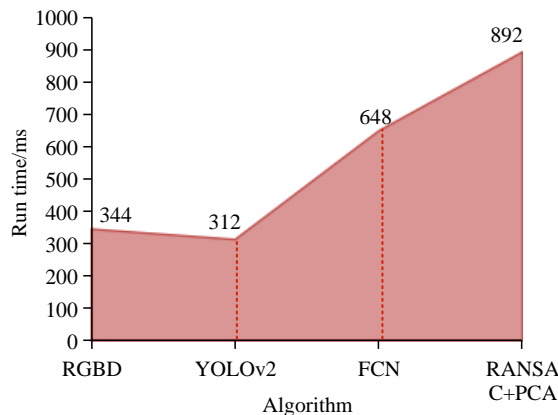

Object number	Surface center coordinate point	Coordinate point directly above	Surface normal vector	Center pixel coordinates	Pixel coordinates directly above
1	(0.09,0.24,1.84)	(0.12,0.24,1.64)	(-0.17,0.00,0.99)	(710,665)	(751,688)
2	(-0.06,0.11,1.36)	(-0.07,0.15,1.39)	(0.03,0.87,0.25)	(621,537)	(614,385)
3	(-0.10,0.07,1.54)	(-0.11,0.12,1.51)	(0.04,1.00,0.14)	(556,548)	(543,367)
4	(0.00,0.14, 1.50)	(0.06,-0.05,1.45)	(-0.28,0.95,0.17)	(646,608)	(708,434)
5	(0.05,0.21,1.18)	(0.05,0.31,1.01)	(-0.04,0.50,0.87)	(699,727)	(722,906)
6	(0.07,0.06,1.27)	(0.08,-0.12,1.19)	(-0.03,0.91,0.42)	(721,546)	(734,337)
7	(0.08,0.05,1.37)	(0.09,-0.13,1.28)	(-0.03,0.89,0.45)	(728,532)	(740,340)
8	(0.06,0.16,1.35)	(0.07,0.27,1.18)	(-0.04,-0.52,0.86)	(710, 649)	(728,796)
9	(0.07,0.04,1.28)	(0.08,-0.11,1.37)	(-0.03,0.82,0.49)	(725,518)	(746,322)
10	(-0.08,0.06,1.14)	(-0.09,0.08,1.46)	(0.05,1.01,0.15)	(558,543)	(547,361)

In the physical object grasping experiments, a total of 10 unknown objects were grasped, with object numbers 1 to 5 for normal-sized objects and 6 to 10 for smaller-sized objects. In Table I, the surface center coordinate point indicates the three-dimensional spatial point of the absorbable point on the object's surface in the corresponding coordinate system, and the coordinate point directly above indicates the three-dimensional spatial point at 20 cm directly above the center coordinate point. The robot arm system controls the end of the robot arm to move to the upper coordinate point, and adjusts the direction of the end nozzle to be consistent with the PNV, and then makes it move to the surface center coordinate point along the normal direction for completing the grasping of the target. The pixel coordinates projected to the color camera coordinate system are the center pixel point and the upper pixel point. The results of the grasping success rate and the each algorithm's time are shown in Fig. 11 for 50 grasps of each object.

(a) Success rate result of grasping target object

(b) Running time of each algorithm in the process

Fig. 11. The success rate of grasping objects and the running time of each algorithm in the process.

In Fig. 11(a), the success rates of physical grasping for objects 1~5 of normal size are all over 90%, while the success rates of physical grasping for objects 6~10 of smaller size are reduced but still maintain around 80%. The average success rate of physical object grasping reaches 86.4%, which tests the practicality of the physical object grasping algorithm proposed in the study. The study also tested the running time of the

vision algorithm for each stage. In Fig. 11(b), although the neural network algorithm is computationally intensive, it does not account for a large percentage of the total algorithm running time because the target detection algorithm runs on the GPU and the optimization of the DL framework substantially increases the neural network's speed. The RANSAC algorithm takes up the largest percentage of the time because it requires multiple iterations and the iterative process also uses PCA to calculate the interior point error.

## V. CONCLUSION

As robots are used to replace tedious manual labor in more and more industries, the use of mobile robots to complete the handling of goods in the logistics industry has gradually become a hot research topic nowadays. The study designs a set of vision algorithms for a mobile robot platform for the vision system of fully automated handling, mainly including a target object detection and localization algorithm based on the embedded platform with improved convolutional structure and an object PE algorithm based on FCN semantic segmentation network. While the detection accuracy of the original anchor frame mechanism decreases by 3.65%~3.77% due to the overfitting phenomenon, the proposed adaptive anchor frame mechanism can still maintain a high detection accuracy with good resistance to overfitting when the number of anchor frames is 3 and 4. In the experiments of detection and localization of different objects, the target localization algorithm proposed in the study improves the detection accuracy by 2.22% and 2.09% compared with the SVM algorithm and the SSD algorithm, respectively, with better localization results. The average success rate of grasping physical objects also reaches 86.4%, which effectively tests the algorithm's practicality proposed in the study for physical object grasping. However, although the study has optimized the convolutional structure and reduced the network's model parameters, the computational burden is still too large for the embedded platform, and the base convolutional layers can be considered to be combined together in subsequent studies to further reduce the model size of the network.

## VI. DISCUSSION AND PROSPECTS

The study used object detection networks to determine the three-dimensional position information of objects and semantic segmentation networks to assist in estimating the pose of objects. Although the research has optimized the convolution structure of the network, reduced the model parameters of the network, and improved the operation efficiency of the feedforward network, for the embedded platform, the computational burden of using two convolutional neural networks is still too large, resulting in the overall operation efficiency of the system is not very ideal. Jiang D et al. used an improved Fast RCNN to achieve tasks such as semantic segmentation, object classification, and detection in indoor scenes, resulting in a model with good performance and high efficiency [18]. Scholar Feng T used Mask RCNN combined with a single multi box detector algorithm to achieve gesture detection and recognition in human-computer interaction, which has high detection accuracy and speed [19]. Therefore, in future research, it can be considered to draw on the solutions of these two networks and merge the basic convolutional layers

together to reduce repetitive operations in the network. The results of the target detection network can also be projected onto the intermediate feature map, and the FCN head network can be run on the extracted feature image pixels to further improve the running speed of the feed forward network.

# Character Representation and Application Analysis of English Language and Literature Based on Neural Network

Yao Song

School of Foreign Languages,  
Henan University of Animal Husbandry and Economy,  
Zhengzhou, 450000, China

**Abstract**—The development of computer technology has promoted the continuous progress of Natural language processing technology and the great development of ideology and culture, and also prompted literary workers to create a large number of literary works. This poses a new challenge to the application of Natural language processing technology. Text analysis and processing is realized by Natural language processing technology. In the information society, the amount of data is increasing exponentially, and the number of literary works produced is also rapidly increasing. In order to gain a comprehensive understanding of domestic and foreign history and culture, some Chinese readers are not only satisfied with reading Chinese works from ancient and modern times, but also hope to read and understand foreign literary works. Current mainstream methods for literary character analysis are manual, making the results highly subjective and inefficient for large-scale literary works. To address this problem, this study proposes a character representation and analysis method based on neural networks using English novels as an example. By preprocessing data and utilizing the word dependency relationship to represent character vectors and calculate similarity, the study uses the Skip-gram model to train character vectors and K-means for clustering. An AGA-BPNN model is proposed for character and gender prediction and classification, with a 95.42% accuracy rate achieved in character prediction classification, and an average accuracy, recall, and F1 score of 0.953, 0.962, and 0.962, respectively, in gender prediction and classification. The results demonstrate the effectiveness of the method and propose a new approach for novel character analysis.

**Keywords**—Neural network; English; literary image; character vector; similarity calculation

## I. INTRODUCTION

In literary works, fiction is one of its important forms of expression. In novel analysis, the analysis of novel characters, including gender, personality, etc., is the basic work to help readers understand novels [1]. Analyzing and researching the characters in novels can help readers understand the characteristics of characters, social environment and the author's thought expression in literary works from the aspects of society, history and literary value [2-3]. In the traditional analysis of characters in novels, the mainstream method is mainly manual. As a result, the analysis results are highly subjective. In addition, the efficiency is low and it takes a long

time to analyze large literary works [4]. In China, due to the fact that most modern Chinese literary works are protected by copyright, it is relatively difficult to obtain a large number of Chinese literary texts and conduct analysis and research on them. However, some English literary works are no longer within the copyright protection period. In order to facilitate the processing, analysis, and research of these works, English novels are used as a novel corpus for study and analysis. With the help of Natural language processing technology, analyzing literary works and extracting useful information from them can help readers better read literary works. Using computer to analyze characters in novels requires the use of Natural language processing related technologies to transform the expression of characters in novels into data that can be understood by computers. Neural network (NNs) is an algorithm model that imitates the structure of the human brain and realizes high-precision, high-efficiency distributed parallel information processing. The advantage of NNs is that it can process large-scale data in parallel, and the accuracy and operation speed of the model will not be greatly affected. In classification problems, NNs has important and wide applications [5]. To this end, the study takes English literary works as an example, and builds a model based on the Skip-gram model, K-means and neural network to analyze the characters in the novel. The main purpose of the research is to apply NLP technology and NNs technology to large-scale novel character analysis, so as to improve the efficiency of novel character analysis, strengthen readers' understanding of the work, and help readers better understand the connotation and history of the novel's heritage.

## II. RELATED WORKS

In a literary work, characters are one of the three elements of a novel, the core part of a literary work, and an important content that embodies the literary value of a novel. Analyzing and researching the characters in novels can help readers understand the characteristics of characters, social environment and the author's thought expression in literary works from the aspects of society, history and literary value. Therefore, the research on the analysis of literary characters is very common. Shutan MI took the literary characters that appeared in the tenth grade Russian literature class as examples, such as Andrei Bolkonsky and Nikolai Rostov, to reveal the parallelism among literary characters, so as to ensure the effective cognition of student's sex [6]. Ravela took

“White Boys Shuffle” as an example to analyze the experience and growth of the protagonist in the novel, and discussed the racial ideology in the novel, believing that the novel has to some extent promoted the global conceptualization of race [7]. Rebel analyzed the works of three famous writers, and compared the content including the structure, theme, genre and ideology of the works, so as to dynamically analyze the development process of nineteenth-century literature. The analysis results show that ideological disputes have a greater impact on the fate of characters in Turgenev’s novels [8]. From a narrative perspective, Bai and others analyzed the protagonist’s image and character in the work of Nobel Prize winner William Faulkner - A Rose for Emily, to help readers better understand the thoughts expressed in “A Rose for Emily” [9]. Nischik took the novel "Penelope Piad" as an example to compare the mythical characters in Canadian mythology and Greek mythology, and reimagined the characters in "Odyssey" to reveal the genders contained in the concept of ancient mythology [10]. In a study by Ni, the language, use of behavior, and descriptions of the characters in Miracle are analyzed, and the techniques, intentions, and types used by literary characters to convey between words are explored. After summarizing, the researchers believe that their types include assertiveness, empathy, instruction, and expression [11]. Starkowski believes that in the study of literary works, more energy and attention should be devoted to the study of secondary characters. And taking Dickens' "Still There" as an example, he discusses the inadequacy of the traditional interpretation of secondary characters and the reflection of secondary characters in the novel on the society in the work [12]. In a study by Indrasari et al., taking Bronte’s novel Wuthering Heights as an example, they used sociological methods and qualitative description methods to conduct an in-depth analysis of the middle-class female roles in the novel in the 19th century, thereby deepening the understanding of these roles [13].

NNs is an algorithm model that imitates the structure of the human brain and realizes high-precision, high-efficiency distributed parallel information processing. The advantage of NNs is that it can process large-scale data in parallel, and the accuracy and operation speed of the model will not be greatly affected. Therefore, NNs has important and wide applications in classification problems. For example, CNN, which performs well in image recognition and classification, and BPNN, which appears frequently in automatic data classification research, etc. In recent years, scholars have made more and more in-depth research on neural networks. Plonka et al. analyzed the structure of one-dimensional ReLU DNN, and proposed a recursive algorithm to remove parameter redundancy in the deep ReLU neural network (ReLU DNN), thereby optimizing the network structure of ReLU DNN and improving its performance [14]. Raghu et al. discussed the similarity between CNN and visual transformer, and based on this similarity, discussed the possibility and operability of complementary fusion between the two [15]. Jiang designed a photonic device evaluation model based on an improved DNN, and discussed the model’s learning of device geometric features in the context of photonics, and the robustness of the model under large-scale data [16]. In order to better understand the problem solving ability and

interpretability of problem solving strategies of deep neural networks, Samek et al. conducted a comprehensive discussion and analysis of relevant research literature in recent years. And its application fields, application effects, and application prospects were analyzed and discussed [17]. Chung et al. proposed a neural population geometry method, and used this method to explain and analyze the structure and function of ANN. The actual application effect of the method was tested. The test results verified the effectiveness of the method [18]. Based on the latest research contents, Zhou et al. reviewed the construction, optimization and application of graph neural network (GNN), and discussed the application and performance of GNN variants, pointing out the direction for the development of GNN [19]. Wright et al. designed a deep physical neural network (DPNN) trained by backpropagation, which can effectively reduce the energy consumption required in scientific and engineering applications [20]. Ghosh et al. provided a comprehensive description of the basic structure, foundation, research progress, and main application fields of CNN, and pointed out the important contributions of CNN in the field of artificial intelligence [21]. Kong et al. proposed an Audio Neural Network (PANN) for audio recognition in large-scale data. Tests show that the model outperforms recent state-of-the-art audio recognition models [22].

In summary, CNN can perform image recognition and classification, and has excellent performance in automatic data classification research. In Computer language, ReLU DNN carries out vector training for fictional characters through Natural language processing, and uses mathematical methods to express characters, so that people can be counted and analyzed. The above content indicates that character analysis in literary works is very important, as it is the foundation for readers to understand the novel. However, the existing analysis of characters in literary works is based on a small number of novel characters, which is inefficient, and the analyzed literary works are also extremely limited. Therefore, this study applies neural networks to the analysis of characters in English literary works, and efficiently analyzes a large number of characters in novels through Big data technology and NLP technology. Thus, it can help readers of different novels more conveniently understand the content of the novel, as well as the corresponding characters' history and culture in the novel.

### III. REPRESENTATION AND APPLICATION OF LITERARY CHARACTERS BASED ON NEURAL NETWORK

Neural network technology is the foundation of all subsequent research in this paper. The main content of this chapter is to construct a corpus and preprocess the data using the corpus. At the same time, the Skip gram model is used to train character and feature word vectors, thereby calculating the training of novel character vectors and character similarity. Then, K-means is used to cluster and analyze feature vectors, and an adaptive mutation improved genetic algorithm (AGA) is proposed to obtain the optimal parameters of BPNN and improve model performance. Finally, the feature vectors are input into AGA-BPNN to achieve prediction and classification of feature features and gender.

#### A. Corpus Construction and Data Preprocessing

In literary works, fiction is one of its important forms of expression. In novel analysis, analyzing the characters in the novel, including gender, personality, etc., is the fundamental work to help readers understand the novel. In recent years, with the rise and development of AI, it is very feasible to use NLP technology to perform automatic, intelligent, and efficient clustering, classification, and analysis of novel characters, which has aroused the interest of some researchers. To this end, the paper takes English literary works as an example, and builds a model based on a neural network to analyze the characters in the novel. The first is to collect data in Project Gutenberg (PG) and build a corpus. PG is a text database that contains a large number of novels of different genres and authors. After the corpus is constructed, the corpus data is preprocessed to facilitate subsequent natural language processing (NLP). The preprocessing of literary works includes lexical and syntactic analysis, clustering of names, etc., as shown in Fig. 1.

The part of speech tagging and Named-entity recognition in Fig. 1 are implemented in this study using conditional random field model (CRF). If there are two groups of random variables  $x$  and  $y$ , when input  $x$ , the conditional

probability distribution of the  $p(y|x)$  output is expressed as  $y \cdot y$  can be regarded as a Markov random field at this time, but  $p(y|x)$  is a conditional random field. At this time, the conditional probability is obtained by formula (1).

$$p(y|x, \theta) = \frac{1}{Z(x, \theta)} \exp\left(\sum_{c \in C} \theta_c^T f_c(x, y_c)\right) \quad (1)$$

In formula (1),  $\theta_c$  is a weight vector.  $\theta$  is the weight vector in any potential energy function.  $f(\cdot)$  is the activation function.  $c$  is the largest set of conditional random fields, and  $Z(x, \theta)$  is the normalization term, which can be expressed as formula (2).

$$Z(x, \theta) = \sum_y \exp\left(\sum f_c(x, y_c)^T \theta_c\right) \quad (2)$$

In the vocabulary tagging process of the English novel corpus, if the structure of  $x$  and  $y$  is the same, a linear chain CRF will be formed, as shown in Fig. 2.

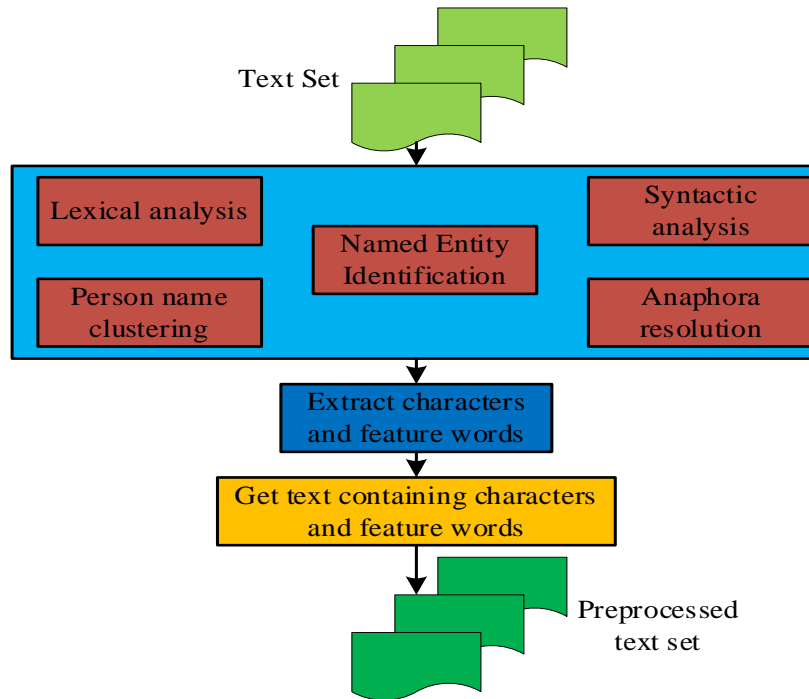

Fig. 1. Pretreatment of literary works.

Fig. 2. Linear chain CRF.

The conditional probability at this time is obtained by formula (3).

$$p(y|x, \theta) = \frac{1}{Z(x, \theta)} \exp \left( \sum_{t=1}^{T-1} \theta_1^t f_1(x, y_t) + \sum_{t=1}^{T-1} \theta_2^t f_2(x, y_t, y_{t+1}) \right) \quad (3)$$

In formula (3),  $f_1(x, y_t)$  is a position  $t$ -related state feature, and  $f_2(x, y_t, y_{t+1})$  is a state transition feature that can be represented by a state transition matrix. In Natural language processing, specific words are divided into five categories according to the dependency grammar relationship between specific words and Chinese characters, namely possessive case (poss), direct object (doobj), noun subject (nsubj), adjective subject (amod) and passive noun subject (nsubjpass). The character words and feature words in the corpus are extracted and expressed as binary phrases (characters and feature words). According to the dependency grammar relationship between feature words and Chinese characters, the top 4 words in each category are selected. The extraction results are shown in Table I. It can be seen that the feature words in Table I are closely related to the behavior or attributes of the characters.

A word, the basic unit of a language, with its own sound, meaning, and syntactic function, expresses ideas and information that are universally and intuitively understood by its native speakers. In terms of novel, a word plays an essential part in composing an outstanding masterpiece, portraying striking characters, and sculpturing a unique style.

The scope of English vocabulary is wide and has different types. For example, from formal to informal, simple to complex, standard to non-standard, common to rare, written to colloquial, general to specific, conceptual to associative, elegant to rough, monosyllabic to polysyllabic, Anglo Saxon to Latin. The artful and skillful choice of words is crucial for achieving special effect and getting desired texture in novels. However, the author does not randomly choose vocabulary, but deliberately chooses vocabulary after carefully considering the purpose, theme, and readers.

Word frequency refers to the times of words appeared in literary works. From Table I, it can be clearly observed that most of the top 4 word in each category are from Anglo-Saxon.

English vocabulary mainly comes from Anglo Saxon, French, Latin, and Greek. The vocabulary derived from Anglo Saxon forms the basic vocabulary of English speakers, who have known these words since childhood and frequently use them in daily life. These words are short, simple, basic daily words --- monosyllables and disyllables, indicating that authors tend to use common words to portray characters, create a brisk rhythm and convey the theme to readers.

Verbs occur as part of the predicate of a sentence and carry markers of grammatical categories, such as person, number, tense, aspect, and mood. Verbs can be stative ones, referring to state of affairs; as well as dynamic ones, referring to actions and events. Table I shows that the most commonly used verbs are simple but dynamic, and many of them refer to characters' movements. The frequently used verbs add rhythmic value to novels and make the characters in novels full of vivid energy.

Nouns are commonly divided into two categories --- the concrete nouns and the abstract nouns. The former refers to a real, physical thing with a definite indication vividly and clearly; while the latter mostly refers to a quality, state, action, perception or any other implicit concepts. It is eye-catching that top 4 words in poss (possessive case) are all concrete nouns, which transmit specific and accurate meaning and thought to readers and produce vivid impressions.

Adjective can be used to express psychological, physical, auditory, visual, color, evaluative, and emotive attributes. Moreover, they can be used to portray characters and convey the thematic meaning of novels. The abundant adoption of adjective can assist in the vivid portrayal of the characters, enrich the setting of novels, as well as push forward the development of the story. Frequently used adjectives present the beauty of language and charm of novels before readers.

### B. Character Vector Training and Character Similarity Calculation in Novels

After preprocessing the corpus, feature words with dependent syntactic relationships can be obtained. At this point, the Skip-gram model is used to train character word vectors and feature word vectors. In a text data set  $D$ , the probability distribution model is expressed as formula (4).

$$p(D = 1|w, c) = \frac{1}{1 + e^{-v_w \cdot v_c}} \quad (4)$$

TABLE I. TOP 4 WORDS IN EACH CATEGORY

Category	Terms	Word frequency	Category	Terms	Word frequency
poss	hand	323364	a mod	old	89334
	the face	225147		young	54381
	life	119574		major	46453
	mind	101435		great	33680
doobj	tell	183454	nsubjpass	call	19405
	take	80144		bear	19241
	meet	58442		make	15403
	reply	50554		know	14428
nsubj	say	2122164	-	-	-
	be	754572		-	-
	go	469388		-	-
	come	369643		-	-

In the formula (4),  $w$  and  $c$  represent character words and feature words, respectively, and the word pairs formed by the two are  $(w, c)$ .  $v_w$  and  $v_c$  represent the vectors of character words and feature words, respectively.  $p(D=1|w, c)$  represents the probability of word pairs in  $D$ . In Equation (4),  $v_w$  and  $v_c$  are the main learning parameters of the model. In order to maximize the target word pair in  $D$ , using the objective function of formula (5) to constrain it.

$$\arg \max_{v_w, v_c} \sum_{(w, c) \in D} \log \frac{1}{1 + e^{-v_w \cdot v_c}} \quad (5)$$

In formula (5), by adjusting the value in the data set  $w, c$ , the value of  $v_w = v_c$  and  $v_w \cdot v_c$  is large enough. To use the Skip-gram model to train character word vectors. The process is shown in Fig. 3(a), where  $n$  represents the number of character words in the data set.

According to the parts of speech of the five specific words mentioned above, they are divided into five categories. Among them, the first group combines the above characteristic words to represent a vector, where the vector is denoted as  $c\_Pdnan\_Vec$ , using this method to represent character vectors; The second group uses  $nsubj$  and  $nsubjpass$ , with the vector recorded as  $c\_Nn\_Vec$ ; The third group is through  $dobj$ , and

the vector at this time is recorded as  $c\_d\_vec$ ; The fourth group is through  $poss$ , and the vector at this time is recorded as  $c\_p\_vec$ ; The fifth group is through  $amod$  to represent the characters in the novel, and the vector at this time is recorded as  $c\_a\_vec$ . Fig. 3(b) shows the representation and classification of five groups of character vectors in the process of training character word vectors by the Skip-gram model. In Fig. 3, the trained character vectors all have 200 dimensions. After extracting all characters and related feature words, the character vector is represented by the word heat method, denoted as  $c\_Pdnan\_Hot$ . In this method, the characteristic words of any novel character only have one chance to appear.

After the character vector is generated, to calculate the character similarity of the characters in the novel. The principle of character similarity calculation is that in the two novels A and B, if the context of the characters in A is similar to that of the characters in B, it is considered that these two characters are similar, and their vectors in multidimensional space are also similar. The paper adopts the cosine similarity method to calculate the similarity between person vectors. Assuming that the vectors of each dimension of a character in a novel  $P$  are expressed as  $[P_1, P_2, \dots, P_{200}]$ , and the vectors of each dimension of another character in a novel  $Q$  are expressed as  $[Q_1, Q_2, \dots, Q_{200}]$ , the cosine similarity value between the two is calculated by formula (6).

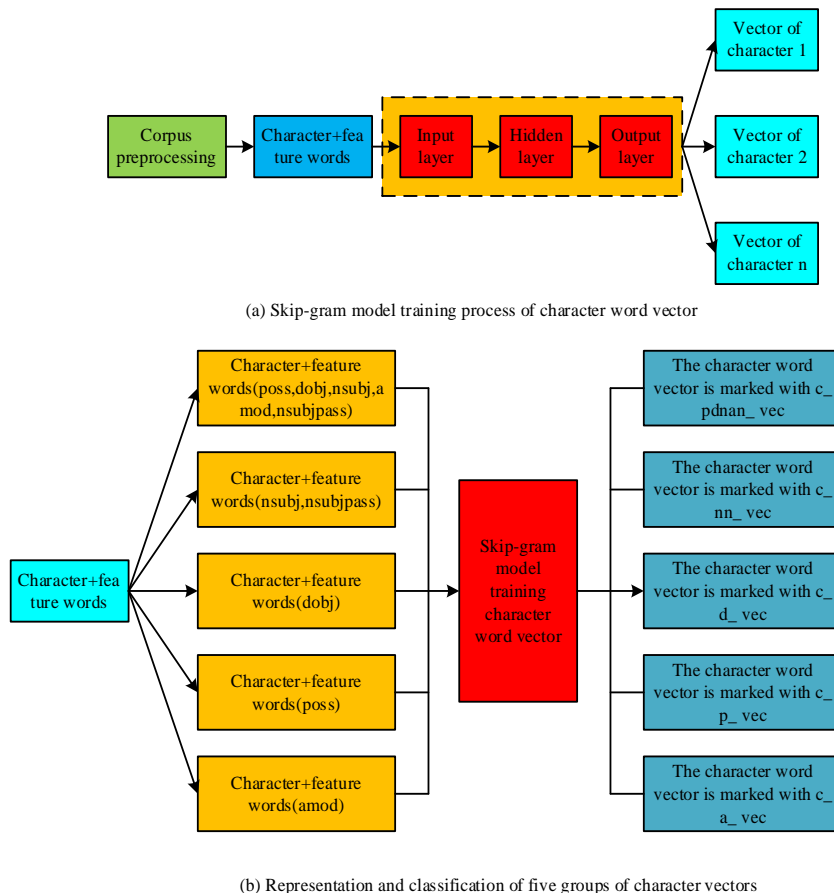

Fig. 3. Word vector training.

$$Sim(P, Q) = \cos(\theta) = \frac{P \cdot Q}{\|P\| \|Q\|} \quad (6)$$

In formula (6),  $\theta$  represents the angle between the vectors of the two novel characters  $Q$  and  $P$  in the vector space. Based on the above content, the extraction of novel character vectors and the calculation of novel character similarity are completed.

### C. Clustering and Classification of Novel Characters Based on Neural Network

In order to obtain the relationship between the characters in the novel more clearly, the study uses K-means to perform cluster analysis on the character vectors. The clustering steps of K-means are shown in Fig. 4.

In the clustering of K-means, the  $k$  samples in the data set are divided into  $k$  clusters by selecting an initial cluster center; and then iteratively optimizes the cluster center and refines the grouping. If the division of clusters is expressed as  $(B_1, B_2, \dots, B_k)$ , then the iterative goal of K-means is to minimize the value of formula (7).

$$E = \sum_{i=1}^k \sum_{x \in B_i} \|x - \mu_i\|_2^2 \quad (7)$$

In formula (7),  $\mu_i$  represents the centroid of the  $i$ -th cluster, that is, the  $B_i$  is the mean vector of all sample data in the  $i$ -th cluster, which can be calculated by formula (8).

$$\mu_i = \frac{1}{\|B_i\|} \sum_{x \in B_i} x \quad (8)$$

If the input data sample in K-means is expressed as  $A = \{A_1, A_2, \dots, A_m\}$ , a sample  $k$  is randomly selected in the data set  $A$  as the initial  $k$  centroid, expressed as  $\{\mu_1, \mu_2, \dots, \mu_k\}$ . At this time, the distance between a  $i$ -th sample  $x_i$  and the  $j$ -th centroid  $\mu_j$  is shown in formula (9).

$$d_{ij} = \|x_i - \mu_j\|^2 \quad (9)$$

$d_{ij}$  is the distance between all centroids and the sum  $x_i$  according to formula (9). Selecting the smallest centroid of  $d_{ij}$  as the new cluster center, and updating the cluster, such as in formula (10).

$$B_{\lambda i} = B_{\lambda i} \cup \{x_i\} \quad (10)$$

In formula (10), it represents the  $B_{\lambda i}$  th cluster after updating in the data set.  $i$  At this time, the centroid is recalculated. When the vectors of all centroids in the data set are no longer changing, it indicates that the clustering effect at this time is optimal, and the cluster division result is output at this time, see formula (11).

$$B = \{B_1, B_2, \dots, B_k\} \quad (11)$$

After the character clustering is completed, a model needs to be built to automatically classify novel characters, including character classification and gender classification. Among them, character traits are an important content for readers to understand the characters in novels, and also an important entry point for readers to analyze characters in novels. In psychology, there are many ways to analyze the character of a character. The paper selects the most authoritative and commonly used Myers-Briggs type index to analyze the character of the characters in the novel. The gender prediction is classified according to the characteristics of the characters, such as titles, actions, language, and emotions. The classification model is constructed using a neural network. In the work of automatic data classification, commonly used neural networks include perceptrons, BPNNs, and RBFNNs. This paper builds a classification model based on BPNN, and optimizes BPNN to improve classification performance. Firstly, an improved genetic algorithm with adaptive mutation (AGA) is proposed to obtain the optimal parameters of BPNN. The adaptive mutation probability of AGA is calculated by formula (12).

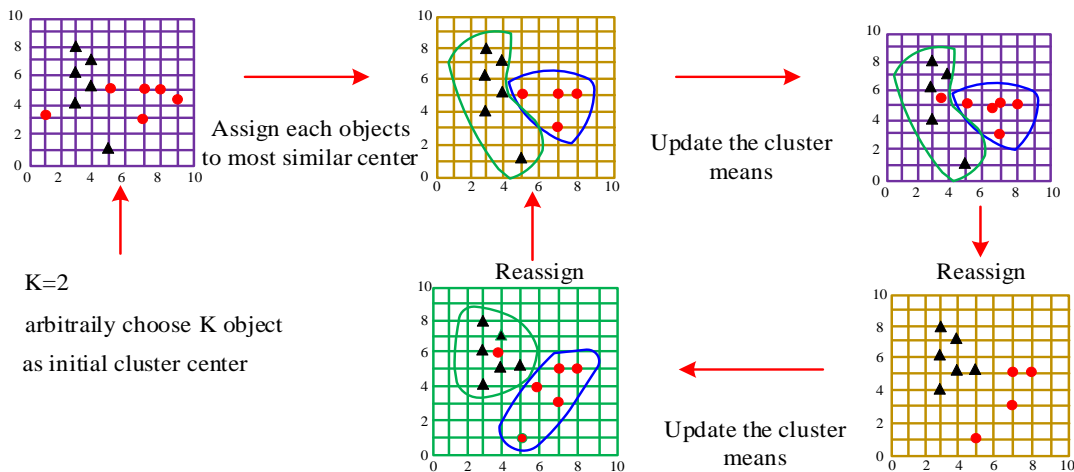

Fig. 4. Clustering steps of K-means.

$$P = \frac{P_1 + P_2}{2} = \frac{[P_0 - (P_0 - P_{\min}) \cdot m]}{M} + \frac{[P_0 \cdot \max_{X_k \in \Omega} F(X_k) / \bar{F}]}{2} \quad (12)$$

In formula (12),  $M$  is the total number of the updates of the algorithm.  $m$  is the current iterative update number of the algorithm.  $P_0$  is the initial variation probability.  $P_{\min}$  is the minimum mutation rate.  $\bar{F}$  is the average fitness value  $\max_{X_k \in \Omega} F(X_k)$  of the current population of the algorithm. In any update iteration of the algorithm, the probability of any individual in the population  $a_j$  being selected for mutation in this iteration can be calculated by formula (13).

$$z(a_j) = \frac{f(a_j)}{\sum_{j=1}^d f(a_j)} \quad (13)$$

In formula (13) of  $f(a_j)$ ,  $a_j$  is the fitness value, and  $d$  is the number of all individuals in the current population in AGA. Through the formula (13), the mutation probability of all individuals in the current population is calculated, and according to the accumulated probability value, it is judged which individuals can be inherited to the next generation. By this method, the prematureness of the algorithm can be avoided, and the deficiency of the weak global optimization ability of GA can be made up. Compared with the fixed mutation probability strategy adopted by traditional genetic algorithms, the adaptive mutation probability of genetic algorithms can adjust the mutation probability of the population according to the situation. This can enable the algorithm to better jump out of local optimization and enhance its global optimization ability. Therefore, using AGA to optimize BPNN can find the best parameters of BPNN better and faster and improve the performance of the model. Input the character vector into AGA-BPNN to realize the prediction and classification of character and gender. Based on the above content, the representation of novel characters based on neural network is realized, and then the intelligent and automatic analysis of novel characters is realized.

#### IV. EFFECTIVENESS ANALYSIS OF CHARACTER REPRESENTATION METHOD BASED ON AGA-BPNN

##### A. Effectiveness of $c\_pdnan\_vec$ Vector Representation

Based on the Skip-gram model, the study extracts and classifies novel character vectors, uses cosine similarity to calculate the similarity between different novel characters, and then uses K-means to cluster the extracted novel character vectors. In addition, the novel character vector is input into AGA-BPNN for training and learning, and the gender and

personality of the novel characters are predicted and classified through AGA-BPNN. Based on the above strategies, the intelligent and automatic analysis and representation of novel characters is realized. The English novels in PG are collected as experimental data to test the effectiveness of the proposed method. First, the validity of  $c\_pdnan\_vec$  character vector representation is verified. Four assumptions commonly used by literature researchers are used to verify  $c\_pdnan\_vec$ ,  $c\_nn\_vec$ ,  $c\_d\_vec$ ,  $c\_p\_vec$ ,  $c\_a\_vec$ ,  $c\_pdnan\_hot$ . The above six kinds of character vectors are used to represent the similarity between people in the four categories of hypotheses, and the similarity evaluation accuracy of each vector in the four categories of hypotheses is compared. The results are shown in Table II. It can be seen that on the four major assumptions, the average accuracy of the  $c\_pdnan\_vec$  vector representation is 1.00, 0.85, 0.76, and 0.62, and it performs best among the six vector representations. The  $c\_a\_vec$  vector representation has the worst performance. In the first type of hypothesis, the performance of the  $c\_pdnan\_hot$  vector representation is close to that of the  $c\_pdnan\_vec$  vector representation, but on the second to fourth types of hypotheses, the performance of the  $c\_pdnan\_vec$  vector representation is significantly better than that of the  $c\_pdnan\_hot$  vector. This is because  $c\_pdnan\_vec$  vector representation is more comprehensive and can reflect the character characteristics from many aspects. The test results verify the correctness of the  $c\_pdnan\_vec$  vector representation.

##### B. K-means-based Novel Character Cluster Analysis Effect

The paper uses the K-means algorithm to cluster novel characters. In order to verify the application effect of K-means in novel character clustering, it is compared with K-MEDOIDS, fuzzy C-means algorithm (FCM) and density-based clustering algorithm (DBSCN). Purity and clustering accuracy (ACC) are used to compare the performance of several methods on novel character clustering. See Table III for the Purity values of several methods. It can be seen that in the five experiments, the average value of K-means Purity is 0.75, which is 0.12, 0.11, and 0.13 exceed that of K-MEDOIDS, FCM, and DBSCN, respectively. These data show that the clustering effect of K-means is better. The distance between the readers and the characters in the novels can be shortened, and the distance between the readers and the author can also be shortened. Readers are more likely to feel that they are invited to experience the whole story.

The ACC are shown in Table IV. In the five experiments, the average ACC of K-means is 0.86, which is 0.05, 0.05 and 0.08 exceed that of K-MEDOIDS, FCM and DBSCN respectively. The above results indicate that K-means has a better application effect in novel character clustering and is more suitable for clustering analysis of novel characters, verifying the correctness of the K-means algorithm. This can achieve the goal of vividly portraying characters and creating a certain rhetorical effect.

TABLE II. SIMILARITY EVALUATION ACCURACY OF EACH VECTOR IN THE FOUR CATEGORIES OF ASSUMPTIONS

Vector representation	Number of experiments	Four categories of assumptions			
		1	2	3	4
c_pdnan_vec	1	1.00	0.86	0.76	0.68
	2	1.00	0.83	0.77	0.65
	3	1.00	0.87	0.75	0.62
	Average	1.00	0.85	0.76	0.65
c_nn_vec	1	0.80	0.68	0.18	0.25
	2	0.82	0.66	0.20	0.21
	3	0.75	0.64	0.17	0.25
	Average	0.79	0.66	0.18	0.24
c_d_vec	1	0.25	0.25	0.17	0.27
	2	0.20	0.26	0.19	0.29
	3	0.23	0.28	0.18	0.25
	Average	0.23	0.26	0.18	0.27
c_p_vec	1	0.50	0.50	0.48	0.14
	2	0.54	0.51	0.52	0.12
	3	0.45	0.53	0.53	0.11
	Average	0.50	0.51	0.51	0.12
c_a_vec	1	0.00	0.00	0.32	0.00
	2	0.00	0.00	0.30	0.00
	3	0.00	0.00	0.31	0.00
	Average	0.00	0.00	0.31	0.00
c_pdnan_hot	1	1.00	0.45	0.50	0.53
	2	1.00	0.43	0.49	0.52
	3	1.00	0.42	0.54	0.53
	Average	1.00	0.43	0.51	0.53

TABLE III. PURITY VALUE OF SEVERAL METHODS

Number of experiments	Purity value			
	K-means	K-MEDOIDS	FCM	DBSCN
1	0.75	0.63	0.64	0.55
2	0.73	0.66	0.52	0.54
3	0.75	0.58	0.68	0.63
4	0.78	0.69	0.70	0.71
5	0.74	0.59	0.65	0.65
Average	0.75	0.63	0.64	0.62

TABLE IV. ACC VALUE OF SEVERAL METHODS

Number of experiments	Purity value			
	K-means	K-MEDOIDS	FCM	DBSCN
1	0.85	0.80	0.76	0.76
2	0.91	0.82	0.85	0.75
3	0.87	0.84	0.82	0.72
4	0.82	0.83	0.77	0.84
5	0.86	0.78	0.86	0.82
Average	0.86	0.81	0.81	0.78

C. Effect Analysis of AGA-BPNN Classification Model

To verify the application effect of AGA-BPNN model in novel character gender prediction classification, this paper borrowed the Myers Briggs type index to analyze the personality characteristics of novel characters in personality prediction classification. Recording several personalities of the characters as 1~5. Compare the AGA-BPNN, GA-BPNN, and BPNN models to classify character personalities under different sample sizes, and verify the optimization effect of AGA on BPNN, as shown in Fig 5. In Fig. 5, when the number of samples ranges from 0 to 80, the prediction accuracy of the three models for character personality is high. When the number of samples exceeds 80, the prediction accuracy of BPNN drops significantly, the accuracy of

GA-BPNN model decreases to a certain extent, while the accuracy of AGA-BPNN model hardly changes. Overall, the accuracy of the AGA-BPNN model reaches 95.42% when performing character prediction and classification of novel characters; while the accuracy of the GA-BPNN model reaches 90.66%, which is 4.76% lower than the AGA-BPNN model; the accuracy of the BPNN model reaches 86.53% %, 8.89% lower than the AGA-BPNN model. It can be seen that in the prediction and classification of characters in novels, the accuracy of the AGA-BPNN model is significantly better than the other two models.

The same data is used to evaluate the gender prediction and classification ability of the above three models. Accuracy, Recall and F1 are selected as evaluation indicators. Fig. 6

shows the gender prediction and classification performance of the three models. It can be seen that the average accuracy, average recall and average F1 values of AGA-BPNN are 0.953, 0.962 and 0.929, respectively, which exceed GA-BPNN and BPNN models. The above results show that the model proposed in the study has better performance in gender prediction. This is because after the optimization of the AGA algorithm, the accuracy and convergence of the BPNN model have been improved, thus improving the accuracy of the

BPNN model for novel character classification. The average accuracy of the BPNN model reached 0.929, which has higher accuracy compared to the ReLU DNN network structure proposed by Plonka G et al. and the DPNN network proposed by Wright L G et al. To sum up, the methods proposed in the paper can accurately realize intelligent novel character representation and analysis, thus helping readers better understand the novel.

Fig. 5. Accuracy of AGA-BPNN classification of character.

Fig. 6. Gender prediction and classification ability of three models.

## V. CONCLUSION

Character analysis in literary works is very important, and it is the basis for readers to understand novels. However, the existing analysis of characters in literary works is based on a single or a small number of novel characters, which is inefficient. Aiming at this problem, the paper is based on the Skip-gram model and the AGA-BPNN model to realize the vector representation. In the experiment, on the four assumptions, the average accuracy of c\_pdnan\_vec vector representation is 1.00, 0.85, 0.76, 0.62. Therefore, c\_Pdnan\_Vec vectors perform the best in terms of comprehensiveness among the six vector representations. The performance of VEC vector representation is the worst, which verifies the validity of c\_pdnan\_vec vector representation. The average value of K-means Purity is 0.75, 0.12, 0.11, and 0.13 exceed K-MEDOIDS, FCM, and DBSCN, respectively. The average value of ACC is 0.86, which is 0.05, 0.05, and 0.08 exceed K-MEDOIDS, FCM, and DBSCN, respectively. This confirms the effectiveness of K-means in novel character clustering work. When predicting and classifying characters in novels, the accuracy of the AGA-BPNN model reaches 95.42%, which is 4.76% exceed that of the GA-BPNN model and 8.89% exceed that of the BPNN model. When the sample size is between 0 and 80, the three models have higher prediction accuracy for character traits. When the number of samples exceeds 80, the prediction accuracy of BPNN decreases significantly, and the accuracy of GA-BPNN model decreases to a certain extent, while the accuracy of AGA-BPNN model remains almost unchanged. The accuracy of the AGA-BPNN model is significantly better than the other two models in predicting and classifying the personalities of novel characters. In the gender prediction classification of novel characters, the average accuracy rate, average recall and average F1 value of AGA-BPNN are 0.953, 0.962 and 0.929, respectively, which are exceed those of GA-BPNN and BPNN. The average accuracy of the BPNN model reached 0.929, which has higher accuracy compared to the ReLU DNN network structure proposed by Plonka G et al. and the DPNN network proposed by Wright L G et al. Compared to Bai X et al.'s approach of analyzing novel characters from a narrative perspective, research based on the Skip gram model and AGA-BPNN model provides a better understanding of character characteristics and article ideas. Therefore, the method proposed in the paper can accurately realize intelligent novel character representation and analysis, thereby helping readers to better understand the novel. However, the novel text data used in the experiment are all English novels, so the experiment only verifies the effect of the proposed method in the analysis of characters in English novels. In-depth research is needed in the future to verify the application effect of the proposed method in the analysis of characters in novels in other languages.

# NLPashto: NLP Toolkit for Low-resource Pashto Language

Ijazul Haq, Weidong Qiu, Jie Guo, Peng Tang  
School of Cyber Science and Engineering,  
Shanghai Jiao Tong University, China

**Abstract**—In recent years, natural language processing (NLP) has transformed numerous domains, becoming a vital area of research. However, the focus of NLP studies has predominantly centered on major languages like English, inadvertently neglecting low-resource languages like Pashto. Pashto, spoken by a population of over 50 million worldwide, remains largely unexplored in NLP research, lacking off-the-shelf resources and tools even for fundamental text-processing tasks. To bridge this gap, this study presents NLPashto, an open-source and publicly accessible NLP toolkit specifically designed for Pashto. The initial version of NLPashto introduces four state-of-the-art models for Spelling Correction, Word Segmentation, Part-of-Speech (POS) Tagging, and Offensive Language Detection. The toolkit also includes essential NLP resources like pre-trained static word embeddings, Word2Vec, fastText, and GloVe. Furthermore, we have pre-trained a monolingual language model for Pashto from scratch, using the Bidirectional Encoder Representations from Transformers (BERT) architecture. For the training and evaluation of all the models, we have developed several benchmark datasets and also included them in the toolkit. Experimental results demonstrate that the models exhibit satisfactory performance in their respective tasks. This study can be a significant milestone and will hopefully support and speed-up future research in the field of Pashto NLP.

**Keywords**—NLP; text processing; word segmentation; POS tagging; BERT, LLMs; Pashto; low-resource languages; CRF; CNNs; RNNs

## I. INTRODUCTION

Pashto is an Indo-European language primarily spoken in Afghanistan and Pakistan. Written in the Perso-Arabic script, Pashto is also cursive, written right-to-left (RTL), and the letters take on different forms depending on their position in the word. Despite being the native language of a large population, NLP research in Pashto is still very rare, and sophisticated tools can hardly be found even for basic text-processing tasks, such as word segmentation and spelling correction. Additionally, the tools developed for other languages are not sufficient for Pashto text processing due to the complex and unique morphology of the language. Pashto is not a standardized language, lacking any golden rules to impose a uniform way of writing. For instance, it is a good practice to add space after each word in typing (writing with a keyboard), but in some cases, space omission is acceptable for human readers, which creates an issue for NLP applications. Without space between words, a naive NLP algorithm will consider the whole string as a single word. Due to this inconsistency in writing, any arbitrary Pashto text, whether on social media, news websites, or even books, is noisier compared to any other language.

This study aims to address the challenges in Pashto text processing and develop essential resources and state-of-the-art (SOTA) models for preliminary NLP tasks. All these resources and models, along with the benchmark datasets, are packaged in a toolkit named NLPashto, publicly available on GitHub and PyPi hub. The objective of toolkit is to enhance re-usability, avoid reinventing the wheel, and provide a single point of entry for further research in Pashto NLP. The initial prototype of NLPashto includes static word embeddings (Word2Vec, fastText and GloVe) and the first monolingual Pashto BERT, pre-trained on our custom-developed Pashto text corpus of 15 million words. The toolkit includes four SOTA models, three of which are general-purpose tools for basic text processing: spelling correction, word segmentation, and POS tagging, while the fourth model is for offensive language detection.

Most NLP algorithms require the input text split into individual units before processing. Two baseline techniques commonly used for converting text into tokens/words: whitespace tokenization and lexicon-based word segmentation. In whitespace tokenization, words are separated by whitespaces (spaces, tabs, or line breaks), commonly used in Western languages like English. On the other hand, languages that do not have spaces between words, such as Chinese and Japanese, use word segmentation, which is typically more complex because it involves identifying the boundaries between words and deciding which character belongs to which word. However, none of these techniques is perfect for the Pashto language. In Pashto, unlike English, the "space" is not consistently used for word separation and is not a reliable word delimiter, and unlike Chinese, space is a part of writing and cannot be completely ignored. To handle these limitations, we have developed two specialized machine learning models, one for spelling correction and the other for word segmentation. The spelling correction model can be used to identify the proper position of spaces in the text, remove extra spaces, or insert spaces where required. Once the spaces are corrected, we can use the baseline whitespace tokenizer to convert the text into tokens. The word segmentation model can be used in applications that need to split the text into "full" words rather than space-delimited tokens. For example, a NER application may need to extract "whole" words from text like "New York" rather than "New" and "York". Therefore, we have developed a specialized word segmenter for the Pashto language that will not break the compound words, such as *واره خواره* (dispersed) or *چيان مظاهره* (protesters).

POS tagging is also a fundamental text pre-processing task that involves assigning a grammatical category to each word

in a sentence, such as a noun, verb, adjective, or adverb. POS information is very helpful for AI models better understand the language, as they can learn more about the grammatical structure of the text, which could improve models' ability to generate coherent and grammatically correct text. It is one of the earliest types of annotation performed on corpora and is still used, for example, BNC [1], Brown Corpus and LCMC. POS tagging is not intuitive, as a particular word can have different tags based on the context. For example, in the sentence *وريکي واوره غرونو په* (it is snowfall on the mountain), the word *واوره* is a noun, while in the sentence *واوره خبره زما* (listen to me), *واوره* means "listen," which is an imperative verb. For automatic POS tagging, we have developed a machine learning-based POS tagger and included it in the toolkit.

The rise of social media has led to an increase in the dissemination of offensive language, which has a profound negative impact on the targeted individuals and the community. The sheer volume of content posted everyday, makes the manual removal of offensive content by human moderators unfeasible. Therefore, automated NLP systems for detecting offensive content have become essential. Significant research has been dedicated to this area in other languages, such as English [2], Chinese [3], Arabic [4], [5], [6], [7], Hindi [8], and German [9], to name a few. However, for the Pashto language there is no such research work available. In this study, we have developed a SOTA AI model for Pashto offensive language detection, trained on a dataset of tweets manually categorized as "offensive" and "not-offensive."

Toolkit development is an ongoing process, and we are actively working on NLPashto to make it more inclusive, though the progress we have already achieved can be summarized as follows:

We developed a *Pashto text corpus* of around 15 million words and used it to pre-train the *Static Word Embeddings* for Pashto. We developed the first monolingual *Pashto BERT* from scratch. We developed benchmark datasets and used them to develop four SOTA models for *Spelling Correction*, *Word Segmentation*, *POS Tagging*, and *Offensive Language Detection*. Finally, we packaged all the resources, benchmark dataset, and pre-trained models in a *Toolkit* and distributed them publicly on GitHub and PyPi hub to facilitate and speed up future research in this domain.

## II. RELATED WORK

Natural language toolkits have been utilized in the research and development of various NLP applications. One of the most widely known NLP toolkits is the Natural Language Toolkit (NLTK) [10], which is a Python library providing a comprehensive suite of tools and resources for NLP tasks, including tokenization, POS tagging, NER, sentiment analysis, and more. Another popular NLP toolkit is CoreNLP [11], which offers a set of core NLP tools similar to NLTK, such as tokenization, POS tagging, parsing, and NER. It also encompasses advanced tools like coreference resolution, relation extraction, and sentiment analysis.

In recent years, language-specific NLP toolkits have gained prominence, offering SOTA tools, datasets, and pre-trained models for specific languages. An example of such toolkits

is FudanNLP [12] for the Chinese language. FudanNLP employs statistics-based and rule-based methods to tackle various NLP tasks, including word segmentation, POS tagging, NER, dependency parsing, anaphora resolution, and time-phrase recognition. For Urdu, a sister language of Pashto, [13] developed the UNLT toolkit, which includes three preliminary NLP tools: word tokenizer, sentence tokenizer, and part-of-speech tagger. The word tokenizer utilizes a morpheme-matching algorithm combined with a stochastic n-gram model. The toolkit addresses space-omission through back-off and smoothing characteristics, and space-insertion is handled using a lexicon-based look-up technique. The POS tagger is based on HMM entropy-based stochastic and lexicon-based look-up techniques. InaNLP [14] is a natural language toolkit for the Indonesian language, which integrates several NLP modules, such as tokenization, sentence splitter, POS tagger, NER, syntactic parser, and semantic analyzer, with most of the models being rule-based. [15] developed a toolkit named CAMEL for the Arabic language. CAMEL provides tools for preliminary NLP tasks, including morphological analysis, dialect identification, and NER, with support for various Arabic dialects. DaNLP [16] is another toolkit for low-resource languages, specifically designed for Danish. It contains pre-trained models for NER, POS tagging, coreference resolution, and sentiment analysis and also includes benchmark datasets and static word embeddings. IceNLP, developed by [17], is an NLP toolkit for the morphologically complex Icelandic language. It encompasses essential pre-processing tools, such as tokenizer, sentence segmenter, rule-based taggers, finite-state parser, and morphological analyzer. For Vietnamese, [18] have developed VnCoreNLP, a toolkit that provides solutions for preliminary NLP tasks such as word segmentation, POS tagging, NER, and dependency parsing. Lastly, [19] developed an NLP toolkit for the Bengali language, which includes supervised machine learning models for tokenization, POS tagging, and NER, as well as other resources like word embeddings.

## III. CHALLENGES IN PASHTO TEXT PROCESSING

Pashto is not a standardized language, and there are no golden rules for the proper usage of space in the writing system, which leads to two typical spelling errors, space omission, and space insertion error. Besides that other challenges in Pashto text processing include non-standardized transliteration and homograph ambiguity.

### A. Space-omission Errors

A space-omission error occurs when the space between two words is ignored, causing the words to merge into a single string. For example, the phrase *داميز* (this table) has two words, *دا* (this) and *ميز* (table), but the space between the words is omitted, which is perfectly readable to a human reader and thus it is not considered to be a typo in Pashto; however, an NLP system will interpret and process the phrase as a single word.

### B. Space-insertion Errors

A space-insertion error occurs when a "useless" space is inserted within a word, splitting it into two or more (possibly meaningless) parts. For example, the words *خبريال* (reporter) and *يال خبر* look very similar, but the latter one has an extra

space between the two ligatures *خير* and *يال*. A human reader may consider it correct, but an NLP application treat each ligature as a separate word. An example sentence in Fig. 1, highlights the issues of both the space-omission and space-insertion errors.

Figure 1. Example of space-omission and space-insertion errors.

### C. Non-standardized Transliteration

Transliteration is the process of converting the characters of one writing system into another, preserving the pronunciation of original words. Transliteration is very common in Pashto, but there are no standard rules to enforce one common spelling for foreign words transliterated into Pashto. The spelling of transliterated words usually depends on the choice of the writer (translator or transliterator), resulting in several variants of spellings for one word. For instance, the word "Coronavirus" has more than ten variants in our Pashto text corpus, e.g., *کرونا*, *کرونا وائرس* and *وائرس کورونا وائرس*.

### D. Homograph Ambiguity

Homograph ambiguity is a common issue, not only in Pashto but in many languages, which occurs when a word has more than one meaning. It can create ambiguity in the language, as the meaning of a homograph may be unclear based solely on its spelling. For example, the word "tear" in English can refer to a "liquid from the eyes" or "to rip apart forcefully". Similarly, in the Pashto sentence, *تور هغه* (he is wearing a black jacket), the word *تور* is an adjective, means "black", while in the sentence *تور دې د هغوي لکوي هیواد گاونډي په* (they blame the neighboring country for it), the word *تور* refers to "blame", which is a Common Singular Masculine Noun.

## IV. TEXT CORPUS AND BENCHMARK DATASETS

This project involves the development of word embeddings and a BERT model. Training these models requires a substantial corpus of text that should be diverse and representative of the entire language. However, Pashto is a low-resource language, where electronic textual content, large-scale corpora, and well-organized datasets are hard to find. Therefore, we developed a Pashto text corpus, for which we collected text from four primary sources: news websites, Wikipedia articles, books, and Twitter tweets. The corpus size is over 15 million tokens, with an average token length of 3.6 characters.

### A. Dataset for Spelling Correction and Word Segmentation Models

To develop the dataset for spelling correction, the first step was to obtain raw sentences. We used our Pashto text corpus, which consisting around 400K sentences. Our goal was to annotate each sentence for explicit word-boundary information. However, manually annotating such a large dataset was not feasible. So, we initially employed a lexicon-based approach to mark word boundaries.

Lexicon-based segmentation is an intuitive technique often used to divide text into words [20], [21]. It involves scanning a sequence of input characters and matching them against a lexicon of words. If the sequence is found in the lexicon, it is considered a word. To ensure matching the longest possible sequence, a variant of the lexicon-based approach called the Longest Matching (LM) algorithm is used. The LM is a greedy algorithm that strives to find the longest sequence. Since the LM algorithm starts the search from the beginning and moves forward, it is also called Forward Longest Matching (FLM). Another variant of the LM algorithm performs the search in the backward direction, known as Reverse Longest Matching (RLM). Sometimes, both FLM and RLM are combined to form Bidirectional Longest Matching (BMM).

To annotate our corpus, we incorporated the BLM technique with a small modification. Instead of looking up sequences of characters, we looked up sequences of tokens obtained from whitespace tokenization. A space in Pashto can either be a word delimiter or part of the word, where the purpose of annotation was to discriminate these spaces and mark them with explicit labels. We used the label "B" for word delimiters and "S" for the spaces that were part of the words. In the first round, after passing all 400K sentences through the lexicon-based model, 95K sentences were "fully" annotated, where no out-of-vocabulary (OOV) tokens were found. The "partially" annotated sentences, where at least one token was OOV, were further processed. The OOV tokens were extracted, manually inspected, and added to the lexicon if they were valid Pashto words. These partially annotated sentences once again passed through the lexicon-based segmenter, where some more sentences were fully annotated. This process was repeated several times with an updated lexicon each time. Finally, the size of the dataset reached 150K sentences (nearly 4 million words). It is worth mentioning that we used the same dataset for training both the spelling correction and word segmentation models.

### B. Part-of-Speech Dataset

To develop the POS dataset, we annotated the spelling correction and word segmentation dataset with POS information. For POS annotation, we initially employed the lexicon-based approach, in which the words in the sentences are looked up one by one in the lexicon and labeled with the corresponding POS tags. It is a context-free approach in which the surrounding information of the taken are not taken into consideration. In the first round, after passing all 150K sentences through the lexicon-based model, 80K sentences were fully annotated, with every word assigned a POS tag. Two example sentences are given in Fig. 2, annotated using this approach. In both sentences, the word *تور* has been assigned

the Singular Masculine Noun tag, though, in the first sentence تور means (black), which is an Adjective.

غوستی_NNM	كوت_NNM	تور_NNM	هغه_PRPIii
wearing	jacket	black	he

Meaning ≈ He is wearing a black jacket

لگوي_VBP	ولسمشر_NNM	په_IN	تور_NNM	دي_VBPC	د_IN	هغوي_PRPIii
...ing	president	on	blame	of the		they

Meaning ≈ They blame president for that

Figure 2. Example sentences, annotated using the lexicon-based technique.

After the lexicon-based annotation, we randomly selected 10K of the sentences for manual correction. Using a specialized web application we developed, sentences from the database were presented one by one to the annotators (human experts), with each word already assigned a static tag (by the lexicon-based tagger), and the job of the annotators was to verify or change the tags. This way, all 10K sentences were annotated for POS information with 100% (theoretical) accuracy. By analyzing the results of manual correction, we found that changes were made to around 7% of the tags by human annotators. It shows that the lexicon-based POS tagger can achieve an accuracy of 93%.

### C. Pashto Offensive Language Dataset

The Pashto Offensive Language Dataset (POLD) is a collection of tweets manually categorized into two classes: "offensive" and "not-offensive" (Fig. 3). The first step in creating the POLD dataset was to collect raw tweets in Pashto from Twitter. However, offensive tweets only make up a small portion of overall tweets, therefore, annotating random tweets was inefficient. To increase the size of the offensive class, we used a seed list of offensive words to filter tweets. To minimize bias and maintain diversity in the dataset, firstly, we made the seed list large and inclusive, and secondly, we analyzed many tweets and observed common patterns in offensive tweets, such as the use of second-person pronouns, i.e., ت (you: singular) or تاسو (you: plural), and included these patterns in the seed list. Using the Twitter Search API, we searched for each word and pattern in the seed list and collected nearly 300K raw tweets between January 10 and February 10, 2023.

The tweets corpus underwent several pre-processing steps, which involved removing HTML tags, URLs, usernames, and other special characters. Digits in non-Pashto format were normalized to the Pashto format, i.e., 1234 became . Duplicate tweets were deleted, and tweets with less than 10 characters or more than 150 characters were also discarded. The final corpus size dropped to 70K tweets, from that we randomly selected 35K (50%) for manual annotation.

The manual annotation was carried out by a total of five participants, including one of the authors and four paid professionals. Tweets containing any type of offensive language, such as hate speech, cyberbullying, aggression, abuse, or profanity, were assigned the label "1" (offensive), and the rest (normal or positive tweets) were assigned the label "0" (non-offensive). Each annotator individually tagged the complete

corpus without knowing the decisions of other annotators. The decision regarding the final status of the tweets made by a majority vote. The final POLD dataset consists of 34,400 tweets, with 12,400 labeled as offensive and 22,000 labeled as non-offensive.

## V. WORD EMBEDDINGS

Word embedding is a process that involves mapping words from a vocabulary to vectors of real numbers. The basic idea behind word embeddings is to learn a distributed representation of words based on their co-occurrence in a large corpus of text. A neural network is trained to capture the syntactic and semantic meaning of the words in the text. The network learns to associate words that appear in similar contexts with similar vector representations. The resulting vector representations can then be used as input for other machine learning models. NLP researchers generally prefer to utilize pre-trained word embeddings, typically trained on extensive corpora. However, for Pashto, no pre-trained word embeddings are currently available except fastText. Nevertheless, we pre-trained static word embeddings and a BERT model for the Pashto language and included them in NLPashto.

### A. Static Word Embeddings

We used the Pashto text corpus and trained the three popular types of static word embeddings: Word2Vec, fastText, and GloVe, and included them in the toolkit. For all three models, most of the hyper-parameters were kept uniform. The vector size was fixed at 100, the window size at 5, and the minimum count at 2, which is the minimum frequency needed for a word to be included in the final vocabulary. We chose the skip-gram architecture for Word2Vec and fastText and trained each model for 5 epochs. The GloVe model was trained using the GloVe package, while Word2Vec and fastText were trained using the Gensim and fastText Python libraries.

### B. Pashto BERT

The recent progress in Large Language Models (LLMs) has revolutionized the field of NLP. Some of the most popular LLMs in use today include BERT [22], GPT [23], XLM-R [24], and RoBERTa [25], to name a few. LLM takes into account the context in which a word appears in a sentence when generating the embeddings, which allows the model

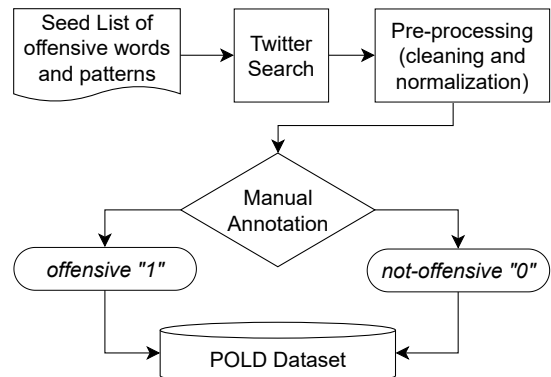

Figure 3. Procedure of POLD dataset development.

to capture the meaning and nuances of words in different contexts. These models are usually trained on multilingual data and can understand and generate text in several languages. However, for language-specific tasks, monolingual models generally outperform the multilingual models. In this study, we have trained a Pashto monolingual language model and included it in the NLPashto toolkit as well as publicly uploaded it to the Huggingface hub.

The model we utilized for training Pashto BERT is the BERT<sub>Base</sub>, which has 12 layers, 768 hidden states, 12 attention heads, and 110M parameters. Training data is our Pashto text corpus of 15 million tokens. To tokenize the input sequences, we used WordPiece tokenizer [26], which is the recommended tokenizer for BERT<sub>Base</sub>. We fixed the vocabulary size at 30K words and used special [CLS] and [SEP] tokens at the beginning and end of the sequences, respectively. To enable the model to differentiate between original and padded tokens, we employed an attention mask to generate a vector of 1s and 0s for each input sequence, where 0s indicate the padded tokens and 1s indicate the original ones. The hyper-parameters setup for pre-training is shown in Table I. We implemented the model architecture and training pipeline using PyTorch and the Huggingface transformers library, where training of the model performed on a cloud GPU – NVIDIA Tesla P100 that took nearly 2 hours to complete.

TABLE I. HYPER-PARAMETERS SETUP FOR PRE-TRAINING THE PASHTO BERT MODEL

Hyper-parameters	Values
Batch Size	32
Sequence Length	128
Padding	Post-padded
Learning Rate	1e-4
Linear Warmup Schedule	10K steps
$\beta_1$ and $\beta_2$	0.9, 0.999
L2 Weight Decay	0.01
Epsilon	1e-8

## VI. MODELS

The initial prototype of the NLPashto toolkit includes four SOTA AI models for (i) Spelling Correction, (ii) Word Segmentation, (iii) POS tagging, and (iv) Offensive Language Detection. The first three are essentially sequence tagging models that involve assigning a label or tag to each element in the sequence of input data. For sequence tagging tasks, NLP researchers use several supervised machine learning algorithms, such as HMM (Hidden Markov Model) [27], [28], RNN (Recurrent Neural Networks) [29], [30], [31], [32], [33], and CRF (Conditional Random Fields) [34], [35], [36], [37]. For various sequence tagging tasks, such as Word Segmentation and POS tagging, the CRF usually outperforms the other models. We have also incorporated CRF for training the three sequence tagging models. On the other hand, the model for offensive language detection is essentially a (binary) sequence classifier, which discriminates the input sequences into two categories, offensive and not-offensive. For that, we fine-tuned our pre-trained Pashto BERT model.

### A. Spelling Correction Model

The spelling correction module is aimed to remove the two typical spelling errors, the space-omission, and space-insertion. This model will predict the correct position of space in the text, insert a space where necessary, remove extra spaces from the sequence, and will return the noise-free text with the minimum required spaces.

1) *Features for Spelling Correction Model:* For modeling the spelling correction task, the “character” was considered as the basic text unit (like Chinese), and Pashto text was formalized as a series of characters and intervals as shown in Eq 1.

$$C_1I.C_2I.C_3I...IC_n \quad \text{for } I \in \{J, S\} \quad (1)$$

where  $C$  means a character, and  $I$  means an interval between the two characters, where the interval can be a space or “none”. Each character in the dataset was assigned with one of the two tags: an “S” if the character is followed by a space or a “J” otherwise, where “J” stands for “Joined”. Features for training the spelling correction model are the target character itself and n-grams of characters before and after the target character, based on which the CRF algorithm predicts whether the character is followed by a space or not. A summary of the features for the spelling correction model is as follows:

- The target character  $C$
- Check if  $C$  is the first character in the sentence, last on neither
- n-grams of characters before and after  $C$ , where the value of  $n$  ranges between 1 and 4

2) *Experimental Results:* For the experiment, we used the sklearn-crfsuite library in Python. Hyper-parameters were tweaked for optimal results, where both  $c_1$  and  $c_2$  were set to 0.1, representing  $L_1$  and  $L_2$  regularization, respectively. The L-BFGS method was selected as the training algorithm. The dataset of labeled characters was converted into a CRF-friendly dataset of features. 80% of the dataset was used for training, and the remaining portion was used to test the model.

The spelling correction model achieved an F1-score of 99.16% with an accuracy of 99.35%. The contribution of different pairs of n-grams and their combined effect is given in Table II. The model performed its best for n-gram in the range between 1 and 4, which is very logical considering the average token length of 3.6 characters. By utilizing 4-grams before and after the target character, the model captures information from a total of 9 characters. Overall the model’s performance is quite satisfactory, making it useful in practical applications.

TABLE II. CONTRIBUTION OF THE PREVIOUS AND NEXT N-GRAMS AND THEIR COMBINED EFFECT IN MODEL’S PERFORMANCE, IN TERMS OF F1-SCORE (%)

n-grams	Previous	Next	Combined
1	82.42	88.18	91.22
2	88.25	93.78	96.99
3	92.86	96.61	98.87
4	94.61	97.44	<b>99.16</b>

## B. Word Segmenter

Similar to the spelling correction model, the word segmenter is also a sequence tagging model based on the CRF algorithm. However, the word segmenter considers the token-level information instead of character-level information. A token is the basic unit for feature extraction, which can be the character in Chinese [31] and Javanese [34], syllable in Burmese [38], or character cluster (KCC) in Khmer [39]. In the proposed Pashto word segmenter, a token is a space-delimited “string” of characters, which can be a single character, such as د (of), or a string of any arbitrary length like افغانستان (Afghanistan), which has nine characters.

1) *Features for Word Segmenter*: For modeling the word segmentation task, the token was considered as the basic unit, and Pashto text was formalized as a series of tokens and intervals as shown in Eq. 2.

$$T_1 I T_2 I T_3 I \dots I T_n \quad \text{for } T \in \{S, B\} \quad (2)$$

where  $T$  means a token, and  $I$  means Interval (or space) between two tokens. The space can be a word-delimiter or a separator between two ligatures of a compound word. All the tokens in the dataset were assigned one of the two tags, an “S” if the token is followed by a “simple” space or a “B” if the token is followed by a word-breaker (word boundary). Pashto is a language with a rich morphology, and words are inflected to express various grammatical and syntactic information. These inflections are mostly exhibited in the form of prefixes and suffixes of the words, which are very informative and, in most cases, enough for locating the word boundary. The features for the word segmenter include these morphological attributes and context information of the token. Following is the list of features, finalized after trial and error:

- The *token*
- Length of the *token*
- One and two characters prefixes and suffixes of the *token*
- All the above features for previous and next token
- Three-characters prefix and suffix of the *token*
- Is *token* first in the sentence, last or neither
- Is *token* numeric
- Previous and next tokens up to two places

2) *Experimental Results*: The contribution of various features and their combined effect on the model’s performance is presented in Table III. The results show that without context information (Previous and Next tokens), the model achieves an F1-score of 79.87%. However, combining the features of surrounding tokens increases the F1-score to 96.81%. It demonstrates the model’s ability to predict the boundary of the word, even if it has not been encountered before, thereby overcoming OOV errors that occur in the baseline lexicon-based segmentation approach.

## C. Part-of-Speech Tagger

Similar to the previous two models, the POS tagger is also modeled as a sequence tagger based on the CRF algorithm. However, the dataset for the POS tagger has 10K sentences, which is comparatively smaller. Unlike the lexicon-based word segmenter, the lexicon-based POS tagger yields a very high error rate (around 5%), leads to a laborious and time-consuming manual correction phase. To extend the size of the dataset with reasonable speed, we adapted an iterative approach where the model training and dataset development were carried out in parallel in several rounds, as shown in Fig. 4.

In the first round, we used the POS dataset of 10K sentences to train the initial prototype of the model. This model was then used to annotate another chunk of 10K sentences, followed by a manual correction phase add then added to the dataset. This process was repeated for several rounds, where each round has basically two phases, an automatic POS assignment, and manual correction. In each round, the amount of training data was increased by an amount of 10K sentences, and consequently, the accuracy of the model increased as well. With the reduction in the error-rate of the model, the burden on human annotators reduced as well, and the manual correction phase became less time-consuming.

1) *Tagset*: A Tagset is a list of POS labels/tags used to indicate the part-of-speech of each word in a text corpus. In this study, we used the tagset proposed in [40], which follows the naming convention similar to the Penn Treebank [41] that is one of the commonly adopted conventions by various corpora. Our tagset has a total of 38 tags, which is very concise and pragmatic and enough to encompass all the words. The disagreement of the researchers is respected, and a non-tagged version of the corpus is also included in the toolkit, which can be tagged using any preferred tagset.

2) *Features for Part-of-Speech Tagger*: The contexts used to predict the POS tag in Pashto are roughly similar to that used for English. These are the surrounding words and word components. Pashto has a similar or maybe richer morphology than English, where words are enriched by various affixes that

TABLE III. CONTRIBUTION OF VARIOUS FEATURE SETS AND THEIR COMBINED EFFECT ON MODEL’S PERFORMANCE

Feature set	Accuracy (%)	F1-score (%)
Token	98.12	79.87
Previous	98.31	81.24
Next	98.61	86.34
Combined	99.65	<b>96.81</b>

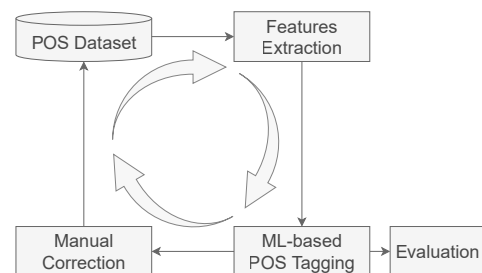

Figure 4. Iterative training of the POS tagger.

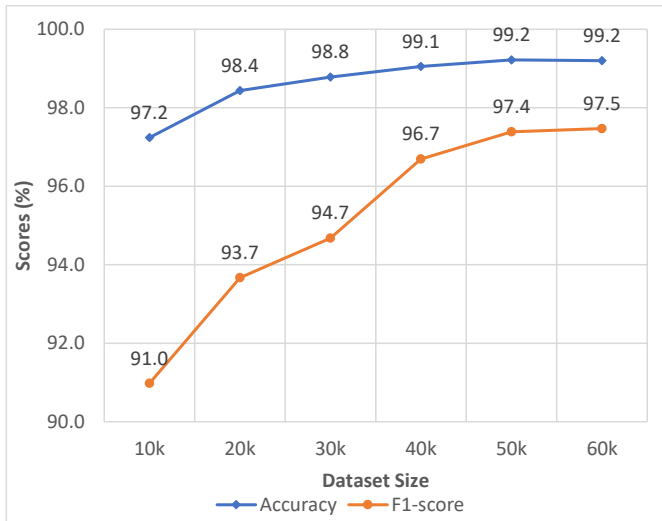

Figure 5. Improvement in performance of the POS tagger with the increasing dataset size. Lx.B represents the lexicon-based segmentation.

can be exploited for feature extraction. For training the POS tagger, we considered the same features as the word segmenter model, which are the morphological components of the token and the neighboring tokens.

3) *Experimental Results:* For the implementation and training of the POS tagger, we followed the same experimental setup as the previous two models, including the hyper-parameters and ratio of the dataset train and test splits. However, we trained the POS tagger in several rounds, starting from a dataset of 10K sentences and gradually increasing the dataset size until the model achieved significant performance. The model's performance was evaluated after each round, as plotted in the graph in Fig. 5. In the first round, the model secured an accuracy of 97.2% with an F1-score of 91.0%, which was an improvement of 4.2% in terms of accuracy in comparison to the baseline lexicon-based approach, which achieves an accuracy of 93.0%. After six rounds of training, the dataset size reached 60K sentences (nearly 1.5 million words), and consequently, the accuracy of the model reached 99.2% with an F1-score of 97.5%. This performance is significantly better than the baseline.

#### D. Offensive Language Detection Model

The model for Offensive language detection is based on the transfer learning approach. Conventional machine learning generally involves training a model from scratch using a large dataset, whereas transfer learning uses a pre-trained model as a starting point to solve a new task, called fine-tuning. The pre-trained model we fine-tuned is our Pashto BERT model, which is pre-trained on a generic text corpus; where the purpose of fine-tuning is to adapt it to the specific task of offensive language detection by fine-tuning its parameters on the labeled dataset, POLD.

To our knowledge, no previous research work is available on Pashto offensive language detection. Hence, for the evaluation, we also fine-tuned a multilingual language model, XLM-R [24]. Several other multilingual models are also available,

TABLE IV. PARAMETERS FOR FINE-TUNING THE TRANSFORMER MODELS

Parameters	XLM-R	Ps-BERT
Learning Rate	2e-5	5e-5
Batch Size	16	16
Sequence Length	100	100
$\beta_1, \beta_2$	(0.9, 0.999)	(0.9, 0.999)

though most of these are missing Pashto, while XLM-R can understand text in 100 languages, including Pashto. Besides transfer learning, we also investigated the classic neural network-based models, such as CNNs and various types of RNNs, using the static word embeddings, Word2Vec, GloVe, and fastText as features.

1) *Fine-tuning BERT models:* Fine-tuning a BERT model involves adding a classification layer on top of the model and training it on a specific dataset. For sequence classification, BERT takes the final hidden state of the classification token, identified by [CLS], as the representation of the whole sequence of text. We fine-tuned both the multilingual XLM-R and monolingual Pashto BERT on the task-specific POLD dataset. We tokenized the tweets and added special tokens [CLS] and [SEP] to mark the beginning and end of the sequence, respectively. However, the tokenizers used by the XLM-R and vanilla BERT are different, where XLM-R uses SentencePiece [42] tokenizer, while BERT expects the text to be tokenized by the WordPiece tokenizer. We implemented the models in PyTorch and Huggingface transformers library and used a GPU-facilitated Kaggle platform to conduct the experiments. We used the hyper-parameters given in Table IV and trained each model for 3 epochs.

2) *Neural Network-based Models:* As the baseline classifiers, we examined the performance of five neural networks, the CNNs, and four types of RNNs (LSTM, Bi-LSTM, GRU, and Bi-GRU), across three types of word embeddings: Word2Vec, fastText, and GloVe, as features. The primary components of our neural network models are the embedding layer, hidden layer, and output layer. The Embedding layer is the first hidden layer, which is a matrix of size  $pq$ , where  $p$  is the vocabulary size, and  $q$  is the sequence length, fixed at 64 tokens. To prevent overfitting, We used a dropout of 0.2. The output layer employs the Sigmoid activation function and Adam optimizer and uses cross-entropy loss to predict the tweet's category.

Besides the upper-mentioned common components, each model has its own adaptation and hyper-parameters setup. For CNNs, we constructed a 1D convolutional layer with 100 filters and a kernel size of 4. The next layer is max-pooling, followed by a dropout layer, and finally the output layer. The LSTM model has one LSTM layer with 100 units and a dropout layer, followed by a classification layer. The same architecture is used for the GRU model also, with the LSTM layer replaced by GRU. To build the Bidirectional LSTM, we construct one Bi-LSTM layer with 100 hidden units. The output vectors are flattened and fed to the classification layer. The Bi-GRU is using the same configuration of Bi-LSTM, except for the first layer which is replaced by the Bi-GRU. We used the batch size of 32 and trained each model for 5 epochs.

3) *Experimental Results:* We performed a series of experiments investigating various models for the task of Pashto

TABLE V. COMPARISON OF ALL THE MODELS FOR OFFENSIVE LANGUAGE DETECTION

Model		Accuracy (%)	F1-score (%)
Features	Classifier		
Word2Vec	BiGRU	92.33	91.50
	BiLSTM	92.85	92.09
	CNN	90.29	89.08
	GRU	92.94	92.18
	LSTM	93.23	92.52
GloVe	BiGRU	93.40	92.74
	BiLSTM	93.40	92.76
	CNN	92.97	92.24
	GRU	93.43	92.75
	LSTM	93.40	92.78
fastText	BiGRU	93.46	92.82
	BiLSTM	93.49	92.81
	CNN	92.24	91.44
	GRU	93.49	92.82
	LSTM	93.72	93.08
XLM-R		94.48	94.01
Ps-BERT		94.77	94.34

offensive language detection. A performance evaluation is presented in Table V. The results exhibit that the transformer models achieve comparatively better performance than the classic neural networks. Among all the models we examined, the fine-tuned monolingual Pashto BERT demonstrates the best performance which yields an F1-score of 94.34% with an accuracy of 94.77%. The XLM-R performed poorly compared to the Pashto BERT, yet better than the neural networks. Concerning the neural network models, the results indicate that the RNNs performed better than CNNs, where the LSTM classifier with fastText embeddings outperforms the other models and achieve an F1-score of 93.08% with an accuracy of 93.72%. In bidirectional RNNs, BiGRU performs the best with fastText features and achieves an F1-score of 92.82% with an accuracy of 93.46%. On the downside, the CNN model with Word2Vec embeddings exhibits the lowest performance.

### E. Comparison of Static Word Embeddings

Fig. 6 illustrates the performance comparison of the static word embeddings, using the LSTM classifier. The results show that the fastText achieves the highest F1-score of 93.08% with an accuracy of 93.72%. One reason is that the fastText model uses sub-word tokenization, which is particularly useful for the task of offensive language detection, as the OSN users commonly write half words instead of the full form, or use alteration. For example, on English social media, words like “f\*ck”, “b!tch”, “c#ck”, etc., are commonly used, where the same convention is used in Pashto also. This way of writing often leads to OOV errors in Word2Vec and GloVe, while in fastText, if a word is not present in the vocabulary the sub-words might be, which is useful in obtaining representations for altered, misspelled, or half-words.

## VII. CONCLUSIONS

Pashto is a low-resource language and lacks the basic tools and resources required for NLP. This study aimed to develop SOTA models, benchmark datasets, and other preliminary resources necessary for the research in Pashto NLP. To facilitate the reuse of our findings, we packaged everything

in a toolkit called NLPashto and distributed it publicly on GitHub<sup>1</sup> and PyPi<sup>2</sup> hub. The initial prototype of NLPashto consists of three general-purpose models for basic text pre-processing, a spelling correction model, a word segmenter and a POS tagger, and a special-purpose model for detecting offensive language (particularly on social media). Additionally, the toolkit includes three pre-trained static word embeddings: Word2Vec, fastText, and GloVe, as well as a pre-trained monolingual Pashto BERT for dynamic word embeddings. All the SOTA AI models we developed are based on the supervised learning approach, trained on labeled datasets. The toolkit also includes the benchmark datasets we developed for training and evaluating the models. The evaluation results show that our Pashto BERT model outperforms the multilingual XLM-R, even though the corpus used for training the Pashto BERT is much smaller in comparison to the XLM-R corpus. Similarly, all the other models included in the NLPashto toolkit perform quite satisfactorily on their respective tasks and can be used in practical applications. In summary, this is a pioneering study on Pashto NLP, and we hope that our findings and the resources and tools we developed will facilitate and speed up future research in this domain.

Toolkit development is an ongoing process, and we are continuously working to add more modules in the upcoming prototypes of NLPashto, such as NER and Constituency and Dependency Parsing. Apart from that, there are several research areas yet to be explored in Pashto NLP, such as stemming, lemmatization, machine translation, text-to-speech, and speech-to-text.

**Abstract**—Intelligent transportation is a system that combines data-driven information with traffic management to achieve intelligent monitoring and retrieval functions. In order to further improve the retrieval accuracy of the system model, a new retrieval model was designed. The functional requirements of the system were summarized, and the three stages of data preprocessing, feature matching, and feature extraction were analyzed in detail. The study adopted preprocessing measures such as equalization and normalization to minimize the negative effects of noise and brightness. Based on the performance of various algorithms, the distance method was selected as the feature matching method, which has a wider applicability and is better at processing bulk data. Next, the study utilizes Euclidean distance method to extract keyframes and divides the feature extraction into three parts: color, shape, and texture. The methods of color moment, canny operator, and grayscale co-occurrence matrix are used to extract them, and ultimately achieve relevant image retrieval. The research conducted multiple experiments on the retrieval performance of the model, and analyzed the results of retrieving single and mixed features. The experimental results showed that the algorithm performed better in the face of mixed feature extraction. Compared with the average value of a single feature, the recall and precision of the three mixed features increased by 13.78% and 15.64%, respectively. Moreover, in the case of a large number of concurrent features, the algorithm also met the basic requirements. When the concurrent number was 100, the average response time of the algorithm is 4.46 seconds. Therefore, the algorithm proposed by the research institute effectively improves the ability of video retrieval and can meet the requirements of timeliness, which can be widely applied in practical applications.

**Keywords**—Matching extraction; feature fusion; image retrieval; intelligent transportation

## I. INTRODUCTION

As the economy continues to grow, the basic needs of the people continue to develop, which is reflected in the field of transportation by the large increase in the number of private cars, which not only causes serious environmental pollution, but also provides greater pressure on traffic management. Therefore, China vigorously promotes the intelligent transportation, combining data-based information with traffic management to achieve automated detection and retrieval of surveillance images, which greatly improves the efficiency of transportation and reduces the burden of manpower, and is an effective way to retrieve target images [1]. Today's video image retrieval systems have been able to achieve real-time extraction functions, while providing appropriate processing

methods. First of all, it is necessary to install surveillance at different intersections or streets, and the intelligent transportation system is divided and displayed according to the area. The supervisory equipment of the video can help the relevant staff to realize the real-time processing of effective information, and also has five functions of list classification, live video, quick screenshot, remote lens control and setting up display image parameters. Among them, the list display can make the video classification more efficient. The system automates the display of list data through a tree diagram format, with the installation location as the title and the boundaries according to each area, and can usually view 1 to 16 surveillance screens simultaneously. It can also be further assisted by features such as quick screenshots and remote control of footage. Human adjustment of each parameter can also be utilized during live video streaming to assist in completing the work efficiently. Administrator-centric maintenance of organizational units, devices, i.e., surveillance points, and electronic maps can be implemented at [2, 3]. Image retrieval can be applied to areas such as traffic flow statistics, i.e., the use of image features to count the flow of people and vehicles. These informational functions greatly reduce the pressure of traffic management, because the traditional manual detection methods are not only time-consuming and laborious, but also have a very limited scope of work. The new digital management can help traffic management to be smoother and more accurate [4]. The video image retrieval system can provide great value to the traffic field, so the study explores the intelligent traffic system based on image processing and feature extraction algorithm, and designs three stages of data pre-analysis of traffic, feature matching of video and image, and feature extraction, and the study aims to further enhance the development of intelligent traffic. The main contribution of the research is to design and build the architecture of video surveillance systems, complete the collection and monitoring of image data, and then utilize video stream keyframe extraction technology to integrate various image analysis and processing sub-functional modules, forming effective algorithms for analyzing and identifying surveillance objects.

The research content is mainly divided into four parts. The first part is a summary and analysis of domestic and foreign scholars' research on image retrieval technology and image processing technology. The second part is to study and construct a smart transportation model, which describes the extraction of image color and texture features. The third part is to conduct performance experiments on the proposed method

through experiments, and verify the feasibility of the research method through scientific control. The fourth part summarizes the research and analyzes the shortcomings in the current research, while proposing future research directions.

## II. RELATED WORKS

The image retrieval function of video has been studied by many scholars in various fields. Yan et al. [5] concluded that video image retrieval also has some security privacy issues. Based on this, they proposed a new class of secure video retrieval method to maintain user privacy based on cryptographic type vector expansion approach, and experimentally verified that this cryptographic retrieval yielded the same results as ordinary retrieval. Radenović et al. [6] proposed a convolutional neural network based image retrieval method; This method is highly compact as well as extremely efficient in extraction, at the same time it also requires a large amount of data support for the training of the model; The study used the method of adjusting cellular neural networks, using automated retrieval of random images, introducing concepts such as hard positives. This is to further improve the efficiency of the algorithm and achieve efficient operation of image retrieval. Veres and Moussa [7] considered that the transportation system is a more complex. This system requires the modules to operate in cooperation with each other, which contains a large number of temporal and spatial features, so building a model for this system is difficult. The study then proposes a deep learning theory, gives a detailed overview of its development in transportation systems, and provides solutions for its development and other problems. Chen et al. [8] argued that traditional transportation systems should have been overturned long ago. Consequently, the study applies a deep learning theory based on edge nodes to traffic flow data, introduces a detection algorithm for YOLOV3 and a deep simple online tracking algorithm for vehicle detection purpose. Gohar and Nencioni [9] combined smart transportation with 5G technology. Then they provide an overview of the background as well as the prospect of 5G technology and describe its application in smart transportation system in detail and also analyze its application in other fields. The study uses image processing based as well as feature extraction algorithms to design traffic systems. Rovithakis et al. [10] used hybrid neural networks as well as genetic algorithms for feature

extraction and apply it to medicine. This is to identify normal and cancerous cells whose features generate highly dispersed classes in space while using spectral classification to achieve further testing. Xu et al. [11] considered the use of the study discussed the temporal characteristics of the data and proposed a nonlinear data feature extraction technique, i.e., kernel principal component analysis. This technique first maps the low-dimensional data into a high-dimensional space and completes the feature extraction in that control. Then the study compared this method with the linear PCA method experimentally, and obtained that the kernel principal component analysis method has better. The key to more efficient feature extraction is to compress the data, which can achieve the purpose of discarding irrelevant signals, excluding noise and various redundant feature data. Zebari et al. [12] used a combination of FS and FE method for feature extraction and verified the reliability performance of the method through comparative experiments.

In the above analysis, scholars have used various algorithms to retrieve videos or images, etc., in order to achieve intelligent transportation. Their research used combinatorial algorithms to construct models and obtained relatively reliable results. However, the results basically only meet the minimum requirements for practical applications, and in the face of complex video environments, its performance is difficult to achieve the same effect. Therefore, research suggests that in smart transportation, algorithms still need to have better performance. Inspired by the above literature, the study combines image processing technology, feature extraction technology, and other technologies to form a composite model. This model is applied to the field of transportation.

## III. INTELLIGENT TRAFFIC SYSTEM BASED ON VIDEO IMAGE RETRIEVAL

### A. Intelligent Transportation System Data Pre-processing

The study adopts a video retrieval system based on image processing technology and feature extraction algorithm. The system contains five main aspects, which are: image processing, data storage, monitoring and management, and traffic flow statistics. The flow chart of the whole system is shown in Fig. 1.

Fig. 1. Intelligent transportation system.

Data preprocessing is performed in order to eliminate as many extraneous signals as possible and to make the subsequent image processing steps more efficient. Data preprocessing includes data normalization, noise exclusion, and attenuated luminance [13]. The formula is shown in Equation (1):

$$f(D) = \frac{D_m}{A_0} \int_0^D H(u) du = D_m \int_0^D \frac{H(u)}{A_0} = D_m P(D) \quad (1)$$

In Equation (1),  $D_m$  denotes the maximum gray value in the image set;  $A_0$  denotes the total pixel value in the image set;  $H(u)$  denotes the total number of all pixels in the image set whose gray value is not equal to 0;  $P$  represents the probability of the occurrence of grayscale values in an image. This equalization method is based on the mutual difference relationship of pixel gray values for feature recognition. The difference between the gray value of a pixel and its neighboring pixels within a certain range is used as the judgment criterion. When it exceeds a certain threshold value, it means that the point is an irrelevant signal, i.e., it has a correlation crossover with other points and should be discarded; on the contrary, the point can be regarded as a valid signal to be retained, and the expression of the whole process is shown in Equation (2):

$$y_{ij} = \begin{cases} med(W[x_{ij}]), x_{ij} = \min \text{ or } \max \\ x_{ij}, x_{ij} = \text{other} \end{cases} \quad (2)$$

In the above Equation (2),  $y_{ij}$  represents the pixel value of the output point  $(i, j)$  after equalization;  $x_{ij}$  represents the initial pixel value of the input;  $W$  represents the weighting operation; and  $med$  represents the intermediate value function of the solution. In summary, the pre-processing of video, i.e., screening key frames and eliminating noisy signals, finally constructs an image basic element that can realize feature extraction. The basic principle of feature matching is to realize the feature matching process by comparing the feature data of the desired image with the image feature information in the database, and using the similarity as the judgment criterion. There are five main categories of feature vector matching algorithms that are relatively advanced in development today. One of them is the histogram crossover algorithm described above, and the second one is the cardinality split-box algorithm, i.e., feature matching by means of cardinality test, when the cardinality value  $\chi$  is small, the correlation is weak, and vice versa, the correlation is strong [14]. The expression is shown in Equation (3):

$$\chi^2 = (Q, I) = \sum_i \frac{(Q_i - I_i)^2}{(Q_i + I_i)^2} \quad (3)$$

In the above Equation (3),  $Q$  and  $I$  represent the histogram of the target image and the histogram of any image in the database, respectively,  $i$  represents the stalk in each histogram. The Kolmogorov-Smirnov algorithm is a method of dimensionality reduction of data using spectral analysis, which can reduce the storage cost, but a large number of

decomposition clusters will increase the computational pressure and lead to lower efficiency. The distance method  $L^p$  is calculated as shown in Equation (4) [15].

$$L^p(x, y) = \left( \sum_i |x_i - y_i|^p \right)^{1/p} \quad (4)$$

In the above Equation (4),  $x$  and  $y$  represent the contents of the target image and the value of the image matched with it in the database, respectively. When the parameter  $p$  is 1, the algorithm uses the Euclidean paradigm, i.e., the distance of  $L1$ , as the basis of the calculation result; when the parameter  $p$  is 2, the Manhat tan paradigm, i.e., the distance of  $L2$ , is used as the basis of the calculation result. Considering according to the research needs and combining the advantages and disadvantages performance of each algorithm, the study selected  $L^p$  distance method as the matching feature method, which is not only applicable, but also has short computation time and relatively easier to implement [16].

### B. Extraction of Color Features in Video Images

The image retrieval requires a combination of feature matching and feature extraction. Then comes the feature extraction of video images, which can be roughly divided into three parts: color feature extraction, texture feature extraction, and shape feature extraction. In this study, color moments are used to achieve feature extraction, and the overall color feature matching process is shown in Fig. 2.

Fig. 2. Color feature extraction.

Different color models usually differ in their feature representation methods. The study is modeled by the perceptual color model HSV (Hue, Saturation, Value). This model describes colors according to the three attributes of hue, luminance and saturation, and input to the Munsell 3D spatial coordinate system for further analysis. Generally, video images are stored in the RGB model, so the first step is to change the video image from the traditional RGB format to the HSV

format [17]. It is known that all parameter values in the RGB model  $(r, g, b)$  are in the interval  $[0,255]$ , and the conversion expression is shown in Equation (5):

$$\left\{ \begin{array}{l} s = \frac{\max(r, g, b) - \min(r, g, b)}{\max(r, g, b)} \\ h' = \begin{cases} (5+b'), \text{if } r = \max(r, g, b) \text{ and } g = \min(r, g, b) \\ (1-g'), \text{if } r = \max(r, g, b) \text{ and } g \neq \min(r, g, b) \\ (1+r'), \text{if } g = \max(r, g, b) \text{ and } b = \min(r, g, b) \\ (3-b'), \text{if } g = \max(r, g, b) \text{ and } b \neq \min(r, g, b) \\ (3+g'), \text{if } b = \max(r, g, b) \text{ and } r = \min(r, g, b) \\ (5-r'), \text{otherwise} \end{cases} \\ h = 60 \times h' \end{array} \right. \quad (5)$$

It is known that the values of  $h$  in the HSV model are in the interval  $[0,360]$ , the values of  $s$  and  $v$  are in the interval  $[0,1]$ , and all the parameter values of  $(r, g, b)$  in the RGB model are in the interval  $[0,255]$ , when  $v' = \max(r, g, b)$ , then  $v = \frac{v'}{255}$  is defined. In the above Equation (5), the expressions of  $r'$ ,  $g'$  and  $b'$  are shown in Equation (6):

$$\left\{ \begin{array}{l} r' = \frac{v' - r}{v' - \min(r, g, b)} \\ g' = \frac{g' - g}{v' - \min(r, g, b)} \\ b' = \frac{b' - b}{v' - \min(r, g, b)} \end{array} \right. \quad (6)$$

The HSV color model has the most accurate description in terms of individual subjective perception. To further improve the accuracy of the model, the study segmented the output video images in the form of  $3 \times 3$ . Then it ensured that the description values of the three different dimensions were normalized and pre-processed before extracting the features, which can avoid the computational error of taking too high a local value. The accuracy of video images retrieved using only histograms is not high because histograms are weak in considering spatial location, lighting intensity and element correlation; This can lead to more subjective results [18]. Based on this, the study introduces the "color-space" theory, the principle of which is to infinitely partition the color space, and extract the corresponding color features from the divided small space, and finally form a sequence of feature vectors. The similarity of the feature vectors is used to compare and sort the video images for retrieval. This recognition method, which takes into account the spatial location information, greatly improves the accuracy of the model. In the retrieval of each feature in space, the center distance according to the three orders of the image is used as the index term, denoted by  $E$ ,  $\sigma$ , and  $S$ , corresponding to the description of the color mean, standard variance, and cubic root asymmetry, as shown in Equation (7):

$$\left\{ \begin{array}{l} E = \frac{1}{A} \sum_i \sum_j p_{ij} \\ \sigma = \left[ \frac{1}{A} \sum_i \sum_j (p_{ij} - E)^2 \right]^{\frac{1}{2}} \\ S = \left[ \frac{1}{A} \sum_i \sum_j (p_{ij} - E)^3 \right]^{\frac{1}{3}} \end{array} \right. \quad (7)$$

In the above Equation (7),  $A$  represents the number of pixel values of the complete image;  $E$  also represents the pixel values at the  $(i, j)$  coordinates. The image retrieval is achieved by comparing the target image with the color principal feature vector of the retrieved image  $Vector(E, \sigma, S)$ , and the expression is shown in Equation (8):

$$D(Q, I) = D(Vector_Q, Vector_I) = W_E |E_Q - E_I| + W_\sigma |\sigma_Q - \sigma_I| + W_S |S_Q - S_I| \quad (8)$$

In the above Equation (8),  $Q$  represents the target image;  $I$  represents an arbitrary image in the database;  $D(Q, I)$  represents the similarity value between the two images;  $Vector_Q$  and  $Vector_I$  represent the feature vectors of the target image and the arbitrary image, respectively;  $W_E$ ,  $W_\sigma$ , and  $W_S$  represent the weights corresponding to the color mean, standard variance, and cubic root asymmetry, respectively. Since the color mean is greatly affected by the light intensity, the study will moderately reduce its weight value.

### C. Extraction of Texture Features in Video Images

The study uses a grayscale co-occurrence matrix to extract the texture features of the image, which can be used to describe the pixel changes in a certain direction in space. The position distance of two pixels is defined as  $\delta = (D_x, D_x)$  and their probability of occurrence can be expressed by the gray value  $P(i, j | \delta, \theta)$ . Under the condition that the position  $\delta$  and the space  $\theta$  are certain, the gray value can be simplified to  $P(i, j)$  and the parameter  $(i, j)$  takes a range of values related to the number of gray levels  $L$ , which is a natural number less than or equal to  $L-1$ . The grayscale co-occurrence matrix uses the grayscale correlation of each pixel in the space to predict the probability of a certain grayscale value, and ultimately to achieve the description of texture features [19]. However, the computational pressure of the model would be too high if the probability of a gray value is calculated for all locations in the space. The study introduces moment of inertia, energy, entropy, and correlation as the four basic attributes of the feature vector. The flow of the algorithm implementation is shown in Fig. 3.

From Fig. 3, the system should first convert the original image to a gray image, and the conversion formula is shown in Equation (9):

$$gray = 0.30 \times R + 0.59 \times G + 0.11 \times B \quad (9)$$

Fig. 3. Texture feature extraction.

where, the number of gray levels  $L$  is 256; however, too many gray levels will lead to the non-representation of viewing differences and increase the computational pressure. Consequently, before creating the gray symbiotic matrix, the number of gray levels should be compressed in advance, and the study sets the total number to 8, as shown in Equation (10):

$$\begin{aligned}
 Q1 &= \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} p(i, j)^2 \\
 Q2 &= \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} (i-j)^2 p(i, j) \\
 Q3 &= \left\{ Q1 = \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} (i+1)(j+1)p(i, j) - u_1 u_2 \right\} / (\delta 1 \delta 2) \\
 Q4 &= \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} p(i, j) \log_2 p(i, j)
 \end{aligned} \quad (10)$$

The four matrices constructed are all characterized by the four perspectives of  $\theta = 0^\circ, 45^\circ, 90^\circ, 135^\circ$  for the eigenvalues, and the interval between pixels  $d$  is set to 1. Then the pixels that meet the conditions such as location features are filtered and filled into the matrices respectively. The four attributes of each feature covariate in the formed gray co-occurrence matrix are further analyzed and calculated. Finally, the features are extracted and formed into a  $4 \times 4$  matrix. The mean as well as the standard deviation of the texture features are calculated. The sequence is shown in Equation (11) as follows:

$$F = [\mu_1, \mu_2, \mu_3, \mu_4, \sigma_1, \sigma_2, \sigma_3, \sigma_4] \quad (11)$$

It is also necessary to normalize the parameters in the above Equation (11) and rank the similarity by the Euclidean distance method to retrieve the most appropriate image.

#### D. Extraction of Shape Features in Video Images

Shape features are one of the most important aspects of image matching. The shape analysis starts with enclosing the region with a closed curve, which can be divided into two types: by boundary and by region. The extraction of shape features focuses on shape area, aspect ratio, and moment invariants, and therefore invariant moments are used to extract shape features. However, image area, orientation, and distortion affect the accuracy of the algorithm, so it is necessary to introduce algorithms that change with these three aspects to achieve feature extraction. The complete flow of shape feature extraction is shown in Fig. 4.

Fig. 4 showcases that the study first extracts image contours as well as core features based on the canny operator method. It is a method for boundary detection based on the first-order derivatives of Gaussian functions and strong and weak thresholds. However, there may be breakpoints at the edges, and the study uses a closed-loop operation to connect the edge breakpoints to form a complete closed loop to avoid the influence of noise signals. Then the seeds are filled using the diffuse water method, and whether they are filled or not is judged according to whether they match the pixel values of the initial image; If they are filled, the lightness and darkness of the pixel point as well as the color value need to be adjusted until all points within the closed loop are finished testing [20]. Then the invariant moments in the closed loop are calculated and the feature vectors are refined. The main purpose is to calculate the 7 HU invariant moment features in the image, and further revise the calculation results before completing the final vector sequence. Finally, a normalization operation is performed on all element values using Gaussian method to ensure that there is a difference between the elements. And even if there are extreme values, the complete shape matrix is guaranteed and normalized as shown in Equation (12):

$$\begin{cases}
 h_1 = \eta_{20} + \eta_{02} \\
 h_2 = (\eta_{20} - \mu_{02}) + 4\eta_{11}^2 \\
 h_3 = (\eta_{30} - 3\mu_{12})^2 + (3\eta_{21} - \mu_{03})^2
 \end{cases} \quad (12)$$

Finally, based on the calculation results, feature matching is performed using Euclidean distance. The calculation formula is shown in Equation (13):

$$S_{im}(Q, I) = \sqrt{\sum_{i=1}^n (h_i^q - h_i^l)^2} \quad (13)$$

In the above Equation (13),  $h_i^q$  and  $h_i^l$  are the normalized sequences of the two compared images. The three features of color, texture and shape of the images are considered together and the features are fused, as shown in Equation (14):

$$L^2(x, y) = \alpha \sqrt{\sum_i (x_{ia} - y_{ia})^2} + b \sqrt{\sum_i (x_{ib} - y_{ib})^2} + c \sqrt{\sum_i (x_{ic} - y_{ic})^2} \quad (14)$$

Fig. 4. Shape feature extraction.

In the above Equation (14),  $x$  and  $y$  represent the fused feature vectors of the target image and any image in the database, respectively;  $x_i$  and  $y_i$  represent the vector values of different features of each image, and  $abc$  represents the basic weights of color, texture and shape features, respectively. To ensure the normal and efficient operation of the system, the performance metrics are also required, which usually include response time, load condition and retrieval accuracy. If the bandwidth is sufficient, the response time should be less than or equal to 2 seconds, and vice versa, less than or equal to 5 seconds; And considering the possibility of a large number of search workers entering the system at the same time, the system should reach a minimum concurrency value of 100; Finally, the retrieval accuracy of the retrieval system designed in the study should be at least 75%.

#### IV. SIMULATION EXPERIMENTS

The study conducts simulation experiments for the designed video image retrieval system, which can be divided into function-based experiments as well as performance-based experiments, that is, to verify the reliability of the system's business capabilities and performance indicators. The experimental environment includes both the user platform and the server platform. The specific environment parameters and data sets are shown in Table I.

The implementation of the algorithm not only requires the aforementioned hardware facilities, but also the control of algorithm-related parameters. The color value in the color space must meet the condition of [0,255], and the h parameter

value converted to HSV color space should be in the range of [0,360], and the s and h parameters should be in the range of [0,1]. In the texture features, setting different concurrency numbers and testing the response speed of the model under different conditions can obtain the results shown in Fig. 5.

Fig. 5 demonstrates that the response times from 20-100 concurrency number all meet the requirements, i.e., the response time is no more than 2 seconds when the bandwidth is sufficient, and no more than 5 seconds when the bandwidth is not sufficient. In the case where the number of concurrency is 40 or less, the model responds quickly and does not fluctuate much over multiple attempts, and is relatively stable overall. When the number of concurrency is 20, the average response time of the model is only 1.38 s. As the number of concurrency increases, the response time of the model keeps rising, but all of them are at normal values. At 60 concurrency, the average response time of the model reaches 2.75 s, and the convergence speed decreases slightly. When the number of concurrency reaches 80 and 100, the average response time of the model is 3.87 s and 4.46 s, respectively, and the fluctuation increases, but it still falls within the good convergence speed. In summary, it can be concluded that the image retrieval model is in compliance with the corresponding performance and criteria. To further understand the recognition accuracy of the model, the study conducted a comparative test of the model according to different feature extraction requirements, which are known to be 40 for all retrieval results and 35 for all suspicious images, and the results of the number of recognition when only a single feature is retrieved are shown in Fig. 6.

TABLE I. ENVIRONMENTAL PARAMETERS AND DATA SETS

Database/server platform					
Configuration Content	CPU	Memory	Hard drive capacity	Operating System	Database/ Development Environment
Configuration details	5.4GH. Intel i5. Quad-Core Processor	16GB	20TB/ 5TB	Windows Server 2012.	Oracle11n Eclipse112
User Platform					
Configuration Content	Model		Operating system		Quantity
Configuration details	DELL530, Intelis, Memory 8G.		Windows 7		10
Number	1	2	3	4	5
Frame Rate	1525	1841	1562	1845	1956
Detailed parameters					
Regular video rate, resolution 720P.					
	420 keyframes	510 keyframes	432 keyframes	395 keyframes	448 keyframes

Fig. 5. Response time of the model with different number of concurrency.

Fig. 6. Quantitative result graph for single feature retrieval.

Fig. 6 showcases that there is little difference in the number of results when the model retrieves a single feature, with the known number of all images being 40, the number of suspect images being 35, and the number of retrieved color, texture, and shape features is 32, 30, and 31, respectively. The algorithm performs best when retrieving color features, due to the fact that in traffic flow, color features are usually large in area and therefore they are also the easiest to detect. Texture features, on the other hand, are often hidden deeper and are not as easy to detect. Even so, the algorithm's detection results for each feature are relatively complete. The study conducted several experiments and finally the algorithm's detection rate and accuracy on a single feature are shown in Fig. 7.

Fig. 7 showcases that the retrieval accuracy of the algorithm for a single feature is in the reasonable range, with the highest retrieval accuracy and recall for a single color feature, 77.34% and 83.21%, respectively. Compared with the single texture feature with the worst retrieval performance, it has improved by 1.47% and 7.06%, respectively. It demonstrates that the accuracy of the algorithm is closely related to the feature attributes. Large area features are more easily recognized by the algorithm, and the average recall and precision of the algorithm on a single feature are 76.45% and 79.32%, respectively. Then, further analysis was conducted on the retrieval of mixed features in the experiment, and the results shown in Fig. 8 were obtained.

Fig. 7. Retrieval accuracy of single feature.

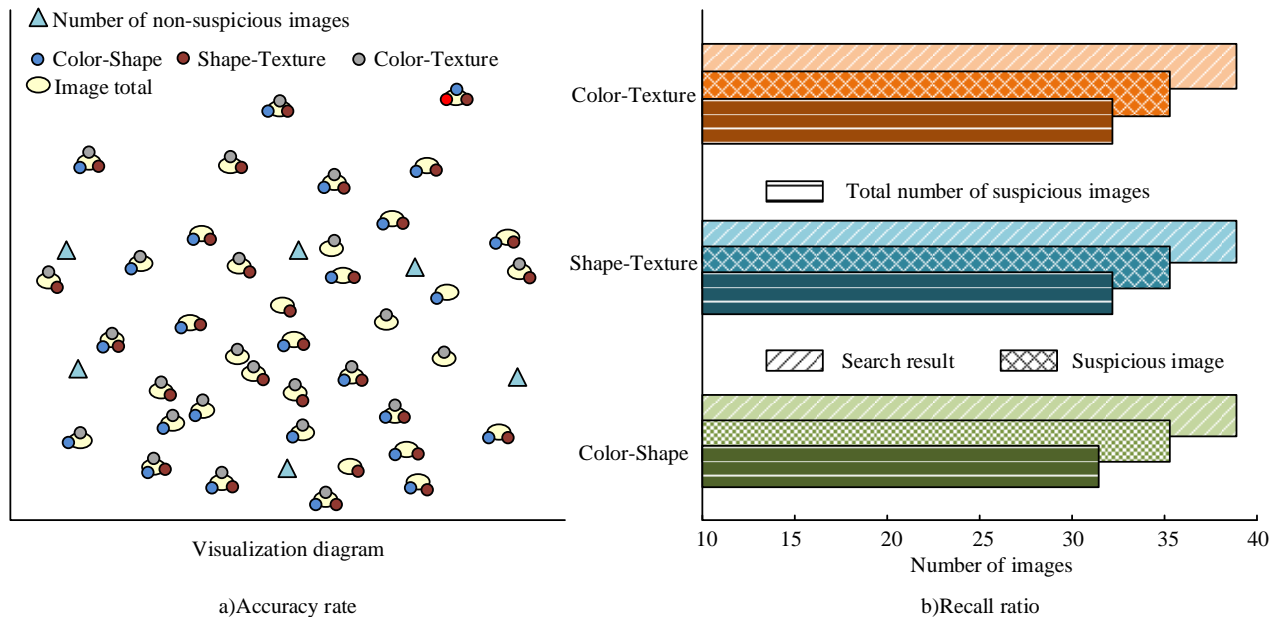

Fig. 8. Number of correct retrievals of mixed features.

Fig. 8 demonstrates that the model has a corresponding improvement for the retrieval of mixed features, which are color-shape, color-texture, and shape-texture, respectively. There are some differences in the correct retrieval values, but they can be ignored. The correct retrieval values of the three mixed features are 32, 33, and 33, which are less different from the correct values. The model's retrieval values for the color-shape hybrid features are relatively weak, but are within the good range. Thus the model also has excellent performance for the retrieval of both hybrid features. The study conducts several experiments and finally results in the algorithm's find-all and find-accurate rates on the two mixed features as shown in Fig. 9.

Fig. 9 showcases that the algorithm has significantly improved its performance in mixed features compared to single features. Among the three mixed features, the shape texture retrieval ability is the best, with a precision and recall rate of 85.35% and 88.24%, respectively. Compared with color shape features, the algorithm has improved by 1.13% and 3.45%, respectively. The average retrieval recall and precision of two-dimensional mixed features were 85.37% and 87.05%, respectively, which increased by 8.92% and 7.73% compared to single features. The study further validated the algorithm for 3D mixed features and obtained the results shown in Fig. 10.

Fig. 9. Retrieval accuracy of two-dimensional features.

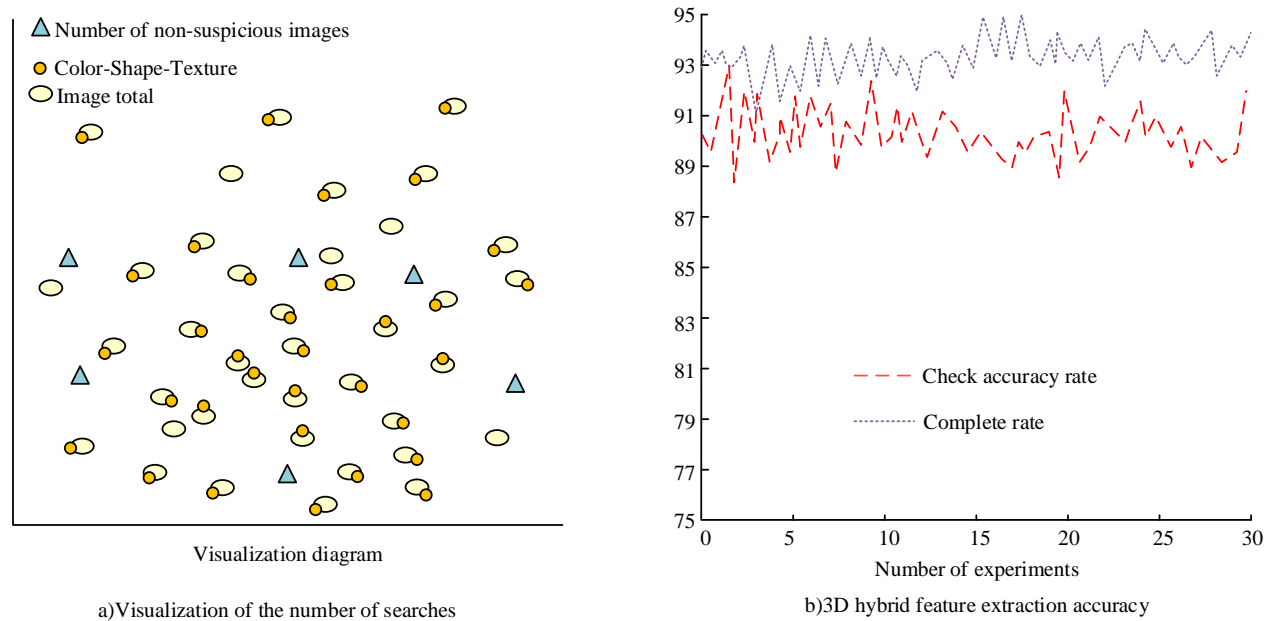

Fig. 10. Retrieval accuracy of 3D features.

Fig. 10 illustrates that the increase of feature parameters is not a decrease of algorithm accuracy, but an effective improvement. The total number of detected suspicious images reaches 34, which is only one bit away from the true value, and the detection accuracy and completion rates reach 90.23% and 94.96%, respectively. Compared with the retrieval averages of single features, the improvement is 13.78% and 15.64%, respectively; compared with the retrieval averages of 2D mixed features, the improvement is 4.86% and 7.91%, respectively. It can be seen that the increase of feature dimensionality leads to higher accuracy of the algorithm. In summary, it can be

concluded that the accuracy of the model meets the corresponding criteria and is excellent in the performance of mixed features.

To further validate the feasibility of the proposed method, the study conducted comparative experiments with other advanced methods to verify the feasibility of the research method. The experiment used Adaboost algorithm, Mean Shift algorithm, and Hard Triplet algorithm for comparative experiments. The model performance was tested through detection accuracy and recall indicators, and the results are shown in Table II.

TABLE II. ALGORITHM PERFORMANCE COMPARISON RESULTS

Algorithm	Rrecision	Recall	Reaction time (s)
Research algorithms	0.964	0.951	0.62
AdaBoost algorithm	0.958	0.946	0.58
Mean shift algorithm	0.967	0.948	0.64
Hard Triplet algorithm	0.955	0.952	0.59

In Table II, the accuracy of the AdaBoost algorithm is 0.958, the recall rate is 0.951, and the model response time is 0.58 seconds. The accuracy of the Mean shift algorithm is 0.967, the recall rate is 0.946, and the model response time is 0.64 seconds. The accuracy of the Hard Triplet algorithm is 0.955, the recall rate is 0.952, and the model response time is 0.59 seconds. It can be seen that the currently used algorithms have high accuracy and recall in video image detection, as well as fast response speed, which can meet the accuracy and real-time requirements of practical applications. The accuracy of the research method is 0.964, the recall rate is 0.951, and the reaction time is 0.62 seconds. From the analysis of the results, the proposed method has a relatively close performance to the current advanced methods, with an accuracy second only to the Mean shift algorithm, a recall second only to the Hard Triplet algorithm, and a reaction time difference of only 0.4 seconds. Therefore, the method proposed in the study can meet practical needs in use.

## V. CONCLUSION

The intelligent traffic system integrates digital information technology into traffic management, and is a novel method to achieve real-time and efficient monitoring and retrieval of traffic flow. The study has developed and designed the video image retrieval module in Java EE platform. Pre-processing measures such as normalization and equalization are performed to reduce the influence of irrelevant signals.  $L^p$  distance method and Euclidean distance method are used for data feature fusion and key frame extraction, and finally feature extraction methods are introduced according to three features: color, texture and shape, respectively. The study conducted simulation experiments on the model, and firstly, the convergence performance of the algorithm was tested, divided into 20-100 concurrency experiments. The experimental results show that the convergence effect of the algorithm decreases as the number of concurrency increases, but they are within the appropriate range, and when the number of concurrency is 20, the model retrieval time is only 1.38 s; and when the number of concurrency reaches 100, the retrieval time also reaches 4.46 s, which is less than the allowed the maximum value. Then the model was experimented for feature extraction, and several trials were done according to 1D, 2D and 3D features. The experimental results showed that the more feature elements, the higher the accuracy of the algorithm. The retrieval accuracy and completeness of 3D features, compared with the retrieval average of single features, improved by 13.78% and 15.64%, respectively. It can be seen that the model has better retrieval performance. However, the model also has some limitations, because video image retrieval should have a place in both the intelligent transportation field and other fields. This requires that the system should be extensible so that new modules can

be added at any time. The study has yet to improve its performance in this regard.

**Abstract**—The effectiveness and efficiency of enterprise knowledge management depends on the effectiveness and efficiency of the enterprise's implementation of knowledge management. Big data technology can collect, analyse and apply the massive amount of data in an organisation to support the implementation of knowledge management. Therefore, exploring the role of big-data knowledge management in the development of enterprise innovation will help enterprises to better implement knowledge management. Based on this, the study aims to propose a model for predicting big data knowledge management and enterprise innovation development for high-tech enterprises in China. The study firstly used Principal Component Analysis (PCA) to decrease the dimensionality of the model, and then used the particle swarm algorithm to optimize BP neural network (PSO-BP). Network (PSO-BP) was used to evaluate enterprise knowledge management and enterprise innovation development. The results of the study show that the absolute values of the relative errors of the pre-processed model do not exceed the 5% threshold, and only the relative errors of some indicators are relatively large, such as X5 and X7, with values of 4.5% and -3.8%, indicating that the model has a good performance in predicting the innovation effect of enterprises.

**Keywords**—Big data knowledge management; BP neural network algorithm; enterprise innovation development; principal component analysis; particle swarm optimization algorithm; correlation analysis

## I. INTRODUCTION

With the advent of the information age, the amount of data and information has increased exponentially, and how to effectively manage big data knowledge has become an important research direction for the current development of the country and enterprises [1,2]. At the same time, managing big data can strengthen enterprises' cognition of data-related knowledge, find their own positioning, better access the dividends of the times, and enhance their attention to big data capabilities. At the same time the rational use of big data can also enable the whole enterprise to enhance the innovation ability of products and improve the performance of the enterprise [3]. However, the current research on big data is at the initial stage, and many of the constructed algorithm models cannot comprehensively analyze the characteristics of big data knowledge management, for example, the commonly used back propagation neural network (BPNN) algorithm cannot analyze larger and broader data, while the slow computing speed also causes problems for data analysis of big data knowledge

management. Although the particle swarm optimization (PSO) algorithm is simple and easy to implement with few parameters, the poor performance and troublesome network parameters also make the algorithm unable to better solve the problems arising in big data knowledge management. Meanwhile, many current studies on big data knowledge management are still in the dialectical analysis stage [4-5]. Based on this, this experiment will study big data knowledge management by using principal component analysis (PCA) to organize and analyze the data, then using PSO algorithm to determine the weights of the factors influencing knowledge management on the development of enterprise innovation (EnIn), and finally using BPNN algorithm to predict the data set and determine the role of big data knowledge management on the development of EnIn and the feasibility of its development. This research is divided into four parts, the first part is to explain the current research status of big data knowledge management at home and abroad, the second part establishes a new optimization algorithm model by analyzing the indicators of big data characteristics, the third part is to analyze the performance of the optimization algorithm and the data processing results, and the fourth part is to conclude the whole article.

## II. RELATED WORK

Goncharenko et al. aimed to study the functional support of organisational and economic mechanisms of innovation and integration potential management in enterprises. The study examines the organisational and economic mechanisms of innovation and integration potential management in enterprises. The study showed that organisational and economic mechanisms are the basis for the management of innovation and integration potential of enterprises and that their functional support is divided into four areas: internal management support, market support, policy support and social support [6]. Zadorozhnyi et al. aimed to explore the determinants of innovation affecting enterprises and assessed them on the basis of actual data from financial statements. It was found that the financial statements of firms can provide useful information reflecting the innovation of the firm, which includes investment, profit and asset structure. In addition, financial statements can increase the transparency of financial statements by providing information on details such as technology development, organisation and management of the firm [7]. Katsarski discussed the relationship between integrated business management and water ecosystems,

summarised the importance of integrated business management and its role in water ecosystem conservation, and made recommendations for future research and practice [8]. Vasylytsiv et al. aimed to explore the creativity, information and knowledge determinants of economic growth in the EU region in the context of smart development strategies. The study provides an integrated analysis of smart development strategy research and economic growth. The findings show that economic growth in the EU region depends mainly on policy creativity, effective transmission of information and the driving force of knowledge. In addition, factors such as technological innovation and innovative social networks also have a significant impact on economic growth in the EU region [9]. Straková et al. examine trends in organisational and managerial structures, exploring many of the key issues involved in practice and research, such as organisational structure, management theory, organisational culture and leadership styles. The article also details the changes in organisational and management structures and how the changes affect organisational performance. Finally, the article offers suggestions for addressing these issues to help managers better manage organisational and management structures [10].

To explore the strategy of obtaining sustainable competitive advantages in emerging wine producing regions in southern Sweden, Kompaniets introduced the concept of this advantage and explored various strategies. This includes resource base, technology base, customer base, market base, and organizational base, which can be transformed into a sustainable competitive advantage for the region by implementing specific strategic measures [11]. Chatterjee et al. aimed to explore knowledge sharing for product and process innovation in international markets in order to better knowledge sharing and thus more benefits of innovation [12]. Lopes et al. aimed to explore how competitiveness management, knowledge management and corporate education are implemented in Brazilian companies, collecting data from three Brazilian companies. The study found that competitiveness management and knowledge management contributed to the efficiency of the enterprise, while corporate education helped to improve the skills and knowledge of employees [13]. Babgohari et al. aimed to explore the relationship between knowledge management competencies, entrepreneurial creativity, entrepreneurial passion and corporate performance, processing and analysing survey data from 385 of these companies. It verified that there was a prominent positive relationship between knowledge management capabilities and entrepreneurial creativity, entrepreneurial passion and firm performance, with the dual power of the firm playing a mediating role [14]. Wang et al. aimed to explore the relationship between market orientation

and service innovation, and the study used a quantitative research approach to analyse data from three major Chinese airlines. The conclusion was that there was a remarkable positive relationship between market orientation and service innovation, while knowledge sharing contributed moderately to this relationship. The results provide valuable management guidance for the company's market orientation and service innovation activities [15].

It can be seen through the research of scholars at home and abroad that there are more studies on the relationship between enterprise knowledge management and EnIn, but most of them stay in the perspective of empirical analysis and do not adopt algorithmic models to further dissect them. Based on this, the research is mainly built on the PCA-PSO-BPNN algorithm to design and study the role mechanism of big data knowledge management in the development of EnIn, and then analyse the specific mechanism of big-data knowledge management on the development of EnIn.

### III. BUILDING A MACHINE LEARNING-BASED ENTERPRISE INNOVATION MODEL IN A BIG DATA ENVIRONMENT

This chapter mainly provides an overview of the characteristics of big data knowledge management and data management process, discusses some data knowledge management metrics and pre-processing work, then establishes a big data knowledge management algorithm model by BP neural network, and finally improves and optimizes the BP neural network algorithm model by combining with PSO neural network.

#### A. Establishment of Big Data Knowledge Management in Enterprise Innovation Index System and Pre-Processing Work

Big data knowledge management mainly involves various aspects such as data collection, data cleaning, data analysis, knowledge discovery and knowledge application [16]. When establishing an EnIn model, the EnIn index system should first be established to detect the innovation level of the enterprise, and the technology of big data knowledge management can be used to realize data collection, data cleaning and data analysis, so as to establish an EnIn index system. In establishing the EnIn model, machine learning technology can be used to fully explore the innovation elements in the EnIn index system, so as to establish a machine learning-based EnIn model. According to the EnIn index system, a classification model can be constructed using supervised learning methods in combination with machine learning techniques to detect the innovation level of the enterprise. The research has initially constructed the big data capability index system and the EnIn performance system (Table I).

TABLE I. BIG DATA CAPABILITY INDICATORS AND ENTERPRISE INNOVATION PERFORMANCE INDICATOR SYSTEM

Main target	Subgoal	Numbering	Index
Metrics for big data capabilities	Access to resources Ability to access resources	X <sub>1</sub>	Ability to access internal and external data sources on a continuous, real-time basis to support the company's business
		X <sub>2</sub>	Possess and master the technical equipment required for big data analysis
	Analysis of integration Integration capabilities	X <sub>3</sub>	Ability to process large amounts of data and obtain valuable information
		X <sub>4</sub>	Ability to analyse a wide range of structured and unstructured data in real time
	Insightful anticipation Predictability	X <sub>5</sub>	The company is able to achieve real-time market insights based on big data and thus identify new business opportunities
		X <sub>6</sub>	Ability to forecast consumer behaviour and corporate opinion based on big data
	Knowledge Discover	X <sub>7</sub>	There is a dedicated process for obtaining relevant information from external sources
		X <sub>8</sub>	Access to timely and relevant information on customers and suppliers
	Knowledge Integration	X <sub>9</sub>	Ability to effectively integrate internally created knowledge with externally acquired knowledge
		X <sub>10</sub>	Ability to effectively integrate knowledge belonging to different technologies or application areas
	Knowledge Applications	X <sub>11</sub>	Regularly evaluate and adjust our forecasts based on new knowledge of market trends and technology Long-term forecasts
		X <sub>12</sub>	regularly evaluate our investment and resource allocation decisions in the light of new knowledge
A measure of corporate innovation and development	Patent results	A <sub>1</sub>	The research uses the R&D input ratio to total assets to express R&D intensity
	R&D intensity	A <sub>2</sub>	The research uses the amount of utility model, invention and design patents granted to measure the number of patent achievements in the innovation development of enterprises

As shown in Table I, the study divided the big data capability indicators into eight categories, based on which the study further divided them into six indicators of enterprise access to big data capability and two indicators of EnIn performance. The six indicators of enterprise access to big data capability were, in order, enterprise resource access capability, enterprise analysis and integration capability, enterprise insight and prediction capability, enterprise knowledge discovery capability, enterprise knowledge integration capability and enterprise knowledge application capability; the innovation development of enterprises is divided into two major indicators, namely patent achievement and R&D intensity. Based on this, the study selected the financial data of all A-share listed companies in the high-tech industry in Shanghai and Shenzhen from 2013 to 2020. The sample was selected as follows: firstly, A-share listed companies in the financial and insurance industries were excluded; secondly, there were and are only A-share shares in circulation; thirdly, listed companies with missing relevant data were excluded, and the final sample size was 1344; fourthly, R&D expenditure data were mainly collected manually by reviewing the annual reports of listed companies. In view of the differences between the old and new standards on the accounting treatment of R&D expenditures, we specifically divided the time periods from 2013 to 2016 and 2017 to 2020 for collection respectively, and other research

data were obtained from the CSMAR database.

The big data knowledge management in EnIn index system constructed by the study includes 14 indicators, and if all of them are incorporated into the BP neural network model, it will make the complexity and operation speed of the network increase significantly, the network performance decreases and the generalization ability of the neural network decreases [17]. Therefore, it is essential to comprehensively analyse the micro factors that affect the degree of innovation and scientific research of enterprises, and reduce the number of indicators while minimising information loss, which means reducing the dimensionality of evaluation indicators while ensuring the evaluation effect. PCA is a multivariate statistical correlation analysis of multivariate correlations, where a small number of main components (linear combination of the original variables) are used to account for changes in multiple variables, i.e. a small number of main components are deduced, thus keeping as much information as possible about the original variables and not correlating with each other, thus making the data more simplified. The specific working procedure is as follows, first setting the indicators for the evaluation of corporate innovation research as  $x' = (x_1', x_2', \dots, x_n')$  and assigning an empirical weight to these parameters  $W_x = (W_{x_1}, W_{x_2}, \dots, W_{x_n})'$ , where  $W_{x_1} + W_{x_2} + \dots + W_{x_n} = 1$ . Then find out its covariance, i.e., find

$$V = \begin{Bmatrix} v_{11} & v_{12} & \cdots & v_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ v_{ni} & v_{n2} & \cdots & v_{nm} \end{Bmatrix}$$

out the eigenvalues of  $V$  and arrange them in order of alphabetical size, i.e.  $\lambda_1 > \lambda_2 > \cdots > \lambda_r, \lambda_{r+1} = \lambda_{r+2} = \cdots = \lambda_n = 0$ , find out the cumulative contribution ratio and get the first  $m$  eigenvolume at  $\sum_{j=1}^m (\lambda_j / \sum_{i=1}^n \lambda_i) \geq 90\%$  first and round off the others to find out the eigenvector corresponding to  $\lambda_j (j=1,2,\dots,m)$   $r_j (j=1,2,\dots,m)$ , find out its  $x_1 = y_1' w_x, x_2 = y_2' w_x, \dots, x_m = y_m' w_x$ , so there is  $x = (x_1, x_2, \dots, x_m)'$ . To better grasp the role of enterprise big data capability on the impact of R&D EnIn.

**B. Establishment of an Original Model of Corporate Innovation Based on the BPNN Algorithm**

Neural networks are a multidisciplinary intersection whose definition varies greatly across disciplines. Research has proposed one of the most widely used concepts to date, which can be used to simulate various informations in the brain by organising the network with a variety of intelligent behaviours such as self-organisation, self-learning and self-adaptation [18]. Its individual neuron model is Fig. 1.

Fig. 1. M-P neuron model.

The specific neuron model listed in Fig.1 is also known as the M-P neuron model.  $x_i (i=1,2,\dots,n)$ ,  $x_0$   $\omega_i (i=1,2,\dots,n)$   $x_i$   $\theta$   $f(\cdot)$   $y$   $x_i$   $x_0$  The signal transmission procedure between  $x_0$  and  $x_i$  is approximately as follows: first, the input signal from the  $n$  neuron connected to the current neuron  $x_i$  is received and the corresponding connection weighting  $\omega_i$  completes the transmission of the full input signal, followed by the activation threshold  $x_0$  to compare the activation threshold of with the full input signal received. threshold  $\theta$  to compare the start threshold of  $x_0$  with the total input signals received. The final output  $y$  is displayed in the Equation (1).

$$y = f\left(\sum_{i=1}^n \omega_i x_i - \theta\right) \quad (1)$$

In the M-P neuron model, a step function is a temporal function with a specific continuum that converts inputs into outputs, and its expression is shown in Equation (2).

$$f(x) = \begin{cases} 0 & x < 0 \\ 1 & x \geq 0 \end{cases} \quad (2)$$

The Sigmoid function has the properties of a single increasing and inverse function, and its function image is shown in Fig. 2.

Fig. 2. Sigmoid function.

The M-P neuron model describes the neuron in terms of a logical function, which allows it to theoretically understand the information better. The input layer of the perceptron is in line with the M-P neuron as the output layer, and the specific model structure is Fig. 3.

Fig. 3. Perceptron model with two input neurons.

During the training period of the perceptron, it is assumed that the weighting value at a node is  $\omega_i (i=1,2,\dots,n)$ . The training sample set denotes  $(x, y)$ , the actual output value is  $y'$  and the learning rate is  $\eta$ . Then the perceptron will modify the learning rules for the connection weighting  $\omega$  as shown in Equations (3) and (4).

$$\omega_i \leftarrow \omega_i + \Delta\omega_i \quad (3)$$

$$\Delta\omega_i = \eta(y - y')x_i \quad (4)$$

From Equation (3) and Equation (4), it can be seen that there is no change in the connection weighting  $\omega$ , when the sensing machine correctly predicts the training example  $(x, y)$ , which is  $y = y'$ , otherwise the connection weights  $\omega$  will be

adjusted and modified accordingly according to the learning rules. The multi-layer neural network structure is exhibited in the form of Fig. 4.

Fig. 4. Multilayer feedforward neural network model.

As shown in Fig. 4, the samples of the training set are fed from the input layer of the multilayer feedforward network, and then the output of the neuron in each layer is considered as its next input. The specific unfolded connection weight matrices  $W^1$  and  $W^2$  matrices are shown in Equations (5) and (6).

$$W^1 = \begin{bmatrix} \omega_{11}^1 & \omega_{12}^1 & \cdots & \omega_{1m}^1 \\ \omega_{21}^1 & \omega_{22}^1 & \cdots & \omega_{2m}^1 \\ \vdots & \vdots & \ddots & \vdots \\ \omega_{l1}^1 & \omega_{l2}^1 & \cdots & \omega_{lm}^1 \end{bmatrix} \quad (5)$$

$$W^2 = \begin{bmatrix} \omega_{11}^2 & \omega_{12}^2 & \cdots & \omega_{1l}^2 \\ \omega_{21}^2 & \omega_{22}^2 & \cdots & \omega_{2l}^2 \\ \vdots & \vdots & \ddots & \vdots \\ \omega_{n1}^2 & \omega_{n2}^2 & \cdots & \omega_{nl}^2 \end{bmatrix} \quad (6)$$

In Equations (5) and (6),  $m$ ,  $l$  and  $n$  denote the neurons number in the input, hidden and output layer, respectively. The neuron activation threshold vectors in the hidden and output layers of the network are distributed as  $\theta^1 = [\theta_1^1, \theta_2^1, \dots, \theta_l^1]^T$  and  $\theta^2 = [\theta_1^2, \theta_2^2, \dots, \theta_n^2]^T$ , and the output of the neuron  $O_j$  can be pushed out of the network's hidden layer, as Equation (7).

$$O_j = f\left(\sum_{i=1}^m \omega_{ji}^1 x_i - \theta_j^1\right) = f(net_j) \quad (7)$$

In Equation (7),  $j = 1, 2, \dots, l$  and  $f(\bullet)$  are the functions of the activation functions expressed in the hidden layer,  $net_j = \sum_{i=1}^m \omega_{ji}^1 x_i - \theta_j^1$ . The resulting expression for the neuron  $z_k$  in the output layer is shown in Equation (8).

$$z_k = g\left(\sum_{j=1}^l \omega_{kj}^2 O_j - \theta_k^2\right) = g(net_k) \quad (8)$$

In Equation (8),  $k = 1, 2, \dots, n$ ,  $g(\bullet)$  is the activation function of the output layer, and the error value  $E$  is derived by performing an error operation on the true output value and the desired output value as shown in Equation (9).

$$E = \frac{1}{2} \sum_{k=1}^n \left( y_k - g\left(\sum_{j=1}^l \omega_{kj}^2 f\left(\sum_{i=1}^m \omega_{ji}^1 x_i - \theta_j^1\right) - \theta_k^2\right) \right)^2 \quad (9)$$

The link weights of the neurons in the hidden and output layers were optimally learned by calculating the error value of the network  $E$  and the partial derivative of the error value  $E$  with respect to the link weights  $\omega_{kj}^2$  is expressed as shown in Equation (10).

$$\frac{\partial E}{\partial \omega_{kj}^2} = \frac{\partial E}{\partial z_k} \frac{\partial z_k}{\partial \omega_{kj}^2} = -(y_k - z_k) g'(net_k) O_j = -\delta_k^2 O_j \quad (10)$$

In Equation (10),  $\delta_k^2 = (y_k - z_k) g'(net_k)$ , the connection weights of the neurons in the input and hidden layers are optimally investigated and the link weighting of the neurons in the input and hidden levels is optimally investigated and the error values are biased differential for the connection weights  $\omega_{ji}^1$  as shown in Equation (11).

$$\frac{\partial E}{\partial \omega_{ji}^1} = \sum_{k=1}^n \sum_{j=1}^l \frac{\partial E}{\partial z_k} \frac{\partial z_k}{\partial O_j} \frac{\partial O_j}{\partial \omega_{ji}^1} = -\delta_j^1 x_i \quad (11)$$

In Equation (11),  $\delta_j^1 = \sum_{k=1}^n (y_k - z_k) g'(net_k) \omega_{kj}^2 f'(net_j) = f'(net_j) \sum_{k=1}^n \delta_k^2 \omega_{kj}^2$ , the connection weights between its networks  $\omega_{ji}^1$  and  $\omega_{kj}^2$  modified by Equation (10) can be derived as shown in Equation (12).

$$\begin{cases} \omega_{ji}^1(t+1) = \omega_{ji}^1(t) + \Delta \omega_{ji}^1 = \omega_{ji}^1(t) - \eta^1 \frac{\partial E}{\partial \omega_{ji}^1} = \omega_{ji}^1(t) + \eta^1 \delta_j^1 x_i \\ \omega_{kj}^2(t+1) = \omega_{kj}^2(t) + \Delta \omega_{kj}^2 = \omega_{kj}^2(t) - \eta^2 \frac{\partial E}{\partial \omega_{kj}^2} = \omega_{kj}^2(t) + \eta^2 \delta_j^2 O_j \end{cases} \quad (12)$$

In Equation (12), the learning efficiencies in the hidden and output layers are  $\eta^1$  and  $\eta^2$ . For the neuronal activation threshold of the network output layer  $\theta_k^2$ , the partial differential representation of the computational error value  $E$  is shown in Equation (13).

$$\frac{\partial E}{\partial \theta_k^2} = \frac{\partial E}{\partial z_k} \frac{\partial z_k}{\partial \theta_k^2} = (y_k - z_k) g'(net_k) = \delta_k^2 \quad (13)$$

For the neuronal activation threshold of the hidden layer  $\theta_j^1$ , the partial differential representation of the error value  $E$  is calculated as shown in Equation (14).

$$\frac{\partial E}{\partial \theta_j^1} = \sum_{k=1}^n \frac{\partial E}{\partial z_k} \frac{\partial z_k}{\partial O_j} \frac{\partial O_j}{\partial \theta_j^1} = \sum_{k=1}^n (y_k - z_k) g'(net_k) \omega_{kj}^2 f'(net_j) = \delta_j^1 \quad (14)$$

Thus, based on Equations (13) and (14), the modulation formulae for the neuronal activation thresholds  $\theta_j^1$  and  $\theta_k^2$  can be derived and expressed as shown in Equation (15).

$$\begin{cases} \theta_j^1(t+1) = \theta_j^1(t) + \Delta\theta_j^1 = \theta_j^1(t) + \eta^1 \frac{\partial E}{\partial \theta_j^1} = \theta_j^1(t) + \eta^1 \delta_j^1 \\ \theta_k^2(t+1) = \theta_k^2(t) + \Delta\theta_k^2 = \theta_k^2(t) + \eta^2 \frac{\partial E}{\partial \theta_k^2} = \theta_k^2(t) + \eta^2 \delta_k^2 \end{cases} \quad (15)$$

### C. Establishment of an Innovation Model for PSO-based Optimization Neural Network Firms

BP neural networks can better reflect the complex non-linear relationships in the model, thus improving the prediction accuracy. However, BP neural networks also have their limitations. Firstly, BP neural networks are basically in a "black box" state during the solution process, and their results are difficult to be understood, and secondly, the neural networks have the phenomenon of overfitting. Based on big data technology, a sound knowledge management system can be established to collect and collate innovation indicators of enterprises and build an innovation model to measure the innovation capability of enterprises. Machine learning techniques, especially neural networks, can be effective in building an EnIn model, but it is difficult to find the optimal parameters due to the large number of parameters in a neural network model. For this reason, particle swarm algorithms (PSO) can be used to optimise neural network models to obtain the optimal parameters. Therefore, a corporate innovation model based on PSO optimised neural networks can be effectively constructed to measure the innovation capability of a company. The particle swarm algorithm model can be used to efficiently search for optimal parameters and to obtain a more accurate model of corporate innovation.

The PSO is an evolutionary algorithm, which is a technique based on group intelligence and on the simulation of group forces. The basic idea of the PSO algorithm is that each particle has a current position and an optimal position, and the current position of the particle is influenced by two forces, one from the particle itself and the other from the global optimal position. The current position of the particle is influenced by both forces, while the force of the global optimum position is influenced by the global optimum position, which is the influence of the optimum positions of all the previous particles. The optimization steps of the PSO algorithm are: first, initialize the particle swarm, each particle has a position and a velocity; then, calculate the fitness function of each particle; then, calculate the optimum position of each particle, the global optimum position. Finally, the particle positions and velocities are updated and terminated when convergence to the optimal solution is achieved. The particles have both velocity and position properties and are adapted using independent search and position sharing, with the update rules shown in Equations (16) and (17).

$$v_i = v_i + c_1 rand(pbest_i - x_i) + c_2 rand(gbest_i - x_i) \quad (16)$$

$$x_i = x_i + v_i \quad (17)$$

In Equations (16) and (17),  $v_i$  represents the particle

velocity,  $rand$  represents the random number,  $x_i$  represents the current particle position,  $c_1$  and  $c_2$  represent the learning factors. The PSO is a commonly used parameter search method, which can find the best parameters in the training set, and it can cut down the optimization time and strengthen the accuracy of the search with fewer iterations compared with the traditional grid search method [19]. The steps of its optimisation algorithm are shown in Fig. 5.

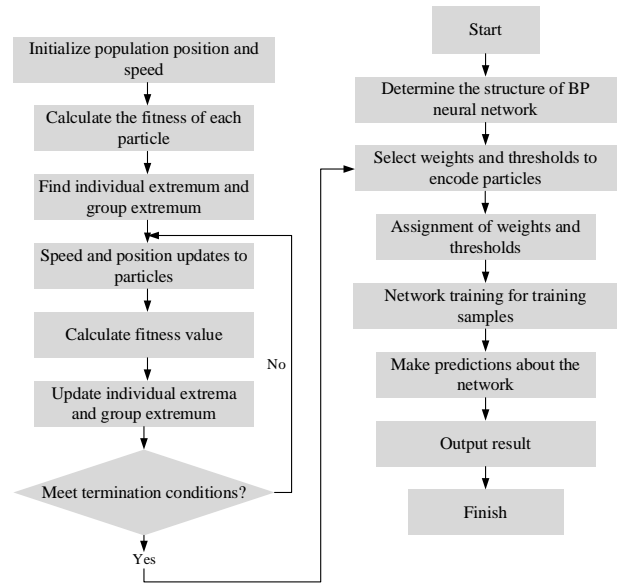

Fig. 5. Flow chart of PSO optimizing BP neural network model.

The node numbers in the input layer are first considered, as the system is based on the sample data of the enterprise big data knowledge evaluation index, and the node numbers in the input layer is decided by the amount of features extracted through PCA transformation [20]. The number of nodes in the output layer is decided by the size of the network connection power, i.e. the number of input nodes, output nodes and implied nodes, for both "yes" and "no" judgments. A particle is randomly generated with a position at (0,1) and the dimension of the velocity vector. The starting position of the particle is assumed to be pbest, and the optimal value of pbest is gbest. For each particle, if the exactness requirement is satisfied or the full evolution has reached the max iteration number (set to 2000), the algorithm ends and the current optimal individual in the full population is recorded, otherwise return to step 5.

## IV. ANALYSIS OF THE EFFECT OF THE APPLICATION OF MACHINE LEARNING-BASED ENTERPRISE INNOVATION DEVELOPMENT ASSESSMENT MODEL IN THE BIG DATA ENVIRONMENT

The study carried out a PCA using Matlab software-based on the above model and its theory. The data used for the study was derived from references, using a PCA of the 14 main use assessment indicator factors to derive the contribution of each major component, as shown in Fig. 6.

Fig. 6. PCA contribution rate statistics chart.

As can be clearly seen from Fig. 6, the cumulative contribution of the 20 indices when the number of principal components is 12 is a cumulative 89.365%. This method reduces the input nodes of the neural network from 14 to 12 and simplifies the input indices, causing a significant reduction in the size of the neural network and its reduction of 30%.

Fig. 7. Colour temperature diagram for the analysis of various factors related to the development of corporate innovation.

From Fig.7, we can see that among the 12 enterprise knowledge management and research innovation assessment indicators, the correlation coefficients are mostly around 0.5, for example, the correlation coefficients of X2, X8 are 0.519 and 0.553 in order, which have higher correlation, indicating that the previous PCA is effective, and the factors with poor correlation have been eliminated. The factors with high correlation are used as input data matrices, which lays the foundation for the next action of introducing the PSO-BPNN model.

Fig. 8. Model training set accuracy curve and loss value curve.

The prediction error curves for the training samples are given in Fig. 8(b), with the number of training steps on the horizontal axis and the results of the errors on the vertical axis. Through 15 epochs of learning and training, the error results of the model proposed in the study were obtained close to 0. The other three lines in Fig. 8 are the model combining BP neural network and particle swarm algorithm, the model combining PCA method and BP neural network, and the model combining PCA method, particle swarm algorithm and BP neural network. Comparison shows that the PCA-PSO-BPNN has the highest training efficiency, reaching the target expectation after 15 steps. The training accuracy plots of the four models are given in Fig. 8(a), which clearly shows that the PCA-PSO-BPNN achieves 98% accuracy after 20 steps, which is significantly better than the other three models, so the model proposed in the study has good performance.

As can be seen in Table II, when the four algorithms were tested on the test and training sets, the RMSE values of the PCA-PSO-BPNN algorithm model for both the test and training sets were much lower than those of the other three algorithms, as can be seen from the enterprise R&D intensity dataset which has an RMSE value of 3.56 for the training set and 3.18 for the test set, and a value of 0.9982 for the R2 training set and 0.9915, which is higher than the other three algorithms. Meanwhile, from the data of corporate patent licensing, the RMSE values of the PCA-PSO-BPNN algorithm for the test set and training set are much lower than the other three algorithms, with 3.09 for the test set, 3.18 for the training set, 0.9451 for the R2 training set, and 0.9569 for the test set, which are also higher than the other three algorithm models. This shows that the PCA-PSO-BPNN algorithm model has better test results, higher test accuracy and more stable model.

The relative error histogram in Fig. 9 clearly displays that the absolute value of the relative error of each indicator does not exceed the 5% threshold, and only the relative errors of individual indicators have relatively large problems, such as X5 and X7 with the values of 4.5% and -3.8%. But the relative errors of the rest of indicators remain at correspondingly low levels. Better predictive capability for corporate innovation R&D and has excellent practicality. Finally, the study compared the training accuracy analysis of the PCA-PSO-BPNN algorithm with the conventional BP algorithm, PCA-BPNN and PSO-BPNN algorithms under different data set capacity sizes, and the results are shown in Fig. 10.

TABLE II. RMSE AND R2 FOR FOUR MODELS ON X1 AND X2 DATASETS

Datasets	Algorithm	Training		Testing	
		RMSE	R <sup>2</sup>	RMSE	R <sup>2</sup>
A <sub>1</sub>	BPNN	30.85	0.8545	32.11	0.8351
	PSO-BPNN	25.66	0.8965	26.78	0.8647
	PCA-BPNN	15.98	0.9014	16.85	0.8994
	PCA-PSO-BPNN	3.56	0.9982	3.18	0.9915
A <sub>2</sub>	BPNN	31.49	0.8214	30.98	0.8211
	PSO-BPNN	26.77	0.8851	27.54	0.8913
	PCA-BPNN	16.56	0.9052	16.99	0.9115
	PCA-PSO-BPNN	3.18	0.9451	3.09	0.9569

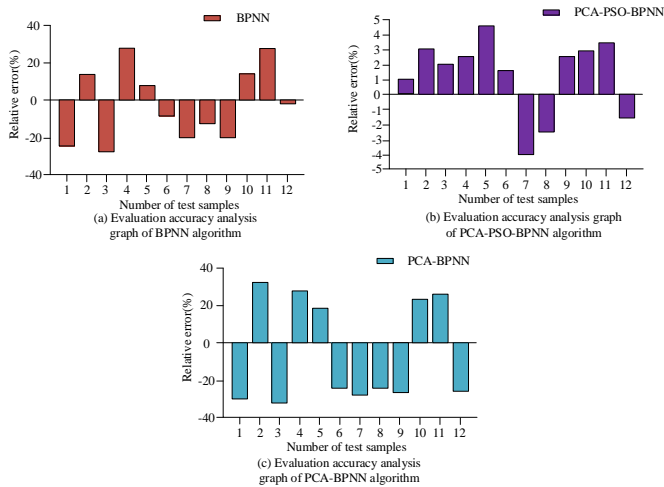

Fig. 9. Relative error in predicting corporate knowledge management and corporate innovation indicators based on the PCA-PSO-BPNN.

Fig. 10. Comparison of recognition accuracy of different algorithms trained on different datasets.

From Fig. 10, the study of the PCA-BPNN algorithm optimised by the PSO has the highest prediction accuracy among the four algorithms that conducted the experiment, and its average recognition rate can reach 94.21%; the recognition rate of the traditional BP algorithm model is slightly lower than that of the PCA-PSO-BPNN algorithm model, with an average recognition rate of 74.52%; the PSO-BPNN model The average recognition rate was 72.74%; the PCA-BPNN model had the lowest average recognition rate of 53.1%. The experimental results verify that the PCA-BPNN model optimised by the particle swarm algorithm is the best among the four models.

## V. CONCLUSION

With the development of Internet technology and big data technology, knowledge management has become one of the important factors for enterprise innovation and development. In this study, we first introduce the improved PSO-optimized BP neural network (PSO-BP) for evaluating the degree of the role of big data knowledge management in EnIn development, based on which PCA is conducted to reduce the dimensionality of the model and the weights of PSO-optimized BP neural network are used. The test results verified that the cumulative contribution value of the 14 indicators reached 89.365% cumulatively when the master-formation score was 12, which simplified the input indicators and made the neural network much smaller, and its reduction reached 30%. Secondly, the color temperature plot of Spearman rank correlation test shows that its correlation is high among 12 enterprise knowledge management and innovation evaluation indexes, which indicates that the previous PCA is effective, and the factors

with poor correlation are eliminated and entered into the established model as input data. It can be concluded that the model is effective with RMSE and R2 values of 3.56 and 0.9982 for the X1 training set and 3.18 and 0.9915 for the X2 test set, respectively. The results show that PSO-BP neural network can effectively reduce the dimensionality of the input indicators, simplify the neural network, and achieve a significant reduction in size. The high correlation between 12 corporate knowledge management and innovation assessment indicators indicates the importance of these factors in promoting corporate innovation. Although this study has achieved considerable results but there are still many problems, firstly, the study for enterprise big data knowledge management only evaluates enterprise innovation development without considering other factors and the feasibility of the algorithm will be considered subsequently for market conditions, regulatory environment and other factors. In addition, for this data study only one set of data was used for testing, and more data will be used to test the generality and accuracy of the algorithm in the follow-up.

# A Roadmap Towards Optimal Resource Allocation Approaches in the Internet of Things

Jiyin Zhou

College of Big Data, Chongqing Vocational College of Transportation Chongqing 402247, Chongqing, China

**Abstract**—Introducing new technologies has facilitated people's lives more than ever. As one of these emerging technologies, the Internet of Things (IoT) enables objects we handle daily to interact with each other or humans and exchange information through the Internet by being equipped with sensors and communication technologies. IoT turns the physical world into a virtual world where heterogeneous objects and devices can be interconnected and controlled. IoT-based networks face numerous challenges, including energy and sensor transmission limitations. New technologies are needed to spread the IoT platform, optimize costs, cover heterogeneous connections, reduce power consumption, and diminish delays. Users of IoT-based systems typically use services that are integrated into these networks. Service providers provide users with on-demand services. The interrelationship between this request and response must be managed in a way that is done using a resource allocation strategy. Therefore, resource allocation plays a major role in these systems and networks. The allocation of resources involves matters such as how much, where, and when available resources should be provided to the user economically. The allocation of resources in the IoT environment is also subject to various challenges, including maintaining the quality of service, achieving a predetermined level of service, storing power, controlling congestion, and reducing costs. As the IoT resource allocation problem is an NP-Hard one, many research efforts have been conducted on this topic, and various algorithms have been developed. This paper reviews published publications on IoT resource allocation, outlining the underlying principles, the latest developments, and current trends.

**Keywords**—Internet of things; resource utilization; resource allocation; systematic review

## I. INTRODUCTION

Over the last decade, the Internet of Things [1] has acquired popularity as a worldwide network, allowing physical objects to be controlled, monitored, and managed via the Internet and communication networks [2]. The integration of 5G connectivity [3], cloud computing [4], smart grids [5], and plasma sources [6] in IoT plays a vital role in enabling high-speed, scalable, reliable, and energy-efficient communication, storage, energy management, and advanced sensing capabilities, paving the way for a new era of interconnected devices and intelligent systems. Physical objects become smart by integrating radio frequency identification tags, sensors, actuators, etc. The most important characteristic of IoT objects is the ability to sense the surroundings, communicate, and interact with other objects. IoT devices operate on rechargeable batteries and non-renewable energy sources [7]. Whenever this equipment is deployed for permanent purposes, like ongoing environmental monitoring, it becomes imperative to extend the

life of the network. Wireless communication is the main source of energy consumption in IoT devices, which must operate over an extended time with limited resources [8]. The development of IoT devices requires both hardware and software to facilitate access at any place and at any time, and they also need to use the most efficient method for communication and resource allocation [9].

The optimum allocation of resources has always been of significant importance in improving the efficiency of the network. Resource allocation in IoT networks is challenging due to complex and large-scale communication between objects, heterogeneity, and the traditional characteristics of Wireless Sensor Networks (WANs) [10]. In addition, the IoT is not characterized by a uniform and fixed correlation. Therefore, in this environment, where the order and location of the nodes change regularly and quickly, resource allocation should be done in a distributed manner. Also, as mentioned above, owing to the limitations of energy sources, low power processors, limited memory capacity, wireless communication range, and communication bandwidth, the allocation of resources in this environment should bear lower overhead, reducing communication costs [11].

Two general aspects of resource allocation should be discussed and investigated to ensure high performance and create resource allocation strategies within an acceptable time frame. Several factors influence resource allocation, including cost, energy, response time, and security. The problem of reducing delay in resource allocation is also a critical and fundamental issue facing researchers in this research area [12]. The IoT has become an important and fundamental issue because of the connection of countless objects, the high volume of traffic, the storage of data and information, and the need for high-speed resources [13].

Machine learning and Artificial Intelligence (AI) have emerged as indispensable tools in the field of IoT resource allocation, revolutionizing the way resources are managed and utilized in complex and dynamic IoT ecosystems. The sheer volume and heterogeneity of IoT devices, coupled with the varying resource requirements and dynamic nature of IoT applications, pose significant challenges for efficient resource allocation. Machine learning algorithms, coupled with AI techniques, offer a powerful solution by leveraging data-driven insights and intelligent decision-making capabilities [14, 15]. One of the primary benefits of machine learning and AI in IoT resource allocation is their ability to analyze vast amounts of data collected from IoT devices and sensors. These technologies can extract meaningful patterns, detect anomalies, and predict resource demands with high accuracy. By

leveraging this data-driven intelligence, resource allocation algorithms can dynamically adapt and optimize resource allocation strategies based on real-time conditions and demands [16].

Moreover, machine learning algorithms can learn from historical resource allocation patterns and optimize resource utilization, leading to enhanced efficiency and cost-effectiveness [17]. These algorithms can identify resource bottlenecks, predict resource congestion, and dynamically allocate resources to alleviate these issues. By intelligently managing resource allocation, machine learning and AI techniques can improve system performance, reduce energy consumption, and enhance the overall quality of service in IoT networks [18, 19]. Furthermore, machine learning and AI can enable proactive resource allocation by considering contextual information, user preferences, and application requirements [20]. These technologies can learn from past user behavior and application performance to make intelligent predictions and allocate resources accordingly [21]. This personalized resource allocation approach can lead to enhanced user satisfaction, improved application performance, and efficient resource utilization.

This paper makes several significant contributions to the field of resource allocation in the IoT. First and foremost, it provides a comprehensive review of existing literature on IoT resource allocation, outlining the underlying principles, latest developments, and current trends. Furthermore, the paper analyzes the characteristics of datasets used in the evaluation of resource allocation algorithms. It considers factors such as the heterogeneity of IoT devices, data traffic patterns, and resource requirements. This analysis provides insights into how these dataset characteristics can impact the performance and suitability of resource allocation algorithms. It highlights the need for tailored approaches that consider the specific requirements of different types of data and IoT scenarios. The paper also conducts a detailed analysis of comparative results obtained from different datasets. It identifies patterns, trends, and discrepancies in algorithm performance, shedding light on the strengths and weaknesses of various resource allocation approaches. This analysis enhances our understanding of which algorithms may be better suited for specific types of data or IoT deployments.

The rest of the paper is organized as follows. Section II will provide a comprehensive background on the IoT and its significance in enabling objects to interact and exchange information through the Internet. It will highlight the challenges faced by IoT-based networks, particularly in terms of resource allocation, and emphasize the need for efficient resource utilization and allocation strategies. In Section III, we will conduct a systematic review of published publications on IoT resource allocation. We will discuss the underlying principles and concepts related to resource allocation in IoT systems. The review will encompass various algorithms, techniques, and methodologies proposed in the literature, highlighting their strengths, limitations, and applicability in different scenarios. We will analyze the latest developments and trends in resource allocation approaches, considering factors such as quality of service, power consumption, congestion control, and cost reduction. Section IV will provide

a comprehensive discussion and analysis of the reviewed resource allocation approaches. We will compare the different strategies, identify common challenges and emerging trends, and discuss their implications for future research and practical implementations. Additionally, we will address any gaps or limitations in the existing approaches and propose potential avenues for further exploration and improvement. Section 5 outlines V the potential research directions. The final section of the paper will summarize the key findings and contributions of the research.

## II. BACKGROUND

In this section, general information about IoT, resource allocation, and the challenges of resource allocation is given.

### A. Internet of Things

The rapid development of hardware and network technology has allowed a variety of smart devices to connect to the Internet and exchange data. This has led to the development of a new technology called the IoT [22]. IoT has evolved into a worldwide network of physical objects that can be controlled, monitored, and managed through the Internet and communication networks [23]. In IoT-based networks, physical objects are transformed into smart objects using radio frequency identification tags, sensors, actuators, and other components and then managed and controlled via mobile applications. With these capabilities embedded in the IoT, many applications have been developed, including home automation, industrial automation, the medical and healthcare industry, energy management, traffic management, and many more. By connecting physical objects, such as sensors, with the Internet, IoT technology can capture real-time data and then process and analyze it to create insights that can decide and take action. This makes it possible to automate various processes and create intelligent systems that can respond to events in real-time [24].

The IoT devices communicate with each other, share information, and take coordinated actions by sharing their vision, hearing, and thinking. IoT also faces challenges, such as technical difficulties, standardization, security, efficient resource utilization, and privacy concerns. With the significant growth of IoT resources in recent years, much data has been produced, which requires storage, processing, security, and management. To handle and manage such a large amount of data, it is necessary to use new technologies [25]. IoT-based networks and their nodes are challenging to manage due to the increase in data volume, the diversity of the nodes, and the requirement for resource allocation. Because countless objects in this network generate data in real time [26], IoT is characterized by the architecture shown in Fig. 1. Several factors have been considered and addressed in this architecture, including scalability, interoperability, reliability, and quality of service. This architecture is composed of five layers, which are described as follows.

- Perception layer: This layer, called the objects layer, represents the lowest layer of physical or hardware components. Data is collected at this layer and converted into signals that can be transmitted over networks and accessed by applications.

- Network layer: This layer facilitates the exchange of information between objects by connecting them. This layer ensures the secure transfer of information from sensor devices to the information processing system.
- Service management layer: This layer allows IoT programmers to work on heterogeneous devices regardless of their hardware configuration. Also, this layer handles the management of services, gathers data from the network layer, and archives it in the database.
- Application layer: This layer is typically responsible for providing services and applications that enable the integration and analysis of information received. This layer is crucial to providing high-quality intelligent IoT services.
- Business layer: This layer manages IoT services and activities and creates flowcharts, graphs, and business models based on the information derived from the application layer.

IoT capabilities are based on six key elements. These six key elements are essential for maximizing the potential of IoT technology.

- Identification: Identification is crucial in determining the IoT's purpose and providing services under customer demand. Identification can be accomplished using a variety of methods. An electronic product code is a permanent tagging technology containing a unique code for everything anywhere in the world.
- Sensing: Sensing in the IoT involves capturing data generated by sensors located on the network and forwarding it to a central repository, database, or the cloud. The collected data is processed to perform specific tasks in accordance with the requested services.

This data can identify patterns, anticipate future needs, and improve the efficiency of the IoT system.

- Connectivity: This technology enables heterogeneous objects to communicate with each other to provide intelligent services. IoT nodes should be capable of operating with limited power supplies and weak or noisy communication links. Bluetooth, IEEE 802.15.4, and Wi-Fi are common IoT communication protocols.
- Computing: The computing ability of the IoT is represented by the processing unit (for example, a microcontroller) and application software. A variety of software platforms provide IoT capabilities. For instance, Amazon Web Services (AWS) provides users with a range of tools for developing and deploying applications for the IoT, such as AWS Greengrass, AWS IoT Core, and AWS IoT Analytics.
- Services: IoT services are classified into four groups, namely ubiquitous, collaborative, information aggregation, and identity-related. Identity-related services provide valuable services that can be incorporated into other services. Aggregation services summarize or aggregate sensed data. Collaborative services use information obtained by information-gathering services to react and decide. Ubiquitous services make collaborative services available to anyone, anywhere, at any time.
- Semantics: to provide services, knowledge must be intelligently extracted from different devices. Knowledge extraction includes discovery, resource utilization, and information modeling. It involves identifying and analyzing data to provide accurate services.

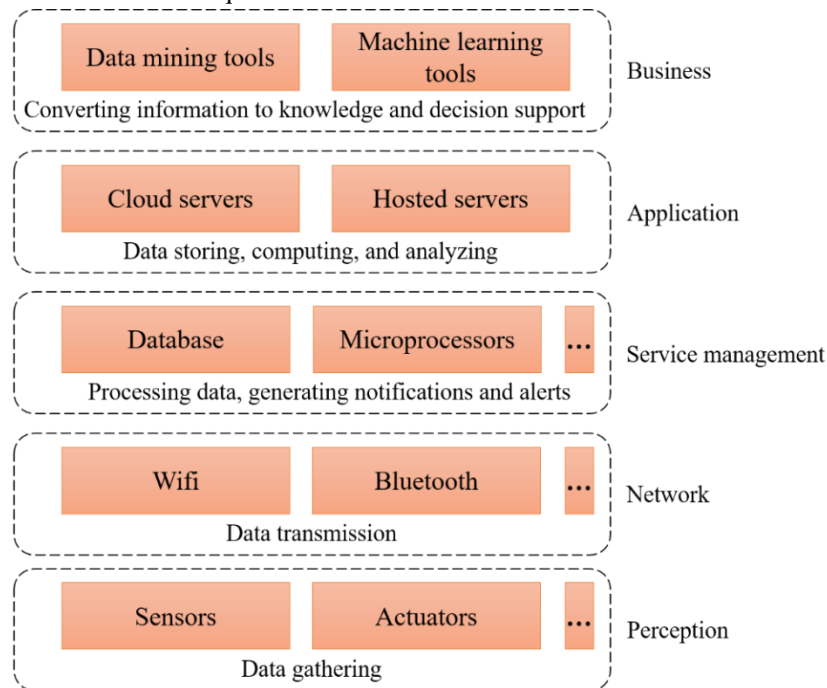

Fig. 1. IoT architecture.

## B. Resource Allocation

Resource allocation refers to allocating available resources to users efficiently regarding CPU, memory, network, bandwidth, etc. Also, resource allocation in IoT environments is subject to several challenges, including maintaining the quality of service, ensuring an agreed service level, conserving energy, handling congestion, and reducing costs. These challenges arise from the need to balance the conflicting objectives of allocating resources fairly and equitably to all users, while also optimizing the utilization of those resources. Resource allocation must consider that IoT environments are often characterized by heterogeneity, dynamism, and unpredictability [27]. Key considerations in allocating IoT resources are briefly stated in the following.

- **Heterogeneity:** The main idea of IoT is the widespread presence of objects in human life. Such an environment contains a wide range of different hardware and devices in diverse shapes and sizes. These devices can be very diverse. Computers, mobile phones, personal digital assistants, and wireless devices, such as radio frequency identification chips, have various communication ranges. Therefore, resource allocation should be conducted by considering the different computing capabilities of objects.
- **High adaptability:** IoT objects operate in unpredictable patterns and establish ad hoc connections with other nearby objects. Therefore, the movement of nodes cannot be ignored, and the network is expected to be highly dynamic. Centralized resource allocation is inappropriate in a dynamic structure, where nodes are moved around regularly and frequently. The resource allocation process must be flexible to respond to the dynamics of network connectivity.
- **Scalability:** Another challenge in IoT resource allocation is the need for interaction between thousands of devices at any time and place. As the network dimensions increase, creating a logical structure, such as a tree structure, becomes more challenging. It is also difficult to allocate and manage resources because of a lack of uniform coordination.
- **Energy awareness:** Energy consumption for communication and computing is a significant constraint for various IoT entities. Since IoT devices are powered by batteries for a long period, resource allocation should be done in a manner that minimizes energy consumption so that the network's energy status is used when allocating resources.
- **Load balancing:** The system load must be balanced for optimal resource utilization. During the resource allocation process, the workload, which includes energy consumption and communication activities, should be distributed throughout the network so that no part of the network runs out of resources more quickly than others.

## C. Mathematical Formulations of the Problem

It is first necessary to define the parameters, conditions, and characteristics of resources and tasks to explain the resource

allocation problem. Virtual Resources (VRs) are expressed as follows.

$$VR = \{CP_r, SR_r, SW_r, CO_r, ER_r\} \quad (1)$$

In Eq.1,  $CP_r$  refers to the number of computing resources,  $SR_r$  denotes the memory space,  $SW_r$  represents the set of software supported by VR,  $CO_r$  signifies the cost of VR per unit of time, and  $ER_r$  reflects the energy consumption of VR. Since certain tasks may require more than one machine, each task is divided into sub-tasks based on priority and execution order. Subtasks are defined as follows:

$$ST = \{CP_t, SR_t, SW_t\} \quad (2)$$

STs are measured in terms of three parameters: number of computing resources required ( $CP_t$ ), memory space required ( $SR_t$ ), and software type required ( $SW_t$ ). Therefore, the following tasks are included in each task.

$$T = \{ST_1, ST_2, \dots, ST_{nT}\} \quad (3)$$

In the above definition,  $nT$  indicates the number of sub-tasks related to task  $T$ . Assuming that there are  $N$  tasks and  $M$  VR nodes, the problem of assigning tasks to resources involves assigning all the sub-tasks of these  $N$  tasks to  $M$  VRs. Allocation is subject to several basic conditions as follows.

- **Software limitation:** Each task with its sub-tasks must be assigned to a machine that can execute the software requirements of the corresponding task.
- **The number of resources:** The number of resources required for the task with its sub-tasks should not exceed the number of VR resources to which the task is allocated.
- **Order and priority of execution of sub-tasks:** The order of execution of sub-tasks should be based on the sequence of its execution process, and all the sub-tasks of the sequence should be assigned to a VR for execution.
- **Time:** Tasks must be assigned to resources executed and completed within a specified time frame. The execution of all sub-tasks must start and end within the specified time interval.

## III. REVIEW OF RESOURCE ALLOCATION APPROACHES

In this section, previous methods in IoT resource allocation are examined in five different categories.

### A. QoS-aware Approaches

Two key factors in an IoT ecosystem are providing different service quality requirements and quick access to resources. These parameters represent resource distribution across different layers of the IoT environment, encompassing context awareness, performance, response time, and availability. Fog computing is one of the effective techniques to increase service quality, reduce network latency and energy consumption for IoT devices.

In [28], to minimize the network overhead, including delay and energy consumption, while meeting the quality of service requirements, a quality of service-aware resource allocation

approach is proposed that jointly communicates between fog nodes and IoT nodes. Transfer and allocation of computing resources are considered optimizing allocation decisions and minimize network overhead. First, an evaluation framework based on a hierarchical process is developed to prioritize the QoS parameters and different IoT tasks. Then, a resource block allocation algorithm is proposed to allocate resources to IoT devices based on device priority, satisfaction level, and resource quality. In addition, a QoS-aware bilateral matching game is introduced to optimize communication between cloud computing nodes and IoT devices. The simulation results show that the proposed method effectively ensures network load balance, improves resource utilization, and reduces network overhead.

New-generation networks have become increasingly important in the transfer of heterogeneous data streams. In fact, besides typical data and multimedia traffic, intelligent IoT applications create new types of traffic and interactions among millions of devices. This traffic creates a scalability issue, particularly regarding resource management and decision-making. The method presented in [29] aims to synthesize a flexible 5G radio frame by packing heterogeneous streams from multiple users into rectangular grids of time-frequency resources. The proposed approach includes the classification of flows based on quality of service, followed by the development of two offline databases.

In [30], a new QoS-aware resource allocation policy based on users' implicit feedback ratings is proposed for mobile edge computing for IoT to overcome service delays. The proposed method selects the user based on previous purchase preferences and implicit feedback from the cluster generated using similarity calculation. Using time-based collaborative filtering, resources are recommended for qualified users according to users' implicit feedback. The selected user receives the resource according to the minimum distance between the user and the resource. In [31], an effective algorithm is presented to solve the resource allocation problem in an IoT environment to minimize communication costs. A multi-layered resource allocation strategy is presented based on the meta-heuristic and data clustering paradigm for reducing latency in IoT applications. Several aspects of the proposed algorithm are discussed in depth, such as the coding of solutions for resource allocation, transitive operators, an objective function, and an analysis of the algorithm's time complexity.

In [32], a cellular-based frequency resource sharing (CFRM) approach is introduced for multi-cell device-to-device connectivity. Each cell consists of two zones, each with a different spectral source assigned to it to minimize interference between neighboring cells. The uplink resources of cellular users are shared between D2D users, thereby reducing the interference from device-to-device users to cellular users. The proposed design of the paper is a frequency multiplexer based on cross-cell FFR in D2D communication. It distributes different frequency resources to system users and cells in the local area while also investigating how well each cell can multiplex resources to a system that maximizes system/network performance. This paper provides the following key contributions: 1) In the cross-cell and FFR-based D2D communication context, an optimization scheme is

planned to optimize the network capacity, which supports the SINRs of cell users and devices, and the interference with cell users and devices in comments 2) A Cross-Cell Frequency Resource Sharing (CFRM) strategy for multi-cell D2D communications is developed to enhance network throughput and reduce interference with cell and system users.

### B. Context-aware Approaches

Context awareness in ICT refers to considering the state of entities, such as users or devices. Context-aware computing performs well in the IoT due to its importance in handling very large data sets. In [33], In 2, the optimization of channel selection is discussed, which is critical for reliable and efficient task delivery. The proposed approach's primary goal is to maximize the long-term throughput of energy and service reliability limitations. A combination of machine learning, matching theory, and Lyapunov optimization proposes a learning-based channel selection approach with conflict awareness, energy awareness, and service reliability awareness.

In [34], resource allocation for wireless IoT networks with short packet communications is discussed. A wireless IoT network with short packet communications is studied and investigated, where a hybrid access point first wirelessly supplies power to IoT devices. Then the devices transmit their short data, which has disadvantages: the destruction rate and packet error. To increase the efficiency and reliability of transmission, first, the efficiency values and the effective amount of information are defined as parameters to ensure a balance between transmission rate and packet error rate, and then the transmission time and packet error for each user is maximized so that the total throughput is Maximize or minimize the total transfer time that is effective for the user and this is achieved through the algorithms used in this paper.

In [35], the authors presented a method for allocating resources in edge computing for the IoT. Connecting objects to the Internet to make them intelligent is very important, but massive connectivity, big data processing, and significant energy consumption limit the use of the IoT. To address these challenges, a novel architecture for resource allocation at the edge is presented in this paper. Radio resource management and computing resource management in the IoT have also been evaluated in edge computing to improve system performance. The evaluation and review of the conducted studies show that the proposed resource allocation through this method can improve the system's efficiency and minimize the delay.

In [36], the authors have taken advantage of the satisfaction level of the quality of experiments (QoE) to obtain smart center-based services. The innovation of this paper is that it uses reinforcement learning (RL) to achieve superior accuracy in resource allocation. Two algorithms based on reinforcement learning are presented to obtain the cost of mapping tables and optimal resource allocation. The proposed method of the article is entitled "Smart Center-Centered Services for IoT (SCCS-IoT)," which uses an address and route-oriented architecture for communication. The term intelligent in the proposed model is intelligent operation capable of providing the most optimal solution using low-level or cost-effective computing resources. Furthermore, the proposed strategy focuses on two aspects. The first area of interest is the IoT resource allocation problem,

and the paper has proposed a new method that uses the RL mechanism to construct the resource allocation strategy. Implementing the RL mechanism is aimed at avoiding conflicts and intelligent resource allocation operations. As a second focus, QoE is considered when constructing RL value functions. A method that incorporates the quality of experience with learning power is being proposed. The cost of each type of task for a computing node comprises a state. The response given by the user determines the status value.

### C. SLA-aware Approaches

The heterogeneity and dynamic nature of IoT have made service-level agreements a key component of consumer-provider relationships. Ongoing monitoring of quality-of-service features shall be performed actively to provide this agreement. Furthermore, customers should consider several factors, such as trust (in the provider). In [1], a new mechanism for resource allocation considering buffering, scheduling, and rate limiting methods is proposed to address service level agreement problems.

In [37], the execution time constraint is considered the service level agreement constraint in the hybrid auction system. In the proposed approach, to optimally allocate resources and reduce costs, the winners in each tender round are determined according to the urgency of the tasks and based on the execution time deadline. To evaluate the performance of the suggested mechanism, the resource provider's profit and task completion success rate is compared to existing mechanisms using real workload data.

Collaboration between cloud computing and fog computing has proven extremely effective for resource allocation modeling and service delivery. The authors in [38] have developed a new approach for resource allocation to provide QoS requirements and service level agreement. This algorithm considers three parameters of completion time, service size and virtual machine capacity to manage user requests.

### D. Resource Utilization-aware Approaches

These approaches focus on the optimal use of IoT resources. Optimal resource utilization impacts profits and revenue in the IoT. For this purpose, usage-aware resource allocation methods are essential for reducing energy consumption, optimizing resources, and distributing resources fairly. In [39], a hierarchical architecture using a gateway connects IoT devices to eNB to use network resources optimally, and a multi-class resource allocation algorithm is presented for LTE-based IoT communications. The simulation outcomes indicate that the proposed algorithm performs well regarding latency and data rate.

Software-oriented networks are a promising technology for simplifying network management due to the provision of reconfigurable network elements; therefore, integrating this approach and the IoT provides a potentially practical solution to enhance the management and control capabilities of the IoT network. By using software-based networking technology, resource efficiency in the IoT network can be further improved. In [40], the authors have proposed a new architecture for allocating IoT resources based on software-oriented networks. In this article, the resource allocation

problem is planned as a Markov decision process, and the optimal solution is obtained using the relative value iteration algorithm.

In [41], a new solution to the resource allocation problem by adopting cooperative game values is presented. In the proposed game model, the concept of Shapley value is developed and used to design a bandwidth allocation algorithm. The results demonstrate that the proposed approach enhances the optimal use of network resources while ensuring performance balance compared to previous methods.

In [42], the fifth-generation mobile communication system is mentioned as an important factor in increasing the importance, value, and increasing use of the Internet of Things, which requires high speed in data transmission, permanent and uninterrupted connection, and very low delay. Therefore, to achieve these requests, this paper presents a new biologically inspired resource allocation method for network slices in the 5th generation IoT with activation capability. Personal service allocation and users' evolutionary interest relationships are used to model the dynamic and complex network, and a biological allocation strategy inspired by nature is used, which is continuously updated. By observing the proposed results, the evidence shows that the proposed method has improved efficiency and flexibility in resource allocation.

### E. Energy-aware Approaches

Energy consumption and heat production in data centers are important factors in dealing with challenges related to energy consumption-aware resource allocation techniques. The primary cause of energy consumption and unnecessary heat generation is the increase in the number of servers, rapid data center growth, power loss, high load, and high demand.

Integrating mobile edge computing and IoT enables IoT devices with limited computational and energy capabilities to offload their latency-sensitive computing tasks to the edge of the network, providing quality services to the devices. In [43], a non-orthogonal multiple access technique is used to enable widespread connectivity, and how to use this technique to achieve efficient mobile edge computing in IoT networks is investigated. To maximize the energy efficiency for loading and the maximum tolerable delay limits of IoT devices, the radio and computing resource allocation problem is formulated in which intra- and extra-cellular interferences are considered.

In [44], a 5G-based communication framework supports the physical-cyber deployment of the IoT in a centrally controlled manner. Based on this structure, several actuators and sensors can communicate with the central controller in a two-way fashion. The resource allocation problem is formulated as an exact non-convex programming problem aiming to maximize energy consumption within the available channel band.

Cognitive radio can reduce the spectrum scarcity issue of IoT applications, and wireless energy harvesting eliminates the need for battery charging or replacement for IoT and cognitive radio networks. For this purpose, in [45], the authors have used wireless energy harvesting for cognitive radio, where cognitive radio devices cannot only cooperatively detect available radio frequencies but also collect the wireless energy transmitted by an access point. An optimization framework is proposed to

strike a balance between the energy efficiency and spectral efficiency of the network.

In [46], an energy-aware and network density-aware approach to address the resource allocation problem in IoT networks based on hybrid optimization strategies is presented. This paper uses data clustering and meta-heuristic algorithms to reduce congestion between IoT devices and gateways. Furthermore, this paper contributes to the path discovery mechanism by proposing a queue-based collective intelligence optimization algorithm that selects the optimal path for the future path based on multiple constraints.

#### IV. DISCUSSION

The processing of an application generates a workload on the IoT system. The workload refers to the number of resources required to complete the tasks required by the program. Workload includes the amount of bandwidth and measurement devices consumed by the program and the amount of memory and processing power consumed. In the previous section, the existing methods for the resource allocation problem in the IoT were examined in 5 categories: service quality-aware, context-aware, service-level agreement-aware, resource-use optimization-aware, and energy-aware approaches. In this section, the main features of the approaches are studied, and the important factors that have been improved in the mechanisms are briefly shown in Table I. Increasing the performance of IoT resource allocation is one of the most important goals in the reviewed articles. In addition, the increase in service quality and its use has been examined in some studies. The reduction of energy and time consumption has been investigated in these articles. Optimizing resource allocation approaches can be obtained by guaranteeing availability and reliability and reducing the failure rate in the IoT ecosystem. The objective functions presented in the reviewed works can be stated as follows:

- Reducing the cost of the network: due to the existence of a large volume of services, users, information, and resources in networks based on the Internet of Things, the cost of creating this type of network has become a fundamental challenge; therefore, minimizing network cost is one of the important functions in IoT-based networks.
- Reducing the number of base stations: with the increase in the number of base stations, the consumption cost of the entire network will increase; therefore, adopting the efficient number of base stations is one of the other objective functions.
- Improving network lifespan: In these models, improving network lifespan is achieved by reducing energy consumption and increasing the lifespan of IoT devices.
- Increasing network coverage: In this model, the area covered by base stations increases.
- Increasing the network output: By maximizing the total transmission rate by the base stations, the output, which is one of the most basic parameters of the network, increases.
- Reducing the total mobile power consumption of base stations: if mobile base stations are used, the lifespan of these stations is improved by minimizing their mobile power consumption.
- Reducing the number of stopping points of base stations: in the models that use mobile base stations, telecommunication communication is considered only if the stations are stationary to reduce the complexity. As the number of static points increases, the delay in the network increases.

According to the previously reviewed articles and works, in most of the presented articles, two types of nodes are studied in the proposed system model for resource allocation in the Internet of Things. The first type of these nodes are resource nodes that provide appropriate services. The second node is the gateways that are connected to the resources. Gateways connect different parts of the IoT system. Each gateway is responsible for controlling the path of several resources. Resources can be connected to different gateways. The communication cost between a gateway and all resources is predetermined. One aspect of this problem is that the resources are distributed among the gateways to create the lowest communication cost. Cost between gateways is also an important part of the total cost, so another aspect of this issue is how the gateways are connected.

Due to the high communication cost between gateways, each solution to the problem connects the gateways with the least number of connections. This connection can be linear or loop. Fig. 2 shows an example of connecting resources and gateways. The communication cost is also different with the change in the communication model. One of the goals of the problem is to find a model for resource allocation with the lowest communication cost. This figure can be considered as an outline of the proposed system model. Of course, parts of this system can be slightly changed depending on the designed scenario.

According to Fig. 2, the considered environment includes IoT resources, gateways, and connections between them. These components are deployed in the environment to respond to users' needs and create integrated services. A composite service includes instances of a service formed by establishing connections between IoT resources to provide capabilities and respond to users' needs. Data must be exchanged between IoT resources to create a suitable hybrid service and perform interaction between services.

A service gateway is a computing node that provides computing capabilities to implement service instances and communication capabilities to enhance IoT resources. Each gateway has a resource-binding capacity that can limit the number of IoT resources allocated to the gateway. IoT resources assigned to different gateways can communicate with each other through gateway connections. Possible connections between gateways are determined when they are deployed. Although not all gateways are directly connected to each other, all gateways must be reachable from any other gateway in the IoT environment. Each resource must be assigned a gateway to pass data to other resources to create a hybrid service. The

connection between a source and a gateway creates this allocation. Each resource has a list of connectable gateways, and the number of connectable gateways varies by resource type. Connections between gateways should also be specified. Gateways can be connected directly or indirectly through other

gateways. Each gateway can directly connect with other gateways within the range of connection capacity. To overcome the limitation of connection capacity, redundancy or ring connections between gateways should be avoided, and connections between gateways should form a tree structure.

TABLE I. A SIDE-BY-SIDE COMPARISON OF IOT RESOURCE ALLOCATION APPROACHES

Category	Reference	Service quality	Delay	Energy consumption	Reliability	Availability	Overhead	Scalability
QoS-aware	[28]	↑	↓	↓			↓

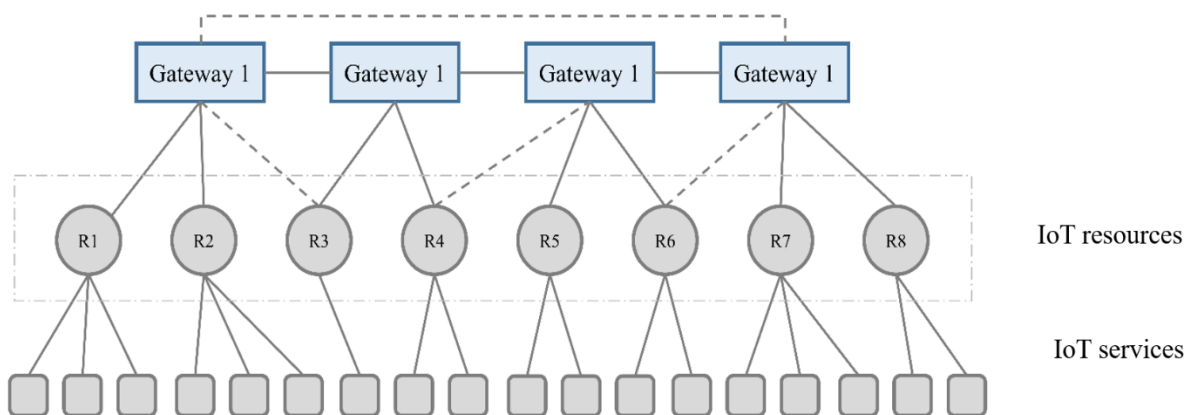

Fig. 2. Resource allocation model.

In the evaluation of the existing resource allocation approaches, it is essential to consider their limitations and

assess their suitability for addressing the resource allocation problem in the IoT. While many of the reviewed methods have

shown promising results, certain limitations need to be acknowledged. One common limitation is the assumption of homogeneous IoT devices in some approaches, which may not accurately reflect the real-world scenarios where devices exhibit varying capabilities and resource requirements. This limitation can impact the performance and effectiveness of resource allocation algorithms in heterogeneous IoT environments. Another limitation is the neglect of dynamic data traffic patterns in certain methods. The resource allocation algorithms that do not consider the varying data traffic characteristics may not be optimal in scenarios where the data flow changes dynamically, leading to suboptimal resource utilization and potential congestion issues.

Furthermore, some existing methods may lack scalability and fail to handle the increasing number of IoT devices and the growing complexity of IoT deployments. As the IoT ecosystem continues to expand, resource allocation approaches should be capable of accommodating the larger scale and diverse requirements of IoT networks. Additionally, the trade-off between energy consumption and service quality is a critical aspect that needs to be addressed. Some methods may prioritize energy efficiency at the cost of compromising service quality, while others may focus more on providing high-quality services but consume excessive energy. Striking a balance between energy conservation and maintaining satisfactory service quality remains a challenge in resource allocation.

## V. FUTURE RESEARCH DIRECTIONS

Future research directions in IoT resource allocation can focus on several key areas to address emerging challenges and further enhance the efficiency and effectiveness of resource allocation strategies. Some potential research directions include:

- **Dynamic resource allocation:** Develop adaptive resource allocation algorithms that can dynamically adjust resource allocation based on changing network conditions, varying demands, and evolving IoT environments. This can improve resource utilization and optimize the allocation of resources in real-time.
- **Energy-efficient resource allocation:** Design energy-aware resource allocation techniques that consider the limited energy resources of IoT devices. Explore energy-efficient algorithms that minimize energy consumption while maintaining desired levels of service quality and network performance.
- **Security-aware resource allocation:** Investigate resource allocation approaches that integrate security considerations into the allocation process. Develop mechanisms to allocate resources in a way that ensures data privacy, confidentiality, and integrity within the IoT ecosystem.
- **Multi-objective optimization:** Explore multi-objective optimization techniques that consider multiple performance metrics simultaneously, such as energy consumption, network latency, resource utilization, and quality of service. Develop resource allocation algorithms that strike a balance between conflicting

objectives to achieve optimal resource allocation outcomes.

- **Edge and fog computing:** Investigate resource allocation strategies that leverage edge and fog computing capabilities to enhance the efficiency of IoT systems. Explore how resources can be allocated across edge devices and fog nodes to minimize latency, improve response times, and optimize overall system performance.
- **Machine learning and AI-based approaches:** Explore the use of machine learning and artificial intelligence techniques to optimize resource allocation in IoT networks. Develop intelligent algorithms that can learn from historical data, predict resource demands, and dynamically allocate resources based on real-time conditions.
- **Scalability and heterogeneity:** Address the challenges of resource allocation in large-scale IoT deployments with heterogeneous devices and varying resource requirements. Develop scalable and adaptive resource allocation algorithms that can handle the complexities of diverse IoT environments.

## VI. CONCLUSION

The IoT provides an environment in which physical and digital devices, equipped with identification, processing, diagnosis, and network functions, can communicate through the Internet to achieve a specific goal. In fact, the IoT turns everyday devices into a diverse set of smart objects in order to realize useful applications such as traffic management, energy management, education, finance, and smart transportation. Generally, in IoT-based systems, IoT users use the services available in these types of networks. Service providers offer services on demand to users. Resource allocation strategy as an effective method is used to manage requests and responses. In line with the allocation of resources in the IoT environment, this article presented a background of the IoT and the resource allocation issue. Then the available methods were divided into five categories and examined. Finally, a proposed model for the allocation of IoT resources was presented. The IoT network is often used as a special purpose network according to the application that the network has; therefore, in this network, some nodes (network resources) have a high priority according to the type of data they produce, and therefore these resources should have a high priority in network activities, including resource allocation.

In most of the methods used for resource allocation, all network nodes and their resources are considered with the same priority. This causes network power, network delay, and network resources to be used in a non-optimal way in these networks. Resources with high priority are considered the same as resources with low priority, and optimal resource allocation is not done. Therefore, in the IoT network, for the users of this network to have optimal access to the network resources and to somehow allocate the resources according to the wishes and expectations of the network users and the network requirements, it is better to use the network and also prioritizes the data that the network nodes produce and sent and processed

to be determined. For example, in networks used for real-time applications, a series of resources are more important than other network resources in terms of time and delay, so an optimal allocation should be made for these types of resources.

# Social Media Mining to Detect Online Violent Extremism using Machine Learning Techniques

Shynar Mussiraliyeva, Kalamkas Bagitova, Daniyar Sultan  
Al-Farabi Kazakh National University, Almaty, Kazakhstan

**Abstract**—In this paper, we explore the challenging domain of detecting online extremism in user-generated content on social media platforms, leveraging the power of Machine Learning (ML). We employ six distinct ML and present a comparative analysis of their performance. Recognizing the diverse and complex nature of social media content, we probe how ML can discern extremist sentiments hidden in the vast sea of digital communication. Our study is unique, situated at the intersection of linguistics, computer science, and sociology, shedding light on how coded language and intricate networks of online communication contribute to the propagation of extremist ideologies. The goal is twofold: not only to perfect detection strategies, but also to increase our understanding of how extremism proliferates in digital spaces. We argue that equipping machine learning algorithms with the ability to analyze online content with high accuracy is crucial in the ongoing fight against digital extremism. In conclusion, our findings offer a new perspective on online extremism detection and contribute to the broader discourse on the responsible use of ML in society.

**Keywords**—NLP; machine learning; social networks; extremism detection; textual contents

## I. INTRODUCTION

In the burgeoning digital age, the ubiquity of social media as the world increasingly navigates towards digitization, the rise of social media and the vast landscape of user-generated content it produces have opened up new vistas of communication and social interaction [1]. However, this digital evolution has also given rise to formidable challenges, one of the most pressing being the proliferation of online extremism. The cloak of anonymity provided by the internet, along with the unprecedented reach of social media, has exacerbated the spread of extremist ideologies, thereby necessitating effective detection mechanisms. This paper is dedicated to exploring the application of Machine Learning (ML) techniques for the detection of online extremism on social media platforms [2].

The cornerstone of our study revolves around the deployment of six specific Machine Learning algorithms. The comparative analysis of these methodologies forms a significant part of our research, enabling us to discern the relative strengths and weaknesses of each in the context of online extremism detection.

The nature of online extremism is as complex as it is harmful [3]. To address it effectively, we need to delve into the intricacies of online communication patterns, exploring how coded language and digital interaction networks serve as conduits for the spread of extremist ideologies [4]. In this context, our study is not merely a technical exploration of

machine learning techniques but also a sociolinguistic inquiry into the nature of online extremism itself [5].

Machine Learning has an ability to sift through vast datasets and identify patterns that may be invisible to the human eye [6]. By training ML algorithms to recognize and flag extremist sentiments, we aim to create an effective line of defense against the spread of dangerous ideologies.

However, the application of Machine Learning in such a sensitive domain also raises ethical considerations. With the power to scrutinize digital communication comes a responsibility to use it wisely and fairly. Therefore, we also dedicate a portion of our research to discussing ethical considerations surrounding the use of ML for online extremism detection.

In essence, our exploration is multifaceted, combining a technical examination of Machine Learning methodologies with an investigation into the sociolinguistic phenomena that characterize online extremism [7]. We conclude with a discussion on the ethical implications of applying these techniques, thereby providing a holistic view of the challenge at hand.

In this paper, we investigate the challenge of identifying extremist views and appeals for violence on social media platforms. More specifically, our emphasis is on comprehending and identifying extremist ideas in the information posted by online users. In order to comprehend the appeals made by extremist groups through a data extraction point of view, we first undertake an in-depth study of the material, including vocabulary and subject descriptors [8]. In order to detect extremist views included in the data, six distinct sets of relevant traits were uncovered, and multiple training methods were evaluated against one another. This is an original use for the automated identification of violent extremism in material, and it uses a mix of the efficient attribute architecture and classifiers that we have provided.

The following are some of the ways in which this paper significantly contributes to the body of knowledge and pioneers new ground in the field:

1) The use of information extraction as well as knowledge mining to identify the distinctive characteristics of violent extremism and appeals to conduct violent actions that are included in the material created by internet users. This technique exposes details regarding extremist ideologies through the lens of data analytics.

2) Corpus: this paper introduces the social network and compiles a fresh collection of information for the purpose of identifying extremist communications and appeals to extremism [22], which is now the most widespread social network among young people in Kazakhstan [9]. Psychologists divide the dataset into two groups based on whether or not it contains extremist statements or appeals to violence. The dataset was acquired from a social network that is extensively utilized in the republics of the Commonwealth of Independent States (CIS).

3) Applying machine learning: There, we applied six machine learning algorithms to violent extremism detection problem. The results are given using different evaluation parameters of machine learning methods.

This paper provides an in-depth analysis of the use of ML in online extremism detection, offering insights into both the technical and ethical aspects of this issue. Our findings contribute to the broader conversation on online safety, the responsible use of AI, and the role of digital platforms in our society. This research underlines the necessity of a multidisciplinary approach to address the escalating issue of online extremism and exemplifies the crucial role of machine learning in curbing this growing menace. Our paper contributes to the broader discourse on online safety, the responsible use of artificial intelligence technologies, and the role of digital platforms in maintaining the fabric of our social structure. Through our research, we strive to shed light on how a multidisciplinary approach can effectively address the escalating issue of online extremism and underline the pivotal role of Machine Learning in combating this digital menace.

## II. RELATED WORKS

Machine learning models are used in different applied tasks as smart city and smart energy [10], security-related problems [11], and text processing [12]. The issue of detecting and mitigating online extremism has evolved over time, calling for more sophisticated, adaptable, and scalable solutions. This review delves into the transition from traditional methodologies to machine learning (ML) techniques and offers a comparative analysis of these two broad categories.

### A. Conventional Methods for Online Extremism Detection

The initial responses to online extremism have largely been traditional in nature, utilizing manual review processes and rule-based algorithms [13]. These methods involve human moderators, who, based on their interpretation of the content, decide on its appropriateness or otherwise. Similarly, rule-based algorithms operate by matching specific patterns, keywords, or blacklisting certain types of content or users known to promote extremist views [14].

While these traditional methods have proven effective to some extent, they are not without significant limitations. The major constraint is the issue of scalability, given the exponential growth of user-generated content on social media [15]. Manual review processes are inherently time-consuming and labor-intensive, making them less practical for large scale operations [16]. Rule-based algorithms, despite being automated, are often rigid, unable to adapt to the evolving

nuances of online extremism [17]. Furthermore, both methods carry the risk of inherent bias due to the subjective nature of interpretation, which can lead to both over-censorship and under-censorship.

Traditional methods of addressing online extremism have relied predominantly on manual and rule-based approaches [18]. While these methods have provided a starting point, they grapple with issues related to scalability, adaptability, and inherent bias. As user-generated content has grown exponentially, the limitations of these methods, in terms of time, resources, and subjectivity, have become increasingly pronounced [19].

### B. Machine Learning Methods for Online Extremism Detection

To overcome these limitations, researchers have turned to ML techniques that can handle vast amounts of data and adapt to evolving online communication patterns. These techniques rely heavily on feature extraction methods, which transform raw text data into a structured format that ML algorithms can understand and analyze.

The limitations of traditional methods have driven the exploration of more advanced solutions, leading to the adoption of Machine Learning (ML) techniques. These methods offer key advantages including scalability, accuracy, adaptability, and the potential for real-time detection [20]. This study focuses on six ML algorithms: Support Vector Machine (SVM), Decision Tree, Random Forest, K Nearest Neighbors (KNN), Naive Bayes, and Logistic Regression. Each algorithm exhibits unique strengths and weaknesses, offering a versatile toolkit for addressing the multifaceted challenge of online extremism detection [21].

A critical component of ML success in detecting extremist content lies in feature extraction, where raw data is transformed into a format that these algorithms can utilize. Techniques such as Term Frequency-Inverse Document Frequency (tf-idf) [22], Bag of Words (BoW) [23], and Word2Vec have been commonly employed for this purpose [24]. Tf-idf emphasizes the importance of words in a document, BoW assesses the frequency of words independent of the order or grammar, and Word2Vec encapsulates semantic relationships between words, by mapping them as vectors in a multidimensional space.

In a seminal work, authors employed the tf-idf method in text categorization, highlighting its effectiveness in weighing the importance of words within a given document [25]. By measuring the frequency of a term adjusted by its rarity in the entire corpus, tf-idf helps identify key terms that might indicate extremist content.

The BoW method, despite its simplicity, has been extensively used due to its effectiveness and interpretability. In this approach, text is reduced to a 'bag' of its words, disregarding grammar and word order but preserving frequency. Researchers have shown how BoW can be powerful when combined with ML techniques, particularly in topic modeling [26].

Part of Speech (PoS) tagging has also been used to improve the performance of ML algorithms in detecting extremist

content. Next study demonstrated that PoS features, when used in conjunction with SVM, significantly improved the detection of hate speech [27].

Word2Vec, goes beyond simple frequency-based methods and captures the context and semantic relationships between words [28]. By representing words as vectors in a high-dimensional space, it enables the detection of patterns and associations that can be indicative of extremist ideologies.

.When comparing traditional methods with ML techniques, it's evident that each offers distinct advantages. Traditional methods are relatively straightforward to implement and their outputs are easily interpretable. However, their scalability issues and inability to evolve with the changing landscape of online extremism significantly limit their efficacy.

Conversely, ML methods present greater adaptability and scalability. Their ability to learn from data patterns, adapt to new information, and handle extensive and diverse content make them a promising solution for online extremism detection. However, the complexity of ML models can pose challenges, specifically in interpretability and transparency [29]. Additionally, the effectiveness of ML methods is inherently tied to the quality of input data and the relevance of the features extracted.

In conclusion, despite the efficacy of traditional methods in certain contexts, ML techniques appear to be a more potent solution for detecting online extremism on a large scale. However, careful consideration must be given to ethical

implications, such as potential privacy infringements and biases, as we harness the power of these advanced technologies in our quest to maintain safe and respectful online environments.

### III. DATASET

We first wanted to establish the hazard criterion before we could decide if a text was connected to extremism or not. Putting together a list of phrases is one such method. For the purpose of defining the term, a collection of key terms was compiled and used to conduct an investigation into the data contained inside the social networking site [30]. The software program deduces that the text should be further investigated because it contains the stated keywords, and this conclusion is based on the fact that these keywords are present in the content. The whole data collection, an analysis of the postings, and a categorization of the texts are shown in Fig. 1.

The achievement of data collecting might be carried out differently depending on the source of information, but the fundamental idea of its framework should be maintained throughout. The component of the program that is required for the extraction knowledge from publicly accessible sources has as its primary objective the successful completion of tasks in a timely and efficient manner. It is vital to make advantage of the built-in techniques for receiving data from sources (API) in order to achieve a high level of effectiveness [31]. In the event that such techniques are not available, it will be essential to collect the relevant data via making HTTP queries.

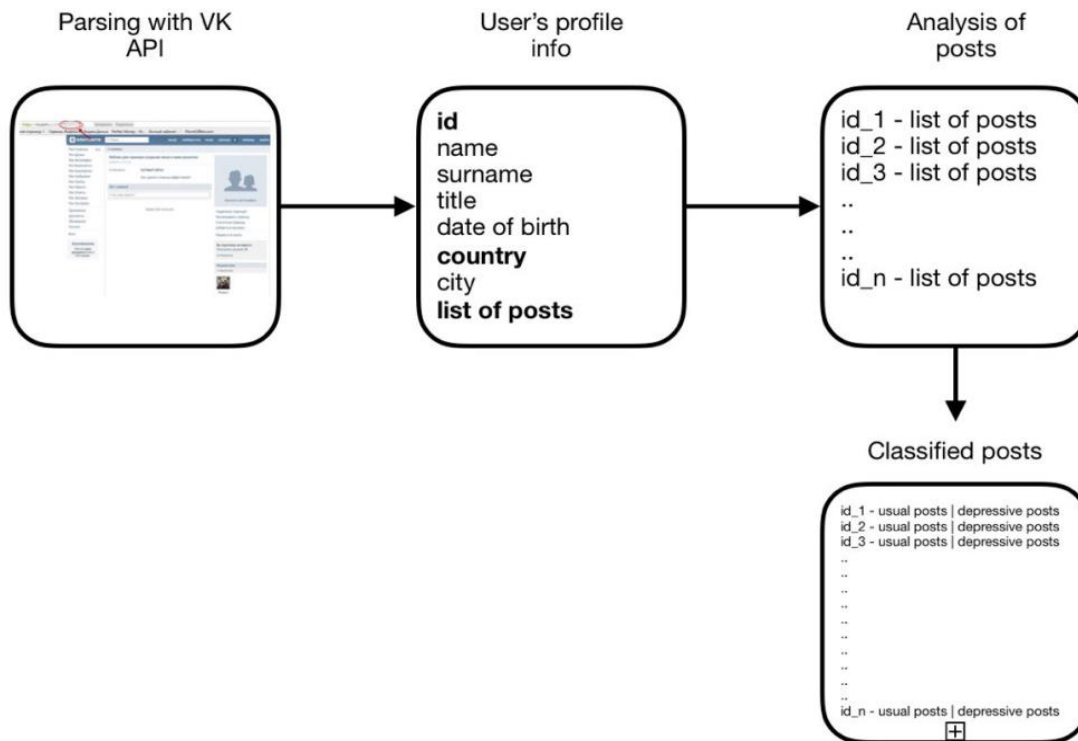

Fig. 1. Architecture of the data collection unit.

The application is comprised of three separate components as data collection unit, keyword scan unit, and machine learning unit which are as follows:

1) The Data Collection Unit is in charge of gathering data from publicly available channels and sending it on for further processing; In order to process the data coming from the VKontakte social network, an application written in Python programming language has been created. We partly parsed open access profiles using the publicly available VK API [32], which we accessed.

2) The Keyword scan unit is liable for detecting keywords in a vast quantity of data; because we had earlier a list of keywords that are often discovered in communications connected to violent extremism, we used a linear search for terms in each written content, and then partitioned the text into tokens. Specialists were consulted and had a role in the development of keywords that may be utilized when searching for potentially harmful content;

3) The determination of whether or not the data is connected to violent extremism falls within the purview of the textual content classification module. In this stage, we apply different machine learning algorithms for online extremism detection problem.

Data collection unit is the initial stage of the proposed framework. For the purpose of data collection, we make use of the VKontakte social network. For the purpose of data collecting, a parser is developed in Python version 3.6. The query was used in order to interact with the application

programming interface (API) of the social networking site. It was decided that the program package Pycharm will serve as an experimental platform.

#### IV. MATERIALS AND METHODS

##### A. Feature Engineering

It is vital to specify the criterion of "hazard" before assigning the material to being associated to violent extremism in any way. Defining a list of keywords is one possible solution to the problem. The produced application made use of this strategy for identifying the different kinds of information that may be found. For the purpose of defining the term, a list of keywords was developed, and those keywords were utilized to conduct an analysis of the material contained inside the social network VKontakte. The conclusion reached by the software application about the text's suitability for more investigation is based on whether or not the text contains the keywords that were provided. In our research, we used statistics, POS features, features based on LIWC features, and features based on TF-IDF word frequency.

In order to get an understanding of the informativeness of these feature sets, we use principal component analysis (PCA) [33] in Fig. 2 to create a visual representation of the features on the gathered corpus in a two-dimensional space. When we look at Fig. 2, we can see the polarity and subjectivity of the explored dataset to detect violent extremism. This suggests that our classifier should have an easier time distinguishing between the two categories.

Fig. 2. Extracted features.

1) *Classification Models:* Messages relating to extremism that are found within the content of social networks may be detected using the normal supervised learning based classification problem. We created classifiers to train data couples of input objects  $\{x_i, y_i\}_i^n$  and supervisory signals

$\{x_i\}_i^n$  [34], taking into consideration a corpus that consisted of texts with tags  $\{y_i\}_i^n$ .

$$Y_i = F(x_i) \quad (1)$$

If  $y_i=1$  indicates that the text in question is "extremist intended text," then  $y_i=0$  indicates that the text in question is "not extremist intended text." The goal of training phase of the classification is to reduce the amount of incorrect classifications made in the data used for training. The inaccuracy in the prediction is going to be presented in the form of a loss function called  $L(y, F(x))$ , where  $y$  will represent the actual label and  $F(x)$  will represent the anticipated label. In broad strokes, the purpose of training is to arrive at the best possible prediction model  $F(x)$  by finding solutions to the following optimization problems:

$$\hat{F} = \arg \min_F E_{x,y} [L(y, F(x))] \quad (2)$$

The categorization of extremism-related writings is shown in Fig. 3, which illustrates the schema. The methods of oversampling and undersampling, in addition to statistics, LIWC, POS, and TF-IDF, are included in the features. These approaches are used to manage unbalanced data. The machine learning models were given access to all of the retrieved characteristics.

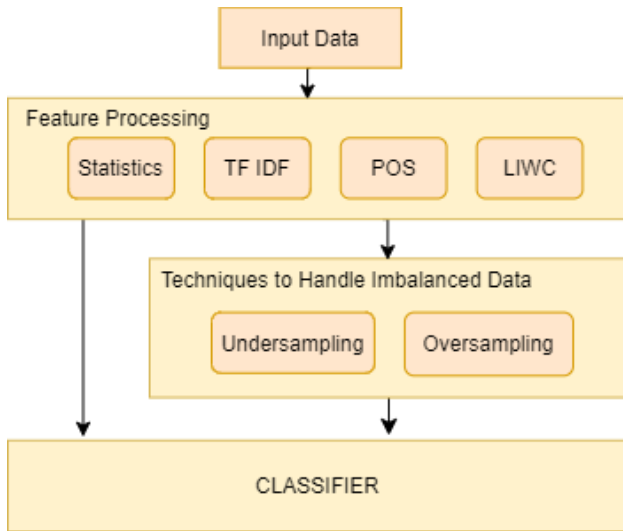

Fig. 3. Architecture of the proposed framework.

Our primary objective is to detect and isolate any content within the chosen dataset that exhibits ties to violent extremism, sourced from any participating users. The initiation of our text classification process involves engaging with the entirety of the domain, which consists of multidimensional objects procured from the dataset under scrutiny.

Our fundamental feature extraction mechanisms stem from a diverse array of methodologies, namely, possibilities offered by N-gram [34], Linguistic Inquiry and Word Count (LIWC) category functions [35], the Latent Dirichlet Allocation (LDA) model [36], and an assortment of their combinational elements. These characteristic traits, constituting the foundation of our analytical tools, are solely derived from the training data that we have meticulously collated.

This holistic approach facilitates a comprehensive understanding of the data, subsequently enabling the successful identification of any material that may be associated with

violent extremism. It is through the deployment of these robust methods and their respective combinatory factors that we are able to achieve our mission in an effective and efficient manner.

The confusion matrix is an instrumental method for collating an encapsulated summary of the results stemming from a classification process. Relying on accuracy as a solitary metric can potentially lead to misleading interpretations, particularly in scenarios where the volume of observations in individual classes is imbalanced. This tool offers a comprehensive insight into our methodology's effectiveness in discerning correct classifications from erroneous ones, and its proficiency in successfully obtaining correct outcomes.

It becomes manifestly clear through the confusion matrix that correct classification occurrences for classes with low extremity are fewer, which is predominantly responsible for their dismal accuracy and recall rates. This phenomenon underlines the importance of considering multiple performance metrics beyond mere accuracy, especially when dealing with data that is inherently imbalanced. It underscores the necessity to implement more nuanced approaches that can accurately reflect the capabilities of the classification model in diverse scenarios, thereby contributing to a more informed interpretation of its performance.

Accuracy is sometimes referred to as positive predictive value, while precision is the ability to remember information. This is the fraction of comparable examples that were retrieved from the total number of instances. The sensitivity is measured by the recall, which is the percentage of the total number of appropriate cases that is equal to the number of relevant examples that have been retrieved. When it comes to classification, accuracy is determined by dividing the number of true positives (TP) by the total number of labeled members (TP + FP) that belong to this class. It is important to keep in mind that the total number of true positives (TP) in classification is split into the number of instances that do in fact belong to the class (TP+FN), so, in this research we used accuracy [37], precision [38], recall, and F1-score [39].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP} \quad (3)$$

$$precision = \frac{TP}{TP + FP} \quad (4)$$

$$recall = \frac{TP}{TP + FN} \quad (5)$$

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall} \quad (6)$$

In this part, we evaluate the outcomes of using several ML techniques for the categorization of violent extremism using a variety of distinct feature sets.

As can be seen in Table I, the general efficacy of each approach increases when more characteristics are combined

into one cohesive whole. This finding provides further evidence that the traits that were obtained are both informative and useful. However, the role of each characteristic fluctuates quite a bit, which shows that there are oscillations in the outputs of the different techniques. When using all groupings

of characteristics as input data, the SVM and LR techniques showed the highest levels of productivity compared to the other methods that were utilized. Both Random Forest and Naive Bayes have shown impressive performance in F1.

TABLE I. RESULTS OF APPLYING MACHINE LEARNING IN ONLINE EXTREMISM DETECTION

Approach	Applied Feature	Accuracy	Precision	Recall	F-measure	AUC-ROC
SVM	Statistics	78.64%	78.17%	77.29%	74.16%	74.72%
	Statistics&TF-IDF	79.35%	79.08%	79.75%	79.43%	78.17%

	Statistics&TF-IDF	59.35%	59.08%	58.75%	58.43%	58.17%
	Statistics&TF-IDF&POS	60.31%	60.15%	59.68%	59.37%	59.07%
	Statistics&TF-IDF&POS&LIWC	62.97%	61.28%	61.21%	61.08%	61.01%
LR	Statistics	79.64%	79.17%	78.29%	77.16%	77.72%
	Statistics&TF-IDF	82.35%	82.08%	81.75%	81.43%	81.17%
	Statistics&TF-IDF&POS	83.31%	83.15%	82.68%	82.37%	82.07%
	Statistics&TF-IDF&POS&LIWC	85.97%	85.28%	84.21%	84.08%	84.01%

The Area Under the Receiver Operating Characteristic Curve (AUC-ROC), encompassing all of the extracted features, is a crucial metric employed for evaluating the performance of each classification task [40]. This measure offers a comprehensive overview of the effectiveness of our classification model across different thresholds, serving as a critical instrument for performance evaluation.

Based on our empirical findings, it was observed that an incremental enhancement in the AUC-ROC performance was intimately linked with an increase in the quantity of incorporated features. This positive correlation signifies the importance of feature richness in enhancing classification performance and illuminates the consequential role these characteristics play in fine-tuning the efficacy of our model.

This discovery substantiates the concept that extending the complexity of our feature space, through the addition of more

discriminative characteristics, is likely to augment the accuracy and reliability of our classifier. Therefore, this observation can inform future developments and refinements to optimize the model's predictive capabilities.

Employing the Logistic Regression methodology yielded an Area Under the Receiver Operating Characteristic Curve (AUC-ROC) score of 0.893. This value surpasses the AUC generated by any other method, signifying its superior performance in the classification task. Remarkably, a considerable portion of the alternate strategies we explored also achieved AUC values exceeding 0.9, an indication of their substantial classification prowess.

In an attempt to critically evaluate the performance of our textual classification model and its capability to discern content affiliated with extremism from a diverse set of online communities, we embarked on a systematic enhancement of

our textual corpus. The purpose of this extensive augmentation was to ensure a broad array of data sources, providing a more diverse and encompassing data set for the model to learn from.

The expanded corpus, characterized by a heterogeneous amalgamation of data, was deployed to test the efficiency of our algorithms across a wide spectrum of contexts. These contexts comprised news articles, which offer a formal representation of language, content identified as toxic that typically involves aggressive or harmful language, spam that usually entails repetitive or irrelevant content, promotional material characterized by persuasive language, and humoristic entries, encapsulating a different style and tone of language.

Upon examination of the results, it was observed that our models exhibited a remarkable precision exceeding 90% in successfully identifying and distinguishing text related to extremism from the various other domains tested. Thus, these findings indicate that the utilization of our chosen methodology to extract distinctive features was indeed efficacious in categorizing instances of extremist rhetoric emanating from diverse sources.

This suggests a significant potential of our models to detect and isolate such extremist content from a wide array of online communities, thereby reaffirming their reliability and precision. The success of our approach opens a new path in text classification, particularly in areas related to security and online community management, demonstrating the power of advanced artificial intelligence in dealing with complex, real-world challenges.

Fig. 4. Confusion matrix of three class classification.

Fig. 4 provides a visual representation of a confusion matrix, a potent tool adopted in the context of discerning violent extremism through textual analysis. This specific matrix employs a tripartite classification scheme. Class 0 constitutes texts which display no correlation with violent extremism, thereby serving as a benchmark of non-extremist discourse. Class 1 comprises neutral texts which, although not explicitly extremist, contain terminology and phrases associated with violent extremism. Consequently, these texts present a subtler form of discourse that necessitates nuanced understanding.

Finally, Class 2 envelops texts that are unequivocally linked to violent extremism, highlighting the most explicit and overt instances of such discourse.

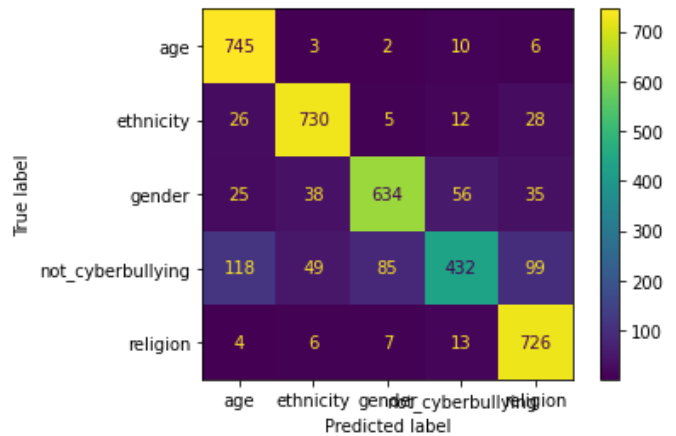

Fig. 5. Confusion matrix of five class classification.

The empirical evidence gleaned from the outcomes of this classification scheme underscores the effectiveness of the proposed framework. Not only does it showcase a capacity for binary classification - differentiating between extremist and non-extremist content - but it also adeptly navigates the intricate landscapes of multi-classification challenges. This includes distinguishing between varying degrees and types of extremist discourse. Thus, the framework's success in such a complex task accentuates its potential for broader application in the realm of text classification.

Fig. 5 provides an illustrative exposition of the application of a five-category classification scheme, implemented within the conceptual framework of the proposed model. The quintuple classification strategy organizes the data into five unique classes, namely: age, ethnicity, gender, non-cyberbullying incidents, and religious considerations. This categorization delineates a wide-ranging spectrum of potential data types, offering a comprehensive perspective on the classification abilities of the model across diverse contexts.

The findings derived from the subsequent results suggest the occurrence of a minimal number of false negatives. In classification tasks, false negatives represent instances where a particular data point has been incorrectly labeled, signifying a discrepancy between the anticipated and actual classification. The paucity of false negatives in the results implies a considerable degree of precision in the classification process undertaken by the proposed model.

This high level of accuracy not only provides testimony to the model's proficiency in accurately classifying data but also underpins its potential for trustworthy deployment in scenarios necessitating precise data categorization. Therefore, this finding bolsters the robustness and versatility of the proposed model in undertaking a variety of data classification tasks.

## V. DISCUSSION

As we navigate the complexities of detecting and mitigating online extremism, the power of Machine Learning (ML) stands out as a promising tool in this ongoing struggle. This

discussion delves into the practical applications, limitations, and future perspectives associated with the use of ML for online extremism detection.

#### A. Practical Use

The emergence of ML techniques in the realm of online extremism detection opens up myriad practical applications. As a technology that can process large volumes of data swiftly and accurately, ML algorithms provide a feasible solution for monitoring the vast and rapidly expanding universe of user-generated content on social media platforms.

In the context of public safety and national security, ML algorithms can help law enforcement agencies to proactively identify potential threats by detecting extremist narratives or recruitment attempts within the vast amount of social media content [41]. On a similar note, social media companies can leverage these technologies to maintain community standards, flagging and removing harmful content, thereby preserving the platform's integrity and ensuring the safety of their users.

Furthermore, the use of feature extraction methods like tf-idf, Bag of Words, Part of Speech, and Word2Vec facilitates the identification of underlying themes, patterns, and trends that may not be apparent to human observers [42]. This assists not only in the identification of extremist content but also in understanding its context, evolution, and influence.

#### B. Limitations

Despite its promise, employing ML in this arena is not without its challenges. First and foremost is the issue of accuracy. False positives (non-extremist content wrongly flagged as extremist) and false negatives (extremist content that goes undetected) can both have severe implications [43]. The former risks infringing upon freedom of speech, while the latter fails to stem the spread of harmful content. Balancing sensitivity and specificity in model performance is an ongoing challenge.

Secondly, the effectiveness of ML algorithms heavily depends on the quality of the training data. Gathering extensive, representative, and accurately labeled data for training purposes is a significant challenge due to the sensitive and dynamic nature of extremist content.

Thirdly, ML algorithms often suffer from a 'black box' problem, where the decision-making process is opaque and hard to interpret. This can lead to difficulties in understanding why certain content was flagged, hindering improvements and adjustments to the system.

Lastly, there are ethical considerations. While using ML to detect online extremism has clear security benefits, it may also raise concerns about user privacy and data misuse. Achieving a balance between security needs and user privacy is a delicate and complex task.

#### C. Future Perspectives

In this research we consider detection of violent extremism in online user contents. Nowadays, different methods are used to teach students in low school and high school to give children and students good knowledge ethics [44] and righteousness [45]. In our study, we used a machine learning approach that is

the one of the state-of-the-art methods in this area. Looking forward, the application of ML for online extremism detection presents a vibrant research area with numerous exciting prospects [46]. The development of more sophisticated algorithms and feature extraction methods can further improve the accuracy and efficiency of detection systems.

Further exploration into hybrid models combining multiple ML algorithms or integrating ML with traditional rule-based methods could leverage the strengths of both approaches. Moreover, the integration of ML with Natural Language Processing (NLP) and sentiment analysis techniques could offer a more nuanced understanding of extremist narratives and rhetoric [47].

Additionally, interpretability of ML algorithms is a critical area for future work. Developing techniques to enhance the transparency of these models will not only increase trust in their decisions but also provide more insight into the underlying patterns of extremist content [48].

Finally, research should also focus on ethical and privacy-preserving ML methodologies. This includes exploring how to minimize data requirements, anonymize data used, and ensure that the application of these technologies respects user rights and societal norms.

In conclusion, the adoption of Machine Learning for online extremism detection presents a potent tool with numerous practical applications. However, addressing its limitations and considering future directions is crucial for the responsible and effective use of this technology in ensuring a safer digital landscape.

## VI. CONCLUSION

Online extremism poses a significant challenge in today's digital society, with its rapid dissemination and evolving nature causing widespread concern. This research has examined the use of Machine Learning (ML) methods as a valuable solution for detecting such extremist content within the vast landscape of user-generated social media content. The use of ML techniques, particularly in conjunction with feature extraction methods such as tf-idf, Bag of Words, Part of Speech, and Word2Vec, has been demonstrated to offer a scalable, adaptable, and effective approach.

However, as we progress in the application of ML techniques for online extremism detection, it is crucial to address the inherent limitations. These include issues of accuracy, dependency on the quality of training data, the interpretability of ML models, and the ethical implications related to user privacy and data usage.

Looking forward, there is vast potential for further development and refinement of ML algorithms, particularly in enhancing interpretability, improving data collection and labeling, integrating with other computational techniques, and considering ethical and privacy-preserving strategies. We must strive to balance security needs with preserving user rights and societal norms.

Ultimately, the objective of this research and the broader field is to contribute towards a safer and more respectful online

environment. ML has demonstrated significant promise in this regard, but its application must be conscientiously guided, ethically aware, and continually adapting to the evolving challenges of online extremism. It's a powerful tool in our arsenal, but like any tool, its effectiveness will depend on how we wield it.

# Text Mining-based Enterprise Financial Performance Evaluation in the Context of Enterprise Digital Transformation

Changrong Guo, Jing Xing

Department of Accounting, Xinzhou Normal University, Xinzhou, 034000, China

**Abstract**—As enterprises gradually move towards digitalization, it is increasingly difficult to accurately evaluate changes in corporate financial performance. To improve this situation, the study uses a text mining algorithm based on the web crawler principle to extract keywords from corporate annual reports, select representative financial performance indicators through IF-FDP, and construct a corporate financial performance evaluation model using the entropy weighting method. The performance comparison experiments of the text mining algorithm proposed in the study show that the accuracy-recall rate area under the line of the text mining algorithm proposed in the study is 0.83 and the average F-value is 0.34, which are both better than other algorithms. In the empirical analysis of the financial performance evaluation model, it was found that the financial performance evaluation model had the smallest absolute error of 0.3%, which was lower than the other models. The above results indicate that both the text mining algorithm and the performance evaluation model proposed in the study outperform the comparison algorithm and model. Therefore, the performance evaluation model proposed by the study can be used to effectively evaluate the financial performance of enterprises accurately and promote the development of enterprises, which has practical application value.

**Keywords**—Web crawler; text mining; IF-FDP; entropy method; financial performance; evaluation model

## I. INTRODUCTION

As the world enters the information age in the 21st century, the traditional economy is surging towards the digital economy. In the face of the impact of the digital economy, traditional enterprises are transforming and upgrading with the help of digital technology [1]. In order to explore the financial changes of traditional enterprises in the process of digital transformation and to understand the significance of digital transformation to the development of enterprises, the study will delve into the financial performance performance of transforming enterprises. Studies have mainly focused on the analysis of the financial mechanism of digital transformation and the analysis of the path of digital transformation, and there is less analysis of the financial performance changes in the process of digital transformation of enterprises [2]. However, in the face of the performance assessment of digitally transformed enterprises, the use of traditional performance assessment methods may not be comprehensive and accurate enough. Therefore, there is an urgent need to develop a performance evaluation model that is suitable for use by

transforming companies.[3] Text mining algorithms are intelligent algorithms that extract knowledge from large amounts of unstructured or semi-structured text, organise that knowledge into complete information and apply it [4]. Text mining algorithms have a wide range of applications in financial management because of their multi-scientific knowledge advantages due to their integration of multiple scientific fields[5]. In order to better evaluate the financial performance of enterprises accurately, the study applies text mining technology to the enterprise financial performance evaluation model, using its function of extracting textual information to complement the traditional evaluation model and thus improve the overall performance of the performance evaluation model. This research innovatively combines the Text mining algorithm based on the Pathon crawler principle with enterprise financial performance evaluation, and proposes a new enterprise financial performance evaluation model. This model not only makes up for the gap in the integration of enterprise finance and Text mining related fields, but also improves the accuracy of enterprise financial performance evaluation, It provides data support for the development of enterprise financial performance evaluation in the process of Digital transformation. This paper is mainly divided into the following five parts. The first section is the analysis of the research status in the field of performance evaluation and Text mining technology. The second section mainly constructs the financial performance evaluation model based on Text mining algorithm. The third section mainly analyzes the actual performance of the financial performance evaluation model constructed through research. The fourth section discusses the results of this experiment. The fifth section is the conclusion of this study.

## II. REVIEW OF THE LITERATURE

Performance evaluation is a clear indication of performance over time, so performance evaluation metrics are widely used in many fields [6]. Xu et al. apply machine learning techniques to a performance evaluation model based on a two-layer overlay framework to address the lack of accuracy in the transaction and risk assessment of second-hand property prices. The results of the empirical analysis of the model show that the performance evaluation model has higher accuracy and outperforms traditional performance evaluation methods [7]. The Fanelli team proposed a performance evaluation model based on a specific frequency of survey results to address the issue of poor performance in the public health sector. Empirical analysis of

this performance evaluation model found that its implementation can improve the performance of the public sector, which has practical significance [8]. Karimi et al. propose a performance evaluation model based on enhanced additivity ratios to address the problem of inaccurate performance evaluations of knowledge workers, and test the model to find that it outperforms traditional methods for evaluating the performance of knowledge workers, with a significant increase in accuracy over traditional models [9]. The Galagedera team addresses the question of whether mutual funds The results of an empirical analysis of a network data envelopment analysis model of mutual fund management performance, which addresses the question of whether costs and expenses can be effectively managed, show that the performance indicator model proposed in the study can effectively improve the efficiency of payment management and has practical application [10].

Text mining has applications in the fields of intelligent systems, information retrieval, information processing, etc. Akundi et al. observed a significant increase in academic and industrial research in the field of systems engineering and proposed a comprehensive and structured integration of research in the field through the use of text mining techniques in order to understand the existing research directions in the field. “system modelling language”, “physical system” and “production” are the most used terms in systems engineering research, with system modelling language being the most widely used modelling language [11]. Leem et al. propose a text mining approach to sentiment analysis of customers’ online evaluations for Kakao mobile banking service, which is ambiguous and unclear. Through regular analysis, it was found that the proposed method is of practical use to improve service quality, increase customer satisfaction and assist in maintaining and upgrading the application, thus effectively increasing the completion rate of mobile banking services [12]. Zhou’s team proposed to use text mining techniques to extract experimental data related to minimum streaming speed to address the problem that the selection of minimum streaming speed is easily influenced by subjective impressions, and to build a database was established. The method was validated and found to be 83% accurate in extracting the function

parameters and more objective and accurate in selecting the minimum fluidisation velocity, which can effectively solve the problem of high empirical correlation in data selection [13]. An empirical study found that anaesthesia, oestrogen receptors and fengi hydrogen receptor mediators were the most important event drivers in aquatic systems distributed across China, and the proposed approach can provide objective and valid information for water quality assessment in the era of big data [14].

To sum up, text mining method has strong text processing ability, which can meet the need of extracting and processing a large amount of text data in financial performance evaluation model. In addition, it can be found that the current financial evaluation model often only focuses on a single index, ignoring other important factors. This kind of single index evaluation is easy to ignore the overall risk and performance of the enterprise, and cannot fully and accurately evaluate the value of the enterprise. At present, there are few researches on the combination of text mining technology and financial performance evaluation model, so the combination of performance evaluation model built based on text mining algorithm is studied, hoping to improve the overall evaluation performance of enterprise financial performance evaluation model with the help of the comprehensive performance of text mining, so as to accurately evaluate the value of enterprises.

### III. CONSTRUCTION OF A FINANCIAL PERFORMANCE EVALUATION MODEL BASED ON TEXT MINING ALGORITHMS

#### A. Text Mining Algorithms based on Pathon Crawler Principles

A web crawler, also known as a web spider, is a web technology in which a computer automatically collects specific data through a program or script according to certain rules [15-16]. Python, one of the most widely used crawler programming, can not only automatically crawl text, images, audio and video information in large quantities, but Python also provides a large number of third-party libraries to assist in information crawling [17]. The principles of web crawling technology are shown in Fig. 1.

Fig. 1. Web spider principle.

As shown in Fig. 1, first the web crawler needs to send a URL to the engine, which in turn forwards the URL to the scheduler. The dispatcher then processes the URL, and the processed URL is returned to the engine. The engine takes the received URL and gets the response information through the downloader intermediate component, which is then parsed, filtered and stored by the crawler. Finally, the remaining filtered data is forwarded to the pipeline for processing. Text mining algorithms are a process of fusing word processing techniques with intelligent learning algorithms to extract

valuable textual information and knowledge from text and reorganise the extracted information. The research uses text mining algorithms as semi-structured text information processing algorithms, the process of which can be divided into three parts, i.e. text information acquisition and processing, text information parsing and thesaurus building and text information quantitative analysis. The structure of the text mining algorithm proposed in the study is shown in Fig. 2.

Fig. 2. Text mining algorithm structure.

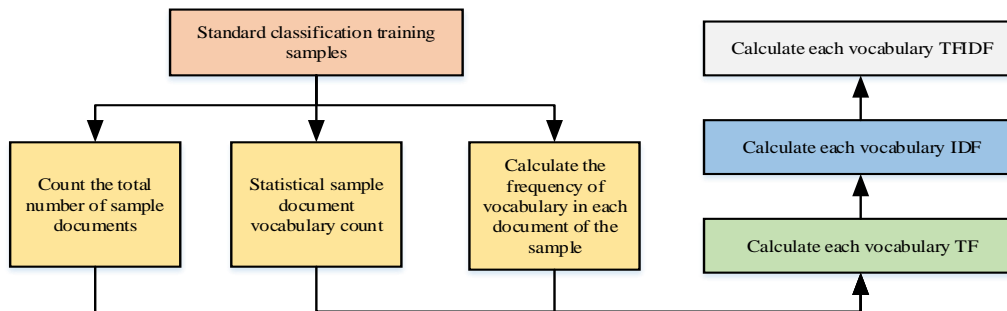

Fig. 3. Text word frequency feature weight calculation process.

As shown in Fig. 2, the proposed text mining algorithm firstly crawls the annual report text of enterprises through Python web crawler technology technique, and pre-processes, feature selection and keyword selection for the crawled text. Finally, the keywords are classified and calculated statistically through classifier and word frequency statistics techniques. In the text data acquisition and storage part of the text mining algorithm, the study collected the text of annual reports of A-share high-end manufacturing enterprises in Shanghai and Shenzhen from 2012 to 2022, converted the text to TXT format through PDFminer, and then carried out word separation processing, de-duplication operations, word extraction and information storage on the converted text. In the subject keyword acquisition part, the algorithm uses the jieba word splitter to cut words and clean the stored information, eliminating companies with abnormal financial or other conditions, as well as samples with serious data deficiencies, and completing the operation of removing obsolete words, thus obtaining the text word set. The text mining algorithm filters out the discontinued words according to the text requirements, selects the appropriate keywords and

calculates their corresponding feature weights. Finally, the selected keywords are fed into the classifier to build a subject classification keyword database. As an important technique for text mining, the word frequency statistical calculation method is an objective statistical method that can identify hot words and quantify the change trend by the frequency of occurrence of keyword words of a specific topic. The process of calculating the word frequency feature weights is shown in Fig. 3.

As can be seen from Fig. 3, after the study has counted the pre-processed text information, the feature weights will be calculated by the feature algorithm, i.e. Term Frequency-Inverse Document Frequency (TF-IDF) algorithm for the feature words.  $tP$  is the number and frequency of occurrences of the feature words in the text, and its calculation formula The formula is shown in equation (1).

$$TP_{i,j} = \frac{n_{i,j}}{\sum_k n_{k,j}} \quad (1)$$

In equation (1),  $n_{i,j}$  indicates the number of times the keyword  $t_i$  appears in the document  $d_j$ . IDF is the frequency of the subject keyword in other texts, and is a quantitative indicator of the prevalence of the keyword. If the IDF value of a keyword is smaller, it means that this keyword has a good classification function; if its IDF value is larger, it means that this keyword is common. The formula for calculating IDF is shown in equation (2).

$$IDF_i = \log \frac{|D|}{1 + |j: t_i \in d_j|} \quad (2)$$

In equation (2),  $|D|$  is the number of all documents;  $|j: t_i \in d_j|$  indicates the number of documents containing the keyword  $t_i$ . TF-IDF is a quantitative indicator of the importance of keywords in the text and is calculated as shown in equation (3).

$$TP-IDF_{i,i} = \frac{n_{i,j}}{\sum_k n_{k,j}} * \log \frac{|D|}{1 + |j: t_i \in d_j|} \quad (3)$$

In equation (3),  $n_{i,j}$  indicates the number of occurrences of the keyword  $t_i$  in the document  $d_j$ ;  $|D|$  is the number of all documents;  $|j: t_i \in d_j|$  indicates the number of documents containing the keyword  $t_i$ . After calculating the TF-IDF values of the keywords, the study used the cardinality check combined with the weights of the feature terms to evaluate and select the feature terms. The formula for calculating the keyword cardinality value is shown in equation (4).

$$x^2 = \frac{N(AD - BC)^2}{(A + C)(A + B)(B + D)(B + C)} \quad (4)$$

In equation (4), indicates the frequency of the keyword  $A$   $t_i$  in positive documents; indicates the frequency of the keyword  $B$   $t_i$  in positive documents;  $C$  indicates the frequency of the keyword  $t_i$  not in positive documents;  $D$  indicates the frequency of the keyword  $t_i$  not in negative documents. The study derived the text feature word selection score based on normalisation, which is shown in equation (5).

$$Score(t_i) = \alpha \cdot \left[ \frac{n_i}{N} * 100 \right] + \beta \left[ \frac{c_i}{N} * 100 \right] \quad (5)$$

In equation (5),  $n_i$  denotes the keyword  $t_i$  in the TF-IDF positive order number;  $c_i$  denotes the keyword  $t_i$  in the chi-square test positive order number;  $\alpha$  and  $\beta$  set the parameter value to 0.5. The feature words were sorted into sequences according to the selected scores, and the weight scores of the keyword propagation nodes were calculated as shown in equation (6).

$$S(V_i) = (1-d)W'(V_i) + d * W'(V_i) \sum_{j \in Ln(V_i)} \frac{w_{ji}}{\sum_{k=V_j} w_{ji}} S(V_j) \quad (6)$$

In equation (6), is the weight of the node  $S(V_i) V_i$ ,  $w_{ji}$  is the weight of the nodes  $V_i$  and  $V_j$ , is the set of nodes, and  $j \in Ln(V_i) V_i k = V_j$  is the set of nodes  $V_j$  refers to. After convergence of the weights of the nodes, the nodes are normalised for sorting, so that keywords can be selected. The normalisation formula is shown in equation (7).

$$Score(t_i) = \left[ \frac{n_i}{N} * 100 \right] \quad (7)$$

In equation (7),  $n_i$  denotes the positive ordinal number of the keyword  $t_i$  in the keyword weighting. After counting the frequency of the main keywords, the study selects the companies that are in digital transformation from 2012-2022 by portraying the degree of digital transformation through the weight of digital keywords. The specific calculation formula equation (8) is shown.

$$q_i = \frac{a_{it}}{\sum_i a_{it}} \quad (8)$$

In equation (8),  $a_{it}$  indicates the total number of digitised keywords for the company  $i$  in the year  $t$ .

## B. Construction of a Financial Performance Evaluation Model based on the Entropy Method

Financial performance evaluation models are models that quantify financial data through performance evaluation indicators, and then make a comprehensive evaluation of performance based on set evaluation criteria [18]. The most widely used performance evaluation models are the financial management theory performance evaluation model, and the mathematical and statistical model financial performance evaluation model [19]. The financial evaluation model proposed in the study belongs to the mathematical statistical model, which is a performance evaluation model based on the text mining algorithm and the entropy weight method.

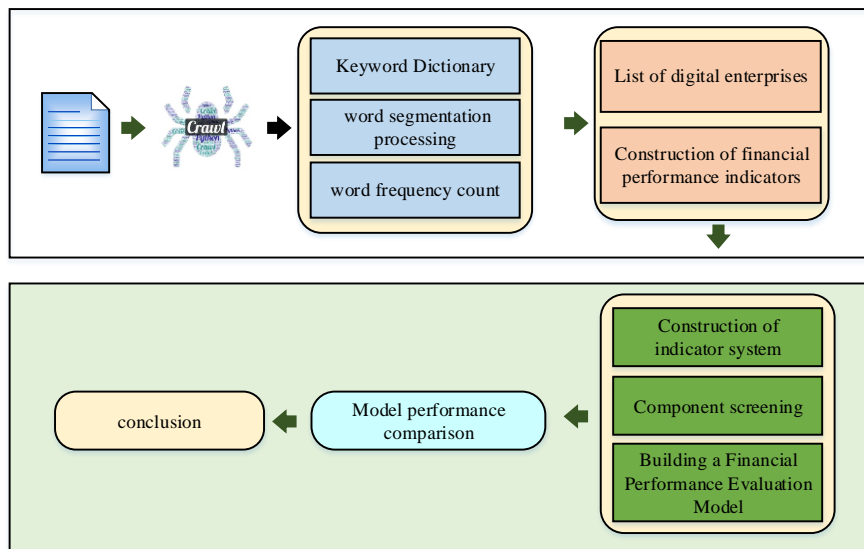

Fig. 4. Structure of performance evaluation model based on text mining.

Fig. 5. Structure of enterprise financial performance evaluation index system.

As can be seen from Fig. 4, the first step of the model is the processing of text information. The model constructs a digital keyword dictionary through a text mining algorithm based on the principle of crawlers, and carries out word separation processing to obtain the required digital keywords, and finally carries out quantitative analysis on the obtained keywords, calculates the keyword word frequency and inverse document frequency, and selects a list of enterprises for digital transformation. The second step is to build an enterprise financial performance evaluation index model. In order to comprehensively reflect the business quality and financial performance of the enterprise into the whole cycle, and to solve the problem that a single financial indicator can only evaluate the unilateral financial situation of the enterprise, the

study integrates the entropy weight method with each indicator of the financial dimension to build a more scientific and reasonable enterprise financial performance evaluation index model. An empirical analysis of the current financial situation is carried out, and statistical descriptions of the full range of financial conditions in each dimension are separately conducted to explore the changes in the financial performance of manufacturing enterprises. Finally, the entropy method financial performance evaluation model is compared with the performance of other algorithmic financial performance evaluation models to verify the reasonableness of the improved performance evaluation model proposed by the study. The structure of the enterprise financial performance evaluation index system is shown in Fig. 5.

As shown in Fig. 5, the study establishes an enterprise financial performance evaluation index system in terms of the relevance, systematicity, importance and feasibility of the enterprise's financial performance in accordance with four

dimensions: profitability, debt servicing, development and operational capability. The study constructed a total of 17 indicators for the preliminary index system of enterprise financial performance evaluation, as shown in Table I.

TABLE I. PRELIMINARY SELECTION INDEX SYSTEM FOR ENTERPRISE FINANCIAL PERFORMANCE EVALUATION

Dimension	Indicator code	Financial index	Indicator Definition
Profitability	A1	Return on assets	Pre tax profit/average total assets
	A2	Net profit margin of total assets	Net profit/average balance of total assets
	A3	Net return on assets	Net profit/average balance of shareholders' equity
	A4	Operating profit margin	Operating profit/revenue
	A5	Return on invested capital	(Net profit+financial expenses)/(Total assets -Current liabilities+Notes payable+Short term borrowings+Non current liabilities due within one year year)
	A6	Cost profit margin	Total profit/total cost expenses
	A7	Earnings per share	Current net profit attributable to ordinary shareholders/weighted average number of outstanding ordinary shares in the current period
Debt repayment ability	A8	Quick ratio	Quick assets/current liabilities
	A9	Current ratio	Current assets/current liabilities
	A10	Asset liability ratio	Total liabilities/total assets
	A11	Cash to current liability ratio	Net cash flow from operating activities/total liabilities
	A12	Total asset growth rate	Increase in total assets this year/total assets at the beginning of the year
Development capability	A13	Net asset growth rate	Increase in net assets this year/total net assets last year
	A14	Operating revenue growth rate	(Current year's operating revenue - previous year's operating revenue)/previous year's operating revenue
	A15	Current Asset turnover	Operating income/average occupancy of current assets
Operational capacity	A16	Net profit growth rate	(Current net profit - Previous net profit)/Previous net profit
	A17	Total Asset turnover	Main business income/total assets

As shown in Table I, the study divided the financial performance indicators into four dimensions, in which profitability is the ability of an enterprise to earn profits within a certain period of time; solvency is the ability of an enterprise to use its assets to repay short-term and long-term debts, and cash payments; development capacity refers to the trend of future cash flows from operating activities; and operational capacity is the ability of an enterprise to manage its operations within a certain operating period [20]. The study uses principal component analysis to screen the 17 primary indicators under these four dimensions, determines the principal components through the cumulative variance contribution rate, and selects representative indicators according to the criterion of cumulative variance contribution rate of 75%. The formula for calculating the contribution value of financial indicators' contribution ratio is shown in equation (9).

$$a_i = \frac{\lambda_i}{\sum i^m \lambda_i} \tag{9}$$

After determining the representative indicators for performance evaluation, the weighting of each financial indicator needs to be assigned, and the weighting method used in the study is the entropy method. The entropy weighting method is a method of objectively assigning weights to the indicator system using known data, which can avoid errors arising from subjective impressions and has the advantages of high calculation precision and accuracy. The higher the entropy value, the less information the indicator contains, and

the more information it contains. The entropy weighting method first requires pre-processing of the original data, including the standardisation of positive indicators, negative indicators and moderate indicators. The formula for the standardisation of positive indicators is shown in equation (10).

$$Y_{ij} = \frac{X_{ij} - \min(X_{ij})}{\max(X_{ij}) - \min(X_{ij})} \tag{10}$$

The formula for the standardisation of negative indicators is shown in equation (11).

$$Y_{ij} = \frac{\max(X_{ij}) - X_{ij}}{\max(X_{ij}) - \min(X_{ij})} \tag{11}$$

The formula for the standardisation of moderate indicators is shown in equation (12).

$$Y_{ij} = 1 - \frac{|X_{ij} - X_j|}{\max |X_{ij} - X_j|} \tag{12}$$

In equation (12),  $X_j$  is the fixed value of the moderate indicator. After pre-processing the indicators, the characteristic contribution of the indicators is calculated as shown in equation (13).

$$P_{ij} = \frac{Y_{ij}}{\sum_{ij}^n Y_{ij}} \quad (13)$$

In equation (13),  $P_{ij}$  is the characteristic contribution of the  $j$  indicator for the  $i$  company. The higher the value, the more information is contained in the indicator. The calculation formula is shown in equation (14).

$$e_j = -\frac{1}{\ln n} \sum_{i=1}^n P_{ij} \ln(P_{ij}), 0 \leq e_j \leq 1 \quad (14)$$

For the calculation of the degree of variation of the indicators, the formula for calculating the coefficient of variation is shown in equation (15).

$$g_j = 1 - e_j \quad (15)$$

Finally, in order to calculate the comprehensive evaluation score of the indicators and determine the weight of the

evaluation indicators, the calculation formula is shown in equation (16).

$$W_j = \frac{g_j}{\sum_{i=1}^m g_j}, j = 1, 2, \dots, m \quad (16)$$

#### IV. TEXT MINING ALGORITHM PERFORMANCE COMPARISON AND PERFORMANCE EVALUATION MODEL EMPIRICAL ANALYSIS

The study extracts keywords from corporate annual report texts by text mining algorithms and classifies the results, using the TF-IDF metric to calculate the frequency of keywords in corporate annual report texts. In order to better analyse the keywords with higher hotspots, the study results only show the top ten digitisation-related keywords that appear frequently in the text of corporate annual reports from 2012 to 2022. Also to verify the practicality of the text mining algorithm, the study verifies the accuracy of the classification results of the text mining algorithm. The keyword frequency calculation results and text mining ROC curves are shown in Fig. 6.

Fig. 6. Keyword frequency results and text mining algorithm ROC curve.

Fig. 7. Accuracy-recall rate and f-value results of four algorithms.

Fig. 6(a) shows the top ten digital keywords appearing in the text of annual reports from 2012 to 2022, of which the top three are “information technology”, “intelligence” and “robotics”. The top three keywords are “informatization”, “intelligence” and “robotics”. Fig. 6(b) shows the ROC curve of the text mining algorithm. From Fig. 6(b), it can be seen

that the area under the ROC curve of the text mining algorithm is 0.87, which is significantly higher than that of the traditional standard algorithm and has practical application value. The study compares the performance of the text mining algorithm with other algorithms. The experiment was conducted in MATLAB 2017b and simulated using Simulink.

The basic experimental environment settings are shown in Table II.

TABLE II. THE EXPERIMENTAL BASIC ENVIRONMENTAL PARAMETERS

Parameter variables	Parameter selection
Overall implementation platform	Simulink
Operating system	Windows10
Operating environment	MATLAB
PC side memory	12G
CPU main frequency	2.62Hz
Global procurement unit	RTX-2070
Central Processing Unit	i7-8700
Data storage	MySQL data bank
Data regression analysis system	SPSS26.0

The results of the accuracy-recall curve and F-value comparison of the four algorithms are shown in Fig. 7.

Fig. 7(a) shows the accuracy-recall curves of the text mining algorithm and the comparison algorithm, the comparison algorithm is the random forest algorithm, the support vector machine (SVM) algorithm, and the boosting method algorithm. From Fig. 8(a), it can be seen that the accuracy-recall curves of both the text mining algorithm and the comparison algorithm algorithms show a decreasing trend, with the area under the line of the text mining algorithm being 0.83, the area under the line of the SVM algorithm being 0.56, the area under the line of the boosting method algorithm being 0.62, and the area under the line of the random forest algorithm being 0.46. From the above results, it can be concluded that the area under the line of the accuracy-recall rate of the text mining algorithm is significantly larger than

that of the rest of the algorithms, with the best performance. Fig. 7(b) shows the F-values of the text mining algorithm and the comparison algorithm. From Fig. 7(b), it can be seen that the F-values of the four algorithms show an overall increasing trend with the increase of k. The average value of the F-value of the text mining algorithm is 0.34, the average value of the SVM algorithm is 0.31, the average value of the boosting method is 0.29, and the average value of the random forest algorithm is 0.23, and all the F-values of the text mining algorithm are higher than the F-values of the remaining algorithms values, and the keyword selection accuracy performance was significantly better than the other compared algorithms. The study conducted principal component analysis on the nine indicators under the profitability dimension in Table I, and selected representative indicators by calculating the correlation coefficient selection and score coefficients through SPSS, and the correlation coefficient matrix is shown in Fig. 8.

As shown in Fig. 8, the horizontal and vertical coordinates are the coefficients of the corresponding indicators A1-A9. From the results of Fig. 8, it can be seen that the index coefficients of five indicators, A1, A2, A3, A4 and A6, are relatively high, so these five indicators are selected as the main component representative factors. The study then evaluates the 2012-2022 annual reports of enterprises through the entropy weighting method financial performance evaluation model, and Fig. 9 shows the results of the evaluation of enterprise profitability and development capability.

Fig. 8. Correlation matrix.

Fig. 9. Profitability and development ability of the enterprise.

Fig. 10. Enterprise operational capability and debt repayment capability.

Fig. 9(a) shows the results of the enterprise profitability assessment. From Fig. 9(a), it can be found that the mean of return on assets, total profitability of assets, return on assets, return on assets and cost margin in enterprise finance are 5.44%, 3.70%, 6.10%, 5.15% and 9.29% respectively, and the standard deviation in enterprise profitability indicators are 8.2%, 7.64%, 18.01%, 12.3% and 28.36%, indicating a high degree of dispersion in the profitability indicators. Fig. 9(b) shows the results of the assessment of the development capability of the enterprise. The development curve of the enterprise fluctuates greatly during the period 2012-2022, with the growth rate of total assets and operating income reaching a peak of 15.4% and 23.2% respectively in 2018; the growth rate of total assets reaches a minimum of 5.3% in 2020; and the growth rate of operating income reaches a minimum of 12.4% in 2021. Fig. 10 shows the results of the evaluation of the company's operating capacity and debt servicing capacity for the period 2012-2022.

Fig. 10(a) shows the analysis of the operating capacity of the enterprise during the period 2012-2022. In 2012, the

company's operating capacity reached a maximum with a total asset turnover ratio of 1.46% and a current asset turnover ratio of 0.78%; in 2017, the company's operating capacity reached a minimum with a total asset turnover ratio of 1.29% and a current asset turnover ratio of 0.68%. Fig. 10(b) shows the analysis of corporate debt service capacity results for the period 2012-2022, with the corporate quick ratio reaching a maximum value of 1.95% in 2012 and the quick ratio reaching a minimum value of 1.52% in 2016. In 2019, it reaches a minimum value of 42.9%, with a difference of 3.5%. In order to test the performance of the entropy method performance evaluation model proposed by the study, the study compared the performance of the entropy method financial performance evaluation model with other algorithmic models for performance experiments. The study used the scores of the four dimensions of performance and the absolute difference with the actual value as the comparison index for performance analysis. Fig. 11 shows the performance comparison results between the entropy method performance evaluation model and the comparison model.

Fig. 11. Performance comparison results of performance evaluation models.

Fig. 11(a) shows the results of the entropy method of evaluating the financial performance of enterprises, which are the actual value, the traditional model and the Economic Value Added (EVA) algorithm model. As can be seen from Fig. 11(a), the actual scores for profitability, solvency, growth and operational capability are 15.7%, 14.8%, 16.2% and 19.8%. The traditional, EVA and entropy models have profitability scores of 20.5%, 12.6% and 16.4%, respectively; debt servicing scores of 18.6%, 10.6% and 15.9%, respectively; development scores of 13.3%, 18.8% and 15.9%, respectively; and operational capacity scores of 26.7%, 12.7% and 18.3%, respectively. Fig. 11(b) shows the absolute error curves of the performance evaluation models and the actual values. As can be seen from Fig. 11(b), the absolute error curve of the entropy method performance evaluation model is lower than that of the other algorithm models, and the absolute error of the three algorithm models is the lowest in the evaluation of development capability. The absolute error of the entropy method performance evaluation model is 0.3%, which is lower than that of the traditional model (2.4%) and the EVA algorithm (2.6%); the absolute error of the entropy method performance evaluation model is 1.1%, which is lower than that of the traditional model (3.8%) and EVA algorithm (4.2%). The entropy method performance evaluation model is the closest to the actual value and has the best performance.

## V. CONCLUSION

Due to the low accuracy of traditional performance evaluation models in assessing enterprise performance, in order to more comprehensively and accurately explore the changes in financial performance of digital enterprises during the period 2012-2022, the study proposes to use a text mining algorithm based on crawler technology to filter the keywords of enterprise annual reports and construct a list of digital enterprises. The financial performance data of the selected enterprises were input into the financial performance evaluation model proposed in the study, and it was found that the digital enterprises had the best growth capacity in 2018, with the annual growth rate of total assets and operating revenue reaching the peak of 15.4% and 23.2%, and the maximum operating capacity in 2012, with the total assets turnover ratio of 1.46% and current assets turnover ratio of 0.78%. A performance comparison experiment of the text mining algorithm revealed that the area under the accuracy-recall line of the algorithm was 0.83 and the mean value of F-value was 0.34, which was better than other

algorithms. The entropy method financial performance evaluation model has a minimum absolute error of 0.3% and a maximum of 1.1% from the actual value, and its absolute error is lower than the traditional model absolute error of 3.8% and the EVA algorithm absolute error of 4.2% at its maximum, and its performance is optimal. The above results indicate that the model proposed in the study has good evaluation effect and has good potential for application in enterprise performance evaluation. The shortcoming of this study is that the model proposed in this study has a narrow scope of application, which can only be applied to the period of enterprise digital transformation, and cannot accurately evaluate the financial status of enterprises before and after the transformation. The subsequent research direction is to improve the scope of application of enterprise financial evaluation model.

## VI. FINDINGS

The research is supported by Teaching Reform and Innovation Project of Colleges and Universities in Shanxi Province in 2021: Research on the Reform of "Principles of Accounting" Flip Classroom Teaching Methods Based on Online Teaching (J2021586).

PRINCE Laboratory Research-ISITcom-Hammam Sousse, University of Sousse, Tunisia

**Abstract**—Surveillance of pharmacovigilance, also known as drug safety surveillance, involves the monitoring and evaluation of drug-related adverse events or side effects to ensure the safe and effective use of medications. Pharmacovigilance is an essential component of healthcare systems worldwide and plays a crucial role in identifying and managing drug safety concerns. Natural language processing (NLP) can play a crucial role in surveillance activities within pharmacovigilance by analyzing and extracting information from various sources, such as clinical trial reports, electronic health records, social media, and scientific literature. It is important to note that while NLP can be a powerful tool in pharmacovigilance surveillance, it should always be used in conjunction with human expertise. NLP algorithms can assist in the identification and extraction of relevant information, but the final assessment and decision-making should involve the knowledge and judgment of trained pharmacovigilance professionals. In this paper, we intend to train and test our models using the dataset from the Medication, Indication, and Adverse Drug Events challenge. This dataset will include patient notes as well as entity categories such as Medication, Indication, and ADE, as well as various sorts of relationships between these entities. Because ADE-related information extraction is a two-stage process, the outcome of the second step (i.e., relation extraction) will be utilized to compare all models. The analysis of drug-related adverse events using electronic health records and automated approaches can considerably increase the effectiveness of ADE-related information extraction, although this depends on the methodology, data, and other aspects. Our findings can help with ADE detection and NLP research.

**Keywords**—Natural language processing; surveillance of pharmacovigilance; drug-related adverse

## I. INTRODUCTION

Adverse drug events are caused by medications, and these forms of injuries are referred to as adverse drug events (ADEs). A few years ago, data mining techniques for identifying adverse drug events (ADEs) by analyzing information were discovered. These data mining tools examine complex data extracted from huge electronic medical databases [1, 2]. The International Standard Organization (ISO) defines electronic health database (EHR) as a repository of patient-related databases in digital form, securely stored and shared, and accessible by various authorized healthcare users. Clinical information such as frequency of drug use, adverse effects, and

so on can be found in electronic databases [3]. Randomized controlled clinical trials (RCTs) are considered the gold standard for investigating the pros and cons of drugs; however, due to limitations such as shorter duration and restricted inclusion criteria, the development of data mining databases and algorithms for Pharmacovigilance tasks has resulted [4]. Since 1960, the most widely available type of medical database for adverse events has been the spontaneous reporting system (SRS) database. The notable SRS databases are the Adverse Event Reporting System (ARRS), the Medicines and Healthcare Products Agency's (MHRA) Yellow card scheme, the European Agency for the Evaluation of Medicinal Products (EMA), and the World Health Organization. The Adverse Event Reporting System (ARRS) and the General Practice Research Database (GPRD) are still operational. ARRS is a well-known adverse event database that supports the FDA's safety program for all approved pharmaceuticals, while the GPRD database (Pharmacoepidemiology database) is a significant database of medical records [5].

The significance of our work is that several phase clinical trials assess the adverse effects of each licensed drug, whereas clinical studies typically target only one drug. The specific effects of multiple-drug administration become harder to analyze. People, on the other hand, take many medications, which creates a chasm between research trials and actual drug use by patients. As a result, information about Adverse Drug Reactions (ADEs) is critical for ensuring patient safety [5]. Clinical information cannot be retrieved from biomedicine literature or narrative clinical reports; consequently, natural language processing (NLP) has been developed expressly for this purpose, which identifies, extracts, and encodes information from biomedicine literature and clinical narratives [4].

The practice of collecting useful information from vast amounts of unstructured text using computational algorithms is known as text mining [6,7]. In the context of pharmacovigilance, "meaningful information" is information that can aid in the detection and assessment of adverse drug events (ADEs). Because text mining provides a technique for converting free text into computable knowledge, it is developing as a method for exploring, analyzing, querying, and managing unused drug safety information. Pharmacovigilance is now based on the analysis of clinical trials and spontaneous reports, as well as a review of biological literature to some

extent. Domain experts often do the study on a case-by-case basis. Statistical approaches have recently been included into standard Pharmacovigilance practice, and these are applied to spontaneous reports [8, 9] and clinical trials [10] to further discover ADE signals. Nonetheless, well-known limitations [11, 12] inherent in the type and range of data sources used in routine Pharmacovigilance, as well as rising public concern about medication safety, have sparked a slew of global research and legislative initiatives [13, 14] aimed at enhancing Pharmacovigilance. It is well acknowledged that development in pharmacovigilance is dependent on a comprehensive methodology that analyses ADE-related data from a diverse range of potentially complementary data sources. With the passage of the Food and Drug Administration Amendments Act (FDAAA) of 2007 [15], Pharmacovigilance research has centered on the expanding secondary use of electronic health records (EHRs) [16]. Other sources, such as biological literature, product labels, social media content, and logs of information seeking activities on the Web, have been explored in recent years to assist holistic Pharmacovigilance. Each source offers a distinct point of view, and each has its own set of advantages and disadvantages.

EHRs contain the promise of active surveillance, the ability to quantify the incidence or risk of ADEs, the ability to identify at-risk patients, and the possibility to deliver more accurate and earlier ADE identification. Unlike the current manual approach, it is conceivable to utilise the biomedical literature computationally for a variety of Pharmacovigilance goals, including signal detection [17]. Product labels offer a wealth of information spanning from adverse medication responses to drug efficacy, risk management, contraindications, drug interactions, and many other topics. Several attempts have evolved to computationally extract information from product labels in order to build a database of known ADEs [18]. The generated knowledgebase can be utilized for additional ADE assessment, determining benchmarks for signal identification, prioritizing and filtering ADEs under research, and detecting class effects. Social media, for example, patients' experiences with pharmaceuticals that are explicitly shared through online health forums and social networks, as well as implicit health information contained in major search engine search logs, are among the potential data sources. Text mining combines a wide range of statistical, machine learning, and linguistic approaches related to natural language processing to address the issues given by unstructured text (NLP). It is helpful to think of text mining as a process that employs tools, methods, and heuristics created by those who study natural language processing. Text-mining workflows can employ varying degrees of sophistication in NLP approaches, depending on the use case. As a result, unlike traditional NLP, which employs sophisticated language models and computationally intensive syntactic and semantic analyses to extract meaning from text, text mining favors the use of simpler but less costly approaches that scale to large data sets.

Typically, a text mining process begins with multiple pipelined NLP subtasks that structure the text in preparation for the statistical analysis or pattern identification phase. A set of foundational low-level syntactic activities and a set of high-

level tasks that build on the low-level tasks and entail semantic processing are among the subtasks.

The primary goal of this study is to use natural language processing technology (NLP) to extract potential adverse events from the notes section of electronic health records, and then to use traditional bio statistical approaches to detect associations with specific medications that patients are taking.

## II. METHODS AND MATERIALS

### A. Population and Study Sample

Patient data from Columbia University Hospital, which contains over free text documents such as correspondence, discharge letters, and events, and are growing at a rate of new documents each month, will be used for research purposes. The Clinical Record Interactive Search System (CRIS) [19], a de-identified version of the EHR, will be implemented to create a research resource, and we are also planning to enhance it with language processing tools to extract information from the vast amount of free text format data stored within our database. The clinical dataset Columbia University EHR Structured and Unstructured ADE corpus, which contains information for all patients at Columbia University Hospital, will be used in this investigation. Data will be extracted from the EHR in Columbia University hospital. The data is gathered from 10th June 2019 to 16th August 2019.

### B. Study Significance

The major goal of medication safety regulators and researchers is to discover and monitor ADEs that have the potential to cause public harm [20]. Many ADEs are discovered after a medicine has been commercialized, when it is taken by a broader and more diverse population than in clinical trials [21]. Because ADEs detected after a drug has been widely used can be a significant cause of morbidity and mortality, good post-marketing drug safety surveillance is crucial for public health protection. Only after a new drug's efficacy and safety have been demonstrated in a series of clinical studies is it granted regulatory approval. Randomized, controlled, phase 3 clinical trials/studies are regarded as the most rigorous method of investigating drug efficacy and safety. However, due to their precise inclusion and exclusion criteria, these clinical studies frequently enroll a relatively small number of patients, which may not always reflect all possible consumers of the therapy. Clinical studies are also undertaken for a short period of time, making ADEs with a lengthy latency difficult to identify. Furthermore, following regulatory clearance, drug labeling and/or prescribing practices may change to incorporate new indications or patient populations, off-label usage, or concurrent use with other pharmaceuticals. Each of these new variables may lead to the development of ADEs that were not previously reported during clinical trials. Even over-the-counter pharmaceuticals, such as nonsteroidal anti-inflammatory drugs and phenylpropanolamine, have been linked to documented adverse drug reactions (ADRs) following regulatory approval, resulting in product withdrawal or labeling modifications [22, 23].

Data mining medication safety record databases, medical literature, and other digital resources could be useful in supplementing information concerning ADEs gathered during

short-term clinical studies. Data mining for Pharmacovigilance may also create an "early warning system" that can discover drug safety risks faster than existing approaches. For these reasons, the FDA, the pharmaceutical industry, and drug safety experts are all interested in data mining these sources for ADEs.

### III. RESULTS

In the first part of the data analysis, we look at six filters that cause the distribution of average age by gender to change the most. Fig. 1 above shows the patients who most affect the distribution of the patients' ages. Patients 737, 1234 and 64 are among the patients who most affect the distribution of age.

Fig. 1. Affect the distribution of the patients' ages.

The visit derived from HR record, Long Term Care visit and Outpatient visit most affect the distribution of gender versus age at 10.9%, 1.4% and 10.6% of records respectively, as shown in Fig. 2.

Fig. 2. The distribution of gender versus age.

Among the drug concept names, Dexpanthenol and Atorvastat are the drugs that most affect the distribution of the age and gender, as shown in Fig. 3.

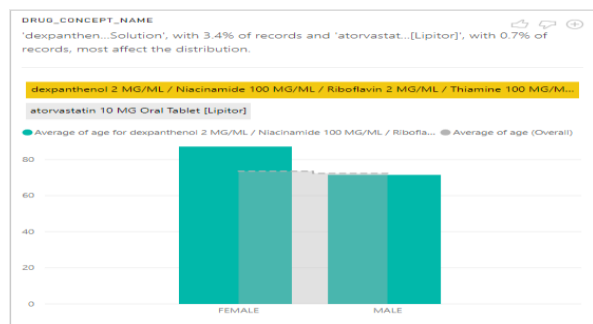

Fig. 3. The distribution of the age and gender.

Among the Cohort start dates, Monday, March 10, 2014, with 12.6% of records; Thursday, August 4, 2016 with 13.8% of records and Saturday, December 27, 2014 with 8.1% of records, among others, most affect the distribution of gender and age, as shown in Fig. 4.

Fig. 4. The distribution of gender and age on March 10, 2014, August 4, 2016 and December 27, 2014.

Among the ingredient concepts, Carvedilol, Furosemide and Atorvastatin most affect the distribution of gender and age comparison at 1.2%, 2.6% and 1.4% respectively, as shown in Fig. 5.

Fig. 5. Effect of the distribution of gender and age.

Among the ingredient concepts, Carvedilol, Furosemide and Atorvastatin most affect the distribution of gender and age comparison at 1.2%, 2.6% and 1.4%, respectively, as shown in Fig. 6.

Fig. 6. Distribution of gender versus age comparison.

Among the ingredient concepts, Carvedilol, Furosemide and Atorvastatin most affect the distribution of gender and age comparison at 1.2%, 2.6% and 1.4% respectively, as shown in Fig. 7.

Fig. 7. Ingredient concepts Carvedilol, Furosemide and Atorvastatin.

Among the drug exposure start dates, Saturday, December 19, 2015, with 0.8% of records; Friday, March 3, 2017, with 1.3% of records and Wednesday, April 12, 2017, with 1% of records most affect the distribution, as shown in Fig. 8.

Fig. 8. The drug exposure starts dates.

A. Age of Patients Compared with Drug Exposure End Date

The year 2015 seems to have the oldest patients at the drug exposure end date at an average of 76 years old, as shown in Fig. 9.

Fig. 9. Age of patients compared with drug exposure end date.

Fig. 10 shows the analysis of the 2.39% increase in average age between 2014 and 2015.

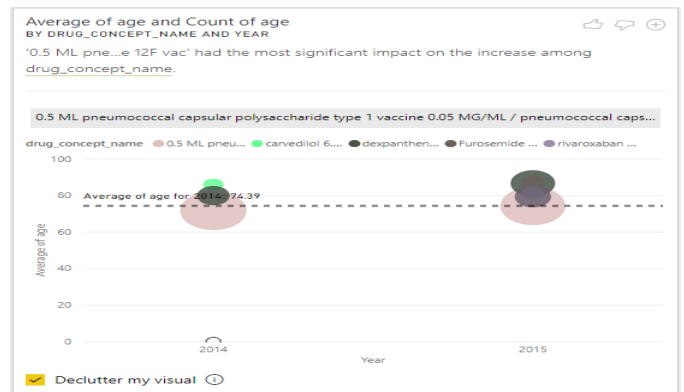

Fig. 10. Average age between 2014 and 2015.

An analysis of drug concept versus age compared by year shows that 0.5 ML pneumococcal had the most significant impact on the increase among drug concept names, as shown in Fig. 11.

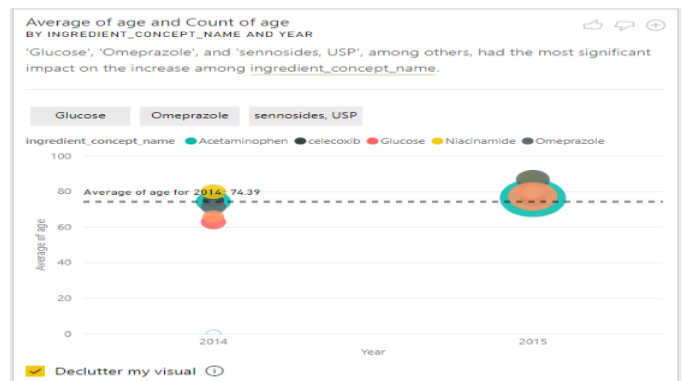

Fig. 11. Analysis of drug concept versus age.

Glucose, Omeprazole and Sennosides had the most significant impact on the increase among ingredient concept names, as shown in Fig. 12.

Fig. 12. Effect of the Glucose, Omeprazole and Sennosides.

Thursday, May 1, 2014, had the most significant impact on the increase among drug exposure start date. Table I above shows that visits derived from EHR record make up 10.9% of all patients followed closely by outpatient visits at 10.6%. Women are the majority at 52% of all the patients, as shown in Table II.

TABLE I. VISITS DERIVED FROM EHR RECORD

Type of visit	Frequency	Percent
Missing	1499	75.9
Emergency Room Visit	15	0.8
Inpatient visit	8	0.4
Long term care visit	27	1.4
Outpatient visit	209	10.6
Visit derived from HER record	216	10.9
Total	1974	100

TABLE II. FREQUENCY OF GENDER

Gender	Frequency	Percent
Female	1017	51.5
Male	957	48.5
Total	1974	100

The Cramer's V value measures the strength of the association between two categorical variables. The value of Cramer's V in this test is 0.97 which implies that there is a strong association between the cohort start date and the drug exposure start date, as shown in Table III.

TABLE III. ASSOCIATION BETWEEN THE COHORT START DATE AND THE DRUG EXPOSURE START DATE

Symmetric Measures

	Cramer's V	0.9708237	0
N of valid cases		1974	

The Cramer's V value measures the strength of the association between two categorical variables. The value of Cramer's V in this test is 0.74 which implies that there is a strong association between the type of hospital visit and the type of drug administered, as shown in Table IV.

TABLE IV. ASSOCIATION BETWEEN THE TYPE OF HOSPITAL VISIT AND THE TYPE OF DRUG ADMINISTERED

Symmetric Measures			
		Value	Approximate Significance
Nominal by Nominal	Phi	1.6622077	0
	Cramer's V	0.7433619	0
N of valid cases		1974	

The Cramer's V value measures the strength of the association between two categorical variables. The value of Cramer's V in this test is 0.18 which implies that there is a weak association between the gender of a patient and the type of hospital visit, as shown in Table V.

TABLE V. ASSOCIATION BETWEEN THE GENDER OF A PATIENT AND THE TYPE OF HOSPITAL VISIT

Symmetric Measures			
		Value	Approximate Significance
Nominal by Nominal	Phi	0.1789966	0
	Cramer's V	0.1789966	0
N of valid cases		1974	

### B. Discussion

The preferred spelling of the word "acknowledgment" in America is without an "e" after the "g". Avoid the stilted expression "one of us (R. B. G.) thanks ...". Instead, try "R. B. G. thanks...". Put sponsor acknowledgments in the unnumbered footnote on the first page.

Results from the data analysis show that patients 737, 1234 and 64 are among the patients who most affect the distribution of age. When we look at the purpose of the hospital visit, the visits derived from HR record, long term care visit and outpatient visits most affect the distribution of gender versus age at 10.9%, 1.4% and 10.6% of records respectively. Among the drug concept names, Dexpanthenol and Atorvastat are the drugs that most affect the distribution of the age and gender.

As for the Cohort start dates, Monday, March 10, 2014, with 12.6% of records; Thursday, August 4, 2016, with 13.8% of records and Saturday, December 27, 2014, with 8.1% of records, among others, most affect the distribution of gender and age. Among the ingredient concepts, Carvedilol, Furosemide and Atorvastatin most affect the distribution of gender and age comparison at 1.2%, 2.6% and 1.4%, respectively.

The year 2015 seems to have the oldest patients at the drug exposure end date at an average of 76 years old. There was a 2.39% increase in the average age of all patients between 2014 and 2015. An analysis of drug concept versus age compared by year shows that 0.5 ML pneumococcal had the most significant impact on the increase among drug concept names. Glucose, Omeprazole and Sennosides had the most significant impact on the increase among ingredient concept names.

Thursday, May 1, 2014, had the most significant impact on the increase among drug exposure start date. The visits derived from EHR record make up 10.9% of all patients followed closely by outpatient visits at 10.6%. Women are the majority at 52% of all the patients. Most females' visit was derived from EHR record while majority of the males visited the hospital for outpatient services.

There is a statistically significant relationship between the cohort start date and the drug exposure start date. The p-value is less than 0.05 and we therefore reject the null hypothesis and conclude that there is an association between the cohort start date and the drug exposure start date. The Cramer's V value measures the strength of the association between two categorical variables. The value of Cramer's V in this test is 0.97 which implies that there is a strong association between the cohort start date and the drug exposure start date.

There is a statistically significant relationship between the type of hospital visit and the type of drug administered. The p-value is less than 0.05 and we therefore reject the null hypothesis and conclude that there is an association between the type of hospital visit and the type of drug administered. The value of Cramer's V in this test is 0.74 which implies that there is a strong association between the type of hospital visit and the type of drug administered.

There is a statistically significant relationship between the gender of a patient and the type of hospital visit. The p-value is less than 0.05 and we therefore reject the null hypothesis and conclude that there is an association between the gender of a patient and the type of hospital visit. The value of Cramer's V in this test is 0.18 which implies that there is a weak association between the gender of a patient and the type of hospital visit.

#### IV. CONCLUSION

In conclusion, it is clear that there is a statistically significant association between several variables in our sample data. For instance, there is a fairly strong association between the type of hospital visit and the type of drug administered, which could imply that doctors prescribe medicine based on the type of visit to the hospital by the patient. However, it is worth noting that correlation or association between two variables does not imply causality and we recommend further research to delve deeper into the insights garnered by this study.
