Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Deep Neural Network-based Methods for Brain Image De-noising: A Short Comparison

Keyan Rahimi[1], Noorbakhsh Amiri Golilarz[2]

Department of Computer Science, Brown University, Providence, RI 02912, USA [1]
Department of Computer Science and Engineering, Mississippi State University, Mississippi State, MS 39762, USA [2]

***Abstract*—Various types of noise may affect the visual quality of images during capturing and transmitting procedures. Finding a proper technique to remove the possible noise and improve both quantitative and qualitative results is always considered as one of the most important and challenging pre-processing tasks in image and signal processing. In this paper, we made a short comparison between two well-known approaches called thresholding neural network (TNN) and deep neural network (DNN) based methods for image de-noising. De-noising results of TNNs, Dn-CNNs, Flashlight CNN (FLCNN) and Diamond de-noising networks (DmDN) have been compared with each other. In this regard, several experiments have been performed in terms of Peak Signal to Noise Ratio (PSNR) to validate the performance analysis of various de-noising methods. The analysis indicates that DmDNs perform better than other learning-based algorithms for de-noising brain MR images. DmDN achieved a PSNR value of 29.85 dB, 30.74 dB, 29.15 dB, and 29.45 dB for de-noising MR image 1, MR image 2, MR image 3 and MR Image 4, respectively for a standard deviation of 15.**

Keywords—*CNN; Deep neural network; de-noising; MR image; PSNR*

I. Introduction

Noise is considered as unwanted signals causing imperfections and low resolution in image and signal processing, and may happen during the receiving and transmitting processes. Thus, further image analysis and processing may not be possible until we discard or reduce the noise in the images. In image de-noising, the main goal is enhancing the visual quality. Various methods are available in literature for removing the possible noise from images.

Donoho and Johnstone proposed adapting to unknown smoothness [1] and ideal spatial adaptation [2] using wavelet shrinkage for de-noising in 1994 and 1995, respectively. These techniques became the foundation for further gradient descent learning based methods. Zhang took one step forward in de-noising by proposing a learning-based method for improving the conventional approaches [3]. He developed a thresholding neural network using an improved and non-linear hard-soft threshold function. Sahraeian et al., proposed an improved TNN and cycle spinning for image de-noising [4]. Nasri and Nezamabadipour tried to improve Zhang's results by proposing another data driven function with three shape tuning parameters [5]. To enhance the results of TNN based methods, instead of using gradient descent algorithm, the authors in [6] proposed an optimized based technique.

Although the results were satisfactory, the researchers did not want to stop at this stage, and they wanted to go beyond the conventional gaussian denoisers. In this regard, convolutional neural networks are widely used in image processing due to their excellent performance for obtaining high quality output images. Jian and Seung developed a combined CNN with unsupervised learning for natural image de-noising [7]. Vincent et al. developed a new training principle for unsupervised learning and it became one of the basic deep learning techniques for noise removal aspects [8]. While using deep convolutional neural networks there is an issue in which we cannot train deeper networks easily. To address this problem, Mao et al. proposed symmetric skip connection combined with auto-encoders [9]. Zhang in [10] proposed a Dn-CNN method consisting of two main stages, residual learning and batch normalization. Deeper networks also cause gradient dispersion in which residual learning has been utilized in Dn-CNNs to tackle this issue [11]. There are also some other issues which deep neural network-based methods are suffering from. One is diminishing feature reuse, and the other is that increasing the number of parameters and layers does not have any advantage for them [12]. To address these issues Bin et al. developed a flashlight CNN method based on deep residual and inception networks that is able to hold many parameters [12]. Additionally, J. Zhang in [11] developed a diamond denoiser to deal with the issue of losing network's gradient caused by deeper networks.

A self-supervised based method for fluorescence image denoising has been proposed by Huang et al., [16]. In this approach, the authors utilized Wiener filtering and wavelet transformation, as two classic denoising techniques as well as DeepCAD to perform comparative experiments [16]. In another study conducted by Yang et al. [17], an efficient auto-encoder technique using convolutional neural networks to perform both classification and de-noising has been developed.

Content-noise complementary learning has been presented in [18] to denoise medical images. In this study to validate the performance of various de-noising methods, MR, CT, and PET images have been utilized. Structural priors based deep MRI super resolution has been developed in a study conducted by Cherukuri et al., [19]. Low rank structure and sharpness priors have been utilized in this study to enhance the visual quality of images. Convolutional de-noising autoencoders to discard noise from MR images has also been proposed in [20]. This technique provided better accuracy with less computation and data for de-noising the medical images.

In this paper we have a brief survey on several state-of-the-art de-noising approaches. We analyzed the results for MRI brain image de-noising. Thresholding neural networks, Dn-CNNs, Flashlight CNNs, and Diamond de-noising networks have been taken into account. The results indicate that deep neural network based methods have superior results compared to TNN based techniques. Among these deep neural network based approaches, Diamond de-noising networks (DmDN) perform well, followed closely by FLCNN, and DnCNN.

The rest of the paper is organized as follows: Section II is about CNN based image de-noising. A brief discussion about CNNs and how to perform CNN based de-noising has been provided. In Section III, we discuss image de-noising using thresholding neural network. In Section IV, we discuss several deep neural network methods. Section V is results and discussion. Finally, Section VI concludes the paper.

II. De-noising Using CNN

Sitting as a contrast from more traditional methods, convolutional neural networks can be used to great effect on de-noising images. CNNs have been the neural network of choice in the field of image processing due to their high effectiveness and can also be used when de-noising. These networks use their convolutional layers. There are multiple different methods regarding deep learning, but the ones that we discuss in this paper are feed-forward convolutional neural networks (DnCNN) and flashlight CNNs (FLCNN).

In order to de-noise an image, CNNs traditionally require a large training sample size, and learns by training with input-output pairs, images of noisy scans, followed by its clean variation. The network learns kernels through its convolutional layers, small weights that can detect patterns over the input image. The convolutional layers create a hierarchical representation of the input and can use this separation to learn to differentiate between the noise and the features of an image. Non-linear activation functions are then applied for complexity, and the network's outputs are compared to the actual clean image through a loss function, where it can adjust and try again. After much iteration, it then is tested on new images that have had Gaussian white noise added to them, tasking the CNN to de-noise the image [22].

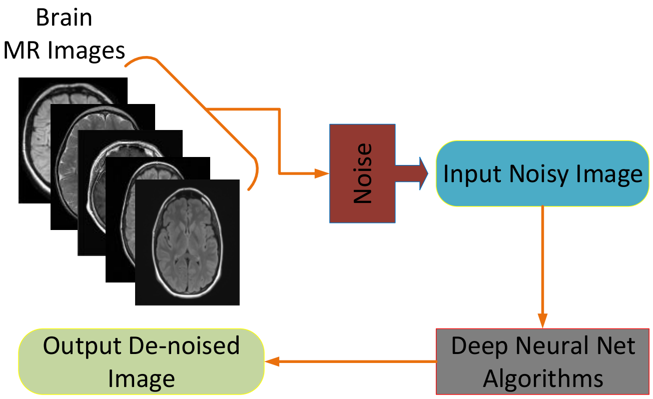

Fig. 1. The procedure of deep learning-based de-noising.

One of the methods we discuss however uses a deep feed-forward network, which can not only learn with overall smaller sample sizes but uses residual learning. It trains on images that already have noise and learns from it, working along with batch normalization in order to increase its accuracy [23]. In the case of the flashlight CNN, it uses a very similar strategy, while also using inception layers that help the network better handle Gaussian white noise. Fig. 1 shows the main procedure of de-noising using learning based approaches. Images have been obtained from [21].

III. TNN Based Methods

Standard hard and soft thresholding functions were first proposed in [3]. In this case, these functions became the basis and foundation of further thresholding based de-noising. Since the obtained results using these functions were not satisfactory, the researchers in the fields of image and signal processing attempted to enhance these methods and add more parameters to make them non-linear and differentiable to be used in a network called, “thresholding neural network’’. These functions which are the enhanced version of standard thresholds are called “improved thresholding functions’’ which were first introduced by Zhang [3]. The equations below indicate these improved soft and improved threshold functions:

$$L_{soft}(u,\tau) = u + \frac{1}{2}(\sqrt{(u-\tau)^2 + l} - \sqrt{(u+\tau)^2 - l}) \tag{1}$$

where, $L_{soft}(u,\tau)$ denotes the non-linear soft threshold, u is the WT components, τ is the threshold value and $l > 0$ is a function parameter (user defined) [3].

$$L_{hard}(u,\tau) = \left(\frac{1}{1+\exp\left\{\frac{-u+\tau}{\psi}\right\}} - \frac{1}{1+\exp\left\{\frac{-u-\tau}{\psi}\right\}} + 1\right)u \tag{2}$$

where, $L_{hard}(u,\tau)$ denotes the non-linear hard threshold, u is the WT coefficients, τ is the threshold value and $\psi > 0$ is a fixed function parameter (user defined) [3].

Although these functions have been used in various studies for image denoising, the results have not been quite satisfactory and there is some space for improvement. Thus, another nonlinear and differential threshold function has been presented by Sahraeian [4] as shown by Eq. (3). This function has been inspired by Zhang’s improved hard threshold function.

$$L_S(u,\tau) = \begin{cases} m(e^{n|u|} - 1).\mathrm{sgn}(u) \quad , & |u| \le \tau \\ (|u| + he^{-n|u|}).\mathrm{sgn}(u), & |u| > \tau \end{cases} \tag{3}$$

where, $L_S(u,\tau)$ is the Sahraeian’s nonlinear threshold, n controls the function’s shape and refers to the thresholding effect’s degree. Additionally, parameters m and h are used to preserve the continuity and derivative at τ [4].

The researchers did not want to stop here, and they moved forward to present a function with more flexibility and capability. Thereafter, Nasri and Nezamabadi-pour [5] presented other nonlinear functions with three shape tuning parameters which are formulated.

$$\Gamma(u,\tau,i,j,g)=\begin{cases} u - 0.5\dfrac{\tau^{i}\times g}{u^{i-1}}+(g-1)\tau \quad , & |u|>\tau \\ 0.5\dfrac{g\times|u|^{j}}{\tau^{j-1}}\operatorname{sgn}(u) \quad , & |u|\le\tau \\ u+0.5\dfrac{(-\tau)^{i}\times g}{u^{i-1}}-(g-1)\tau \ , & |u|<-\tau \end{cases} \tag{4}$$

where, τ is the threshold value, u denotes the WT coefficient, i and j controls the function's shape, and g calculate the asymptote of the function [5]. For further details and information about the structure of TNN and WT based de-noising, please refer to [3].

IV. Deep Learning Based Methods

A. *DnCNN*

Nowadays, due to the availability of large-scale datasets and progress in deep learning algorithms, CNN approaches attract lots of attention in imaging technologies [10]. The construction of feed-forward convolutional neural networks (DnCNNs) for de-noising has become the basis for de-noising using deep learning [10]. In this structure, to improve the computational time and also to enhance the quality of the de-noised image, batch normalization and residual learning have been utilized, leading to this approach becoming one of the more efficient and effective gaussian denoisers. Conventional deep NNs can estimate a clean image directly, but DnCNNs can remove and discard the clean image by adapting it to the residual learning strategy [10]. Training a single DnCNN as a blind gaussian denoiser gives better results compared to alternative methods. As mentioned earlier, residual learning and batch normalization are used in this structure. Residual learning has been utilized for solving performance degradation issues [14].

The developed DnCNN utilizes only one residual unit for predicting the residual image [10]. If we compare residual mapping with the original unreferenced mapping in terms of learning, residual mapping is easier, so deep CNN models can be trained easily [14] [10]. On the other hand, although training based on stochastic gradient descent (SGD) is effective and simple, internal covariance shifts can largely reduce the training efficiency [15] [10]. So, alleviating the covariance shift is also a challenging task in deep CNN models and is the reason that batch normalization is used in these networks [15] [10]. The combination of residual learning and batch normalization provides us with stable training, fast training procedure (because of using batch normalization), better qualitative and quantitative results [10]. The main structure of the DnCNN model is depicted in Fig. 2.

As can be seen, the network's input is a noisy image corrupted by gaussian noise. Here, instead of learning a mapping function, we can proceed by adapting residual learning for training the residual mapping [10]. Additionally, in the proposed network with depth *D*, there are three types of layers [10]:

- Conv+ReLU is used for the first layer with 64 filters with the size 3×3×c. Note that *c* is the channels' number. Also, ReLU has been utilized to give nonlinearity.
- Conv+BN+ReLU is used from layer 2-D-1 with 64 filters of size 3×3×64. Batch normalization (BN) has also been used in these layers.
- Conv is utilized in the very last layer with c filter of size 3×3×64 for reconstructing the output image.

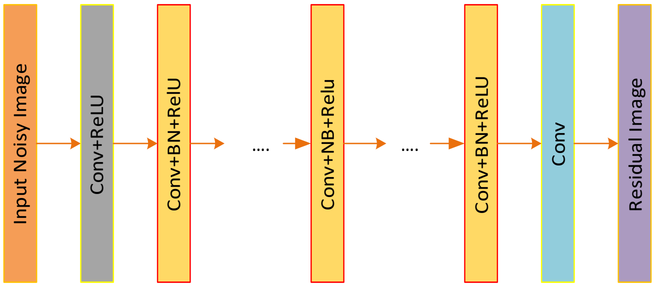

Fig. 2. The structure of DnCNN [10].

B. *Flashlight CNN (FLCNN)*

Flashlight CNNs are another type of convolutional neural network implementing deep NN for noise removal processes. The main structure of this method is based on the combination of deep residual and inception networks [12]. Utilizing inception layers provides us with overcoming and addressing the reuse of diminishing features while tackling additive white gaussian noise. As shown in Fig. 3, this network consists of two main phases [12]:

- Warmup phase which utilizes convolutional layers (typical or conventional CNN). There are two main stages in this phase. The first one employs 3×3 kernels with 64 features and the second one employs 5×5 kernels with 64 features.
- Boost phase utilizes wider inception layers (residual) leading to growth and increment in the number of networks' parameters while overcoming the reducing feature reuse.

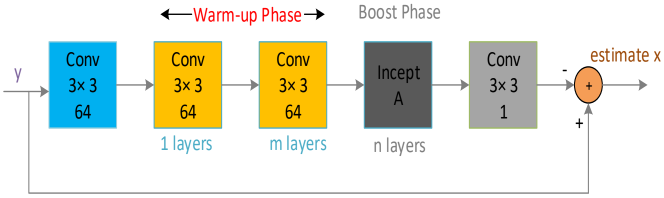

Fig. 3. The architecture of FLCNN with noisy input of *y* and estimate *x* [12].

C. *Diamond De-noising Network (DmDN)*

Images' detail and important characteristics and information may be diminished by doing excessive scaling [11]. Although the convolutional network is deeper, it may be easy to lose the gradient of the network. To address these issues, Diamond Shaped (DS) multi-scale feature extraction has been utilized in this network to extract the information of the images' features [11]. This fixed scale-based network is called a Diamond De-noising network (DmDN) [11]. This network contains three main parts as below [11]:

- Feature extraction of input noisy images.
- Feature extraction of multi scales.
- Clean image reconstruction or output image.

V. Results and Discussions

In this part, we have performed two experiments to validate the efficiency of various de-noising methods. Note that the images have been contaminated by additive white gaussian noise (AWGN) with zero mean and different standard deviations. For TNNs we used "sym4" with one decomposition layer. The training parameters are available in [11] and are the same as the original works used in this study. Axial DWI brain imaging obtained from [13] is used in the experimental part. We have used four single images at various moments of the original data (see Fig. 4). The de-noising results in terms of PSNR values for various standard deviations are shown in Table I. As neatly shown, DmDNs perform better than other de-noising approaches as it achieved the highest PSNR values. The results indicate that deep learning-based techniques outperform TNN models for de-noising MR Images.

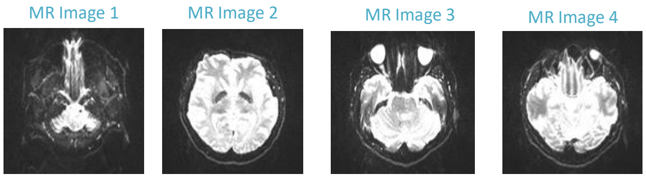

Fig. 4. Four test single images [13].

TABLE I. Denoising Comparison of Various Learning Approaches in Terms of PSNR Values (dB)

MR Images	**sigma**	**TNN-Zhang**	**TNN-Nasri**	**Dn-CNN**	**FLCNN**	**DmDN**
MR Image 1	15	24.02	24.23	29.72	29.83	**29.85**
	25	21.98	22.14	27.23	27.36	**27.47**
	50	19.45	19.54	24.25	**24.47**	24.46
MR Image 2	15	24.65	25.16	30.61	30.72	**30.74**
	25	22.75	23.11	28.42	28.59	**28.62**
	50	19.86	20.10	25.44	25.61	**25.64**
MR Image 3	15	23.78	24.10	29.01	29.11	**29.15**
	25	21.83	22.05	26.84	27.01	**27.06**
	50	19.53	19.78	24.03	24.24	**24.29**
MR Image 4	15	24.01	24.31	29.33	29.41	**29.45**
	25	21.45	22.14	27.01	27.14	**27.17**
	50	19.20	19.84	23.84	24.02	**24.09**

In the next experiment we utilized another data set obtained from Kaggle [21] to compare the performance of various deep neural net based approaches quantitatively. Some of these images are depicted in Fig. 5. In this experiment, as can be seen from Fig. 6, we compared DmDn, FLCNN, DnCNN, TNN-Nasri and TNN-Zhang over several standard deviations. The results indicate that the first three deep learning methods perform well in de-noising brain MR images. Among the first three neural net approaches, DmDn outperforms the others. Although these methods perform well in de-noising MR Images, they may not work perfectly for other types of datasets such as hyper-spectral remote sensing and standard test images or even if we apply other types of noise and perturbations.

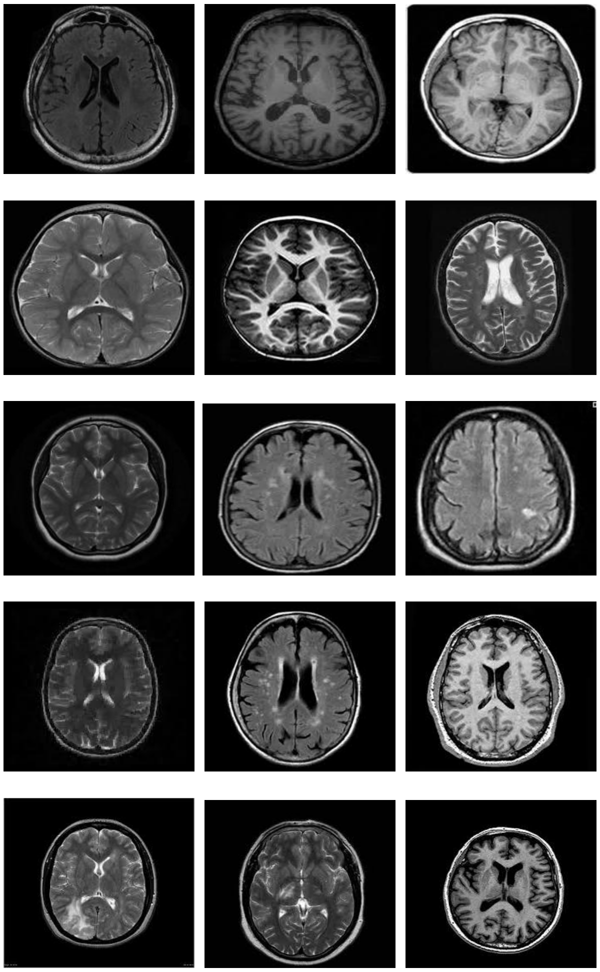

Fig. 5. Some of the brain MR images used in the experimental part [21].

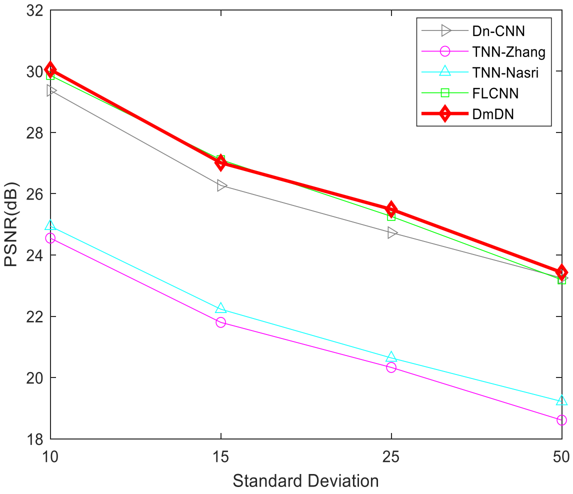

Fig. 6. Comparison of performance analysis of various learning algorithms for different standard deviations.

VI. CONCLUSION

Images may be influenced by many types of noise, leading to a decrease in their visual quality. Trying to find a suitable de-noising method for discarding this noise has always been categorized as a challenging task for researchers in the fields of signal and image analysis. This work provides a survey and comparison between several learning based de-noising methods such as TNNs, Dn-CNNs, Flashlight CNNs (FLCNN) and Diamond de-noising networks (DmDN) in terms of PSNR values. The quantitative results indicate that DmDN can be a promising method for brain MRI de-noising as it achieved the highest PSNR values for de-noising MR images 1-4 for a standard deviation of 15. In this study we have used AWGN, and we realized that increasing noise level decreases PSNR values. For future work, we will analyze the performance of some state-of-the-art methods in the presence of various types of noise.

Abstract*—The Internet of Things (IoT) has gained momentum across various sectors, particularly in the consumer market with the adoption of smart devices. IoT extends internet connectivity to physical devices, enabling control via smartphones, environmental sensing, and updates. However, smart home devices are susceptible to cyberattacks due to vulnerabilities, lack of monitoring, and built-in security. They can also participate in botnets, leading to large-scale attacks. Vulnerabilities in these devices may exist at the sensing, network, or application layers, impacting data confidentiality, integrity, and service availability. This research aims to identify network-layer vulnerabilities affecting the 'Availability' of Philips Hue and Nest Protect. By establishing a test environment, the baseline behavior of these devices is examined, followed by scans for open ports and services to detect network-based threats. Volumetric flood attacks are then conducted to assess susceptibility, and findings are shared to define the devices' default security posture. The research also addresses security issues related to home routers and aims to reduce the attack surface of smart home devices through isolation and network-level protection. This involves deploying a Firewall to isolate smart devices from non-IoT devices and prevent intrusions.

I. INTRODUCTION

The Internet of Things (IoT) has been an important technological revolution that has enabled the emerging Industry 4.0 [1]. By extending the capabilities of physical devices used in our daily life to the Internet, IoT, with the use of standard Internet Protocols, has allowed communication between humans and things [2], [3]. Smart devices are context-aware, perform autonomous computing, and connect using wired or wireless mediums [4]. Since these devices carry out only a limited set of tasks, they have low hardware specifications [5]. Some smart devices require intermediate nodes to communicate on the internet. Owing to these reservations, smart devices use lightweight communication methods and lack complex built-in security schemes [6].

In a smart home, internet connectivity is extended to consumer appliances [7] such that human–device communication can occur seamlessly. For example, the Philips Hue smart lights can be controlled using a smartphone, and the Nest Protect alerts the user whenever smoke is detected [8], [9]. Smart Home Devices (SHDs) have gained immense popularity and have become an important part of modern living. In 2019, an estimated 8.6 billion devices were connected worldwide [10] and this number is expected to increase to 29.4 billion by 2030. The worldwide unit shipments of SHDs for 2021 were nearly 900 million [11], [12], [13]. While one set of statistics shows how popular SHDs are becoming, another set of statistics questions how secure these devices are. In 2022, the worldwide annual number of IoT-related cyberattacks amounted to 112 million [14].

Security is a vital requirement for all communication systems. Numerous security solutions that have evolved have focussed only on traditional computing. SHDs are the least secure of internet hosts [15] and both their widespread growth and heterogeneity have opened new and significant attack surfaces [16], [17]. Hence, the security of IoT devices is more critical than that of traditional computing devices [2], [18]. As in [19] cautioned, a compromise in SHD security not only affects the digital world but can also have serious implications in the physical world, causing harm to people.

In an enterprise, the complex task of monitoring and managing both IoT and non-IoT devices is handled by automated solutions and dedicated technical staff. In contrast, the security responsibility of a smart home falls on the user. Unfortunately, many consumers lack awareness about the potential risks these connected devices can cause and fail to implement adequate security measures [20]. Furthermore, many manufacturers of consumer network devices may not find an incentive to release frequent updates and patch vulnerabilities [21]. These gaps form the primary motivation to conduct this research and find out whether the devices we use have vulnerabilities. Hence, this research aims to secure two SHDs – the Philips Hue Smart Lighting and the Nest Protect Alarm.

The commonly prevalent security issues are highlighted by foundations such as the OWASP [22] and recommendations are provided by institutions such as the UK Government, ENISA, and the ETSI [23], [24], [25]. However, owing to inexperience in Cybersecurity and lack of security-focussed development, manufacturers still flood the market with insecure devices. For example, the DDoS attack against Dyn, in 2016, was conducted using compromised consumer IoT devices. This suggests that vulnerabilities in a SHD, when not addressed, can turn it into digital weapon [26].

Davis et al. [27] categorize SHD vulnerabilities as Physical, Network, Software, and Encryption. While software and encryption related vulnerabilities are more manufacturer-centric, this research focuses on the network-level vulnerabilities. It is a cause for great concern that SHDs lack security standards and that vulnerabilities get exposed only during usage. It is imperative to perform vulnerability assessments of SHDs and identify network insecurities. Two studies have assessed the security posture of both the Philips Hue and the Nest Protect and have provided security ratings [20], [28]. Both Copos et al. [29] and Yadav et al. [30] have conducted a traffic analysis of the Nest Protect. The first objective of this research is to setup a test network to assess the network insecurities in the Philips Hue and the Nest Protect. Based on the vulnerabilities identified, attacks are launched against the devices and the responses are recorded. This forms the second objective of this research.

A typical Smart Home follows a flat network architecture – both IoT and non-IoT devices are on the same subnet served by a home Gateway. It is highly possible that such a coexistence may open new avenues for cyberattacks [31]. In addition, the home Gateway is the most compromised device and its services may increase the attack surface [15]. Hence, this research also discusses vulnerabilities in the home Gateway and how those could increase the risk factor.

Generally, devices in a traditional network are secured using three approaches namely: 1) device-level protection, 2) isolation, and 3) network level protection. Unlike computers, SHDs lack power and computing resources to apply device-level protection [31], [32]. Considering the lack of first-line defence mechanisms, the third objective of this research is to apply a second line defence mechanism. The research proposes that by isolating the SHDs and applying network-level protection, the attack surface can be reduced. Studies suggest that Firewall, IDS, and IPS as solutions to the threats occurring at the network layer [33], [34]. A security solution that both acts as a Firewall and that has the capability of an IPS is deployed. The objective is to segregate devices into separate zones and by apply access rules such communications among the IoT and non-IoT devices are curtailed. Tests are performed to validate if the artefact could successfully reduce the attack surfaces of the SHDs.

II. Background Information

The OWASP Project provides an overview of the top 10 security issues [22] found in IoT. This can be taken as a guideline to assess the type of insecurities found in SHDs. Especially, insecure network services that is ranked as a serious security issue pertains to the unneeded or insecure services in the device. Such a vulnerability can impact Confidentiality, Integrity, and Availability.

itaThreats to SHDs need not always arise from the internet; As proved by Chan et al. [35] a threat actor who has access to the internal network can misuse a vulnerability for larger attacks. As pointed out by Loi et al. [16], lack of vigour in fixing vulnerabilities in devices, lack of awareness among consumers about potential risks, and lack of network isolation or separate security solutions in home networks are seen as incentives by threat actors. With access to LAN, malicious actors may not only fingerprint every device using tools but also launch passive or active attacks.

The first aspect of this research is focussed on analysing the network-level vulnerabilities in Philips Hue Smart Light and Nest Protect Smoke Alarm. The work of Loi et al. [16] informs that both the Hue Light and the Nest Protect have open TCP and UDP ports and that the Hue Light is more vulnerable. In the case of Philips Hue, the authors indicate that the open TCP port 80 is the vulnerable port. This claim is further supported by CVE-2018-7580 [36] that a SYN-Flood DoS can result in an consume resources of the Philips Hue in an uncontrolled manner, resulting in unavailability of service. The SYN-Flood which is a Protocol based attack exploits the TCP 3-way Handshake by flooding the endpoint with excessive SYN packets. When the OS exceeds the threshold of concurrent connections it can maintain, it denies access to TCP services [37].

Network tools such as ‘hping3’ aid in generating large number of packets against a target [38], and when proper security measures are not employed, such floods result in unavailability of service – in this case a user may not be able to switch on/off the smart lights. Although the vulnerable TCP port 80 was reported for SYN-Flood, what other forms of attacks or information can be gathered from this open port is question that needs to be addressed. TCP port 80 falls under the well-known ports category [39], denoting that a server providing http service is listening on this port. Hence, this vulnerability not only allows a threat actor to conduct a Protocol DoS but also an Application Layer DoS against the device.

In the case of Nest Protect Smoke alarm, Loi et al. [16] state that numerous UDP ports in the ‘registered ports’ category remain open. Their work does not provide specific information about these ports and the functions. This research includes finding more information about those open ports and other direct flood attacks that impact the Nest Protect.

Although identifying open ports in each SHD provides information about the associated protocol and service, this process must be augmented with the capture the network traffic. This is the second aspect of this research. Capturing network traffic with packet sniffing tools such as Wireshark provides more insights. By studying the ingress and egress traffic of the devices, one can chart out not only the device, domains, and services contacted but also the frequency of such conversations. This research involves capturing traffic for both the Philips Hue and the Nest Protect and presents the baseline behaviour of these devices.

The third aspect of this research discusses about the impact of SHD vulnerabilities on a network, in general. As mentioned in the first paragraph, typically, home networks are ‘flat networks’ without any segmentation or isolation. This model in which traditional computers coexist with SHDs only increases security concern. Without isolation a compromised device can inflict damage on other IoT and non-IoT devices. Hence, this research proposes a solution that applies not only for the Philips Hue and the Nest Protect, but also for SHDs in general. By identifying vulnerabilities, understanding network traffic patterns, and by isolating IoT devices and applying a firewall the attack surface can reduced.

III. Examine, Attack, and Implementation

This research aims to identify network-layer vulnerabilities affecting the 'Availability' of Philips Hue and Nest Protect. The objective of this study is to evaluate the security of the Philips Hue smart light system and the Nest Protect smoke detector alarm as network-connected devices. The research begins by examining these devices using open-source tools to identify vulnerabilities and understand how they impact the devices' services and other connected devices. By using Philips Hue and Nest Protect as case studies, this study seeks to provide insights into the broader challenges of securing smart home devices in networked environments.

The Philips Hue Bridge version 2.1 functions on Mains power supply, connects to the network using Ethernet, and communicates with bulb using Zigbee protocol [36]. The Nest Protect is a second-generation smoke alarm that is powered by batteries, connects to the network using the IEEE 802.11 b/g/n 2.4GHz Wi-Fi standard, communicates with smartphones using BLE, and exchanges information with other connected Nest products using the IEEE 802.15.4 2.4 GHz standard [8].

The heterogeneity of IoT devices is quite evident that the SHDs used in this research vary in terms of power and communication technologies. Such heterogeneity, consequently, has a bearing on the lab network setup used for assessing the SHDs. For security reasons, the lab setup uses dedicated desktop, laptop, and networking devices.

A. *Examining the Philips Hue Smart Lighting*

As shown in Fig. 1, the TP-Link Archer C60 wireless router acts as a gateway and leases IP addresses. The TP-Link TL-SG108E switch has built in functionality for port mirroring and is used for traffic capture. Kali Linux 2023.2 which has the tools to examine the Hue Bridge is installed on the Raspberry Pi 4B. The Hue App to control the smart bulbs is installed on an iPhone 6s running iOS 15.7.x. Devices that require authentication are configured with a 12-character password that includes uppercase and lowercase characters and numbers.

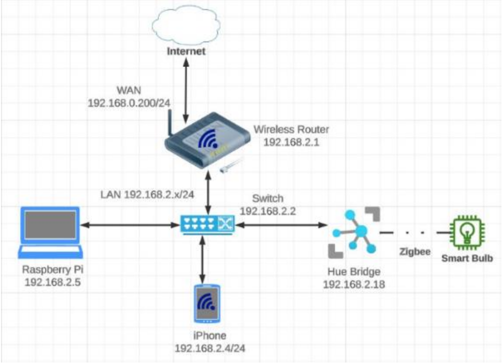

Fig. 1. Network setup – hue port scan and packet capture.

From the Raspberry Pi, a subnet scan was conducted. The network ports that are open in each of the five devices mentioned above are listed. TCP ports 80, 443, and 8080 are open in the Hue Bridge. Using the Nmap scan options -sS and -sT, a TCP SYN and TCP Connect scans are conducted. Using the -p switch, ports 1-65535 were scanned. Results show the same set of open TCP ports as the subnet scan. Further investigation carried out using an Nmap command with switches -sC -sV -O against the Hue reveals the 'Service' listening on the open TCP ports. As opposed to the SYN and Connect scan, the Fingerprint scan includes only the 1000 most popular ports. A web server is listening to TCP port 80, 443, and 8080. Out of these three open ports, 80 and 8080 use the plaintext HTTP whereas 443 uses SSL – a protocol that uses encrypted link between the client and the web server [37].

All the above scans have listed information only about the TCP ports. However, UDP based open may also be employed in this device. To find the open UDP ports we conduct a UDP scan using Nmap with the -sU switch. UDP scans can be very slow, scanning 65535 ports took around 18 hours. The UDP scan reveals three more open ports (1900, 5353, and 5540).

B. *Examining Network Behaviour of the Philips Hue Smart Lighting*

Taking advantage of port mirroring, ingress and egress traffic of the Hue Bridge was captured using both TCPDump and Wireshark. Traffic was captured based on 4 scenarios – 1. Powering on the Hue Bridge, 2. Idle Operation for 60 minutes, 3. Switching ON/OFF the bulbs using Wi-Fi, and 4. Switching ON/OFF the bulbs using 4G mobile data.

As the Hue Bridge begins to operate, it contacts the domains, almost all the domains/services are Cloud-based services hosted by AWS, Google Cloud, and Alibaba Cloud. The packet capture was repeated on different days, and it was observed that although the domains contacted were the same, the Public IP Addresses of those providers did not remain a constant. Although this observation did not hold for all the services hosted on Google Cloud, it holds true for services hosted on AWS.

HTTP traffic was found only at two instances 1) During the initial pairing between the Bridge and the smartphone and 2) At regular intervals between the Bridge and the domain www.ecdinterface.philips.com. Investigating the HTTP traffic between the Hue Bridge and the Cloud-service, reveals the type of device, its MAC address, and Public Key details. This is seen as a vulnerability as this can be of value to a malicious actor eavesdropping on the network.

C. *Vulnerabilities of the Philips Hue Smart Lighting*

As discussed above, the Philips Hue has TCP ports 80, 443, 8080 and UDP ports 1900, 5353, and 5540 open. The number of open ports may signify more vulnerabilities, resulting in an increased the attack surface. Loi *et al.* [16] in their research have stated that TCP port 80 in the Hue is vulnerable, and from CVE-2018-7580 [36] it is evident that a SYN-Flood against port 80 render the Hue unresponsive.

The SYN Flood is a technique that misuses the TCP 3-way handshake by sending large amounts of SYN packets to an endpoint. The device responds to each SYN packet and keeps waiting with open connections expecting a graceful connection closure. On the contrary, the closure may not arrive, resulting in exhaustion of resources and denial of new connections.

We have also validated this technique by creating test environment that includes three virtual computers running Kali Linux, Ethernet Switch that supports Port Mirroring, Hue Bridge, and the smartphone with the Hue App (see Fig. 2).

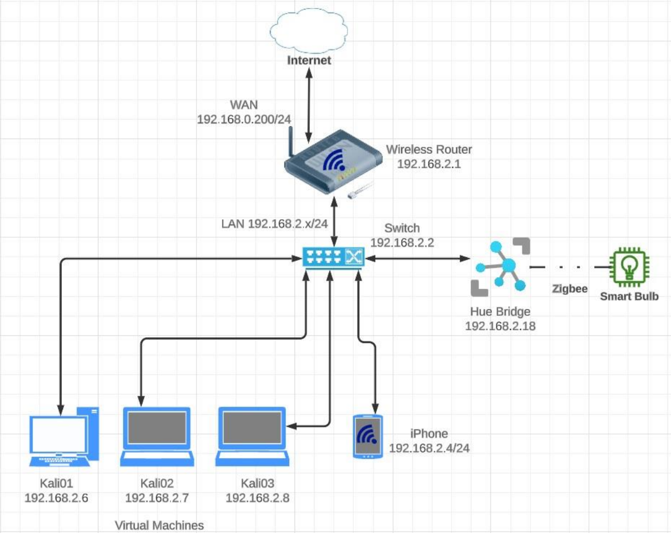

Fig. 2. Lab setup for DoS attack.

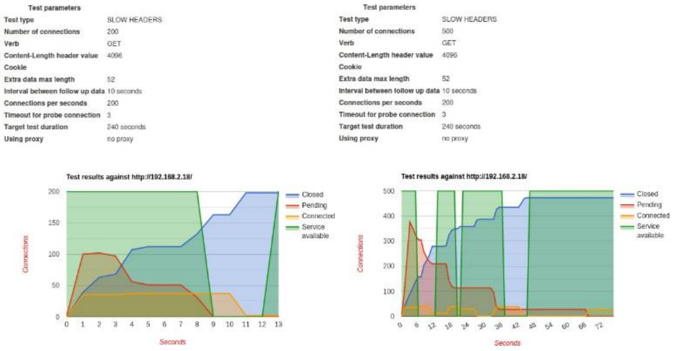
It is interesting to note that the first two sets of SYN-Floods which had a count of 500 and 750 from each machine did not have any effect. Despite the excessive amount of traffic, the Bridge and Hue App continued to remain functional throughout the test. However, in the case of the third test in which the count was raised to 1000, the impact rendered the service unavailable.

Two sets of SYN-Flood from each virtual machine was launched against TCP port 8080. However, there was no impact on the 'Availability' of the service. This proves that, with respect to SYN-Floods, TCP port 8080 is indeed the vulnerable port (Loi et al., [16]). Additionally, Hue can be subjected to HTTP and ICMP attacks. 'SlowHTTPTest' is a tool that simulates Application Layer DoS attacks and is part of Kali Linux. Using this tool two DoS attacks with 200 and 500 connections were launched, both tests disrupted the availability of the service (see Fig. 3).



Test parameters

Test type	SLOW HEADERS
Number of connections	200
Verb	GET
Content-Length header value	4096
Cookie	
Extra data max length	52
Interval between follow up data	10 seconds
Connections per seconds	200
Timeout for probe connection	3
Target test duration	240 seconds
Using proxy	no proxy

Test parameters

Test type	SLOW HEADERS

Interval between follow up data	10 seconds
Connections per seconds	200
Timeout for probe connection	3
Target test duration	240 seconds
Using proxy	no proxy

Fig. 3. DoS attack results.

An important observation that has not been mentioned in research articles is that the Hue Bridge suffers from ICMP Flood. Three sets of ICMP Flood tests were conducted from the virtual machines and the service was unavailable during each test. Loi et al. [16] state that the Hue Bridge remains protected from ICMP DoS. However, the test result shows that the impact of ICMP flood is worse compared to SYN and HTTP Floods.

D. *Examining Nest Protect Smoke Alarm*

In contrast to the Hue Bridge, the Nest Protect uses Wi-Fi and not Ethernet. Hence to address this the lab setup was changed to conduct the Port Scans and Traffic Analysis. As shown in Fig. 4, the Raspberry Pi was used as a Wi-Fi Access Point to which the Alarm and the smartphone connect. With this setup, traffic passing through the WLAN adapter can be captured.

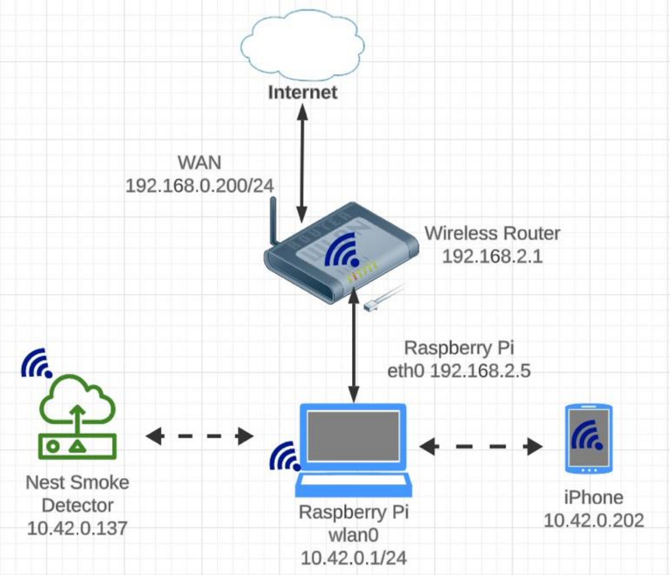

Fig. 4. Lab setup for Nest Protect.

During the initial phases of testing, it was observed that TCP SYN, Connect and Fingerprint scans did not yield any result. It was assumed that all the ports in the Nest Protect Alarm were either filtered or closed. A Ping scan of the subnet would result in displaying two hosts - the Raspberry Pi and the smartphone, but not the Alarm. It was assumed that the manufacturer had also locked ICMP Request/ Reply. Later, during a second round of analysis, it was found that the Nest Protect remains awake only for a duration of 120 seconds and goes to sleep-mode. By pressing the button on the smoke detector, the device is again activated, and communication is restored. During sleep-mode, network communication is cut off, possibly, as a power saving measure. TCP scans were set to defaults and performed within 120 seconds of each activation. It can be noted that the IP addresses of the devices during the initial phase and the second phase are different since the test environment was set up again. In contrast to the results present by Loi et al. [16], the targeted UDP port scans were not able to find any open ports in the 17000-20000 port range. It is assumed that the manufacturer must have closed these ports in a software update.

E. Examining Network Behaviour of Nest Protect Smoke Alarm

Unlike Philips Hue, both the Nest smoke detector and the smartphone app contact Cloud services. Certain surprising observations from traffic analysis reveal that the Nest smoke detector generates comparatively very less traffic – also validated by Yadav *et al.* [30]. This condition is true even when a safety check is initiated. The only HTTP traffic that was observed was between the alarm and clients.l.google.com. Rest of the traffic generated from the alarm were only TCP that used Dynamic port numbers at the source and Registered port 11095 at the Cloud servers. Further investigation reveals that Nest Protect uses the 'Weave' protocol to connect with its Cloud servers [40].

The smartphone with the Nest App makes an alarming amount of NTP requests to Google's Time Servers. However, the Nest App uses only TCP and TLS encrypted communication to all the servers it contacts. The communication with the alarm occurs only when it is active or manually invoked by pressing the button on the alarm or by using the App. The alarm does respond to ICMP until the time it is active.

From this section, it can be inferred that by comparison the Philips Hue has more open ports than the Nest Protect. This translates to more vulnerabilities and increased attack surface. In the next section, DoS attacks will be launched against the Philips Hue and the Nest Protect Alarm, and the impact of those attacks will be recorded. Solutions to reduce the attack surface and mitigate the attacks are implemented and their efficiency is validated.

F. Vulnerabilities of the Nest Protect Smoke Alarm

Compared to the Hue Bridge, it can be claimed that the Nest Protect Alarm has a lower attack surface. Since the Nest Protect does not reveal ports and services in use, it is difficult for a threat actor to attack. However, the Alarm is still vulnerable to ICMP Flood. During an ICMP Flood the Nest App could not establish a connection with the device. However, the device remains active only for a duration of 120 seconds and the chances of successful ICMP Flood attacks remain slim. As stated by Notra et al. [41] the Nest Protect Alarm is indeed a secure product. It is possible that the Nest Protect could be vulnerable to sleep-depravation attacks, but those attacks are beyond the scope of this research.

G. Implementing Solutions to Secure SHDs

Securing a device is a two-fold process – host-based security and network-based security. SHDs lack built-in security owing to their size, computational power, and power consumption. This means that unlike computers security cannot be enhanced using host-based security solutions. Also, any shortfall in security, such as open ports or unnecessary services cannot be fixed (Shirali-Shahreza and Ganjali, [42]). Since device-level security cannot be applied, the artefact applies the other two security approaches, 1) isolation and 2) network-level protection, as suggested by Hamza et al. (Hamza, Gharakheili and Sivaraman, [31]).

1) Isolation and network-level protection of SHDs: As the research involves real SHDs, to implement a solution a device had to fulfil certain conditions: it must be affordable, portable, must serve the Ethernet-based Philips Hue and the Wi-Fi based Nest Protect, and must fit in the existing network without major changes. Based on these conditions a Raspberry Pi 4B was chosen. To avoid license costs, a Linux Kernel based distribution was the preferred choice of OS for the Raspberry Pi. Open-source tools such as Snort, pfSense, OpenWrt, and IPFire were considered. pfSense was not tested as it supported only certain architectures. Ubuntu Desktop 22.04 LTS was installed on the Raspberry Pi as installing Snort is a straight-forward process in Ubuntu. However, owing to the sluggish behaviour of the OS and difficulties in successfully installing configuring dependent packages such as 'dnsmasq' and 'hostapd' the idea was aborted. Since OpenWrt and IPFire both were supported, both tools were installed in separate SDXC cards and tested.

Both OpenWrt (2023) and IPFire (2023) are open-source and community-supported products that ensure security by default. Both the products are compatible with the Rapberry Pi, satisfy conditions for isolation and network-level protection, and offer GUI. However, IPFire was chosen over OpenWrt as the former is designed and optimised to be a Firewall whereas the latter includes Firewall functionality. Unlike commodity Home Gateways and OpenWrt, IPFire enables HTTPs based GUI by default.

It is straightforward to choose a network configuration in IPFire that supports WAN, LAN, and WLAN interfaces required for this research. The WAN interface or the RED zone has been connected to the existing network and the SHDs are isolated from each other and from the existing home network. The Hue Bridge is part of the GREEN zone (Subnet-02 - 10.100.100.0/24) and the Nest Protect is part of the BLUE zone (Subnet-03 – 10.100.200.0/24) as shown in Fig. 5. Although the installation of IPFire in Raspberry Pi is not straightforward, it can still be achieved with support from the developer [43], a process that is easier in OpenWrt.

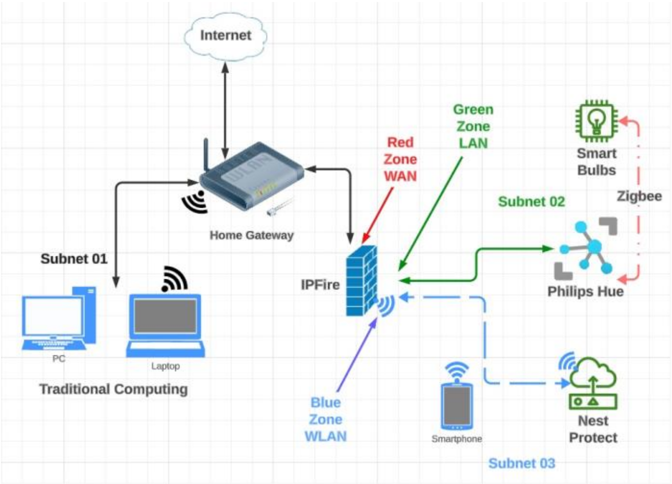

Fig. 5. Network setup and artefact placement.

Through the 'PakFire' module additional packages such as 'hostapd' which enables the Wi-Fi access point can be installed. By default, IPFire enables MAC filtering for wireless clients. Hence every new device connecting to Wi-Fi must be approved. This security features disallows rogue devices connecting to Wi-Fi. Although IPFire can be remotely accessed via SSH, as a security feature it is disabled by default.

IPFire's SPI firewall, based on 'netfilter', by default restricts traffic between the zones [44]. In addition, the Firewall provides 'IP Address Blocklists' to deal with traffic based on the reputation of IP Address [45], and 'Location Block' to block incoming connection from certain Geo-locations [46].

One of the most important features of IPFire is its ability to function as an IPS. IPFire employs Suricata [47], an open-source software for intrusion prevention [48]. Although, this feature is disabled by default, it can be enabled on more than one interfaces. Traffic passes through the IPS before it is sent to the Firewall, and malicious traffic is dropped by the IPS. IPS works based on 'Rulesets' and IPFire allows an user to choose more than one ruleset. Some community rulesets are free whereas some need add a subscription. By this, IPFire achieves the functionality of Snort IPS. The Firewall, IP Blocklists, and IPS have separate logs that can be accessed through the GUI. Connections are tracked and are displayed in the GUI. In addition, CPU load, Memory usage and Processes are displayed graphically [49].

IV. Conclusion And Future Work

Smart Home systems are becoming more popular and the rate of adoption of these devices has been tremendous. SHDs make our life easier by allowing physical devices to be controlled over the internet. However, SHDs may have vulnerabilities and can introduce new challenges to home network security. The DDoS attack against Dyn that was conducted using compromised consumer IoT devices is proof that smart devices can participate in larger attacks.

Typically, IoT and non-IoT devices coexist in home networks. In many cases SHDs remain unmonitored and consumers are unaware of the security issues that may exist in these devices. Weak authentication methods and insecure network services have been the top security issues found in IoT devices. Hence, it is imperative to study the insecurities in SHDs and deploy security solutions to reduce the attack surface.

Vulnerabilities may reside in any of the three layers in the IoT architecture. However, this research focussed in identifying the vulnerabilities at the network layer. A test lab was setup to examine the Philips Hue and the Nest Protect. The baseline behaviour of each of these devices were recorded. It is evident that both the devices depend on various Cloud-hosted services. Although both the devices use secure protocols and encrypt application data, the Philips Hue still uses HTTP based communication to a cloud service.

The research then involved Nmap port scans which revealed the open ports and the associated services. Abusing these ports and services by sending excessive amounts of traffic can directly impact the 'Availability'. This was demonstrated by conducting volumetric flood attacks against the Philips Hue. Owing to open ports, a threat actor can launch SYN Flood, HTTP Flood, and ICMP Flood against the Philips Hue, turning the device unresponsive.

On the other hand, services such as UPnP that advertise the capabilities of a device on the network can be misused, exposing devices to the internet. In the case of the Philips Hue, the UPnP service exposes the device's unique identifiers. Such details can result in spoofing attacks. It is evident that the Nest Protect alarm is, comparatively, a safer device as it does not expose its ports and services. Still, an ICMP Flood launched against the Nest Protect turned the device, temporarily, unresponsive. It is possible that the Nest Protect can suffer from sleep deprivation attacks, however such attacks were outside the scope of this research.

Unlike computers, IoT devices cannot be protected using device-based security solutions. Hence, the focus was shifted to protecting these devices through isolation and applying network-level protection. In addition, the Philips Hue and the Nest Protect are heterogeneous – the former uses Ethernet and the later Wi-Fi for communication. Hence the solution must encompass both standards. Deploying IPFire, a powerful open-source Netfilter based SPI Firewall on a portable device like Raspberry Pi 4B fulfils the requirements. IPFire separates the flat home network into three zones, and by default curtails communications between the LAN and WAN zones. Through Firewall rules, it was demonstrated that complete isolation between LAN and WLAN zones can be achieved.

Unlike commodity Gateways and Wi-Fi Routers, IPFire neither has in-built UPnP nor does it allow the service to be installed. This ensures that malicious programs cannot open ports without user consent. The Suricata IPS engine is one of the important aspects of IPFire since packets are analysed by the IPS and any malicious traffic is dropped before reaching the firewall. This feature ensures that only legitimate traffic reaches the SHDs. In addition, IP Blocklists can also be configured to drop traffic from IP Addresses with poor reputation. IPFire by default enables DNSSEC and the user can enable DNS over TLS. Such features reduce the chances of DNS spoofing and cache poisoning. With these features, IPFire reduces the attack surface of the Philips Hue and the Nest Protect. Although deploying a Firewall and IPS ensure security, improving the efficiency of such systems is a continuous process that involves scrutinising the Firewall and IPS logs and applying relevant rulesets.

Insecurities exist in all layers of the IoT architecture, but this research was limited only to the network layer and to certain types of DoS attacks. In the future work, sensing layer related vulnerabilities will also be included. Another limitation is, IPFire supports only IP address-based access rules. A Firewall that supports Fully Qualified Domain Name (FQDN) based rules will involve less overhead since Cloud providers tend to assign various public IP addresses for hosted services. The methods followed in this research can be expanded to include other devices. Hence, the future work will include devices such as the Smart TV.

***Abstract*—The importance of the detection of vacant parking spaces is increasing gradually. A system capable of detecting vacant parking spaces in real-time can play an important role in saving valuable time for motorists, decreasing traffic jams, and reducing air pollution. Vision-based parking space detection methods are advantageous in terms of installation and maintenance as existing security cameras in a parking area can be used without the requirement of additional hardware and the detection program can be run on a local or a remote server. One major problem of the vision-based detection method in this context is making the model generalized for detection in various weather conditions. This research proposes a hybrid method to detect vacant parking spaces that use texture and color descriptors. A weighted KNN is used for the classification of parking spaces. The proposed method experimented on PKLot, a large benchmarking dataset that contains images of three parking areas in three weather conditions. The proposed model achieves an accuracy of 99.47% on average while training with 10-fold cross-validation and achieves an accuracy of 99.41% accuracy on average while testing with unseen data. The model shows robustness and better performance in terms of accuracy and processing speed. Several comparisons are also done to show how well it performs with methods found in previous research.**

Keywords*—*Texture; color descriptor; k-nearest neighbors; computer vision; image processing

I. Introduction

The requirement for vehicle parking space is increasing due to the increasing number of people owning vehicles causing unbalance in demand and supply of parking spaces. In addition, another underlying reason is the number of parking spaces in a certain location is fixed but the demand for parking spaces varies at different times of the day. People may not be able to locate parking spaces even after spending significant time looking for one during rush hours. Utilization of the available parking space efficiently can be a key solution in this regard where motorists will need real-time information of the available parking spaces of the nearby parking areas. In this context, the necessity of automatic vacant parking space detection is a demanding research topic in the field of computer vision domain. Vision-based automatic vacant parking space detection can help to find available parking spaces at certain locations using images from preinstalled cameras in a parking area.

Previous researchers proposed various approaches to solve vacant parking space detection, i.e., various sensors-based detection [1, 2], counter-based detection [3, 4], and vision-based detection [5, 6, 7]. Wireless sensors were previously used to develop parking monitoring systems but the problem with the sensor-based method is that deployment and maintenance of sensors are required also the sensors add additional costs [2]. Counter-based methods keep track of the number of vehicles entering and exiting the parking area, however, counter-based methods cannot provide information about parking space location which cannot be used for a wide range of applications [4]. Although previously some research criticized the vision-based approaches technique because of expensive camera equipment and the need to deal with a large amount of data [6], a vision-based vacant parking space detection system can easily be deployed using existing security cameras of the parking space without additional hardware requirements in parking area [7]. This research focused on detecting vacant parking spaces using texture analysis based on Gray Level Co-Occurrence Matrix (GLCM) also known as Grey Tone Spatial Dependency Matrix and RGB color descriptors. The proposed method was validated using the PKLot dataset [7] which is a large dataset of three parking areas with different weather conditions and different times of the day. PKLot dataset was previously used for validating various previous methods, i.e. CarNet [8], mAlexNet [9], and Deep CNN [10] which are compared with the proposed method based on various performance metrics.

The rest of the research paper is structured as follows: Critical previous research is illustrated in the background study, mentioned in Section II, comprehensive details of the proposed methodology are elaborated in Section III, details of experimental results with analysis for experimental validation are demonstrated in the experimental results and analysis in Section IV and finally, the conclusion in Section V presents concluding remarks.

II. Background Study

Several research has been done to solve the parking space detection problem while keeping three factors in consideration, i.e., mind robustness, deployment effort, and maintenance cost. Previous research has been conducted resulting in different methods i.e., multicamera vehicle detection [11], drone-based and aerial image analysis [12, 13], image descriptor-based [14], geometric features-based [15], edge-based [16], plane-based [17], convolutional neural network [18, 19], sensor network [2] [20]. Some of the previous research was done based on wireless sensor networks. Sensors are being placed in parking spaces to transmit data to a server to detect if space or unoccupied is occupied [2] [20]. However, existing related methods related to sensors, cost, and maintenance were not feasible in large parking areas. Currently, researchers are more focused on vision-based parking space detection where images of the parking area are taken using the camera. Research in [21] used two types of approaches for image-based systems, one of them was car-driven and another one was space-driven. In the car-driven approach, methods were developed to detect cars as objects as the main objective. However, the problem with this approach was that when a camera was placed at an angle, images of vehicles near the camera and far from the camera have a significant difference in quality as the number of pixels will be less for far images. So, the detection of objects or vehicles became complex. In the space-driven approach, the detection of space was the main objective. The space-driven approach was less complex than the car-driven approach because space has more similarity than vehicles at a particular place. However, the challenge of the space-driven approach was to create robust methods for different parking areas under different scenarios.

Research in [15] proposed a geometric feature-based method to detect vacant parking space where a line segment was used to detect an algorithm for creating a line-clustering method consisting of several parallels for separating lines with a fixed distance and one guideline. The false line was removed and then the guideline was detected using a learning-based method. This method performed better than the single bird's eye view method proposed by research in [15]. However, this method was unable to meet real-time processing. Research in [13] used aerial images and line detection and combined selective filtering calculated using the prevalence of line length and angle. Their algorithm aimed to do automated detection of parking space regions in parking lot images for collecting parking occupancy information. The advantages of this method have four aspects, i.e., provided well enough results for automatic region extraction, fast, covered a large area, and can be used for automatic segmentation. However, some lines were not detected by that method due to light and shadow variance. Research in [22] used a deep convolutional network by introducing an architecture called "Siamese architecture" for learning robust features of the parking spaces for eliminating inter-object occultation and increased performance in various illumination conditions. They also used three space input patches of a single parking space and trained the network for the classification of parking occupancy. The method proposed by research in [22] was better than the method proposed by research in [13] due to the usage of a drone coupled with a line detection algorithm to detect parking space which was not robust, and the deployment and maintenance would be more difficult than just using single or multiple fixed place cameras. In addition, research in [22] performed better in different illumination conditions wherein research in [13] method of light and shadow variance caused problems in line detection.

Research in [11] proposed a method based on dilated convolution neural networks. They claimed their model to be more robust than other methods proposed by research in [14] and [16]. Research in [8] used the dataset that was created by research in [2] named PKLot and compared the results with other research methods. There was a significant difference when the dataset was trained in one parking lot and tested in other parking lots. Results by research in [5] showed that their method was more robust as their accuracy did not fall like previous research while training and testing in different datasets. In this context, research in [7] used two texture-based features, i.e., local binary patterns and quantization of the local phase. Support Vector Machine (SVM) was trained in their research to detect vacant parking spaces and received an accuracy of 99% when the model was trained and tested on the same dataset. However, for other datasets, they achieved the best accuracy of 89% using textural features. The method proposed by research in [5] performed better than research in [7] in terms of robustness. Experimental results by research in [8] showed that their proposed method accuracy did not fall like research in [7] while training and testing in different datasets.

Existing research methods need to be robust for parking space detection in terms of various illumination and environmental conditions like sunny, cloudy, and rainy. In addition, these methods need to be easily deployable, and maintenance should be cost-effective. The method proposed by research in [15] was able to provide real-time parking space detection. However, that method cannot be used for a large number of parking areas because outdoor parking areas contain a large number of parking spaces. Research in [13] used aerial images for the detection but using a drone is not cost-effective and not suitable for daily use as the drone has a very limited battery life and high maintenance cost. Research in [22] used fixed-place cameras to detect vacant parking spaces, they used three space input patches of a single parking space detection using CNN and were able to achieve good accuracy. However, research in [7] used only a single patch and texture-based features for the detection which claimed to be performed better compared with research in [22]. Research in [7] and research in [18] lack in terms of robustness because despite providing good accuracy on a single parking area, their accuracy decreased when multiple parking areas were used in the scenario. This research proposes an efficient method for parking space detection using texture and color-based features to make the validation robust. In addition, the proposed method is easily deployable and has low maintenance costs as it can be deployed using the camera that already exists in parking areas.

III. PROPOSED METHODOLOGY

The proposed method aims to detect vacant parking spaces in different weather and illumination condition of the day shown in Fig. 1. The proposed method mainly focuses on the extraction of features that reflect the difference between unoccupied and occupied parking spaces. The overall methodology consists of four steps, i.e., acquisition of images for processing, segmentation of parking spaces using a fixed mask and preprocessing segmented images, color descriptors-based feature and texture-based feature extraction, and detection of parking spaces using supervised machine learning algorithm k-nearest neighbors. The proposed method by this research is depicted in Fig. 1.

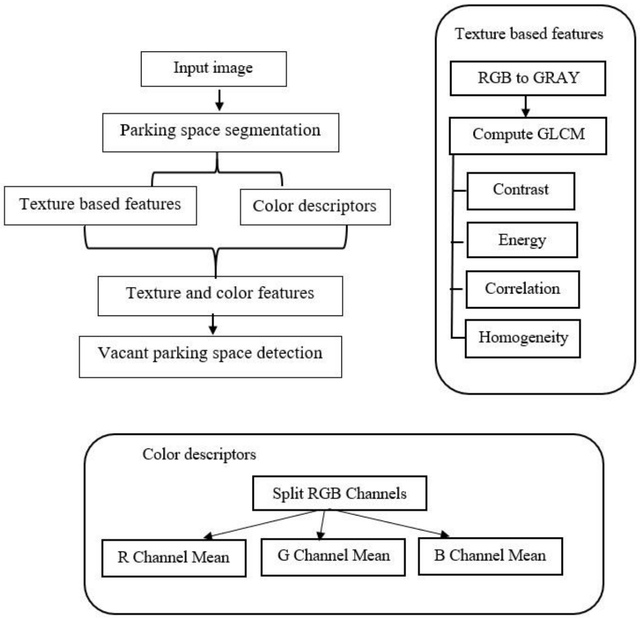

Fig. 1. Proposed method.

A. *Input Image*

This research used the PKLot dataset of three different parking areas. According to research in [7], a single camera covering the whole parking area was enough for the detection of vacant parking spaces. The dataset was annotated with information of the locations of parking spaces and occupancy status. In terms of real-life use, camera calibration was followed as research in [4] [23]. PKLot Dataset consists of three subsets for three parking spaces, i.e., PUCPR, UFPR04, UFPR05, and images of three different weather conditions sunny, cloudy, and rainy for each parking area. Sample images of the PKLot dataset are mentioned in Table I.

B. *Parking Space Segmentation*

The parking area may consist of many parking spaces. For this reason, automatic segmentation of parking space will produce extra computational overhead and causes the process not suitable for real-time use. For faster segmentation, a fixed mask once for all spaces was created manually as research in [7] and [24] did in their research which leads them to achieve very fast segmentation of parking spaces. The fixed mask uses the coordinates of the parking spaces. After placing the camera, coordinates of the parking spaces were collected to crop out the patches of the parking spaces from images. The terminology is that for a fixed camera, the parking spaces are static, only a vehicle will move into a parking space or will move out of one. Two copies of a segmented parking space were created for two types of feature extraction, i.e., color feature-based and texture feature-based extraction. For color-based feature extraction in preprocessing part, a segmented RGB parking space is split into three channels R, G, and B as the intensity of the pixels also varies on different channels. The R, G, and B channels of occupied parking space have more variations than the unoccupied parking space, also there is a significant difference between occupied and unoccupied R, G, and B channels, and can be used as features to distinguish between occupied and unoccupied parking spaces. After color-based features, texture-based features were extracted for the highly distanced parking spaces from the camera which are smaller than less far parking spaces from the camera in addition, highly distanced parking make the structural or geometrical features extraction more complex and not effective but texture-based features can be used to find the similarities and dissimilarities between occupied and unoccupied parking spaces in that scenario. For texture-based feature extraction, images were converted RGB to grayscale followed by median filtering. Details of features extraction regarding color features extractions and texture features extractions are explained comprehensively in the next section.

TABLE I. SAMPLE IMAGES IN DATASETS

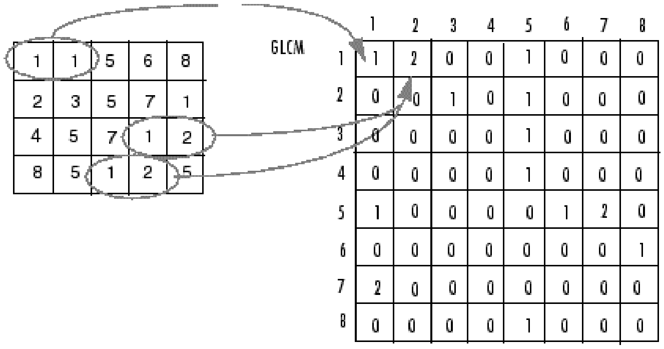
SUNNY			

C. *Color Descriptors and Texture-based Features*

This research used texture features-based information of the parking space which were collected from the Gray Level Co-Occurrence Matrix and combining them with color-based feature helped to achieve more accuracy and even if the parking space was near or far from the camera, they had similar values and leading to more robust methodology comparing with the previous research. In this section, color descriptors-based features and texture based-features were extracted. For color descriptors-based features, there is a significant difference in occupied and unoccupied RGB channels. Using Eq. (1), the mean value of each channel is calculated to estimate significance difference in occupied and unoccupied RGB channels.

$$\bar{k} = \frac{1}{z}\sum_{j=1}^{z} k_j \qquad (1)$$

where, k¯is the mean of a channel and z is the number of pixels and k_j is the value of the intensity of a pixel. For texture-based features, Gray Level Co-Occurrence Matrix (GLCM) was used to derive some statistical values of the images. The GLCM is constructed from gray images. GLCM has rows and columns that are equal to the number of tones or gray levels in a grayscale image. In addition, GLCM calculates how often a gray tone or intensity occurs with the adjacent pixels from the input image.



1	1	5	6	8
2	3	5	7	1
4	5	7	1	2
8	5	1	2	5

	1	2	3	4	5	6	7	8
1	1	2	0	0	1	0	0	0
2	0	0	1	0	1	0	0	0
3	0	0	0	0	1	0	0	0
4	0	0	0	0	1	0	0	0
5	1	0	0	0	0	1	2	0
6	0	0	0	0	0	0	0	1
7	2	0	0	0	0	0	0	0
8	0	0	0	0	1	0	0	0

Fig. 2. GLCM construction example for 8-tone grayscale [25].

Fig. 2 shows the calculation of GLCM of 8 tone grayscale images, but in this research, GLCM was calculated for 256-tone grayscale images. GLCM can extract certain texture properties from the spatial distribution of the gray image. In the proposed method by this research, four statistical texture features were computed from the GLCM matrix, i.e., Contrast, Correlation, Energy, and Homogeneity. Various texture features were extracted based on Eq. (2) to Eq. (5) [26].

$$C = \sum_{m,n=0}^{L-1} Q_{m,n}(m-n)^2 \tag{2}$$

$$\mathrm{D} = \sum_{\mathrm{m,n=0}}^{\mathrm{L-1}} \mathrm{Q_{m,n}} \frac{(\mathrm{m}-\mu)(\mathrm{n}-\mu)}{\mu^2} \tag{3}$$

$$E = \sum_{m,n=0}^{L-1} (Q_{m,n})^2 \tag{4}$$

$$H = \sum_{m,n=0}^{L-1} \frac{Q_{m,n}}{1+(m-n)^2} \tag{5}$$

where, L = number of intensity levels, Q_{mn}= element at (m,n), μ = mean of GLCM, σ^2= intensity variance. Thus, the proposed method dealt with multiple features which were extracted and used for the detection of vacant parking spaces by manipulating the correlation among these multiple features.

D. Vacant Parking Space Detection

The proposed method extracted features represented as numeric values collected from many images from subsets of the PKLot dataset with three different weather conditions. Several classifiers, i.e., logistic regression, Support vector machine, k-nearest neighbor, weighted k-nearest neighbor, and linear discriminant were tested to check how these classifiers perform on the features extracted by this research. Among all the classifiers, the weighted k-nearest neighbors algorithm worked well for the classification of parking space. The parameters used for the model are shown in Table II.

Due to better performance and low complexity, this research used a weighted K-nearest neighbor as the classifier. As all the extracted features are numerical using KNN which makes training and testing the model less complex. The weighted KNN model was trained and tested with the features that were extracted using the proposed methodology. As the supervised machine learning algorithm needs labeled data, vacant information was collected from the PKLot Dataset [7]. Classified parking spaces were marked as green for unoccupied ones and red for occupied ones shown in Fig. 3 as a result of the proposed method.

TABLE II. PARAMETERS USED FOR WEIGHTED KNN

Parameters	Value	Formula
Distance Metric	Euclidean	$d = \sqrt{\sum_{i=1}^{n}(x_i - y_i)}$
Distance Weight	Squaredinverse	w= 1/d^2
Break ties	Smallest	-
Number of Nearest Neighbors	10	-
Nearest Neighbor Search Method	kdTree	-

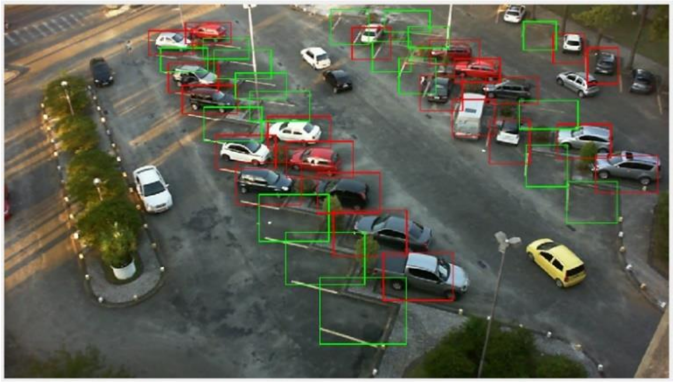


Fig. 3. Classified parking spaces UFPR05-Sunny.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This research was validated using several phases during experimentation shown in Fig. 4.

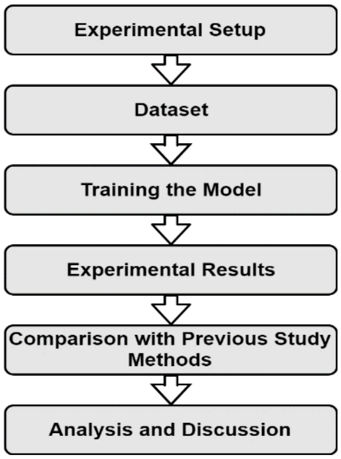

Fig. 4. Experimental framework to validate the proposed method.

A. Experimental Set Up

Proposed method experimented on the environment with a hardware configuration of Intel(R) Core (TM) i7 CPU540 @ 3.07GHz (4 CPUs) ~3.3GHzProcessor, 16GB RAM, Windows 10 64-bit operating system, and MATLAB R2019a. MATLAB provides a very good environment for rapid prototyping and debugging. MATLAB's image processing and machine learning environment provide an efficient set of optimized functions to make the workflow faster. The proposed method requires the parking area image as input and outputs the classified parking areas as green and red.

B. *Datasets*

The proposed method is experimented using the dataset PKLot [7] for validation. There was a total of 653169 numbers of observations extracted from the actual dataset out of which 72,000 observations are used as training samples. Out of 72,000 observations shown in Table III, 24,000 observations are used from each of the parking areas such as Pontifical Catholic University Paraná - Parking Lot (PUCPR – PKLot), Federal University of Parana - Parking Lot (PKLot - UFPR04) from 4th Floor, Federal University of Parana - Parking Lot (PKLot - UFPR05) from the 5th floor. These 24,000 observations are randomly sampled from the collection of observations for individual parking areas and weather conditions.

TABLE III. NUMBER OF SAMPLES

	Samples per parking area	Number of Training Samples
PUCPR-Sunny	24,000	72,000
PUCPR-Cloudy		
PUCPR-Rainy		
UFPR04-Sunny	24,000	
UFPR04-Cloudy		
UFPR04-Rainy		
UFPR05-Sunny	24,000	

C. *Training the Model*

72,000 observations are used for training K-nearest neighbor with 10-fold cross-validation for protecting the model from overfitting and the number of neighbors or K used is as 10. After changing different values of K, this research observed that greater than the nearest neighbor value 10, the classification result did not improve and less than k = 10 sometimes leads to false classification. Hence, K=10 is chosen for training the model. Other parameters used for training the KNN model are explained below:

1) *Distance metric:* Euclidean Distance estimated the distance of edges between neighbors as K [27] for the proposed method. Neighbors are m-by-n data vectors where m denotes the number of training samples and n denotes number of features used.

The distance was measured using $d_i(u_s, v_t) = \sqrt{\sum_{i=1}^{y}(u_{si} - v_{ti})^2}$ where d$_i$ is the distance of the edges between neighbors, u_s and v_t are 1-by-y data vector of the source and destination.

2) *Distance weight:* Weight g_i associated with the training samples are estimated as the squared inverse of the distance, $g_i = \frac{1}{{d_i}^2}$ and the weighted distance is calculated as

$$d_{gi}(u_s, v_t) = \sqrt{\sum_{i=1}^{y} g_i(u_{si} - v_{ti})^{2}}$$

3) *Break ties*: Smallest value was used to break the tie in case there were an equal number of neighbors with similar values.

4) *Number of nearest neighbors:* Nearest neighbor K=10 used to take decision of new data.

5) *Nearest neighbor search method:* A k-dimensional tree (Kd-Tree) was used to search for the neighbors [28] instead of an exhaustive method to search faster. The Kd-tree method divides a data vector of n-by-k recursively and distributes n points into a binary tree of K-dimension. Hence, the model grows a multi-dimensional Kd-tree using associated weight and Euclidean distance with a bucket size of 60 which is the maximum number of points in the leaf node [29].

D. *Evaluation Parameters*

The proposed method was validated with the test sets using various metrics, i.e., Confusion Matrix, Accuracy, Area under Curve (AUC), Error, Precision Rate, Recall Rate, Processing Time, and Processing Speed in Frame per Second shown in Fig. 5.

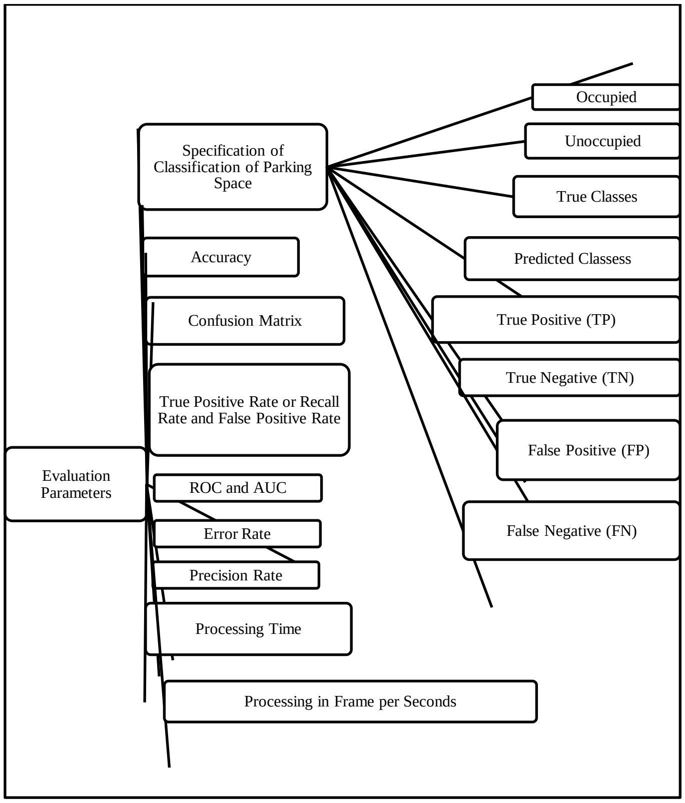

Fig. 5. Performance metrics used for validation.

1) Specification of the classification of a parking space: This research used two possible outcomes to denote the status of a parking space, i.e., occupied, and unoccupied. Occupied space refers to when a vehicle is parked in the parking area otherwise denotes unoccupied. These two statuses are considered classes for the prediction model. The true class represents the actual status of parking spaces that are known, and the predicted classes represent the status predicted by the trained model shown in Table VI to Table IX. In addition, looking for unoccupied space is considered a positive interest, and occupied space is considered a negative interest. Classifying a Positive sample as Positive is considered a True Positive (TP), Classifying a Negative sample as Negative is True Negative (TN), Classifying a Negative sample as Positive is False Positive (FP), and Classifying a Positive sample as Negative is False Negative (FN).

2) Performance metrics: The proposed method estimated the Confusion matrix which denotes the information about actual status and predicted status of training samples [30]. The performance of the trained model is commonly evaluated using the data of the confusion matrix. True Positive Rate and False Positive Rate were implicated to estimate the Receiver Operating Characteristic curve (ROC) and Area Under Curve (AUC) [31, 32]. The proposed research plotted ROC by placing the FAR on the x-axis and the TPR on the y-axis for several different observations. The values of False Positive Rate (FPR) and True Positive Rate (TPR) range from 0.0 to 1.0. A method with the best prediction skill is represented by the curve that goes from the bottom left corner to the top left corner and then towards the right top corner of the ROC plot [32]. This research also used Precision rate which denotes the rate of the positive prediction in terms of total positive prediction. Processing time was also estimated which denotes the time required to process one frame. In addition, the Processing speed in patches per second is calculated from the number of patches and the processing time taken to process them. In this context, Processing speed in frame per second represents the time to process a frame. Other performance metrics were calculated to validate the proposed method mentioned in Table IV which the corresponding equation used.

E. Experimental Results

The proposed method achieved an accuracy of 99.47% during training, which indicates better performance compared with the state-of-the-art. Table V depicts the confusion matrix of the trained model and Fig. 6 illustrates the AUC of the trained model. The total number of Positive samples (unoccupied spaces) used for the trained model is 36967 and the total number of Negative samples (occupied spaces) was 35033. Out of the total Positive samples, 36743 samples are correctly classified using the trained model, and 224 unoccupied spaces are classified as occupied. Besides, out of the total Negative samples (occupied spaces), 34895 spaces are classified as Negative (occupied), and 138 samples are identified as Positive (unoccupied). Hence, the number of FP and FN is comparatively very small compared to TP and TN which leads to higher accuracy compared with existing research.

TABLE IV. PERFORMANCE WITH EQUATION

Name of Metrics	Equation
Accuracy [30, 33]	$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}$
True Positive Rate or Recall Rate [30, 34]	$\text{True Positive Rate or Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$
False Positive Rate [30, 33, 35]	$\text{False Positive Rate} = \frac{\text{FP}}{\text{FP} + \text{TN}}$
Error Rate [30, 31, 36]	$\text{Error} = \frac{\text{FP} + \text{FN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}$
Precision Rate [30, 31, 37]	$\text{Precision Rate} = \frac{\text{TP}}{\text{TP} + \text{FP}}$

TABLE V. CONFUSION MATRIX OF TRAINED KNN MODEL WITH 10-FOLD CROSS-VALIDATION AND K=10

		Predicted Classes	
		Unoccupied	Occupied
True Classes	Unoccupied	36743	224
	Occupied	138	34895

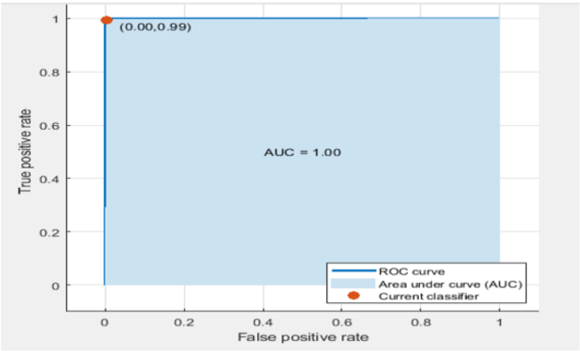

Fig. 6. Area Under Curve (AUC) at training.

Fig. 6 depicts the ROC and AUC curve for the trained model [32]. Here, the curve shown is the ROC curve, the shaded area is AUC which is ≈1and the point represents the used model. Based on the AUC value, the proposed method performed better for the training samples.

Table VI shows the confusion matrix of tested samples from PUCPR parking area images. 399118 samples were extracted from PUCPR which were used for testing the proposed method, each sample represents a parking space labeled either Unoccupied or Occupied. For the PUCPR images, out of the total samples, 211378 samples are classified as unoccupied, and 2183 samples as occupied out of 213,561 samples that were unoccupied. Again, out of 185,557 samples that were occupied, the proposed method predicted 183,890 samples as occupied and 1,667 samples as unoccupied. There were 88,266 samples from FPR04 parking area images that are used for testing the proposed method to estimate the confusion matrix shown in Table IX. For the FPR04 images, 48,700 samples were classified as unoccupied, and 512 samples as occupied out of a total of 49,212 samples that are unoccupied. Again, out of 39,054 images that were occupied, the proposed method predicted 38,754 samples as occupied and 300 samples as unoccupied. 165785 samples from FPR05 parking area images were extracted using the proposed method to estimate the confusion matrix shown in TABLE X. Proposed method classified 67,361 samples as unoccupied, and 998 samples as occupied out of a total of 68,359 samples that were unoccupied. Out of a total of 97,426 images that were occupied, the proposed method classified 96,648 samples as occupied and 778 samples as unoccupied.

TABLE VI. CONFUSION MATRIX FOR PUCPR, FPR04 AND FPR05

PUCPR		Predicted Classes	
		Unoccupied	Occupied
True Classes	Unoccupied	211378	2183
	Occupied	1667	183890
FPR04			
True Classes	Unoccupied	48700	512
	Occupied	300	38754
FPR05			
True Classes	Unoccupied	67361	998
	Occupied	778	96648

Several observations that were used from different parking areas for validating the model along with the number of prediction speeds in terms of observation/millisecond are shown in Table VII. The prediction speed on average was 23.01 observation (obs)/milliseconds(ms).

TABLE VII. NUMBER OF OBSERVATIONS TESTED AND PREDICTION SPEED

Datasets	Number of Testing Observations	Prediction Speed in o obs/ ms
PKLot-PUCPR	Cloudy = 132781	21.23
	Rainy = 83009	
	Sunny = 183329	
PKLot - UFPR04	Cloudy = 39392	24.37
	Rainy = 7951	
	Sunny = 40923	
PKLot - UFPR05	Cloudy = 56985	23.43
	Rainy = 8929	
	Sunny = 99871	

The accuracy of the proposed method for PUCPR, FPR04, and FPR05 were 99.21%, 99.91%, and 99.29% respectively shown in Table VIII. The accuracy of the three subsets does not fluctuate and it stays above ≈99%. The error rates are 0.79%, 0.9%, and 0.71% which on average stays at around ≈ 0.98%. The precision and recall rate are on average 99.16% and 98.7%. The precision rate represents the rate of the positive prediction in terms of total positive prediction which is 99.16%, and the recall is the rate of positive prediction in terms of total actual positive which is 98.7% for the proposed method.

The number of patches or parking spaces used from different parking spaces is shown in Table IX. PUCPR subset images cover many parking spots in a single image but in the experimentation, 102 parking spots were used from each image of PUCPR, 31 parking spaces from UFPR04, and 44 parking spaces from UFPR05 were used, processing a single image of PUCPR, UFPR04, and UFPR045 with total patches for each required 0.14, 0.15, and 0.17 seconds respectively. Processing speed in patches per second was calculated from the number of patches and the processing time taken to process them. Besides, processing speed in frame per second denotes the time to process a frame shown in Table IX. When the number of patches increased, the processing speed decreased in frame per second because it required more processing time.

TABLE VIII. ACCURACY AND DIFFERENT PERFORMANCE MEASURES

Datasets	**Accuracy %**	**Error %**	**Precision Rate %**	**Recall Rate %**
PKLot-PUCPR	99.21	0.79	99.27	98.8
PKLot - UFPR04	99.91	0.9	99.41	98.7
PKLot - UFPR05	99.29	0.71	98.79	98.6

TABLE IX. PROCESSING SPEED IN FRAME PER SECOND

Datasets	Number of Patches in Frame	Processing Time in Seconds	Processing Speed in Patches Per Second	Processing Speed in Frame Per Second
PKLot-PUCPR	102	0.14	44.57	0.39
PKLot - UFPR04	31	0.15	41.3	1.41
PKLot - UFPR05	44	0.17	47.21	1.09

F. Comparison with Previous Research Performance

The proposed method achieved an average accuracy of 99.47% whereas De Almeida et al. [7] achieved an average accuracy of 91.5% using the PKLot dataset as shown in Table X. In this context, the proposed method by this research achieved an accuracy of 99.47% using the same datasets. Besides, De Almeida et al. [7] used texture-based features from PKLot whereas the proposed method used texture and color descriptor features which caused better performance. CarNet by Nurullayev et al. [8] and AlexNet by Amato et al. [9] received an accuracy of 97.04% and 96.74% respectively which is lower than the proposed method. Deep CNN by Valipour et al. [10] provided an AUC (Area Under Curve) of 0.9994. In this context, AUC achieved by the proposed method is 1 shown in Fig. 6 which indicates proposed method performed better than previous research in terms of accuracy and AUC.

The proposed method requires 0.15 seconds to process a single patch or single parking space shown in Table XI. 1.048 frames was processed in 1 sec which consists of 50 parking spaces considered as a baseline to show the difference with previous research methods. AlexNet by Amato et al. [9] required 0.3 seconds to process a single patch and processed only 0.06 frames in 1 second which was slower than the proposed method. The deep CNN method by Valipour et al. [10] required 0.22 seconds to process a single patch and processed only 0.1 frames per second. So, the proposed method performed better in terms of processing speed than

AlexNet by Amato et al. [9] and the Deep CNN method by Valipour et al. [10].

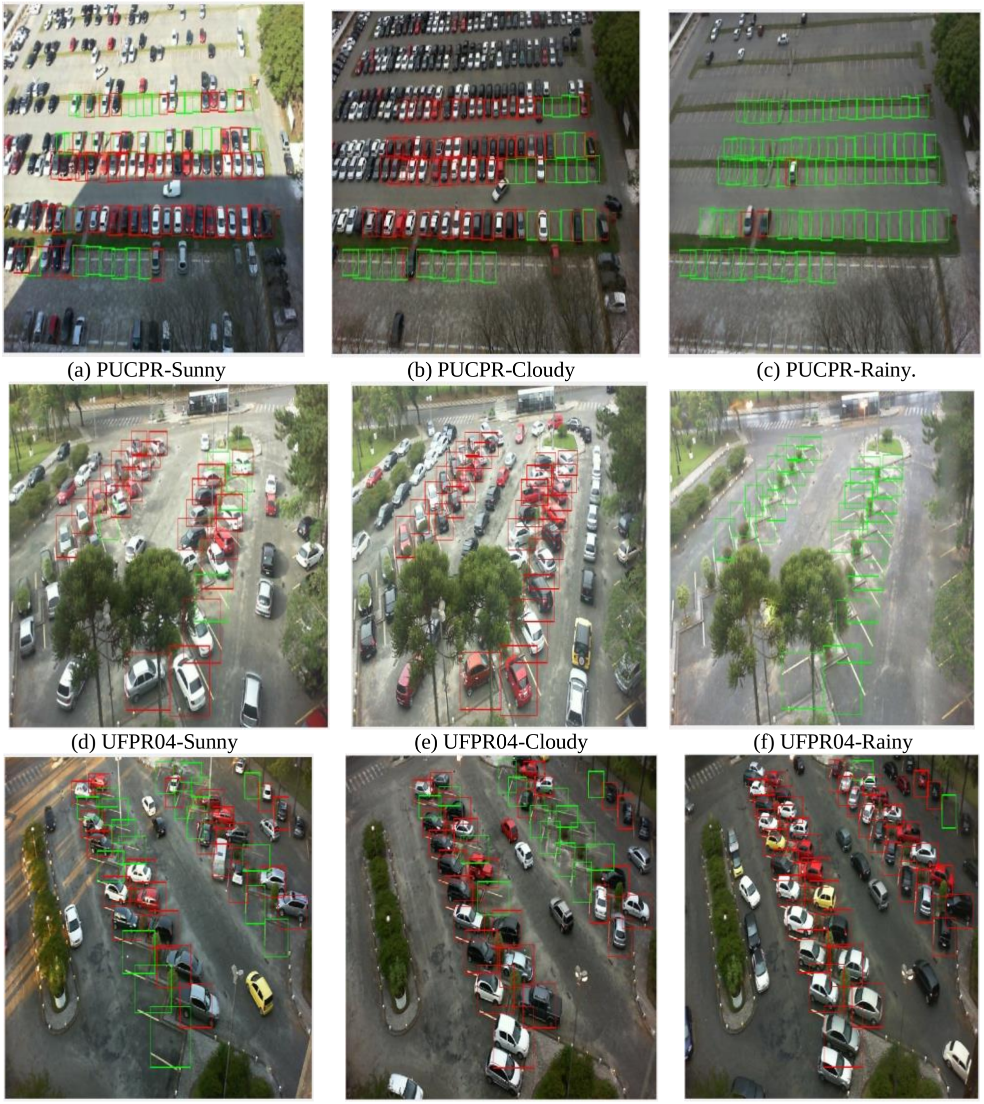
TABLE X. COMPARISON WITH PREVIOUS RESEARCH

Methods	Accuracy	Error	Precision Rate	Recall Rate
Proposed Method	99.47	0.8	99.15	98.83
PKLot[7]	91.52 (averaged) 99.5 (UFPR05)	0.7 (UFPR05)	99.36 (UFPR05)	98.8 (UFPR05)
CarNet[8]	97.04	-	-	-
AlexNet[9]	96.74	-	-	-
Deep CNN [10]	Accuracy Not provided AUC is (0.9994)	-	-	-

Fig. 7(a), Fig. 7 (b), and Fig. 7(c) are the sample output for PUCPR sunny, cloudy, and rainy weather conditions where for each image 100 parking spaces are considered for classification. Fig. 7(d), Fig. 7(e), and Fig. 7(f) are the output for FPR04 sunny, cloudy, and rainy weather conditions where for each image 28 parking spaces are used. Fig. 7 (g), Fig. 7(h) and Fig. 7(i) are the output for FPR05 sunny, cloudy, and rainy weather conditions where for each image 40 parking spaces are used for vacant parking space detection. The output result marks the occupied parking space with red rectangles and unoccupied spaces with green rectangles.

TABLE XI. COMPARISON WITH PREVIOUS RESEARCH IN TERMS OF PROCESSING SPEED

Methods	Processing Time in Seconds Per patch	Processing Speed in Frame Per Second (A frame of 50 patches)
Proposed Method	0.15	1.048
PKLot [7]	Not specified	Not specified
CarNet [8]	Not specified	Not specified
AlexNet [9]	0.3	0.06
Deep CNN [10]	0.22	0.1



(a) PUCPR-Sunny (b) PUCPR-Cloudy (c) PUCPR-Rainy.

(d) UFPR04-Sunny (e) UFPR04-Cloudy (f) UFPR04-Rainy

(g) UFPR05-Sunny (h) UFPR05-Cloudy (i) UFPR05-Rainy

Fig. 7. Out of detected vacant parking spaces.

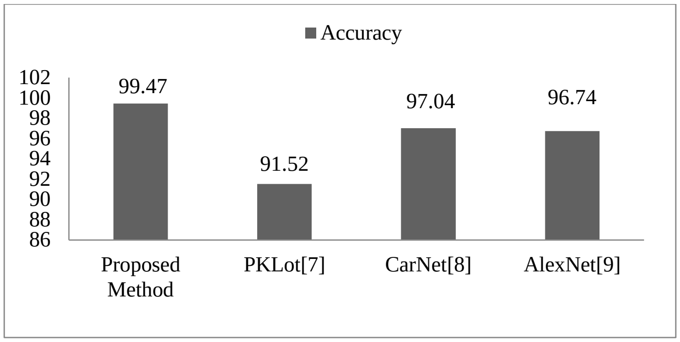


Fig. 8. Accuracy of the proposed method and previous research methods.

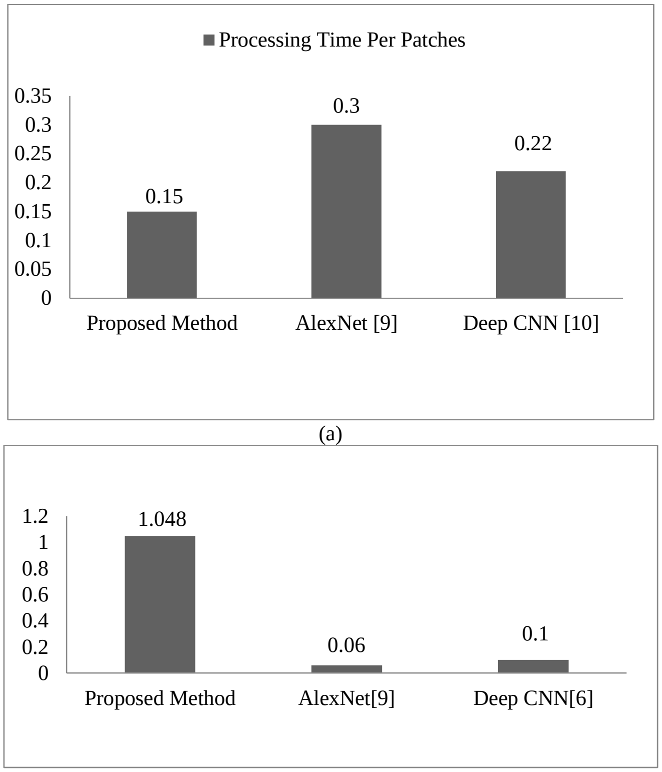
The proposed method achieved higher accuracy compared with previous research shown in Fig. 8 due to the usage of features for training, i.e., Contrast, Correlation, Energy, Homogeneity, and Color descriptors such as red, green, and blue channels. In addition, the proposed method also implicates the squared inverse of the distance as a weight to make the classes more separable while training.



(a)

(b)

Fig. 9. (a) And (b) Processing time comparison with previous research.

Proposed methods required less processing time per patch than previous research methods like AlexNet by Amato et al. [9] and the Deep CNN method by Valipour et al. [10] shown in Fig. 9(a). Besides, the proposed method processed more frames per second than AlexNet by Amato et al. [5] and the Deep CNN method by Valipour et al. [10] where each research method considered processing frames of 50 parking spaces shown in Fig. 9(b). The proposed method extracted features from a patch to predict whereas Amato et al. [9] and Valipour et al. [10] used a convolutional neural network and the whole patch needed to be convolved in each convolution of the neural network which required more time than the proposed method.

The proposed method shows robustness in terms of classifying unseen data. According to the validation results, having enough training data proposed method is expected to be capable to work in newer parking areas. Besides, the proposed method is lightweight and can easily be deployed on the server-side or a single Raspberry Pi 3 or Raspberry Pi 4 can be used to run in real-time implication.

V. Conclusion

This research proposes a hybrid method to detect vacant parking spaces using texture-based features and color descriptors. Features are calculated from gray-level co-occurrence matrix and RGB color descriptors to distinguish between occupied and unoccupied spaces. The proposed method illustrated efficiency in terms of accuracy, processing speed, and other performance metrics. Proposed model archived above average accuracy of 99% including validation with unseen data. Experimentation was done on one of the benchmarking datasets named PKLot parking image dataset which contains images of three different parking areas and for each subset images were taken on three different weather conditions at different times of the day. For a desired parking area, the proposed method can be used to provide prior knowledge of the available parking spaces, and vehicle drivers are expected to be able to locate the parking space efficiently. Besides, the proposed method is expected to decrease traffic load and air pollution. Another use case of the proposed method is to detect illegal parking which will be investigated in the future. In addition, an investigation will be done to implicate the proposed method at night and optimize it to work concurrently for both day and night conditions.

SkySculptor: Intuitive Drone Control Through Ground-Integrated Radar and Foot Gestures in Smart Indoor Environments

Alexandru-Ionuţ Şiean
MintViz Lab, MANSiD Research Center
Stefan cel Mare University of Suceava,
720229 Suceava, Romania

***Abstract*—SkySculptor is a software application designed to optimize drone control in smart indoor environments. The primary focus is on using gesture input for drone control, particularly investigating mid-air free-foot interactions detected by radar sensing. This software application simplifies the process of controlling drones in smart indoor environments. Additionally, outcomes of utilizing a 15-antenna ultra-wideband 3D radar are presented, establishing a dictionary of six directional swipe gestures for controlling drone functions. Based on the findings of this research article, guidelines for the future development of software applications for drone control in intelligent indoor environments are proposed.**

***Keywords*—Drone control; gesture input; ultra-wideband radar; software application; smart environments**

I. Introduction

Efficient, fluid, and expressive interactions that take advantage of body position and movement can be achieved by integrating radar gestures into smart indoor environments. This involves recognizing body position and movement and employing taxonomies to incorporate radar sensing technology [1]. This integration facilitates various interactions, including controlling smart TVs [2], utilizing wearable devices for gesture detection [3], and drone interactions [4]. Airborne gestures can also interact with content displayed on ambient screens [5], while foot movements offer additional avenues for interaction, covering both natural and unnatural gestures [6], [7]. Symbolic touch gestures commonly used on mobile devices can also be incorporated [8].

Recognizing user gestures involves a combination of hardware devices such as accelerometers embedded in smart devices like smart rings [3], [9], [10], various recognition algorithms (e.g., KNN, Random Forests, Convolutional Neural Networks, DTW) and data sets establishing correlations between gestures and system functions. Radar devices such as Google Soli, Walabot, and Sense2Go exemplify non-contact gesture sensors that offer new interaction possibilities with smart environments. Furthermore, attaching a radar device to a drone enables the control of various objects in a smart indoor environment [11]. Radar-detected gestures can range from basic presence and proximity detection to multitouch gestures or foot-based gestures [12], [13], [6]. Studies on radar device interactions suggest various sets of gestures, some focusing on hand gestures [14], [15] while others advocate interactions that involve the whole body [16]. These examples highlight that radar device interactions typically involve the upper body, as detailed by Șiean *et al.* [1]. Despite these advances, the lower part of the body was overlooked in interaction with radar devices.

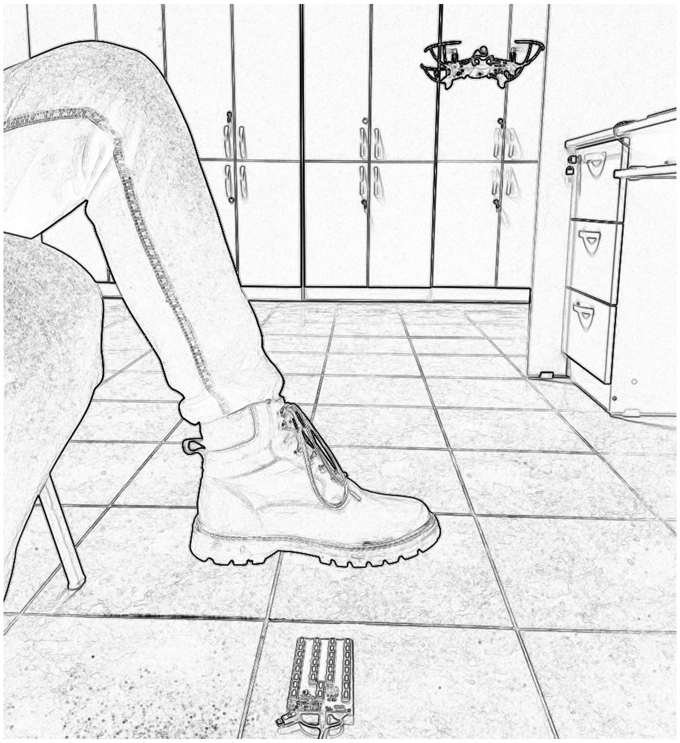

Fig. 1. The walabot radar device, used in SkySculptor, is shown alongside the parrot mambo drone and interaction modes.

In our contribution, emphasis was placed on the following aspects:

1) Software design requirements were defined and incorporated into the design of an interactive system that enables drone control using a radar device integrated, attach, or placed on the floor of a smart environment.
2) A set of six radar gestures executed with the foot was proposed, each associated with specific commands for drone control.
3) An implementation of the software application using a radar with a 15-antenna ultra-wideband 3D radar.

II. Related Work

Gesture-based drone control and radar-based gesture sensing and recognition will be our focus.

A. Gesture-based Drone Control

Research on gesture-based human-drone interaction has explored various approaches [17], [18]. Gestures serve as an effective means of conveying emotions, thoughts, and nonverbal communication, and hand gestures are widely accepted as intuitive communication methods [19]. Controlling drones through hand gestures offers simplicity and intuitiveness. Past studies have investigated hand gesture recognition using vision-based sensors such as RGB and depth cameras, as well as Microsoft Kinect sensors [20]. However, recent developments in safe-to-touch drones have spurred interest in novel forms of interaction, including direct touch and manipulation. For example, HoverBall is a ball-shaped quadcopter capable of sports or game applications [21]. Drones have also been used as haptic feedback devices in virtual reality scenarios [22]. However, these systems face limitations related to environmental factors such as light conditions, viewing angles, and spatial positioning.

B. Radar-based Gesture Sensing and Recognition

The core of radar detection lies in the use of electromagnetic waves. When these waves strike a target, a portion of the signal reflects back to the radar source and the receiver captures the signals. The characteristics of the received signal, such as frequency, amplitude, and delay time, provide information about the detected object, including its shape, orientation, distance, and speed relative to the radar. Radars are advantageous for human detection (e.g. gestures, posts, movement, etc.) as they operate under conditions of high illumination, low lighting, or darkness, when obstructed by surfaces or objects [23], [24], or during different weather conditions [25]. Previous research has presented and evaluated multiple techniques to recognize radar gestures. For example, Gigie *et al.* [14] showcase a case study of data explosion for radar-based human gesture detection. They introduced a simulation framework based on a physical model to generate radar signals corresponding to various human gestures. With the availability of Google Soli in the mobile ecosystem, Leiva *et al.* [26] devised a hybrid CNN+LSTM deep learning model. They conducted a comprehensive study exploring the performance of mid-air gesture recognition while covering the radar sensor with three distinct fabrics (leather, wool, and cotton). The model demonstrated an exceptional average performance accuracy of 95%, AUC of 99%; RadarNet [27] utilizes an effective recognition approach for radar gestures, utilizing a Convolutional Neural Network. It operates efficiently on processors with limited computational capabilities. On the other hand, mHomeGes [28] is a system designed to detect radar gestures with an accuracy of 95%, particularly designed for smart home interactions. Therefore, we propose a radar sensor-based gesture recognition system for drone control that extends body gestures using *foot* gestures.

III. Design Requirements for SkySculptor

By analyzing the relevant scientific literature and considering the potential application domain, which focuses on the interaction between drones and gesture-based foot movements in smart indoor environments using integrated, attached or floor-placed radar devices, we can establish the necessary design requirements for SkySculptor as shown in Fig. 1. Next, the design criteria for the development of the SkySculptor software application.

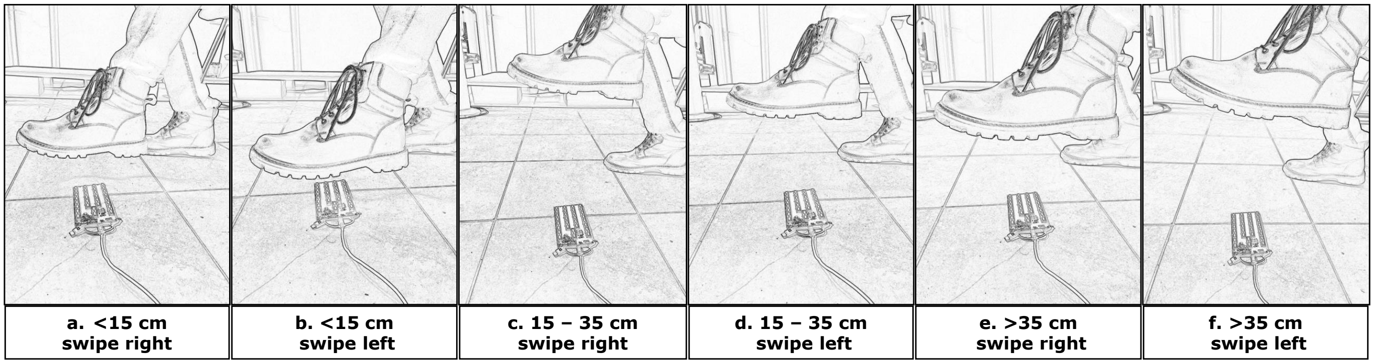
(a) *Open source technology:* SkySculptor strongly emphasizes the adoption of open technologies to promote the development and progress of innovative specialized software applications designed for users who operate drones in smart indoor environments. This guiding principle also applies to SkySculptor, which features a fully developed software application created using open technologies. The goal of this system is to encourage research and support the ongoing advancement of drone interactions in intelligent indoor environments through the use of radar gestures.

(b) *Smart spaces orientation:* Accurate positioning of the radar device in the recommended locations, as proposed by Şiean *et al.* [1], enables effective handling of complex gestural interactions between users. Similarly, for interactions between drones and physical objects, the approach suggested by [2] can be applied. This approach is seamlessly integrated into the software application SkySculptor, with a particular emphasis on the areas of the floor and the interaction facilitated by the movements of the feet.

(c) *Easily integrate, attach, or place the radar sensor on objects or devices:* Traditionally, drone control has been done using joysticks or smartphones. However, in our scenario, we propose a shift towards using an integrated radar device that can be attached to or placed on the floor for drone interaction. Radar devices have unique features that allow them to integrate seamlessly into various objects or be attached by users, providing researchers with the opportunity to propose innovative methods of interaction. The SkySculptor software application places an emphasis on integrating the radar device in the floor and facilitating interaction with the feet. This is motivated by the lack of gestures involving the lower body, despite the numerous proposals for interaction focused on the upper body, as discussed by Şiean *et al.* [1]. By prioritizing the integration of the radar device into the floor and enabling interaction based on leg movements, we aim to enrich and diversify gestures and interactions in intelligent indoor environments within the context of HDI.

Requirement (c) can be satisfied by utilizing the principles that govern the functioning of radar devices and their ability to detect objects. This requirement provides various options for the installation of the radar device, allowing interaction with the drone. At the same time, it addresses the challenges associated with gesture recognition that may arise due to low light or unfavorable weather conditions. When open technology is employed in the development of a software application, it becomes easier to extend and improve its functionality. As a result, a new requirement is introduced for SkySculptor, which specifically describes the ease of its development.

(d) *Python-orientation:* Devices that are capable of running



a. <15 cm swipe right

b. <15 cm swipe left

c. 15 – 35 cm swipe right

d. 15 – 35 cm swipe left

e. >35 cm swipe right

f. >35 cm swipe left

Fig. 2. Various mid-air gestures combining directional swipes and distance from the sensor enable control of drone functions.

SkySculptor are those that have a Python interpreter and are equipped with a USB port for connecting the radar device.

Software applications developed using the Python framework are well known for their fast and reliable performance. This decision was made to ensure that the tools are compatible with various devices that have a Python interpreter, providing a consistent experience for users. Using Python[1], the process of integrating drone and radar device SDKs became easy, making it easier to connect to these devices. Using the drone SDK[2] and establishing a connection to the radar device, we successfully incorporated the necessary functionality to control the drone without any difficulty.

IV. Implementation Approach and Prototype

We propose a gesture recognition system to control drones using radar sensors. The system focuses on using foot gestures for control. To evaluate the technical feasibility of this radar sensor-based gesture recognition system for drone control, taking into account the availability and affordability of radar technology on the market, a prototype SkySculptor was developed using the 15-antenna Walabot Creator device and the Walabot API.[3] The Mambo Parrot drone was used in conjunction with the prototype. The trajectory of the detected target above the radar was captured and expressed as x, y, and z coordinates. Two directional swipe gestures (referred to as *swipe left* and *swipe right*) along the y axis. Furthermore, the distance from the sensor on the z axis at which these gestures were made was used to define three active zones (*near*, *close*, and *far*) above the radar. Fig. 2 shows visual representation of the gesture set. When the two directions and three zones were combined, a total of six gestures were obtained. These gestures can be assigned to three types of functions commonly used in drone control: *take-off/land* for initiating or ending the flight of the drone, *start/stop video* for controlling the camera, such as taking photos or starting/stopping video recording, and *forward/backward* for moving the drone in the forward or backward direction. This method is the same as the paper [2].

We conducted a preliminary evaluation of our application by performing foot gestures that corresponded to various scenarios, including take-off, landing, starting and stopping video recording, moving forward, and moving backward a drone. A visual representation of these gestures can be seen in Fig. 2. If additional gestures are required, modifications to our basic gesture recognition pipeline may be necessary, such as preprocessing the raw signal or implementing new recognition techniques [29]. Fig. 3 displays $\theta-R$ images obtained from the Walabot radar when placed on the floor and corresponding to the gestures shown in Fig. 2, with varying distances measured by the radar sensor.

The Walabot radar sensor was placed on the floor at various locations to generate the heatmap screenshot for different scenarios. This placement was chosen to allow for interaction with the feet. In each scenario, the experimenter sat on a chair and used his right foot to perform gestures (a) and (b) within the active zone labeled *near*. For scenarios (c) and (d), a mouse pad was placed on the floor with the Walabot radar sensor underneath. To represent the situation in which the radar sensor is placed below an object such as a carpet, the experimenter raised his foot higher on the z axis and made gestures for the active zone labeled *close*. In the last case, the radar sensor was placed on a vibrotactile floor, which is available in our research laboratory. The experimenter executed gestures (e) and (f) to simulate the scenario in which the sensor is integrated into the floor within the active zone labeled *far*. This method is the same as the paper [2].

Another assessment was made when the experimenter was seated, allowing interaction through knee gestures. By sliding the knee to the left and right at varying distances from the radar sensor, the experimenter could access three active areas: *near, close,* and *far* for interacting with drone. The Walabot radar device was placed on the wall, 20 cm above the floor. Alternatively, when the experimenter was not seated, more extensive sliding movements of the left or right foot could be performed to execute foot gestures. Fig. 3 illustrates foot gestures, the distance measured by the radar sensor, and the different placements of the sensors. For more examples of where to place radars, we recommend looking at [1].

Different types of data can be extracted from a radar system, such as velocity, range, and direction of motion. The specific details obtained vary depending on the modulation technique utilized to control the drone, for example:

[1] The Python programming language is widely recognized as one of the most popular programming languages. It consistently holds the top position in the Tiobe ranking (https://www.tiobe.com/tiobe-index/), with a steady rating of 13.97% from 2023 to 2024.

[2] https://developer.parrot.com/docs/index.html

[3] https://api.walabot.com/_sample.html

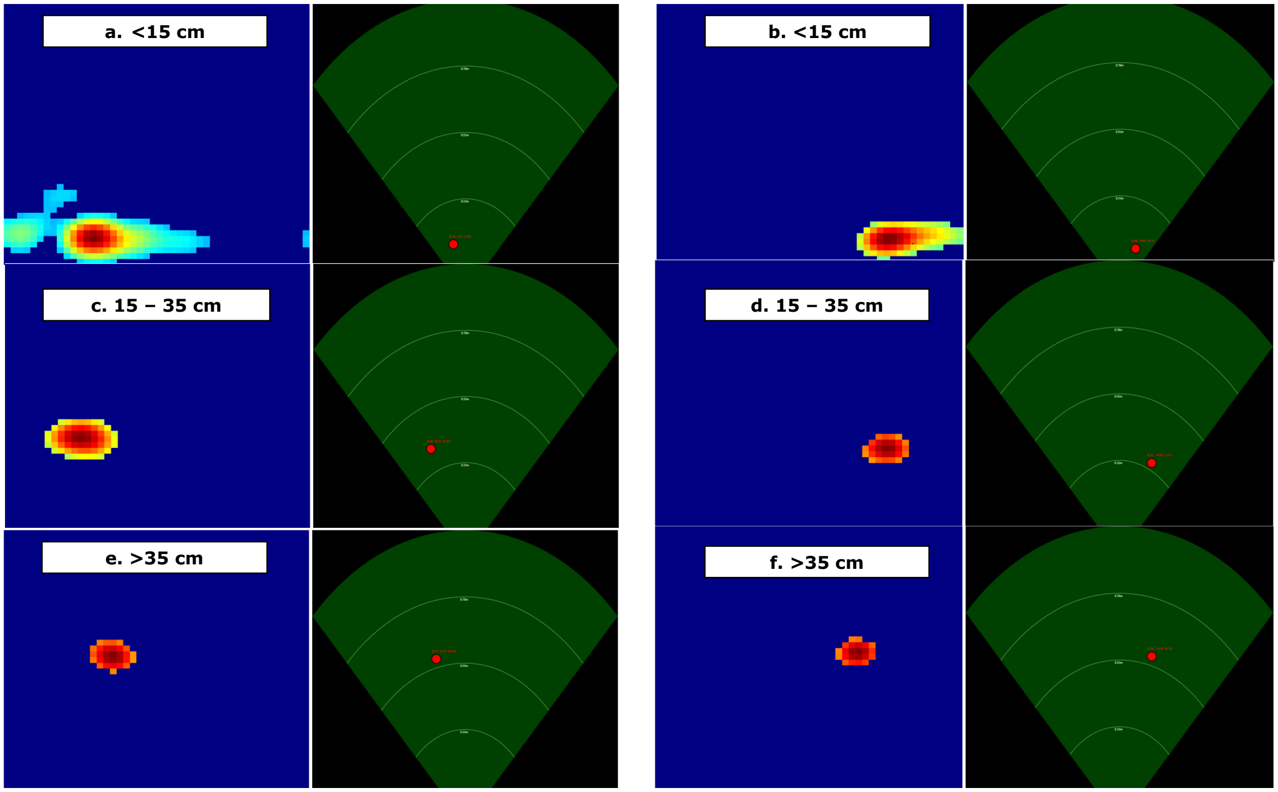


Fig. 3. The radar sensor captures $\theta - R$ images of various actions, including (a) take-off, (b) landing, (c) starting and (d) stopping video recording, (e) moving forward, and (f) moving backward. Each image shows foot gestures and the distance measured by the radar sensor.

- 1D, *continuous-wave (CW)* — modulation separates objects by their velocity. There is no possibility of distinguishing objects of similar velocity from objects' location. Frequently used for motion detection applications. Drones have the potential to be used in various sports, including running [30]. In addition, a 1D radar system can be used to indicate the moment when a runner crosses the finish line.
- 2D, *frequency-shift keying (FSK)* — modulation separates objects by distance and velocity. Location of objects in a one-dimensional environment without information about the angle. The modulation being FSK, it only separates objects based on speed, and it offers the advantage of measuring the distance. Drones, for example, are found on construction sites before or during the execution of construction work, working alongside human workers [31]. The 2D radar will be utilized to gauge the distance between objects.
- 3D, *frequency-modulated continuous wave (FMCW)* — multiple input/multiple output (MIMO) modulation separates objects by velocity, distance and angle. Objects of the same speed, distance, and angular position can be detected and their 2D location determined. Multiple transmission and reception antennas increase the resolution of the sensor. Drones have various applications in emergency situations, such as search and rescue operations [32]. In the event of an avalanche, a 3D radar sensor can be used to determine the distance between the rescuers and the individuals in need of assistance.
- 4D, *FMCW MIMO* — modulation separates objects by velocity, distance and angle (horizontal and vertical). Objects with the same speed, distance, and angular distance can be detected. Objects can be located in 3D. Compared to a 3D radar, 4D radars use more antennas and can detect the angle between horizontal and vertical. This brings about the advantage of locating objects in a 3D environment. Drones or clusters of drones are commonly used for aerial shows [33], as well as for image projection [34] and aiding in projections [35]. The 4D radar sensor can be used to calculate the speed of the aerial displays to coordinate their positions.

We did not use the 1D-RADAR and 2D-RADAR categories because we want to cover as many functionalities SkySculptor as possible and, in certain situations, distinguish gestures from different objects in the room. Depending on the resolution, we can choose different commercial radar sensors, also putting emphasis on the operating distance. For example, in the case of integrating the radar sensor into the floor or wall, we are going to need a much smaller distance, compared to the situation where the sensor is integrated ceil. The initial form of the algorithm scans targets to flip pages of an opened document; If the y coordinates of the identified targets were decreasing, the up button was pressed to access the previous page, and if the targets were increasing, the down button was pressed to access the next page. We modified this algorithm at both the recognition level and the semantic level of gestures. We wanted to better recognize the original form, so we calculated the sum of the evaluated y coordinates. Now, if the values are decreasing and the sum is negative, we stand for a *swipe-left*; otherwise, if the values are increasing and the sum is positive, a *swipe-right* is identified. For each identified gesture, we send a specific command via WebSocket to the Drone running on the PC in our situation, such as: forward [36], [37], backward [38], [39], take a photo [11], etc.

Radar-sensing gestures imply that a gesture is made in air, without touch. To this end, another feature that is interesting for a gesture is the distance of foot from the Walabot. In this way, we modified the original algorithm by also capturing the z coordinate. Because a gesture is made up of a set of points, we calculate the average distance between the foot and Walabot. We obtain the result that a gesture can be performed near *near* Walabot, at a reasonable distance from it *close* or very far from Walabot *far*. In summary, we identified *two* swipe gestures x *3* possible positions of each gesture, that is, a set of *six* gestures.

V. Results

The creation and implementation of SkySculptor, a specialized software designed to improve drone interactions using foot gestures detected by radar, have produced positive results. The software was developed with specific design requirements to ensure smooth compatibility with open-source technologies. Integrating radar sensors into the application's framework enabled drone control by recognizing foot movements detected by the Walabot radar device. A set of six unique directional swipe gestures was introduced, each linked to predefined drone functions, allowing users to easily perform actions like drone take-off/landing, starting/stopping video recording, and changing directions. During the prototype phase, the use of a 15-antenna ultra-wideband 3D radar in combination with the Parrot Mambo drone was used to validate the effectiveness of the gesture recognition system. The ability of the radar sensor to capture detailed foot trajectories at various distances and angles provided reliable data for accurate gesture recognition. Detailed radar heat maps showed the gestures and spatial positions of the radar sensor. Overall, the successful implementation of SkySculptor demonstrates its potential to extend the human-drone interaction in smart indoor environments, paving the way for future advancements in this evolving field.

VI. Discussions

The introduction of SkySculptor, a software application aimed at simplifying drone control through radar-based foot gestures in intelligent indoor spaces, involves a series of discussions. The central theme of this scientific article revolves around the effective merging of open-source technologies with the intricacies of smart indoor environments to ensure a variety of user interaction methods and technological functionalities. Using radar sensors, SkySculptor uses conventional drone control techniques, offering users an intuitive interface based on foot gestures, which improves the accessibility of indoor drone manipulation. Moreover, the successful deployment and verification of SkySculptor underscore the potential to extend radar-based gesture recognition systems to transform the dynamics of human-drone interactions. These outcomes collectively pave the way for a wider acceptance of radar-based foot gesture control systems.

VII. Limitations and Future Work

Our implementation uses Python-based APIs to control drones and radar devices. While Python's versatility and widespread support are commendable, certain specialized or restricted environments may encounter difficulties in fully accommodating Python. This is particularly true for wearable devices or embedded systems, which may have limited resources or be optimized for alternative programming languages. Another limitation is associated with the data transmission capacity of the radar device. Enhancing this capability could enable for a more extensive implementation of a wider range of gestures for drone control. Currently, the SkySculptor software tool does not have a predefined set of user-customized gestures. Future development considerations include improving the gesture dictionary through code generation and incorporating a radar device capable of processing larger volumes of data. Lastly, there is a limitation in terms of drone compatibility, which is currently limited to Parrot drones. Adapting the software implementation to be compatible with other drone brands presents a challenge. In addition, limitations extend to factors such as drone size, flight time, and sensor configurations. These challenges present opportunities for further development within the SkySculptor software system. Furthermore, different types of radar will produce different types of data. Therefore, it is useful to investigate other characteristics of radar sensors, such as resolution or field of view, in future work to implement various designs of gestures. We leave the examination of diverse radar technologies for future research.

VIII. Conclusion

The software application, SkySculptor, presents a novel approach to controlling drones in smart indoor environments by using gestures of the foot on radar. This addresses a gap in the current literature regarding the use of foot gestures for drone control. The article provides an overview of the context and scope of SkySculptor, emphasizing the fundamental principles of radar sensing and the potential of this technology for controlling drones in intelligent indoor environments. The related work highlights the limited information available on foot gestures for drone control despite previous research efforts. Additionally, the paper presents a detailed workflow for SkySculptor, which includes design requirements, an implementation approach, and a prototype of the proposed system.

Classifying Motorcycle Rider Helmet on a Low Light Video Scene using Deep Learning

John Paul Q. Tomas, Bonifacio T. Doma
School of Information Technology, Mapua University, Makati, Philippines

***Abstract*—For safety in transportation, it is important to always monitor the use of proper motorcycle helmet, especially at night. One way to enforce transportation rules and regulations in wearing proper motorcycle helmet is to use computer vision technology. This study focusses on classifying motorcycle rider helmet at low light video conditions, like at dusk and at night, using YOLOv5 and YOLOv7 with Deep SORT. In these deep learning methods, the study tunes and optimizes hyperparameters to attain high accuracy in classifying motorcycle rider helmet at this challenging environment. To accomplish this objective, a vast and diverse dataset was employed, containing classes such as riders, different types of helmets (valid and invalid), and instances of riders not wearing helmets at all in Metro Manila, Philippines. The results show that Hyperparameter 3 consistently outperformed other settings in terms of precision (95.6%), recall (91.2%), and mean average precision (mAP) scores across multiple scales and time frames with 95.1% on mAP@0.5 and 76.3% on mAP@0.95, owing to greater epochs, quicker learning rates, and lower batch sizes.**

Keywords*—Artificial intelligence; computer vision; computer vision problems; object detection; YOLOv5; YOLOv7; Deep SORT; deep learning

I. Introduction

Wearing motorcycle helmets is essential for the safety of riders especially in the Philippines, where over 1,000 motorcycle-related road crashes occurred in 2019 [1-2]. Research from the World Health Organization reveals helmets can reduce motorcycle crash death risk by up to 40% [3]. This emphasizes the necessity of helmets to prevent injury or death for riders [4-8]. Helmet use is mandated by many countries' laws. Yet, detecting helmet use in low-light conditions, at dusk or at night, remains a challenge. This study evaluates You Only Look Once (YOLO) version five models combined with Deep Simple Online Realtime Tracking (Deep SORT) for detecting helmet use in nighttime traffic situations in Metro Manila, Philippines. Meanwhile, Metro Manila's traffic persist due to car-centric policies and resistance to eco-friendly transportation [9]. Efforts like the Public Utility Vehicle Modernization Program face challenges due to historical norms and current crises. Addressing low light conditions in object detection is another hurdle, tackled by a study that integrates multi-scale detection, attention mechanisms, and Convolutional Block Attention Module (CBAM) for improved accuracy in identifying objects under limited light [10]. The YOLOv5 Small – Feature Combinatorial Grouping (FCG) model showcased up to 87.5% mean accuracy precision (mAP) in detecting objects like helmets in challenging low light, highlighting the potential of advanced techniques.

Combining YOLOv7 and Deep SORT offers cutting-edge object recognition and tracking, applied in real-time video analysis [11]. They contribute to safer roads by identifying helmetless riders. These open-source technologies continually evolve, serving the research community and the public. The YOLOv5 algorithm achieves high detection accuracy while maintaining real-time performance, making it suitable for a variety of computer vision applications. On the other hand, YOLOv7 is a one-stage object detection system that divides an image into grid cells and predicts bounding boxes and class labels for each. Both algorithms utilize a convolutional neural network (CNN), mainly employed for calculating bounding boxes, and the use of a SoftMax layer for class label prediction [12]. The architecture of the network consists of three main parts: the backbone network, the neck network, and the head network. The backbone network oversees extracting picture features. The neck network oversees fusing the backbone network's extracted features. The head network oversees predicting the bounding boxes and class labels for the objects in the dataset.

Moreover, the main contribution of this study is the tuning and optimization of hyperparameters within the framework of YOLOv5 and YOLOv7 with Deep SORT to classify accurately motorcycle helmets at low light video scenarios with respect to the authors' previously conducted study [13]. To the best of our knowledge, we believe that this is the first study done on this type of video scenes for this application. The enhancements made will definitely be beneficial to the implementation of transportation rules and regulation on wearing of proper motorcycle helmets at all times using computer vision technology.

II. Related Works

A. YOLOv5

YOLOv5 is an object detection technique that improves on the success of prior YOLO models by introducing a real-time object detection methodology. It performs object detection tasks by dividing an input image into grid cells and predicting bounding boxes and class probabilities for items within each grid cell using a deep CNN architecture [14]. Its methodology includes a novel approach known as a "cross-stage partial network" that improves the network's feature representation capabilities and enables more accurate object detection [12]. The algorithm achieves high detection accuracy while maintaining real-time performance, making it suitable for a variety of computer vision applications. In a study conducted by Jia et al. (2021) [15], they proposed an end-to-end motorcycle helmet detection using YOLOv5 wherein motorcycle riders were detected including the riders wearing helmets. The model was able to achieve an exceptional accuracy having an mAP up to 97% for each classes. However, it is important to note that these results were only evaluated in a high-light condition since the dataset used only contains noon time footages of highways.

B. YOLOv7

YOLOv7 is an improvement of YOLOv5. It is also a one-stage object detection system that divides an image into grid cells and predicts bounding boxes and class labels for each. It also uses a CNN which primarily used to forecast the bounding boxes, and a SoftMax layer is used to predict the class labels [10]. Its network is divided into three sections: the backbone network, the neck network, and the head network. The backbone network oversees extracting picture features. The neck network oversees fusing the backbone network's extracted features. The head network oversees predicting the bounding boxes and class labels for the objects in the dataset. As for the backbone network in YOLOv7, it uses the CSPDarknet53 network [16–19]. CSPDarknet53 is a revision of the Darknet53 network that has been shown to improve performance and accuracy. In YOLOv7, the neck network is the called the YOLOv7-Neck network, which is used in fusing the features extracted by the backbone network. The head network, on the other hand, is in charge of predicting the bounding boxes and class labels for the image's objects. It is trained using a dataset of tagged images with bounding boxes and class labels for the objects in the images. The training procedure is divided into two stages: pre-training and fine-tuning. Moreover, the network is trained on a huge dataset of photos tagged with bounding boxes and class labels for the objects in the images during the pre-training phase. The pre-training phase is used to understand the fundamental properties of objects.

According to Nandhakumar [19], YOLOv7 outperforms earlier object detection algorithms in terms of both speed and accuracy. It can reach real-time speeds of up to 160 frames per second while maintaining great precision. As a result, it is a helpful tool for a wide range of applications, including autonomous driving, video surveillance, and robots. Currently, there have been no studies yet that utilized YOLOv7 in detecting motorcycle helmet specifically in low-light conditions. It has been used before in detecting Camellia Oleifera Fruit in orchard scenes by Wu et al [20], as well as Chicory Plant by Gallo et al. [21]

C. Deep SORT

Deep SORT on the other hand is a method for tracking multiple objects that combines a deep learning-based object detector and the SORT (Simple Online and Realtime Tracking) algorithm. This method improves on traditional tracking methods by employing a deep neural network to generate high-quality embeddings that encode the appearance of seen objects [19-20]. These embeddings are then used in conjunction with a Kalman filter-based tracking framework to associate and track objects over successive frames. Deep SORT provides powerful and dependable tracking by combining appearance, motion dynamics, and temporal information. social distancing measures during the COVID 19 pandemic by Narinder Singh Punn et al. (2020) [22], as well as Pear fruit detection by Addie Ira Borja Parico and Tofael Ahmed (2021) [23].

D. Scale

YOLO has multiple scales, from nano, small, medium, large, xlarge. The nano-scale model is the algorithm's smallest and fastest variant, but least in precision. It contains fewer layers and characteristics than the medium and large scales, making it better suited for deployment on resource-constrained devices. The YOLOv5 small-scale model performs effectively in object detection tasks despite its smaller size. It detects objects in an image using a single convolutional neural network (CNN) architecture, with a focus on small objects, and incorporates data from several sizes of the input image using a feature pyramid network (FPN) [11].

A single convolutional neural network (CNN) architecture is used in the medium-scale model to detect objects. It also anticipates object-bounding boxes through the use of anchor boxes [26]. It does, however, use more anchor boxes than the small-scale model, allowing it to distinguish objects with more precision. It can also detect objects with high precision while maintaining real-time performance as its major characteristic, making it suited for a wide range of real-world applications. Finally, the large-scale model operates similarly to the previous model scales, but because it employs larger layers and a greater number of anchor boxes than the small and medium-scale models, it allows for the identification of objects with even greater precision [14].

E. Inference

To use model testing and inference in YOLOv5, which is the process of using the trained model to make predictions based on new unseen data. The model would be prepared and configured the Python environment with the required dependencies. Then all the test images or videos should be collected to generate the YOLOv5 configuration file, this includes the model's weights and parameters. Then infer by running the test data through the model and generate bounding box predictions for object recognition. The predictions can still be refined by removing redundant detections with non-maximum suppression and scaling the coordinates to fit the original image size. Finally, plot the bounding boxes on the images or videos to visualize the results [1][16].

F. Hyperparameters

In YOLO, adjusting hyperparameters entails fine-tuning several settings to optimize the model's performance. Considering the speed and accuracy requirements, the architecture of the YOLOv5 model can also be adjusted by selecting different scales such as YOLOv5s, YOLOv5m, or YOLOv5l [27]. Experimentation with hyperparameters such as learning rate, weight decay, and batch size, can all have a major impact on training. To boost generalization, regularization techniques such as dropout and data augmentation can be used. It is critical to evaluate the model's performance using evaluation metrics such as mean average precision (mAP) and to iteratively alter the hyperparameters based on the results. By carefully tweaking these hyperparameters, the model's detection accuracy and overall performance can be enhanced [18]. Full model framework can reference based on the image below Fig. 1, the application of Kalman filter in which Deep SORT is integrated for optimization [24] [28].

Fig. 1. YOLOv5 multi-scaled conceptual framework.

Deep SORT is a deep learning-based multi-object tracking algorithm that is capable of tracking objects over time even when they are occluded or partially visible. It uses a combination of appearance information and motion cues to track objects in real-real time. By combining the YOLOv7 with Deep sort, the system works by first using YOLOv7 to detect objects in each frame of a video stream. The detected objects are then passed to the Deep Sort algorithm, which associates objects across frames and tracks them over time. By combining both object detectors, the system can track multiple objects in real time, even in complex and cluttered scenes.

It is critical to apply Kalman filter in improving Deep Sort algorithm's tracking performance as it adds temporal information and refine tracking predictions. The Kalman filter is initially initialized with the object's position and velocity represented by the state vector and covariance matrix, then forecasts the next state based on the object's motion model throughout each time step. When new detection or tracking data becomes available, the Kalman filter updates the measurement, including the measurements into the estimating process and changing the state estimate. This enables the Kalman filter to smooth out noisy detections, handle occlusions, and provide more accurate and consistent object tracking predictions in Deep SORT [24]. The full model framework can be referred to using the graphic below Fig. 2.

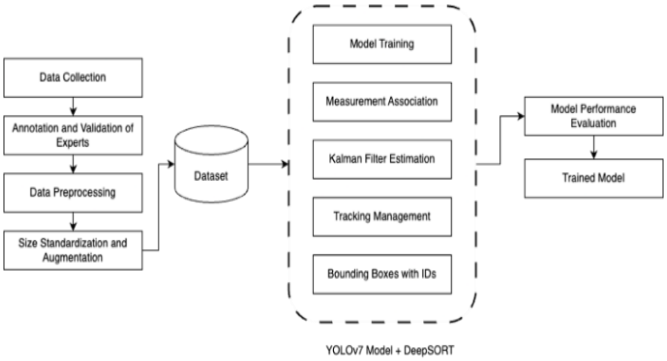

Fig. 2. YOLOv7 + Deep SORT conceptual framework.

G. Synthesis

Reviewed studies indicate that the performance of YOLOv5 is limited in low-light conditions while YOLOv7 remains unexplored along with the implementation of Deep SORT in terms of detecting motorcycle helmets in low-light scenarios. The researchers then aims to address this by exploring the performance of the two models with the help of hyperparameter tuning to achieve optimal results.

III. Methodology

The study compared two YOLO versions: YOLOv5 and YOLOv7. Deep sort was integrated as an optimization in YOLOv7 [24], [25].

A. Scaling

To ensure uniformity in image dimensions and maintain consistency during both the training and inference stages of the model training, each image were resized to a resolution of 640x640 pixels using Roboflow.

B. Inference

The dataset was divided into three parts: 70% for training set, 20% for validation set, and 10% for testing set with the use of Roboflow. After the model has been trained using the training set. The validation set was used to evaluate the performance of the model based on the initial training for the optimization of hyperparameters then the testing set was used to evaluate the unbiased performance of the model on new unseen data.

C. Tuning amd Optimization of Hyperparameters

Three hyperparameter configurations were used: (1) Hyperparameter 1 with 0.01 LR, 64 Batch, and 50 Epochs, (2) Hyperparameter 2 with 0.02 LR, 32 Batch, and 75 Epochs, (3) Hyperparameter 3 with 0.03 LR, 16 Batch, and 100 epochs.

The study also included another version of the YOLO, which is version 7. Most of the initial processes of this model are the same as YOLOv5, but it differs in processes such as measurement association and Kalman Filter Estimation.

D. Data Gathering

The dataset was gathered from a bustling street in Makati City, Philippines, renowned for its substantial motorcycle traffic. The data collection process was strategically conducted during three distinct timeframes to encompass diverse lighting conditions: 5-6 PM, 6-7 PM, and 7-8 PM.

E. Data Pre-Processing

In this step, Smart Video Player was used to monitor the video footage and to identify which timeframes would be relevant to be used in the model. This was followed by annotation. The next step is annotation. The collected footages were monitored to make sure that there were enough types of riders for each scenario: riders with helmets (half-faced or full faced), no helmets, and invalid situations.

The images were then annotated and separated using the training-validation-test splitting method, wherein 70% was used for training, 20% was used for validating, and 10% was used for testing. The images were annotated with four (4) label classes namely Motorcycle Rider, Helmet Full-Faced, Helmet Half-Faced, No Helmet, and Invalid Helmet as shown in Table I.

TABLE I. IMAGE LABEL CLASSES

Class Label	Image Sample
Rider Full Face	
Rider Half-Face	
Rider Helmet Invalid	
Rider No Helmet	

Three strategies were used for pre-processing, including auto-orientation, resizing, and class modification. Images were auto-orientated to align to a standard orientation before feeding them into the model. This technique ensures that the images are in the correct orientation for processing, which can increase the model's accuracy. Because the orientation of the motorcycle rider and helmet might change substantially in different photos, auto-orientation is especially important in the context of helmet recognition for motorcycle riders.

The images were then resized and expanded to the typical size of 640x640. This strategy ensures that all of the photos are of the same size, which is required for the model to efficiently assess the images. Resizing the photos can also help to minimize the model's computational complexity, making it faster and more efficient. In the area of motorcycle helmet recognition, scaling the photos to a consistent size can be very significant because the size of the motorcycle rider and helmet can vary greatly between images.

Finally, the images were class modified by mapping and dropping specific classes from the dataset. In this scenario, 16 classes were mapped while 0 were dropped. This strategy ensures that the model is trained on the relevant classes and can increase the model's accuracy. Dropping classes entails deleting extraneous classes from the dataset whereas mapping classes requires merging comparable classes into a single class. In the domain of motorcycle helmet detection, mapping and removing classes can help to ensure that the model is trained on the necessary classes and can detect helmets effectively.

F. *Data Augmentation*

Various image enhancement techniques were employed to augment the dataset. These included flipping, rotation, cropping, grayscale conversion, and color distortion. Flipping involved horizontal or vertical image flipping, while rotation altered images in clockwise, counterclockwise, or upside-down orientations. Random cropping was applied to zoomed image sections. Grayscale conversion turned images to grayscale, and color distortion adjusted hue, saturation, brightness, and exposure [22]. Applying these enhancements resulted in three training examples per original image, expanding and diversifying the training dataset. These techniques increased the model's resilience to input photo variations.

Bounding box augmentation was also performed, applying the same techniques to helmet-bounding boxes for accurate post-transformation alignment [22]. Augmentation, in the context of motorcycle helmet identification, improved model resilience and accuracy. The augmented, pre-processed dataset was split for model training, validation, and testing. A YOLOv5 model was developed for different scales, with modifications based on three time frames.

The time frames (5-6 PM, 6-7 PM, 7-8 PM) accounted for varying luminance, affecting helmet visibility. Images were tagged into four classes as depicted in Table I, "Rider Full Face" depicted helmets covering the entire head. "Rider Half Face" showed helmets protecting the top and back, excluding the chin. "Other Helmets" encompassed non-motorcycle headgear. "Rider No Helmet" included images of unprotected riders. This approach facilitated effective helmet detection and classification.

G. *Model Training*

The dataset of photos or videos of motorcycles and motorcycle riders wearing helmets was prepared by ensuring the following: bounding boxes were drawn around the objects of interest (motorcycles and helmets), together with class labels indicating whether the object is a motorcycle or a helmet. It is critical to include a diverse range of motorcycle and helmet types in the dataset to guarantee that the model can detect these objects under a variety of situations.

After the dataset has been prepared, the YOLOv5 model architecture must be configured. This entails deciding on a model size (such as YOLOv5s, YOLOv5m, or YOLOv5l) and determining the number of classes to detect. In this particular scenario, the motorcycle and the rider’s helmet.

After configuring the model architecture, the next step is to start the training process. During training, the model iteratively updates its weights based on the loss calculated between the predicted and ground truth bounding boxes and class probabilities. The objective is to minimize this loss function by adjusting selected hyperparameters until the model produces accurate and consistent predictions.

For each of the architecture, time frames were considered to segment changes in lighting conditions. Then, the three hyperparameters were used within the experiment. Aside from using the default hyperparameter setting, additional settings were included by changing the learning rate, batch size, and epoch during training. Learning rate is a hyperparameter that determines the magnitude of the update to the model's parameters during the training process. It controls how quickly the model converges to the optimal solution and can have a significant impact on the model's performance. Batch size refers to the number of training examples used in one iteration of the optimization algorithm during the training process. The batch size is a hyperparameter that can have a significant impact on the model's performance and training time. Lastly, in machine learning, an epoch refers to a complete iteration through the entire training dataset during the training process. The number of epochs is a hyperparameter that determines how many times the algorithm will cycle through the entire dataset. Each epoch is broken down into batches, and the model's parameters are updated based on the loss function calculated on each batch.

To further discuss the optimization process, different hyperparameter settings were applied in the different YOLOv5 architectures (YOLOv5s, YOLOv5m and YOLOv5l) and YOLOv7 as shown in Table II, specifically, the first hyperparameter setting has a configured learning rate of 0.01, batch size of 64, and 50 epochs. The second had a higher learning rate of 0.02, but with a smaller batch size of 32, and more epochs of 75. The third setting has the highest learning rate of 0.03, smaller batch size of 16, and more epochs of 100. Though these settings, and applied in the different time frames, optimized HP can be determined for each of the architectures.

TABLE II. TRAINING HYPERPARAMETERS

Hyperparameter Name	Learning Rate	Batch Size	# of Epochs
H1	0.01	64	50
H2	0.02	32	75
H3	0.03	16	100

Moreover, to improve the robustness of the model, data augmentation techniques such as random cropping, flipping, and resizing were used to create more variations in the training data. Once the training process was complete, the model was evaluated on a validation set to measure its performance. Metrics such as mAP and intersection over union (IoU) were used to evaluate the accuracy and robustness of the model.

H. Model Validation

To validate the model, the "detect.py" script, was used. This script effectively conducted bounding box predictions and class estimations on the designated test images. The core functionality of YOLOv5 was harnessed to accomplish this. Subsequent to the bounding box predictions and class estimations, an essential step known as inference computation was performed. This involved the integration of the predicted bounding box information with corresponding prediction rates.

For a comprehensive model validation process, the "val.py" script was applied. This script, crucially, made use of the optimal model weights contained within the "best.pt" file, ensuring the utilization of the most refined model configuration. This choice of weights maximized model performance. Within the validation process, the script meticulously computed a suite of performance metrics. These metrics encompassed crucial elements such as classes identified, total images assessed, individual instances detected, as well as precision, recall, and mean average precision values. These calculated metrics collectively formed a robust quantitative representation of the model's efficacy and accuracy in object detection and classification [8].

IV. RESULTS

A. Effect of Timeframes

Three different timeframes were used. Each timeframe can be described as follows. During the 5-6 PM timeframe, as depicted in Fig. 3, the environment still retained traces of daylight, albeit with a diminishing intensity. The sun's descent casted elongated shadows, and the street came alive with a mixture of natural and emerging artificial light sources, such as streetlights and the headlights of vehicles.

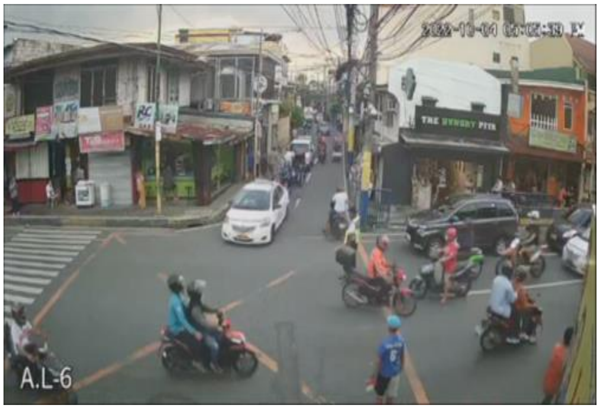

Fig. 3. 5-6 pm footage.

As the clock advanced to 6-7 PM, based on Fig. 4, the setting underwent a noticeable change. The sky took deeper hues of twilight, and the natural light waned further. Streetlights begin to dominate the scene, creating a stark interplay between light and shadow. Details became less discernible, and the environment embraced an ambiance of early evening.

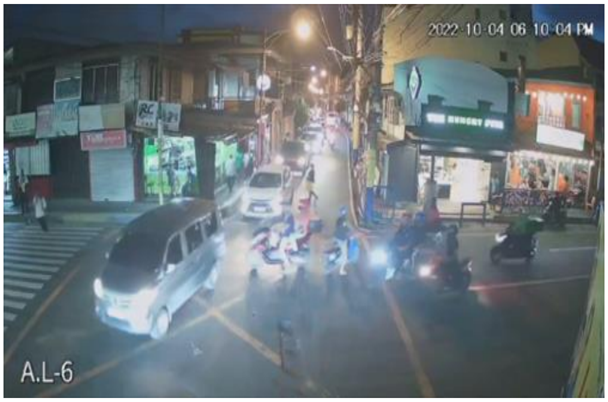

Fig. 4. 6-7 pm footage.

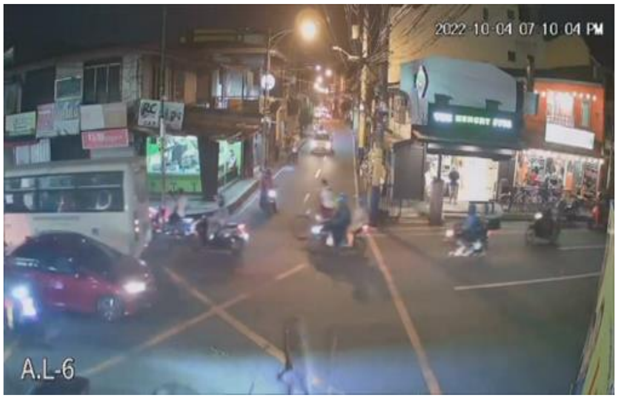

Fig. 5. 7-8 pm footage.

By the time 7-8 PM arrived, as depicted in Fig. 5, darkness had firmly settled in. The streetlights and vehicle headlights became the primary sources of illumination, casting a subdued glow across the surroundings. The scene exuded an atmosphere of low light, with visibility significantly limited compared to earlier hours.

These deliberate timeframes were chosen to comprehensively capture the spectrum of lighting conditions that motorcycle rider's encounter. The resultant dataset's pre-processed videos effectively portrayed the evolving illumination scenarios, enriching the machine-learning model's ability to navigate and respond adeptly across varying levels of lighting intricacies.

B. YOLOv5

The model's performance was evaluated using different hyperparameters in various scenarios and summarized in Table III. In the YOLOv5 Small scale results from 5 to 6 PM, Hyperparameter 3 yielded the best performance, achieving an average precision of 94.4%, an average recall of 89.8%, an average mAP@.5 of 94.3%, and an average mAP@.95 of 73.8%. Moving to the YOLOv5 results from 6 to 7 PM, Hyperparameter 3 also had the best performance, achieving an average precision of 75.6%, an average recall of 65.6%, an average mAP@.5 of 68.3%, and an average mAP@.95 of 40%, especially in the Rider class. In the YOLOv5 Small scale results from 7 to 8 PM, Hyperparameter 2 performed the most achieving an average precision of 62%, an average recall of 59.3%, an average mAP@.5 of 61.4%, and an average mAP@.95 of 49.2%.

Various hyperparameters yielded different results across three varying time frames. While different hyperparameters performed well on certain scenarios. The Hyperparameter 3 performed the most while striking a balance between precision and recall.

C. YOLOv7 with Deep SORT

The results presented in Table III reflects the performance of the YOLOv7 model under different hyperparameters and timeframes. Notably, precision, recall, and mAP (mean Average Precision) scores were evaluated to gauge the model's ability to accurately detect and classify objects within these specified contexts.

During the 5-6 PM timeframe, Hyperparameter 3 exhibited the highest precision (94.4%), recall (89.8%), mAP@.5 (94.3%), and mAP@.95 (73.8%). Shifting to the 6-7 PM timeframe, Hyperparameter 1 stood out with the highest precision (75.6%) and a relatively good recall (65%), leading to a commendable balance between the two metrics. Lastly, in the 7-8 PM timeframe, Hyperparameter 2 demonstrated the highest precision (72.3%), recall (68.2%), mAP (70.6%), and mAP@.95 (63%). These results show that the implementation of Deep SORT to the training of YOLOv7 models had outperformed the results of its predecessor YOLOv5 given the hyperparameter configurations mentioned in Table II

TABLE III. YOLOV5 AND YOLOV7 RESULTS

Model	Parameters			
	Precision (%)	***Recall (%)***	***mAP@.5 (%)***	***mAP@.95 (%)***
Timeframe 5-6 PM				
YOLOv5 (L) H3	94.4	89.8	94.3	73.8
YOLOv7 H3	95.6	91.2	95.1	76.3
Timeframe 6-7 PM				
YOLOv5 (L) H3	75.6	65.6	68.3	40
YOLOv7 H1	86	73	79.5	51
Timeframe 7-8 PM				
YOLOv5 (M) H2	62	59.3	61.4	49.2
YOLOv7 H3	72.3	68.2	70.6	63

V. DISCUSSION

Our study compared three hyperparameter settings in YOLOv5 and YOLOv7 with Deep SORT object identification models which demonstrated the importance of hyperparameter adjustments in achieving superior performance metrics [18]. Particularly for certain classes such as riders and invalid cases, H3 regularly displayed higher precision, recall, and mAP scores. To address issues such as accurate helmet detection, however, fine-tuning and rigorous evaluation are still required. These findings contribute to the continuous developments in object detection models and provide useful insights for computer vision researchers and practitioners.

Based on the outcomes of the different models, it is recommended that researchers and practitioners working with object identification models, particularly YOLOv5 and YOLOv7 with Deep SORT, take into account the ideal hyperparameter settings revealed in study [6] [10] [13] [12]. Specifically, Hyperparameter 3 regularly outperformed other scales and time frames, with higher precision, recall, and mean average precision (mAP) ratings.

Implementing Hyperparameter 3 (higher epochs, quicker learning rates, and smaller batch sizes) can result in enhanced object detection accuracy and better localization of certain classes such as riders and invalid cases. It is crucial to highlight, however, that further study and fine-tuning may be required to overcome difficulties with helmet identification, as this area demonstrated space for development.

Finally, this work emphasizes the need of doing comparative analyses and experimenting with different hyperparameter settings to maximize model performance. As the science of computer vision advances, it becomes increasingly important to adjust and refine hyperparameters to achieve the best results for individual applications.

Overall, this study gives useful insights on hyperparameter tuning in object detection models, as well as practical recommendations for scholars and practitioners in the field. Practitioners can improve the accuracy and performance of their object detection systems by evaluating the findings and using the recommended hyperparameter values, thereby contributing to breakthroughs in computer vision and its diverse applications.

Further research could explore innovative techniques and data augmentation methods tailored to low-light scenarios. Leveraging advancements in low-light image enhancement and night vision technologies could prove beneficial. Additionally, the incorporation of infrared or thermal imaging sensors in object detection models may enhance the accuracy of helmet detection under challenging lighting conditions. Moreover, collaborating with experts in the field of motorcycle safety to collect real-world data from diverse lighting environments and helmet types would be invaluable for training and evaluating detection models. Lastly, an emphasis on fine-tuning hyperparameters, such as those highlighted in this study, should continue to be a crucial aspect of future research efforts to achieve more robust and reliable helmet detection, ultimately contributing to increased safety for riders.

VI. Conclusion

In conclusion, our study comparing YOLOv5 and YOLOv7 with Deep SORT object identification models revealed that YOLOv7 with Hyperparameter 3 consistently outperformed YOLOv5 and other hyperparameter settings in terms of precision, recall, and mean average precision (mAP) scores. Specifically, Hyperparameter 3, characterized by higher epochs, quicker learning rates, and smaller batch sizes, proved to be the superior choice for achieving enhanced object detection accuracy, especially for certain classes like riders and invalid cases. These findings suggest that YOLOv7 with Hyperparameter 3 is the recommended configuration for practitioners and researchers working in the field of object detection, highlighting its potential to contribute significantly to advancements in computer vision applications.

***Abstract*—This study aims to explore the coupling relationship between science and technology finance and economic corridor development in my country based on the life cycle theory of industrial clusters. By analyzing the interaction between science and technology finance and the development of economic corridors, our degree of correlation and influence mechanism at different stages are revealed. The main findings of this study include that at different stages of the life cycle of industrial clusters, there are differences in the effect of science and technology finance on the development of economic corridors, showing a gradually strengthening or decreasing trend; there is a strong positive relationship between science and technology finance and the development of economic corridors. Coupling relationship, the development of science and technology finance promotes the construction and development of economic corridors, and vice versa; the coupling relationship between science and technology finance and the development of economic corridors has important policy implications and provides useful information for government departments, business managers and scientific research institutions Reference and guidance. These findings are of great value to the formulation and implementation of science and technology finance policies, the planning and construction of economic corridors, and the cultivation and development of industrial clusters. Government departments can adjust science, technology, finance and economic corridor development policies based on the characteristics of the coupling relationship to promote their coordinated development and virtuous cycle. Based on the research results, business managers and scientific research institutions can optimize resource allocation, enhance innovation capabilities, and achieve sustainable development.**

Keywords*—Technology finance; regional economic development; industrial clusters; life cycle theory

I. INTRODUCTION

Technological finance has received much attention in regional economic development because it integrates modern technology and advocates innovative financial and technological investment. In recent years, Chinese local governments have kept abreast of national policy trends and vigorously promoted the close integration of technology finance and regional economic development around regional innovation strategies. For one thing, local governments actively offer help in studying and improving science and technology, the change of accomplishment in science and technology, and the industrialization of high-tech. It has a diversified service system of science and technology finance with local characteristics. On the other hand, local governments set out to formulate guidelines for developing Internet finance and explore the path for the healthy and sustainable development of the local Internet finance industry. Technological and financial innovation is a crucial correlative factor for China's regional economy's current and future increase. Combining the two can bring about a qualitative leap in regional economic development. However, innovative elements such as technology, information, and talents tend to agglomerate in economically developed regions in recent years. This leads to a significant gap in innovation capability between regions in China. How to effectively and evenly combine technological finance and regional economic development in different regions has become a problem. Hence, it is of practical importance to study the coupling connection between technological finance and regional economic development.

Tracing the historical development track of science and technology finance and regional economy, financial technology can improve financial services through various technological innovations, so the research on financial technology is becoming increasingly new daily. Ra Jeswari R investigated the evolution of tech finance in global markets. He exposed issues like the driving factors of fintech, the disadvantages of conventional financial services, and technological advances [1]. His research can help us improve fintech innovations, but more experimental verification is needed. Golab P researched the role of technology finance and regional economy and proposed that technological innovation is one of the important factors of financial development [2]. His research can point out the development direction for us in a targeted manner, but more detailed verification is needed in the specific operation. Liu Z studied technology finance from the perspective of environmental protection and advocated its benefits for developing a green economy [3]. His research is very helpful for our sustainable development but lacks specific operational means. Arif M studied the status quo of fintech in the development of financial inclusion in China, and he proposed that although China's financial system has made great progress, the gap between developed and under-developed areas is still huge [4]. Boshkov T's research showed that tech finance improves data transmission and analysis. He also provided opportunities for small companies to build low-cost distribution models and risk administration applications [5].

Life cycle theory is widely used in various fields and solves different problems for different scholars. Oskouei Z H started with cash flow and used life cycle theory to predict a company's profitability [6]. His research can provide a reference for company operations, enhancing the growth of the regional economy. Besides that, scholars often mention the life cycle theory of industrial clusters. Yan S studied the development of population urbanization from the view of industrial cluster life cycle theory [7]. His research is conducive to the balanced growth of urban and rural areas, but whether it is effective still needs experimental verification. Starting from the life cycle theory, Cady SH put forward suggestions on the development of products [8]. His research contributed to better product building, advancing the social product economy. From the perspective of life cycle theory, Gao L H empirically analyzed the influence of innovation and development in technology and finance on industrial agglomeration [9]. His research shows that the government should further complete a coordinated growth strategy, promote regional innovation in technology for future consideration, and achieve integration with financial development. It has to be aware of risks in the process. From the perspective of technological finance development, previous research may have paid more attention to the analysis of technological finance development trends, policy support, financial innovation and other aspects. These studies may focus on the role of science and technology finance in promoting technological innovation and industrial development, as well as the innovation and application of science and technology finance products and services. From the perspective of economic corridor construction, past research may have focused on analyzing the impact of economic corridor construction on regional economic development and coordinated regional development. These studies may focus on the impact of economic corridors on regional industrial structure, industrial layout, talent flow, etc. In terms of the life cycle theory of industrial clusters, past research may have focused more on the characteristics and evolutionary rules of the formation, development, maturity and decline stages of industrial clusters. These studies may focus on the analysis of internal relationships within industrial clusters, industrial chains, technological innovation, etc. Current research focuses more on linking the life cycle theory of industrial clusters with technology finance and economic corridor development to establish a relevant theoretical framework. By integrating theories from different fields, we conduct an in-depth exploration of the impact mechanism of science and technology finance on the development of economic corridors at different stages.

This paper is divided into five sections. Section I introduces the background and significance of the research, summarizes the importance of science and technology finance and economic corridor development, and then briefly expounds the basic concept of industrial cluster life cycle theory and its application value in this study. Section II discusses the research methods of the coupling relationship between science and technology finance and regional economic development in China; Section III uses selected methods and data to analyze the coupling relationship between science and technology finance and economic corridor development. Section IV summarizes the results of empirical analysis, answers the research questions, and validates the hypothesis and finally Section VI concludes the paper.

This paper starts from the life cycle theory of industrial clusters and extracts features from different cycles as indicators to study technology finance and regional economy growth. It also analyzes the coupling degree of the two. The innovation of this paper is to integrate physics knowledge into economic research. Based on the CCD model and classification of physics, it determines the level of coupling and coordinated growth of regional economy growth and technology finance, thereby providing an intuitive basis for the comparative analysis of coupling and coordination degrees.

II. Methods of the Coupling Relationship between China's Science and Technology Finance and Regional Economic Development

A. Theory of Life Cycle of Industrial Clusters (LCIC)

The industrial cluster life cycle theory refers to the following. When people find that industrial clusters have their life course, just like creatures in nature, many economists apply life cycle theory to industrial clusters to analyze their development law more accurately [10]. There are various divisions for the life cycle of industrial clusters, most of which are divided into six stages by European SMEs. The United States divides it into five stages, with four and three-stage divisions [11]. This paper adopts China's usual division method and divides LCIC into four phases, as shown in Fig. 1.

According to Fig. 1, the life cycle of an industrial cluster can be grouped into a formation stage, a growth stage, a mature stage, and a decline stage. The characteristics of these four stages are described in detail below:

1) Formation stage: At the beginning of this stage, only a few related enterprises may gather together. These enterprises take advantage of local resources or locations to develop slowly. Since the aggregation in geographic space reduces the transaction cost and risk of cooperation between enterprises, there is a certain aggregation effect. However, the cluster's development momentum is still weak due to the lack of various factors, such as various markets, government policy support, and related support institutions. However, it is also because the starting point of the base of the company's sales revenue at this time is relatively low, so the development speed of the company at this stage is relatively fast.

2) Growth stage: In this stage, many enterprises bring capital, technology, human resources, management mode, etc., into the cluster. The supporting hardware facilities, regional innovation, and network environment have also greatly increased the internal enterprise's economic strength. Universities, research institutions, and industry associations also increase, making the cluster a strong driving force for development [12]. The economic effect produced by the industrial cluster has become the economic growth point of the region, and the government, therefore, gives more support in terms of policies and other aspects. Industrial clusters have entered a stage of rapid growth. Clusters also increase the entry threshold of enterprises due to the improvement of various internal levels.

3) Mature stage: In the mature stage, after the accumulation and precipitation of the formation stage and the growth stage, the scale of the industrial cluster begins to stabilize gradually. The development speed has also gradually slowed, and many funds, technologies, and human resources have gathered within the cluster. Still, the attractiveness of various external resources has begun to decline. It should be noted that the resources the developing enterprises rely on after the formation and growth period are gradually exhausted, and their efficiency begins to decrease. At the same time, the over-aggregation of enterprises in the cluster also led to the decline of the industrial cluster [13].

4) Recession stage: In the recession phase, many companies within the cluster relocate, and the problem of losing technical talents and funds of the remaining enterprises also becomes serious. Malicious competition within enterprises is becoming more and more frequent. If some new major changes, such as major innovations, can occur at this stage, the cluster can be transformed into a new life cycle stage. It would otherwise not change the recessionary trend [14].

B. *Inflection Point of the LCIC*

In the development course of the LCIC, three turning points of acceleration, consolidation, and control usually appear. Fig. 2 shows a schematic diagram of the inflection point in the life cycle of an industrial cluster.

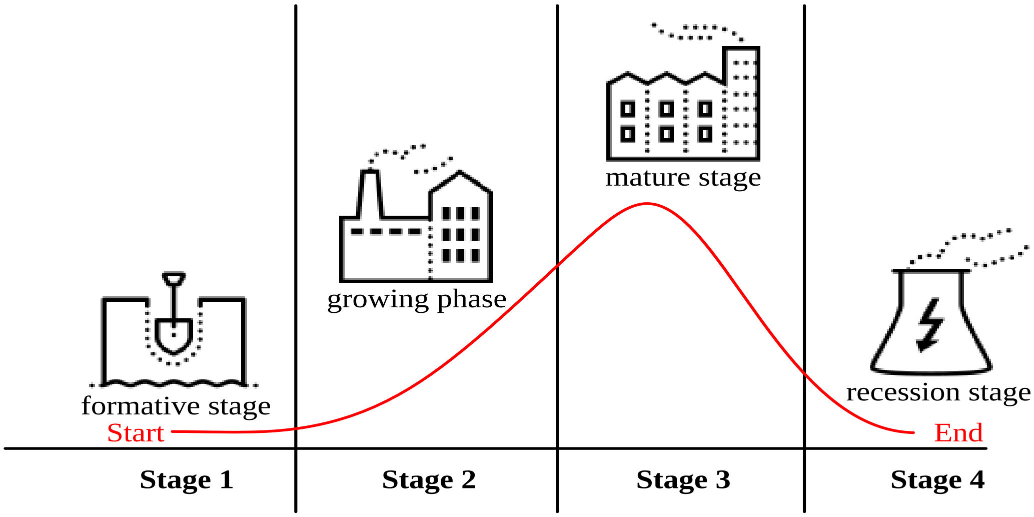

Fig. 1. Four stages of LCIC.

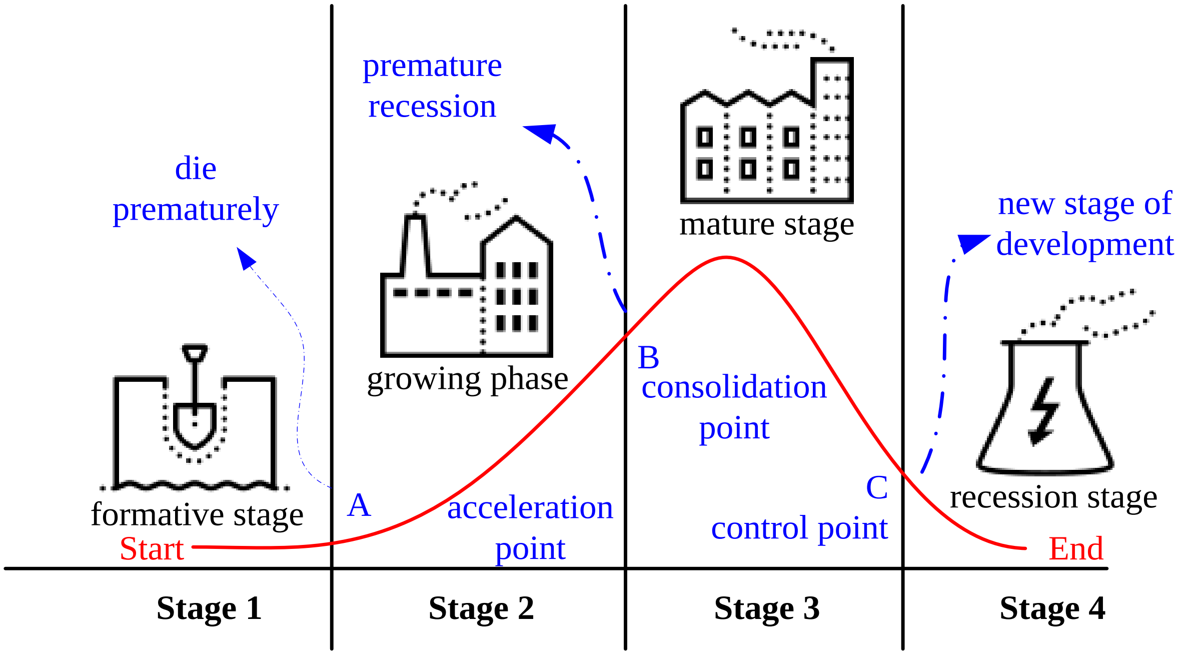

Fig. 2. Inflection points in LCIC.

As shown in Fig. 2, the four stages of LCIC and the three inflection points can be seen in the development process. From the mature phase of the industrial cluster, the mature stage can be classified into two parts: the upper-rush phase and the falling phase. Due to various reasons inside and outside the cluster, the cluster will have a decline stage until after the control point. Finally, the development of the industrial cluster will gradually decline, and it will enter the decline stage until it disappears.

The inflection points of acceleration, consolidation, and control mentioned above are a few special and critical periods in the life cycle development of industrial clusters. After different inflection points, the clusters will face different situations and characteristics. Whether these inflection points can be accurately judged plays an important role in judging the life stage of the industrial cluster and the possible future trend [15]. On the one hand, judging these inflection points can provide us with reasonable suggestions and measures to improve the overall competitiveness of the cluster and prepare for breaking through the inflection points to accumulate strength. On the other hand, according to the internal situation of the cluster after different inflection points, its characteristics can be extracted as an indicator of the coupling system of technology finance and regional economy growth.

C. Coupling and Coordinating Index System of Technological Finance and Regional Economy Growth

1) Index selection: According to the system coupling theory, this paper regards technology finance and regional economic development as two subsystems of system coupling $S = \{T, F\}$. Among them, T is technology finance, and F is regional economy. By dividing different inflection points in the life cycle of industrial clusters in the previous section, based on grasping the stage characteristics and influencing factors of technological finance and regional economic development, it comprehensively considers China's actual national conditions. It selects static and dynamic indicators and then scientifically and reasonably constructs an indicator system for the coupling and coordination degree of science and technology finance and regional economy suitable for panel data spanning two dimensions of time and space. Table I shows the contents of each indicator.

Science and technology finance support policies refer to the policies and measures introduced by the government in the region to support the development of science and technology finance, including tax incentives, loan support, entrepreneurial subsidies, etc.; regional economy measures the driving effect of the construction of economic corridors in the region on the surrounding regional economy, including employment growth, industrial upgrading etc.

2) Entropy weight determination: Determining the weight is a necessary link in the comprehensive evaluation process and a key step in quantifying the comprehensive evaluation index. The results of determining the weights can have an important impact on rationality and scientific evaluation. The entropy weighting method belongs to the objective weighting method. It generally uses mathematical operation technology to determine the weight, which can avoid the interference of human and subjective factors. It has been widely discussed and applied by academia in recent years [16].

First, it makes assumptions about the selected indicator variables. It represents the number of years, K means the number of indicators, and J means the number of regions. Then x_{ijk} stands for the k-th index variable in the j region of the ith year, and the value of the index variable is X. The specific calculation process is as follows:

a) Standardization of indicators: Since each evaluation index has different dimensions and units, it is necessary to continue to standardize the index variables, and the normalization method is used in this paper. The calculation process is shown in Formula (1):

$$x'_{ijk} = x_{ijk} - xminmax_{min} \tag{1}$$

b) Calculate the index entropy value: After the standardization process, each index variable's weight 'y ijk is calculated, and the calculation process is shown in Formula (2). According to the weight results of the index variables, the entropy value e_k of the k-th index can be calculated, and the calculation process is shown in Formula (3), $k \geq 0$, $k = ln(IJ)$.

$$y'_{ijk} = x_{ijk} / \sum_i \sum_j x'_{ijk} \tag{2}$$

$$e_k = -k \sum_e \sum_j y'_{ijk} \, ln\left(y_{ijk}\right) \tag{3}$$

TABLE I. THE INDEX SYSTEM OF THE CCD OF SCIENCE AND TECHNOLOGY FINANCE AND REGIONAL ECONOMY

System Layer	Target Layer	Indicator layer	Variable explanation
Technology Finance (T)	Technology innovation investment	Human input	Full-time equivalent of R&D personnel (person-year)
		financial input	Fiscal spending on technology (%)
	Technological innovation output	Licensing	Number of Patents Accepted (%)
		technology export	Total merchandise exports (%)
Regional Economy (F)	economy of scale	Financial depth	Deposit and loan balance (%)
		financial competitiveness	Number of listed companies (s)
	economic performance	capital allocation ratio	Loan balance (%)
		Insurance depth	Premium income (%)

TABLE II. THE WEIGHT OF THE INDEX WEIGHT OF THE COUPLING AND COORDINATION DEGREE OF SCIENCE AND TECHNOLOGY FINANCE AND REGIONAL ECONOMY

Indicator variable	2016	2017	2018	2019	2020	2021
Human input	0.0658	0.062	0.0562	0.0636	0.0694	0.0714
financial input	0.0637	0.0674	0.0565	0.0755	0.0725	0.0969
Licensing	0.0832	0.0696	0.0583	0.0597	0.0674	0.0658
technology export	0.0267	0.0361	0.0303	0.0384	0.0636	0.0320
Financial depth	0.1335	0.1340	0.1496	0.1622	0.0864	O.1641
financial competitiveness	0.0739	0.0686	0.066 1	0.0722	0.0699	0.0638
capital allocation ratio	0.0771	0.0774	0.0708	0.0715	0.0696	0.0683
Insurance depth	0.0580	0.0582	0.0504	0.0597	0.0689	0.0496

c) Calculate the indicator weight: Then, through the entropy value of each index, the information entropy redundancy d_k of each index is calculated, and the calculation process is shown in the following formula:

$$d_k = 1 - e_k \tag{4}$$

$$\lambda_k = d_k / \sum_k d_k \tag{5}$$

Next, this article selects the panel data of six regions in China from 2016 to 2021. The professional programming software MATLAB2016 uses the entropy weighting approach to calculate the weight results of each index in the technological finance and regional economic index system. The clear results are in Table II.

3) Efficacy function: Based on the entropy weighting method, this paper continues to introduce the efficacy function. The power coefficient method can reduce the bias of a single approach, which is more suitable for analyzing complex systems. The power function can measure the function of the subsystem to the composite system from disordered to ordered evolution [17]. The degree of coupling coordination is just a measure of the degree of effect in the evolution of the system coupling from disorder to order. The specific calculation process of the power function model is as follows:

a) Efficacy coefficient: Assuming a variable, $u_{nm}(n = 1,2,3\ldots,p; m = 1,2,3\ldots q)$ is the contribution of the mth index in the nth subsystem to the coupling order degree of the system, that is, the efficiency coefficient of the subsystem. Among them, $u_{nm} \in [0,1]$, when the efficiency coefficient is closer to 1, indicates that the contribution of the subsystem to the system coupling is greater. Technological finance and regional economy, as two subsystems coupled by the system, can calculate the efficacy coefficient u_{nm} of technological finance and regional economy on the degree of order through the Formula (6) of the efficacy coefficient, that is, when $n = 1,2, m = 1,2,3\ldots 7$.

$$u_{nm} = \begin{cases} \frac{Z_{nm} - b_{nm}}{a_{nm} - b_{nm}}, & proves \text{ u}_{\text{nm}} \text{ positive} \\ \frac{a_{nm} - Z_{nm}}{a_{nm} - b_{nm}}, & \text{proves u}_{\text{nm}} \text{ negative} \end{cases} \tag{6}$$

In Formula (6), Z_{nm} stands for the value of the mth index of the nth subsystem, and a_{nm} and b_{nm} represent the upper and lower limits of each index variable in the subsystem, respectively.

b) Efficacy value: Through the efficacy coefficients of regional innovation in science and technology and regional financial innovation, and using the Formula (7) of the efficacy value, the efficacy values u_n of regional innovation in science and technology and regional financial innovation on the degree of order can be calculated, namely u_1 and u_2.

$$u_n = \sum_{m=1}^{q} \lambda_{nm} u_{nm}, \sum_{m=1}^{q} \lambda_{nm} = 1 \tag{7}$$

In Formula (7), λ_{nm} is the index weight calculated by the entropy weighting method in the previous section.

4) CCD function: The CCD model is an optimization and upgrade for the defects of the coupling degree model. This paper draws on scholars' research on the CCD of multiple systems, and firstly constructs the coupling degree model of regional innovation in science and technology and financial innovation. On this basis, it continues to develop the coupling coordination model of the two [18].

a) Coupling degree model: To measure the coupling degree of regional technological innovation and financial innovation, this paper adopts the interdisciplinary expansion model of the physical capacity system model. The specific model is shown in Formula (8). When p=2, it is the coupling degree model of regional technology and finance innovations, as shown in the following formulas.

$$C_p = \sqrt{\frac{(u_1 \cdot u_2 \cdot \ldots \cdot u_p)}{\prod(u_1 + u_2 + \ldots + u_p)}} \tag{8}$$

$$C_2 = \sqrt{\frac{(u_1 \cdot u_2)}{\prod_{n=1,2,m=1,2\ldots 7} u_1 + u_2}} \tag{9}$$

In Formula (8) and Formula (9), p is the number of subsystems constituting the composite system. C is CCD between subsystems. The value range of CCD is $C \in [0，1]$. The larger the CCD value is, the stronger the CCD is. Among them, when $C = 0$, the CCD value is small, indicating no coupling between subsystems, and the composite structure tends to have a disordered structure. When $C = 1$, the value of CCD is large, indicating that the degree of coupling between subsystems is strong, and the composite system tends to be newly ordered.

b) Coupling coordination degree model

$$\begin{cases} T = \mathrm{au}_1 + \beta u_2 + \ldots + \pi \mu_p \\ D = \sqrt{C \cdot T} \end{cases} \tag{10}$$

Since the research objects of this paper are scientific and technological finance and regional economy, respectively, the CCD model of regional innovation of science and technology and financial innovation is deduced. The model is as follows:

$$\begin{cases} T = \mathrm{au}_1 + \beta u_2 \\ D = \sqrt{C \cdot T} \end{cases} \tag{11}$$

In the above formula, $D \in [0,1]$, the larger the value of coupling coordination degree, the stronger the CCD and coordination between regional technological innovation and financial innovation. Among them, when $D = 0$, it shows that there is no coupling relationship between the two systems, and there is no coordination; when $D = 1$, it means that the CCD in the two systems reaches a large value, and the coupling state presents a high level. Both systems develop in an orderly fashion [19]. Based on the actual situation of the research object in this article, only CCD $D \in (0，1]$ is considered here.

III. Coupling Experimental Design and Data Sources

This article uses the panel data of six regions in China (Northeast China, North China, Central South, East China, Southwest China, and Northwest China) from 2016 to 2021 as a sample. All data used in the study came from relevant statistical yearbooks for each year from 2016 to 2021. The indicator data comes from fiscal science and technology expenditures, public financial expenditures, technology market turnover, and total commodity exports in the "China Industrial Statistical Yearbook" of each year. In addition, due to changes in China's statistical caliber, the indicator data of "high-tech industry output value" from 2016 to 2021 is replaced by the main business income of high-tech industries. Statistics such as "technological market turnover" and "total commodity exports" in Tibet are missing. It was removed from this paper's research so as not to affect the overall results.

To realize the idea of the thesis, it is necessary to combine the relevant theoretical knowledge of industrial cluster life cycle theory, technology finance and economic corridor development, and use technical information for data collection, analysis and demonstration. The following is technical information that may be used:

1) Data collection technology: Web crawler technology: used to obtain a large amount of relevant literature, statistical data, policy documents and other information from the Internet to support the theoretical basis of research.

a) Database technology: used to establish and manage databases related to technology, finance, economic corridor development and other related data for data analysis and mining.

b) Questionnaire technology: used to survey relevant enterprises, government departments, experts and scholars, etc., to obtain their views and opinions on the coupling relationship between technology finance and economic corridor development.

2) Data analysis technology: Statistical analysis software: such as SPSS, R, etc., used to conduct descriptive statistics, correlation analysis, regression analysis, etc. on the collected data to discover the relationship between the data.

a) Data mining technology: such as cluster analysis, association rule mining, etc., used to mine hidden patterns and trends in data and reveal the potential correlation between technology finance and the development of economic corridors.

3) Model building technology: Industrial cluster life cycle model: Based on the industrial cluster life cycle theory, a life cycle model of technology finance and economic corridor development is established to describe and analyze the characteristics and development patterns of different stages.

a) Economic corridor input-output model: Based on the economic corridor theory, an input-output model is established to quantitatively evaluate the driving effect of economic corridor construction on the regional economy.

4) Visualization technology: Data visualization tools: such as Tableau, Power BI, etc., used to visually display research results in the form of charts, maps, etc., to improve the understandability and attractiveness of research results.

IV. Experimental Result

A. Calculation Results of Coupling Coordination Degree

Using MATLAB2016 software and the efficacy function formula in the second section, this paper can calculate the efficacy values of 6 science and technology finance and regional economies in China from 2016 to 2022. The coupling degree model formula in Section II can calculate the CCD of technology finance and regional economy. It can calculate the CCD index through the CCD formula. In terms of the CCD and CCD index, the coupling and coordination degree between technology finance and regional economy can be finally calculated, as shown in Table III.

B. Variation Trend of CCD

Based on the above empirical results, this article analyzes the growing tendency of CCD of scientific and technological finance and regional economy in the time dimension through the change of the mean value, ranking, and numerical value of CCD. In addition, through the consequences of efficacy value, this article compares and analyzes the development status between technology finance and the regional economy [20].

The mean is one of the important indicators reflecting the central tendency of the data, which can be used to describe the trend characteristics of the data. The mean analysis of different years can reflect the growing trend of the CCD of science and technology finance and regional economy over time. Fig. 3 shows the average change in CCD in technology finance and regional economy.

TABLE III. EMPIRICAL RESULTS OF THE CCD IN SCIENCE AND TECHNOLOGY FINANCE AND REGIONAL ECONOMY

Regions	2016	2017	2018	2019	2020	2021	2022
Northeast	0.4471	0.4408	0.4542	0.4511	0.4511	0.4440	0.4540
North China	0.2553	0.2478	0.2552	0.2751	0.2751	0.2594	0.2364
Central South	0.1531	0.1535	0.1840	0.1584	0.1584	0.1688	0.1620
East China	0.1732	0.1774	0.1907	0.1971	0.1971	0.1913	0.1133
Southwest	0.1245	0.1389	0.1465	0.1353	0.1353	0.1230	0.1530
Northwest	0.2552	0.2271	0.2169	0.2203	0.2203	0.2058	0.1098

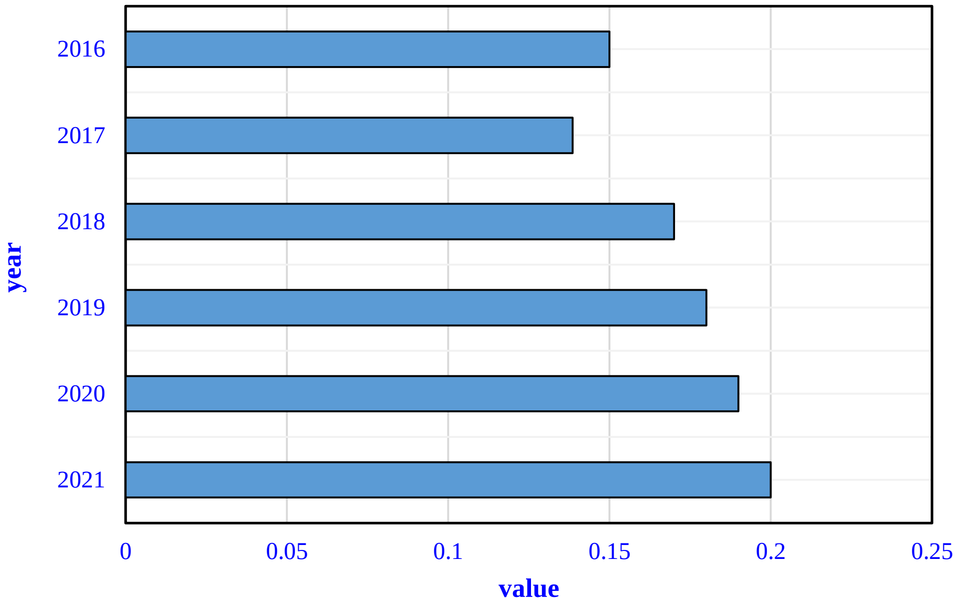

Fig. 3. The mean change of CCD between science and technology finance and regional economy.

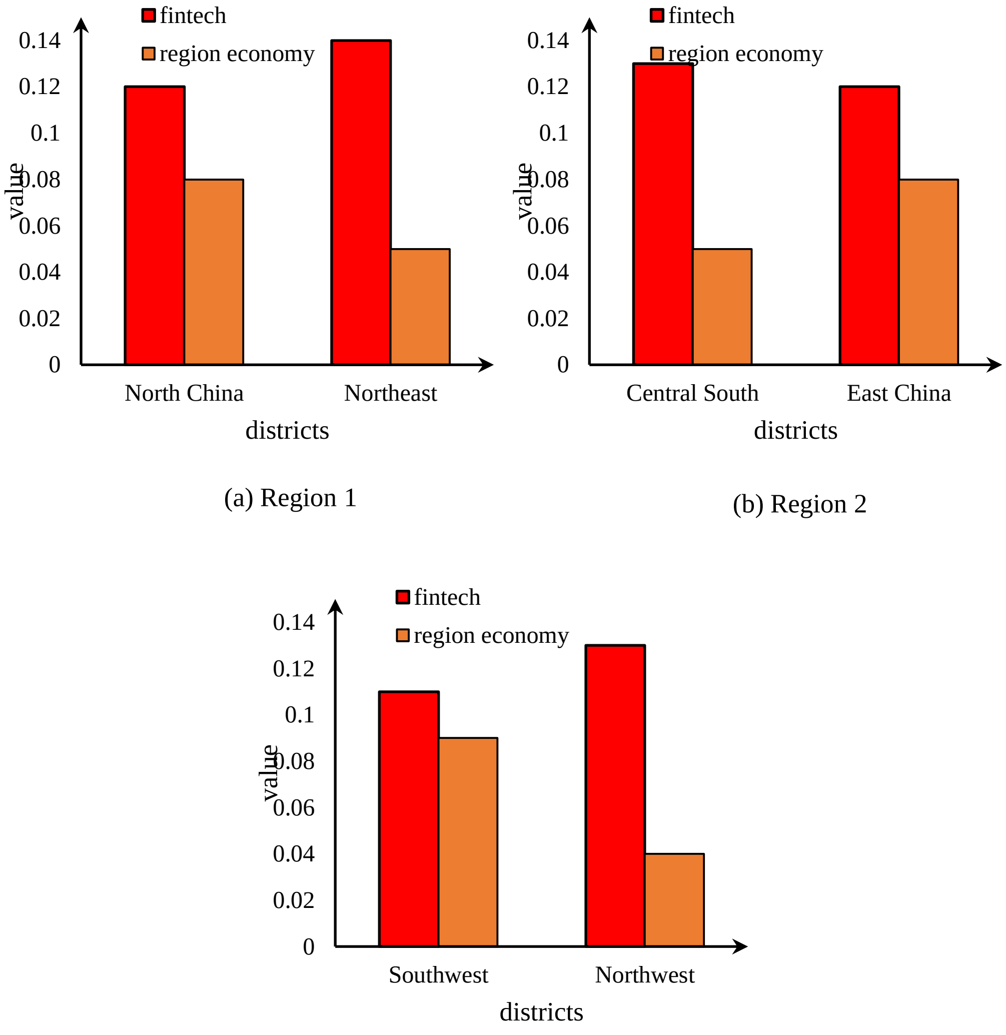
According to Fig. 3, from 2016 to 2022, the average value of CCD in technological and financial innovation in China reached 0.1508. Among them, in 2017, the mean value of CCD is the smallest, and its value is 0.1386. In 2018 and 2019, the mean value of CCD was the largest, and its value was 0.1760, which was 0.0374 different from the small value. From 2016 to 2018, the mean value of CCD increased. After 2018, the average value of CCD is generally higher than other years in the past. Apart from a mild drop in individual years, the average value of CCD in scientific and technological finance and the regional economy maintains a slow increase trend.

C. Comparison of Efficacy Values

The efficacy value can reflect the development level of regional technological innovation and financial innovation. Fig. 4 compares the efficacy values of technology finance and the regional economy in each region from 2016 to 2022.

As shown in Fig. 4, the efficacy values of technology finance in the six regions have been higher than the regional economies in the past five years, and technology finance has always been in a leading position. In 2017, the efficacy value of science and technology finance was the largest, with a value of 0.1286, and the efficacy value of the regional economy was the smallest, with a value of 0.0809. The gap between the two was large, as high as 0.0477. The regional economic development momentum slowed down. The gap between the two slowly narrowed until the gap between the two was small, only 0.0172 in 2022. Regional science, technology, and finance innovation are developing in a more coordinated direction.



(a) Region 1

(b) Region 2

(c) Region 3

Fig. 4. Comparison of efficacy values between technology finance and regional economy.

D. Variation Results of CCD in Different Regions

Based on the size of CCD, the changes in CCD in each of the six regions from 2016 to 2022 are counted, and the results in Fig. 5 are obtained:

From the numerical change of CCD in Fig. 5, from 2016 to 2022, the value of CCD of innovation in science and technology and financial innovation in East China reaches an average of 0.2676. Except for occasional large fluctuations, the overall fluctuation of CCD in East China is not large, and the changing trend is relatively moderate. From 2016 to 2022, the value of CCD of innovation in science and technology and financial innovation in the central and southern regions reached an average of 0.1649. Compared with the eastern provinces, the variation range of the numerical fluctuation of CCD in the central and southern regions is obvious. The value of CCD of innovation in science and technology and financial innovation in the northwest region reaches an average of 0.1687. The numerical change of CCD in the northwest region fluctuates very obviously, and the changing trend generally shows a tortuous trend. Generally, CCD in East China is the most stable, maintaining a leading position in the country. The ranking of CCD in the central and southern regions fluctuates greatly and is the most backward overall. CCD in the western region also fluctuates greatly and is backward.

Fig. 5. Numerical changes in CCD in science and technology finance and regional economy in various regions.

V. Conclusion

Based on LCIC, this paper extracts features through different life cycle stages as indicators for studying the coupling connection between technology finance and regional economy. In the end, the coupling relationship between them is studied. Judging from the existing research on science and technology finance and regional economy, scholars have confirmed a dynamic relationship between the two: mutual demand, mutual promotion, and integrated development. Technological finance and regional economy are coupled through the connection between internal elements, and the degree of coupling between the two determines the properties of spillover effects. The positive spillover effect of coupling technology finance and regional economy can be 1+1>2. This paper regards China as a study of the whole region, which is more in line with the basic national conditions of China's uneven regional development and the current regional development pattern. In this paper, when investigating the course of the coupling and coordinated development of regional technological innovation and financial innovation, due to limited scientific research ability and theoretical foundation, the research on the characteristics and factors of the coupling and coordinated development stage is relatively simple. Individual views are yet to be discussed and discussed. In the future, it looks forward to further research and more profound views. In terms of in-depth study of the coupling relationship mechanism, further explore the coupling relationship mechanism between science and technology finance and the development of economic corridors, including the impact of different types of science and technology finance products on the development of economic corridors, the synergy between government policies and the development of industrial clusters, etc.; In addition, it is necessary to Strengthen interdisciplinary research cooperation with economics, management, finance and other related fields, and fully tap the application potential of industrial cluster life cycle theory in the development of science and technology finance and economic corridors. It is difficult to obtain data on science, technology, finance and economic corridor development, and problems such as insufficient data collection and uneven quality need to be overcome. At present, there are still limitations in research methods, and it is necessary to combine more quantitative and qualitative research methods to improve the scientific nature and accuracy of the research. The theoretical integration between science and technology finance, economic corridors and industrial cluster life cycle theory is not yet complete, and the construction and integration of theoretical frameworks need to be strengthened.

Correlation Analysis Between Student Psychological State and Grades Based on Data Mining Algorithms

Zeng Daoyan, Chen Disi[*]
Sichuan Huaxin Modern Vocational College, Chengdu Sichuan, 610000, China

Abstract*—As society has evolved and educational reform has become more profound, the psychological state and academic performance of vocational college students have become the focus of attention for educators. This study aims to construct a correlation model between the positive psychological state and academic performance of vocational college students based on data mining algorithms to offer a conceptual foundation and practical guidance for the optimization of vocational education. The relationship between positive psychological state and academic performance was analyzed through a literature review, as well as the application of data mining algorithms in the field of education. A certain amount of data on vocational college students was collected using questionnaire surveys and empirical research methods, including their basic information, positive psychological status indicators, and academic performance data. Subsequently, data mining algorithms were used to preprocess and analyze the collected data, and a correlation model between the positive psychological state and academic performance of vocational college students was constructed. Finally, through validation and evaluation of the model, it was found that there is a significant positive correlation between positive psychological state and academic performance, and the model has high predictive accuracy. The study's results suggest that the positive psychological state of vocational college students has a significant impact on their academic performance. Educators should consider students' mental health and take effective measures to enhance their positive psychological state, thereby improving their academic performance. This study provides a new research perspective and method for the field of vocational education, which helps to promote the development and reform of vocational education.

Keywords*—Data mining algorithms; vocational students; positive psychological state; academic performance; correlation model

I. Introduction

In the context of modern education, the relationship between students' psychological state and academic performance is increasingly receiving attention. The psychological state of students, such as emotions, motivation, anxiety, and stress, can have a profound impact on their academic performance. Therefore, understanding and exploring the correlation between these two is of great significance for improving educational quality, optimizing student mental health support, and implementing personalized educational strategies [1]. With the rapid development of information technology, the application of data mining algorithms in the field of education is gradually becoming prominent. These algorithms can extract valuable information from large-scale and complex educational data, thereby providing decision support for educators. The correlation model between student psychological state and academic performance based on data mining utilizes these advanced algorithms to analyze the relationship between student psychological state and academic performance from multiple dimensions and perspectives, in order to provide scientific basis for educational practice [2].

In the context of the information society, vocational education, as an important way to cultivate applied talents, has received widespread attention in terms of its educational quality and training effectiveness [3]. The positive psychological state and academic performance of students are important indicators for measuring the quality of vocational education, and the application of data mining technology in the field of education provides new perspectives and methods for studying this issue. This study aims to provide theoretical support and practical guidance for the reform and development of vocational education by constructing a correlation model between the positive psychological state and academic performance of vocational students based on data mining algorithms [4]. Firstly, the development process of research on the positive psychological state and academic performance of vocational college students at home and abroad was reviewed, and research achievements and theoretical systems in related fields were summarized. On this basis, the challenges and problems faced by current vocational education, such as students' mental health issues, unreasonable allocation of educational resources, and imperfect teaching methods and evaluation systems, were analyzed. To address these issues, a research approach and method for constructing a correlation model between the positive psychological state and academic performance of vocational college students based on data mining algorithms has been proposed [5]. A detailed introduction was given to the application of data mining technology in the field of education, including the basic concepts, technical principles, and methods of data mining, as well as the current application status and development trends in education. Especially for the core technology of constructing a correlation model between the positive psychological state and academic performance of vocational college students, - data mining algorithms - in-depth exploration was conducted, and the advantages, disadvantages, and application scenarios of various algorithms were analyzed.

On this basis, this study proposes a method for constructing a correlation model between positive psychological state and academic performance of vocational college students based on data mining algorithms. By collecting and organizing data on the psychological state and academic performance of vocational college students, a dataset containing multidimensional features was constructed. Then, appropriate data mining algorithms were used to analyze and mine the dataset, discovering the correlation between students' positive psychological state and academic performance. A correlation model between the positive psychological state and academic performance of vocational college students was constructed based on the mining results, and the effectiveness and reliability of the model were verified. By constructing a correlation model between the positive psychological state and academic performance of vocational college students based on data mining algorithms, this study provides useful theoretical support and practical guidance for the reform and development of vocational education. At the same time, this study also pointed out the shortcomings of current research and the issues that need further exploration, providing direction and ideas for subsequent research.

This article constructs a correlation model between student psychological state and academic performance based on data mining algorithms. The innovation contribution lies in:

1) By mining historical student performance data, discover the relationship between student academic performance and various factors, and provide targeted teaching suggestions for teachers. By mining teaching data, the effectiveness of teaching methods and strategies can be evaluated, providing a basis for teaching reform.

2) This article implements a closed-loop early warning system targeting college students. This structure effectively avoids the drawbacks of traditional systems centered around counselors or related institutions.

3) The student psychological state module uses the powerful non-linear approximation ability of artificial intelligence algorithms to fit the relationship between the two, achieving the conversion of psychological category data to student psychological state.

Section I of the study elaborates on vocational education as an important way to cultivate applied talents in the context of the information society. This article introduces the techniques for constructing a model related to the positive psychological state and academic performance of vocational college students. Section II provides an immediate overview of the proposed data algorithms and discusses the main application areas of data mining algorithms. By analyzing student behavior data on online learning platforms, we can discover their learning paths, understand their learning progress and difficulties, and provide personalized learning advice and assistance to students. Section III analyzed the correlation between the positive psychological state and academic performance of vocational college students. Section IV is about the uses of various dimensions of psychological capital as independent variables and SCL-90 total score as dependent variable. The analysis elaborates on the results of multiple regression analysis of variables. Section V conducted model construction based on data mining algorithms. According to the implementation process of the system, the design scheme was experimentally validated in vocational colleges. Section VI and Section VII summarizes the entire text by providing discussion and conclusion. This study provides a new research perspective and method for the field of vocational education, which helps to promote the development and reform of vocational education.

II. Related Work

In vocational education, there is a complex and subtle correlation between students' psychological state, academic performance, relative deprivation, and academic procrastination behavior. This association not only affects the academic performance of students, but also directly relates to their mental health and future career development. Therefore, Xu et al. conducted an in-depth conditional process analysis on this issue. Firstly, it clarifies the concept of "relative deprivation". Relative deprivation is a psychological state in which an individual feels inferior or insufficient in certain aspects after comparing themselves with others. In the context of vocational college students, this sense of deprivation can be attributed to various factors such as unsatisfactory academic performance, social pressure, and uncertainty in future career planning. When students feel this deprivation, their psychological state is often negatively affected, such as anxiety, depression, and inferiority [6]. In vocational education, the relationship between students' psychological state and academic performance is not only related to their academic achievement, but also closely related to the cultivation of their key abilities. Key abilities usually refer to the core skills and psychological qualities that students need when facing future career challenges. With the development of educational technology, data mining algorithms have provided powerful tools for exploring this relationship in depth [7]. With the development of preschool education in vocational colleges, the correlation between students' psychological state and academic performance is increasingly attracting the attention of educators. The stability and well-being of psychological state are particularly important for students majoring in preschool education, as it not only affects their individual learning outcomes, but also directly relates to their future professional qualities and abilities as educators. Therefore, Wu and Yan used data mining algorithms to deeply explore the correlation between the psychological state of vocational preschool education students and their academic performance, in order to provide scientific basis for educational practice [8]. Students majoring in preschool education in vocational colleges will bear an important responsibility in cultivating the next generation in the future, and their psychological state will directly affect their educational behavior and quality [9]. Meanwhile, academic performance, as an important indicator of student learning effectiveness, is also closely related to their psychological state. Therefore, studying the correlation between psychological state and academic performance is of great significance for improving the teaching quality of preschool education in vocational colleges, optimizing student mental health education, and cultivating students to become educators with good psychological literacy [10].

In the current field of education, the relationship between students' psychological state and their academic performance has become an important issue of concern for researchers and practitioners. Previous research literature has provided us with rich knowledge background and research foundation, revealing the multiple effects of psychological state on academic performance, including motivation, emotional regulation, cognitive processing, and other aspects [11]. These studies not only emphasize the importance of psychological state in the learning process of students, but also point out the limitations and shortcomings of traditional assessment methods [12]. Although some research has achieved certain results, there are still some problems and challenges. For example, previous studies have mostly used traditional data collection methods such as questionnaire surveys and interviews, which are difficult to comprehensively and objectively reflect the psychological state of students. In addition, research methods are mostly descriptive statistics or simple correlation analysis, which makes it difficult to deeply reveal the complex relationship between psychological state and academic performance. Therefore, it is necessary to introduce advanced technologies such as data mining algorithms to analyze the correlation between the two in a more scientific and accurate way [13]. With the rapid development of information technology, the field of education is undergoing unprecedented changes. Education data mining, as an important technology, provides strong support for the analysis and prediction of student academic performance. Feng et al. aim to explore how to use educational data mining methods to effectively analyze and predict student academic performance, thereby providing valuable references for educational decision-making and practice [14]. The analysis and prediction of student academic performance based on educational data mining has broad application prospects in educational practice [15]. Firstly, it can provide scientific teaching decision-making support for teachers, helping them better understand students' learning situations and needs, and develop personalized teaching plans. Secondly, it can provide personalized learning advice and guidance to students, helping them identify their learning problems and improve their learning methods. In addition, it can also provide data support for education management departments to help them formulate more reasonable and effective education policies [16].

This study aims to construct a correlation model between student psychological state and academic performance based on large-scale educational data using data mining algorithms. We hope that through this model, we can further reveal the internal relationship between mental state and academic performance, and provide more accurate and personalized guidance for educational practice. Meanwhile, this study is also an important supplement and expansion to existing research, providing new ideas and methods for the future development of the education field.

In summary, the analysis of the correlation model between student psychological state and academic performance based on data mining algorithms has important theoretical and practical significance. Through this study, we hope to provide educators with more scientific and effective decision support, promote the comprehensive and healthy development of students, and also expand new ideas and methods for the application of data mining algorithms in the field of education.

III. Overview of Data Mining Algorithms

With the increasing development of data mining technology, various data mining tools have sprung up like mushrooms after rain. How to choose the most suitable data mining tool for needs has become a question worth pondering. Generally speaking, data mining tools are mainly divided into two categories: one is domain-specific data mining tools and the other is general data mining tools. Domain-specific data mining tools are customized and developed for specific domains or requirements. When designing algorithms for such tools, the specificity of data and requirements can be fully considered for optimization. These tools typically use special algorithms to process specific data to achieve specific goals. Due to its high degree of customization, the reliability of the discovered knowledge is usually high. However, universal data mining tools do not target specific data meanings but instead use universal mining algorithms to handle common data types. The advantage of such a tool lies in its wide applicability. For example, the Mine Set system developed by SGI, the QUEST system developed by IBM Almaden Research Center, and the DB Miner system developed by Simon Fraser University in Canada are typical representatives of universal data mining tools.

A. Main Application Fields of Data Mining Algorithms

The application of data mining algorithms in vocational education has achieved significant results. As big data technology develops, the collection and analysis of educational data have become increasingly important, and the application of data mining algorithms in vocational education is also becoming increasingly widespread. This article will elaborate on the main application fields of data mining algorithms in vocational education.

Student academic performance prediction: By mining historical student performance data, the relationship between student academic performance and various factors can be discovered, providing targeted teaching suggestions for teachers. Data mining algorithms can help teachers predict students' academic performance, identify their learning difficulties in advance, develop personalized teaching plans, and improve teaching quality.

Student turnover warning: The issue of student turnover in vocational education has always been a focus of attention for education managers. By analyzing students' behavioral data through data mining algorithms, it is possible to predict whether there is a risk of student turnover and take corresponding intervention measures to reduce the rate of student turnover. For example, by mining data on students' online behavior, course participation, and grades, it is possible to identify risk factors such as psychological problems and learning difficulties that students may have and provide targeted intervention suggestions for education managers.

Course recommendation: Data mining algorithms can recommend suitable courses for students based on their interests, background knowledge, and learning abilities. By analyzing students' course selection records, grades, and other data, students' interests and potential needs can be identified, providing personalized course recommendations to improve their learning interests and satisfaction.

Teaching quality evaluation: Data mining algorithms can help educational managers objectively and scientifically evaluate teaching quality. By analyzing data such as teachers' teaching records, students' academic performance, and course evaluations, problems and deficiencies in the teaching process can be identified, providing a basis for educational managers to improve teaching quality.

Optimization of educational resources: Data mining algorithms can help educational managers optimize the allocation of educational resources. By analyzing students' course selection records, course satisfaction, and other data, it is possible to discover the popularity of courses and students' needs, thereby providing educational managers with a basis for reasonable adjustment of course settings, teacher allocation, and other resources. There are many tools for data mining, but it is a process that only closely integrates the technology provided by data mining tools with the needs of enterprises. Only by constantly running in during the implementation process can success be achieved. When choosing data mining tools in vocational colleges, multiple factors should be comprehensively considered, such as the capability to resolve difficult issues, operational performance, and data access ability.

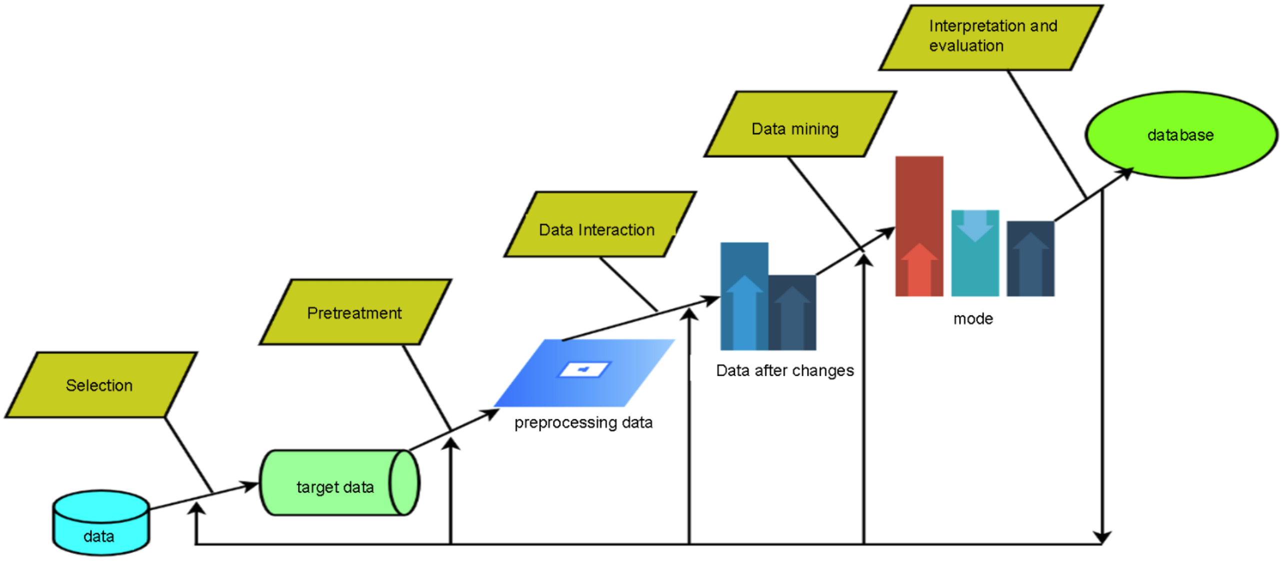

Fig. 1. Data mining process model.

Fig. 1 shows the data mining process model. In the entire data mining process, the most significant aspect is data preparation. This stage can be further divided into three sub-steps: data selection, data preprocessing, and data transformation. Data collection mainly involves finding all internal and external data information related to business objects and selecting data suitable for data mining applications. Data preprocessing involves deep processing of the extracted data to meet the needs of data mining, laying the foundation for subsequent analysis, and determining the type of mining operation to be carried out. The main job responsibilities include checking spelling errors, eliminating duplicate records, completing incomplete records, deriving missing data, completing data type conversions, and more. The data conversion process is to convert the data into an analytical model, which is established for mining algorithms. The main goal is to identify truly useful features from the initial features in order to reduce the number of features or variables that need to be considered in data mining.

B. Research on the Application of Data Mining Algorithms in the Field of Education

The application of data mining in the field of education has become an important direction of educational research. Through data mining technology, valuable information and knowledge can be extracted from a large amount of educational data, providing an important basis for educational decision-making. The learning behavior of students can be examined through data mining. By mining students' learning behavior data, it is possible to discover their learning patterns, understand their learning habits and preferences, and provide support for personalized teaching. For example, by analyzing students' behavior data on online learning platforms, it is feasible to discover their learning paths, understand their learning progress and difficulties, and provide personalized learning suggestions and assistance to students. Data mining can be used for evaluating teaching effectiveness. By mining teaching data, the efficacy of teaching methods and strategies can be evaluated, providing a basis for teaching reform. For example, the effectiveness of teaching methods can be evaluated by analyzing student performance data.

C. K-Means Algorithm

The K-means algorithm is a traditional unsupervised clustering algorithm based on distance. Finding the number of clusters and the centers of each cluster is the first step in the main concept. Then, each data point is assigned to the nearest cluster center. When all of the data points are assigned, it is the step to recalculate the center of each cluster and perform iterative calculations until the change in the cluster center is small or no longer changes. Excellent clustering results should meet the requirement that data points within the same cluster have high similarity in various attributes. In contrast, data points between different clusters have low similarity in various attributes. Definition 1 Sample Set X: Assuming there is a sample set X in a certain space, which contains m attributes and a total of n samples, A sample can be represented by Xi, and an attribute of a sample can be represented by Xit, with i ranging from 1 to n and t ranging from 1 to m. Definition 2 center point set C: Assuming there are K center points $\{c_1, c_2, \dots c_k\}$. The range of K is 1 to n, and a certain center point is represented by Cj, where the range of j is 1 to k. Definition 3: Euclidean distance: Euclidean distance is the linear distance between points in space. For example, the calculation formula from a sample point Xi to a center point Cj is shown in Eq. (1):

$$dis(x_i, c_j) = \sqrt{\sum_{t=1}^{m} (xit - cjt)^2} \quad (1)$$

Definition of MeanShift algorithm-related knowledge:

Definition 1 Sample Set X: Assuming there is a sample set X in the space, a certain sample point can be represented by Xi, and there are k such sample points. Definition 2: Region set S_h: Region set S_h represents a multi-dimensional spherical space formed by taking a point x in space as the center of a circle and then drawing a multi-dimensional circle with h as the radius. Sample set X is a collection of all data points in a region set. S_h can be represented by Eq. (2):

$$S_h = (xi|(xi - x)(xi - x)^T) \quad (2)$$

The definition form of the MeanShift vector is shown in Eq. (3):

$$M_h(x) = \frac{\sum_{xi \in Sh}(xi - x)}{k} \quad (3)$$

In Eq. (3), xi is a sample in sample set X, x is the center of the region set, and k is the number of sample points. However, in Eq. (3), the MeanShift vector has shortcomings: within the S_h region, each point plays a different role in the sub-center point. The role it plays is related to the distance between each point and the sub-center point, so improvements can be made to address this drawback.

IV. Research on the Correlation between Positive Psychological State and Academic Performance of Vocational College Students

A. Basic Situation of Psychological Health Level of Vocational College Students

To understand the mental health level of adolescent students, descriptive statistics were used to analyze the scores of ten factors in SCL-90. The results are shown in Table I. Secondly, screening was conducted on single factor scores $\geq 2, \geq 3, and \geq 4$ to obtain the rate at which mental health issues is detected (see Table II).

Firstly, according to Table I, among the SCL-90 factors, the mean of obsessive-compulsive symptoms is the highest, at 2.15 points. Rank the scores in descending order: obsessive-compulsive symptoms (2.15)>interpersonal sensitivity (1.87)>depression (1.73)>hostility=paranoia (1.72)>anxiety (1.67), terror (1.44)>somatization (1.43). The average total score of SCL-90 is 1.69, indicating that most of the student's mental health levels are normal, but they should not be underestimated for students who measure their psychological status.

TABLE I. The Overall State of Students' Mental Health in Vocational Colleges

Factor	Minimum value	Maximum value	Mean	Standard Deviation
Somatization	1	4.33	1.4	0.52
Obsessive-compulsive disorder	1	4.60	2.0	0.69
Sensitivity to interpersonal relationships	1	4.78	1.8	0.76
Depressed	1	4.62	1.7	0.67
Anxious	1	4.40	1.6	0.62
Hostile	1	5.00	1.7	0.78
Terror	1	4.43	1.4	0.52
Scl-90 total score	1	4.41	1.6	0.54

TABLE II. Detection Rate of Mental Health Problems among Vocational College Students

Factor Somatization	Factor Score⩾2		Factor Score⩾3		Factor Score⩾4	
	Number of people	*Percentage*	*Number of people*	*Percentage*	*Number of people*	*Percentage*
Compulsive symptoms	40	13.25 %	5	1.66 %	2	0.66 %
Sensitivity to interpersonal relationships	169	55.96 %	34	11.26 %	7	2.32 %
Depressed	112	37.09 %	25	8.28 %	9	2.98 %
Anxious	82	27.15 %	17	5.63 %	4	1.32 %
Hostile	72	23.84 %	14	4.64 %	3	0.99 %
Terror	92	30.46 %	25	8.28 %	8	2.65 %
Factor	45	14.90 %	5	1.66 %	1	0.33 %
SCL-90 Total score	69	22.85 %	12	3.97 %	1	0.33 %

B. Regression Analysis of Positive Psychological Capital of Vocational College Students on their Mental Health Level

Regression analysis can reveal the quantitative relationship between positive psychological capital (such as confidence, hope, resilience, optimism, etc.) of vocational college students and their mental health level. This analysis not only helps to understand which psychological capital factors are more important, but also predicts what range a student's mental health level may be in given levels of psychological capital. Confidence refers to an individual's affirmation of their abilities and values. Regression analysis can help us understand how hope affects mental health, such as whether students with stronger feelings of hope exhibit fewer symptoms of anxiety or depression. The method of gradually entering variables is used, with each dimension of psychological capital as the independent variable and the total score of SCL-90 as the dependent variable. Table IV represents the results of the multiple regression analysis that was performed on the variables.

TABLE III. REGRESSION ANALYSIS RESULTS OF POSITIVE PSYCHOLOGICAL CAPITAL ON MENTAL HEALTH LEVEL

Order	Entering variables	R2	F	B	SE	β	T
1	Toughness	0.208	78.679	-0.255	0.029	-0.456	-8.870***
2	Toughness	0.259	52.269	-0.179	0.033	-0.319	-5.495***
	Optimistic			-0.118	0.026	-0.264	-4.549***

***P＜0.001

From Table III, it can be seen that psychological resilience and optimism enter the regression equation, with resilience entering first, indicating that psychological resilience has the greatest predictive effect on mental health levels by predicting 20.8% of variables. The combined predictive power of psychological resilience and optimism is 25.9 percent. Hope and self-efficacy did not enter the regression equation. For mental health, the total score is 1.69, indicating that there are little or no psychological symptoms, but their occurrence is not frequent. The most prominent symptom among various factors is obsessive-compulsive disorder, with a mean score of 2.15, indicating that students attending vocational colleges experience mild to moderate degrees of this symptom. Impulses and thoughts are examples of compulsive symptoms that repeatedly invade an individual's daily life, and they are able to experience that they, themselves, are the source of these impulses and thoughts despite being aware of their meaninglessness. Although they resist vigorously, they are still unable to control them. The first reason for this is that students have high demands on themselves. They have been facing overly strict education from their families and schools since birth and must comply with regulations and orders. Otherwise, they will be denied, belittled, or even scolded by parents and teachers, as well as ridiculed by peers. Over time, these rules will be internalized into their strict standards. Secondly, students face negative emotions such as grievances, fears, anxiety, and depression that they experience in their emotions, learning, and interpersonal relationships, coupled with a lack of skills to express themselves directly through language or obtain satisfaction through appropriate behavior, making it difficult for them to rely on their own demands and external environment.

Environmental review. So, it transforms into symptoms of thought, emotion, and behavior and becomes compulsive symptoms through self-suppression. There were no significant differences in the analysis of psychological health factors among vocational college students from four aspects: gender, place of origin, and whether they are only children or are in single-parent families. However, the research results show that girls score significantly higher than boys in the dimension of terror, indicating that girls are more susceptible to psychological distress caused by terror. Psychological development is related to the education provided by family, school, and society. In many people's minds, there is a stereotype of girls, believing that they are not as good as boys in higher vocational education, especially in subjects such as mathematics, physics, and chemistry. Simultaneously, girls tend to experience tension, anxiety, and unease due to the mounting pressure of appearing for college entrance exams, and their fear will become apparent. Given that girls are more delicate and sensitive than boys, from the standpoint of evolutionary psychology, it is especially crucial to pay attention to their inner experiences and offer guidance on girls' mental health. The positive orientation of students' psychological capital in all dimensions$dimension\ score \geq 4$), $hope\ (57.95\%) > optimism\ (53.64\%) > resilience\ (35.43\%) > self-efficacy\ (28.48\%)$, indicates that more than half of students have more optimistic positive psychological capital. The highest scores for resilience and self-efficacy were in the range of 3 to 4, with resilience scoring 57.62 percent and self-efficacy scoring 63.58%. This indicates that vocational college students are in a general state in these two dimensions. Many students in traditional teaching methods have poor learning and personality development and need more successful experiences, which may affect their self-efficacy. Other contributing factors include the single assessment and evaluation system, low teacher-student ratio, and other issues. Social support levels, academic stress, and interpersonal relationships all have an impact on how resilient students become psychologically. No significant differences were seen in the psychological capital dimensions of vocational college students from four aspects: gender, place of origin, whether they are only children and single parent families. However, in terms of self-efficacy, boys are significantly higher than girls, and the gender differences in self-efficacy are closely related to factors such as social expectations, gender role concepts, and social reality. In addition, students from non-single-parent families are more optimistic than students from single-parent families for the following two reasons. Firstly, there is a lack of emotions, as teenagers have not only material needs during their growth process but also indispensable emotional experiences from their families. Some divorced parents do not care enough about their children and do not have their children's emotional needs. Some parents, although accepting their children, do not truly take responsibility, which leads to abandonment or neglect, affecting the personality development of teenagers. Secondly, there is a bias in social evaluation, where children from single-parent families often become the focus of discussion and are criticized or even distorted, leading to students developing a sense of inferiority.

V. Model Construction Based on Data Mining Algorithms

Fig. 2 indicates the system's overall architecture, which mainly consists of five parts: control center, warning object, data acquisition, psychological analysis, and psychological warning. For college psychological warnings, the control center mainly refers to college counselors or psychological counseling institutions, who are the executors of the plan and are mainly responsible for the operation and maintenance of the intelligent warning system and the processing of student psychological abnormal warning information. The warning targets are college students. The data acquisition mainly includes a depth-of-field data acquisition module and a data preprocessing module. The former obtains and records three-dimensional data of warning objects by reading the depth of field camera port. The latter processes the obtained raw data through data mining methods and transforms the data into standard data that can be directly input into intelligent algorithms through normalization methods. The psychological analysis section mainly includes an intelligent classification module and a psychological state module. The intelligent classification module takes standardized data as input and the psychological category of the warning object as output. By fitting the relationship between the two through the powerful nonlinear approximation ability of artificial intelligence algorithms, the psychological state module achieves the conversion of psychological category data to students' psychological state. The psychological warning section is composed of an abnormal warning module, which detects students' psychological status based on the output results of psychological status data. When an abnormal state occurs, an alarm is sent to the control center for processing. Then, the control center handles the abnormal students, thus achieving a closed-loop early warning system with university students as the warning object. This structure effectively avoids the drawbacks of traditional systems centered around counselors or related institutions. It improves the initiative and timeliness of psychological early warning work in universities by focusing on students.

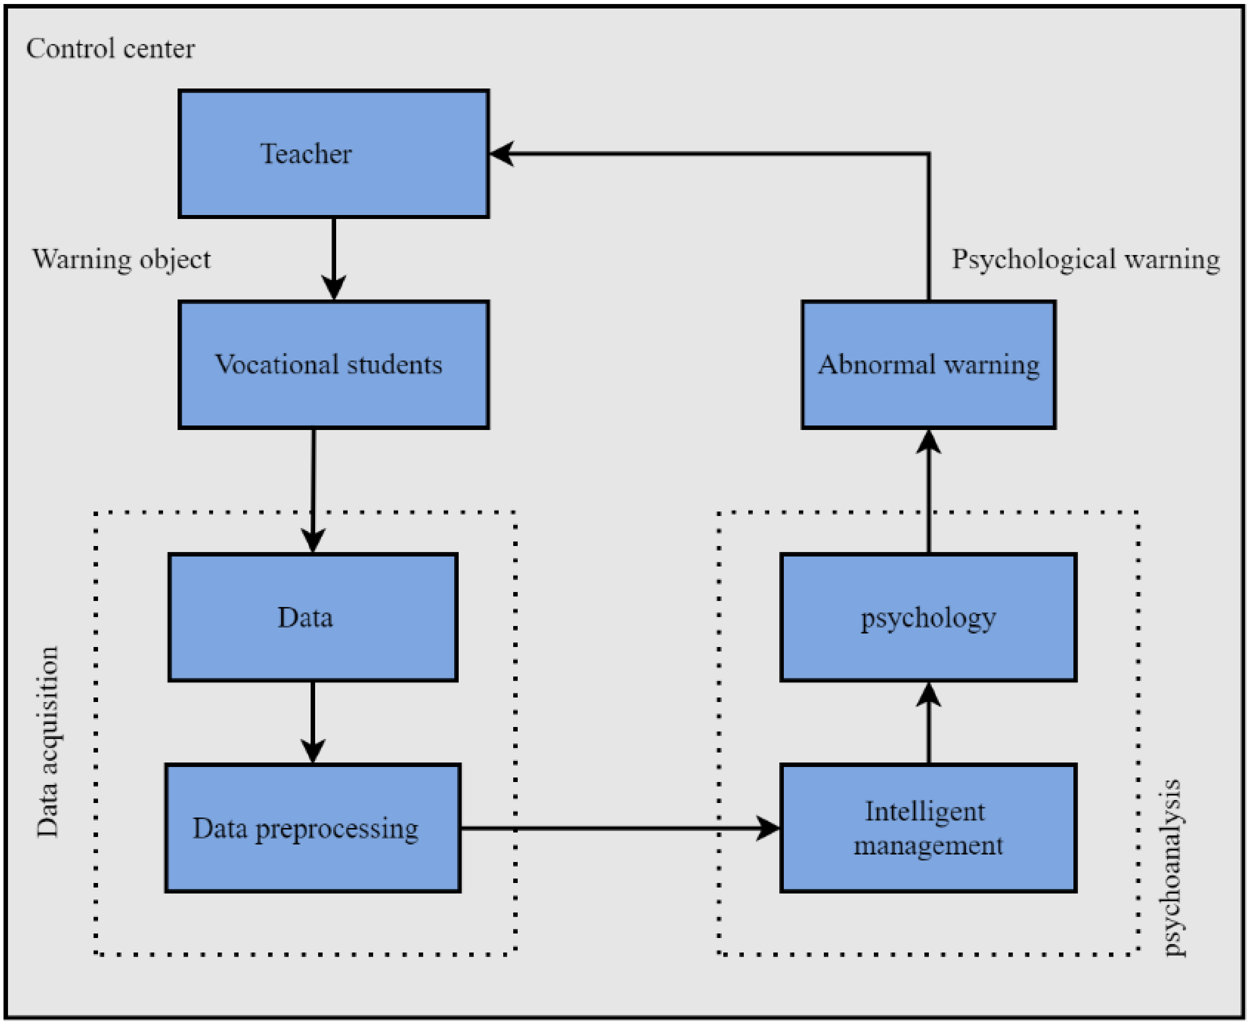

Fig. 2. Overall architecture.

A. Data Collection and Preprocessing

Due to the complexity of psychological warning problems, it is necessary to accurately extract the psychological feature data of the warning object while minimizing interference with the warning object as much as possible while considering the timeliness of data acquisition. This design uses a depth-of-field camera as the data collection device. It uses the 3D image data of the warning object in a specific area as the raw data for extracting the psychological characteristics of the warning object. In addition, in order to reduce the difficulty of data processing, this design selects the Kinect V2, a new generation somatosensory camera launched by Microsoft that currently has a relatively complete API as the data collection device. It has a high accuracy of about 2mm and has an infrared camera, making data collection possible in the case of gray and dark algorithms. By utilizing TOF technology to collect deep data, the accuracy is sufficient to identify human hand posture and even heart rate, fully meeting the requirements of psychological data extraction in this system. This article uses the official development toolkit Kinect for Windows SDK v2.0 to extract relevant data easily. The following describes the specific data acquisition and preprocessing process, as shown in Fig. 3.

B. Analysis and Interpretation of Model Results

According to the implementation process of this system, experimental verification of this design scheme was conducted in vocational colleges. Due to the particularity of the psychological abnormality warning, the recognition results of facial expression categories for the warning object in this design were verified. The validation process and results are as follows: 500 college student volunteers were selected as samples for the validation of this system. 300 of them served as the training set for the BP neural network, with each volunteer creating six types of facial expressions and using Kinect V2 to obtain training after data preprocessing, data is inputted into the neural network for training, and the remaining 200 volunteers are the test set of the scheme. The classification results of the trained BP neural network for six facial expressions in the test set are presented in Table IV.

From Table IV, it can be seen that the BP neural network designed in this article has a recognition rate of 79% for complex expressions such as expressions 4 and 6 in the recognition of facial expression states of warning objects. The overall average recognition rate is 88.6%, and the error rate is 2.3%. It can meet the needs of psychological warning and also verify the effectiveness of this system.

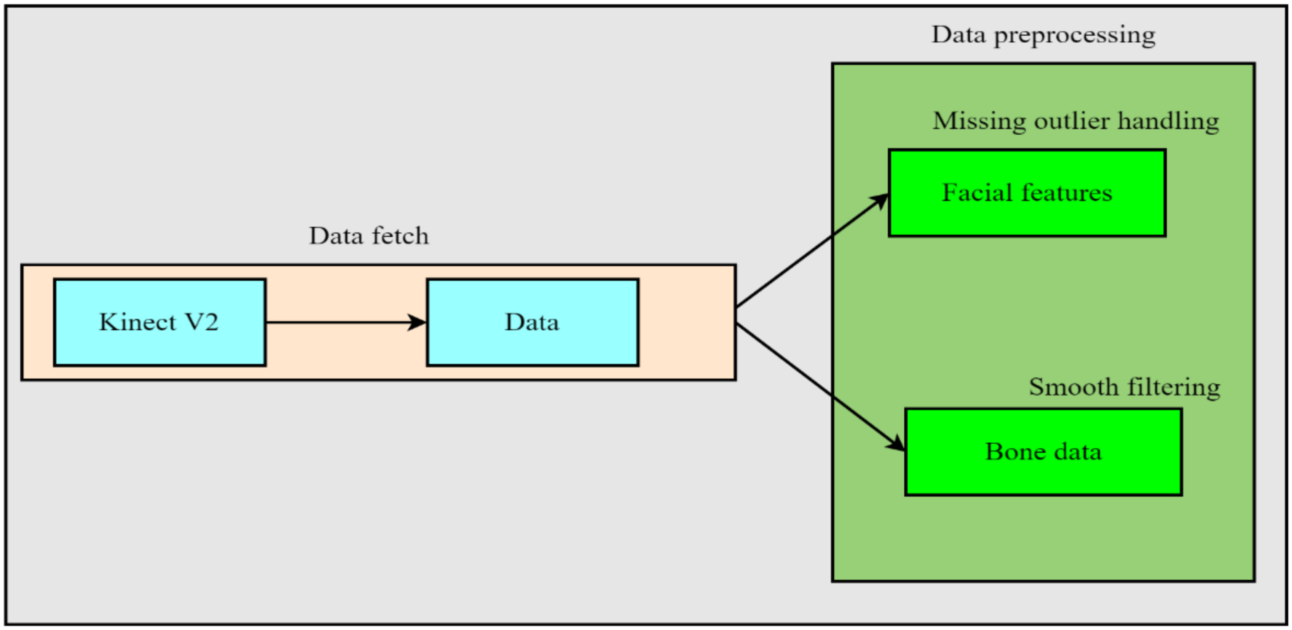

Fig. 3. Data acquisition and processing framework diagram.

TABLE IV. BP NEURAL NETWORK RECOGNITION RESULTS

VI. Discussion

This study explores in depth, the correlation between student psychological state and academic performance through the application of data mining algorithms. The results reveal a significant correlation between the two, providing a new perspective for us to understand the learning process and psychological development of students. The stability and positivity of psychological state have a significant positive impact on the improvement of academic performance, and vice versa. This discovery emphasizes the importance of mental health in the learning process of students.

Comparing the results of this study with existing theories, we found that they have some extent support relevant theories in cognitive psychology and educational psychology. For example, according to the theory of emotional regulation, the psychological state of students can affect their learning strategies and effort levels, thereby affecting their academic performance. The results of this study are consistent, indicating that psychological state is indeed one of the important factors affecting student academic performance.

Understanding the correlation between student psychological state and academic performance is of great guiding significance for educational practice. Educators can provide personalized support and intervention based on the psychological state of students, helping them adjust their mentality, enhance their learning motivation, and thus improve their academic performance. In addition, this also helps us to evaluate students' academic performance more comprehensively, not limited to a single performance indicator.

VII. Conclusion

This article explores the construction of a correlation model between the positive psychological state and academic performance of vocational college students based on data mining algorithms. An effective method suitable for the field of education has been discovered through analysis of existing data mining tools and algorithms. In the data preparation stage, data was collected, preprocessed, and transformed to meet the needs of data mining better. In the algorithm application stage, a detailed discussion was conducted on the application research of data mining algorithms in the field of education in order to find an effective method to predict the relationship between students' positive psychological state and academic performance. Through in-depth research on data mining algorithms in the field of education, vocational colleges have discovered some interesting results. A significant correlation was found between students' positive psychological state and academic performance. This means that students' psychological state during the learning process has a significant impact on their academic performance. Therefore, educators should pay attention to students' mental health in order to improve their academic performance. Data mining algorithms have broad application prospects in the field of education. By mining students' learning data, educators can better understand their learning needs and difficulties and thus develop more effective teaching strategies. In addition, data mining algorithms can also help school managers identify potential problems, such as students' mental health issues, academic misconduct, etc., and take corresponding measures to intervene. How to combine data mining algorithms with other educational technologies to enhance education quality, way of using data mining algorithms to predict students' future academic performance, and provide personalized learning suggestions for students. The resolution of these issues will bring more innovation and development to the field of education. By constructing a correlation model between the positive psychological state and academic performance of vocational college students based on data mining algorithms, a new research method is provided for the field of education. With the continuous development and improvement of data mining technology, it will become more and more significant in the field of education, making greater contributions to enhancing the quality of education and promoting educational equity.

However, there are certain limitations to the research. When collecting data, we may rely on self-report methods such as questionnaire surveys and online tests, which may lead to subjectivity and bias in the data. In addition, some important psychological state indicators may be difficult to quantify or accurately measure, thereby affecting the accuracy and reliability of the model. In future research, we need to fully consider these limitations and take corresponding measures to improve and perfect research methods, in order to more accurately reveal the relationship between psychological state and academic performance, and provide more scientific and effective decision support for educational practice.

Physical Training in Higher Vocational Colleges Based on Sequencing Adaptive Genetic Algorithm

Quanzhong Gao*
Anhui Institute of International Business, Hefei City, Anhui Province 231131 China

***Abstract*—This study is based on the sequencing adaptive genetic algorithm and conducts an in-depth discussion on optimization issues in the field of higher vocational sports training. By analyzing the shortcomings of traditional genetic algorithms in optimizing training plans, a new sequencing adaptive genetic algorithm is proposed to improve the optimization effect and adaptability of training plans. First, the optimization goals and constraints in higher vocational sports training were studied, including the diversity of training content and the rationality of training intensity. Secondly, based on the sequencing adaptive genetic algorithm, an optimization algorithm framework suitable for higher vocational sports training was designed, including key steps such as individual coding, fitness evaluation, and crossover mutation. Then, the proposed algorithm was verified and analyzed using experimental data. The results showed that the algorithm can effectively improve the optimization effect of the training plan and has strong adaptability and generalization capabilities. Finally, through comparison with traditional genetic algorithms and other optimization algorithms, the superiority and practicability of sequencing adaptive genetic algorithms in higher vocational sports training are further verified.**

Keywords—Sequencing adaptive genetic algorithm; higher vocational colleges; sports training; convergence speed

I. Introduction

With the continuous optimization and improvement of vocational education, higher vocational academic education has received more and more attention [1]. On the one hand, the cultural education of higher vocational colleges is further enriched. Still, on the other hand, the lack of physical education and training in HVC is relatively weak. For high-quality students, it is the embodiment of cultural ability and the improvement of physical quality [2], [3]. From the perspective of practicality, the physical training and education of HVC can be carried out to cultivate students' physical fitness, exercise their will, improve students' abilities from many aspects, and give play to the multiple effects of higher vocational education, the characteristic training advantages of HVC [4].

However, it is worth noting that, how to set up physical education classes in HVC and arrange them to combine work and rest, which can exercise physical fitness and relax better. In response to this problem, scholars have proposed many methods, such as introducing basic genetic algorithms, trying to change the problems of slow convergence and poor stability, and avoiding the two-level differentiation [5]. Still, the basic genetic algorithm has certain application limitations. Therefore, some scholars further optimize, introduce the genetic algorithm's incorporation of co-evolution, conduct competition among multiple courses to improve global convergence, and achieve the optimization balance of multiple courses. However, this is prone to weakening and degradation [6], [7]. Physical training in higher vocational colleges is one of the important ways to improve students' physical quality and sports skills, its purpose is to cultivate students' physical quality, improve athletes' competitive level, and promote the overall development of students' physical and mental health. The traditional training methods of higher vocational sports are often subject to the design and implementation of training plans, and there are problems such as unstable training effect and low degree of individuation, so it is necessary to introduce more scientific and effective optimization methods to improve training effect. Genetic algorithm is a common heuristic optimization algorithm in the research field of optimization problems, which has strong global search ability and adaptability. In recent years, with the continuous development and improvement of genetic algorithm, sequencing adaptive genetic algorithm, as a variant of genetic algorithm, has been widely concerned and has achieved some successful applications in many fields. Sequencing adaptive genetic algorithm is an optimization method based on population evolution. Its basic idea is to continuously select individuals with higher fitness from the initial population to solve the optimization problem by simulating the selection, crossover and mutation operations in the process of biological evolution. Compared with traditional genetic algorithms, sequencing adaptive genetic algorithm has stronger adaptability and flexibility in individual evaluation and selection, crossover and variation, and can better cope with the solving needs of different problems. In the field of higher vocational sports training, optimizing the training plan is the key to improve the training effect and individuation degree. The traditional training plan design usually relies on experience and professional knowledge, and it is difficult to fully take into account the characteristics and needs of different athletes, so it is necessary to introduce more scientific and effective optimization methods to improve the design of training plans. As a new optimization method, sequencing adaptive genetic algorithm has good application potential and development prospect, and can provide new ideas and methods for the improvement and promotion of physical training in higher vocational colleges.

In summary, as a new optimization method, sequencing adaptive genetic algorithm has the potential and prospect of application in the field of higher vocational sports training, but the relevant research is still relatively limited, and its specific application and effect in this field need to be further discussed.

The field of higher vocational sports training has made some progress in recent years, including the improvement and innovation of training methods, the improvement of athletes' technical level, and the quantitative evaluation of training effects. With the development of sports science and the advancement of technology, more and more scientific methods and technologies are introduced into higher vocational sports training, making the training process more scientific and personalized. However, the field of higher vocational sports training still faces some challenges. This includes the optimization of training plans, the satisfaction of athletes' personalized training needs, and the quantitative evaluation methods of training effects. Traditional training methods may not fully take into account the characteristics and needs of different athletes, resulting in unsatisfactory training results. There are still some unresolved issues in the field of higher vocational sports training, such as how to better realize the personalization and differentiation of training plans, how to improve the accuracy and scientificity of evaluation of training effects, how to effectively adjust and Optimize training plan, etc. Solving these problems will help improve athletes' training effects and competitive levels. This study is based on the sequencing adaptive genetic algorithm and focuses on the optimization problems in higher vocational sports training. Compared with traditional training methods, sequencing adaptive genetic algorithms are more personalized and adaptable and can better meet the training needs of different athletes. The importance of this study is that by introducing new algorithmic methods, it improves the optimization effect and degree of personalization of the training plan, and provides new ideas and methods for the improvement and improvement of higher vocational sports training. At the same time, this research also fills the gap in optimization methods in the field of higher vocational sports training, and is innovative and advanced to a certain extent.

Based on this, the article relies on the sorting adaptive genetic algorithm through the introduction of adaptive genetic operators so that each course has its cross arrangement, and it is gradually tried and automatically changed, aiming to adjust the optimal sports training in HVC.

Section I briefly introduces the background and significance of physical training in higher vocational colleges, discusses the problems and challenges existing in physical training in higher vocational colleges, and puts forward the purpose and significance of this research; Section II analyzes the present situation of PE teaching in higher vocational colleges; Section III discusses the relationship between higher vocational education and physical training. Section IV proposes the exercise training based on adaptive genetic algorithm; Section V determines the research object and data source of the experiment, and describes the experimental design and setting, including participant selection, experimental conditions, evaluation indicators, etc. Discussion is given in Section VI. Finally, the main findings and contributions of this study are summarized, the direction and suggestions for further research are put forward, and the application prospect of sequencing adaptive genetic algorithm in higher vocational sports training is prospected in Section VII.

II. An Analysis of the Current Situation of Physical Education in Higher Vocational Colleges

A. *Physical Education Teaching Goal*

The so-called PE is not only simple sports such as long-distance running and hurdles, but also actively guides students, such as adding group gymnastics, Tai Chi, and other sports, integrating traditional culture and sports, and guiding students in team spirit, Physical and mental health, and other aspects have been fully displayed and embodied.

B. *Physical Education Teaching Methods*

Concerning the approach of physical education, the traditional methods are led by teachers, imparting the corresponding knowledge to students, and it is difficult for students to choose according to their interests. The consequence is that the development of all students cannot be satisfied, making physical education teaching quality cannot be significantly improved [8], [9].

C. *Physical Education Content*

At present, physical education courses and physical training are mostly based on exercise methods. On the one hand, physical training with a large amount of exercise may only suit some students. On the other hand, repeated courses will be produced, which are only continuously strengthened. Over a long period, students will become tired of learning, leading to a continuous decrease in the quality of teaching.

D. *The Need for Constructing Special Sports Courses in Higher Vocational Colleges in the New Era*

Different HVCs have different school-running ideas and concepts, and their characteristics are also different. Therefore, higher vocational physical education curricula and physical training should also be their focus [10]–[13]. Quality education can be introduced and integrated with the physical education courses of HVC, guide students to conduct comprehensive development training, comprehensively cultivate all aspects of quality, complement cultural courses, and finally realize the high-quality sports training and cultivation of HVC.

E. *The Need of Physical Education Reform in Higher Vocational Colleges*

Given the traditional teaching methods, teaching goals, and teaching content, traditional methods need to be reformed, which is mainly reflected in (1) ideological reforms to guide students’ independence and innovation, comprehensively considering students’ intelligence and other factors to develop and integrate Quality education is expanded to cultivate students with good habits and good ideas; (2) Reform of the model, change the traditional teacher teaching, students passively accept teaching, guide the gradual participation of academics, full participation, from the beginning of the physical training design and implementation, Give full play to individual initiative and creativity, assisted by teachers, and cooperate; (3) Reform in methods. From the perspectives of thinking mode and physical instinct, carry out effective sports training guidance, complete the concept change and plan formation, and raise the standard of instruction; (4) Reform in evaluation. Transform from traditional evaluation indicators to comprehensive evaluations of students’ progress, physical fitness, sports skills, and learning attitudes to guide students' physical and mental health.

III. Higher Vocational Education and Sports Training

A. The Content of Physical Education in HVC aiming at Quality Education

For physical education and training in HVC, it is necessary to fully consider the feasibility and integration of quality education in teaching content, fully integrate market needs and teaching, and arrange the content and training of teaching scientifically, effectively, and reasonably [13], [14]. The goal of its teaching is to enhance the physical fitness of students and cultivate comprehensive graduates. Therefore, in addition to traditional sports, it is necessary to add or set up some new sports training content according to the local characteristics of the advantages of the school, such as Tai Chi, Boxing, group gymnastics, swimming, etc.

B. Carry out Physical Education Based on Students' Professional Characteristics

The PETs and resources of higher vocational colleges are different. Therefore, in addition to traditional physical training, it is necessary to design the division of labor according to the existing profession. Teaching physical education requires a thorough understanding of the factors that affect the students, designing teaching content that aligns with students' interests and sports, and conducting practical sports training to improve students' physical fitness and effectively give full play to physical education in HVC. The role of quality education in students' life is very important.

At the same time, different sports training courses and contents are set up for the student subjects of different majors in HVC. It is optional for all students to make a unified selection. According to the characteristics of different majors and occupations when selecting courses, they are classified and pushed and selected separately to ensure that there are Course selection is required to ensure that the selection is more scientific, reasonable, and effective.

To continue the physical education process of higher vocational colleges from inside to outside, HVC should investigate the combination of extracurricular physical activity and intramural physical education to form a unity of teaching and practice to ensure the unity of students inside and outside the campus to the greatest extent and completeness, but also to ensure the connection between HVC and enterprises.

C. Physical Education Teaching Form That Highlights Practical Ability

The higher vocational college's PE should highlight students' practical abilities. Simulating professional scenes and social situations, physical training, and future work abilities should conduct comprehensive training. According to different majors, different genders, and different interests, they are separately cultivated. Design different physical education or physical training content to reserve enough knowledge of physical education for students. At the same time, students experience different roles in sports training, such as referees, athletes, captains, etc., to fully exercise their resilience and unity ability, and they can also exercise other abilities while exercising. At the same time, by simulating the requirements of the enterprise, it is required not to be late or leave early and to attend sports training fully.

IV. Sports Training Based on Adaptive Genetic Algorithm

In adaptive Genetic Algorithms Based on Co-evolution (SAGA) based on co-evolution, in each iteration of the algorithm, the evolution process and the collaborative process are carried out in sequence [15], in which the evolution process uses adaptive genetics. With a strong global search capability and a good convergence speed, the SAGA algorithm's genetic operation seeks to improve the genetic algorithm from both local and global perspectives.

The objective function is the core indicator in the genetic algorithm (GA) optimization process. It defines the goals or performance evaluation criteria that need to be optimized. In the scenario of higher vocational sports training, the objective function may be diverse, such as the overall performance index of the training plan, the athlete's training effect evaluation index, etc., which are determined according to the specific content and purpose of the research. Generally speaking, genetic algorithms can be used for optimization problems as well as search problems. In optimization problems, genetic algorithms find optimal solutions or near-optimal solutions through iterative evolution; while in search problems, genetic algorithms are used to find solutions that meet specific conditions in a large-scale search space. In the scenario of higher vocational sports training, if it is a training plan optimization problem, the genetic algorithm is used to optimize the objective function, that is, to find the best training plan; if it is a training plan design problem, the genetic algorithm is used Search for the optimal training plan.

A. Framework Description of Co-Evolution

The two-layer co-evolutionary framework is shown in Fig. 1. The population is separated into n sub-populations. Enhanced co-evolution is employed to prevent early maturation within the populations. The phenomenon continues to uphold the global search capability. The local population forms the lower layer, and a neighborhood-based local adaptive evolution algorithm is applied for conducting the local lookup. Enhancing convergence speed and promptly locating the best local solution are the goals. The local population is promoted to the top performers in the global group through the promotion operation association between the two layers. Subsequently, the local adaptive algorithm converges to the local optimum quickly.

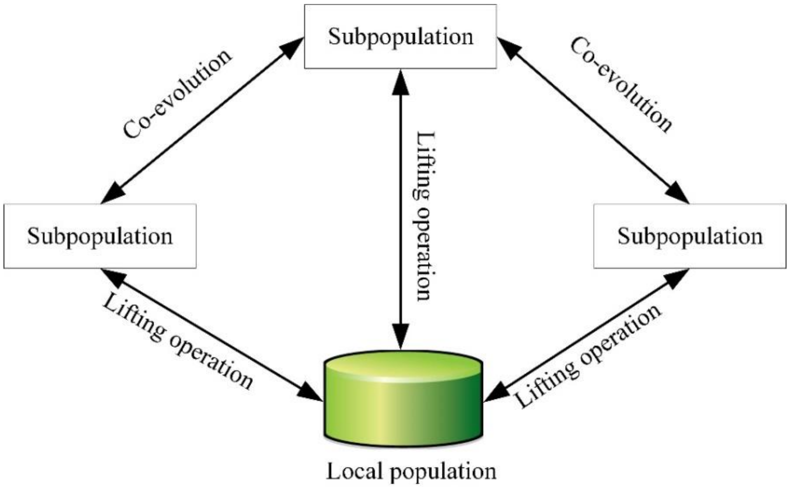

Fig. 1. Two-layer framework model diagram of co-evolution.

B. Adaptive Mutation Strategy of Local Evolution

The lifting operation concentrates the better individuals between the n subpopulations of the world and local populations. The local evolution uses a neighborhood-based local adaptive evolution algorithm to rapidly allow the local population to converge to the ideal solution. In this algorithm, selection and crossover operations are not used; only mutation operations are used, and the mutation rate that adapts is employed. The mutation is restricted to the individual's Δ neighborhood, and the purpose is to accelerate the convergence speed of the local population. The adaptive mutation rate among them is described as follows:

$$P_m(t) = 0.01 + NG \times cof \quad (1)$$

Of them, t denotes the algebra of the current iteration, and NG denotes the algebra for which there hasn't been a better solution since the last generation, at which point an excellent solution first surfaced. Typically, a small value, like 0.01, is used to determine the threshold for a coefficient called cof, which increases the mutation rate.

Formula (2) illustrates that if the evolution process is smooth—if a better solution emerges in every generation—then NG=0. In this case, it can be concluded that the current mutation operation effect is preferable, and raising the mutation probability is unnecessary. If it has not evolved, the longer the time will be. The greater the NG, the higher the mutation probabilityP_m, and the need to expand the search range, but once a particular threshold for the number of non-evolved generations is reached (if cof=0.01, the threshold is 100 generations), then $P_m = 1$ can be considered as the population at this time There is no better solution in the 4-neighborhood, and the evolution process is terminated.

C. SAGA Algorithm Description

Through the analysis of the above two-layer framework and operation strategy, the steps of the adaptive algorithm based on co-evolution (SAGA) are described as follows:

1) Perform a random initialization on the global population and set the population to n;

2) Improve the algorithm of the sub-population and form the coverage of the global population;

3) For the local adaptive evolution, the formation of a new population is optimized;

4) Cooperate based on the new population to achieve continuous improvement;

5) If the termination conditions are met, then end. Otherwise, go to (2).

Chromosomes are usually represented by bit strings, where each bit represents the value of a gene or variable on the chromosome. The following is a simple example. Suppose there is a chromosome containing 5 genes, and each gene has 2 possible values (0 or 1). The chromosome can be represented as a 5-digit bit string, for example: 10110.

In genetic algorithms, crossover and mutation are two common genetic operations used to generate new individuals. Their probabilities are usually specified by the user during algorithm design.

The crossover operation partially exchanges the chromosomes of two parent individuals to produce new offspring individuals. For example, for chromosomes represented by bit strings, crossover can cut the two chromosomes at random positions and swap the parts after the cut point. Suppose there are two parent individuals A and B, respectively 10110 and 01101, then the possible offspring individuals are 10101 and 01110. The probability of the crossover operation is usually specified by the user and is generally set between 0.6 and 0.9; the mutation operation randomly changes the values of some genes in the individual chromosomes to introduce new changes and diversity. For example, for a chromosome represented by a bit string, a mutation could randomly invert certain bits in the chromosome. Suppose there is a chromosome 10110, which may become 10100 after mutation. The probability of mutation operations is usually low and is generally set between 0.001 and 0.01. It should be noted that the probability of crossover and mutation can be adjusted according to specific problems and experimental experience. Certain experiments and tuning are usually required to determine the best parameter settings.

V. Experimental Verifications

According to the dual consideration of the majors studied by the students of HVC and their future occupations, the student's physical fitness requirements are integrated, and the focus is on selecting courses to improve their physical fitness and, at the same time, related skills. The specific physical education training is shown in Fig. 2.

Fig. 2. Practical physical education curriculum in higher vocational education.

To further clarify the effectiveness of the SAGA algorithm, this paper uses this method, the ECCGA algorithm, and the FLAGA algorithm to optimize the performance of the physical education curriculum setting. The relevant parameters are set as follows: the physical education class hours are set to 240, divided into three sample groups, respectively 90, 80, and 70. The probability of coordination is set to 0.42. m is set to 4, the environmental load K is set to [80, 80, and 20], and the probability of promotion is set to 0.4, so the selected test function is as in Formula (2), Formula (3), Formula (4) as shown in:

$$f_1 = \left| \frac{\sum_{i=1}^{n} cos^4(x_i) - 2\prod_{i=1}^{n} cos^2(x_i)}{\sqrt{\sum_{i=1}^{n} x_i}} \right|, 0 \le x_i \le 10, 1 \le i \le n, \prod_{i=1}^{n} x_i = 0.75 \tag{2}$$

$$f_2 = \sum_{i=1}^{n} \{x_i^2 - 10\,cos(2\pi x_i) + 10\}, -5.12 < x_i < 5.12 \tag{3}$$

$$f_3 = -20\,exp\left\{-0.2\sqrt{\frac{1}{N}\sum_{i=1}^{n} x_i^2}\right\} - exp\left\{\frac{1}{N}\sum_{i=1}^{n} cos(2\pi x_i^2)\right\} + 20 + exp(1), -32 < x_i < 32 \tag{4}$$

F1 is a non-linear function, and f2 and f3 are multi-dimensional and multi-modal. It is simple to become mired in a locally optimal solution when solving. Set n to 30, then the results of a certain iterative optimization process can be obtained, as shown in Fig. 3, Fig. 4, and Fig. 5.

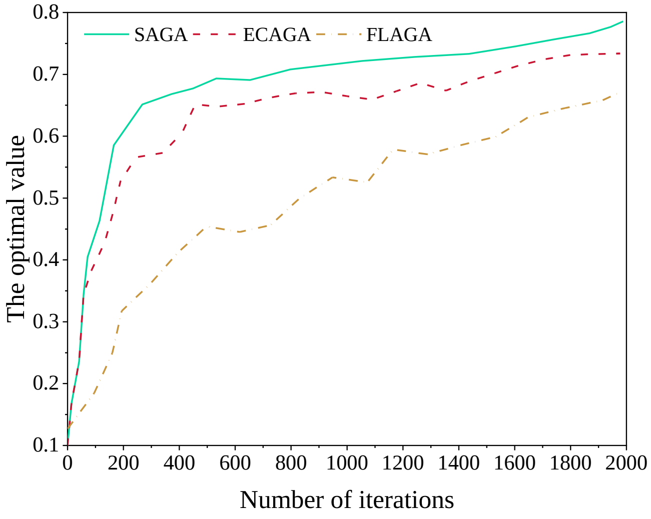

Fig. 3. Iterative process of function f1.

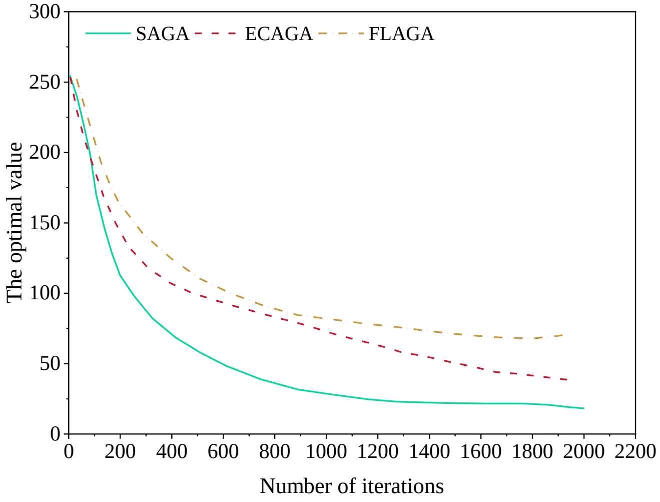

Fig. 4. Iterative process of function f2.

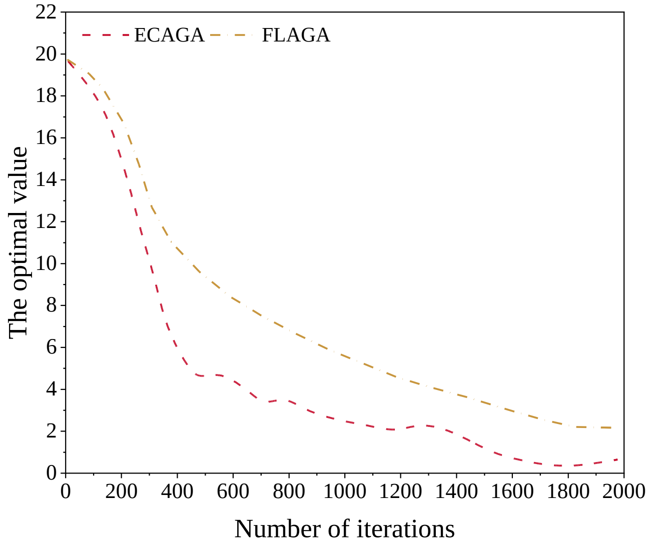

Fig. 5. Iterative process of function f3.

It can be seen from the results in Fig. 3 that it is the iterative process of the function. Compared with the other two functions, the convergence speed of the SAGA algorithm is faster and closer to the optimal value of 0.81; from the two calculation results in Fig. 4 and Fig. 5, you can see the convergence process of the SAGA algorithm has fewer fluctuations, so it can be obtained that compared to the other two algorithms, the SAGA algorithm not only has a faster convergence speed but also has a higher accuracy. Similarly, when solving the maximum value of the function value, when the SAGA algorithm is iterated 8000 times, the optimal function value 0.81 is obtained. Still, the traditional method is iterated 40,000 times more than the SAGA algorithm. Therefore, the SAGA algorithm has more obvious advantages.

VI. Discussion

The traditional training plan design is often based on expert experience and general rules; it is difficult to fully consider the individual differences and training needs of different athletes. The sequencing adaptive genetic algorithm can automatically adjust the training plan according to the characteristics and goals of each athlete to achieve personalized and differentiated training, so as to better meet the needs of athletes. Through the comparison of experimental results, it is found that the training plan optimized by sequencing adaptive genetic algorithm has certain improvement in training effect. Compared with the traditional training plan, the optimized training plan is more scientific and reasonable, and can better improve the training effect and competitive level of athletes. In this study, we adjusted and optimized the parameters of the sequencing adaptive genetic algorithm in a certain range, and compared the optimization effects under different parameter settings. The results show that the algorithm parameters have a certain influence on the optimization results, and reasonable setting of algorithm parameters can improve the optimization effect and convergence speed. Although the experimental results of this study show that the personalized training plan based on sequencing adaptive genetic algorithm has certain advantages, its feasibility and stability in practical applications still need to be further verified. Future studies can further expand the sample size and experimental scope to explore the applicability of the algorithm in different scenarios and sports. There are still some limitations in this study, such as small sample size and insufficient control of experimental environment. Future studies can further improve the experimental design, strengthen the evaluation of algorithm performance and stability, and explore more effective and reliable methods for optimizing personalized training plans.

In summary, the optimization method of higher vocational physical training based on sequencing adaptive genetic algorithm has certain potential and application prospect, but it needs further verification and improvement in practical application. We believe that with the progress of technology and in-depth research, this method will bring more innovations and breakthroughs in the field of higher vocational sports training.

VII. Conclusions

As a group of important academic institutions for cultivating skilled students, vocational colleges are receiving more and more attention. The students who are trained should also integrate academic and practical skills to improve the physical fitness of students. This article uses a ranking adaptive genetic algorithm. As a basis, it has absorbed the advantages of strong convergence and put forward an adaptive genetic algorithm to protect sports training and the algorithm's stability on time, which is advantageous to setting sports courses in HVC and has obvious effects.

Packaging Beautification Design Based on Visual Image and Personalized Pattern Matching

Deli Chen
School for Creative Studies, Chongqing City Vocational College, Chongqing, 402160, China

***Abstract*—Visual image technology is widely used in the field of product art design, enriching the visual beautification design effect of products. To improve the design effect of product packaging, a personalized packaging pattern matching technology is proposed based on computer vision image technology. Firstly, based on user needs, a pattern feature extraction technology is proposed, which uses the total variation model and GrabCut model to smooth and segment the image. Secondly, an improved style transfer generative adversarial network model is proposed for transfer training between feature elements and targets. Considering the problem of insufficient detail preservation in traditional transfer models, attention layers are incorporated into the transfer model for improvement. In the pattern feature extraction experiment, the proposed model had the best pixel accuracy in Image 1. In the pattern matching experiment, the proposed model had the lowest mapping loss in both pattern combinations, with a value of 0.135 in the Zhuang brocade pattern and 0.236 in the blue and white porcelain pattern, which was superior to other models. Comparing the effect of different model pattern combinations, in the blue and white porcelain pattern combination, the proposed model had an optimal peak signal-to-noise ratio of 32.32, which was superior to other models. The proposed model has excellent application effects in packaging design beautification. The research content will provide critical technical references for e-commerce product packaging design and intelligent image processing.**

Keywords—Visual images; personalized patterns; total variational model; GrabCut model; migration model

I. Introduction

Visual image technology is a technique that processes and analyzes images through computers. This includes image recognition, image processing, and image generation. Visual image technology is widely applied in multiple fields, such as medical image analysis, security monitoring, intelligent transportation, etc. [1]. In product packaging design, visual image technology can be used to enhance the design effect of packaging, making it more attractive to consumers [2]. Pattern packaging design refers to the use of various pattern elements and styles on the outer packaging of products to attract consumer attention. However, traditional pattern packaging design has shortcomings, such as the inability to meet the personalized needs of different users in packaging design, and the lack of innovation in pattern elements in traditional design, which cannot convey the connotation that the product needs to express [3]. Therefore, a packaging beautification design method based on the combination of visual images and personalized patterns is proposed. Images are processed through pattern feature extraction technology to achieve personalized matching of pattern elements and styles. The innovation of the research lies in the emphasis on considering the impact of different pattern elements on packaging design, proposing a multi-model fusion pattern feature extraction technology to effectively extract pattern features and preserve details. Secondly, an improved transfer model is introduced for pattern matching training, achieving optimization of pattern packaging design. This technology has important application value in the field of packaging. While meeting the requirements of packaging beautification design, it improves the detail retention ability of traditional transfer models. Research technology will drive the development of the e-commerce industry and provide new methods and ideas for the beautification design of product packaging.

The research content is composed of six sections. Section I and Section II introduces the application of relevant visual images and the latest cutting-edge technologies, and discusses and analyzes the application of visual image technology in fields such as image segmentation and image matching. Section III analyzes the characteristics of packaging design and proposes a feature extraction model and pattern matching model to achieve personalized design of packaging. Section IV is to apply the mentioned technology to specific scenarios and assess the performance of the proposed packaging beautification design technology in practical scenarios. Section V delves in to discussion and finally, Section VI concludes the paper.

II. Related Works

Computer vision image is a technique that utilizes computers to process, analyze, and understand images. It is widely applied in fields such as facial recognition, image processing, and object recognition, and researchers all over the world have organized relevant research on this. The study by Penumuru et al. aimed to propose a universal method for automatic material recognition using machine vision and machine learning techniques to enhance the cognitive abilities of material processing equipment such as robots deployed in machine tools and Industry 4.0. The study selected four common materials and prepared and processed their surface datasets. By extracting the red, green, and blue components of the three primary color model as features and applying support vector machines and other classification algorithms, the proposed method has been studied and verified to recognize different material groups [4]. The results indicated that the proposed method could be implemented in a manufacturing environment without significant modifications. Secondly, the research of Uthayakumar et al. focused on computer vision-based applications in wireless sensor networks. Research results showed that visual sensors generated a large amount of multimedia data in sensors, while image transmission consumes more computing resources. To address this issue, a study proposed an image compression model using neighborhood related sequences. This algorithm performed bit reduction operations and further compressed the image through a codec. The proposed NCS algorithm improved the compression performance of sensor nodes and reduced energy utilization while maintaining high fidelity. Through experimental evaluation on test images, the results showed a better compromise between compression efficiency and reconstructed image quality [5]. Finally, Huang et al.'s research aimed to raise the real-time performance of image segmentation. The study introduced a fruit fly model into image segmentation and obtained a fusion image processing technique. By using optimization strategies to search for the optimal segmentation threshold, the model could converge faster and consume less time without sacrificing segmentation accuracy. The research results indicated that this method significantly reduced segmentation time while keeping the segmentation effect basically unchanged [6].

With the development of visual image technology, it has important applications in fields such as image design, segmentation, and matching. Agarwal et al. found that with the development of image editing tools, image forgery activities are on the rise. To protect the authenticity of images, a deep learning-based detection, replication, movement, and forgery image technology was proposed. This technology involved processes such as segmentation, feature extraction, dense depth reconstruction, and ultimately identifying tampered areas. Finally, the technology was applied to specific scenarios, and it had good image visual processing effects [7]. Li et al. found that effective image segmentation in image design faced challenges, and proposed a convolutional neural network that combines attention mechanism (AM). The network structure studied consists of a basic feature layer and an attention module, which is utilized to capture global information and enhance features. The experimental outcomes showed that this method was superior to other existing mainstream image processing methods and had fewer parameters, improving the application of visual technology in related fields [8]. Chen et al.'s research focused on the importance of image matching in fields such as augmented reality, synchronous localization, and visual design. The study improved the accuracy of feature matching in visual design by incorporating instance aware semantic segmentation into visual feature matching for corner detection and rotation. Research used pixel level object segmentation and semantic information limitation to perform feature matching on adjacent images. The research findings indicated that this method improved the accuracy of feature matching and met the requirements of visual design [9]. Hu et al.'s research was dedicated to the study of image segmentation techniques. So, a parallel deep learning algorithm with mixed AM was proposed to enhance the effectiveness of pattern design work. This algorithm extracted pattern feature information from preprocessed images and inputs the images into a mixed AM and densely connected convolutional network module. The mixed AM consists of spatial AM and channel AM. The experiment outcomes denoted that this technology can significantly improve the image processing efficiency of design work, while also improving the processing effect of image data [10].

In summary, computer vision image technology has important applications in many fields. With the advanced visual image and machine learning techniques, problems such as image editing, segmentation, and matching in image design can be effectively solved. However, there are relatively few applications of visual image technology in the field of product appearance. In this regard, applying visual image technology to the packaging beautification design process provides relevant technical guidance for product packaging design and beautification.

III. Construction of Packaging Beautification Model based on Personalized Pattern Matching

This section mainly focuses on the research of product packaging beautification design, proposing pattern feature extraction models and pattern personalized matching models for product packaging design, and constructing relevant models separately.

A. *Extraction of Personalized Packaging Pattern Features*

In recent years, with the continuous improvement of people's quality of life and consumption ability, pursuing personalized consumption has become a social development trend. Personalized product packaging design can not only impress people, but also enhance the competitiveness of the product with personalized patterns. Therefore, in response to the growing demand for personalized packaging appearance, a personalized packaging pattern matching technology based on visual image technology is proposed [11]. To meet user needs, it is necessary to fully consider pattern design elements. Taking blue and white porcelain products as a case study, in the design of packaging patterns for blue and white porcelain, it is necessary to extract target features based on consumer needs and product attributes [12]. The process of product feature extraction technology is shown in Fig. 1.

Fig. 1. Product feature extraction process.

According to the technical process in Fig. 1, feature extraction of patterns includes pattern, color, and tissue extraction. In the extraction of the above feature information, to meet the personalized design requirements of product packaging, it is necessary to process the above features accordingly. If the extracted pattern features contain a large number of organizational textures, it will have an impact on the personalized information processing of the pattern itself. Therefore, in the study, a Relative Total Variation (RTV) model is adopted to optimize the feature extraction. The RTV model can make the image texture smooth and highlight the main feature details needed [13]. In smoothing processing, any point in the product feature image is defined as p, and the RTV of the image's P points is calculated as shown in Eq. (1).

$$RTV(P)=\sum_{q\in N_P} w_{pq}\cdot\| I_P-I_{q_s}\|^2\cdot\lambda_r \tag{1}$$

In Eq. (1), N_P is the set of points adjacent to P. λ_r represents the degree of smoothness. w_{pq} is the weight between point P and adjacent point q_s. I_P and I_q are the grayscale values of point P and adjacent point q. After completing the image smoothing process, it is also necessary to segment the image in order to better obtain different background features [14]. In the study, GrabCut was used as an image segmentation technique to perform local segmentation on the target image. The specific process is shown in Fig. 2.

Fig. 2. GrabCut segmentation process.

In the target feature map, multiple targets containing T rectangles are defined, and the external background of the rectangle is set to T_B, while the internal area of the rectangle is used as the foreground area, which is T_F. This expression is shown in Eq. (2).

$$\begin{cases} T_F=\varnothing \\ T_U=T_B \end{cases} \tag{2}$$

In Eq. (2), $\varnothing$ represents an empty bag. If any pixel T_F within T_B is initialized with a label, then the label $a_n=0$ represents the background pixel, and for each pixel in T_F, the T_F label is initialized with $a_n=1$ as the possible target pixel. The foreground and background regions are clustered into K-type using a clustering model, and a Gaussian Mixture Model (GMM) is constructed for the foreground and background. The three primary colors of the target pixel n are brought into each Gaussian component of the GMM model, and the K_n th Gaussian component of pixel T_F is the target pixel, as shown in Eq. (3).

$$k_n := arg\min_{KN} D_{\mathrm{n}}(\alpha_n,k_n,\theta,z_n) \tag{3}$$

In Eq. (3), θ represents the initial parameters of GMM, and z_n is the image matrix. For the given image data Z. D_n represents the Gaussian component. The GMM model is applied for parameter training, and the expression is shown in Eq. (4).

$$\theta' := arg\min_{\theta'} U(\alpha_n,k_n,\theta,z_n) \tag{4}$$

In Eq. (4), $U(\cdot)$ represents GMM parameter learning. The maximum minimum flow strategy is used to segment pixels and obtain the minimum energy, as shown in Eq. (5).

$$\min_{\{a_n,n\in T_U\}} = arg\min_{K} E(\alpha_n,k_n,\theta,z_n) \tag{5}$$

In Eq. (5), E represents the energy value. Repeating Eq. (3) and Eq. (5) until convergence is achieved to obtain the image segmentation result. Considering the issue of color difference in feature extraction, the Otsu segmentation method (OTSU) is adopted to handle the differences between extracted features. The OTSU idea is to segment a single feature, divide the target feature into foreground and background parts through grayscale features, and achieve black and white color gamut division by searching for grayscale levels and OTSU thresholds [15]. OTSU image segmentation is shown in Fig. 3.

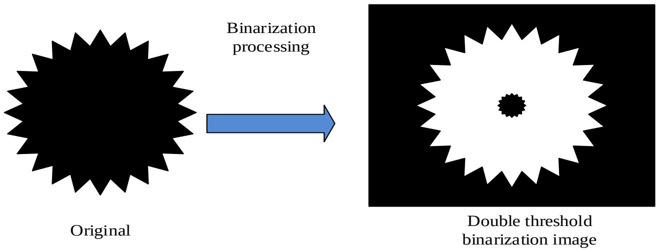

Fig. 3. Schematic diagram of OTSU image segmentation.

It defines the grayscale image as F, uses F as a matrix of $M\times N$, sets the pixel value to (0255), and uses n_i as the amount of pixels with a grayscale pixel level of i. The probability of selecting the grayscale pixel i is denoted in Eq. (6).

$$\begin{cases} p_i=\dfrac{n_i}{n_0+n_1+\cdots+n_{255}} \\ \sum_{i=0}^{255} p_i=1 \end{cases} \tag{6}$$

In image segmentation, the foreground and background segmentation thresholds of the image are set to k_l. According to the segmentation threshold, there are a large number of pixels that are greater than or less than k_l, namely C_A and C_B. The probability of selecting the two types of pixels is set to P_A and P_B, and the grayscale mean of the two types of pixels is set to m_A and m_B. If the grayscale level accumulation value is set to m_l, the global mean of the image is shown in Eq. (7).

$$m_G = p_A(k_l) \times m_A(k_l) + p_B(k_l) \times m_B(k_l) \tag{7}$$

In Eq. (7), there is a relationship as shown in Eq. (8).

$$p_A(k) + p_B(k) = 1 \tag{8}$$

Then, the expression equation of variance is used to obtain the value of the image segmentation method, as shown in Eq. (9).

$$\sigma^2 = p_A(k_l)(m_A(k_l) - m_G)^2 + p_B(k_l)(m_B(k_l) - m_G)^2 \tag{9}$$

In Eq. (10), σ is the spatial scale adoption number, and the square difference is subjected to deformation processing. The result is shown in Eq. (10).

$$\sigma^2 = \frac{(m_G * p_A(k_l) - m_l)^2}{p_A(k_l)(1 - p_A(k_l))} \tag{10}$$

The traversal is used to obtain the maximum threshold k_l between variances, and then re-segment the image through binarization. The result is shown in Eq. (11).

$$img(i,j) = \begin{cases} maxval & ifimg(i,j) > threshold \\ 0 & othenuise \end{cases} \tag{11}$$

The extraction of pattern features is the key to packaging beautification design, and it is necessary to extract the main pattern feature elements from the target, including patterns, colors, and organization, to provide basic elements for subsequent packaging beautification design.

B. Construction of a Personalized Pattern Transfer Model Based on Packaging Beautification

In product packaging beautification design, it is necessary to combine the extracted multiple style features with the target product, meeting both the product style features and the visual aesthetic design requirements. To effectively match the elements in the pattern with the target product, a personalized pattern transfer model based on the Improved Style Transfer Generative Adversarial Networks for Image to Illustration Translation (GANILLA) was proposed in the study. By fusing the features of different styles of patterns with the target, personalized packaging matching was achieved [16]. The GANILLA model was proposed by Samet Hicsonmez et al. in 2020 as an image style transfer learning model. In image feature processing, the original image content details were preserved as much as possible to achieve different style feature transfer methods. Among them, the structural framework of the GANILLA model is shown in Fig. 4.

From Fig. 4, the GANILLA model used convolutional layers for downsampling. At the same time, the inverse convolutional layer was used for upsampling, and a concatenated residual layer was used in the model. The inverse convolutional layer was replaced by a sampling operator. In the given pattern element features, it was necessary to combine the extracted pattern elements with different styles to fuse and generate new design patterns [17]. The pattern features are independent data, and the product packaging data is target data. The GANILLA model sampled feature maps through a skip connection generator. At the same time, to better preserve the transmission pattern features, upsampling and skip connections were used to merge high-level and low-level features, thereby improving the image composition quality [18]. The distance between the synthesized image and the real image is defined as $L1$, where the number of samples is set to N, the predicted pixels are set to y, and the pixels of the real image are x. The comparison between the synthesized image and the real image is shown in Eq. (12).

$$L_{rec} = \frac{1}{N}\sum_{i}^{N}\frac{\|y - x\|}{WHC} \tag{12}$$

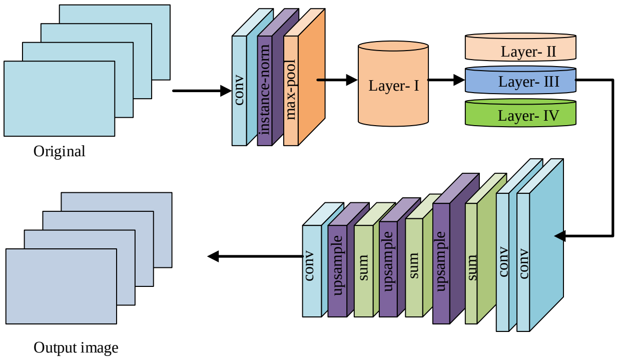

Fig. 4. GANILLA model structure.

In Eq. (12), W, H, and C respectively represent the width, height, and amount of channels of the image. Then, the discriminator adversarial loss is calculated, as shown in Eq. (13).

$$\begin{aligned} L_{GAN}(G,D) &= E\left[\log(Dx)\right] \\ &+ E\left[\log(1 - D(G(x')))\right] \end{aligned} \tag{13}$$

In Eq. (13), x' means the input damaged image, G represents the output target, D is the discriminator, and E represents the energy loss value. Then the joint loss is calculated, as shown in Eq. (14).

$$L = \lambda_1 L_{rec} + \lambda_2 L1 \tag{14}$$

In Eq. (14), λ_1 and λ_2 are both loss optimization parameters. In the actual pattern transfer, although the GANILLA model has good adaptability to the processing of pattern texture features, there are still shortcomings in handling individual feature details, such as the problem of detail loss in the transformation of texture features. In this regard, improvements will be made from two methods: feature analysis and model performance. In the analysis of pattern features, attention SE block modules will be added to the Residual Block layer to improve the model's attention to key positions in the image. At the same time, the addition of AMs can improve the acquisition of useful features without suppressing useless features [19]. The SE block module structure framework is shown in Fig. 5.

Fig. 5. SE block module structure framework.

In terms of model performance, considering the addition of AM, the computational complexity of model parameters is increased, and a parameter compression model, Residual block, is introduced to reduce network parameters and floating-point computational complexity in the model. Two generators and discriminators are included in the generative adversarial loss function of the improved GANILLA model. Firstly, the adversarial loss is adopted in the mapping network, and the target mapping relationship is expressed as Eq. (15).

$$G^*, F^* = arg\min_{G,F} \min_{D_X, D_Y} L(G, F, D_X, D_Y) \tag{15}$$

In Eq. (15), F represents the mapping target, and F and D_Y are the discriminators corresponding to the X domain and Y. The image $G(X)$ generated by G will continuously approach Y, enhancing the similarity between the two sides of the mapping. D_Y can be used to distinguish the two targets y and $G(X)$. Simultaneously, the minimum target in the target G mapping relationship is applied to counter the discriminator. In adversarial training, learning training can be used to learn the mapping relationship between G and D [20]. Finally, the various loss functions are combined, and the loss optimization parameter λ is introduced to optimize the real image pixel x. The target loss is shown in Eq. (16).

$$\begin{aligned} L(G, F, D_x, D_\gamma) &= L_{GAN}(G, D_Y, X, Y) \\ &+ L_{GAN}(F, D_X, X, Y) + \lambda L_{cyc}(G, F) \end{aligned} \tag{16}$$

In Eq. (16), the larger the loss optimization parameter value λ, the closer each pair of discriminators will be. Through the above techniques, the extracted personalized pattern elements can be style transferred to achieve personalized design of packaging patterns.

IV. Algorithm Model Simulation Testing

This section conducted performance tests on the two proposed models to evaluate their practical application effects. The main evaluation indicators included pixel accuracy (PA), signal-to-noise ratio (SNR), peak signal-to-noise ratio (PSNR), and loss.

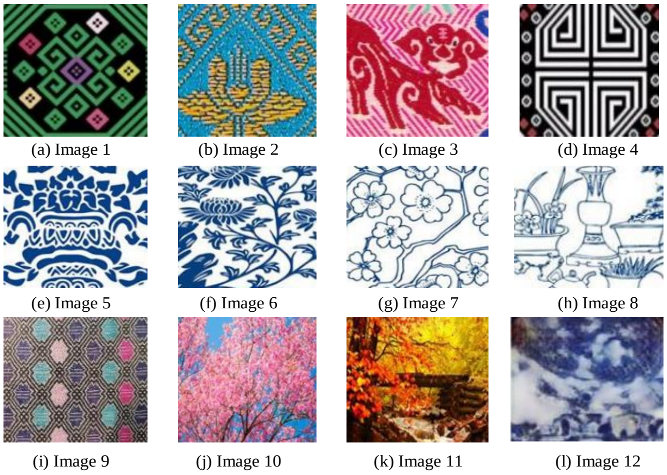
A. Experimental Analysis of Pattern Feature Extraction

To improve the proposed packaging beautification design model, experimental testing was conducted on the Windows 10 64 bit platform. The processor was a Zhiqiang 64 core processor, the graphics card was NVIDIA RTX4060ti, and the running content was 64G. The experimental data was sourced from the integrated packaging graphic design website, which included 15564 image feature data, including pattern, color, tissue and other feature data. The initialization parameters of the experimental model are expressed in Table I.

TABLE I. Model Initial Parameters

Parameter indicator type	Numerical value
Smoothness parameter r λ_r	0.005 to 0.03
Spatial scale parameter σ	0 to 6
Model iteration times	100
Float	Le-3
Execute initialization times	1

PA and SNR were introduced as evaluation indicators. 12 patterns were selected for feature extraction, and some pattern samples are shown in Fig. 6.



(a) Image 1 (b) Image 2 (c) Image 3 (d) Image 4
(e) Image 5 (f) Image 6 (g) Image 7 (h) Image 8
(i) Image 9 (j) Image 10 (k) Image 11 (l) Image 12

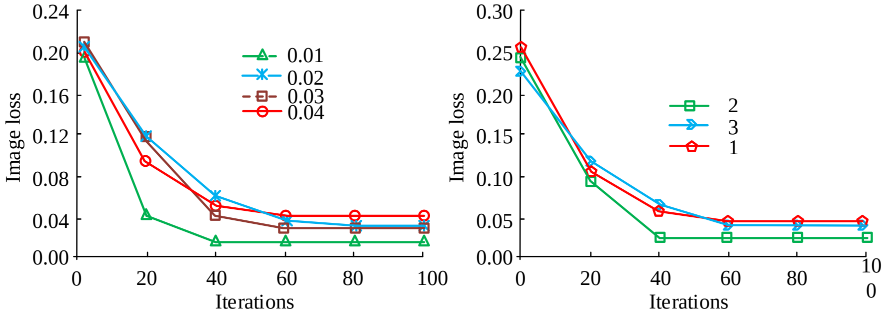
Fig. 6. Partial pattern data.

In actual feature extraction, the difference between λ_r

value and σ would directly affect the effect of image detail texture processing. Therefore, it is necessary to compare the image feature extraction under different parameters, as shown in Fig. 7.

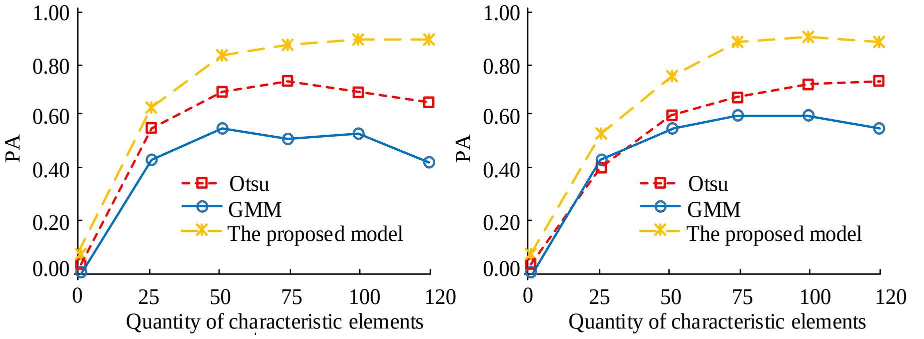
Fig. 7(a) and Fig. 7(b) express the comparison outcomes of λ_r and σ, respectively. Among them, when the λ_r parameter was set to 0.01, the model training image loss was the lowest, which was 0.012. At the same time, comparing the σ parameter settings of the model, when σ was set to 2, the training loss of the model was the lowest and the convergence effect could be achieved the fastest. Therefore, in subsequent experimental testing, the parameters were set to 0.01 and the σ parameter was set to 2. Image 1 and Image 2 were selected for feature extraction testing, and the test results are shown in Fig. 8.

Fig. 8(a) denotes the feature extraction test outcomes of Image 1. According to the results, when the amount of image elements was 120, the PA was the highest, at 0.903. Compared to this, both OTSU and GMM had a decrease in feature extraction performance after the number of pattern elements was 75. When the amount of image elements was 120, the PA of OTSU and GMM was 0.689 and 0.403, respectively. Fig. 8(b) shows the feature extraction test results of Image 1. The proposed model realized the highest PA of 0.909 when the number of pattern elements was 120, while the GMM model gradually decreased in PA after the amount of pattern elements was 100. The highest PA of OTSU and GMM were 0.786 and 0.526, respectively. Finally, the SNR was used to reflect the quality of feature extraction for different model elements. The effect of extracting cluster features for multiple models is shown in Fig. 9.



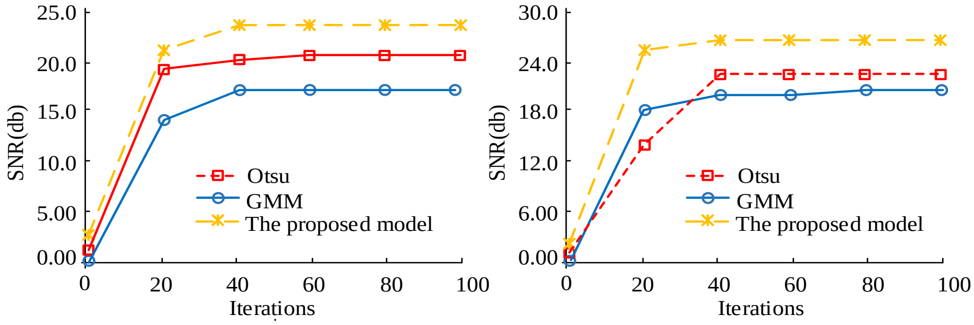
(a) Comparison of values for λ_r (b) Comparison of values for σ

Fig. 7. Comparison of image loss under different parameters.



(a) Image 1 (b) Image 2

Fig. 8. Comparison of pixel accuracy among different models.



(a) Image 1 (b) Image 2

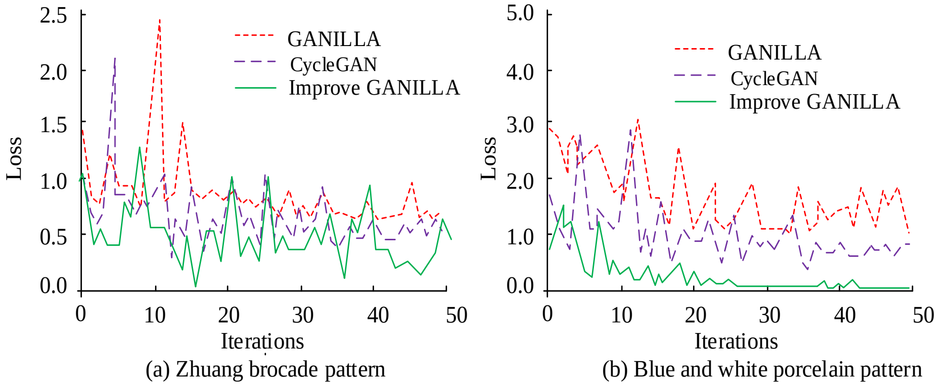
Fig. 9. Comparison of optimal SNR among different models.

Fig. 9(a) shows the feature extraction quality results of Image 1. From the data outcomes, as the amount of iterations increased, the image quality of all three models continued to improve. The best performing model was the one proposed, with an optimal SNR of 23.56 at convergence, followed by OTSU with an optimal SNR of 20.65, and GMM with an optimal SNR of 17.56. Fig. 9(b) shows the feature extraction quality results of Image 2. Before 40 iterations, the GMM model performed better than the OTSU model in extracting pattern features. In the early training, the GMM model had better feature extraction performance than the OTSU model. After training, the OTSU model could retain more black and white details during training, which was better than the GMM model. Overall comparison showed that the proposed model had the best feature extraction performance, followed by OTSU, and finally the GMM model. The optimal SNRs for the three models, from high to low, were 25.65, 22.86, and 19.98, respectively.

B. *Experimental Analysis of Personalized Packaging Pattern Matching*

In the personalized packaging matching experiment section, the selected pattern features would be used as experimental data, and the proposed improved GANILLA model would be used as the pattern matching model. Meanwhile, the Cycle-Consistent Generative Adversarial Networks (CycleGAN) and GANILLA were introduced as experimental testing benchmarks. In the parameter settings, the Bachsize was 1, the optimization algorithm was Adam, the initialization step factor was 0.0002, and the experimental analysis was completed using the Pytorch platform. Mapping loss (Loss) and PSNR were introduced to reflect the quality of reconstructed images in the model. Two types of styles, Zhuang brocade pattern and blue and white porcelain pattern were selected for packaging matching. Fig. 10 shows the Loss results of different models.

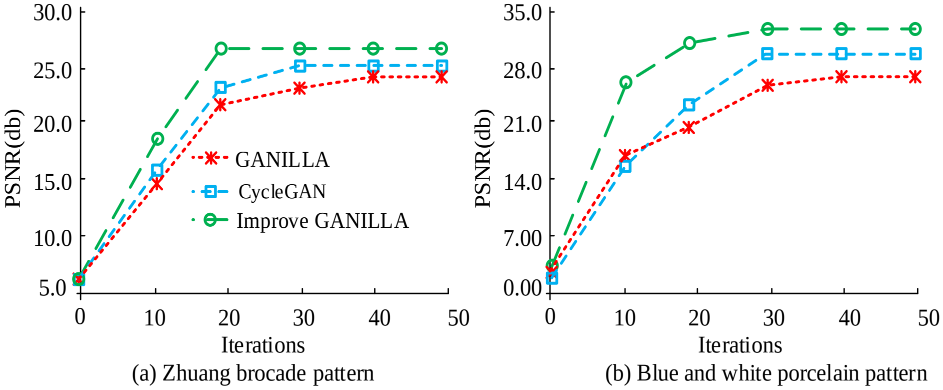
Fig. 10(a) shows the packaging matching test results under the Zhuang brocade pattern. In the early stage of testing, both the CycleGAN model and the GANILLA model showed significant fluctuations. Considering the overall situation, it was possible that the two models were unable to accurately recognize the color of the pattern during the early training, resulting in a decrease in image transfer quality. Compared to this, the proposed model had smaller overall fluctuations during training and lower Losses. When GANILLA, CycleGAN, and improved GANILLA converged, the Losses were 0.542, 0.512, and 0.135, respectively. Fig. 10(b) shows the packaging matching test results under the blue and white porcelain pattern. Due to the presence of more feature elements in the blue and white porcelain pattern, it further tested the model's ability to recognize features. Overall, the proposed improved GANILLA model performed the best with a Loss of 0.236 at convergence, while the CycleGAN model and GANILLA model had Losses of 0.956 and 12.35 at convergence, respectively. Finally, the PSNR was used to reflect the quality effect of pattern matching, as shown in Fig. 11.



(a) Zhuang brocade pattern

(b) Blue and white porcelain pattern

Fig. 10. Comparison of mapping loss results for different models.



(a) Zhuang brocade pattern

(b) Blue and white porcelain pattern

Fig. 11. Comparison of peak signal-to-noise ratio for different model pattern combinations.

Fig. 11(a) and Fig. 11(b) respectively show the packaging matching test results of Zhuang brocade pattern and blue and white porcelain pattern. In the combination of Zhuang brocade patterns, the proposed improved GANILLA converged the fastest and had the highest PSNR of 25.65 among the three models. The GANILLA model performed the worst, with the best PSNR of 24.15 during convergence. In the combination of blue and white porcelain patterns, the best performance was still the proposed improved GANILLA model. The improved GANILLA, CycleGAN, and GANILLA had the best PSNRs at convergence of 32.32, 29.32, and 27.03, respectively. From the above experiment, the proposed model had better testing performance in packaging pattern matching. The matching effect of the final packaging pattern is shown in Fig. 12.

V. Discussion

In recent years, with the rapid development of the e-commerce industry, product packaging has played an increasingly important role in attracting consumer attention and increasing sales. The diversification and personalization of packaging design have become one of the important strategies for brand competition. The packaging beautification design based on the combination of visual images and personalized patterns is an innovative design method proposed to meet this demand. The study will conduct in-depth discussions on it. Visual image technology refers to an interdisciplinary technology that utilizes computer vision and image processing techniques to analyze, process, and apply images. It mainly includes image acquisition, processing, analysis, and application. In the field of design, visual image technology has been widely applied in product, web, advertising designs, and other aspects. By processing and analyzing images, functions such as image enhancement, restoration, segmentation, and detection can be achieved, thereby improving design effectiveness and user experience. Packaging beautification design refers to the design and adjustment of the appearance, pattern, color, form, and other aspects of product packaging to meet the aesthetic needs and brand image of consumers, and to attract the attention of target consumers, enhancing the market competitiveness of the product. Packaging beautification design includes various contents, such as the selection and design of packaging patterns, color matching, material selection, position and size of patterns, etc. By cleverly utilizing these design elements, product packaging can be made more attractive, unique, and effectively convey the brand's value and characteristics.

A visual image-based packaging beautification design technology was proposed in the study, which utilized advanced image segmentation processing technology and image transfer technology to achieve personalized and efficient development of packaging images. In the experiment of pattern feature extraction, by comparing the image feature extraction under different parameters, it was found that the proposed model achieved the best training loss and convergence effect when the parameters were set to 0.01 and 2. Meanwhile, compared with traditional OTSU and GMM models, the proposed model performed better in PA and SNR, and had higher feature extraction quality. This indicated that visual image technology had significant advantages in packaging image data processing compared to similar technologies, laying the foundation for subsequent packaging beautification design. In the personalized packaging pattern matching experiment, by comparing the proposed improved GANILLA model with CycleGAN and GANILLA models, it was found that the improved GANILLA model achieved better Loss and PSNR ratio results in the packaging matching of Zhuang brocade patterns and blue and white porcelain patterns. This meant that the proposed model could more accurately transfer the colors and features of patterns during the pattern matching process, improving the quality and effect of pattern matching.

It can be seen that by using visual image technology, accurate extraction and analysis of image features can be achieved, providing scientific basis and guidance for packaging beautification design. The proposed technology also has significant advantages compared to similar technologies. In the experiments of pattern feature extraction and pattern matching, the proposed techniques have shown excellent results. Therefore, research-proposed technology can make packaging design more creative and personalized, improving the attractiveness and competitiveness of packaging.

VI. Conclusion

Product packaging design is one of the important means to showcase product functions and concepts, and the effectiveness of product packaging design has a significant impact on product competitiveness. Traditional packaging design faces problems such as long design cycles and single packaging design. An intelligent packaging pattern beautification technology was proposed for this. Firstly, based on product positioning, a pattern feature extraction method was proposed, which preserved the main features of pattern elements through pattern smoothing, segmentation, and binarization processing. Secondly, a pattern matching technique was proposed, which used the GANILLA model to train features and experiment with the transfer of pattern features. Simultaneously, AM was introduced to improve the model and enhance image details. In the feature extraction experiment of Image 1, when the number of image elements was 120, the PA of OTSU, GMM, and the proposed model were 0.689, 0.403, and 0.903, respectively. In the SNR test, the optimal SNRs of the proposed model, OTSU, and GMM models in Image 2 were 25.65, 22.86, and 19.98, respectively.

In the packaging pattern matching experiment, the Losses of different models were compared. Under the Zhuang brocade pattern, the sound losses of CycleGAN, GANILLA, and improved GANILLA were 0.542, 0.512, and 0.135, respectively. Finally, the matching effects of different model patterns were compared. In the PSNR test of blue and white porcelain patterns, the improved GANILLA, CycleGAN, and GANILLA had the best PSNRs at convergence of 32.32, 29.32, and 27.03, respectively. The proposed model had excellent application effects in packaging beautification design. However, the study did not provide personalized design for different target groups. However, there are also limitations to the research technology. This technology has a slower efficiency in image processing, and in the future, model parameters can be optimized to improve image processing efficiency. At the same time, image data can be preprocessed to improve the application effect of the technology.

FUNDINGS

The research is supported by Chongqing Municipal Education Science "14th Five-Year Plan" Project "Research on the Promotion Strategy and Implementation Path of Higher Vocational Classroom Revolution under the Background of Intelligent Education" (No. 2021JZ007); The platform of "Digital Creative Design Industry-Teaching Integration Collaborative Innovation Center" of Chongqing Urban Vocational College.

***Abstract*—The typical cannabis supply chain is encountering obstacles with the traceability of product regulations and standards. It is a complex structure involving multiple organizations and healthcare products. Questionable products finding their way onto the legal market are potentially dangerous. The proportion of Tetrahydrocannabinol (THC)/Cannabidiol (CBD) and the source of the cannabis strains have an impact on human treatment, limiting the traditional cannabis supply chain from seed to sale. Currently, the cannabis supply chain involves multiple stakeholders, which complicates the validation of various essential criteria, including license management, Certificate of Analysis (COA), and conformance quality standards and regulations. Existing traceability systems involve a centralized authority, leading to a lack of transparency and tracking system immutability. This study offers a Polygon blockchain-based strategy using smart contracts and decentralized on-chain and off-chain storage for efficient information searches in the cannabis supply chain. Eliminating the need for middlemen, the blockchain-based solution gives data security and transaction immutability history to all stakeholders. The storage structure comprises on-chain and off-chain components, algorithms, and the operating principles of the suggested solution. In addition, the suggested system delivers query efficiency and assures supply chain management authenticity and dependability. To assess the performance of the cannabis supply chain, scalability in developing a blockchain-based traceability process avoids delays and high transaction fees.**

***Keywords*—Blockchain; cannabis; traceability; supply chain management; polygon; on-chain and off-chain**

I. Introduction

The cannabis supply chain comprises a complicated network of enterprises. In conjunction with healthcare goods, the bad impacts are detrimental to individual health, the economy, and society. The supply chain for cannabis extract products consists of the selection of seeds, cultivation, production, distribution, and sale of the finished product. Therefore, traceability of product standards and regulations is prone to a lack of confidence, transparency, and immutability of the tracking system. Due to the COVID-19 pandemic, the challenge is to prevent questionable products from finding their way onto the legal market. Consequently, providing traceability is essential for isolating and eliminating potentially dangerous products. Cannabis-extracted products are produced from an identifiable source to make them appear genuine, such as apoptosis induction on human cancer cells by cannabis sativa L [1]. The proportion of THC/CBD is also used as a criterion for identifying cannabis strains or cultivars [2].

As reported by the World Health Organization (WHO), cancer is a primary contributor to mortality worldwide, responsible for more than 10 million deaths in the year 2020. It is estimated that by 2041, there will be more than 30 million new cases and more than 20 million deaths. Treatment with the use of chemotherapy is a popular choice due to its high efficiency. However, it has been found that many patients experience side effects from the use of the drug, including the high cost of medicines or treatment methods [3]. Currently, the US Food and Drug Administration (US FDA) approves the utilization of Dronabinol and Nabilone, which contain THC as the main ingredient, for treating cancer patients experiencing dizziness, nausea, vomiting, and loss of appetite due to chemotherapy [4].

In 2021, the legal cannabis industry provided US$ 17.8 billion to the world economy. This figure is expected to increase by 25.3% between 2022 and 2030 [5]. Thailand is at the leading edge of cannabis liberalization in Southeast Asia. The region decriminalized medical cannabis in 2018, and Thailand then decriminalized the cannabis plant in a push toward commercialization in June 2022 [6].

Fig. 1 depicts the cannabis supply chain distribution process. A seed provider is responsible for distributing seeds to Thailand’s FDA-approved producers (Thai FDA). The grower is responsible for nurturing cannabis plants from seed and must register a “Plookganja” application. The grower then delivers the cannabis plants to the manufacturer. The manufacturer produces cannabis extract products in lots and sends each lot to a laboratory. The two most prevalent cannabinoids produced from cannabis are CBD and THC.

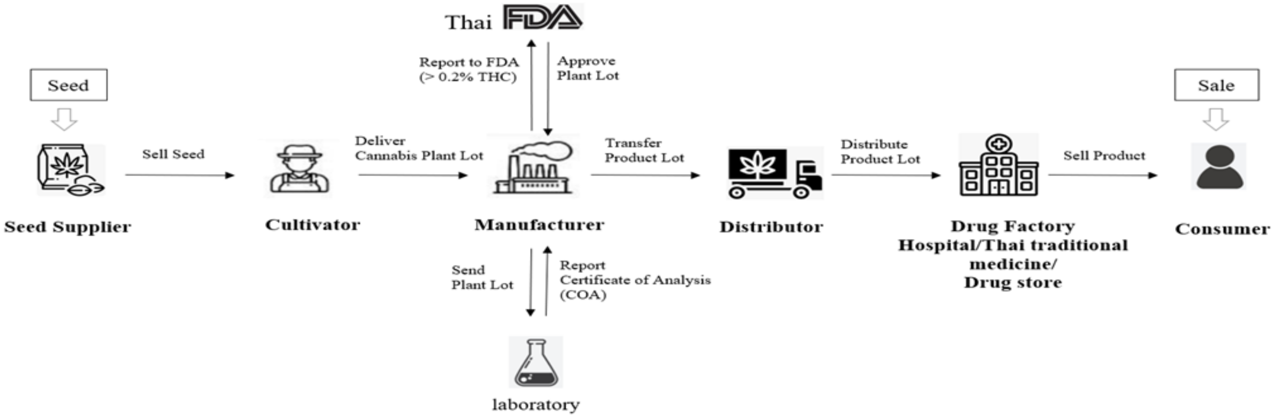

Fig. 1. Product flow and stakeholder relationship in the cannabis supply chain from seed to sale.

In the case of THC, the concentration level exceeds 0.2% and must be tested with the results reported to the Thai FDA. The distributor receives a large amount of cannabis extract products and is responsible for transferring them to hospitals, medicine practices, and drug stores. Finally, they dispense the products to consumers typically based on formulated, processed, or synthetic cannabis sold as a finished product. From seed to sale, the whole cannabis supply chain can be traced and validated. This can help reduce the risk of errors, fraud, or other irregularities that may occur in the supply chain. This includes tracking the origin of the cannabis plant, processing the plant, and distribution of the final product. Consequently, monitoring, improving quality control, and tracking product standards and regulations are fundamental to cannabis supply chain traceability.

Several nations, including the United States [7, 8], Canada [9], the Asia-Pacific region [10], and so on, are progressively emphasizing and mandating the necessity of cannabis traceability. Thai cannabis products are subject to strict regulations, and the IT system and applications can help ensure they are not tampered with or diverted from the legal supply chain. Decentralized control makes it difficult for bad actors to alter or manipulate the data recorded on the ledger.

Blockchain represents a distributed and decentralized ledger that retains and distributes all transactional records or alternate data and enables all forms of peer-to-peer value transactions [11], protected by encryption and regulated through a process of collective agreement [12]. The data structure of the blockchain is composed of a succession of blocks. A network of computers maintained by users or participants through a network of computers constitutes the interconnected sequence of a distributed ledger or list of entries. Cryptography is employed by blockchain to handle and authenticate ledger transactions. Users of the network authorize and record all transactions. Apart from being assigned to chronological timestamps, being interconnected with the previous block, and becoming unalterable once uploaded onto the network, these blocks constitute an essential building block of the blockchain structure [13]. Continuous updates of real-time data reduce the necessity for intricate and error-prone reconciliation processes involving the internal records of each party.

Blockchain is an essential technology for modernizing supply chain management in the industry 4.0 era [14], including the Internet of Things (IoT), and smart contracts [15]. Cannabis supply chains are concentrating on transparency, real-time monitoring, and securing transactions. Customers demand product visibility and traceability throughout the entire supply chain.

This paper seeks to illustrate how blockchain technology may be employed for the traceability of cannabis extract goods. By employing the distributed storage, hash encryption, and programmable smart contract attributes inherent in blockchain technology, this research proposes designing and implementing a blockchain-based traceability system for cannabis extract goods. The system design method is detailed in-depth, and the associated important breakthrough technologies, encompassing both the on-chain and off-chain storage architectures, are elucidated. To demonstrate the system's viability, the blockchain network is based on performance testing and actual applications of cannabis supply chain traceability.

The significance of this study is summarized as follows:

- A blockchain-based system that offers data security, immutability, and decentralized control for cannabis extract products is offered for the cannabis supply chain.
- A smart contract capable of processing multiple transactions between stakeholders in the cannabis supply chain is presented.
- A blockchain network founded on a Polygon and cannabis supply chain traceability is presented to facilitate the storage and retrieval of cannabis product traceability data.
- As the recommended solution, blockchain-based cannabis traceability is developed and evaluated for performance and cost.

The composition of the subsequent parts can be outlined as follows: In Section II, a literature review of blockchain-based traceability solutions is presented. Section III elaborates on the construction of a smart contract and the traceability of the cannabis supply chain. Section IV describes the implementation and test performance of the suggested system.

Section V provides an evaluation, and then Section VI describes the discussion. Finally, Section VII provides conclusions and recommendations for future research.

II. Related Work

This part provides a critical assessment of current initiatives to solve the product traceability problem. Relevant literature concerning traceability in supply chain management utilizing blockchain technology is recognized and assessed.

A. *Tradition Efforts for Supply Chain Traceability*

Traceability is characterized by the capacity to obtain any or all information pertaining to an item throughout its life cycle by identification methods. Traceability of the supply chain ensures that when quality-related issues arise, the raw materials or processing links in question can be swiftly verified, product recalls can be conducted as needed, and targeted penalties can be used to enhance the quality and safety of cannabis products.

Traceability is shown to be an effective strategy for regulating product quality across the local and global supply chain. Existing supply chain management systems have generally used barcodes and RFID tags for agricultural goods or pharmaceuticals. For example, Qian et al. [16] designed and implemented a system for milling wheat flour by combining 2D barcode and RFID technologies. Jabbar et al. [17] adopted GS1 standard barcodes with a serialized unique product identity, lot production number, and expiry date. The end consumer can utilize the QR code and/or RFID tag to enable them to read all the immutable traceability information [18, 19]. Other technologies have been developed to improve the traceability system [19], such as near-field communication (NFC), wireless sensor networks (WSN), cloud computing technology (CCT), and DNA barcoding. However, the typical traceability system does not sufficiently control the information's openness, making it susceptible to manipulation.

B. *Blockchain-based Solution for Cannabis Supply Chain Traceability*

Conventional approaches to traceability in the cannabis supply chain frequently adopt centralized systems, which tend to lack transparency at the participant level, allowing the central authority to manipulate data without notifying other involved parties.

Supply chain management in a range of sectors makes substantial use of blockchain technology to assist supply chain operations. Many sectors benefit from block-chain-based solutions, such as the agricultural food (agri-food) sector [20-29] to ensure data provenance, decentralized control and gives a secure, immutable history of trans-actions to all parties. In medicine supply chain, Musamih et al. [25] introduced the smart contract to verify data provenance, remove intermediaries, and provide all participants with a safe, unchangeable record of all transactions. Furthermore, the luxury goods supply chain, Chen et al. [30] introduced the smart contract to execute all information related to the production and logistics process of luxury product anti-counterfeiting. Kang et al. [31] introduced the enhancing traceability and authenticity in wine supply chain through a Stackelberg game-theoretical analysis.

Blockchain platforms have been developed to facilitate and accelerate the development of a decentralized application process in supply chain traceability projects. Two popular methods are Ethereum and Hyperledger Fabric.

Shahid et al. [22] and Babu et al. [32] suggested an Ethereum-based solution for the blockchain-based agri-food supply chain that uploads all blockchain-based transactions to IFS (IPFS). An efficient, safe, and reliable storage system creates a hash of the data stored on the blockchain. Using smart contracts and supporting algorithms, this technology displays system interactivity.

Yang et al. [20] introduced the use of Hyperledger Fabric in a blockchain-based traceability system designed for agricultural products such as fruits and vegetables. This system not only improves query efficiency and safeguards privacy but also ensures the legitimacy and dependability of data in supply chain management, all while aligning with the demands of practical, real-world applications.

Nevertheless, the usage of Ethereum with Hyperledger Fabric offers difficulties, including scalability and cost effectiveness.

III. Design for A Blockchain-based Cannabis Traceability System In Supply Chain Management

A. *System Framework*

This study assesses the traceability of cannabis products within Thailand's cannabis supply chain, spanning from the initial stages, such as cannabis seed selection, cultivation, and production, to the ultimate point of sale, where cannabis products are made available to consumers. The first layer of the cannabis supply chain involves selecting the seed of cannabis strains and the effect of seed storage methods on cannabinoids and psychoactive cannabinoids present in cannabis plants. In order to comply with regulations and record essential information about seeds, sales and purchases, and licensing, it is required to conduct an audit throughout the process of selecting seeds. Cannabis cultivation involves planting, transplanting, watering, harvesting, drying, and recording information on the transplant date, pollination control, fertilizer, harvesting process, drying weight, and other key elements. The extraction process requires the provision of the lot number, processing data, extracted oil weight, extraction gain/loss, and COA. Distribution requires a packing number for the lot, delivery information, and shipment date. Furthermore, the entire process is conducted under controlled environmental conditions at every stage, as factors such as temperature, humidity, or other elements can impact the content of CBD and THC. Starting at the distributor level, the retailer obtains limited quantities of finished products equipped with traceable identifiers, which are then sold to consumers. The application programming interface constitutes the second layer (API). The API interfaces directly or indirectly with a blockchain node or client network [33].The third layer, which comprises the traceability system, possesses the capability to identify, track, and trace individual cannabis product components as they navigate through the entire supply chain, spanning from the initial stage of seed selection to the end consumer. The traceability system's data collecting [34], data storage [35, 36], and data processing [37] comprise its data gathering layer. The aim of data collection is to identify and collect the data sources for all units of measurement.

Data storage is used to extract the data from multiple forms and sources into the data warehouse. Data processing analyzes and separates the on-chain and off-chain data. The blockchain is comprised of essential elements, including a smart contract, a consensus algorithm, a blockchain application, and digital storage. Digital data are stored in a decentralized architecture, allowing worldwide access to unused hard drive space. The decentralized infrastructure offers an alternative to centralized cloud storage [38] and is capable of alleviating a number of problems related to centralized systems. As seen in Fig. 2, An abstract model for managing cannabis traceability within the supply chain using blockchain technology [39] is predominantly constituted by four layers: the cannabis supply chain layer, the data interface layer, the traceability system layer, and the blockchain layer.

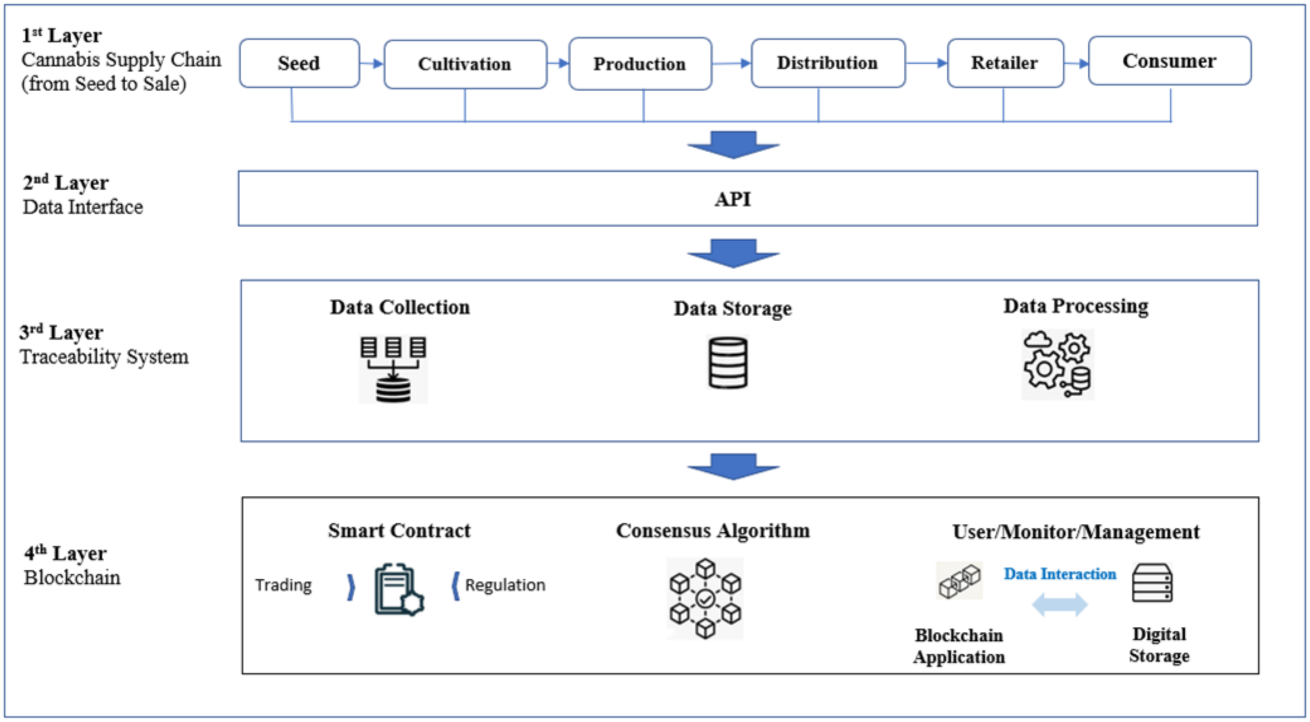

Fig. 2. An abstract model for managing cannabis traceability within the supply chain using blockchain technology.

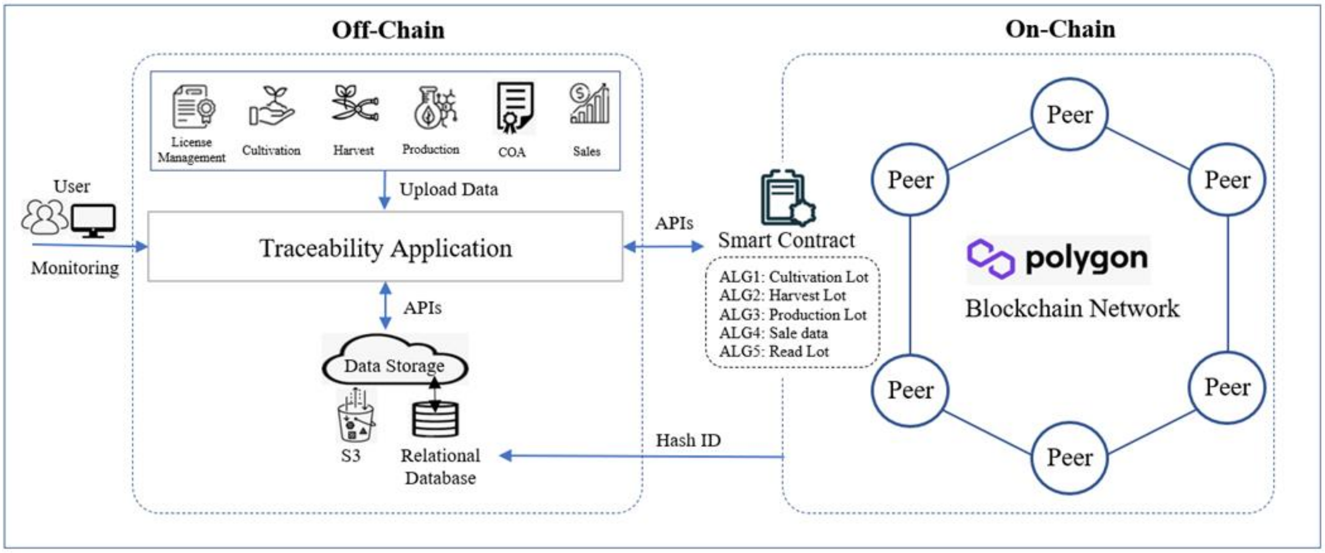

Fig. 3. Architecture of a blockchain-based cannabis traceability system.

B. On-Chain and Off-Chain

The current storage method of the blockchain traceability system requires the direct entry of traceability information for every node of cannabis items directly into the blockchain. As the number of nodes rises, so does the quantity of transaction data, increasing the storage stress on the blockchain. Given the chain-like configuration of the blockchain, query efficiency is relatively poor; only those of the same blockchain network can gain entry to the chain ledger's data. This research develops the storage mode of a blockchain-based traceability system for cannabis goods, which includes a distributed database of traceability information under an on-chain system. Once the traceability data is input into the system, it undergoes a categorization process. The public information about the product is preserved within the local database. As shown in Fig 3, the encrypted ciphertext is posted, and the hash ID of the public information is appended to the blockchain before being conveyed to the relational database.

Fig. 4 presents a data flow diagram illustrating the cultivation data, harvest data, production data, and distribution data between off-chain and on-chain. In traceability applications, all transactions, images, and data are uploaded by the participants. All participants are required to be licensed when uploading the information onto the database as shown in Table I.

TABLE I. VERIFICATION OF PARTICIPANT INFORMATION

Participant	Information	Verification
Seed Supplier	Seed supplier name, Registration, Address	Online
Cultivator	Cultivator name, License, Field name, GPS	Online
Harvest	Harvest name, License, Address, Dryer type	Online
Manufacturer	Manufacturer name, License, Address, Extractor type	Online
Distributor	Distributor name, Driver license, Transportation type	Online
Retailer	Retailer name, License, Address	Online
Lab	Lab name, License, Address	Online
FDA	Name, License, Address	Online

The lot number uploaded by the cultivator is automatically generated using the QR code to prevent error and fraud. The cameras are installed in the field for communicating and taking videos. Blockchain via smart contracts can be automatically programmed to impose penalties on the cultivator if they act dishonestly. Any peers or stakeholders in the blockchain can trust that their content can be disputed or refuted.

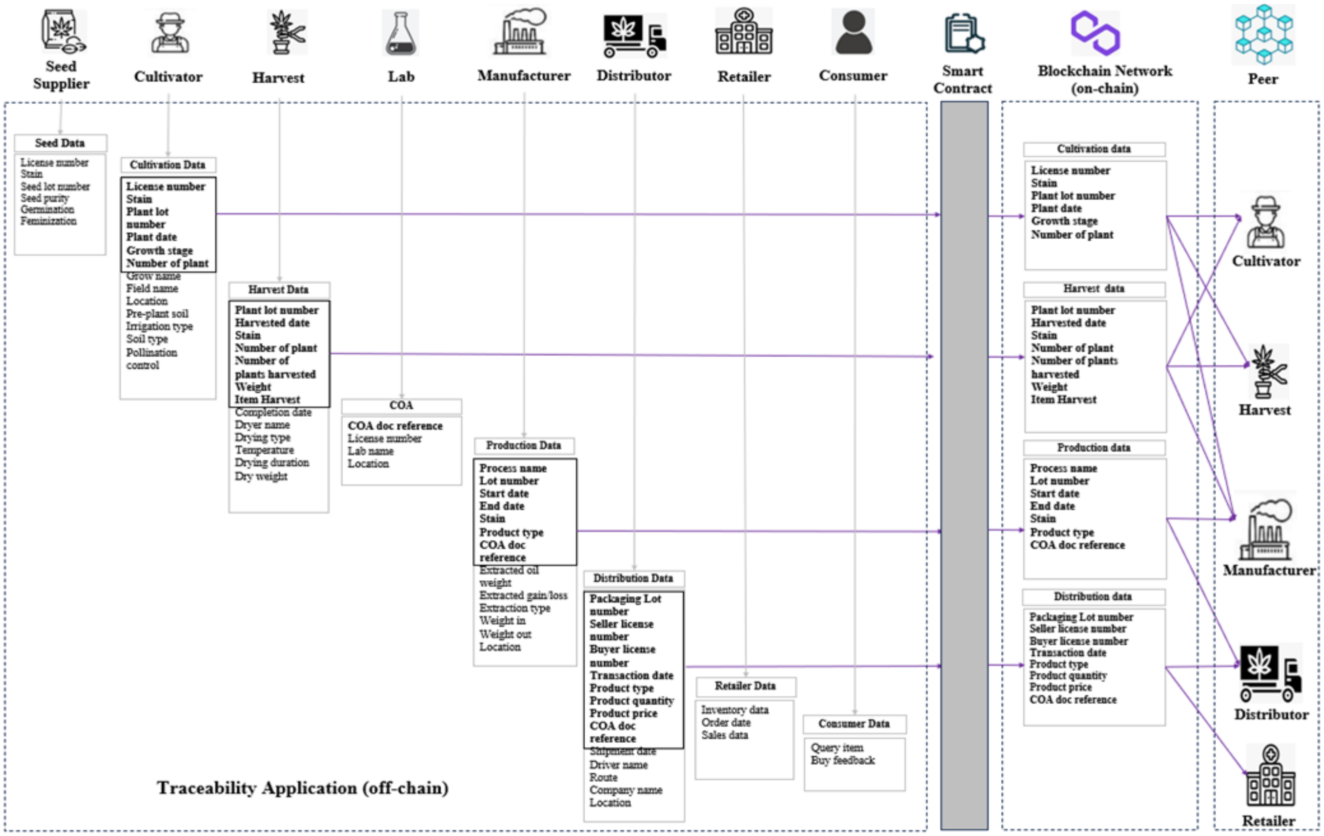

Fig. 4. Data flow diagram.

C. Sequence Diagram

Fig. 5 depicts the interaction between various supply chain actors within the proposed system, broken down into the following three stages.

- Cultivation and Harvest: A cultivator begins the plant lot, uploads it to the blockchain, and then declares an event to all peers, such as cultivator, harvest, and manufacturer. The cultivator updates the growth status, and the image of the license can be uploaded into the blockchain. The plant lot is transported to the harvesting phase when the blockchain is updated with harvest information. All transactions are retained on the blockchain, and the blockchain communicates the hash ID to the data storage.

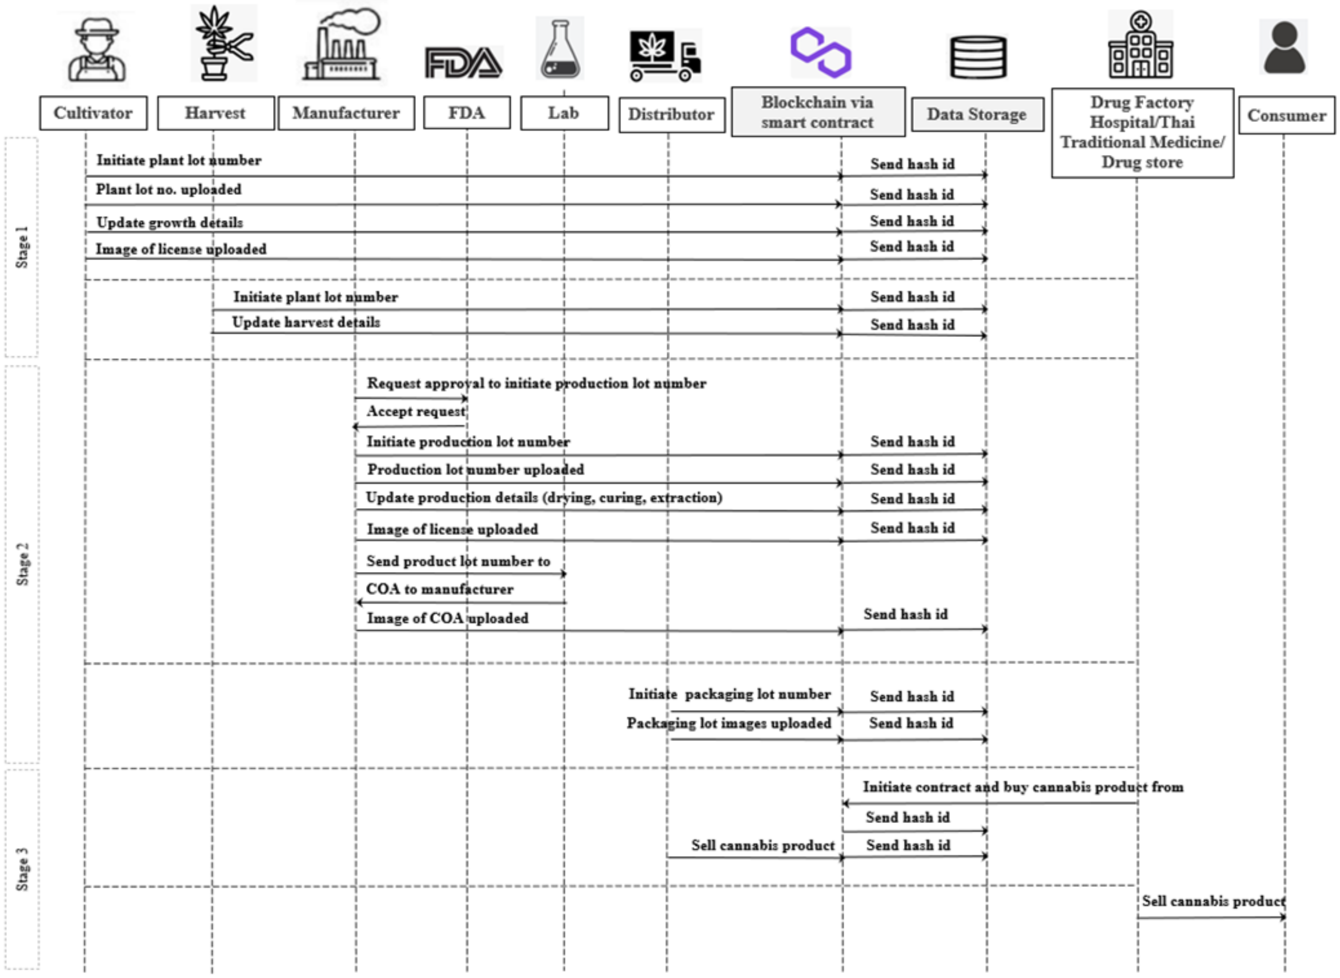
- Production and Distribution: A company submits the Thai FDA a request for permission before starting production. As soon as the Thai FDA authorizes the request, the producer enters the manufacturing lot into the blockchain and declares an event to all peers, such as manufacturer and distributor. The manufacturer uploads photographs of the manufacturing lot to the blockchain, which then sends a hash ID to data storage so that authorized users may view the images in the future. The production batch is sent to the distributor for packing.

- Retailer and Consumer: Finally, interaction takes place between the retailer and the consumer. Thus, the retailer initiates the contract and purchases the product from the distributor, and this is declared to the peers such as the retailer, distributor, and consumer. The cannabis product is sold to the retailer and subsequently to the consumer. This process ensures that all transactions are documented and accessible to all participants within the supply chain, thereby validating the authenticity and legality of products based on the chronological sequence of events.

D. Comparison of Proposed Solution

This section compares the suggested approach for cannabis supply chain traceability with the conventional solution.

Table II provides an overview of this study. Importantly, the decentralization of the proposed system precludes any one organization from influencing or changing the data. Furthermore, the proposed solution has valuable features, providing security, transparency, credibility, and immutability. Blockchain-based traceability is offered as the proposed solution.



Cultivator
Harvest
Manufacturer
FDA
FDA
Lab
Distributor
Blockchain via smart contract
Data Storage
Drug Factory Hospital/Thai Traditional Medicine/ Drug store
Consumer
Stage 1
Initiate plant lot number
Send hash id
Plant lot no. uploaded
Send hash id
Update growth details
Send hash id
Image of license uploaded
Send hash id
Initiate plant lot number
Send hash id
Update harvest details
Send hash id
Stage 2
Request approval to initiate production lot number
Accept request
Initiate production lot number
Send hash id
Production lot number uploaded
Send hash id
Update production details (drying, curing, extraction)
Send hash id
Image of license uploaded
Send hash id
Send product lot number to
COA to manufacturer
Image of COA uploaded
Send hash id
Initiate packaging lot number
Send hash id
Packaging lot images uploaded
Send hash id
Stage 3
Initiate contract and buy cannabis product from
Send hash id
Sell cannabis product
Send hash id
Sell cannabis product

TABLE II. COMPARISON OF THE SUGGESTED AND CONVENTIONAL APPROACHES

	Proposed Solution	**Traditional Traceability System**
Data Storage	Decentralization	Centralization
Data Security	High	Low
Data Transparency	High	Low
Data Credibility	High	Low
Data Immutability	High	Low

The proposed solution uses the Polygon blockchain, which is comparable with other blockchains such as Ethereum and Hyperledger Fabric [40], as presented in Table III. Polygon is a permissionless public blockchain with excellent scalability. The average Polygon transaction fee (gas price) is less than Ethereum, according to the Polygon and Ethereum gas price [41] on May 7, 2023. In addition, data are stored on-chain in all solutions, but the suggested solution includes an extra feature that enables data to be stored off-chain as well. In conclusion, the suggested system includes several programmable smart contract languages.

TABLE III. COMPARISON BETWEEN THE PROPOSED APPROACH AND EXISTING DISTRIBUTED BLOCKCHAIN PLATFORMS

	Polygon	**Ethereum**	**Hyperledger-Fabric**
Type of Blockchain	Public Permissioned	Public Permissioned	Private Permissioned
Scalability	High	Low	Meduim
Average Transaction Fee	<$0.08	<$35.00	No
Monthly Fee	No	No	>$99.00
Native Token	MATIC	ETH	No
Off-Chain Storage	Yes	Yes	No
Programming Language	Golang, Solidity, Vyper, Python	Solidity	JavaScript, Java, Golang, Python

IV. PROPOSED BLOCKCHAIN-BASED CANNABIS TRACEABILITY IMPLEMENTATION

Using the Polygon blockchain platform, the suggested solution is constructed. Polygon is permission less public blockchain, meaning that anybody may access it. The smart contract is scripted in Python and subjected to testing within Visual Studio Code following its development. It is a web-based online environment for authoring and running smart contract code, offering users the capability to debug and test the environment of the solidity code.

A. Implementation Framework

This section discusses the five algorithms of the cultivation lot, the harvest lot, the production lot, sales data and read lot that define the operation of the proposed blockchain-based solution. First, the cultivator initiates the plant lot number and then updates the growth details in the blockchain.

Algorithm 1 describes uploading the cultivation lot number into a blockchain. The inputs for this algorithm include a license number for the cultivator, a unique identifier for the plant lot, the strain name or ID, the date the plants were planted, the current growth stage of the plants, and the number of plants in the lot. First, the cultivation record is created in Cantrak, which is a system for tracking cannabis cultivation. The record includes all the input variables provided. Next, the cultivation record is written into the blockchain, which is a secure and tamper-resistant distributed database. The blockchain ensures that the cultivation record cannot be altered or deleted once it has been written. A hash ID is generated to uniquely identify the cultivation record in the blockchain. Finally, the hash ID is printed to confirm that the cultivation record has been successfully written into the blockchain. This algorithm can be used by cultivators to securely store their cultivation lot numbers and related information on the blockchain for verification purposes.

Algorithm 1 Uploading the cultivation lot number to the blockchain

```
Input:
// Define input variables
license_number = [string]  // license number of the cultivator
lot_number = [string]  // unique identifier for the lot of plants
strain = [string]  // strain name or ID
planted_date = [string]  // date the plants were planted
growth_stage = [string]  // current growth stage of the plants
(e.g., vegetative, flowering)
number_of_plants = [integer]  // number of plants in the lot
// Create cultivation record in Cantrak
cultivation_record = {
  "license_number": license_number,
  "lot_number": lot_number,
  "strain": strain,
  "planted_date": planted_date,
  "growth_stage": growth_stage,
  "number_of_plants": number_of_plants
}
// Write cultivation record to blockchain
hash_id = blockchain.write_data(cultivation_record)
Output:
// Print hash ID for confirmation
Print ("Cultivation record successfully written to the
blockchain with hash ID:", hash_id)
End
```

Algorithm 2 describes the design to upload the harvest lot number into the blockchain. The inputs for this algorithm include a unique identifier for the plant lot, the date the plants were harvested, the specific strain of cannabis, the number of plants harvested, the weight of the harvested material, and part of the plant harvested. First, the harvest record is created in Cantrak, including all the input variables provided. Next, the harvest record is written into the blockchain, a secure and tamper-resistant distributed database. The blockchain ensures that the harvest record cannot be altered or deleted once it has been written. A hash ID is generated to uniquely identify the harvest record on the blockchain. Finally, the hash ID is printed to confirm that the harvest record has been successfully written into the blockchain. This algorithm can be used by cultivators to securely store their harvest lot numbers and related information on the blockchain for verification purposes.

Algorithm 2 Upload the harvest lot number to the blockchain

```
Input:
// Define input variables
plant_lot_number = [string]  // unique identifier for the plant lot
harvested_date = [string]  // date the plants were harvested
strain = [string]  // the specific strain of cannabis
num_plants_harvested = [int]  // number of plants harvested
weight = [float]  // weight of harvested material
item_harvested = [string]  // the part of the plant that was
harvested
// Create harvest record in Cantrak
harvest_record = {
  “plant_lot_number”: plant_lot_number,
  “harvested_date”: harvested_date,
  “strain”: strain,
  “num_plants_harvested”: num_plants_harvested,
  “weight”: weight,
  “item_harvested”: item_harvested
}
// Write the harvest record on the blockchain
hash_id = blockchain.write_data(harvest_record)
Output:
// Print hash ID for confirmation
Print (“Harvest record successfully written to the blockchain
with hash ID:”, hash_id)
End
```

Algorithm 3 describes the process for uploading the production lot number to a blockchain. The inputs for this algorithm include the name of the process (e.g., drying, curing, extraction), a unique identifier for the production lot, the date the production process started, the date the production process ended, the specific strain of cannabis being produced, type of product being produced, and the address of the uploaded Certificate of Analysis (COA) document containing THC% & CBD%. First, the production lot record is created in Cantrak, including all of the input variables provided, such as the reference for the COA document. Next, the production lot record is written into the blockchain, a secure and tamper-resistant distributed database. The blockchain ensures that the production lot record cannot be altered or deleted once it has been written. A hash ID is generated to uniquely identify the production lot record on the blockchain. Finally, the hash ID is printed to confirm that the production lot record has been successfully written into the blockchain. This algorithm can be used by cannabis producers to securely store their production lot numbers and related information on the blockchain for verification purposes. The uploaded COA document can also be easily accessed and verified through the reference address provided in the production lot record.

Algorithm 3 Upload the production lot number to the blockchain

```
Input:
// Define input variables
process_name = [string]  // name of the process (e.g., drying,
curing, extraction)
lot_number = [string]  // unique identifier for the production lot
start_date = [string]  // date the production process started
end_date = [string]  // date the production process ended
strain = [string]  // the specific strain of cannabis being
produced
product_type = [string]  // the type of product being produced
(e.g., dried flower, oil, concentrate)
coa_doc_reference = [string] // address of uploaded coa
document containing thc% & cbd%
// Create production lot record in Cantrak
production_lot_record = {
  “process_name”: process_name,
  “lot_number”: lot_number,
  “start_date”: start_date,
  “end_date”: end_date,
  “strain”: strain,
  “product_type”: product_type
  “coa_doc_reference”: coa_doc_reference
}
// Write production lot record to blockchain
hash_id = blockchain.write_data(production_lot_record)
Output:
// Print hash ID for confirmation
Print (“Production lot record successfully written to blockchain
with hash ID:”, hash_id)
End
```

Algorithm 4 describes uploading *sales data* to a blockchain. It takes several input variables, including the seller’s and buyer’s license numbers, date of the transaction, type and quantity of the product being sold, price per unit, and the reference for a COA document containing information about the product’s THC and CBD content. The algorithm creates a sales record in Cantrak, including all the input variables, and is then written into the blockchain, generating a hash ID that serves as a unique identifier for the record. Finally, the algorithm prints the hash ID for confirmation, indicating that the sales record has been successfully written into the blockchain.

Algorithm 4 Upload the sales data to the blockchain

```
Input:
// Define input variables
seller_license_number = [string]  // license number of the seller
buyer_license_number = [string]  // license number of the
buyer
transaction_date = [string]  // date the transaction occurred
product_type = [string]  // the type of product being sold (e.g.,
dried flower, oil, concentrate)
product_quantity = [float]  // quantity of product being sold
product_price = [float]  // price of the product per unit
coa_doc_reference = [string] // address of uploaded coa
document containing thc% & cbd%
// Create sales record in Cantrak
sales_record = {
  “seller_license_number”: seller_license_number,
  “buyer_license_number”: buyer_license_number,
  “transaction_date”: transaction_date,
  “product_type”: product_type,
  “product_quantity”: product_quantity,
  “product_price”: product_price
  “coa_doc_reference”: coa_doc_reference
}
// Write sales record to blockchain
hash_id = blockchain.write_data(sales_record)
Output:
// Print hash ID for confirmation
Print (“Sales record successfully written to blockchain with
hash ID:”, hash_id)
End
```

Algorithm 5 describes the reading of a *lot number* to the blockchain. This algorithm is designed to retrieve data from the blockchain using a unique lot number as input. It is typically used for tracking the cannabis cultivation process. The algorithm fetches data associated with a specific lot number from the blockchain and displays such data if found. It checks for the existence of data relating to the lot number and prints the details if data are available.

Algorithm 5 Read lot number to the blockchain.

```
Input:
// Define input variables
lot_number = [string]  // unique identifier for the lot of plants
// Fetch data from the blockchain using the entered lot number
fetched_data = blockchain.fetch_data(lot_number)
Output:
// Check if data was found
if fetched_data is empty
  // No data found for the entered lot number
  print("No data found for the entered lot number.")
else
  // Display the fetched data
  print("Data for Lot Number:", lot_number)
  print("----------------------------------------")
  print("Process Name:", fetched_data["process_name"])
  print("Start Date:", fetched_data["start_date"])
  print("End Date:", fetched_data["end_date"])
  print("Strain:", fetched_data["strain"])
  print("Product Type:", fetched_data["product_type"])
  print("COA Doc Reference:", fetched_data["coa_doc_reference"])
  // You can continue displaying other fields as needed
End
```

V. Results

The smart contract is coded in Python and validated through testing in Visual Studio Code once it is constructed. Additionally, an online web-based development environment is utilized for creating and executing programs related to smart contracts. This platform also has facilities for debugging and testing the solidity code’s surroundings.

This section presents a cost evaluation of the Polygon smart contract code. When executing a transaction on the Polygon blockchain, it is important to take into account the gas cost linked with its transmission. The experimental indoor cultivated condition covers a 100 m^2 area with four crops per year. All transactions are simulated according to the sequence diagram in Fig. 5.

TABLE IV. Cost Estimate of the Smart Contract Code for Polygon

Function Name	Transaction	Polygon Gas	Storage Cost	Cost (USD)/Yr.
Cultivation Lot	20800	1664	300	1964
Harvest Lot	10400	832	150	982
Production Lot	31200	2496	450	2946
Sale Data	20800	1664	300	1964

The smart contract uses gas for its different functions, the cost of which is converted into fiat currency (USD) in Table IV. The average Polygon gas price is US$ 0.08, according to the Polygon gas price [41] on May 7, 2023. The manufacturing lot conducted by the smart contract owner (manufacturer) is the most expensive of the four functions. This unusually large cost may be explained by the function needing data storage having six distinct variables. The cultivation lot and sale figures, respectively, represent the second and third greatest expenses.

TABLE V. Transaction Speed for Polygon

Function Name	Transaction Speed (sec)	S.D.
Cultivation Lot	20.20	8.13
Harvest Lot	17.57	3.81
Production Lot	17.20	4.33
Sale Data	19.26	9.59

The performance of the system is tested on the Polygon blockchain network (Standard Polygon speed selection) through use cases and receives performance test results, including transaction speed. The test results of the four functions are shown in Table V. The manufacturing lot is the fastest transaction. The harvest lot and sale data, respectively, represent the second and third speedy transaction.

VI. Discussion

This section examines the extension of the planned Polygon blockchain-based solution and constraints for cannabis supply chain traceability.

The proposed approach demonstrates the potential use of blockchain technology to enhance the traceability of the cannabis supply chain. Similar research has been conducted on the agricultural food (agri-food) supply chain. Even if the information is secure and transparent, it cannot be used by the cannabis sector due to its diverse procedures and complicated organizational structures. In conjunction with healthcare goods, these impacts are not only harmful to persons but also pose a substantial threat to the economy and society. The cannabis supply chain differs from others by emphasizing the identification of strains and THC/CBD ratios [1]. In addition, there are no worldwide guidelines for the traceability of agri-food research. For instance, blockchain-based traceability in medicine supply chain management [25, 42] includes a procedure distinct from cannabis and prioritizes enhanced data security protection to ensure the pharmaceuticals are genuine. Transparency from upstream to downstream still requires decentralized traceability and supply chain efficiency.

The decentralized application may be used in the storage mode of a blockchain-based traceability system for cannabis goods and includes a distributed database containing traceability information under on-chain circumstances. After uploading traceability data, the system classifies the data. The public information of the product is stored within the local database. As seen in Fig. 3, the encrypted ciphertext along with the hash ID for the public information is uploaded onto the blockchain and communicated to associated databases.

The sequence diagram may be used to convey several relationships to cannabis stakeholders. It will be necessary to add the smart contract and specify its interaction with the other entities. Another option is the simultaneous development of many goods, which necessitates an expansion of the functionalities to suit the extra products; this may be accomplished by altering the current smart contract.

This research contributes to the academic field by leveraging existing knowledge to expand and generate new insights into developing a decentralized application for the cannabis traceability process within blockchain-based supply chain management. The emphasis is on enabling trust, transparency, data security, and efficiency in cannabis supply chain management on the blockchain platform. The achievement of these objectives involves architectural design, algorithm development, sequence diagram design, and the creation of blockchain applications. Additionally, this research aims to enhance supply chain management to align with modern standards in the Industry 4.0 era, incorporating IoT technology and smart contracts. This includes ensuring transparency, real-time verification, transaction security, and meeting customer demands for the visibility and traceability of cannabis products throughout the entire supply chain.

This research focuses on developing trust in cannabis traceability using a blockchain platform to make data trustworthy, transparent, secure, and efficient. The blockchain’s consensus mechanism ensures data cannot be altered by using a timestamped, distributed database and decentralizing. This mechanism is crucial in preventing questionable products from entering the legal market, emphasizing the importance of traceability for identifying and disposing of potentially hazardous products. The flexibility introduced by storing data from the cannabis traceability system on-chain and off-chain reduces the loading pressure on blockchain and storing necessary information. Moreover, scalability in developing a blockchain-based traceability process avoids delays and high transaction fees to establish sustainability for the cannabis industry.

Finally, the algorithms are developed in easy stages and may be implemented inside the application for the cannabis supply chain.

VII. Conclusion

This research examines the difficulty of cannabis supply chain traceability and its relevance, particularly in terms of identifying the source to make the product look authentic. It proposes a Polygon blockchain-based strategy for the cannabis supply chain that offers data security, immutability, and decentralized control over cannabis extract products.

The suggested approach leverages a smart contract capable of processing a variety of transactions among cannabis supply chain stakeholders to accomplish the automatic documentation of occurrences that are accessible to all involved parties. The blockchain-based solution includes on-chain and off-chain storage, algorithms, and a sequence diagram. This research reveals that the various smart contract functionalities are responsible for the transaction’s cost-effectiveness in terms of the quantity of gas used. The scalability of the blockchain-based solution is necessary for the sustainable cannabis industry.

Finally, the researchers plan to continue their efforts to enhance the international standards for traceability, the supply chain management to align with modern standards in the industry 4.0 eras, and the efficiency of the cannabis supply chain process in future work.

***Abstract*—Chronic kidney disease (CDK) represents a significant public health concern globally, and its prevalence is on the rise. In the context of Kuwait, this study addresses the imperative of predicting CKD by leveraging the wealth of information embedded in electronic health records (EHRs). The primary objective is to develop a predictive model capable of early identification of individuals at risk for CKD, thereby enabling timely interventions and personalized healthcare strategies and equip clinicians with information that enhances their ability to make well-informed decisions regarding prognoses or therapeutic interventions. In this study, a dataset has been created from Kuwaiti healthcare institutions, emphasizing the richness and diversity of patient information encapsulated in EHRs and a feature engineering step has been applied for labeling it. Various ensemble learning algorithms, Ada Boost, Extreme Gradient Boosting, Extra Trees, Gradient Boosting, Random Forest, and various single learning algorithms, Decision Tree, K-Nearest Neighbors, Logistic Regression, Multilayer Perceptron, Stochastic Gradient Descent, Support Vector Machines, have been implemented. By examining the empirical findings of our tests, our results showcase the models' capability to identify individuals at risk for CKD at an early stage, facilitating targeted healthcare interventions. Decision Tree was the best classifier achieving 99.5% accuracy and 99.3% macro averaged f1-score.**

Keywords*—Chronic kidney diseases; Electronic Health Records (EHR); classification; machine learning

I. Introduction

The digitalization of patient health records has brought about a new era in healthcare, one that offers previously unheard-of possibilities for data-driven research and medical improvements [1]. With the right use, Electronic Health Records (EHR) can become a veritable gold mine of detailed, longitudinal patient data. With the right application, this data can revolutionize the way to anticipate and prevent disease. A major obstacle confronting the healthcare sector is the increasing prevalence of chronic diseases, which contribute significantly to worldwide morbidity and mortality [2]. A growing number of people are interested in using the potential of EHR to create strong predictive models that target early identification, risk assessment, and tailored intervention for chronic diseases. Millions of people worldwide suffer from CKD, a widespread, frequently silent illness that places a heavy burden on healthcare systems around the globe. Innovative methods for identifying those at risk are desperately needed as the frequency of CKD rises, as this will allow for early intervention and individualized care. In this quest, EHRs, which comprise an extensive patient data repository, proves to be a vital asset. They provide a dynamic platform for the creation of predictive models that have the potential to revolutionize the management CKD [3].

When it comes to identifying subtle signs and patterns that precede overt clinical symptoms, traditional diagnostic techniques frequently fall short. Within this framework, EHRs function as a repository for longitudinal patient data, encompassing test findings, medication records, and demographic details, offering a comprehensive perspective of a person's medical journey. By using EHR data, it is possible to identify complex patterns and risk factors related to CKD, which can lead to tailored interventions that can be implemented in a timely manner [3].

In earlier research [4], the same authors suggested using EHRs instead of paper ones to record patients' health information. Also, they highlighted the application of predictive analytics models, which use electronic health data to predict the emergence of chronic diseases early on. According to this study, CKD affects around 700 million people globally each year, and it causes nearly 1.2 million fatalities [4]. The current research contributes to improve the quality of life for those with or at risk of CKD in Kuwait by highlighting the revolutionary potential of predictive ensemble learning and single learning algorithms models using actual Kuwaiti EHRs which are collected from hospitals and health institutes in Kuwait and altering clinical workflows and resource allocation.

Through patient follow-up, changes in several clinical markers could be seen over time and their relationship to the course of the disease. By using this method, we may record the time dynamics and find any patterns or trends that might point to deteriorating CKD. While our study primarily focused on the development and validation of the predictive model, we acknowledge the importance of discussing the practical aspects of its clinical implementation. Addressing issues related to data integration, workflow adaptation, and acceptance by healthcare professionals is critical for the effective deployment of predictive models in routine clinical care.

The following are the primary contributions of the article:

- Using electronic health records instead of paper records.
- Using accessible datasets from patients' medical records, machine learning techniques are used to predict the existence of chronic illnesses.
- Examining medical records of all patients to ensure proper diagnosis of chronic disorders.
- Identifying new patients with comparable symptoms and illness development phases based on physician supervision and medical record analysis for a specific type of chronic disease.

The latter part of the manuscript will delve into related research in Section II, followed by an examination of the datasets employed in this study in Section III. Section IV will provide a comprehensive description of the proposed technique. Subsequently, Section V will present the test results and evaluate the effectiveness of the proposed strategy. Lastly, Section VI and Section VII will present the discussion and conclusions respectively.

II. Related Work

Considerable work has been done to anticipate CKD. This section will include descriptions of a few of these works.

To predict CKD using clinical data, Ekanayake and Herath [5] investigated the use of machine learning techniques. They noted the need of feature engineering, handling missing values, and integrating domain knowledge in the study. They presented a procedure that includes attribute selection, handling of missing values, and data preprocessing. The application of a KNN-based technique to handle missing values in datasets pertaining to several diseases was also taken into consideration in this work. According to the study, the random forest and extra trees classifiers produced the best results for predicting CKD, obtaining 100% accuracy for both training and testing. Furthermore, the study made no mention of any potential privacy or ethical issues with using patient data for predictive modeling.

Q. Bai et al. [6] developed a predictive model for end-stage kidney disease (ESKD) using a dataset of 748 people with chronic kidney disease (CKD). To manage missing data, the authors used a five-set multiple imputation method. They then examined each model's performance on each imputed set, combining the findings to get the result. At 81%, the random forest algorithm produced the best overall performance as determined by the AUC score. On the other hand, the Kidney Failure Risk Equation (KFRE) model, which is based on three straightforward variables, showed the highest accuracy, specificity, and precision along with equivalent AUC scores. The research found a void in the literature about the applicability of predictive models for ESKD in other ethnic groups, including the Chinese population. It also brought attention to the possibility of predicting ESKD without the need for urine testing, which could result in a more straightforward model with comparable reliability. The KFRE model's default threshold sensitivity and the lack of previous attempts to use machine learning techniques to predict the occurrence of ESKD in CKD patients are among the study's shortcomings.

Y. Zhu et al. [7] presented a unique method utilizing longitudinal patient Electronic Health Records (EHRs) to predict the course of CKD. They forecasted the course of CKD with impressive accuracy by combining an AI prediction model with an EHR preprocessing pipeline. Preprocessing the EHR incorporates multiple clinical factors and transforms them into time series data that may be used in Recurrent Neural Network (RNN) modeling. Their main goal was to forecast how quickly CKD will advance from early to late stages. Feature vectors that represent patient data prior to a given period are analyzed for each case patient. Based on patient race, sex, age, and duration of time series, control patients are matched when utilizing the time series of a single variable, eGFR, the RNN model predicts disease development within a year with an average AUROC of 0.957. Due to patient privacy issues and the proprietary nature of the data, there is a research gap in the lack of publicly available datasets.

H. Nayeem et al. [8] applied machine learning approaches to predict chronic kidney disease (CKD). The 400 examples in the sample comprise 25 attributes total one dependent attribute and 24 independent attributes. To predict CKD, the study used methods from Support Vector Machine (SVM), Random Forest (RF), and Artificial Neural Network (ANN). An analysis of the classifiers' comparative performance revealed that ANN performed better than the other techniques, achieving 98.6% and 98% accuracy and f1-score, respectively. The study failed to examine the possibility of biases in the dataset or the applicability of the results to different groups with chronic kidney disease.

D. Chicco et al. [9] examined CKD and found independent risk factors linked to stages 3-5 of the disease by examining a dataset of 491 individuals from the United Arab Emirates. The authors used two different methodologies, one based on machine learning techniques and the other on conventional univariate biostatistics testing. The results of the biostatistical tests showed that while 68.42% of the clinical parameters were significant, they were not precise. As a result, the writers ranked features using Random Forests. The study showed that, independent of temporal information, computational intelligence could predict the development of severe CKD, suggesting that the significance of clinical factors changes when the temporal component is considered. The study is significant because it uses machine learning to uncover critical clinical traits while thoroughly examining risk factors linked to CKD at stages 3-5. Remarkably, the study concentrated on developing and enhancing computational intelligence technologies rather than discussing the therapeutic implications of the results.

In another study on the prediction of chronic renal illness, S. Pal [10] used three machine learning classifiers: Support Vector Machine (SVM), Decision Tree, and Logistic Regression. After the classifiers were assessed, it was discovered that the Decision Tree classifier performed the best, obtaining 95.92% accuracy, 0.99 precision, 0.98 recall, and

0.98 F1-score. To enhance the performance of the base classifiers, bagging ensemble methods were also used in this study. The Decision Tree classifier achieved the greatest accuracy of 97.23%. There may be a research gap because the study did not specify the precise dataset that was utilized to train and test the classifiers.

M. Klamrowski et al. [11] used machine learning to create a prediction model for individuals with advanced chronic renal disease who are at risk of short-term kidney failure. They were intended to be integrated into electronic medical records for clinical use, and they made use of dynamic laboratory data to increase prediction accuracy. They showed that the prediction of short-term kidney failure requires the inclusion of more current follow-up data, especially dynamic lab data. The study also demonstrated how the prediction model may be used to lower the rates of unscheduled dialysis and the negative consequences that are linked with it. The study found that using machine learning methods, such as Cox regression, to take into consideration the complex interrelationships and complexity of the data was the best approach. This study found a knowledge gap on the requirement to increase the generalizability of prediction models to various populations. Furthermore, there is a lack of validating the prediction model's efficacy within the typical renal disease clinic workflow and integration of the model into clinical practice.

A. Islam et al. [12] used machine learning techniques to forecast chronic kidney disease (CKD) in its early stages. To minimize the number of features and get rid of unnecessary data, relationships between various aspects were investigated and the models were trained and validated using input parameters. After preprocessing the dataset, principal component analysis (PCA) was used to determine which features were most important in CKD detection. This study discovered that, after using a filter feature selection approach, hemoglobin, albumin, and specific gravity had the greatest influence on CKD prediction. The best approach involved using machine learning algorithms to predict CKD at an early stage, with a focus on identifying the most dominant features for detecting the disease. The performance of the proposed model was evaluated, and it was suggested that CKD risk factor predicting could be used to identify individuals at risk within the community without the need for hospital admission. The challenge of locating a different dataset with comparable properties for a useful comparison was noted by the authors.

III. Data

In this study, an EHR dataset comprising information about patients in Kuwaiti hospitals was constructed. Each row in the dataset represents a single patient, and the columns indicate all the patient's attributes (laboratory analysis), as detailed in Table I. This dataset was created for the purpose of predicting Kuwaiti Chronic Kidney Diseases (KCKD) by combining all characteristics from original datasets into a single csv file for use in training and testing prediction models, in addition to the personal information of all patients during all hospital visits. This EHR dataset has been acquired from the Department of Health Studies and Research at the Kuwaiti Ministry of Health to get clearance to access medical data and publish under the supervision of National Center for Health Information, and the Department of Prevention and Control of Non-Communicable Diseases in Kuwait. Data authorization has been obtained from the director of Al-Adan Hospital and forward the Request to the appropriate departments. Obtain clearance from the heads of the Medical Board, the Department of Clinical Radiology, the Department of Medical Laboratories, and the Department of Information Systems at Al-Adan Hospital for various departments. The dataset is available on Kaggle, KCKD, in the final version after feature engineering process. Another online labeled CKD dataset with the same features has been used for labeling the first one using feature engineering process that will be discussed in the next section. For the findings of this study to be applicable and generalizable to a wide range of populations, we must take ethnic and cultural heterogeneity into account in our research. We can evaluate potential differences in illness susceptibility, progression trends, and response to therapies by stratifying our dataset according to ethnicity or cultural background. Furthermore, our predictive models may be more accurate and relevant for demographic groups if pertinent cultural determinants of health are included.

TABLE I. Name and Type of each Feature of the EHR Dataset

Feature Name	Type
Potassium	Numeric
Sodium	Numeric
CL	Numeric
Ceriatinin	Numeric
Blood Urea	Numeric

IV. Methodology

In this section, the methodology of the proposed work will be represented and provide an explanation for every step. Fig. 1 represents the block diagram of the proposed work and steps including two phases.

A. Feature Engineering

This paper introduces a feature engineering approach [13] for kidney disease classification, focusing on leveraging known features from a labeled dataset to enhance predictive modeling on an unlabeled dataset. The methodology involves meticulous extraction and refinement of relevant features, employing preprocessing techniques to ensure data quality, and training multiple machine learning [14] classification algorithms. The best-performing model is then selected based on cross-validation results on the labeled dataset. Subsequently, this chosen model is applied to predict classes for the unlabeled dataset, providing a seamless transfer of knowledge between labeled and unlabeled data. The paper concludes with an analysis of the model's performance, highlighting the efficacy of the proposed feature engineering process in improving the accuracy and generalization of kidney disease classification.

B. Data Preprocessing

Preprocessing steps are crucial for kidney datasets as they play a vital role in enhancing the quality of the data and ensuring that machine learning models can effectively learn patterns and make accurate predictions. Here are some key preprocessing steps and their importance for kidney datasets.

1) Handling missing value: Kidney datasets may often have missing values due to various reasons such as incomplete sample collection or laboratory errors. Imputing or handling missing values is critical to maintain the integrity of the dataset and ensure that the analysis is based on as much relevant information as possible. By checking for null values in the aggregated dataset we noticed that there are some missing values in the input features as shown in Table II.

TABLE II. NUMBER OF NULL VALUES IN THE AGGREGATED DATASET

Feature Name	# Null values	# All records
Blood Urea (mgs/dL)	14	680
Serum Creatinine (mgs/dL)	12	
Sodium (mEq/L)	67	
Potassium (mEq/L)	68	

2) Normalization / Scaling: Different features in the dataset may have different scales. Normalizing or scaling features, especially numeric ones like blood pressure or serum creatinine, helps in bringing them to a similar scale, preventing certain features from dominating others during model training. We utilized the Standard Scaler [2] during preprocessing for the kidney dataset. This technique normalizes features to have a mean of 0 and a standard deviation of 1, ensuring uniform scales and enhancing the effectiveness of machine learning models, especially those reliant on distance measures.

3) Data splitting: In the experimentation of this study, for the aggregated dataset, we divided the aggregated kidney dataset into training (85%) and testing (15%) sets. This resulted in 571 instances for training and 101 instances for testing, out of the total 672 instances in the dataset. After labeling the second dataset, we divided it into two portions 80% (1600 samples) for training and 20% (401 samples) for testing as shown in Table III. This approach ensures a comprehensive evaluation of model performance, balancing training, and testing for reliable insights into the effectiveness of the proposed models for kidney disease classification.

TABLE III. NUMBER OF INSTANCES IN AGGREGATED CKD AND KCKD DATASETS

Dataset	Split ratio		Training instances	Testing instances	Total instances
Aggregated Dataset	85% Train	15% Test	571	101	672
Dataset after labeling	80% Train	20% Test	1600	401	2001

TABLE IV. NUMBER OF INSTANCS BEFORE AND AFTER OVER SAMPLING IN THE AGGREGATED DATASET AND NEW DATASET

Dataset	Label	# samples before balancing	# samples after balancing
Aggregated Dataset	non-CKD	216	355
	CKD	355	355
Dataset after labeling	non-CKD	345	1255
	CKD	1255	1255
Total		2171	3220

Table IV displays the impact of oversampling on instance counts in both the Aggregated Dataset and new labeled dataset after feature engineering. In the Aggregated Dataset section, the initial counts show 216 instances for the "non-CKD" class and 355 instances for the "CKD" class. After balancing, both classes have 355 instances, resulting in a total of 710 instances. Moving to the dataset after labeling using feature engineering, the “non-CKD” class initially has 345 instances, while the "CKD" class has 1255 instances. Following oversampling, both classes achieve balance with 1255 instances each, contributing to a total of 2510 instances. This oversampling strategy aims to ensure a more equitable representation of classes for enhanced model training and evaluation.

4) Cross Validation (CV): To rigorously assess proposed machine learning models, we adopted a five-fold cross-validation approach [15]. This method divides the dataset into five subsets, iteratively training the model on four and testing on the remaining one. By calculating and averaging performance metrics, such as accuracy and precision, across all iterations, we obtain a robust evaluation of proposed model's generalizability. This strategy ensures reliability by preventing over-sensitivity to a particular training set composition and guides hyperparameter tuning efforts for optimized model performance.

C. Machine Learning Methods

In this study, we employed two categories of machine learning algorithms, namely ensemble learning algorithms and single learning algorithms, as outlined below.

1) Single learning: In this research, we employed a diverse set of single learning algorithms, each contributing distinct strengths to analysis. The single learning algorithms used are illustrated below.

a) Decision Tree (DT) [16]: A clever and straightforward machine learning predictive model technique called a decision tree classifier uses a tree representation to go from an item's observation to a judgment about the item's target value. The decision tree is a tool for classification, description, and generalization of a given collection of data that combines mathematics and computational techniques.

b) Logistic Regression (LR) [17]: Predicting Binary Probabilities: Logistic Regression serves as a linear classification method that predicts the likelihood of a binary outcome. It accomplishes this by fitting a logistic curve to the data, making it particularly suitable for applications like binary classification tasks such as spam detection or medical diagnoses.

c) Stochastic Gradient Descent (SGD) [18]: SGD stands out as an optimization technique widely employed in machine learning model training. It refines model parameters through iterative and stochastic updates, proving notably efficient for handling extensive datasets. SGD finds frequent use in tasks involving neural network training and other iterative optimization challenges.

d) Support Vector Classifier (SVC) [19]: Using training data at class boundaries, the SVM is a linear classifier. Radial Basis Function (RBF) kernels, which were employed in this work, sigmoid, linear, and other kernel functions are used by the SVM model to classify non-linear data. Assuming that the new sample and the existing samples are similar, the KNN algorithm assigns the new sample to the category that most closely matches the existing categories [19].

e) K-Nearest Neighbours (KNN) [20]: KNN, a straightforward yet powerful algorithm, is adept at classification and regression duties. Its principle lies in classifying data points by considering the majority class among their k-nearest neighbours. KNN's simplicity and ease of implementation make it suitable for diverse applications, ranging from recommendation systems to pattern recognition.

f) Multi-Layer Perceptron (MLP) [21]: MLP, categorized as a neural network with multiple layers, exhibits proficiency in discerning intricate patterns and relationships within datasets. This algorithm's versatility is evident across applications like image recognition, natural language processing, and speech recognition. The depth of the network facilitates the capture of intricate hierarchical features in the data.

These models operate independently, with each algorithm focusing on learning patterns and relationships within the data individually. The application of these single learning techniques allows us to harness the specific capabilities of each algorithm to enhance the understanding of the intricate dynamics within the kidney dataset.

2) Ensemble learning: To further fortify the predictive capabilities of proposed models, we incorporated ensemble learning algorithms, a category renowned for amalgamating multiple models to achieve superior performance. The ensemble learning algorithms utilized in this research encompassed the following types:

a) Random Forest [22]: Random Forest, an ensemble learning algorithm, builds numerous decision trees during training, consolidating predictions to improve reliability and mitigate overfitting. Its versatility has proven effective across diverse domains, including the focus of this research.

b) Ada Boost [23]: Ada Boost, a boosting algorithm, combines weak learners sequentially to form a robust model. Its iterative approach corrects errors from previous models, with a focus on challenging instances. In this research, Ada Boost plays a pivotal role in elevating accuracy in ensemble predictions.

c) Gradient Boosting (GBoost) [24]: Gradient Boosting, an iterative ensemble algorithm, constructs decision trees sequentially to rectify the errors of preceding trees. Known for achieving high precision, GBoost is particularly valuable in scenarios requiring accurate predictions, as exemplified in this research.

d) XGBoost [25]: XGBoost, or Extreme Gradient Boosting, represents an optimized form of gradient boosting with a focus on speed and efficiency. Its parallelized training and regularization techniques make it scalable and efficient for handling extensive datasets. In this research, XGBoost enhances the effectiveness of ensemble learning.

e) Extra Trees [26]: Extra Trees, or Extremely Randomized Trees, is an ensemble algorithm introducing additional randomization during tree construction. This intentional randomness enhances model robustness and generalization. In this research, Extra Trees contributes to the ensemble's diversity, fostering a more resilient predictive model.

Leveraging the collective wisdom of diverse models, these ensemble learning techniques aimed to amplify the robustness and accuracy of the predictions, particularly in the context of kidney disease classification.

D. Performance Metrics

In this section, we detail the evaluation metrics used in the thesis to assess the performance of statistical and machine learning algorithms, including accuracy, the confusion matrix, and the classification report.

1) Confusion Matrix: This matrix [27], a vital tool for classification model evaluation, provides a comprehensive summary of predictions versus actual labels. Comprising elements like True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN), it illuminates the model's performance for positive and negative classes.

2) Classification Report: Offering a detailed assessment across different classes, the classification report presents various metrics per class. It includes equations for accuracy in Eq. (1), precision in Eq. (2), recall in Eq. (3), and F1 score in Eq. (4) derived from the report [28]:

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{1}$$

$$\text{Precision} = \frac{\text{TP}}{(\text{TP} + \text{FP})} \tag{2}$$

$$\text{Recall} = \frac{\text{TP}}{(\text{TP} + \text{FN})} \tag{3}$$

$$\text{F-measure} = \frac{2 * \text{TP}}{(2 * \text{TP} + \text{FP} + \text{FN})} \tag{4}$$

3) ROC AUC Curve: Illustrating a binary classification model's performance across decision thresholds, the ROC curve [29] and its AUC metric (ranging from 0 to 1) indicate discrimination ability, with higher values denoting superior performance.

V. Experimental Results

Several experiments have been conducted to assess the proposed model. The Python programming language and various machine learning toolboxes, such as scikit-learn, imblearn, NumPy, and matplotlib, were used for all experiments, which were conducted using the Jupiter notebook editor.

As shown in Table V, a feature engineering process has been applied for an aggregated CKD dataset with the same attributes to obtain the optimal labels for new EHRs dataset. The aggregated CKD dataset has been trained using nine classifiers, five ensemble learning algorithms (Ada Boost, XGBoost, Extra Trees, GBoost, and RF) and six single learning algorithms (DT, KNN, LR, MLP, SGD, and SVM), and the highest performance was obtained by GBoost classifier, which achieved 97.7%, 97.8, 98%, and 97.8% for precision, recall, accuracy, and macro-averaged f1-score respectively. The RF classifier was in second place achieving 95.6%, 95.6%, 96%, and 95.5% for precision, recall, accuracy, and macro-averaged f1-score respectively.

After obtaining the best labels for each patient in KCKD dataset, it was ready for building the classification model with the same classifiers mentioned above, which can predict the case of patients in Kuwait hospitals, who have the same symptoms with different values.

TABLE V. TRAINING PERFORMANCE OF ALL CLASSIFIERS FOR THE AGGREGATED CKD DATASET

	Classifier	Precision	Recall	Accuracy	F1-score
Single Learning	DT	94.3%	94.9%	95.0%	94.6%
	KNN	92.2%	92.7%	93.1%	92.4%
	LR	86.5%	85.1%	87.1%	85.6%
	MLP	94.1%	90.9%	93.1%	92.2%
	SGD	87.0%	87.0%	88.1%	87.0%
	SVM	86.8%	87.6%	88.2%	87.2%
Ensemble Learning	Ada Boost	86.8%	82.6%	77.6%	74.7%
	XGBoost	**94.9%**	**94.5%**	**90.2%**	**92.6%**
	Extra Trees	81.8%	85.7%	53.6%	54.8%
	GBoost	89.9%	88.5%	68.4%	82.3%
	RF	86.8%	84.6%	71.0%	75.3%

Table VI shows the performance of all classifiers for KCKD dataset. The highest performance was obtained by DT classifier, which achieved 98.9%, 99.7%, 99.5%, and 99.3% for precision, recall, accuracy, and macro-averaged f1-score respectively. The second place for Ada Boost classifier, which we achieved 98.4%, 99.5%, 99.2%, and 98.9% for precision, recall, accuracy, and macro-averaged f1-score respectively.

A recognized confusion matrix is obtained in Table VII and Table VIII for the purpose of estimating four different measures: recall, accuracy, precision, and f-score. The confusion matrix displays the classification results as a matrix. Information for both existing and anticipated classes created with the classification framework is included. The cell shows the sample size that was mistakenly identified as false while quiet (i.e., TN) and as true when it was truly true (i.e., TP). The number of pieces that were erroneously classified is indicated by the two remaining cells.

TABLE VI. TRAINING PERFORMANCE OF ALL CLASSIFIERS FOR KCKD DATASET AFTER LABELING

	Classifier	Precision	Recall	Accuracy	F1-score
Single Learning	**DT**	**98.9%**	**99.7%**	**99.5%**	**99.3%**
	KNN	91.3%	95.1%	94.7%	92.9%
	LR	95.2%	96.5%	97.0%	95.8%
	MLP	97.4%	97.7%	98.2%	97.5%
	SGD	94.1%	96.6%	96.5%	95.3%
	SVM	91.8%	97.1%	95.5%	94.1%
Ensemble Learning	Ada Boost	98.4%	99.5%	99.2%	98.9%
	XGBoost	97.9%	96.4%	98.0%	97.1%
	Extra Trees	38.4%	50.0%	76.8%	43.4%
	GBoost	98.2%	98.9%	99.0%	98.6%
	RF	98.3%	99.2%	99.2%	98.9%

TABLE VII. CLASSIFICATION REPORTS OF SVM, DT, AND MLP CLASSIFIERS FOR AGGREGATED CKD DATASET

Dataset	Classifier	Precision	Recall	F-measure	Class
Single Learning	DT	91.89	94.44	93.15	0

The cells indicating the sample size labeled true when it was incorrect (i.e., FP) and false when it was true (i.e., FN). All measures were calculated using the formulas listed in the previous subsection, 2.4.2. In the class column, "1" means CKD patient and "0" means non-CKD patient.

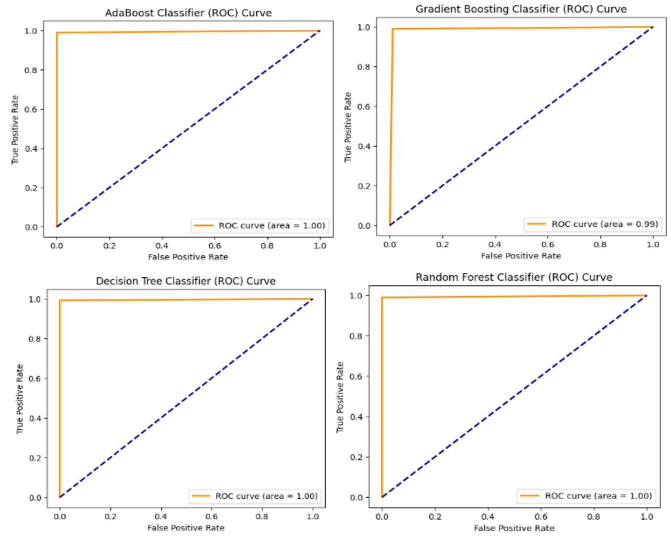

Fig. 2. ROC curve of DT, RF, AdaBoost, GBoost curve for Kuwaiti CKD, from left to right, respectively.

Fig. 2 shows the ROC curve of the best ensemble and single learning classifiers applied for Kuwaiti CKD, DT, RF, AdaBoost, GBoost.

VI. Discussion

The labeled dataset of CKD, as demonstrated in Table VI, presents a comprehensive evaluation of various classifiers, each assessed on key performance metrics including precision, recall, accuracy, and F1-score. Among these classifiers, the results distinctly highlight the exceptional performance of the Decision Trees (DT) algorithm. With a precision of 98.9%, recall of 99.7%, accuracy of 99.5%, and an F1-score of 99.3%, DT emerges as the standout performer across all metrics. The superiority of DT can be attributed to several inherent advantages it offers. Notably, its innate interpretability lends itself well to domains such as CKD, where comprehensible decision-making is crucial for clinical applications. Moreover, DT's ability to effectively capture non-linear relationships within the data proves invaluable in handling the complex patterns often present in CKD datasets. Furthermore, its robustness to irrelevant features ensures efficient feature selection, enhancing model performance and generalization. Given the scalability and efficiency of DT, particularly in managing large datasets, it emerges as not only the best-performing classifier in this evaluation but also a pragmatic choice for real-world CKD classification tasks. This robust performance underscores the utility of Decision Trees as a reliable and effective tool for medical diagnosis and decision support in the context of chronic kidney disease. We carefully selected algorithms based on their proven effectiveness for the task. Through rigorous testing, we found that our chosen ensemble and single learning algorithms consistently delivered high performance. While we acknowledge the potential for different results with alternative algorithms, our focus was on leveraging well-established methods known for their reliability. Our thorough validation process supports the confidence in the efficacy of our selected algorithms for this study. We recognize the importance of clinical interpretability in healthcare settings. While our study primarily focused on performance metrics like accuracy, precision, recall, and F1-score, we understand the need to understand model predictions. By addressing interpretability, we aim to bridge the gap between model performance and real-world healthcare applications, enhancing trust among healthcare professionals.

VII. Conclusion and Future Work

To predict KCKD, we created EHRs dataset using patients' symptoms collected from Kuwait hospitals and health institutions, a feature engineering process has been utilized for this dataset to obtain the optimal labels for each patient by training another CKD dataset with the same attributes using several ensemble learning classifiers, Ada Boost, XGBoost, Extra Trees, GBoost, RF, and several single learning classifiers, DT, KNN, LR, MLP, SGD, and SVM. The study's findings suggest that chronic disease identification and prediction can be accomplished with the help of data mining tools. According to the findings, the DT algorithm was the best option with the highest performance for predicting Kuwait CKD, achieving 99.5% accuracy and 99.3% f1-score, while the GBoost algorithm was the most effective for training the aggregated CKD dataset and obtaining the optimal labels of Kuwait CKD dataset, achieving 98% accuracy and 97.8% f1-score. Strong performance was also shown by the RF and Ada Boost algorithms on both datasets. In further work, we intend to include a portion addressing the practical issues and difficulties related to applying our predictive model in clinical settings. The predictive model's seamless integration into clinical decision-making processes, workflow adaptation to ensure healthcare professionals' acceptance and adoption of the model, and data compatibility and integration with current electronic health record systems will all be covered in this.

Data Manipulation in Wireless Sensor Networks: Enhancing Security Through Blockchain Integration with Proposal Mitigation Strategy

Ayoub Toubi, Abdelmajid Hajami
LAVETE Laboratory Hassan 1er University, Faculty of Science and Technology, Settat, Morocco

Abstract—**In recent years, Wireless Sensor Networks (WSNs) have become integral in various applications ranging from environmental monitoring to defense. However, the security and reliability of these networks remain a paramount concern due to their susceptibility to various types of cyber-attacks and failures. This paper proposes a novel integration of blockchain technology with WSNs to address these challenges. Blockchain, with its decentralized and tamper-resistant ledger, offers a robust framework to enhance the security and reliability of sensor networks. The study begins by analyzing the current security threats and challenges faced by WSNs, emphasizing the need for a solution that can ensure data integrity, confidentiality, and network resilience. We then introduce blockchain technology and discuss its key features such as decentralization, immutability, and consensus algorithms, which are beneficial in creating a secure and reliable WSN environment. Subsequently, we present a detailed architecture of how blockchain can be integrated with WSNs. This includes the deployment of a lightweight blockchain protocol suited for the limited computational resources of sensor nodes. We also explore the use of smart contracts for automated, secure data handling and network management within WSNs. To validate the proposed integration, we conduct a simulations based on network attacks. The results demonstrate significant improvements in the security and reliability of WSNs when blockchain is implemented. This is evidenced by enhanced resistance to common attacks, such as data manipulation and node compromise and increased network uptime.**

Keywords—Wireless sensor networks; blockchain technology; network security; data integrity

I. Introduction

In an era increasingly reliant on the Internet of Things (IoT), the integrity and security of data in wireless sensor networks (WSNs) have become paramount. As these networks form the backbone of critical data collection and transmission in various sectors, including environmental monitoring, healthcare, and industrial automation, the threat of data tampering looms large, undermining not only the reliability of data but also the safety and efficiency of operations. This paper delves into the burgeoning challenge of data integrity in WSNs, specifically focusing on the vulnerability of these networks to data tampering attacks. The exploration begins with a comprehensive overview of the current landscape of WSNs, highlighting their pivotal role and inherent security weaknesses. It then transitions into a detailed examination of data tampering scenarios, illustrating how these breaches can occur and their potential impact on both the networks and the sectors they serve. The core of this study introduces a novel approach to mitigating these risks: the integration of blockchain technology into WSNs. This integration promises a transformative shift in securing sensor data, leveraging blockchain's inherent characteristics of decentralization, immutability, and transparency. Our proposal outlines a mitigation strategy that encompasses the implementation of a blockchain framework tailored for WSNs. Wireless sensor networks have emerged as a cornerstone technology in a plethora of applications. These networks, characterized by their distributed nature and often operating in unattended environments, are inherently susceptible to various security threats, with data tampering being among the most critical. The initial section of this paper illuminates the escalating threat of data tampering in WSNs. It provides an analysis of recent incidents, underscoring the sophisticated methods employed by attackers and the resulting implications for data integrity and network reliability.

A detailed exploration of the vulnerabilities in current WSN architectures that make them prone to tampering is essential. This part of the paper systematically categorizes these vulnerabilities, ranging from hardware limitations to software loopholes, and examines their role in facilitating data tampering. The impact analysis extends beyond the technical repercussions, considering the socio-economic consequences of compromised data, thereby highlighting the urgency of addressing this issue [21, 22].

The introduction of blockchain as a solution is more than just a technical upgrade; it represents a paradigm shift in how network security is approached in WSNs. This segment delves into the fundamentals of blockchain technology, elucidating how its key features - decentralization, immutability, and consensus mechanisms - align perfectly with the needs of secure, tamper-proof WSNs. The discussion also navigates through the challenges and limitations of integrating blockchain into existing WSN infrastructures, setting a realistic foundation for the proposed solution. Building on the theoretical underpinnings of blockchain technology, the paper then presents a comprehensive mitigation strategy [17, 18, and 20].

This strategy is not just a conceptual framework but a blueprint for practical implementation. It includes architectural models, protocol adaptations, and algorithmic solutions tailored to the unique constraints and requirements of WSNs. The proposed strategy also considers the scalability and energy efficiency aspects, ensuring that the integration of blockchain is viable even in resource-constrained sensor networks which spark a conversation about future directions in network security. The integration of blockchain into WSNs, as proposed, could set a precedent for how emerging technologies can be harnessed to fortify digital infrastructures against evolving cyber threats [23, 24, 25].

This study offers a range of significant contributions to the field. Primarily, it introduces the integration of blockchain technology into wireless sensor networks, significantly boosting their security. We begin by methodically identifying and addressing privacy and security concerns at each layer in Sensor Node applications. This is followed by an in-depth exploration of how Sensor Nodes can be effectively integrated with blockchain technology, assessing its capability to resolve these privacy and security challenges [19].

A key focus of our research is the detailed examination and discussion of the security-enhancing aspects of blockchain technology. By implementing blockchain within wireless sensor networks, we enable data authentication through a decentralized or distributed system, thus enhancing network integrity. The principal contributions of our research are twofold: firstly, introducing blockchain technology as a powerful tool to fortify the security framework of wireless sensor networks, and secondly, ensuring the operational efficiency and reliability of these networks through this innovative technological integration in this paper, we will present the related work (see Table I) in the Section II, Section III will address challenges in privacy protection and security in wireless sensor networks, Section IV presents the methodological model, Section V presents the analysis results and discussion, and a conclusion is present in Section VI.

II. RELATED WORK

The most prevalent model in today's network software applications is the centralized system. This model exercises direct control over each unit and handles signal processing at each centralized hub. In this setup, the management of rights by the central entity is entirely dependent on individual nodes, with the entire network infrastructure operating to receive and transmit data based on these rights. In contrast, a distributed network system is exemplified by the peer-to-peer (P2P) model. P2P networks, used extensively in online file sharing and live streaming services, include applications like Torrent file downloading.

Blockchain technology, following the footsteps of BitTorrent, also operates on a peer-to-peer network protocol. In this network, all nodes are of equal status, functioning independently of a centralized control system or an intermediary for transactions. Nodes have the flexibility to join or leave the network at any time and can simultaneously offer and utilize services. Each node in this network acts both as a server and a client. The overall strength of the system, in terms of processing capability, data security, and resilience to damage, grows with the number of nodes. Bitcoin, a well-known application of this technology, also operates on the P2P protocol. Unlike traditional financial systems where trusted central institutions act as intermediaries, Bitcoin's operations are direct between users, facilitated by the peer-to-peer network protocol, as referenced in [5, 6].

A comprehensive blockchain system encompasses various components: data blocks for storing information, cryptographic signatures, system logs, a peer-to-peer network infrastructure, methodologies for system maintenance, computational tasks for data mining, rules for proof-of-work, mechanisms for transmitting anonymous data, “Unspent Transaction Output” (UTXO) models, Merkle trees, among other technical aspects. Leveraging these technological advancements, blockchain creates a continuous, decentralized network powerhouse, facilitating services like transmission, verification, and record-keeping, as detailed in study [7].

This approach allows for the creation of a sensor data record derived from the transaction history of a blockchain. In a typical blockchain network, a new block is generated approximately every ten minutes, consisting of a header and a body. The header of each block includes several key elements: the current block number, the starting block's hash value, a timestamp, a random number (nonce), the hash value of the current block, and a Merkle tree. The body of the block is primarily where the sensor data are located. Each sensor data entry is securely stored in the block of the research system’s record, readily accessible to authorized users. The Merkle tree within the block ensures the integrity of each piece of sensor data by digitally signing it, thereby preventing duplication. Upon gathering all sensor data, the system utilizes the Merkle-tree hash method to generate "Merkle-root" values, which are then included in the block’s description section [8].

Reference in [9] presents data security protocols specifically tailored for wireless sensor net-work environments. Further examination of security threats and their mitigation in wire-less sensor networks, particularly those used in monitoring applications, was suggested in [10]. In study [11], the application of sensor fusion in wireless sensor networks is explored for the purpose of detecting mobile intruders in surveillance scenarios. Reference in [12] introduces a fusion-based system for remote sensing applications, leveraging wireless interactive media sensing devices.

One of the most appealing aspects of blockchain technology is the level of privacy it offers. However, this can sometimes result in transparency issues. The system self-audits, frequently reviewing the digitized value ecosystems that handle transactions, typically every ten minutes. This process ensures transparency and the absence of corruption. In a block-chain, associating a specific user with a public address set is challenging, as the user’s identity is shielded behind a complex encryption [13]. Various security-related studies in different domains are mentioned below with corresponding references.

Research in [14] addresses the development of a blockchain network for cross-domain image sharing. This network employs a consensus blockchain to facilitate the sharing of medical and radiological images among patients. The author emphasizes consensus among select trustworthy institutions to maintain a robust consensus mechanism, simplifying the management of advanced security and privacy modules.

According to research in [15], the application of blockchain technology has significantly improved the transfer of medical records in Health 4.0 applications. This includes enhanced compatibility of healthcare databases, easier access to clinical documentation, prescription databases, and effective tracking of medical devices. Additionally, the authors propose an access control policy designed to optimize the sharing of medical information across various healthcare providers.

Several studies have advocated for the implementation of an ad hoc on-demand distance vector (AODV), a robust routing protocol that leverages prior encoding to counteract

III. Privacy and Security Challenges in Wireless Sensor Networks

With the evolution of sensor node technology, applications based on sensor nodes have begun to replace traditional ones. Significant efforts have been invested in developing the architecture and protocols for sensor node-based products. However, as highlighted in study [1], privacy and security issues within sensor node systems remain a primary concern. These systems face inherent limitations and are susceptible to a range of security threats, which have been systematically categorized in a layer-wise manner for sensor node-based applications.

The structure of sensor node applications, as discussed in [2], involves multiple frame-works for building these applications, each presenting its own set of security and privacy challenges. Eight potential frameworks have been identified, emphasizing the unique concerns in each for securing and maintaining privacy. As noted in references [3, 4], security and privacy issues, particularly in the realms of authentication and data protection, are among the most daunting challenges in the design of sensor node applications. The authors suggest innovative solutions, including the use of blockchain, cloud computing, and advanced device analytics, as potential methods to address these challenges. The sensor node infrastructure is broadly divided into three layers: physical, network, and application.

Each layer presents distinct security vulnerabilities that need to be addressed to ensure the overall integrity and confidentiality of the sensor node ecosystem [16].

Wireless Sensor Networks (WSNs) are fundamental in numerous applications, ranging from environmental monitoring to smart city infrastructures. However, their open and distributed nature introduces significant privacy and security challenges that must be ad-dressed to ensure their effective and safe operation.

1) Vulnerability to external attacks: WSNs are often deployed in unsecured environments, making them susceptible to various forms of cyber-attacks. These include eavesdropping, where attackers intercept sensitive information, and more sophisticated attacks like node capture and physical tampering, where the attacker gains control of a sensor node.

2) Data integrity and authentication issues: Ensuring the integrity and authenticity of the data collected and transmitted by sensor nodes is crucial. Any tampering with data can lead to incorrect decision-making, with potentially catastrophic consequences, especially in critical applications like healthcare monitoring systems.

3) Privacy concerns: Sensor nodes often collect sensitive information. Protecting the privacy of this data against unauthorized access and ensuring compliance with data protection regulations pose significant challenges.

4) Network security weaknesses: Due to resource constraints in WSNs (like limited battery life and computational power), implementing robust encryption and other traditional security measures can be challenging. This limitation makes WSNs more vulnerable to security breaches compared to more resource-rich networks.

5) Internal threats and insider attacks: WSNs are not only vulnerable to external threats but also to internal ones. Compromised or malfunctioning nodes within the network can lead to the dissemination of false data, disrupting network operations.

6) Scalability and dynamic network topology: The scalable nature of WSNs and their dynamic topology, with nodes frequently joining and leaving, complicate the implementation of comprehensive security protocols that can adapt to changing network configurations.

7) Resource constraints and energy efficiency: One of the defining features of WSNs is their limited resources in terms of energy, memory, and computational power. Security mechanisms, which often require substantial computational resources, must be designed to be energy-efficient to prolong the lifespan of the sensor nodes. Striking a balance between security and energy efficiency is a critical challenge [17].

8) Secure data aggregation: In WSNs, raw data collected by individual sensor nodes are of-ten aggregated to reduce communication overhead and save energy. Ensuring the security and integrity of this aggregated data is crucial, as tampering or false data injection at this stage can have wide-ranging implications.

9) Key management and distribution: Secure communication in WSNs typically relies on cryptographic methods, which in turn depend on effective key management strategies. However, the dynamic nature of WSNs, combined with resource constraints, makes key distribution, management, and revocation a complex task.

10) Physical layer security: Given the likelihood of sensor nodes being deployed in physically unsecured locations, they are prone to capture and tampering. Protecting the physical layer of WSNs and developing tamper-resistant hardware are important aspects of ensuring overall network security.

11) Cross-layer security solutions: Traditional network security solutions focus on specific layers of the network. However, in WSNs, a cross-layer design approach — where security solutions are integrated across different layers of the network protocol stack — can offer more robust protection.

12) Trust and reputation systems: Implementing trust and reputation systems within WSNs can help in identifying and isolating malicious or compromised nodes. These systems, however, must be lightweight and scalable to suit the network's constraints.

13) Legal and regulatory compliance: Adhering to evolving legal and regulatory standards for data protection and privacy, especially when WSNs are used in sensitive applications, adds another layer of complexity. Ensuring compliance while maintaining operational efficiency is a significant challenge.

14) User awareness and training: The human factor plays a crucial role in the security of WSNs. Training users and administrators to understand potential security threats and to follow best practices is essential for maintaining network integrity.

The impact of privacy issues on the performance of Wireless Sensor Networks (WSNs) is a multifaceted concern. Privacy challenges can affect WSNs in several ways, often leading to compromises in their efficiency, effectiveness, and overall functionality.

15) Increased overhead and reduced efficiency: To address privacy concerns, additional layers of data protection and encryption may be required. While these are crucial for safe-guarding sensitive information, they also introduce extra computational and communication overhead. This increased load can strain the limited resources of sensor nodes, lea-ding to reduced network efficiency and shorter node lifespans due to faster battery depletion. Implementing privacy-preserving mechanisms often involves complex algorithms and processing, which can result in latency. In real-time applications or scenarios where timely data transmission is critical (such as in emergency response systems), this delay can impair the overall performance of the WSN. Ensuring privacy in WSNs becomes increasingly challenging as the network scales. The larger the network, the more data is transmitted, and the more nodes are involved, increasing the risk of privacy breaches. Maintaining strong privacy protocols in a scalable manner without impacting network performance is a significant challenge. In some cases, to protect privacy, data may be anonymized or aggregated before being transmitted. While this is effective for privacy preservation, it can sometimes lead to a loss of data granularity or specificity, thereby reducing the utility or accuracy of the data for certain applications. WSNs often need to balance resource allocation between primary functions (like data collection and transmission) and privacy-preserving functions. This can lead to sub-optimal resource allocation, where either privacy or primary functionality is compromised. Privacy breaches can undermine the trust in a WSN's reliability.

If end-users or administrators believe that their data is not being handled securely, it can lead to reduced adoption and trust in these networks, thereby impacting their broader application and effectiveness. Addressing privacy issues requires careful planning and de-sign, which can increase the complexity of WSN systems. This might lead to more challenging implementation and maintenance, requiring more skilled personnel and resources, thereby impacting the cost-effectiveness and practical deployment of WSNs. Adhering to privacy regulations and standards can impose additional constraints on the design and operation of WSNs. Navigating these legal requirements can be complex and might limit how WSNs are deployed and used, potentially impacting their performance in certain scenarios.

IV. Proposed Model

Designing a model based on blockchain technology to enhance security monitoring in Wireless Sensor Networks (WSNs) involves addressing (see Fig. 1) several key aspects: the unique characteristics and constraints of WSNs, the principles of blockchain technology, and the integration of these two to improve security.

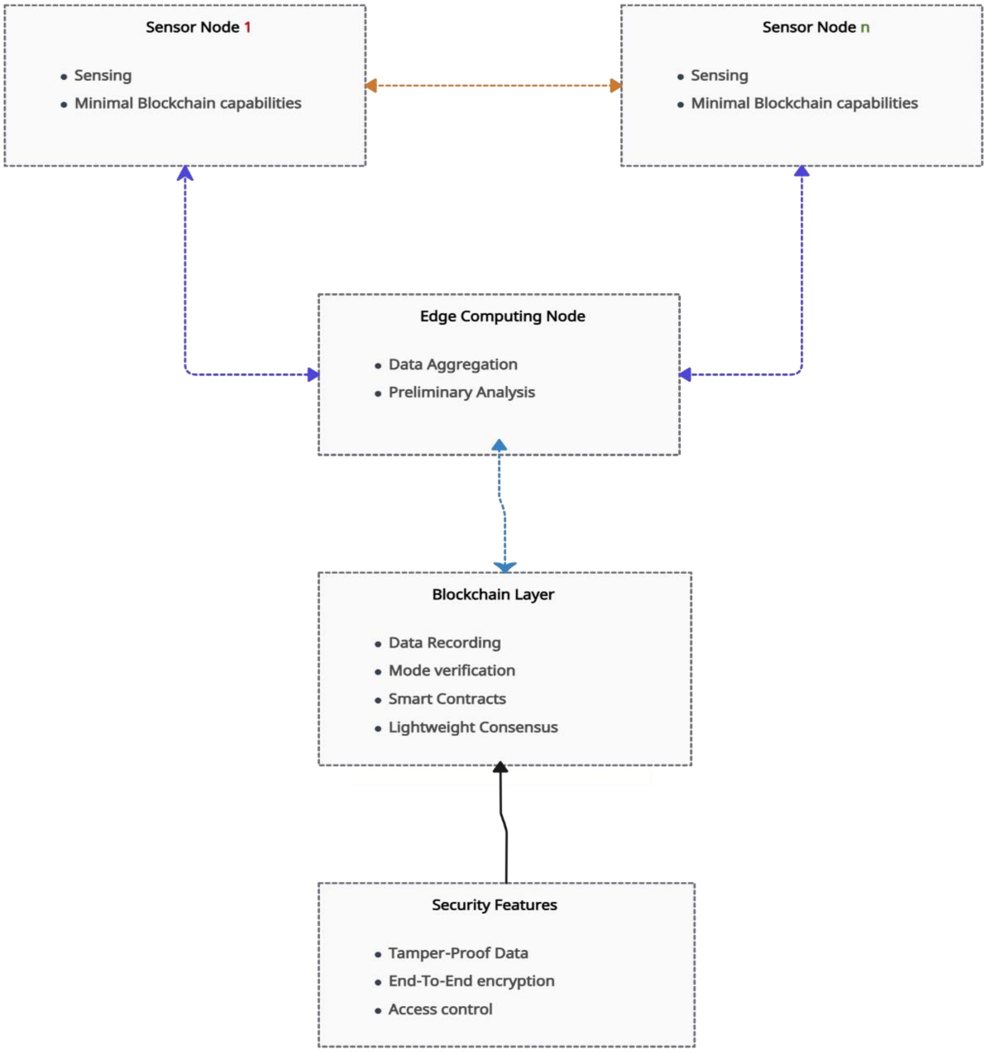

Fig. 1. Proposed model.

Here's a conceptual outline for our proposal model:

A. Architecture

1) Blockchain layer: This involves integrating a lightweight blockchain with the Wireless Sensor Network (WSN). The blockchain layer serves as the backbone for secure data management, ensuring data integrity and facilitating secure communications between nodes. Given the resource constraints in WSNs, the blockchain technology used must be lightweight enough to not overburden the network.

2) Sensor nodes: These are the basic units of WSNs and in this model, they are equipped with minimal blockchain capabilities. This means each sensor node can participate in the blockchain network, contributing to data recording and verification processes, while still performing their primary function of sensing and data collection.

3) Edge computing: To alleviate the computational load on sensor nodes, edge computing is employed. It involves processing data at the edge of the network, closer to where it's being generated. This approach handles computation-intensive tasks, like data aggregation and preliminary analysis, reducing the latency and conserving the energy of sensor nodes.

B. Integration

1) Data recording: Sensor data is recorded on the blockchain, ensuring its integrity and immutability. This aspect is crucial for maintaining the trustworthiness of the data collected by various sensors.

2) Node verification: Blockchain technology is utilized to authenticate sensor nodes. This is essential to prevent malicious or compromised nodes from entering and affecting the network.

3) Smart contracts for automated responses: These are self-executing contracts with the terms of the agreement between nodes written into code. They are used to trigger actions automatically based on sensor data, enhancing the network's responsiveness and automation.

C. Energy Efficiency

1) Lightweight consensus mechanism: Since traditional blockchain consensus mechanisms (like Proof of Work) are energy-intensive, a less energy-consuming mechanism, such as Proof of Authority or a custom lightweight algorithm, is proposed. This mechanism ensures network security and integrity without draining sensor node resources.

2) Data aggregation: Before recording data on the blockchain, it's aggregated at edge computing nodes. This reduces the volume of data that needs to be processed and stored on the blockchain, conserving energy and bandwidth.

D. Security Features

1) Tamper-proof data: Blockchain's immutable ledger ensures that once data is recorded, it cannot be altered, enhancing the security and reliability of the data.

2) End-to-end encryption: Secure communication channels are established between sensor nodes, protecting the data from interception or tampering during transmission.

3) Access control: Smart contracts are employed to manage access to the data, ensuring that only authorized entities can access or modify it.

E. Challenges and Considerations

1) Scalability: As the WSN grows, managing an increasing number of sensor nodes becomes a challenge. The system must be designed to efficiently scale, maintaining performance and security.

2) Interoperability: The system should be capable of working with different types of sensors and networks, ensuring flexibility and adaptability.

3) Resource management: Balancing the resource demands of blockchain (like storage and computational power) with the limited resources available on sensor nodes is critical. Efficient resource management strategies are required to maintain network performance and longevity.

F. Key Elements in the Diagram:

1) Sensor nodes: Represents individual sensors in the WSN with minimal blockchain capabilities for participating in network security functions.

2) Edge computing node: A node that handles data aggregation and preliminary analysis to reduce the load on individual sensor nodes.

3) Blockchain layer: The core of the model, handling data recording, node verification, smart contract execution, and maintaining the consensus mechanism.

4) Security features: Ensuring the integrity and confidentiality of the data through tamper-proof records, encryption, and access control.

G. Simulation Parameters

Before detailing the simulation scenario we have explored in this work, let's look at how data manipulation using the Internet Control Message Protocol (ICMP) involves an adversary exploiting the protocol's functions to alter or interfere with the transmission of data across a network. ICMP, commonly used for sending error messages or operational information in networks (like ping commands to check on the availability of a host), can be an attack vector for malicious entities.

1) Here's how it can be utilized for data manipulation: ICMP Redirection Attacks: Attackers can use ICMP redirect packets to manipulate the routing table of a host. By sending a crafted ICMP redirect message, an adversary can convince a host to route its traffic through an attacker-controlled machine, allowing for the interception and potential alteration of data. ICMP Tunneling: This technique involves encapsulating data within ICMP echo request and response messages. An attacker could leverage this method to bypass security measures like firewalls that may not inspect ICMP packets as rigorously as other protocol traffic, allowing data to be covertly manipulated and extracted from a network.

2) ICMP flood attack: While not a direct method of data manipulation, an ICMP flood attack can overwhelm a target with a barrage of ICMP packets, potentially causing legitimate responses to be lost or delayed. This can indirectly affect data integrity if systems are relying on timely ICMP responses for operations.

3) ICMP payload manipulation: An adversary might alter the data carried within an ICMP packet's payload. Since ICMP can transmit error messages and other network operational data, manipulating this information can lead to misconfigured network devices or misinformed network administrators.

Creating a scenario for an ICMP (Internet Control Message Protocol) attack with data manipulation involving 200 nodes over the course of an hour would involve several steps and considerations. Define a network topology with 200 nodes. These could be servers, IoT devices, computers, etc., connected in a specific arrangement (e.g., star, mesh, or a custom topology). An ICMP flood attack would be simulated, where one or more nodes (the attackers) would overwhelm the network by sending an excessive number of ping requests to one or multiple target nodes. The attack would last for one hour.

During the attack, the network's throughput and energy consumption of each node would be monitored. Measured in bits per second (bps) or packets per second (pps), you'd record the successful transmission rates of data across the network. This data would likely decrease as the ICMP attack impacts the network's performance. Each node's power usage would be monitored; typically increasing due to the processing of the excessive ICMP re-quests.

4) Simulation tools: To simulate this scenario, we use network simulation tools like NS3, OMNeT++ and Mininet for a more controlled environment. These tools allow to model the network, simulate the traffic and attacks, and collect the necessary data.

We will use a Python script to generate throughput and energy consumption data for 200 nodes over the course of an hour (see Fig. 2). In the following section we will discuss and analyze the results of the simulation and demonstrate the role of blockchain in the security of WSNs.

```
import numpy as np
import pandas as pd
# Constants
NODES = 200
DURATION_HOURS = 1

# Assume a normal distribution for throughput (in bps) and energy
consumption (in Joules)

throughput_mean = 10000  # average throughput
throughput_std = 2000    # standard deviation of throughput
energy_mean = 50         # average energy consumption
energy_std = 10          # standard deviation of energy consumption

# Randomly generate throughput and energy consumption data for
200 nodes
np.random.seed(0)  # Seed for reproducibility
throughput_data = np.random.normal(throughput_mean,
throughput_std, NODES)
energy_data = np.random.normal(energy_mean, energy_std,
NODES)

# Ensure that throughput and energy consumption are not negative

throughput_data = np.clip(throughput_data, 0, None)
energy_data = np.clip(energy_data, 0, None)
# Create a DataFrame to represent the array structure
data_array = pd.DataFrame({
    'node_id': range(1, NODES + 1),
    'throughput': throughput_data,
    'energy_consumption': energy_data
})

# Save the complete DataFrame to a CSV file

csv_file_path = '/mnt/data/simulated_icmp_attack_data.csv'
data_array.to_csv(csv_file_path, index=False)

print(csv_file_path)
```

Fig. 2. Python script attack simulation.

V. Results Analysis

The result depicted in the two graphs illustrates the outcomes of a simulated ICMP attack on a network of 200 nodes, focusing on throughput and energy consumption.

The energy consumption graph (see Fig. 3) reveals a relatively uniform distribution across the nodes, with most nodes exhibiting energy consumption around the mean value, though there are some variations. This indicates that the energy usage during the ICMP attack was fairly consistent across the network, with no significant outliers. This could suggest that all nodes were similarly engaged in responding to the ICMP requests, thereby consuming energy at comparable rates.

To formulate mathematical equation for generating energy consumption data, as seen in the simulated ICMP attack scenario.

$$\text{Energy Consumption } (t) = P\text{base} + P\text{attack}(t) \tag{1}$$

Where: Pbase is the base power consumption of the node in a normal state.

Pattack(t) is the additional power consumption due to the attack at time t, which could be a function of the intensity of the attack and the effort involved in running the block-chain-based mitigation. Example Functions Network Efficiency Function E(t) Could be a constant representing average efficiency, say 0.9 (90% efficiency). Alternatively, a more dynamic model could involve a time-varying function, possibly sinusoidal to simulate daily variations. Attack Impact Function A(t): A step function that increases sharply when the attack begins and decreases as mitigation strategies take effect. For a more nuanced model, this could be a sigmoid function to represent a gradual increase and decrease in attack intensity. Additional Power Consumption Function attack Pattack(t): A function that increases from zero to a certain level when the attack starts, reflecting the extra workload. This could also be modeled as a step function or a gradual increase if mitigation strategies ramp up over time.

The throughput graph depicted in Fig. 4, on the other hand, displays a more varied pattern. The throughput for each node varies significantly, with some nodes maintaining high throughput rates while others drop lower. This variation could be a result of the network's attempt to manage the excessive traffic from the ICMP flood. Some nodes may have been more successful in mitigating the attack and thus maintained higher throughput, while others were more adversely affected, resulting in reduced throughput. The peaks and troughs in the throughput graph could also reflect the dynamic nature of network traffic under stress conditions, where certain nodes might be temporarily able to handle the traffic before being overwhelmed.

To formulate mathematical equation for generating throughput, as seen in the simulated ICMP attack scenario, we'll define equations based on typical models used in networking and energy consumption simulations.

$$\text{Throughput } (t) = C \times E\ (t) \times (1 - A\ (t)) \tag{2}$$

Where: C is the maximum network capacity (in bps). E(t) is the network efficiency at time t, ranging from 0 to 1. A(t) is the impact of the attack at time t, ranging from 0 (no impact) to 1 (complete disruption). The network efficiency E(t) could be a function that ac-counts for normal network variability, and A(t) could be a function representing the intensity of the attack over time.

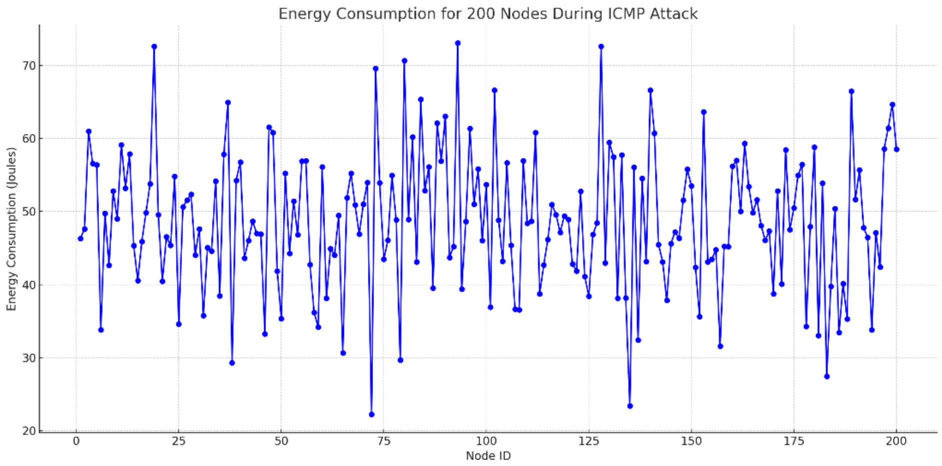

Fig. 3. Energy consumption graph during ICMP attack.

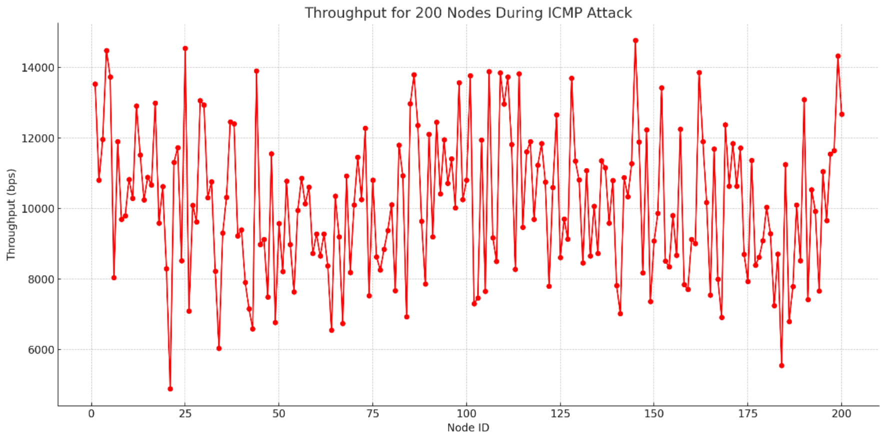

Fig. 4. Throughput graph during ICMP attack.

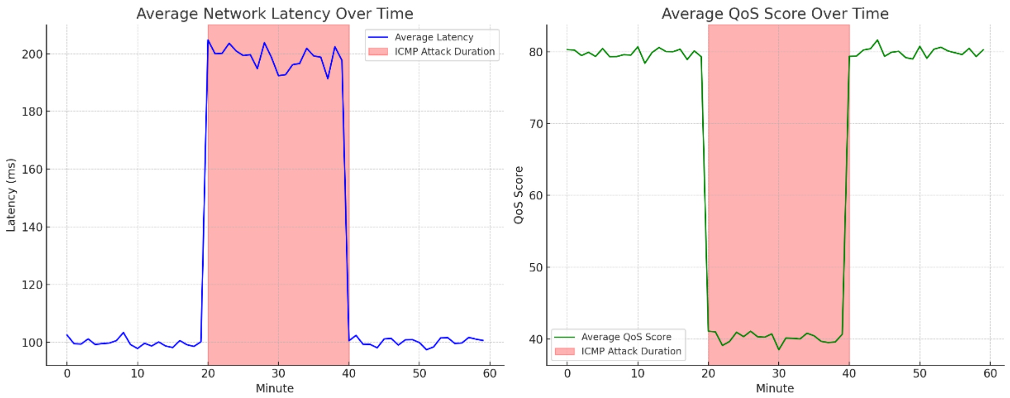

Fig. 5. Latency and lower QoS scores during ICMP attack.

During the ICMP attack (minutes 20 to 40), the nodes experience higher latency and lower QoS scores (see Fig. 5). Outside of the attack period, the nodes have normal latency and QoS levels.

1) Average network latency over time: This graph shows the average latency across all nodes for each minute of the hour. The red shaded area indicates the duration of the ICMP attack (minutes 20 to 40). You can observe a significant increase in latency during the attack period.

2) Average QoS score over time: This graph illustrates the average Quality of Service (QoS) score across all nodes per minute. Similar to the latency graph, the red shaded area marks the ICMP attack duration. The QoS score noticeably drops during the attack, indicating a degradation in network performance.

Designing a blockchain-based model to detect and mitigate ICMP attacks requires leveraging the inherent characteristics of blockchain technology, its distributed nature, immutability, and consensus mechanisms. Below is a high-level design of such a model: Block-chain Model for ICMP Attack Detection and Mitigation. Network Configuration, each node in the network operates as a blockchain peer. The blockchain network uses a consensus protocol that is suitable for the network's scale and transaction throughput needs, such as Proof of Work (PoW), Proof of Stake (PoS), or a Byzantine Fault Tolerant (BFT) consensus mechanism.

Decentralized Consensus for Attack Detection, when a node detects anomalous behavior, it proposes a block that flags the potential attack. Other nodes validate the block by executing the smart contract against their copy of the transaction data. If the consensus is reached that an anomaly exists, the network collectively identifies it as an ICMP attack.

Mitigation Protocol, upon detecting an attack, the smart contract triggers a mitigation protocol. This protocol could involve rate-limiting, automatically blocking traffic from suspicious sources, Transaction and Block Structure, network requests and traffic data are en-capsulated in blockchain transactions. Each transaction includes metadata such as timestamp, source, destination, and packet size. Blocks contain multiple transactions and are linked to previous blocks, creating a tamper-evident chain. Anomaly Detection Smart Contract Deploy a smart contract on the blockchain that defines the rules for normal net-work behavior. The smart contract contains the logic to analyze transactions for signs of an ICMP attack, such as excessive traffic from a single source or high traffic volumes to a specific node. Nodes automatically execute this contract as they process transactions, enabling real-time monitoring or redistributing network load. Mitigation actions are also recorded on the blockchain for accountability and traceability. Continuous Learning, the smart contract can be updated based on the attack patterns observed, which can be done through a governance mechanism allowing node operators to vote on updates. Machine learning algorithms could be integrated to adaptively recognize new types of ICMP attack patterns. Simulation and Testing before deploying simulate the blockchain model in a controlled environment using the previously obtained ICMP attack data. Adjust the model parameters based on the simulation results to optimize detection accuracy and mitigation effectiveness.

Implementation Considerations, Scalability the blockchain must handle a large volume of transactions without significant latency, which is critical for real-time attack detection and mitigation. Privacy, Transaction data should be anonymized to prevent leakage of sensitive network information.

Resource Usage, Blockchain and smart contract operations consume computational re-sources, which must be balanced against the energy consumption of the nodes.

By utilizing a blockchain-based approach, you can create a distributed system that is resistant to tampering and centralized failure points. The model's effectiveness will depend on its proper configuration, smart contract logic, and the network's ability to reach consensus quickly to respond to detected threats.

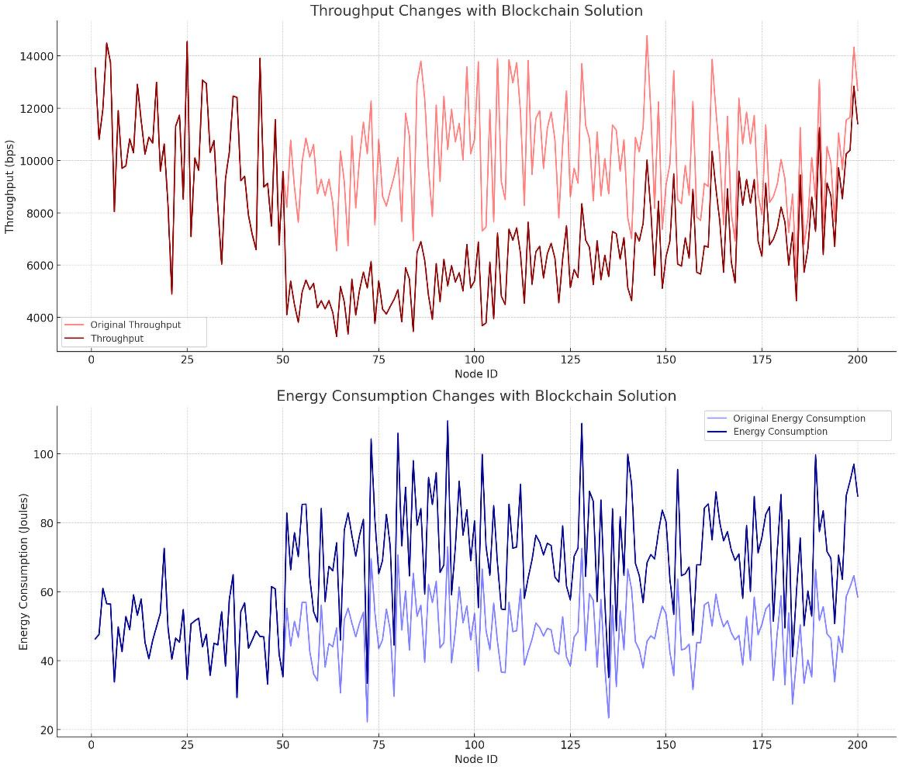

Fig. 6. Expected impact of a Blockchain solution on network performance during and after an ICMP attack.

Fig. 6 present changes in throughput and energy consumption for the 200 nodes in the network, following the implementation of a blockchain solution to detect and mitigate ICMP attacks.

3) Throughput graph (Top): The 'Original Throughput' (in red) shows the throughput before implementing the blockchain solution. The 'Throughput' (in dark red) indicates the expected changes after the blockchain solution is in place. There is a significant drop in throughput around node 50, representing the onset of the ICMP attack. Post node 100, where the mitigation starts to take effect, the throughput gradually recovers, although it does not fully return to the original levels.

4) Energy consumption graph (Bottom): The 'Original Energy Consumption' (in blue) represents energy consumption before the blockchain solution. The 'Energy Consumption' (in dark blue) shows an increase in energy consumption beginning at node 50, coinciding with the start of the attack and the increased processing demands of the blockchain-based mitigation strategies. The energy consumption remains elevated compared to the original levels, reflecting the continuous operation of the blockchain mechanisms.

To incorporate a blockchain solution into this simulation and analyze its impact on latency and QoS (Quality of Service), we need to consider how blockchain technology could influence these metrics (see Fig. 7). Typically, blockchain can enhance security and integrity in network communication, but it might also introduce additional latency due to the time taken for consensus protocols and data verification.

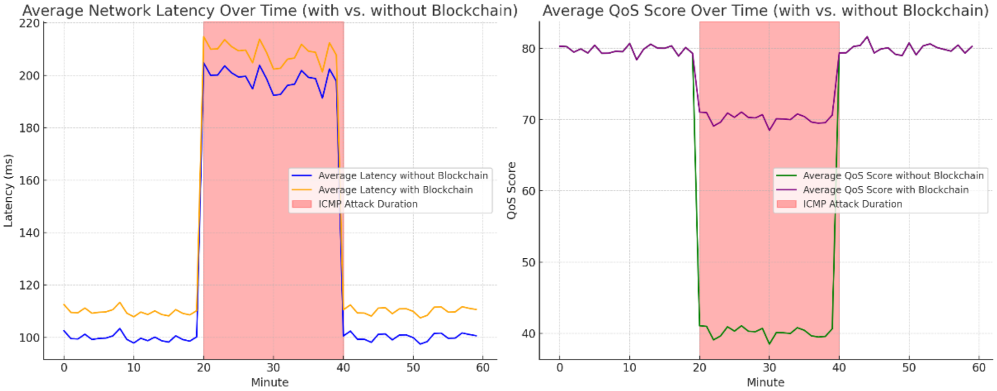

Fig. 7. Network performance with and without a blockchain solution.

Before Blockchain Implementation:

The network behaves as in the previous simulation, with increased latency and decreased QoS during the ICMP attack.

After Blockchain Implementation:

Security Improvement: The blockchain solution significantly mitigates the impact of the ICMP attack, reducing its effect on QoS. Latency Increase: However, due to the overhead of blockchain operations (like consensus mechanisms), there is a slight increase in baseline latency across the network, even outside of attack conditions.

VI. Conclusion

In conclusion, Wireless Sensor Networks (WSNs) are crucial in various applications, ranging from environmental monitoring to industrial automation and healthcare. However, their open and distributed nature makes them susceptible to various cyber-attacks, notably data manipulation and Denial of Service (DoS) attacks like ICMP flooding. These attacks can significantly impair the network's functionality, compromising the integrity and availability of the data. Data manipulation attacks can alter or fabricate sensor data, leading to incorrect decisions or actions based on this compromised data. In our simulation, an ICMP flood attack caused significant spikes in network latency and a notable degradation in Quality of Service (QoS). Blockchain technology, with its inherent characteristics of decentralization, transparency, and immutability, offers a compelling solution to enhance the security of WSNs. By integrating blockchain, each data transaction or sensor reading can be verified and recorded in a tamper-resistant manner. In the simulated scenario, network experienced high latency and low QoS during the ICMP attack, indicating vulnerability to such attacks. There was an overall increase in baseline latency due to blockchain's computational overhead. However, during the ICMP attack, the block-chain-enabled network showed a smaller increase in latency and a significantly lesser decrease in QoS. This resilience can be attributed to the blockchain's ability to maintain data integrity and network operation even under attack conditions. About Mitigation Strategy, Implementing a lightweight blockchain protocol, optimized for WSNs, to ensure data integrity and resilience against manipulation attacks. Hybrid Security Approach combines traditional security measures (like firewalls and intrusion detection systems) with block-chain to provide a layered defense mechanism. Optimization for Latency develops and integrates blockchain protocols specifically optimized for low latency to mitigate the in-creased baseline latency introduced by blockchain. Dynamic Adaptation implement a system that dynamically adjusts blockchain's security level based on real-time threat analysis, balancing between optimal performance and security. Continuous Monitoring and Updating regularly monitor network performance and security, updating the block-chain protocol as needed to address new vulnerabilities and maintain efficiency. Energy Efficiency Considerations given the limited energy resources in WSNs, tailor the block-chain solution to be energy-efficient, possibly through consensus mechanisms that require less computational power.

Integrating blockchain into WSNs presents a promising approach to enhance security against data manipulation attacks. While it introduces challenges like increased latency and demands on energy, these can be mitigated through careful design and optimization. The proposed strategy aims to leverage the strengths of blockchain while addressing its limitations, ensuring robust, secure, and efficient operation of Wireless Sensor Networks.

Web-based Expert Bots System in Identifying Complementary Personality Traits and Recommending Optimal Team Composition

Web-based Expert Bots System for Optimal Team Composition

Mysaa Fatani[1], Haneen Banjar[2]

Computer Science Department, Faculty of Computing and Information Technology, Jeddah, Saudi Arabia[2]

Abstract*—The use of web-based expert systems in the workplace has become increasingly common in recent years, with companies using these automated tools to streamline a range of tasks, from customer service to employee training. However, the potential of web-based expert bots systems to help build more effective teams by identifying employees with complementary personality traits and providing recommendations for team composition has received less attention. This paper investigates the application of a web-based expert bots' system in identifying complementary personality traits among employees to recommend optimal team compositions. We developed a web-based expert bot system, augmented by a chatbot interface, to evaluate and synthesize employee personality profiles for improved team alignment. The results, derived from questionnaire feedback and prototype assessments, demonstrate the system's capability to enhance team performance metrics and behavioral competencies. The discussion outlines the system's advantages, and its potential in organizational settings, and acknowledges its limitations. Web-based expert systems with chatbots that exhibit unique personalities tend to be more engaging and effective. Consequently, this system is expected to not only foster better team cohesion but also to increase user involvement and satisfaction. Future work is dedicated to expanding the system's capabilities and conducting extensive field testing to establish its practical effectiveness.

***Keywords*—Web-based expert system; personality traits; team composition; workplace efficiency and chatbot integration**

I. Introduction

Team composition is a multifaceted challenge, requiring a delicate balance of skill sets, personality traits, and roles [1]. This complexity is further underscored by the influence of individual differences, such as personality traits, values, and demographics, on team dynamics and performance [2]. In the context of software engineering project courses, team composition is particularly challenging due to the need to consider practical constraints, skill distribution, and project motivation [3]. The difficulty lies not only in identifying these characteristics but also in predicting the dynamic interplay between them, which can significantly impact team cohesion, adaptability, and ultimately, the success of the team's objectives. Effective team composition requires a nuanced approach that takes into account the individual and collective needs of the team and the goals of the project.

The evolution of web-based expert systems in organizational settings has been marked by significant advancements in artificial intelligence and machine learning. Initially, these systems focused on automating simple tasks and evolved to perform complex functions like data analysis and decision support. Currently, they are integral in streamlining operations, enhancing decision-making, and providing predictive insights across various business functions. Their ability to process vast amounts of data with sophisticated algorithms allows for unprecedented accuracy in tasks such as market analysis, customer service, and strategic planning, making them indispensable in modern organizational infrastructure.

Research on the significance of expert systems in human resources, particularly in identifying and harnessing complementary personality traits for team composition, has yielded valuable insights. Radović et al. [4] found that a combination of extraversion and openness to experience is crucial for team performance, while Gilal et al. [5]identified extroversion as a dominant personality type for effective software team roles. It has been emphasized the importance of emotional stability, agreeableness, and a predisposition to be a team player in predicting task performance and cohesion [6]. These findings underscore the potential of expert systems in optimizing team composition by considering these key personality traits.

Moreover, the use of chatbots in team optimization has been explored in various studies. It has been highlighted the potential of chatbots to enhance team performance [7], [8]. Bansal et al. [9] takes this a step further by proposing the optimization of AI systems for teamwork, emphasizing the need for human-centered design. Tennent et al. [10] introduces the concept of a peripheral robotic object, Micbot, which has been shown to improve group engagement and problem-solving performance. These studies collectively underscore the potential of chatbots and AI systems in team optimization, particularly in the areas of emotion management, and productivity in workplace environments.

The primary aim of this study is to explore the efficacy of web-based expert bots systems in enhancing team effectiveness within organizations. This inquiry is driven by the central research question: How can web-based expert bots systems help employers build more effective teams by identifying employees with complementary personality traits, team performance, team behavioral competencies and providing recommendations for team composition? To achieve this aim, the study is guided by several key objectives: Firstly, to create a robust knowledge base that informs team composition, derived from three distinct assessment methods. Secondly, to develop an interactive chatbot tailored for individual employer assessments. Finally, to construct a prototype web-based expert bot system capable of accurately identifying crucial factors such as personality traits, team performance metrics, and team behavioral competencies. Through these objectives, the study seeks to contribute significantly to the field of organizational psychology and team dynamics, leveraging advanced technology to foster more efficient, cohesive, and productive workplace environments.

The subsequent section provides an overview of team composition strategies. It is followed by a methodology section that outlines the framework of the integrated system, comprising a rule-based chatbot for personality analysis and a comprehensive web-based expert system equipped with team management and assessment tools. Results from questionnaires and prototype evaluations are presented next. The discussion emphasizes the system's benefits and acknowledges its limitations. The paper concludes by reflecting on the findings and suggesting directions for future research.

II. Background

Building productive teams is vital for organizations looking to maximize productivity and innovation in the dynamic, collaborative work environments of today. The personality alignment of team members is a crucial factor to consider because it affects team performance. Team dynamics, creativity, and problem-solving skills have all been shown to improve when team members have complementary personality traits. Radović et al. [4] stated that a team's performance may be influenced by a combination of personality qualities. While there has been much research on how team dynamics and members' personality traits affect team performance,

A team employee refers to an individual who is part of a team within an organization and works collaboratively with other team members to achieve shared goals and objectives. Unlike individual contributors who work independently, team employees actively engage in group dynamics, contribute their skills and expertise, and collaborate with others to accomplish tasks and projects. The term "team composition" describes the composition or structure of a team, including the traits, competencies, and roles of each member. It entails carefully selecting and assigning people in order to create a strong team that can work together to accomplish its goals.

This study focuses on three assessment ways which are: personality traits, team performance, and team behavioral competencies. Firstly, personality traits are recurring patterns of ideas, emotions, and actions that define a person's distinct and persistent psychological profile. These characteristics shape people's attitudes, motives, and behaviors in a variety of circumstances and contexts by affecting how they perceive and engage with the world around them. Secondly, team performance is the overall efficiency and accomplishment of a group of people working together to achieve a common goal or aim. To produce high-quality outputs and obtain desired goals, a team must be able to cooperate, communicate, and coordinate their efforts. Thirdly, behavioral competencies commonly referred to as soft skills or interpersonal skills, are a collection of personal traits, characteristics, and behaviors that enable people to work with others, carry out tasks, and achieve goals in a professional or social setting. Issues with team composition can come up while putting together a team and selecting the most compatible members to work with. Finding a balance between team dynamics and individual competencies can be difficult when putting together a team. Conflicts between team members or clashing personalities can cause a breakdown in communication, lower motivation, and lessen production. As a result, putting together a team would be simpler and more effective with the usage of the previous three assessment methods, and the results would be high quality.

III. Literature Review

Recent developments in artificial intelligence (AI) have made it possible for we-based expert systems and chatbots to become useful tools for a variety of applications. By utilizing their capacity to assess and interpret personality traits, such systems have the potential to assist companies in creating more productive teams.

According to Aonghusa and Michie [11], the use of AI in behavioral research is still in its early stages, and changing present procedures is necessary to fully realize AI's potential. AI technology offers significant potential in behavioral science by enabling researchers to analyze vast amounts of data, make predictions, simulate human behavior, and develop personalized interventions. Aonghusa and Michie [11] stated that the goal of predicting behavior change intervention results using data that is automatically retrieved from intervention evaluation reports is one that AI offers great potential for achieving. AI enables researchers in behavioral sciences to gain insights into various aspects of human behavior, improve data analysis, and enhance the understanding of complex behavioral phenomena.

A web-based expert system is a software application that applies artificial intelligence principles to deliver professional-level information and judgment through a web interface. Ramadhani et al. [12] conducted a study using knowledge-based web-based expert systems to help them achieve their goals, and the research analyses the efficacy and accuracy of the web-based expert system. Saiful and Nur [13] stated that in general, expert systems are systems that attempt to convey human knowledge to computers so that computers can solve issues the way experts often do. Data can be gathered by expert systems that keep the expertise of one or more experts on a computer. According to Thorat and Jadhav [14], a common method for managing conversations is chatbots. However, A damopoulou and Moussiades [15] stated that although chatbots can simulate human communication and amuse users; this is not their only purpose. Wolff et al. [16] and Singh et al. [17] both highlight the potential of rule-based chatbots in workplace settings, with the former identifying support and self-service as key areas of application, and the latter demonstrating the use of a rule-based chatbot for student enquiries. Handel et al. [18] provides a broader perspective on the use of synchronous messaging applications, including chatbots, in workplace teams, emphasizing their role in supporting work tasks and negotiating availability. Hwang and Won [19] further explores the potential of chatbots in team creativity, finding that participants contributed more ideas and of higher quality when they perceived their partner to be a chatbot. These studies collectively suggest that rule-based chatbots can be effectively integrated into workplace environments to facilitate team composition, support work tasks, and enhance team creativity.

Current research in web-based expert systems and team dynamics primarily focuses on the harnessing of collective intelligence for team formation and the intricate impact of these systems on job evaluation and psychological design considerations. Research on web-based expert systems and team dynamics has explored the use of collective intelligence in team formation [20], the impact of expert systems on job evaluation and decision-making [21], and the psychological issues in the design of these systems [22]. These studies highlight the potential of web-based expert systems in optimizing team dynamics by leveraging collective intelligence and providing decision support. However, there is a need for further research at the intersection of artificial intelligence and personality trait analysis to fully understand the role of these systems in team optimization.

A range of studies have explored the use of web-based expert bots to identify complementary personality traits and recommend optimal team compositions. N et al. [23] developed a recommendation engine using the Myers-Briggs Type Indicator (MBTI) and deep learning to accurately predict personality traits and suggest team compositions. Davoodi et.al. [24] proposed a hybrid expert recommendation system that considers both content-based profiles and social network-based collaborative filtering to improve recommendation accuracy. Oliveira et. al. [25] focused on a model for analyzing personality traits to support project team recommendations based on complementarity. Lastly, Gilal et al. [26] used a rule-based approach to identify effective personality types and diversity in software team roles, finding that extrovert personality types and team homogeneity or heterogeneity play key roles. These studies collectively highlight the potential of web-based expert bots in identifying complementary personality traits and recommending optimal team compositions.

IV. Methods

A. *Web-based Expert Bot System Framework*

The framework of the web-based expert system developed in this study consists of two principal components (see Fig. 1): a rule-based chatbot and a comprehensive web-based expert system. The rule-based chatbot is intricately designed with a knowledge engineer at its core, facilitating the accumulation and organization of expertise. It is supported by a robust knowledge base and specialized personality knowledge resources, which are essential for accurate personality trait analysis. An inference engine is integrated into the chatbot, enabling it to intelligently process user inputs. This chatbot functions through an interactive interface, engaging users via a series of questions and answers, thereby gathering essential data for team composition analysis. The second component of the framework extends beyond the chatbot, encompassing the company team manager and a diverse team group. This component is equipped with a dynamic assessment notification system, a comprehensive database for storing and retrieving data, and functionalities for both new assessments and reassessments of team dynamics. It specifically addresses the nuances of first-time group formations and role-specific group assemblies. The entire framework is seamlessly integrated into a user-friendly website interface, ensuring ease of access and interaction for all users, from team managers to individual team members. This dual-component framework aims to provide a thorough and interactive experience, leveraging both rule-based and expert system technologies to optimize team composition and performance in the workplace.

1) Knowledge base and personality knowledge resources: To inform the development of our knowledge base and ensure it is attuned to the needs of the workplace, a comprehensive survey was conducted. This survey targeted employers and team leaders, with the objective of gathering insights into their experiences and perspectives on the significance of personality traits, teamwork, and leadership within their organizational contexts. Respondents were presented with queries regarding teamwork dynamics, common workplace challenges, and their openness to utilizing the website developed through this research. The data collected from this survey serves as a vital component of our knowledge base, influencing the design and functionality of the expert system to better address the intricacies of workplace interactions and team efficiency.

Regarding the structural aspect of our knowledge base, this study has adopted frames as the method of knowledge representation. Frames offer a dynamic way to encapsulate knowledge about various concepts, ideas, or situations through their two fundamental elements: components and slots. Components are responsible for providing specific values for certain attributes, while slots are designed to denote the attributes or characteristics themselves. This structured approach allows for the intricate organization and representation of complex knowledge within the system. Within our knowledge base, frames have been instrumental in organizing three distinct assessment methods: personality traits assessments (X), team performance assessments (Y), and team behavioral competencies assessments (Z).

2) Knowledge engineer: A knowledge engineer is an individual who creates and develops systems to successfully gather, arrange, and use information. They make sure that knowledge is accessible to and effectively used by both humans and machines.

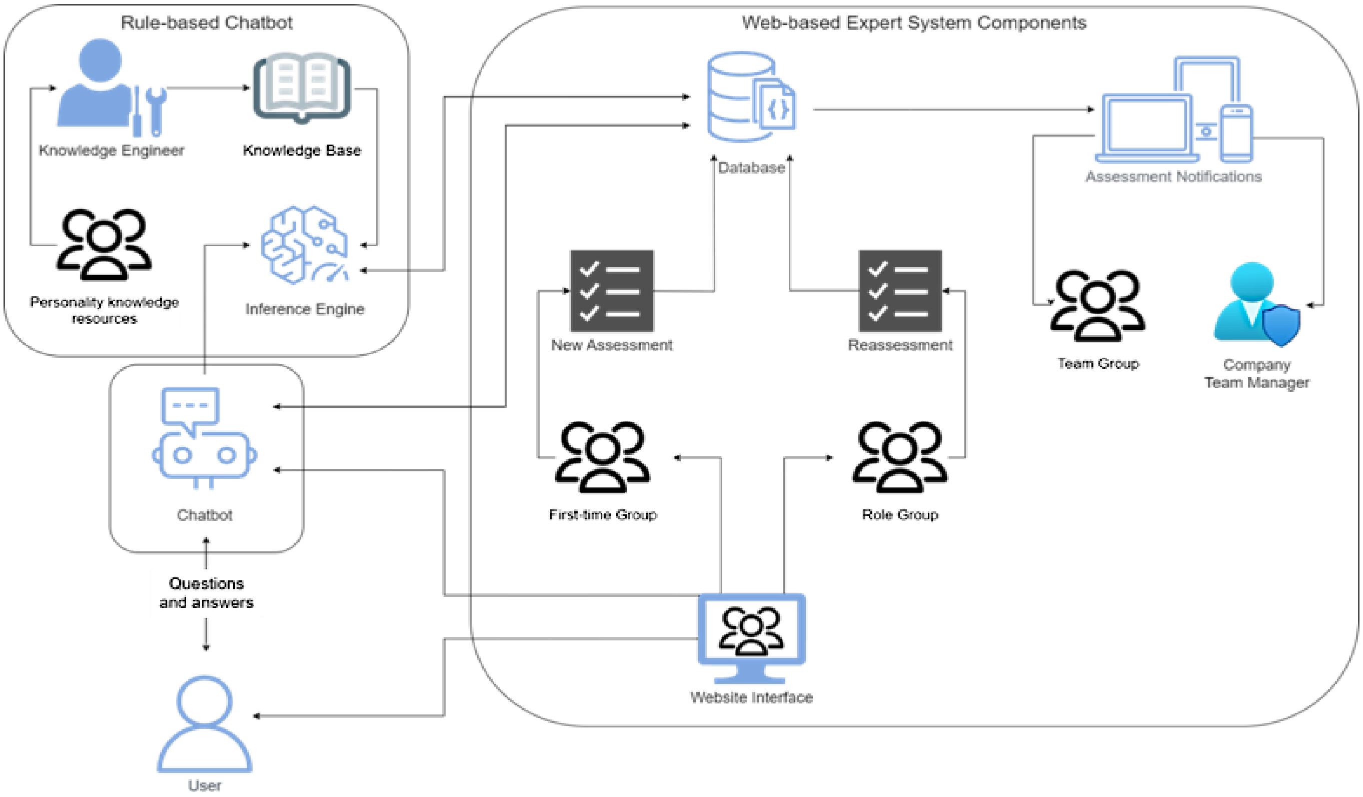

Fig. 1. Web-based expert bot system framework.

3) Inference engine: Two common methods used in inference engines to draw conclusions and make inferences based on existing knowledge are forward chaining and backward chaining. However, the forward chaining approach is the main focus of this paper. Forward chaining starts with a base set of predetermined facts or data and then applies rules that apply to those facts to produce new data. The knowledge base is expanded with the generated data, which is then used to make additional inferences.

4) Chatbot: In the context of this study, we have utilized the Landbot platform to design our chatbot. Landbot stands out as a user-friendly platform that enables the creation of conversational chatbots and interactive experiences tailored for website integration. Its appeal lies in its accessibility, as it requires no coding or technical expertise, making it an ideal choice for creating a chatbot suited to our research needs. This chatbot plays a pivotal role in our study, engaging with users in an intuitive and seamless manner, thereby facilitating the collection of data and enhancing the user experience without necessitating complex programming skills. The choice of Landbot for our chatbot design underscores our commitment to leveraging advanced yet accessible technology to achieve our research objectives effectively.

5) Database: Oracle Database is utilized to facilitate our data management requirements. Oracle Database is known for its efficiency and versatility as a proprietary multi-model database management system, produced and marketed by Oracle Corporation. It is especially suited for handling complex datasets and supporting the sophisticated queries that our study demands. Fig. 2 presents the ER schema diagram, illustrating the relational structure among the nine entities central to our study: Team, Team Member, Company, Project, Assessment Test, Assessment Results, Behavioral Competence Criteria, Team Performance Criteria, and Personality Trait Criteria. Within this structure, a Company creates a Project, which is overseen by a Team Manager. The Team Manager is responsible for assembling a Team, selected based on Assessment Results derived from Assessment Tests. The Company is tasked with establishing the Criteria for Behavioral Competence, Team Performance, and Personality Traits, which are critical for the project's success. This relational database design is crucial for capturing the intricate relationships and dependencies among these entities, ensuring that data integrity and access efficiency are maintained throughout the study.

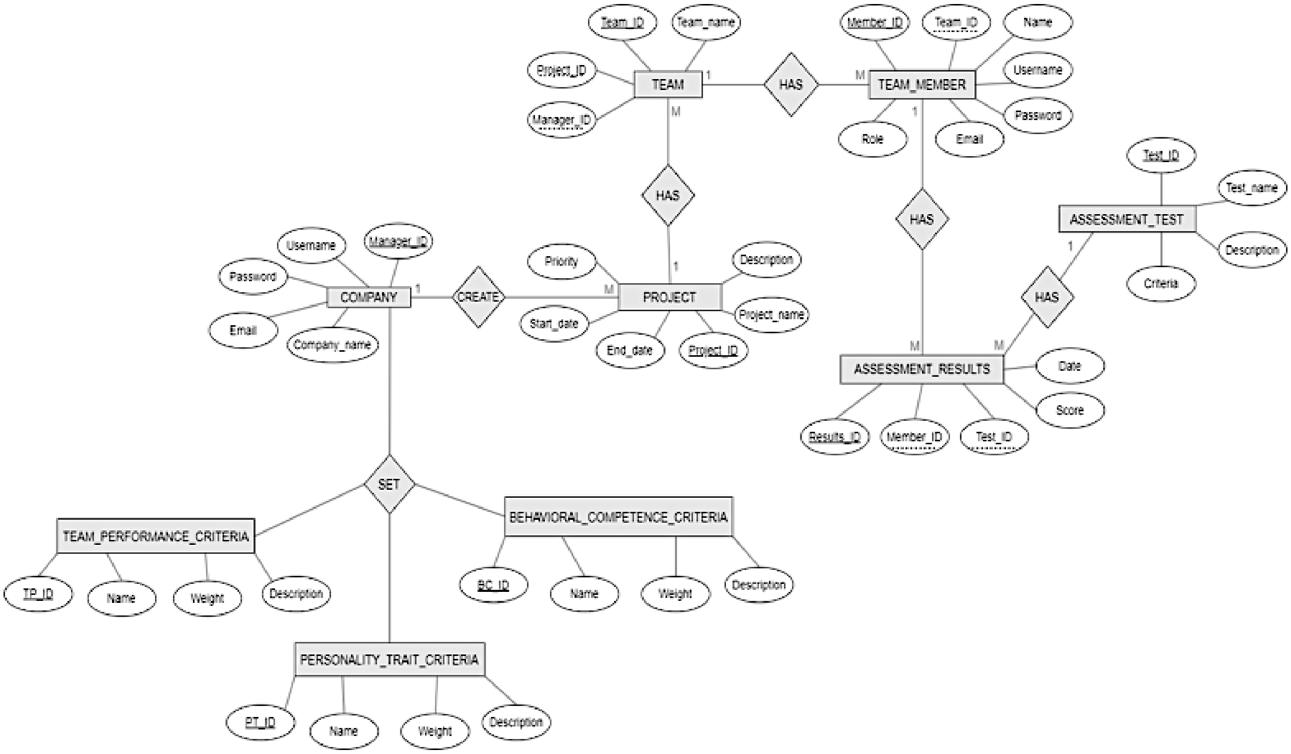

Fig. 2. The ER schema diagram.

6) User interfaces: The design considerations and functionalities of the interface are detailed from the perspectives of two types of users: the Company Team Manager and the Team Member. These roles are integral to the interaction with our web-based expert bot system and are outlined as follows:

- Company Team Manager: This user is granted comprehensive access to the company's account on the platform. The interface is designed to be intuitive, allowing the team manager to seamlessly set up and input data for projects and employee profiles. A key feature of this role is the ability to view and analyze test results from every employee, enabling the manager to make informed decisions based on the robust team recommendations generated by the system. The interface is crafted to ensure that the manager can easily navigate through various projects, manage teams, and access a holistic view of employee assessments and recommendations.

- Team Member: The team member's user interface is tailored to provide individual access to specific functionalities. Through this interface, a team member can receive and respond to tests dispatched by the company's team manager. Post-assessment, the interface allows team members to view their own personality assessments and understand the context of their roles within the team's recommendations. The design of the team member interface is focused on user-friendliness and personal data security, ensuring that team members can engage with the assessment process in a straightforward and secure manner.

To encapsulate the various interactions each user type will have with our system, Table I is provided, which details user types and their corresponding functions. This table serves as a reference for the access levels and capabilities that each user type possesses, ensuring clarity in the system's functionality and user privileges. The user interface is developed with a focus on clarity and ease of use, to facilitate efficient interaction with the system's comprehensive functionalities.

B. Prototype

For this study, we have utilized Proto.io, a highly versatile platform that specializes in creating interactive and high-fidelity prototypes for websites. Proto.io has enabled us to design and iterate upon our website's prototype rapidly, allowing us to explore various user interface designs and functionalities in a real-world, interactive environment. This approach has been instrumental in refining our concept into a tangible and testable product. By using Proto.io, we have effectively bridged the gap between theoretical design and practical application, providing us with valuable insights into user experience and system performance prior to the full-scale development and deployment of the system.

V. Results

A. Knowledge Base and Personality Knowledge

The findings from a survey was presented to understand the perceptions of employers and team leaders regarding the dynamics of the workplace. This survey, which gathered around 140 responses, probed the value placed on personality traits, teamwork, and leadership, and evaluated the potential adoption of the research website developed for team composition and management. A significant majority of participants, 59.6%, affirmed that effective teamwork stands out as one of the paramount strengths within a workplace, as highlighted in question (1) of the survey. Delving into the challenges of teamwork, question (6) revealed a compelling consensus with 93.6% of respondents agreeing that conflicts among team members are a predominant barrier to meeting organizational goals. Further insights from question (7) indicated that 37.6% of respondents attribute team member conflicts to ineffective leadership and management, while 27% cited personality clashes as a crucial factor, thereby substantiating the rationale behind this research.

Moreover, the survey brought to light a near-universal acknowledgment of the uniqueness of individual personality attributes, with 99.3% of respondents concurring with this view in response to question (9). This perspective is complemented by findings from question (2), where 49.6% of participants identified poor leadership as a pivotal issue in failing to achieve goals. Question (8) underscored the eagerness of leaders to understand the personality traits of their team members, with a remarkable 97.9% expressing the desire to gain a deeper insight into their teams.

Finally, the concept of the research website garnered robust support, with over 85% of respondents affirming the utility of such a tool in questions (10) and (11). This overwhelming approval validates the direction and objectives of our research, highlighting the demand for innovative solutions in understanding and harnessing the potential of workplace dynamics. The results from the survey are not only reflective of current workplace sentiments but also reinforce the need for the tools and analyses provided by our web-based expert system in optimizing team performance. Read A1 section of the supplement file for detailed survey results while the following were the survey questions:

1) *What* is the strongest strength of any workplace?

2) *What* is a big reason for not achieving goals at work?

3) *Do* you think that communication is one of the reasons for failure to achieve goals?

4) *What* is the most basic skill for achieving effective communication?

5) *Do* you think that misunderstanding and miscommunication are due to your lack of understanding of the other person?

6) *Do* you think that one of the reasons for the failure of work teams to achieve goals is due to conflicts and differences between team members?

7) *What* do you think the most important reason for differences and conflicts among team members?

8) *If* you have a project to complete and you are the team leader, do you think it is important to understand the personalities of the team members so that it is easier for you to distribute tasks?

9) *Do* you believe that every individual has a personality?

10) *If* there was a website that studied the personalities of your employees, would you use it?

11) *If* there is a website that helps a manager achieve the goals of a project through analyzing the project, its objectives, its implementation plan, and analyzing the personalities who help in completing the project, would you use it?

In this research, the decision to not collect demographic information was deliberate and based on several considerations. First and foremost, the focus of the study was to gauge attitudes and opinions on teamwork and leadership in the workplace, which are aspects that transcend demographic categories such as age, gender, or ethnicity. By omitting demographic questions, we aimed to prevent any potential bias that could arise from preconceived notions about certain demographic groups and their relationship with the workplace dynamics being studied. Furthermore, the anonymity of responses was prioritized to ensure that participants felt comfortable sharing honest opinions without concern for personal identifiers being used in the analysis. This approach was intended to enhance the integrity and applicability of the data across diverse workplace settings, making the findings more universally relevant and reducing the risk of demographic data skewing the interpretation of the core research questions.

TABLE I. USERS TYPE AND THE RELATED FUNCTIONS

Users Type	Functions
Company team manager	1. Sign in/up to the company's account as a manager. 2. Fill out the manager's personal information. 3. Set employee criteria, the weight of each criterion. 4. Set project requirements (project name, description, start date, end date, and priority). 5. Set team information. 6. Send the assessment test link to employees. 7. Display the team recommendations.
Team member	1. Sign in/up to the company’s account as an employee. 2. Fill out personal information. 3. Display test results. 4. Receive assessments test (new or retake). 5. Receive team recommendations. 6. Display registered team. 7. Receive notification if chosen for the team.

Fig. 3 provides a detailed visual representation of the architecture underlying the knowledge base and personality knowledge resources utilized in our study. It meticulously outlines how frames are employed to structure and organize the complex information integral to the research. These frames act as the building blocks of our knowledge base, enabling us to systematically categorize and access data on personality traits, team performance, and behavioral competencies. The figure serves to demonstrate the interconnectivity and flow of information within the system, ensuring that data retrieval is both logical and efficient. For an in-depth understanding of the specific personality knowledge frames, read section A2 of the supplementary files, where each frame is delineated, providing transparency and further insight into the foundational elements that support our expert system. This delineation is crucial for appreciating the sophistication and nuance of the system's design and its capacity for contributing to the field of team dynamics and organizational psychology.

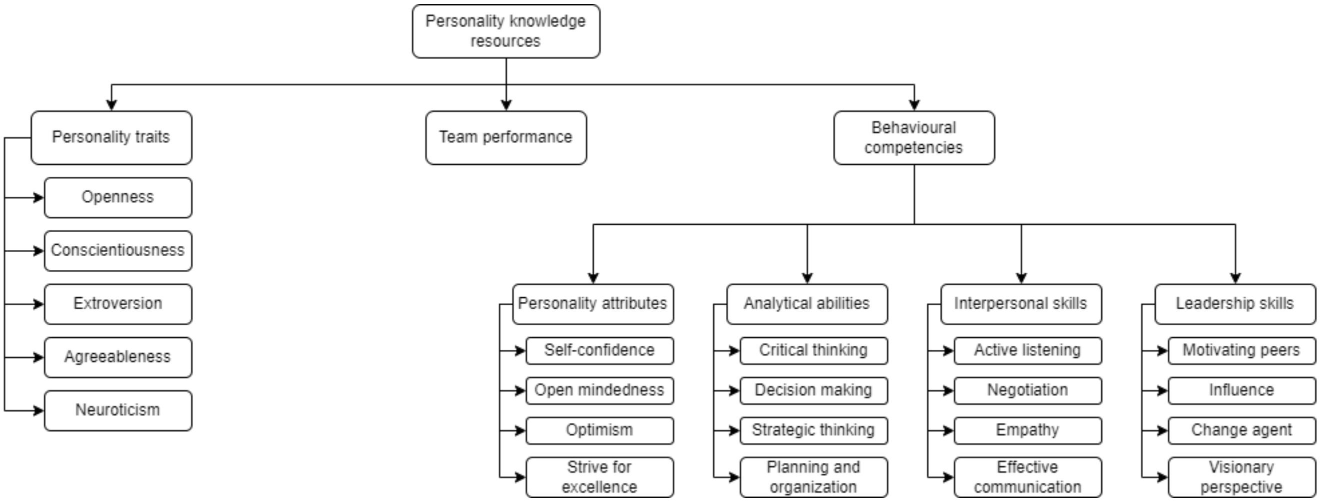

Fig. 3. The components of the knowledge base and personality knowledge.

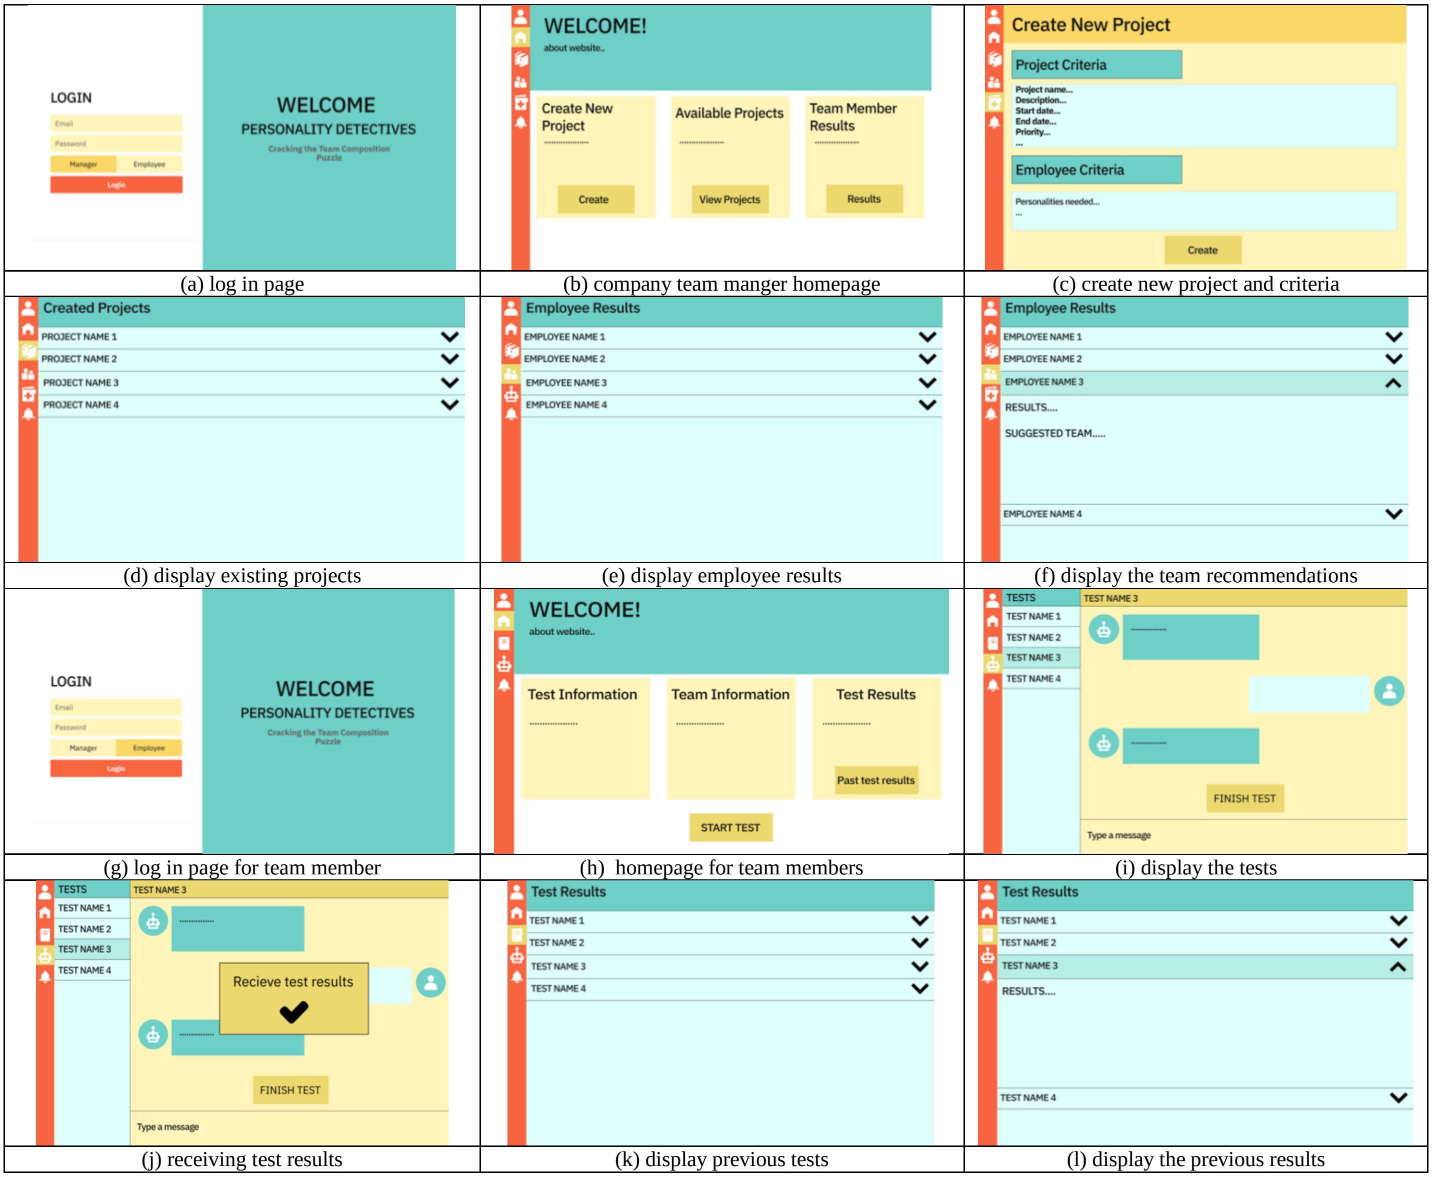

(a) log in page
(b) company team manger homepage
(c) create new project and criteria
(d) display existing projects
(e) display employee results
(f) display the team recommendations
(g) log in page for team member
(h) homepage for team members
(i) display the tests
(j) receiving test results
(k) display previous tests
(l) display the previous results

Fig. 4. Web-based expert bot system user interfaces.

B. Web-based Expert Bot System Prototype

The prototype of the Web-based Expert Bot System is presented, focusing on its user interface design for two distinct user roles: the Team Member and the Team Manager. Fig. 4 provides a comprehensive visual breakdown of the user interfaces, meticulously detailing the functionalities and navigational flow tailored to each type of user. The interfaces designated for the Company Team Manager are showed in print screen (a) through (f) of Fig. 4. These segments illustrate the breadth of control and oversight that a team manager possesses within the system, from project initiation and data management to team assessment and recommendations. On the other hand, the Team Member's interface is presented in printscreen (g) through (l), emphasizing the user-centric design that provides team members with access to personality assessments, team evaluations, and managerial feedback. This delineation within Fig. 4 not only demonstrates the system's dual-interface capability but also highlights the intuitive design and functionality that cater to the specific needs and roles of the users within a team-oriented workplace setting.

C. Chatbot Prototype

The development of the chatbot prototype plays a significant role using the Landbot platform, this prototype exemplifies a user-friendly approach to engaging with users in an interactive and conversational manner. One of the key features of our chatbot is its integration of personality knowledge, which is crucial for identifying and administering personality tests in an accessible and engaging way.

Through this chatbot, users are navigated through a series of questions enabling the system to gather essential information on individual personality traits. The design of the chatbot prioritizes ease of use and interactivity, ensuring that users can participate in the assessment process without the need for extensive instructions or guidance. This approach not only enhances user engagement but also improves the accuracy and relevance of the data collected.

For a more comprehensive understanding of how the chatbot functions and interacts with users, we invite readers to explore the live prototype available at (https://landbot.online/v3/H-1692227-0Q820B5ZRGJJXKW7/index.html).

VI. Discussion

The development of a web-based expert bot system, augmented by a chatbot interface, for evaluating and synthesizing employee personality profiles can offer several advantages. Research has shown that incorporating personality into chatbot design can significantly improve user experience [27]. This is particularly relevant in the context of employee mental health assessments, where chatbots have been found to be highly engaging and effective [28]. Furthermore, the use of chatbots with distinct personalities can enhance the naturalness and effectiveness of the system [29]. Therefore, the proposed system has the potential to not only improve team alignment but also enhance user experience and engagement.

Acknowledging the limitations of our research is vital to contextualize our findings within the scope of their applicability. In our study, the use of a web-based expert bot system for enhancing workplace team dynamics is an innovative approach; however, it is not without constraints. Primarily, the system's reliance on self-reported data could introduce biases, as participants might provide socially desirable responses rather than accurate portrayals of their personality traits. Additionally, while our sample size was adequate to establish preliminary insights, a larger and more diverse cohort would be necessary to affirm the robustness of our findings across different industries and organizational cultures. Our framework's current configuration is tailored to specific personality models and team roles, which might not be universally applicable or reflective of all workplace environments. Future research could focus on expanding the adaptability of the system to include a broader range of psychological theories and occupational settings. Moreover, as our study is cross-sectional, it limits the ability to infer causality between team composition and performance outcomes. Longitudinal studies could provide a deeper understanding of these dynamics over time. By addressing these limitations in subsequent research, we can refine the application of expert bot systems to more accurately predict and enhance team performance.

VII. Conclusion

The conclusion of this study underscores the critical importance of building effective teams for companies looking to optimize production and foster innovation. The interplay between individual personality traits and team dynamics plays a significant role in team performance, warranting thorough examination and understanding. While numerous studies have investigated these elements, this research extends the discourse by incorporating a knowledge-based system and a rule-based chatbot into the organizational environment.

Our findings illuminate the transformative potential of web-based expert bot systems in assembling more productive teams. By leveraging the systems' sophisticated capabilities to identify complementary personality traits and assess team performance and behavioral competencies, organizations are empowered to make informed, data-driven decisions. This approach facilitates enhanced team dynamics, elevates performance levels, and ensures a more effective allocation of organizational resources.

However, the adoption of these technologies is not without its challenges. To truly reap their benefits and mitigate any potential drawbacks, a deliberate and informed implementation strategy is essential. Further research is also necessary to continue refining these systems, addressing any issues that arise, and expanding their applicability within diverse organizational contexts. In this pursuit, the future of work may be shaped by a more intelligent, intuitive, and data-oriented approach to team composition and management.

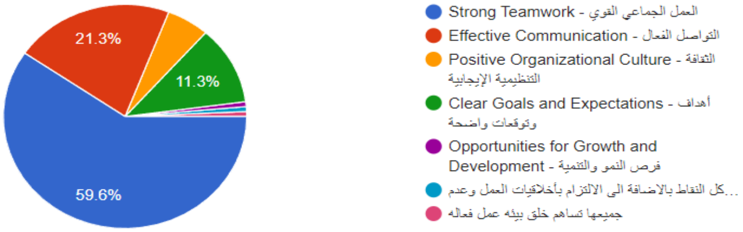
SUPPLEMENTARY MATERIAL

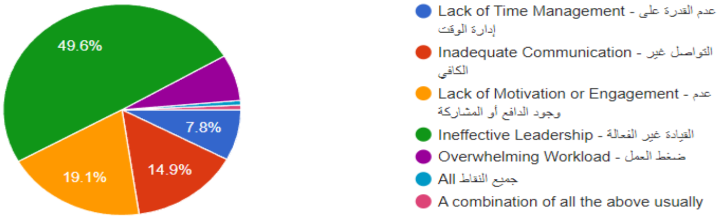
Supplementary Material: Knowledge base and personality knowledge

A. *Survey Results*

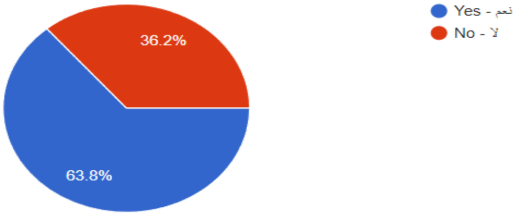
12) What is the strongest strength of any workplace?



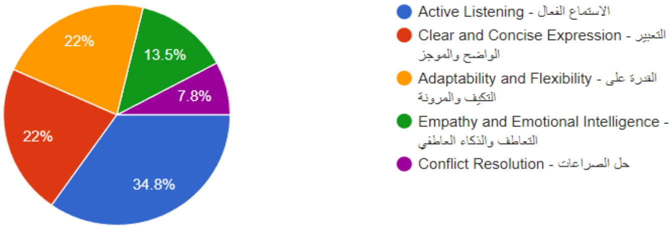
13) What is a big reason for not achieving goals at work?



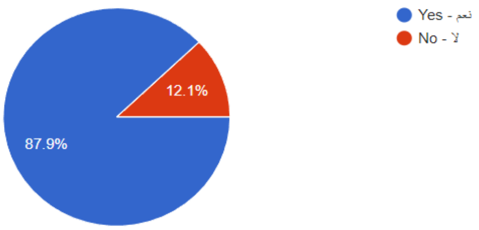
14) Do you think that communication is one of the reasons for failure to achieve goals?



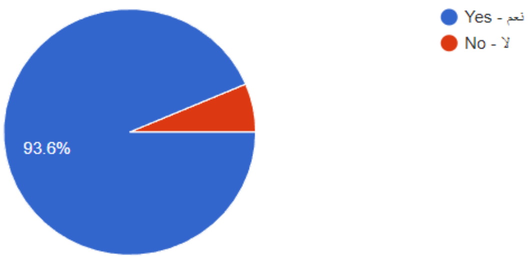
15) What is the most basic skill for achieving effective communication?



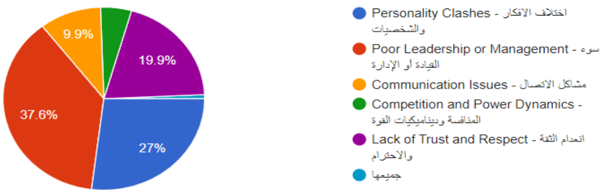
16) Do you think that misunderstanding and miscommunication are due to your lack of understanding of the other person?



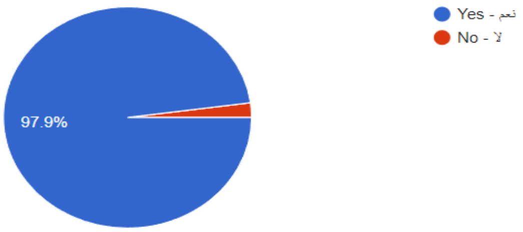
17) Do you think that one of the reasons for the failure of work teams to achieve goals is due to conflicts and differences between team members?



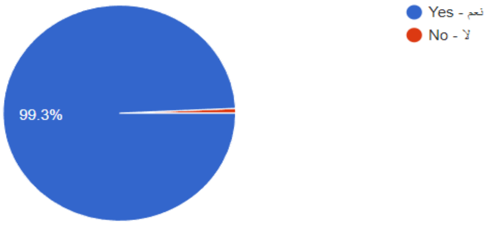
18) What do you think the most important reason for differences and conflicts among team members?



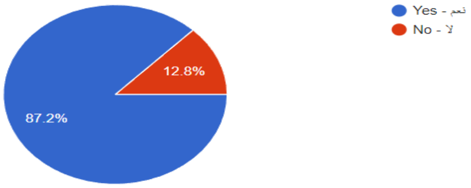
19) If you have a project to complete and you are the team leader, do you think it is important to understand the personalities of the team members so that it is easier for you to distribute tasks?



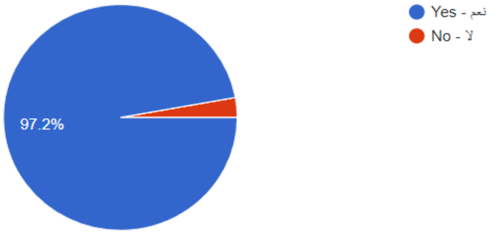
20) Do you believe that every individual has a personality?



21) If there was a website that studied the personalities of your employees, would you use it?



22) If there is a website that helps a manager achieve the goals of a project through analyzing the project, its objectives, its implementation plan, and analyzing the personalities who help in completing the project, would you use it?



A2. Personality Knowledge Frames

Assessment	Phases	Variables		Questions	Possible answers	Chatbot output
Personality traits	Phase 1	Personality trait 1: Openness		1. I see myself as someone who is original, unique, and comes up with new ideas. 2. I see myself as someone who is curious about many different things. 3. I see myself as someone who is sophisticated in art, music, or literature. 4. I see myself as someone who has a lot of artistic interests. 5. I see myself as someone who has an active imagination. 6. I see myself as someone who values artistic and creative experiences. 7. I see myself as someone who is inventive.	yes>=4	You have the “openness” personality trait.
					yes<4	You do not have the “openness” personality trait.
	Phase 2	Personality trait 2: Conscientiousness		1. I see myself as someone who does a thorough job. 2. I see myself as someone who is extremely careful. 3. I see myself as someone who is a reliable worker. 4. I see myself as someone who tends to be organized. 5. I see myself as someone who tends to be diligent. 6. I see myself as someone who perseveres until the task is finished. 7. I see myself as someone who does things efficiently. 8. I see myself as someone who prefers work that is routine. 9. I see myself as someone who is cerebral and enjoys thinking deeply. 10. I see myself as someone who makes plans and follows through with them. 11. I see myself as someone who is not easily distracted.	yes>=6	You have the “conscientiousness” personality trait.
					yes<6	You do not have the “conscientiousness” personality trait.
	Phase 3	Personality trait 3: Extroversion		1. I see myself as someone who is outgoing. 2. I see myself as someone who is full of energy. 3. I see myself as someone who generates a lot of enthusiasm. 4. I see myself as someone who tends to be loud. 5. I see myself as someone who has an assertive personality. 6. I see myself as someone who can be warm and friendly. 7. I see myself as someone who likes to reflect and ponder different ideas. 8. I see myself as someone who is outgoing and sociable. 9. I see myself as someone who is talkative.	yes>=5	You have the “extroversion” personality trait.
					yes<5	You do not have the “extroversion” personality trait.
	Phase 4	Personality trait 4: Agreeableness		1.I see myself as someone who is helpful and unselfish when it comes to others. 2. I see myself as someone who avoids arguments with others. 3. I see myself as someone who has a forgiving nature. 4. I see myself as someone who is considerate and kind to almost everyone. 5. I see myself as someone who likes to cooperate with others. 6. I see myself as someone who is rarely rude to others. 7. I see myself as someone who is generally trusting. 8. I see myself as someone who does not look for fault in others.	yes>=5	You have the “agreeableness” personality trait.
					yes<5	You do not have the “agreeableness” personality trait.
	Phase 5	Personality trait 5: Neuroticism		1. I see myself as someone who is depressed. 2. I see myself as someone who can be tense. 3. I see myself as someone who worries a lot. 4. I see myself as someone who is emotionally stable and doesn't get upset easily. 5. I see myself as someone who can be moody. 6. I see myself as someone who is sometimes shy and inhibited.	yes>=5	You have the “neuroticism” personality trait.
					yes<5	You do not have the “neuroticism” personality trait.

				7. I see myself as someone who gets nervous easily. 8. I see myself as someone who does not remain calm in high-pressure situations. 9. I see myself as someone who does not remain calm in tense situations.		
Team performance	Phase 6			1. Do you provide regular feedback and guidance to help improve team performance? 2. Are you able to identify and leverage the strengths of your team members to enhance overall performance? 3. Are you able to address and resolve conflicts or issues that may impact team performance? 4. Are you able to identify and address any barriers or challenges that may hinder team performance? 5. Do you set clear performance expectations for your team members?	yes>=3	You have team performance traits. Proceed to phase 7
					yes<3	Proceed to phase 7
Team behavioral competence	Phase 7	1-Personality attributes	PA 1: Self-confidence	1. Do you generally feel confident when facing new challenges? 2. Do you tend to trust your abilities and judgment in decision-making? 3. Can setbacks or failures shake your self-confidence easily? 4. Do you feel comfortable expressing your opinions and ideas in group settings? 5. Do you find it easier to take risks when you have a high level of self-confidence?	yes>=3	Proceed to next part
					yes<3	
			PA 2: Open mindedness	1. Are you open to considering different perspectives and opinions? 2. Do you actively seek out new experiences and ideas? 3. Do you enjoy engaging in discussions with people who have different viewpoints? 4. Do you find it easy to adapt to new situations and environments? 5. Are you willing to change your beliefs or opinions when presented with new evidence?	yes>=3	Proceed to next part
					yes<3	
			PA 3: Optimism	1. Do you generally maintain a positive outlook on life? 2. Are you generally hopeful about the outcomes of your efforts? 3. Do you tend to focus on solutions rather than dwelling on problems? 4. Are you able to maintain an optimistic attitude even in the face of uncertainty? 5. Do you believe that setbacks are temporary and can lead to growth and learning?	yes>=3	Proceed to next part
					yes<3	
			PA 4: Strive for excellence	1. Do you consistently set high standards for yourself? 2. Are you motivated to constantly improve and achieve your personal best? 3. Are you willing to put in extra effort to achieve exceptional results? 4. Are you driven by a desire to surpass expectations? 5. Are you willing to go above and beyond what is expected of you?	yes>=3	You have _/4 of personality attributes.
					yes<3	Proceed to phase 8
	Phase 8	2-Analytical abilities	AA 1: Critical thinking	1. Are you skilled at analyzing complex problems and breaking them down into manageable parts? 2. Are you able to identify logical inconsistencies or flaws in arguments? 3. Can you effectively separate facts from opinions or biases? 4. Are you open to changing your beliefs based on new evidence or persuasive arguments? 5. Do you question assumptions and seek evidence before forming conclusions?	yes>=3	Proceed to next part
					yes<3	
			AA 2: Planning and organization	1. Do you create detailed plans and schedules to guide your work? 2. Are you able to prioritize tasks effectively based on their importance and urgency? 3. Are you skilled at breaking down complex projects	yes>=3	Proceed to next part
					yes<3	

				into smaller, manageable tasks? 4. Are you able to meet deadlines consistently through effective planning and time management? 5. Do you value planning and organization as important factors in achieving success?		
			AA 3: Decision making	1. Do you carefully consider available options before making decisions? 2. Are you comfortable with making decisions based on data and evidence? 3. Do you weigh the potential risks and benefits before making a decision? 4. Are you able to analyze and evaluate the potential outcomes of different choices? 5. Are you able to make decisions efficiently, even under time constraints?	yes>=3	Proceed to next part
					yes<3	
			AA4: Strategic thinking	1. Do you consider the long-term implications and consequences of your actions? 2. Do you proactively identify opportunities and challenges that may arise in the future? 3. Are you able to develop and communicate a clear vision for achieving desired outcomes? 4. Are you skilled at analyzing trends and patterns to inform strategic decisions? 5. Do you consider multiple possible scenarios and their potential outcomes when making decisions?	yes>=3	You have _/4 of analytical abilities.
					yes<3	Proceed to phase 9
	Phase 9	3-Interpersonal skills	IS 1: Effective communication	1. Are you able to clearly articulate your thoughts and ideas? 2. Are you skilled at adapting your communication style to different audiences? 3. Are you able to resolve conflicts and negotiate with others through communication? 4. Do you ask clarifying questions to ensure understanding during conversations? 5. Are you able to convey information in a concise and organized manner?	yes>=3	Proceed to next part
					yes<3	
			IS 2: Active listening	1. Do you focus your attention on the speaker and avoid distractions when engaging in a conversation? 2. Do you refrain from interrupting or speaking over others when they are expressing their thoughts? 3. Do you ask relevant and probing questions to gain further clarity and encourage the speaker to share more? 4. Are you patient and willing to give the speaker sufficient time to express their thoughts fully? 5. Are you able to maintain eye contact and show nonverbal cues that indicate your active listening?	yes>=3	Proceed to next part
					yes<3	
			IS 3: Empathy	1. Do you actively listen to others to understand their emotions and experiences? 2. Are you able to put yourself in someone else's shoes to see things from their perspective? 3. Do you show genuine care and concern for the well-being of others? 4. Are you able to detect subtle cues and signals to understand how others are feeling? 5. Are you skilled at providing emotional support and encouragement to others?	yes>=3	Proceed to next part
					yes<3	
			IS 4: Negotiation	1. Are you skilled at finding common ground and areas of agreement during negotiations? 2. Are you able to effectively communicate your own needs and interests during negotiations? 3. Are you able to manage conflicts and reach compromises during negotiations? 4. Do you listen actively to the perspectives and concerns of the other party during negotiations? 5. Are you able to identify and understand the needs and interests of others during negotiations?	yes>=3	You have _/4 of interpersonal skills.
					yes<3	Proceed to next phase 10

	Phase 10	4-Leadership skills	LS 1: Motivating peers	1. Do you actively encourage and inspire your peers to achieve their best? 2. Are you able to identify and leverage the strengths of your peers to motivate them? 3. Do you offer support and guidance to help your peers overcome obstacles and challenges? 4. Do you lead by example, displaying a high level of motivation and enthusiasm yourself? 5. Are you able to effectively communicate the purpose and vision of the team to motivate your peers?	yes>=3	Proceed to next part
					yes<3	
			LS 2: Influence	1. Are you able to effectively persuade and convince others to adopt your ideas or viewpoints? 2. Are you skilled at building strong relationships and networks that allow you to influence others? 3. Do you have the ability to inspire and motivate others to take action? 4. Are you able to adapt your communication style to connect with different individuals and groups? 5. Are you comfortable challenging the status quo and proposing innovative ideas to influence change?	yes>=3	Proceed to next part
					yes<3	
			LS 3: Visionary perspective	1. Do you have a clear and inspiring vision for the future of your team or organization? 2. Do you regularly assess and reassess your vision to ensure it remains relevant and aligned with changing circumstances? 3. Do you actively seek input and feedback from others to shape and refine your vision? 4. Are you able to break down your vision into actionable steps and goals? 5. Are you able to effectively communicate your vision to others?	yes>=3	Proceed to next part
					yes<3	
			LS 4: Change agent	1. Do you actively seek opportunities to drive positive change within your team or organization? 2. Do you lead by example, demonstrating a willingness to embrace and adapt to change yourself? 3. Do you value continuous improvement and actively seek ways to innovate and evolve? 4. Do you encourage and support others in embracing and adapting to change? 5. Are you skilled at identifying and addressing resistance to change?	yes>=3	You have _/4 of leadership skills.
					yes<3	FINISH

Hybrid Intrusion Detection System Based on Data Resampling and Deep Learning

Huan Chen[1], Gui-Rong You[2], Yeou-Ren Shiue[3]

***Abstract*—The growth of the internet has advanced information-sharing capabilities and vastly increased the importance of global network security. However, because new and inconspicuous abnormal behaviors are nearly impossible to detect in massive network access environments, modern intrusion detection systems have identified a high rate of false-positive (FP) and false-negative (FN) attacks. To overcome this, this paper proposes a hybrid deep learning model that significantly mitigates the disadvantages of consistently imbalanced sample attack data. First, it resolves imbalanced data using random undersampling and synthetic minority oversampling techniques. Then, convolutional neural networks (CNNs) extract local and spatial features, and a transformer encoder extracts global and temporal features. The novelty of this combination increases recognition accuracy at the algorithm level, which is crucial to reducing FPs and FNs. The model was subjected to multiclassification testing on the NSL-KDD and CICIDS2017 benchmark datasets, and the results show that our model has higher classification accuracy and lower FP rates than state-of-the-art intrusion detection models. Moreover, it significantly improves the detection rate of low-frequency attacks.**

Keywords—Intrusion detection; deep learning; random undersampling; synthetic minority oversampling technique; convolutional neural network; transformer

I. Introduction

The ubiquity of mobile handheld internet devices allows people to access digital information quickly and effortlessly, just about anywhere. The associated transference and storage of vast volumes of data over computer networks have created new and evolving opportunities for cybercriminals [1]. From 2019 to 2022, the cost of repairing cyberattack damage increased by USD 6T, and the average detection time increased from 57.4 to 93.2 days [2]. Traditional cybersecurity methods (e.g., firewalls, user authentication, and data encryption) cannot handle the complex attacks that take place online. Intrusion detection systems (IDSs) are designed to detect a variety of anomalous patterns that serve as the attack signatures of new and known attacks [3], using advanced database systems with machine learning [4]. When an IDS reports potential malicious activities in an information system [5], it kicks off various analytical and alerting processes to confirm the nature of the attack and launch protection measures.

IDSs generally operate in three phases: information collection, data analysis, and response. The fact that most advanced cyberattacks utilize new and unusual network and system penetration methods makes it nearly impossible to train machine learning models to recognize discrete new and seemingly inconspicuous threats. On the other hand, the models must still be trained with legacy class types from past attacks. Hence, IDS training datasets grow heavily imbalanced over time [6]. Supposing the target class is rare (< 10%) in terms of its representation in the training dataset, critical new and unusual network behaviors can be easily overlooked (as with human perception).

Modern machine-learning methods that handle unbalanced classes typically consider both data- and algorithm-level remedies. That is, training data and classification algorithms are modified separately so that their combination will improve the detection and recognition accuracy of minority samples. Hence, advantageous tradeoffs can be gained. Unfortunately, even the most state-of-the-art IDS models continue to suffer high rates of false-positive (FP) and false-negative (FN) attack detection.

To contribute to the robustness of machine-learning IDS accuracy and recognition, this study makes the following contributions. (1) We apply a novel combination of data- and algorithm-level techniques to specifically reduce the FP rate while improving the model's recall rate. (2) We provide legitimate and reproducible results by applying our combined model to state-of-the-art NSL-KDD [7] and CICIDS2017 [8] benchmark intrusion detection datasets as our research objects. (3) To improve data-level class balancing, we provide an ingenious combination of random undersampling (RUS) and synthetic minority oversampling to adjust the data distribution structure and improve minority class detection. (4) To improve algorithm-level class balancing, we apply a hybrid convolutional neural network (CNN) and a Transformer model to adopt new detection performance efficiencies over contemporary models.

Our model's performance is compared with that of state-of-the-art IDS models, demonstrating that our innovations have clear advantages in terms of accuracy, FP rate, and recall.

To convincingly deliver this information, the remainder of this paper proceeds as follows. Section II covers the extant research that has led us to pursue our current motivations. Section III adequately describes the proposed model and the related techniques and technologies applied. Section IV describes our experiments and presents the comparison results,

Fund Project: Natural Science Foundation of Fujian Province, China [grant no. 2021J01332]

configurational impacts, and implications of our findings. Finally, Section V presents the conclusions.

II. Related Works

This study provides an IDS model that can more accurately identify malicious traffic and detect a wider variety of intrusion attacks than current models. First, our model resolves sample imbalance problems at the data and algorithm levels based on the lessons learned from current studies, described briefly in the following sections.

A. Data-Level Mitigation Efforts

In terms of the current data-level mitigation efforts used to overcome problems related to training models with imbalanced datasets, data reconstruction efforts prevail. Related strategies focus on preprocessing original datasets to provide appropriately weighted training sets for model learning and tailoring the model's feature classification methods to maximize learning and retention based on the task at hand.

A healthy number of intrepid researchers have applied oversampling [9-14], undersampling [15-19], and hybrid [20-23] preprocessing methods to restore balance to their training datasets. These methods are combined with feature classification methods to maximize benefits. For example, the synthetic minority oversampling technique (SMOTE) [24] is a widely used data reconstruction strategy that provides good data balancing and classification results while effectively avoiding overfitting. Noting that the SMOTE algorithm analyzes minority class samples and manually synthesizes new ones based on the needed additions, Dablain et al. [25] provided a deep learning-based SMOTE method that applies a novel oversampling method to counter class imbalances and train new skew-insensitive classifiers. Joloudari et al. [26] proposed a CNN that uses SMOTE to achieve a remarkable accuracy of 99.08% on 24 imbalanced datasets, including KEEL, Breast Cancer, and Z-Alizadeh Sani sets.

B. Algorithm-Level Mitigation Efforts

Most current algorithm-level mitigation efforts aim to intuitively process input data algorithmically for better classification results. Modern techniques match the model's internal structure to the distribution characteristics of the original dataset as much as possible. For example, CNN-based autoencoders are extensively used for IDSs, resulting in high detection performance [27]. Yin et al. [28] proposed a recurrent neural network (RNN)-based IDS that provides impressive breakthroughs in accuracy. Vigneswaran et al. [29] used a deep neural network (DNN) to predict attacks directed at network IDSs (NIDS). The famous KDD-CUP99 [30] dataset was used to train and benchmark, revealing that a DNN with three layers outperformed all other classical machine learning algorithms at the time. XIAO et al. [31] proposed IDS to reduce the required CNN features for computational efficiency. The KDD-CUP99 dataset was again used, showing reduced FPs and improved speeds. Belarbi et al. [32] proposed a multi-class NIDS based on a deep belief network (DBN) using the CICIDS2017 dataset to train and evaluate performance. The experimental results demonstrated that DBNs can surpass traditional multilayer perceptron classification performance, significantly improving overall recall. In 2017, Vaswani et al. [33] proposed the transformer model, originally designed to solve the tasks of language modeling and machine translation, achieving good results; this model has also been gradually applied to network IDSs. Wang et al. [34] proposed a robust unsupervised IDS (RUIDS) by introducing a masked context reconstruction module into a transformer-based, self-supervised learning scheme. Extensive experiments on four intrusion datasets were conducted to demonstrate the effectiveness and robustness of the RUIDS. Yang et al. [5] proposed IDS based on an improved vision transformer, demonstrating superior results on the NSL-KDD public intrusion detection via simulation experiments.

C. Hybrid Solutions

As noted, CNNs, RNNs, (Recurrent Neural Networks) and DBNs (Deep Belief Networks) are among the most common IDS solutions used to mitigate imbalanced data problems [36]. Hybrid models have recently become popular, based on their observed improvements to symbiotic and amplified model strength [37]. Indeed, research has shown that combined models consistently perform better than individual algorithms [38]. Table I list the best representative hybrid IDS models and summarize their basic algorithmic models, dataset properties, classification types, and accuracy results. This listing is fully explained in the subsequent narrative.

1) Focused neural network combinations: Zhang et al. [39] proposed an IDS model based on an improved genetic algorithm with a DBN trained and evaluated using the NSL-KDD dataset, demonstrating effective improvements in intrusion recognition rates (> 99%). Wu et al. [40] proposed a hierarchical CNN + RNN model (i.e., LuNet) that effectively extracts spatial and temporal data features, providing higher detection accuracy and fewer FPs than peer methods. LuNet's verification accuracies on the NSL-KDD and UNSW-NB15 datasets were 99.24% and 97.40%, respectively. Souza et al. [41] proposed a hybrid binary classification model comprising a DNN with a k-nearest-neighbors (kNN) function. This method achieved higher accuracy than classical machine learning methods, with 99.77% on the NSL-KDD dataset and 99.85% on the CICIDS2017 dataset. Albahar et al. [42] proposed an approach that combines a regularization algorithm with an artificial neural network, achieving all-time-high true-positive (TP) and accuracy rates on the NSL-KDD, UNSW-NB15, and CIDDS-001 datasets (i.e., 98.53, 94.58, and 97.87%, respectively) using 10-fold cross-validation. Ahsan et al. [43] proposed a hybrid CNN with a long short-term memory (LSTM) network, achieving the highest known accuracy (at the time) of 99.70% on the NSL-KDD dataset. Banaamah et al. [44] adopted a CNN with an LSTM and a gated recursive unit (GRU) model to improve internet-of-things (IoT) security. Using the highly reputable Bot-IoT dataset, the proposed model surpassed the highest accuracy, with a 99.8% ratio. Kamalakkannan et al. [45] developed an improved CNN + LSTM model that learns spatial and temporal data characteristics, demonstrating 98% accuracy and a 98.14% average detection rate on the NSL-KDD dataset.

Shivhare et al. [46] proposed a CNN + LSTM + SVM model to tackle multiclass tasks on the CICIDS 2017 dataset, achieving an accuracy of 97.29%. Qazi et al. [47] proposed a deep-layered CNN + RNN model to detect and classify malicious traffic using the CICIDS-2018 dataset, achieving an average accuracy of 98.90%. Recently, the use of transformers has provided new feature extraction methods. Transformers are deep neural networks wholly based on attention mechanisms that have shown great success in natural language processing (NLP) fields. Their versatility allows them to be applied to other domains, such as image classification, cybersecurity, and more. Xing et al. [48] sought to improve unknown attack learning and detection by extracting data features from different perspectives using CNN and transformer models. Xiang et al. [49] later proposed a transformer-based fusion deep learning architecture in which the transformer is used to adjust the ML-CNN-BiLSTM model to enhance its feature encoding ability. Ullah et al. [50] proposed an IDS using transformer-based transfer learning for imbalanced network traffic (INT). The resulting DS-INT uses transformer-based transfer learning to learn feature interactions in network feature representations, even with imbalanced data. A hybrid CNN-LSTM model was then developed to detect attacks from deep features.

TABLE I. SUMMARY OF THE HYBRID INTRUSION DETECTION SYSTEM

2) Focused Data- and Algorithm-Level combination: Yan et al. [51] proposed a novel combinatorial IDS model based on a deep RNN and a region-adaptive SMOTE technique. This model significantly improved the detection rate of low-frequency attacks and overall efficiency while improving unknown attack detection. Al et al. [52] proposed a hybrid CNN + LSTM + SMOTE and the Tomek–Link sampling method (i.e., STL) to improve system performance to an impressive extent. Cao et al. [36] designed a CNN + GRU model that extracts spatiotemporal features from network data traffic. This model combines adaptive synthetic sampling (ADASYN) and repeatedly edits its nearest neighbors to process positive and negative sample imbalances in the original dataset. This model resolves both low classification accuracy and imbalance problems.

D. Motivation for and Purpose of this Study

Through the research and discussion of the above literature, we can see that model systems combining two or more algorithms can often obtain better detection capabilities than single algorithms. Of course, with that comes an increase in the cost of computation. Therefore, how to achieve better detection results at the exact computational cost, the reasonable choice of classification algorithm will be the key to the problem.

The CNN model has become one of the classification algorithms selected in this paper because it can comprehensively map the data features, mine the relationship between the features, and improve the accuracy of feature extraction. However, the CNN model focuses more on spatial local features and has time series characteristics for the traffic data studied in this paper. Therefore, the processing ability of sequence data will be emphasized in selecting the second classification algorithm. RNN, GRU, LSTM, and Transformer are all sequential models in deep learning. Compared with RNN and LSTM, the Transformer model can obtain the relationship between all the information in the sequence through the self-attention mechanism, which can better cope with the long-term dependency problem and has higher accuracy. The model can be operated in parallel, and the calculation speed is faster. Based on the above reasons, the CNN and the Transformer models have become the algorithm choices for this paper's hybrid intrusion detection system.

In addition, previous studies have primarily focused on the overall detection rate of the system, but for the typical unbalanced network traffic data, identifying a small number of attack samples is the key to detection classification. Therefore, the difference between this paper and previous studies is that the system focuses more on the identification rate of minority species without significantly affecting the overall detection rate. To achieve this goal, the system balances the sample size of the majority class and the minority class at the data level through data resampling technology to adapt to the common classifier that pursues global accuracy.

III. Proposed Model

The model proposed in this study uses the NSL-KDD and CICIDS2017 datasets as the research targets. New training, validation, and testing sets were divided by random sampling to digitize and normalize the original data. Most class samples were randomly undersampled to stress the sample imbalance problem.

The focus of this model is on the classification research of imbalanced data, which are divided into two levels for operation. First, at the data level, a data reconstruction strategy is used to adjust the internal distribution structure of the data so that the imbalanced dataset tends toward a balanced state. The measure is obtained by randomly undersampling the majority class samples in the training set and oversampling the minority class samples with SMOTE to achieve balanced data.

Second, at the algorithmic level, the model adjusts the traditional classification algorithm or proposes the optimization and improvement of existing classification ideas as an adaption technique to handle the inherent characteristics of imbalanced datasets, thereby improving the overall recognizability of the model. Research has shown that combined models consistently perform better than individual algorithms [38]. As mentioned, we combined the classic CNN with a transformer self-attention module to achieve optimization by combining multiple classifiers that adapt to the internal distributed structure of imbalanced datasets. Hence, the detection rate of the model will be improved.

This model accounts for both data- and algorithm-level aspects of the problem and utilizes their combined advantages to achieve superior recognition accuracy with minority class samples. Fig. 1 presents a schematic diagram of our proposed model.

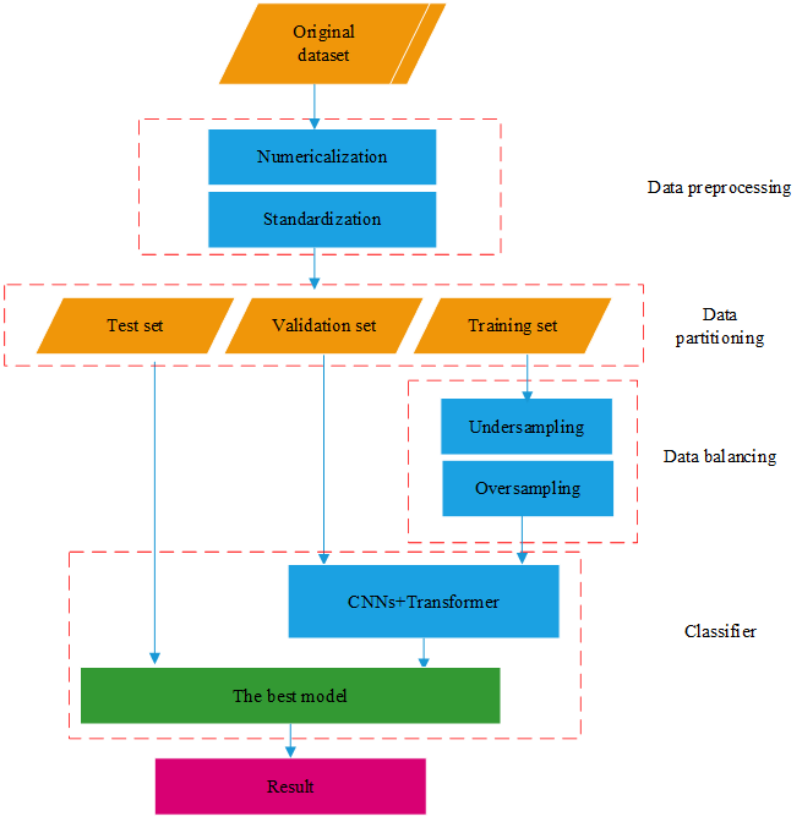

Fig. 1. Schematic diagram of the proposed model.

A. Dataset Description

1) NSL-KDD Dataset: According to [5], NSL-KDD [53] and KDD-CUP99 [54] are the most widely used datasets in IDS research (ca. 2012–2022). The NSL-KDD dataset was generated in 2009 and is commonly used to train models for anomaly detection. It is a revised version of the classic KDD99 dataset but retains its structure. The new dataset consists of four subsets: KDDTest+, KDDTrain+, KDDTest-21, and KDDTrain+_20%, where the latter two are subsets of the first two, respectively.

In the NSL-KDD dataset, each sample record contains 41 attribute features and a classification identifier. Normal and abnormal network connections are marked with the classification identifier. The normal type is represented as "normal," and the dataset contains many anomalies and 39 attack identifiers. These identifiers are divided into four categories by type: denial of service (DoS), probe, root-to-local (R2L), and unauthorized-to-root (U2R).

Our experiment uses the original data sources of KDDTrain+ (125,973 sample records) and KDDTest+ (22,544 sample records). Table II presents the sample size distributions of each attack type.

2) CICIDS2017 Dataset: Table II shows that the NSL-KDD dataset is a typical imbalanced dataset. Notice the small proportion of Probe, R2L, and U2R attack-type samples, especially for U2R attacks. Although this dataset is very popular in IDS studies, some researchers have pointed out that it is somewhat outdated.

Emerging datasets include UNSW-NB15, CICIDS2017, Bot-IoT, and others. Among them, CICIDS2017 is the most popular. Therefore, we chose CICIDS2017 as our second benchmark to gauge performance differences.

The CICIDS2017 dataset was released in 2017 [55], providing normal data and the latest common attack types, similar to real-world data. It contains 2,830,743 network traffic samples, each containing 83 network traffic features. It also includes one benign and 14 attack categories, including the standard DoS, botnet, web, infiltration, file transfer protocol patator, and SSH patator types [56]. Among the 14 attack categories, tags with similar features and behaviors are merged to form five new categories. The distribution of the number of samples in the CICIDS2017 dataset is shown in Table III. The CICIDS2017 dataset is also imbalanced, with bot-and-web attack class samples being particularly scarce.

TABLE II. DISTRIBUTION OF VARIOUS SAMPLES FROM THE NSL-KDD DATASET

Dataset	The number and proportion of various types of samples					
	Total	***Normal***	***DoS***	***Probe***	***R2L***	***U2R***
KDD Train+	125973	67343 (53.46%)	45927 (36.46%)	11656 (9.25 %)	995 (0.79 %)	52 (0.04%)
KDD Test+	22544	9711 (43.08%)	7458 (33.08%)	2421 (10.74%)	2754 (12.22 %)	200 (0.89%)

TABLE III. DISTRIBUTION OF VARIOUS SAMPLES IN THE CICIDS2017 DATASET

Dataset	Number and proportion of various types of samples					
	BENIGN	***Bot***	***BruteForce***	***DoS /DDoS***	***Port Scan***	***Web Attack***
CICIDS2017	2035505 (83.91 %)	1943 (0.08 %)	8551 (0.35%)	320269 (13.20 %)	57341 (2.36 %)	2118 (0.09 %)

B. Data Preprocessing

Using the NSL-KDD dataset as an example, data preprocessing was introduced, and the operation of the CICIDS2017 dataset was similarly manipulated.

1) Numericalization: The NSL-KDD dataset contains 41 attribute features (i.e., 38 digital and three non-digital types). Because the input value of the model should be a digital matrix, it was necessary to use a numerical method to map data with symbolic features into digital feature vectors. We used the LabelEncoder method of the preprocessing module in the sklearn library to convert the three non-digital features (i.e., protocol_type, service, and flag) into digital features.

2) Standardization: Unlike normalization, which is easily affected by outliers, standardization is relatively stable; thus, it is suitable for noisy big data scenarios. Therefore, standardization was used for data preprocessing. The original data were transformed into a range with a mean of zero and a standard deviation of one so that the processed data would conform to a standard normal distribution. The StandardScaler method of the preprocessing module in the sklearn library uses a standard z-score scaling calculation formula, expressed using Eq. (1):

$$X' = \frac{\chi - mean}{\sigma}, \quad (1)$$

where, X' represents the converted data value, χ is the original data value, mean is the mean value of the column data, and σ is the standard deviation of the column data.

C. Dataset Partitioning

The KDDTrain+ and KDDTest+ subsets of the NSL-KDD dataset were used as the original data, and new training, validation, and testing sets were formed by random sampling. It lists the number and proportions of each sample set after division. The CICIDS2017 dataset was also divided according to the same ratio, and the numbers after the division are listed in Table IV. To achieve good data balance, undersampling and oversampling were performed on the training set samples.

TABLE IV. NUMBER AND PROPORTION OF DATASETS AFTER PARTITIONING

Dataset	#training set	#validation set	#testing set
NSL-KDD	103,961	14,852	29,704
CICIDS2017	1,698,008	242,573	485,146
Proportion	70%	10%	20%

D. Data Balancing

1) Undersampling: The undersampling method achieves data equalization by randomly removing a certain proportion of majority instances from the RUS dataset [23]. This process consists of the following steps:

a) The numbers of majority samples, N1, and minority samples, N2, are calculated.

b) Based on the set sampling ratio, r, we calculate the number of majority class samples needing deletion (N1 - N2 * r).

c) Randomly selected samples from the majority class, S_{maj}, to form the sample set E; remove sample set E from S_{maj}; generate a new dataset $S_{new-maj} = S_{maj} - E$.

In the NSL-KDD dataset, NORMAL and DoS samples belong to the majority class, and undersampling was performed using RUS samples. The BENIGN and DoS/DDoS samples of the CICIDS2017 dataset belong to the majority class and are undersampled.

2) Oversampling: Oversampling is used to rebalance a dataset by creating fake minority instances, and SMOTE [22] is the best method [57] in our case as it effectively compensates for the shortcomings of random oversampling and is superior to simple replication, which can easily cause model overfitting and weaken generalizability. SMOTE also has the advantages of a simple design and strong robustness. Moreover, it uses interpolation between minority class samples and their nearest neighbors to generate new synthetic samples [58]. The SMOTE steps are as follows:

a) For each sample X in the minority class, a k-NN is used to sample each minority class sample.

b) We determine the sampling rate, N, based on the sample imbalance ratio and randomly select N samples from K nearest neighbors for random linear interpolations.

c) We construct a new minority class sample using Eq. (2):

$$\mathrm{New} = \mathrm{x_i} + rand(0,1) \times \left(\mathrm{y_j} - \mathrm{x_i}\right), \mathrm{j} = 1, 2, \ldots \mathrm{N} \quad , \tag{2}$$

where, $\mathrm{x_i}$ is an observation point in the minority class, $\mathrm{y_j}$ is a randomly selected K -nearest neighbor, and $rand(0,1)$ represents a random number generated between zero and one.

d) New samples are combined with the original data to form a new dataset.

In the NSL-KDD dataset, Probe, R2L, and U2R samples belong to a minority class and were oversampled with SMOTE to increase the number of class samples. For the CICIDS2017 dataset, the Bot, Brute Force, PortScan, and Web Attack samples belong to the minority class and were oversampled. The training set samples were balanced at the data level via undersampling and oversampling.

E. Model Structure

1) CNN: CNNs are feedforward neural networks with convolution calculations and a deep structure that extract features accurately and efficiently [59]. The error function is obtained by calculating the difference between the actual and predicted values. Network parameters are adjusted retroactively until the model reaches an optimal solution [60]. This method has been widely used in several fields, such as NLP and computer vision.

A CNN generally comprises a convolution layer, activation function, pooling layer, and a fully connected layer [61] as shown in Fig. 2. The convolution layer extracts high-level features from the input data, and the pooling layer performs feature selection and information filtering on the graph data output by the convolution layer, thereby reducing the amount of data processing.

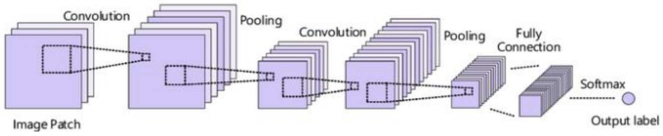

Fig. 2. CNN structure.

2) Transformer: A transformer is a deep learning model [33] that is widely used for NLP and other sequential data processing tasks.

The transformer differs from traditional RNNs and CNNs in that they adopt a novel self-attention mechanism that allows the model to assign different weights to different elements when processing input sequences. It calculates the similarity score between elements and uses the score to calculate the weighted averages of relationships among elements. Notably, the transformer supports parallel computing, this allows it to handle long sequences easily without step-by-step iterations. The self-attention mechanism also allows the transformer to incorporate information from the entire sequence into its calculations, which leads to better long-range dependencies.

CNNs are particularly adept at modeling fine-grained local features due to their convolutional operations and hierarchical structure. Nevertheless, their global modeling ability is weak, whereas the transformer excels at modeling global contextual information [62]. The proposed framework utilizes complementary CNN characteristics to extract local, spatial, and time series features.

3) Hybrid model: This article adopts a hybrid architecture that combines the CNN and the transformer as illustrated in Fig. 3. Spatial features are extracted after preprocessing and sample balancing in one-dimensional (1D) convolutional and pooling layers. Then, by using the self-attention mechanism of the transformer to process the data, the shortcomings of the RNN's short-term memory and the CNN's difficulties in learning remote dependencies are overcome, and temporal and global features are extracted. Finally, using flattening and fully connected functions, the data are classified according to attack type. For the NSL-KDD dataset, the data were divided into five categories: one normal and four attack. The CICIDS2017 dataset was divided into six categories: one benign and five attacks.

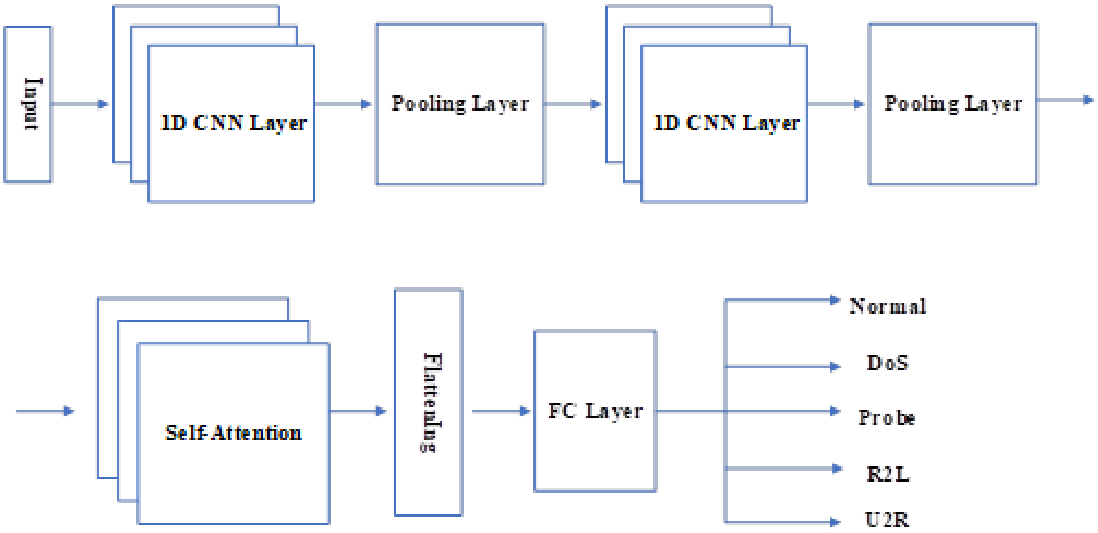

Fig. 3. Hybrid CNN–Transformer architecture.

IV. Experimental Results and Discussion

A. Evaluation Indicators

Commonly used evaluation indicators for classification problems are accuracy (ACC), precision (PRE), recall (i.e., TPR), false-positive rate (FPR), and F1-measure. It is necessary to adopt reasonable evaluation criteria for unbalanced data, including the F1-measure, G-mean, receiver operating characteristic (ROC) curve, and area under the ROC curve (AUC) values.

Accuracy is defined by Eq. (3), which reflects the percentage of correctly predicted samples among the total number of predicted samples:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN}. \quad (3)$$

Precision is the ratio of correctly predicted positive samples to the total number of positive samples, as shown in Eq. (4):

$$\text{Precision} = \frac{TP}{TP+FP}. \quad (4)$$

Recall describes the ratio of the number of correctly predicted positive samples to the total number of positive samples as formulated in Eq. (5):

$$\text{Recall} = \frac{TP}{TP+FN}. \quad (5)$$

FPR is the number of false positive samples detected divided by the total number of TN samples, as defined by Eq. (6):

$$FPR = \frac{FP}{FP+TN}. \quad (6)$$

The F1-measure is a comprehensive assessment of precision and recall and represents the harmonic average between them, as defined by Eq. (7):

$$\text{F1-Measure} = 2\times\frac{\text{Precision}\times\text{Recall}}{\text{Precision}+\text{Recall}} = \frac{2TP}{2TP+FP+FN} \quad (7)$$

The G-mean is a standard that comprehensively considers both recall and accuracy. A high G-mean value indicates good modularity, reflecting the geometric mean of sensitivity (i.e., hit rate or recall) and precision. The G-mean is defined in Eq. (8):

$$G-\text{Mean} = \sqrt{\frac{TP}{TP+FN}\times\frac{TN}{TN+FP}}. \quad (8)$$

The ROC curve defines TPR and FPR in terms of horizontal and vertical coordinates, respectively. Each threshold corresponds to a point (FPR, TPR), and all points are connected as the threshold changes.

Although the ROC curve can comprehensively and intuitively express the performance of a classifier, it cannot provide a specific value. Therefore, it is usually evaluated using the area AUC, as defined in Eq. (9):

$$AUC = \frac{TP \times FP + 2TP \times TN + FN \times TN}{2(TP + FN) \times (FP + TN)} . \qquad (9)$$

AUC values range from zero to one; the larger the AUC, the better the classification performance.

B. Experimental Results

The experiment was conducted on a desktop Intel 3.10 GHz processor with 64-GB memory, no GPU acceleration, and a 64-bit Windows 11 operating system. The programming tool was Keras 2.9.0, based on TensorFlow. The NSL-KDD and CICIDS 2017 datasets were used to train the model shown in Fig. 1. For the NSL-KDD dataset, owing to the small amount of data, the batch size was set to 256, and the training epochs were set to 200. The CICIDS2017 dataset contains a considerable amount of data. To accelerate the convergence speed of the model, the batch size was set to 512, and 40 epochs of training were performed. Finally, the model parameters with the best effects on the corresponding datasets were obtained. Subsequently, the model with the optimal parameters was tested on the testing set to obtain classification results, and the confusion matrix was constructed as shown in Fig. 4 and Fig. 5.

Multiple classification experiments were conducted for different attack categories. The NSL-KDD dataset included normal, DoS, Probe, U2R, and R2L classes. The CICIDS 2017 dataset consisted of BENIGN and five attack classes: bot, brute-force, DoS/DDoS, PortScan, and web types. The experimental results are presented in Tables V and VI, respectively. For most class samples, the classification performance of the model was good. For the minority class samples, the model's classification performance decreased to some extent; however, the degree of decrease was not significant. The model does not sacrifice the classification performance of other categories to improve the classification accuracy of any specific category. Therefore, the overall classification performance of the model is very well-balanced.

The overall classification results of the model are presented in Table VII. Although the overall accuracy was not very high, the model did not sacrifice the classification effects of a few classes in exchange for higher overall accuracy, which is a unique demonstration of superior classification procedures. Therefore, the model showed little difference in the classification effects between the majority and minority classes. Moreover, it tended to improve the recognition rate of minority classes (e.g., U2R and R2L) in the NSL-KDD dataset and Bot and Web classes in the CICIDS2017 Dataset).

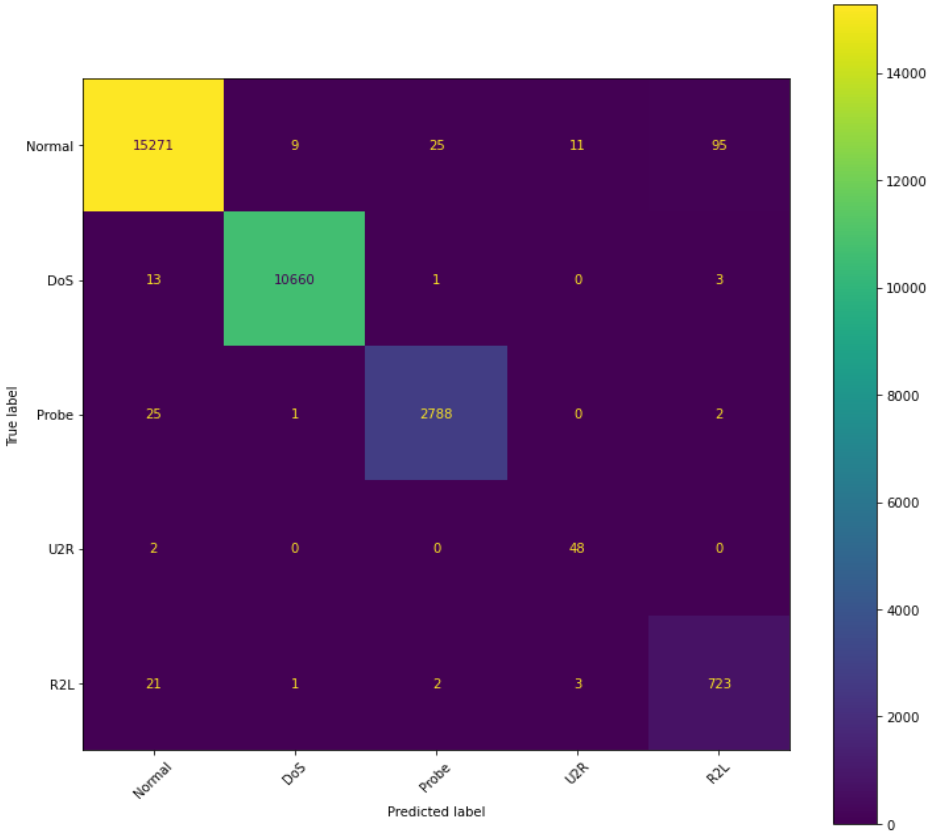

Fig. 4. Confusion matrix of classification results of the NSL-KDD dataset.

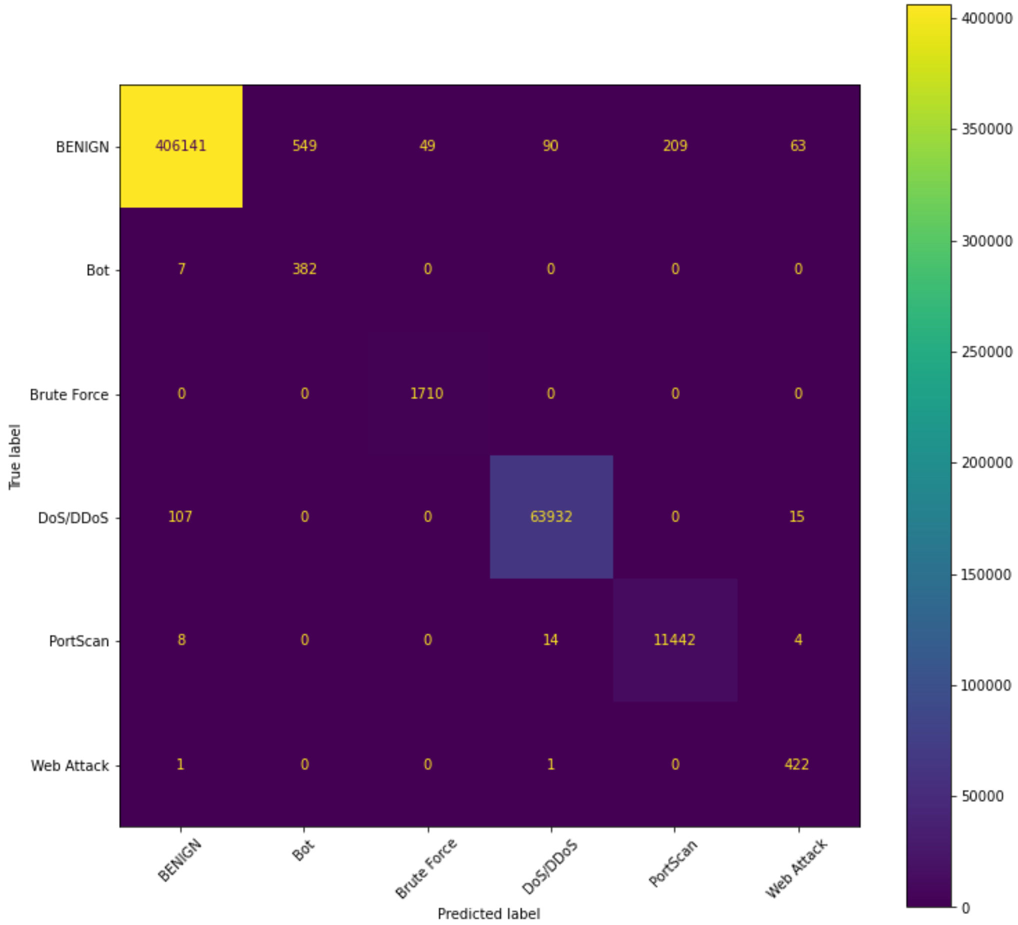

Fig. 5. Confusion matrix of classification results of the CICIDS2017 dataset.

TABLE V. FIVE CLASSIFICATION RESULTS FOR THE NSL-KDD DATASET

Type	Accuracy (%)	Precision (%)	Recall (%)	FPR (%)	F1 (%)	G-mean (%)	AUC
Normal	99.32	99.60	99.09	0.43	99.35	99.33	99.97

Dataset	Accuracy (%)	Precision (%)	Recall (%)	F-Measure (%)
NSL-KDD	99.28	92.75	98.07	95.17
CICIDS 2017	99.77	86.66	99.51	91.01

C. Analysis and Discussion

1) Impact of model structure on results: In this section, the structure of the proposed model is discussed. We compared the classification effects of the model before and after data balancing and the single-network model with the hybrid model of both. The following conclusions were drawn from the NSL-KDD dataset, as listed in Table VIII.

The overall effect of the model after data balancing was better than that of the model without data balancing. Moreover, the impact of the hybrid model was better than that of the single-network model.

At the same time, data balancing is beneficial for improving the classification effect of minority classes. Fig. 6 and Fig. 7 show the comparison of precision before and after data balancing for the minority classes U2R and R2L, respectively. From the figures, we can see that regardless of whether it is a single algorithm model or a hybrid model, the classification accuracy after data balancing has increased to varying degrees. This also confirms the necessity of data balancing operations.

Similar conclusions were drawn for the CICIDS2017 dataset. The effect of the hybrid model was better than that of the single network model. Data balancing provided better improvements to accuracy and precision indicators, as shown in Table IX.

Fig. 8 and Fig. 9 present a comparative analysis of the precision of rare classes—Bot and Web Attack—in the CICIDS2017 dataset, both before and after the application of data balancing techniques. Similar to the NSL-KDD dataset, the conclusion drawn from these figures is that data balancing is beneficial for improving the classification accuracy of minority classes.

TABLE VIII. COMPARISON OF THE RESULTS OF THE NSL-KDD DATASET UNDER DIFFERENT MODEL CONFIGURATIONS

	Before data balancing			After data balancing		
Model	***CNN***	***Transformer***	***CNN+Transformer***	***CNN***	***Transformer***	***CNN+Transformer***
Accuracy (%)	98.47	98.41	98.56	99.24	98.81	99.22
Precision (%)	82.36	80.82	82.62	91.94	86.18	91.68
Recall (%)	97.98	97.47	98.07	98.04	97.82	98.19
F-Measure (%)	87.31	85.35	87.51	94.64	90.47	94.56

	CNN	Transformer	CNN+Transformer
🟦 Before data balancing(%)	99.72	99.59	99.72
🟥 After data balancing(%)	99.93	99.91	99.95

	CNN	Transformer	CNN+Transformer
🟦 Before data balancing(%)	99.57	98.89	99.78
🟥 After data balancing(%)	99.98	99.53	99.98

Fig. 9. Comparison of Web Attack class accuracy rate before and after data balancing.

2) Impact of sampling rate on results: The previous section showed that data balancing benefits minority class detection. In this section, we focus on comparing the different sampling rates of rare classes to explore the impact of sampling rates. For the NSL-KDD dataset, we checked the U2R category. In contrast, for the CICIDS2017 dataset, we checked the Bot and Web Attack categories due to their low representation. During model training, 100, 300, 500, and 1,000% samples were considered for the given categories, and the optimal model parameters generated were predicted using the testing set. The experimental results are presented in Tables X to XII.

TABLE X. COMPARISON OF RESULTS FOR THE U2R CATEGORY UNDER DIFFERENT SAMPLING RATES

Sampling rate (%)	**Recall (%)**	**Accuracy (%)**	**F-Measure (%)**	**G-mean (%)**
100	70.00	99.93	76.09	83.66
300	72.00	99.92	75.79	84.84
500	74.00	99.91	74.00	86.00

TABLE XI. COMPARISON OF RESULTS FOR THE BOT CATEGORY UNDER DIFFERENT SAMPLING RATES

Sampling rate (%)	**Recall (%)**	**Accuracy (%)**	**F-Measure (%)**	**G-mean (%)**
100	32.65	99.95	52.24	57.14
300	61.44	99.94	62.41	78.37
500	94.34	99.93	67.82	97.09
1000	94.86	99.93	69.82	97.19

TABLE XII. COMPARISON OF RESULTS FOR THE WEB ATTACK CATEGORY UNDER DIFFERENT SAMPLING RATES

Sampling rate (%)	**Recall (%)**	**Accuracy (%)**	**F-Measure (%)**	**G-mean (%)**
100	82.08	99.99	96.43	90.59
300	95.52	99.99	96.36	97.72
500	97.41	99.99	95.10	98.67
1000	97.64	99.99	94.49	98.80

These results show that increasing the sampling rate significantly improved the recall rate, F-measure, and G-mean for rare categories. However, this had little impact on overall classification accuracy. Due to the small proportions of rare classes in the original dataset, it was difficult for the model to train effectively for class recognition. Therefore, increasing the sampling rate is equivalent to increasing the training opportunities of the model for that category, thereby improving the recall of subsequent testing data. Thus, improving the detection rate for minority classes comes at the cost of increasing training time.

D. Comparisons of Experimental Results

We compared the above experimental results with methods from the relevant literature to verify our model's effectiveness with multiclassification problems using unbalanced data. We first compared NSL-KDD data, as the related literature is abundant.

First, the classification accuracy of multiple classifications was compared, as presented in Table XIII. Our model had the highest classification accuracy for all five categories, and there were no cases in which the accuracy of a specific category was particularly low. Again, the accuracy of a few categories was not sacrificed in exchange for higher overall accuracy.

TABLE XIII. ACCURACY COMPARISONS OF FIVE CLASSIFICATIONS

References	Normal (%)	DOS (%)	Probe (%)	U2R (%)	R2L (%)
Zhang-2019- [39]	-	99.45	99.37	98.68	97.78
Ahsan-2020- [43]	98.5	98.8	0	99.4	94.6
LIU-2023- [63]	97.7	94.6	94.7	0.3	0.4
Proposed model	99.32	99.91	99.81	99.95	99.57

Next, multi-classification recall rates were compared, and the results are listed in Table XIV. It can be seen from the table that the recall rates of the DOS and R2L categories were the highest compared with those reported in the relevant literature. The difference between the other three categories and the highest values in the literature was insignificant.

TABLE XIV. RECALL COMPARISONS OF FIVE CLASSIFICATIONS

References	Normal (%)	DOS (%)	Probe (%)	U2R (%)	R2L (%)
Zhang-2019- [39]	-	99.7	99.4	98.2	93.4
Albahar-2020- [42]	98	97.8	95.6	96.9	92.4
Ahsan-2020- [43]	98.5	98.8	0	99.4	94.6
Onah-2021- [64]	97.5	96.9	93.4	73.5	77.1
LIU-2023- [63]	97.7	94.6	94.7	0	0
Kamalakkannan-2023- [45]	99.57	99.76	99.15	25	88.41
Proposed model	99.09	99.84	99.01	96	96.40

The classification FPRs of multiple classifications were then compared, as shown in Table XV. It can be seen that, apart from a few R2L cases, the FPR of our model was the lowest of all.

TABLE XV. FPR COMPARISONS OF FIVE CLASSIFICATIONS

References	Normal (%)	DOS (%)	Probe (%)	U2R (%)	R2L (%)
Zhang-2019- [39]	-	0.8	0.7	1.8	7.3
Albahar-2020- [42]	0.73	0.54	0.67	0.33	0.87
Ahsan-2020- [43]	1.5	1.2	1	0.6	5.4
Onah-2021- [64]	0.6	0.6	0.4	0.2	0.1
Proposed model	0.43	0.06	0.10	0.05	0.35

Finally, for imbalanced data classification problems, the F1 measure is often more important than other metrics. Table XVI presents the results of the multicategory F1-measure comparisons. Apart from the U2R category, the F1 measure of our model was the best.

TABLE XVI. F1-MEASURE COMPARISON OF FIVE CLASSIFICATIONS

References	Normal (%)	DOS (%)	Probe (%)	U2R (%)	R2L (%)
Albahar-2020- [42]	98.5	98.3	94.8	97.3	66.5
Ahsan-2020- [43]	99.1	98.3	0	99.2	85.4
LIU-2023- [63]	98.9	97.2	97.3	0.5	0.7
Proposed model	99.35	99.87	99.01	85.71	91.93

Using the CICIDS2017 dataset, our model also showed advantages in accuracy and recall, as shown in Table XVII.

TABLE XVII. COMPARISON OF THE RESULTS OF THE CICIDS2017 DATASET

References	Accuracy (%)	Recall (%)
Abdel-Basset-2021- [65]	99.69	96.29
Khan-2021- [66]	98.76	98.69
Chen-2022- [67]	99.73	79.13
Wu-2022- [68]	99.35	98.83
Proposed model	99.77	99.51

Through the above comparative analyses, our hybrid model, based on data balancing and two deep learning networks, has clear advantages and achieved excellent results in multiclassification problems with unbalanced data.

V. CONCLUSIONS AND FUTURE RECOMMENDATIONS

NIDS plays vital network security roles in identifying, preventing, and countering network threats. Owing to the large amount of unbalanced data collected in network datasets, FPs and omissions significantly reduce the detection efficiency of extant IDSs. This paper proposed a deep learning model that combines data balancing and a CNN + Transformer hybrid to improve the data distribution of the original dataset via undersampling and oversampling techniques. Our data redistribution method increases the likelihood of identifying minority classes based on model training, and the experimental results show that our innovations effectively improve this detection rate. Our hybrid model’s algorithm-level improvements increased recognition training based on fused spatiotemporal features, and the experimental results show that the proposed system, combined with multiple combined processes, identifies anomalies more efficiently and accurately than any single network model.

For the classic NSL-KDD and modern CICIDS2017 datasets, our model was more effective in multiclassification data applications and was superior to existing IDS models in terms of accuracy, FPR, F1-mean, and other indicators. Notably, the CICIDS2017 dataset showed superiority in training compared with existing models in terms of accuracy and recall.

Although the model proposed in this paper has advantages over existing systems, several other data balancing activities, such as the edited nearest neighbor, Tomek–Links, SMOTEBoost, and ADASYN methods described, should be tested. Many LSTM, GRU, DBN, and other variants should also be tested. The objective is to improve the detection effects of data classifications based on innovative model structures so that network security professionals and scholars can obtain better IDS results, even in the face of scarce data.

***Abstract*—The proliferation of internet-connected devices, including smartphones, smartwatches, and computers, has led to an unprecedented surge in data generation. The rapid rise in device connectivity points to an urgent need for robust cybersecurity measures to counter the mounting wave of cyber threats. Among the strategies aimed at establishing efficient network intrusion detection systems, the integration of machine learning techniques is a prominent avenue. However, the application of machine learning models to imbalanced intrusion detection datasets, such as NSL-KDD, CICIDS2017, and UGR'16, presents challenges. In such intricate scenarios, accurately distinguishing network intrusions poses a formidable challenge. The term "imbalance" refers to the imbalanced distribution of data across classes, which adversely affects the precision of machine learning algorithm classifications. This comprehensive survey embarks on a thorough exploration of the spectrum of methodologies proposed to address the challenge of imbalanced data. Simultaneously, it assesses the efficacy of these methodologies within the realm of network intrusion detection. Moreover, by shedding light on the potential consequences of not effectively tackling imbalanced data, this study aims to provide a holistic understanding of the intricate interplay between machine learning and intrusion detection in imbalanced settings.**

Keywords*—Network intrusion detection system; data imbalance; resampling; data level techniques; hybrid techniques

I. Introduction

In parallel with technological advancements and the proliferation of networks, vulnerabilities to diverse attacks have emerged, potentially leading to system damage, network disruptions, data loss, or unauthorized access. The escalation of network intrusions has become a pressing concern, impacting governments, businesses, and essential infrastructure. Network intrusion detection systems (NIDS) have come to the fore as a means of addressing these challenges. These systems employ advanced algorithms to navigate intricate and extensive data landscapes, functioning as vigilant software that enhances the monitoring of network activities. Their primary mission is to identify and categorize attacks [1].

It has become clear in recent times that the ability to identify attack patterns is crucial given the continuous evolution and increasing sophistication of cyber threats. A report by firewall maker SonicWall shows a significant increase in ransomware attacks of 105% in 2021 compared to the previous year. Additionally, there were a staggering 5.4 billion malware attacks in 2022 [2]. Artificial intelligence (AI) has a central role in addressing this pressing issue, leveraging machine learning and deep learning techniques to construct intelligent NIDS. The remarkable capabilities offered by machine learning enable meticulous analysis of vast volumes of network traffic data, tackling intricate classification challenges and automating decision-making processes.

Over the last decade, researchers have introduced a myriad of machine learning and deep learning-based solutions aimed at enhancing the efficacy of NIDS, pinpointing malicious attacks [3] [4] [5]. The architecture of the machine learning network is a core feature of this complex process. This framework encompasses several key stages: data preprocessing to ensure readiness for data analysis, feature selection to identify relevant variables, model selection to determine the optimal algorithm, training to absorb data patterns, evaluation to assess model performance, and prediction to apply trained models to new data, generating actionable outcomes. This framework is visually depicted in Fig. 3.

However, machine learning and deep learning algorithms often face the challenge of imbalanced class distributions, with certain classes significantly more prevalent than others. This imbalance poses a formidable hurdle as learning algorithms tend to gravitate toward the majority class, impacting the accuracy of classification, particularly for specific intrusion types. Several applications, for example, energy forecasting and climate data analysis [6], operate in nonstationary environments. In other words, the process of generating data is changing over time. Branco et al. [7] undertook a negative impact test of class imbalance on classifiers like decision trees, neural networks, and k-nearest neighbor. It is argued that imbalanced domains are caused by a mismatch between the importance assigned by the user to some predictions and the representativeness of those values when they are applied to the available sample data. This misclassification can have dire consequences, necessitating further investigations into intrusions if normal behavior classes are inaccurately categorized. Moreover, inaccurate intrusion categorization has the potential to inflict harm upon systems [8].

From the vantage point of data mining, the minority class often carries heightened significance. To address biases stemming from imbalanced data scenarios, it is essential to create intelligent systems, which constitute the field of "learning from imbalanced data". The essence of the class imbalance problem is often distilled into a ratio reflecting total occurrences in minority classes relative to their majority counterparts. Imbalanced data embody traits such as overlap, minimal distinct density, noisy data, and dataset variance, collectively posing substantial challenges to effective categorization.

Recently, an array of cutting-edge learning techniques has emerged, tailored to confronting classification issues embedded within imbalanced datasets [9]. Navigating the reconciliation of class imbalance is closely intertwined with addressing overlap, consistent with the overarching objective of establishing decisive boundaries between classes and facilitating clear differentiation across the spectrum of learning models [10]. This ensemble of techniques enhances accuracy across various strata, spanning inconspicuous elements and random sampling, all without necessitating replacement.

The main objective of this study is to review scientific papers addressing the problem of imbalanced data in the field of NIDS and analyze the methods used to tackle this issue. The analysis showed that oversampling techniques, such as the Synthetic Minority Over-Sampling Technique (SMOTE) and the Adaptive Synthetic (ADASYN) sampling approach, are commonly used to balance datasets.

The remainder of the paper is structured as follows: Section II outlines the survey methodology, Section III presents a comprehensive overview of the datasets, Section IV examines the prevalent techniques employed to address imbalanced data, and finally, Section V provides concluding reflections and highlights potential avenues for future research.

II. Survey Methodology

To conduct the survey concerning imbalanced data within intrusion detection datasets, the study undertook a meticulous analysis of scholarly articles sourced from esteemed publishers of research literature, namely Elsevier, Springer, MDPI, and IEEE. A two-fold approach was employed to select the most pertinent papers. First, we searched specific keywords associated with unbalanced data, such as "class imbalance" and "intrusion detection system", to pinpoint papers likely to address the subject matter. In the second phase, we conducted a meticulous assessment to exclude scientific papers that did not originate from reputable academic journals. This stringent process guaranteed the inclusion of papers that adhered to rigorous academic standards and were founded on robust research methodologies. By applying these dual steps, we identified and curated research papers that offered valuable insights into the intricacies of imbalanced data within intrusion detection datasets.

The holistic workflow of these techniques to address imbalance is succinctly portrayed in Fig. 1.

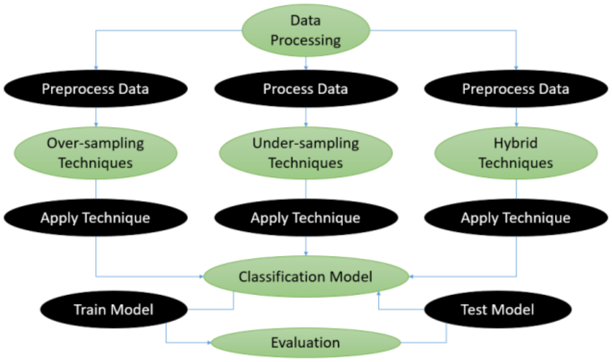

Fig. 1. Flow of imbalance technique approaches.

III. Data Description

Intrusion detection datasets exhibit variations in terms of release dates, sizes, attack classifications, and data collection methods. This section offers a comprehensive overview of prominent datasets utilized in intrusion detection research, providing insights into their key attributes and significance.

A. CICIDS2017

The CICIDS2017 dataset, delivered in 2017, is a significant asset containing roughly 2.8 million records with 83 features. It remains as a demonstration of the developing idea of digital dangers, embodying fourteen unmistakable assault types going from customary Forswearing of Administration (DoS) assaults to additional refined methods like Cross-Site Prearranging (XSS). The expansiveness and profundity of this dataset make it an important resource for concentrating on the complexities of organization intrusion detection [11].

B. CSE-CIC-IDS2018

Presented in 2018 by the Canadian Organization for Network safety (CIC) and Correspondences Security Foundation (CSE), the CSE-CIC-IDS2018 dataset addresses a huge progression in intrusion detection research. With roughly 16.2 million records and 80 features, this dataset gives a rich wellspring of information for examining different sorts of intrusion assaults, including Conveyed Refusal of Administration (DDoS) and beast force web assaults. The sheer volume and variety of assault examples make it an optimal possibility for far reaching examination and assessment of detection systems [12].

C. CIDDS-001

The Coburg Intrusion Detection Data Sets (CIDDS-001), stand apart as a noticeable dataset for network-based intrusion detection, flaunting roughly 32 million records with 14 credits. What sets this dataset separated is its broad inclusion of assault types, incorporating a stunning 92 particular classifications going from Savage Power to Ping Outputs. The wealth and granularity of this dataset make it an important asset for scientists looking to investigate the full range of organization intrusion situations [13].

D. KDD99

The KDD Cup 99 dataset, beginning from 1999 under the support of the Guard Progressed Exploration Ventures Organization (DARPA), addresses a primary asset in the field of intrusion detection. In spite of its age, this dataset remains profoundly significant, containing around five million records with 41 features. Its attention on essential assault types, for example, DoS, test, Client to Root (U2R), and Remote to Nearby (R2L) gives important bits of knowledge into the early scene of digital dangers and the viability of detection procedures. [14].

E. UNSW-NB15

Delivered in 2015 by the Digital Reach Lab, the UNSW-NB15 dataset offers a cutting edge viewpoint on intrusion detection, highlighting 49 features and enveloping nine assault types. Its consideration of assorted assault classes, including Conventional, Exploits, and Observation, mirrors the developing idea of digital dangers in contemporary organizations. Additionally, its generally late delivery guarantees its importance in tending to ebb and flow difficulties in intrusion detection research [14].

F. UNSW-NB18

The UNSW-NB18 BoT-IoT dataset, an expansion of the UNSW-NB15 dataset, addresses a significant extension regarding information volume and assault groupings. With more than 72 million records and assault classes like Keylogging, operating system, and Information exfiltration, this dataset offers remarkable bits of knowledge into the complicated interaction between IoT gadgets and organization security. Its accessibility in different renditions, incorporating a consolidated variant with roughly three million records, gives adaptability for scientists fluctuating computational assets [15].

G. NSL-KDD

The NSL-KDD dataset fills in as an improvement to the KDD Cup 99 dataset, tending to weaknesses like information overt repetitiveness and copies. While its emphasis stays on essential assault classes steady with KDD Cup 99, its smoothed out construction and end of superfluous information make it a more productive and open asset for intrusion detection research [6].

H. UWF-ZeekData22

Arising in 2022, the UWF-ZeekData22 dataset addresses a spearheading exertion in network checking, utilizing imaginative information assortment procedures and examination strategies. With roughly 18 million records and 14 sorts of assaults, this dataset offers new bits of knowledge into arising dangers and weaknesses in present day organizations. Its joining with the open-source Zeek instrument further upgrades its utility for specialists and experts the same [16].

I. UGR'16

The UGR'16 dataset, custom-made for recognizing network security peculiarities, includes two unmistakable sets: Alignment and TEST. Laid out in 2016, this dataset catches a different exhibit of malware classes, including secure shell (SSH), spam, and port filtering. Its attention on abnormality detection highlights the developing significance of proactive safety efforts in alleviating arising dangers [17]. Table I provides a summary of the characteristics of these datasets.

TABLE I. SUMMARIZES THE OVERALL CHARACTERISTICS OF ALL DATASETS

Dataset	Dataset Type	Records	Features	Number of attacks
CICIDS2017	Multi class	2830540	83	14
CIDDS-001	Multi class	31.959.175	14	92
CSE-CIC IDS2018	Multi class	16.232.943	80	6
KDD99	Binary class	4.898.430	41	4
NSL-KDD	Binary class	N/A	41	4
UGR'16	N/A	16.900.000	12	7
UNSW-NB15	Multi class	2.540.044	49	9
UNSW-NB18	Multi class	3.668.522	42	6

In spite of the lavishness and variety of these datasets, a common worry across each of the nine is information lopsidedness. The lopsided conveyance of assault occasion classes and the striking inconsistency between ordinary traffic cases and those addressing different assault classifications present huge difficulties for intrusion detection research. Tending to these irregular characteristics requires cautious thought of examining procedures, highlight determination, and algorithmic ways to deal with guarantee vigorous and dependable detection capacities.

IV. COMMON STRATEGIES FOR ADDRESSING IMBALANCED DATA

Dealing with imbalanced data has emerged as one of the most formidable challenges in the field of machine learning. Studies have proposed various approaches to mitigate this issue, encompassing data sampling, cost-sensitive analyses, ensemble learning, algorithmic methodologies, and more. These strategies can be categorized into three main types, as shown in Fig. 2.

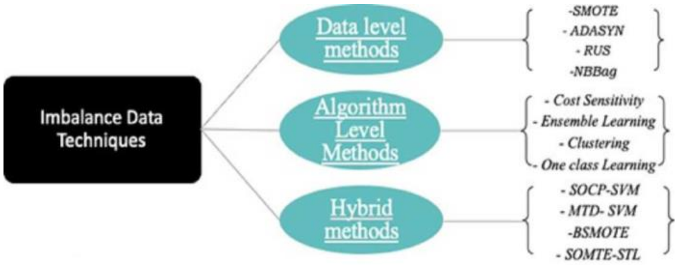

Fig. 2. Handling imbalanced data methods.

Extensive research has been undertaken to tackle the problem of data imbalance, particularly within network intrusion detection systems. This section provides an overview of select studies that examine these techniques. Table II presents a compilation of studies that have employed different approaches across the most widely used intrusion detection datasets to provide a comprehensive understanding of the diverse methodologies aimed at combating imbalanced data issues,

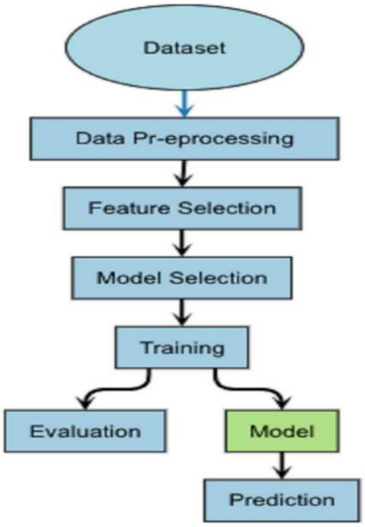

Fig. 3. Machine learning framework.

A. *Data-Level Techniques for Addressing Imbalanced Data*

- Data-level procedures include preprocessing steps pointed toward amending awkward nature inside datasets. These procedures, otherwise called outside strategies, try to accomplish information proportionality by either decreasing greater part class tests or increasing minority-class tests. Normal information level procedures include:

- SMOTE: SMOTE involves generating synthetic instances for the minority class by interpolating existing minority class instances [18]. A new specimen is created by selecting a random k-nearest neighbor (KNN) of an underrepresented instance and generating a value from a random combination of both interpolated instances. This method aids in spreading minority classes into the space occupied by majority classes, resulting in better defined decision boundaries.

- ADASYN: Sampling methods such as ADASYN enhance learning from data distributions by reducing the bias caused by class imbalances and reshaping classification boundaries toward challenging examples [31].

1) Used considerable amount of research has been conducted in the field of NIDS employing data-level techniques, as shown in Table II.

TABLE II. RECENT RESAMPLE TECHNICAL BASED NIDS STUDIES

Dataset	Technique	AI-based approaches		Year	Reference
		ML	DL		
NSL−KDD	SMOTE−ENN	No	Yes	2019	Zhang et al. [19]
CICIDS2017	Uniform Distribution Based Balancing (UDBB)	Yes	No	2019	Abdulhammed et al. [20]

CICIDS2017 KDD99 UNSW-NB15	Ensemble method	Yes	No	2023	Thockchom et al. [30]
UWF-ZeekData22 UNSW-NB15	Random under sampling before splitting. Random under sampling after splitting. (B−SMOTE)	Yes	No	2023	Bagui et al. [16]

a) Ahmed et al. [26] proposed a NIDS framework using various machine learning schemes to detect network attack categories. The framework includes techniques such as data standardization, normalization, and SMOTE. This model achieved 95.1% accuracy on the UNSW-NB15 dataset.

b) Yulianto et al. [21] applied a similar technique to address data imbalance in their proposed IDS. They employed principal component analysis (PCA), ensemble feature selection (EFS), and SMOTE to enhance AdaBoost-based IDS performance on the CICIDS2017 dataset, achieving accuracy, precision, recall, and an F1 score of 81.83%, 81.83%, 100%, and 90.01%, respectively.

c) Karatas et al. [22] employed the CSE-CIC-IDS2018 dataset to build an efficient IDS using the SMOTE technique, resulting in an average increase in accuracy of 4.01% to attain 30.59% accuracy across different machine learning models.

d) Meliboev et al. [27] applied machine learning and deep learning techniques to detect security attacks. They used SMOTE to enhance model performance on the UNSW-NB15, KDD99, and NSL-KDD datasets, achieving accuracy scores of 91.2%, 95.2%, and 82.6%, respectively.

e) Almarshdi et al. [29] developed a hybrid deep learning IDS using convolution neural network (CNN) and long short-term memory (LSTM) algorithms, combined with the SMOTE technique. This model achieved 92.10% accuracy on the UNSW-NB15 dataset compared to 89.90% for the basic CNN model.

f) Fu et al. [28] introduced the Deep Learning Network Intrusion Detection (DL-NID) model using bidirectional LSTM (Bi-LSTM) and attention mechanisms, incorporating the ADASYN technique. This model achieved an accuracy of 90.73% on the NSL-KDD dataset.

g) Liu et al. [25] also employed the ADASYN technique in their proposed IDS, achieving accuracy scores of 92.57%, 85.89%, and an impressive 99.91% on the NSL-KDD, UNSW-NB15, and CICIDS2017 datasets, respectively.

Table III illustrates the ratios of measures that were attained by researchers in each study before addressing the issue of data imbalance using data-level techniques. As can be seen, Liu et al. [25] attained the highest accuracy rate of 99.86% on the CICIDS2017 dataset. In contrast, the lowest accuracy score achieved was 55% in the study conducted by Meliboev et al. [27] on the UNSW-NB15 dataset.

Table IV illustrates the ratios of measures that were attained by researchers in each study after addressing the issue of data imbalance using data-level techniques. Liu et al. achieved the highest accuracy rate of 99.91% when applying the ADASYN technique in their study. Several NIDS models demonstrated improved accuracy after implementing various data-level techniques. For instance, Meliboev et al. conducted a study on the UNSW-NB15 dataset using the recurrent neural network (RNN) algorithm. Initially, they obtained an accuracy rate of 55%, but after applying the SMOTE technique, the accuracy increased significantly to 71.90%. These findings highlight the effect and importance of data-level techniques in enhancing NIDS performance.

TABLE III. RESULTS OF MODELS BEFORE HANDLING IMBALANCED DATA

Algorithm / framework	Dataset	Accuracy	F1-score	Recall	Precision	Reference

		UNSW-NB15	85.89%	-	-	-	
		CICIDS2017	99.91%	-	-	-	

B. Algorithm-Level Approaches

Algorithm-level approaches focus on enhancing the learning capacity of classifier algorithms with regard to minority classes. These methods are often referred to as internal approaches. Techniques such as adjusting the probability estimation or modifying class-specific costs can be employed to benefit minority classes [31].

1) Cost-Sensitive Learning: The cost-sensitive learning framework lies between internal and external approaches. This technique integrates both algorithmic and data-level modifications in a unified approach by altering the learning process and assigning costs to samples accordingly [13].

2) Ensemble Learning: Ensemble learning combines various methodologies to address imbalanced classes. Ensembles based on techniques such as bagging and boosting are commonly used to tackle class imbalance issues.

a) Thockchom et al. [30] employed ensemble methods, specifically the stacking ensemble technique, on the KDD99, CIC-IDS2017, and UNSW-NB15 datasets. The stacking ensemble combined Gaussian naïve Bayes (GNB), decision tree (DT), and logistic regression (LR) classifiers. The proposed model achieved high accuracy levels: 99.80% on CIC-IDS2017, 93.88% on UNSW-NB15, and 99.84% on KDD99.

b) Yilmaz et al. [23] proposed a model for intrusion detection using the UGR'16 dataset. They used generative adversarial networks (GANs) to address the issue of unbalanced data. The degree of balance in the training dataset was determined using multilayer perceptron.

c) Abdulhammed et al. [20] presented an anomaly-based IDS applied to the CICIDS2017 dataset. The imbalanced distribution in the dataset was handled using a uniform distribution-based balancing method. Performance metrics were calculated based on five classifiers: the random forest (RF) algorithm, a Bayesian network, linear discriminant analysis (LDA), and quadratic discriminant analysis (QDA). The model achieved the highest accuracy of 98.80%.

C. Hybrid Approaches

Hybrid strategies amalgamate methods from both algorithmic and information levels in ideal extents. These methodologies consolidate the qualities of algorithmic and information level strategies while relieving their particular shortcomings, at last further developing order accuracy. Normal hybrid calculations include:

1) SOCP-SVM: Support Vector Machines with Second-Order Cone Programming.

2) MTD-SVM: Multi-Threshold Decision-Support Vector Machines.

3) B-SMOTE: Borderline SMOTE.

4) SOMTE-STL: Synthetic Minority Over-sampling Technique-SMOTE with Tomek Links.

Application of Hybrid Techniques for Handling Imbalanced Data

1) Jiang et al. [24] employed two methods to address data imbalance on the NSL-KDD and UNSW- NB15 datasets. They combined one-side selection (OSS) to reduce majority samples and SMOTE to increase minority sample sizes. A deep hierarchical network model integrating CNN with BiLSTM achieved accuracy rates of 83.58% and 77.16%, respectively. Zhang et al. [19] also employed a hybrid sampling method combining SMOTE with edited nearest neighbors (SMOTE-ENN) to achieve an accuracy of 83.31% on the NSL-KDD dataset using CNN.

2) Al and Dener [13] utilized hybrid sampling with SMOTE and Tomek-Links Sampling (STL) to address imbalance in the CIDDS-001 and UNSW-NB15 datasets. Their Hybrid Deep Learning Approach combined CNN and LSTM algorithms, outperforming other deep learning and machine learning algorithms.

Trial review accentuate the power of information driven oversampling calculations in reinforcing base classifier execution, really tending to irregularity issues across different models, including AI and profound learning. The SMOTE has demonstrated success in diverse domains by creating new minority instances, circumventing overfitting and promoting classifier generalization [32]. This approach effectively addresses imbalance issues across various models, including machine learning and deep learning.

V. Conclusions

All in all, this review has embraced an exhaustive examination of strategies for tending to class irregularity in interruption identification datasets, with an emphasis on the viability of different procedures. Through our examination, we have assessed the presentation of oversampling techniques, for example, Destroyed and ADASYN, revealing insight into their adequacy in moderating the difficulties presented by imbalanced information.

Our examination has added to the comprehension of how these strategies can be applied with regards to interruption location, giving bits of knowledge into their assets and impediments. We have emphasized ADASYN's notable effectiveness in rebalancing datasets and increasing classification accuracy in particular.

While our review takes care of many systems, it's fundamental to perceive the developing idea of interruption location research. While we zeroed in basically on oversampling procedures, there are different methodologies, for example, bunch based under-examining that warrant further investigation. This features the continuous quest for creative procedures to handle class unevenness in interruption location situations.

In synopsis, our review fills in as an important asset for scientists and professionals in the field, offering experiences into the present status of the workmanship and making ready for future progressions in tending to the difficulties of imbalanced information in network interruption location.

1) Statistical Analysis: To measure the exhibition of intrusion detection frameworks when applying SMOTE and

ADASYN oversampling methods, we look at the exactness, F1-score, review, and accuracy measurements straightforwardly as shown in Table V and Fig. 4:

TABLE V. AVERAGE TECHNIQUE LIST

Technique	Accuracy	F1-score	Recall	Precision
SMOTE	88.13%	86.96%	85.68%	90.68%
ADASYN	92.28%	89.65%	93.17%	86.38%

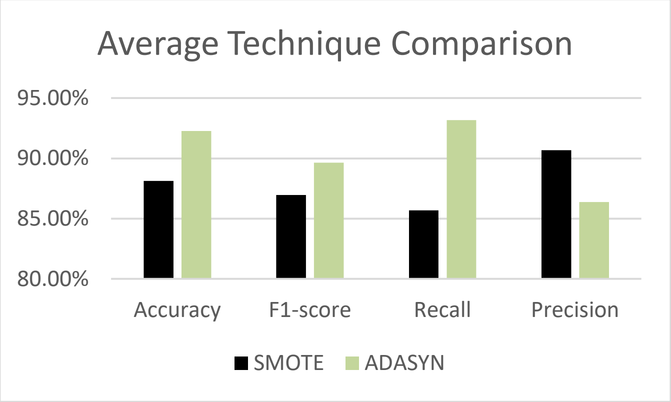

Fig. 4. Average technique comparison.

These discoveries exhibit that while the two strategies work on the general execution of intrusion detection frameworks, ADASYN gives better exactness, F1-score, and review, while SMOTE might be ideal for keeping up with higher accuracy.

Roadmap for Generative Models Redefining Learning in Egyptian Higher Education

Laila Mohamed ElFangary
Professor of Information Systems, Faculty of Computers and Artificial Intelligence,
Helwan University, School of Business and Finance,
NewGiza University, Cairo, Egypt

***Abstract*—Artificial Intelligence (AI) Generative models have become powerful tools in all sciences, research, academia, and businesses. Egyptian Universities need to leverage those models while using them ethically and responsibly to survive in the current global market. This paper explains the evolution of those models, from basic natural language processing by IBM in 1954 to the current powerful revolutionary generative models. The paper presents research that helps us get desired outputs or behaviors from generative models through prompt engineering, chain of thought prompting and ReAct. The paper presents Egypt and Egyptian Universities readiness and steps taken to get advantage of the latest AI technologies. The paper examines the training of those models to identify their advantages and disadvantages for university members focusing on the Egyptian context. The roadmap for Egyptian Universities use of generative models consists of a SWOT analysis; an infographic of policies and guidelines with regard to faculty and students use of generative models at Egyptian Universities promoting academic integrity and innovation, while minimizing the risks associated with this technology; A table of types and severities of penalties for policy violations by students using generative models is specified and finally a framework for nontechnical users of generative models of reusable patterns to get the optimal desired output of the models is developed.**

Keywords—Artificial intelligence; generative models; prompt engineering; higher education; Egyptian universities

I. Introduction

This paper aims to provide a comprehensive framework for the use of generative models in Egyptian Universities. Generative Models are the current revolutionary artificial intelligence (AI) applications that act as our reliable, adjustable, and expert assistant in any research or learning process. Chatbots have automated and personalized services and processes across different industries. Generative models redefined our learning, instead of just using search engines like Google to access information now. We can use conversational engines like Google Bard or Microsoft Bing to not only get the list of sources but also get from it the relevant data presented and analyzed in the format we want. A review of universities adopting generative models and how those models evolved, highlighting their current rapid and revolutionary development is presented. Research on generative models' optimal use and Egypt readiness is examined to develop a roadmap for Egyptian Universities use of generative models.

II. Literature Review

A. *Universities Adopting Generative Models*

Egypt did not make generative models like ChatGPT officially accessible until November 2023 even though ChatGPT was officially introduced to the public in November 2022 [1]. As a result, Egyptian universities are lagging in the use of generative models. A recent study aiming at understanding how universities establish policies regarding the use of AI tools and exploring factors that influence their decisions analyzed top 500 universities according to the 2022 Quacquarelli Symonds (QS) World University Rankings. The study revealed that less than one-third of the universities had implemented ChatGPT policies. The use of generative models like ChatGPT in learning and teaching represented approximately 67.4% of universities, more than twice the number of universities that banned it. The study revealed that there are significant variations of university policies [2]. Generative AI is changing creative work as it can produce new content based on existing data, on creative work and workers. AI can augment human creativity, enhance productivity, and foster innovation through widely available online applications such as ChatGPT, Dall-E, and Midjourney. Today managers and leaders must leverage generative AI for their organizations and teams [3].

Harvard University, a leader and early adopter of generative AI explained, early in 2023 on its website, the concepts, and applications of generative AI and how it can create new content based on existing data. The web page provides guidelines for the responsible and ethical use of artificial intelligence at Harvard University. It covers topics such as data privacy, security, transparency, accountability, and fairness. It also provides examples of how AI can be used to advance research, education, and innovation at Harvard. The web page provides the vision and mission of the AI at Harvard program, which aims to foster collaboration and innovation in AI across the university. AI leaders and partners at Harvard can post their research on generative models. Through its website it showcases AI projects and research conducted by Harvard faculty and students, as well as AI tools and platforms available for the Harvard community. It provides resources and events related to AI education and innovation [4]. Generative models, despite their sophistication, have several limitations, GPT models still grapple with issues such as data biases leading to "hallucinations" or inaccurate outputs [5]. Birmingham University explained generative AI, how it can be used for teaching and learning, the benefits, and challenges of using it. It provided examples of generative AI tools and projects, as well as resources and guidance for educators and students [6]. Imperial College provided guidance for instructors and students on the use of generative AI tools, such as ChatGPT, for academic work. It explained the benefits and risks of using these tools, the ethical and academic implications, and the best practices for citation and acknowledgement [7].

B. *Generative Models Evolution*

Early developments that lead to current generative models started since 1954, with IBM and Georgetown University laying the background for natural language processing (NLP) through automating language translation [8]. In 1966 MIT researcher Joseph Weizenbaum created ELIZA, the chatbot that used pattern recognition and predefined rules to simulate human conversation, marking the beginning of NLP research [9]. In 1983, The Boltzmann machine modeled the probability of the entire network being in a certain state, where neurons influence each other bidirectionally and the strength of these connections is represented by weights, which are learned during training. The evolution of generative models from Boltzmann machines in 1983 to Transformers represent a series of breakthroughs in machine learning which include Deep Belief Networks (DBN) and Restricted Boltzmann machine (RBM) the neural network architectures used for feature learning, classification, and generative models [10].

In the 1990s, the advancements in machine learning took place as deep learning employed neural networks for data processing enabling the development of increasingly sophisticated language models. In 1997, Long Short-Term Memory (LSTM) networks enabled the development of deeper neural networks capable of handling larger datasets [11]. Since 2010 there was dramatic transformation of NLP, as in 2010 Stanford’s Core NLP suite provided algorithms for complex NLP tasks such as sentiment analysis and named entity recognition [12]. In 2011, Google Brain a deep learning artificial intelligence research team of Google AI, applied advanced resources and features like word embeddings allowing NLP systems to better understand the context of words [13].

In 2013, Diederik P. Kingma and Max Welling introduced the artificial neural network architecture Variational Autoencoders (VAE). VAE generates data by learning an approximation of the data's distribution, as the autoencoder has an encoder that maps input data to a lower-dimensional representation, and a decoder that reconstructs the original data from this representation [14]. Generative Adversarial Networks (GAN) developed by Ian Goodfellow and his colleagues in June 2014, enabled the creation of diverse and high-quality data samples that overcame initial training challenges and simplified the process of data representation and generation. GANs consist of two neural networks; the generator produces data samples from random noise, attempting to mimic the distribution of real data, while the discriminator tries to distinguish between real and generated data [15]. GANs enabled the creation of diverse and high-quality data samples. These early developments set the stage for the Transformer model, which has shown remarkable proficiency in tasks like text classification and sentiment analysis.

In 2015, Elon Musk and others endowed one billion dollars for the establishment of Open AI as a nonprofit organization to prepare against the unintended action of robotics and AI [16]. The aim was to have safe artificial general intelligence (AGI) as stated in Open AI mission: “Our mission is to ensure that artificial general intelligence—AI systems that are generally smarter than humans—benefits all of humanity” [17]. The introduction of Transformer models in 2017 revolutionized NLP. This architecture, trained on huge amounts of data, is a Large Language Models (LLM) that understands context and generates human-like text. The Generative Pre-Trained Transformer (GPT), GPT-1 introduced by Open AI in 2018, is a conversational LLM that has progressively increased in size and complexity. Elon Musk left Open AI board in 2018 and cut off funding as he criticized OpenAI’s partnership with Microsoft and was working on his own AI chatbot, TruthGPT. Microsoft invested $11 billion in OpenAI since 2019 and has exclusive access to its technology as it benefits from using OpenAI’s AI services in its products and platforms [18]. Since 2019, Microsoft’s cloud service Azure served as OpenAI’s exclusive provider of cloud computing services.

Generative AI has evolved rapidly since the release of ChatGPT in November 2022, research reveals that it could annually add to the global economy up to $4.4 trillion as it affects different industries, functions, and tasks, with marketing and sales, software development, and knowledge work.[19] In 2022, text-to-image models like Stable Diffusion, Midjourney and Dall-E generated images from textual descriptions. Dall-E uses Transformer architecture, the backbone of today’s NLP models, it is based on Contrastive Language–Image Pretraining (CLIP)'s ability to relate text to images, a neural network model developed by OpenAI, designed to understand, and link images with textual descriptions [20].

Open AI released ChatGPT to the public in November 2022, other companies released new iterations of generative AI on weekly basis. OpenAI’s ChatGPT, powered by GPT 3.5 an improved version of its 2020 GPT3 release, became the first widely used text-generating product, gaining a record one hundred million users in two months, making it the fastest-growing application at the time. As ChatGPT provided human-like conversations with users Microsoft integrated it with Bing search. During December LLM like Cohere supported more than one hundred languages, making it available on its enterprise AI platform and Google’s Med-PaLM trained for specific use cases and domains, such as clinical knowledge. During February Amazon’s Multimodal-CoT model incorporated chain-of thought (CoT) prompting, in which the model explains its reasoning, and outperforms GPT3.5 on several benchmarks; Meta’s LLaMA (Large Language Model Meta AI) became more efficient to use than some other models and Microsoft introduced Kosmos-1, a multimodal LLM that can respond to image and audio prompts in addition to natural language.

In March 2023 alone, there were six major steps forward, as Salesforce announced Einstein GPT, leveraging OpenAI's models, the first generative AI technology for customer relationship management; OpenAI released GPT4, which offers significant improvements in accuracy and hallucinations mitigation, claiming 40% improvement versus GPT3.5; Anthropic introduced Claude, an AI assistant trained using a method called constitutional AI, which aims to reduce the likelihood of harmful outputs; Microsoft announced the integration of GPT4 into its Office 365 suite, potentially enabling broad productivity increases; Google released Bard, an AI chatbot based on the Language Model for Dialogue Applications (LaMDA) family of LLMs; Bloomberg announced an LLM trained on financial data to support natural language tasks in the financial industry. While in April Amazon announced Bedrock, the first fully managed service that makes models available via API from multiple providers in addition to Amazon's own Titan LLM [21].

Chatbot AI the promising and disruptive technology automated and personalized various services and processes across different industries making major technology companies compete in the chatbot market, such as META, Anthropic, Deepmind, and Microsoft [22]. Currently Microsoft announced a new multiyear, multibillion-dollar investment with OpenAI, which is the third phase of partnership, following Microsoft's previous investments in 2019 and 2021, the renewed partnership is seen to accelerate breakthroughs in AI and help both companies engage in supercomputing at scale and commercialize advanced technologies in the future [23]. As of December 2023, ChatGPT has over 180 million users. Chat.openai.com website has around 1.7 billion visits per month [24]. OpenAI Chat GPT expects $200 million in revenues and $1 billion by 2024 [25].

C. Optimizing Generative Model Performance

Prompts are the way of communication with currently popular AI applications based on LLM's like ChatGPT. The quality of outputs from a conversational LLM is due to the quality of the prompts. Prompt patterns systematically guide LLMs enhancing interaction and task automation, providing a reusable solution framework to recurring problems. They provide a structured approach to customizing LLM output and interactions. Prompt Engineering is the art of crafting effective prompts to guide the responses of a machine learning model to achieve desired outputs or behaviors. Prompt engineering is a key strategy for enhancing the effectiveness and efficiency of generative models. Studies related to how best users of the models can craft their prompts classified prompt patterns into input semantics, output customization, error identification, prompt improvement, interaction, and context control [26].

Other research examining language models, including GPT-3 by OpenAI and LaMDA by Google, revealed that standard prompting is not always effective for reasoning tasks but Chain-of-thought prompting where generative models' users give an input, a series of reasoning steps, and an output, proved superior to standard prompting especially in arithmetic, commonsense, and symbolic reasoning. Users provide a step-by-step example of the way to solve a specific problem and the model follows the same sequence. This revealed the capabilities of generative models as it can learn from few natural language examples rather than relying solely on extensive training datasets. Chain-of-thought prompting enabled LLM's detail their reasoning before delivering an answer as users presented it with examples of such reasoning, making it generate its' own chains of thought. It got the model to break down multi-step problems, allowing for detailed reasoning, offering insight into the model's thinking, and facilitating debugging and understanding [27].

Other studies introduced ReAct methodology for the generative models to solve tasks by making language models both "think" (reason) and "do" (act). The models can interact with external information sources, like searching on the internet, and then adjust their reasoning based on what they find. As a generative model is capable of reasoning and acting, it does not just pull information; it thinks about what information to pull next, making its decision-making more dynamic. This method enabled the models to make plans, think of innovative ideas, and change their plans if something new comes up, it is like playing a game where it constantly must decide what to do next. ReAct Compared to other methods gave better results at answering questions, checking if facts are true navigating websites. When compared to other ways of teaching AIs, ReAct was better as the model learns with using few examples helping it make better decisions as it thinks through the problem [28].

D. Egypt's Preparedness for Generative Model Integration

Egypt readiness for generative models is clear in its national AI Strategy, which presents a comprehensive plan for integrating Artificial Intelligence (AI) into various sectors in Egypt, including education and university research. The strategy emphasizes the importance of building human capacity in AI, promoting AI research, and encouraging the integration of AI in university curricula and research projects. This is clear in its vision: "Exploit AI technologies to help achieve Egypt's development goals for the benefit of all Egyptians, and to promote Egypt's regional leading role to be an active global player in AI." Further to achieve its mission: "Create an AI Industry in Egypt, including the development of skills, technology, ecosystem, infrastructure and governance mechanisms to ensure its sustainability and competitiveness" [29]. It highlights the establishment of AI faculties in universities and the development of AI-related educational programs. A priority sector of Egypt AI strategy is Natural Language Processing (NLP) reflecting a strong commitment to integrating generative models and AI technologies in the educational sector. Egypt is producing the "Egyptian Charter on Responsible AI," which is based on the OECD AI Principles. This charter aims to include assessment guidelines, technical guidelines, and best practices for entities utilizing AI systems including universities [30].

Egypt developed various programs and collaboration among government agencies, private sector, and civil society to safeguard Egypt's ICT infrastructure and promote a secure digital environment [31]. Egypt Social Responsibility Strategy focuses on integrating technology in various social sectors including education [32]. Law No. 151 of the year 2020 provides a legal framework for the protection of personal data in Egypt as it establishes guidelines and regulations for electronic processing and control as well as penalties for violations of the law. [33] As the law outlines protection of personal data, and cross-border data transfer rules, it confirms with data subject rights regarding entering sensitive or confidential data into publicly available AI tools to protect privacy and conform to institutional information security policies. Egyptian Universities adhere to data privacy regulations and ensure the secure storage and handling of data this includes data used for training and deploying generative models.

Egypt has been a leader in educating its youth in the field of Artificial Intelligence as it established since 1996, the current Faculties of Computers and Artificial Intelligence to better reflect its educational mission and research focus. Those faculties support national educational objectives that include a strong emphasis on enhancing educational quality and integrating modern technology processes [34]. Egyptian Universities are working closely with government bodies and industry leaders to develop policies and guidelines for AI use in education and research. With regards to AI applications, Egyptian Universities established partnerships with tech companies specializing in AI and generative models to facilitate the exchange of knowledge and resources. One Example is Dell Technologies that has launched an initiative in collaboration with the Ministry of Communications and Information Technology (MCIT) to provide AI training in five Egyptian universities. This included workshops for university professors and students in AI and its applications, such as data science and big data engineering. Participating universities included Cairo University, Ain Shams University, the Arab Academy for Science and Technology, the American University in Cairo, and the German University in Cairo [35]. MCIT and The Egyptian Universities Network for Artificial Intelligence (EUNAI) a consortium of Egyptian universities work collaboratively on AI research and education offering resources and training programs related to generative models 36].

III. Pros and Cons of Generative Models in Egyptian Higher Education

In developing policies and guidelines for the use of generative models, Egyptian Universities should recognize that these engines are essential in teaching and research as they will change the way students learning and practice of humanities and Sciences, offering new products and services. Generative models redefined students learning process as they interact with the models to conduct conversational research to brainstorm summarize and analyze any topics of interest, they can understand new concepts by interactive simulations and games, and they can get advice on any issue [37]. Yet the model can create deepfakes, it may support events or hypothesis that are false and become convincing deceiving people. Students may copy the content in assignments without proper citation will result in the spread of cheating and plagiarism. Students should properly cite the use of AI tools using proper citation format adopted by most academic style guides [38], [39], [40]. Further studies have revealed that AI detection tools are still not reliable, several academic institutions do not recommend using the available automatic detection applications for academic integrity violations using generative AI, given their unreliability and inability to provide definitive evidence of violations [41]. OpenAI withdrew its detection software due to the software’s unreliability [42]. Criteria for approval to use generative models in assignments included academic justification, scope of use, source and type of generative model, data sensitivity and ethical implications, citation and transparency, review and approval process [43],[44],[45],[46]. Top universities presented types and severities of penalties for violations by students using generative models [47], [48].

There are disadvantages specific to Egypt and Egyptian Arabic speaking public universities context, as 59% of websites are in English and only 9% are in Arabic [49]. The results of an analysis of top ten million websites revealed that 60.4 % were in English and 1.1% was in Arabic. Yet from the years 2001 till 2011, the rate of online growth of the Arabic language use increased by 2,501% while it increased by 281% for English language [50]. Hyperscale data centers, which are ones with over 5,000 servers, are around six hundred in the world. Around 39% of them are in the US, while China, Japan, UK, Germany, and Australia account for about 30% of the total. This leaves the rest of the world 31% [51]. The share of internet users as a percentage of the population globally is 63%. In the developed world population, it is 90% while in the developing world it is 57% [52] [53]. Today’s popular generative large language models were trained on internet data these include AI applications developed by OpenAI the GPT-3,[54] DALL-E,[55][56] and Google BERT [57][58]. As Generative models were trained on internet data that is mostly in English presenting the English-speaking population, developed countries point of view. The model may generate content that does not confirm with the culture of the Arab world, it might produce biased information intentionally or unintentionally which may harm faculty members or students. The teaching in Egyptian public universities is in Arabic [59] with which the models may generate text but certainly it is not the language that it had much of its training in.

IV. Roadmap for Egyptian Universities use of Generative Models

The roadmap for Egyptian Universities use of generative models consists of a SWOT analysis; An infographic of policies and guidelines with regard to faculty and students use of generative models at Egyptian Universities promoting academic integrity and innovation, while minimizing the risks associated with this technology; a table of types and severities of penalties for policy violations by students using generative models is specified and finally a framework for nontechnical users of generative models of reusable patterns to get the optimal desired output of the models is developed.

A. *SWOT Analysis of Egyptian Universities*

The following is strengths, weaknesses, opportunities, and threats (SWOT) analysis on the use of Generative Models for Egyptian Universities that aides the development of a policy compatible with Egyptian laws, Artificial Intelligence strategy, cultural and social context. Table I is a SWOT analysis revealing the potential benefits of using generative models in education and research and the potential risks associated with the use of this technology, such as plagiarism and cheating.

TABLE I. SWOT ANALYSIS

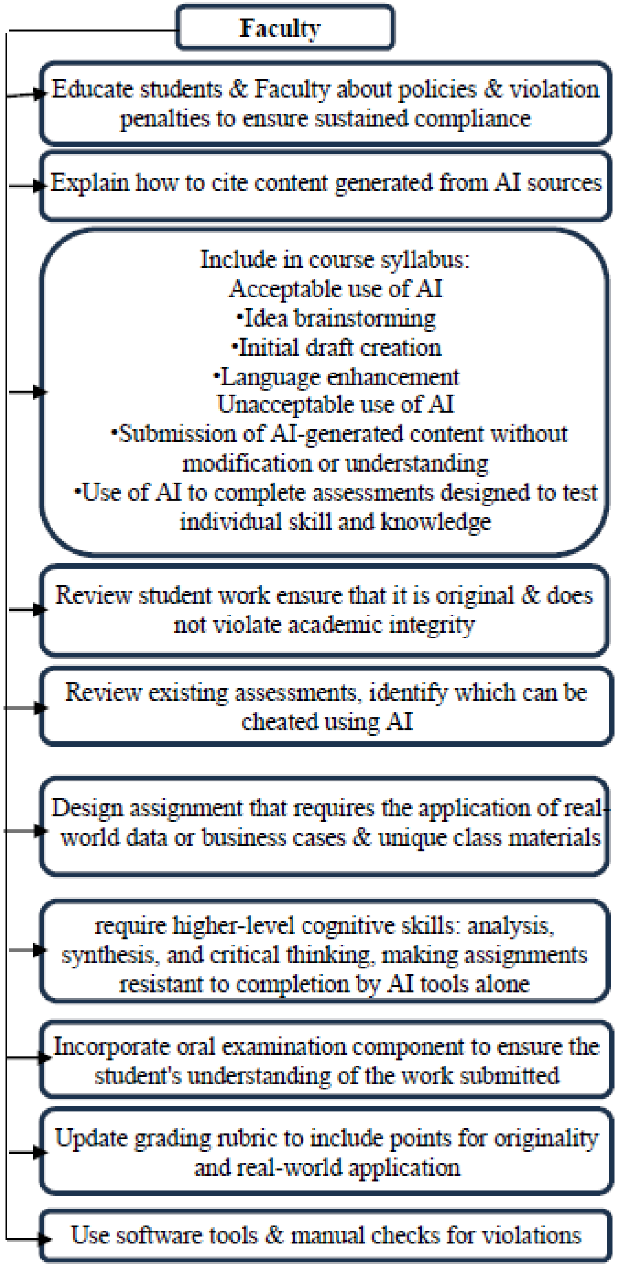
Strengths	**Weaknesses**
-Conversational research, brainstorming, summarization, and analysis on any topic -Create interactive simulations and games that help learn and understand any concept -Provide consulting services	-Present biased content -Generate plagiarized content -Used in cheating -Create deepfakes that can be used to deceive people -Create harmful content
Opportunities	**Threats**
-Revolutionize the way Science and humanities taught and practiced. -Make better decisions in projects and research -Create products and services	-Generate reports against cultural and social context of Egyptians -AI detection applications may result in false negatives or positives -Spread of misinformation and harm of entities

B. *Policy Initiatives for Egyptian Universities*

The following is a suggested policy initiative to ensure that the use of generative models at Egyptian Universities is to promote academic integrity and innovation, while minimizing the risks associated with this technology. The National Council of Artificial Intelligence may collaborate with existing academic integrity committees in public universities and with faculty members to extend the responsibilities of the existing Academic Integrity Committee to review reports of academic misconduct involving generative models. The committee should be responsible for generative model risk assessment evaluating the ethical implications of their use in academic activities.

Based on Egypt AI strategy and aligned with the Universities Organization Law and its executive regulations Universities and Faculties should include the suggested policy statement: In accordance with Egypt AI strategy and The Universities Organization Law and its executive regulations, students must uphold academic integrity while also leveraging the potential of Artificial Intelligence (AI), including Generative Models, for academic endeavors. Use of AI is subject to faculty and instructors' approval. Acceptable uses of AI include idea brainstorming, initial draft creation, and language enhancement. The University prohibits the use of AI-generated content without proper citation or to complete assessments designed to evaluate individual skills. AI detection tools and human judgment may be employed to scrutinize submissions for AI-generated plagiarism. Faculty may require an oral examination to validate a student's understanding of any AI-assisted submissions.

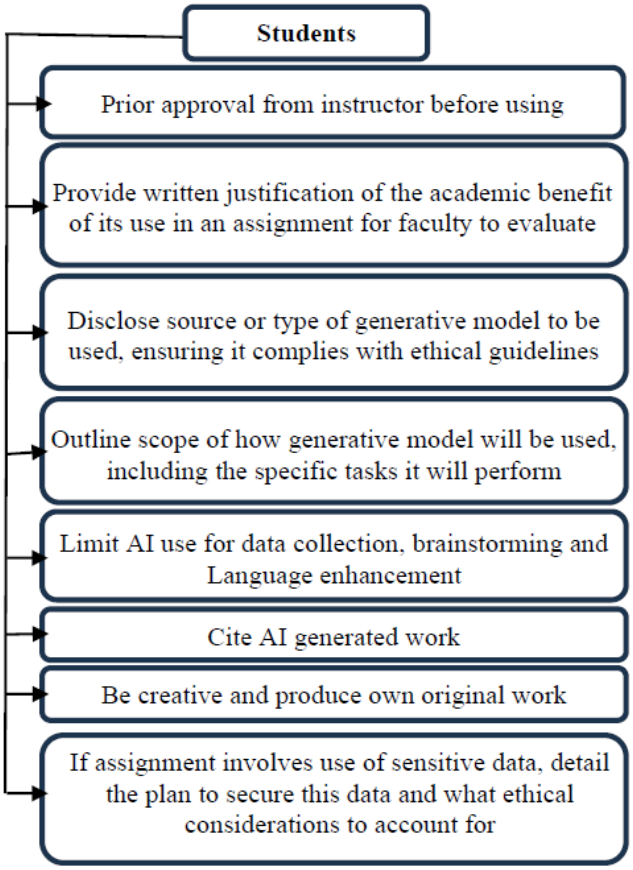
1) Faculty guidelines: For University Faculty, Fig. 1 titled Faculty Guidelines for Integrating Generative Models into Coursework provides step-by-step guidelines. Changes in assignment design, submission protocols and grading rubric should take place to integrate the use of generative models. Faculty should review assessment methods to enable the development of AI resistant assignments and use oral examinations when possible. The Syllabus should include acceptable use that faculty will discuss in classes.



Faculty
Educate students & Faculty about policies & violation penalties to ensure sustained compliance
Explain how to cite content generated from AI sources
Include in course syllabus:
Acceptable use of AI
•Idea brainstorming
•Initial draft creation
•Language enhancement
Unacceptable use of AI
•Submission of AI-generated content without modification or understanding
•Use of AI to complete assessments designed to test individual skill and knowledge
Review student work ensure that it is original & does not violate academic integrity
Review existing assessments, identify which can be cheated using AI
Design assignment that requires the application of real-world data or business cases & unique class materials
require higher-level cognitive skills: analysis, synthesis, and critical thinking, making assignments resistant to completion by AI tools alone
Incorporate oral examination component to ensure the student's understanding of the work submitted
Update grading rubric to include points for originality and real-world application
Use software tools & manual checks for violations

Fig. 1. Faculty guidelines for integrating generative models into coursework.

2) Student guidelines: Student Guidelines for Effective Use of Generative Models in Courses. Fig. 2 include preliminary approval for the use of generative models, responsible use of AI and disclosure of their use. Students can use AI as a tool for data collection, brainstorming and Language enhancement enabling them to be creative and produce their own original work. Faculty should review the request based on these criteria and provide a decision within a reasonable period.



Students
Prior approval from instructor before using
Provide written justification of the academic benefit of its use in an assignment for faculty to evaluate
Disclose source or type of generative model to be used, ensuring it complies with ethical guidelines
Outline scope of how generative model will be used, including the specific tasks it will perform
Limit AI use for data collection, brainstorming and Language enhancement
Cite AI generated work
Be creative and produce own original work
If assignment involves use of sensitive data, detail the plan to secure this data and what ethical considerations to account for

Fig. 2. Student Guidelines for effective use of generative models in courses.

V. Penalties for Student Policy Violations

Penalties for misuse of generative models that fit the Egyptian Universities context include an academic integrity committee to investigate suspected AI-assisted cheating, apply penalties, and regularly review criteria for generative models use with the Egyptian national AI Committee. The academic integrity Committee should decide on the penalty depending on the infraction level ranging from minor, moderate, major to severe, and whether it is a first-time offense or more. Further students that feel that the review committee unfairly penalized them should file an appeal within fourteen days of the committee's decision. The following Table II provides examples of infraction severity and type of penalties applied depending on the number of times the students did the violation.

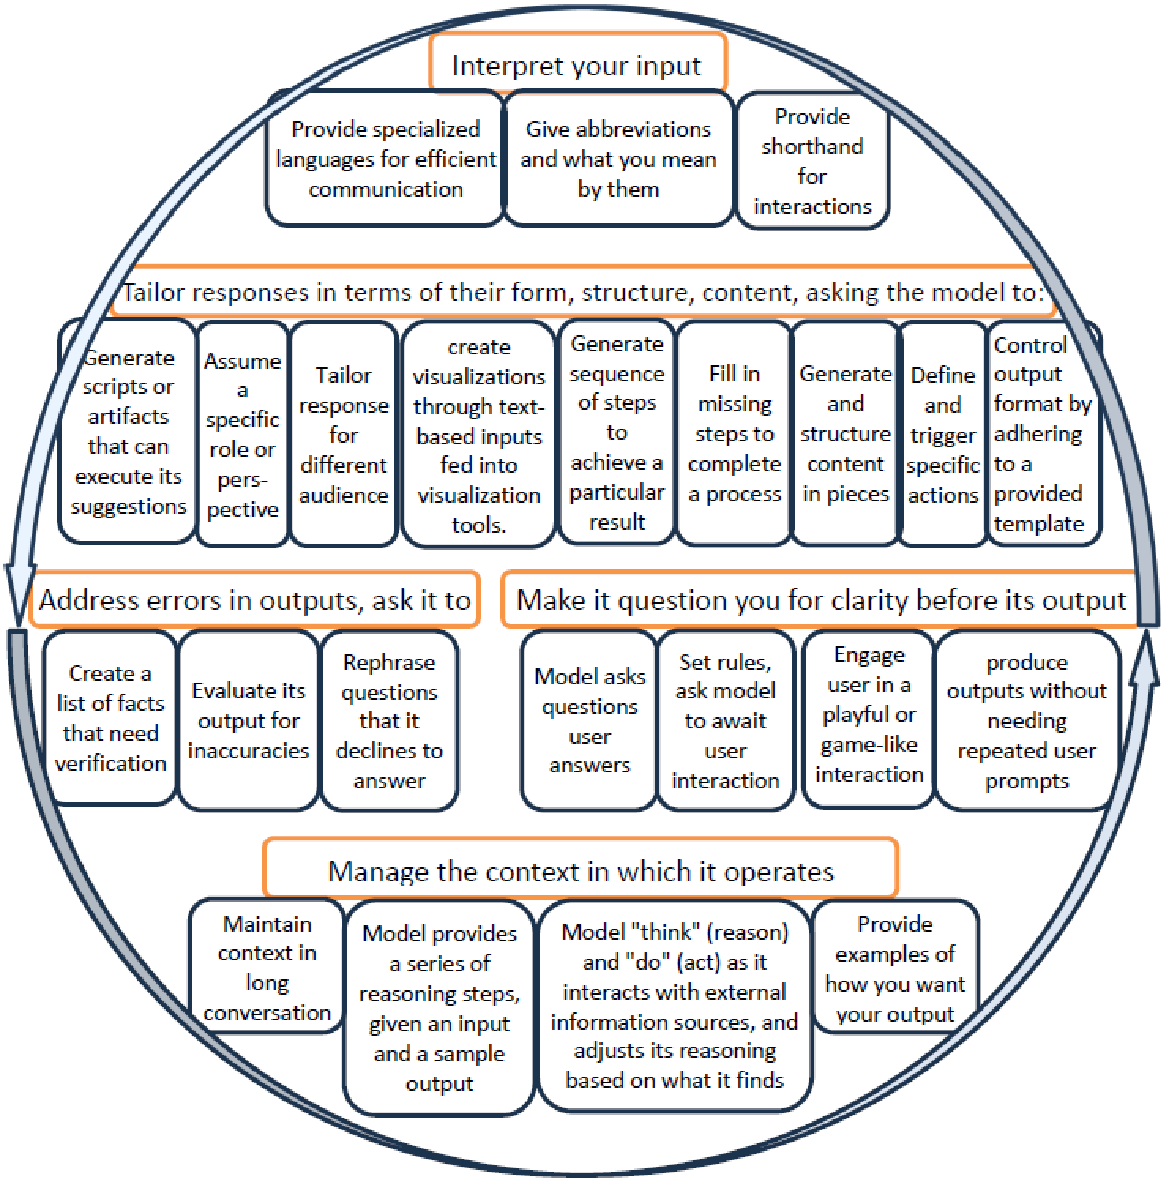
TABLE II. Penalties for Student Policy Violations

Severity / Type of Use	**Offense**		
	First	***Second***	***Third***
Minor: Unauthorized for non-graded class activities, not citing the use of a generative model in a homework assignment	Warning, requirement to attend integrity workshop	20% Deduction of assignment points	Failing grade for the assignment
Moderate: Unauthorized in graded homework assignments, group projects	50% Deduction of assignment points	Failing grade for assignment .	Failing the course
Major: To complete exams, final projects, or thesis work; instances of unauthorized use across several courses	Failing the course and academic probation	Mandatory integrity counseling	Expulsion from the university
Severe: To produce work that is published as original research without citation, plagiarizing on a scale that affects the university reputation	Possible legal action, expulsion from university	Students may file an appeal with the Academic Integrity Committee within 14 days of receiving penalty notice.	

VI. Framework for Optimal Generative Model Output

To get the best out of those models, Egyptian University members whether faculty, students, or administration should build their skills regarding prompt Engineering. Fig. 3 is an infographic for nontechnical users of generative models based on ChatGPT as it has the fastest growing number of users. In my proposed framework users should put in mind that it is useful to interpret the input, for example, when I entered in my prompt course syllabus, I identified that whenever I refer to "course code" it should refer to this course syllabus. It was further useful when identifying the use of common abbreviations instead of repeating the detail in each prompt of the conversation. Persona tailors the model response, for example respond as an information System professor, and further specify the audience as it differs in output sophistication for elementary school students or PhD Students in the field. Today's models can generate code to execute any instructions, create visualization images and graphs to whatever topics discussed through text to image instructions.

Generative models can, if given the steps show alternative results or asked for the steps of a certain result and use templates to generate output in specific structure. To avoid and check for errors the model can identify inaccuracies in its output and create a list of facts that need validation. If it refuses to answer a question the question can be sub divided or rephrased. Further the model can switch roles with the user as it gathers through questions all the data from the user necessary for it to generate the output. The User may present any rules and the model can participate in any game presenting simulations and automating its output. Once the user refers to key aspects in a conversation the model can maintain context, it can provide step by step explanations given a certain input and output showing how to arrive at the desired result using users' resources. The model can reason as it accesses external information whether available over the internet or given to it by the user as attachments and based on this information it will adjust its output. Once you provide an example of how a process should be, it will follow the same process on different data.



Interpret your input
Provide specialized languages for efficient communication
Give abbreviations and what you mean by them
Provide shorthand for interactions
Tailor responses in terms of their form, structure, content, asking the model to:
Generate scripts or artifacts that can execute its suggestions
Assume a specific role or pers-pective
Tailor response for different audience
create visualizations through text-based inputs fed into visualization tools.
Generate sequence of steps to achieve a particular result
Fill in missing steps to complete a process
Generate and structure content in pieces
Define and trigger specific actions
Control output format by adhering to a provided template
Address errors in outputs, ask it to
Create a list of facts that need verification
Evaluate its output for inaccuracies
Rephrase questions that it declines to answer
Make it question you for clarity before its output
Model asks questions user answers
Set rules, ask model to await user interaction
Engage user in a playful or game-like interaction
produce outputs without needing repeated user prompts
Manage the context in which it operates
Maintain context in long conversation
Model provides a series of reasoning steps, given an input and a sample output
Model "think" (reason) and "do" (act) as it interacts with external information sources, and adjusts its reasoning based on what it finds
Provide examples of how you want your output

Fig. 3. Generative model communication framework.

VII. Conclusion

In conclusion, this paper provides a comprehensive framework for the use of generative models for Arabic speaking, developing countries focusing on Egyptian Universities. A roadmap for the use of generative models in redefining the learning is developed. The research presented SWOT analysis on the use of Generative Models for Egyptian Universities where general factors applicable to all academia worldwide and other factors specific to Egypt were analyzed. Further, a policy that is compatible with Egypt laws, initiative, and cultural and social context was developed. This included key aspects of step-by-step guide for faculty inclusion of generative models in curriculum and students use of the models, in addition to a matrix of types and severities of penalties for policy violations by students using the models. This paper proposed an infographic of patterns that work for non-specialized students to get the best out of the generative models' capabilities. The framework is a reference for current generative models' capabilities in communicating with users. Finally, Universities should adjust their policies based on an ongoing monitoring of the actual use of generative models.

VIII. Future Work

Potential directions for further research could include cross-cultural comparative studies as Egyptian universities and universities from different regions with diverse cultural and legal frameworks could be compared to provide insights into how generative models are adapted globally. To fine-tune policies and educational strategies over time, longitudinal studies may be conducted to assess the impact of implementing generative models in the curriculum on students' learning outcomes, faculty teaching methods, and overall academic integrity. Universities should increase adoption and effective use of AI through working on technology acceptance modeling to understand faculty and students' attitudes towards generative models and factors influencing acceptance and resistance of generative models.

A Smart Framework for Enhancing Automated Teller Machines (ATMs) Fraud Prevention

Mohamed Abdelsalam Ahmed[1], Nada Tarek Abbas Haleem[2], Amira M. Idrees[3]
Information Systems Department-Faculty of Commerce & Business Administration, Helwan University, Cairo, Egypt[1]
Business Information Systems Department-Faculty of Commerce & Business Administration, Helwan University, Cairo, Egypt[2]
Faculty of Computers and Information Technology, Future University in Egypt, Cairo, Egypt[3]

***Abstract*—Over the past years, clients have largely depended on and trusted Automated Teller Machines (ATMs) to fulfill their banking needs and control their accounts easily and quickly. Despite the significant advantages of ATMs, fraud has become a very high risk and danger. As it leads to controlling all clients' accounts. In this paper, the proposed framework is using the iris recognition technology combined with the one-time password (OTP) to detect and prevent the known as well as the unknown attacks on ATMs and provide a table of the attackers and the suspected attackers with a counter to take a preventive action with them. Our proposed preventive actions are: card withdrawal, flagging the identified iris as an attacker in the database, notifying the card owner with this suspicious behavior, reporting to the Central Bank of Egypt (CBE), and calling the police when an attacker's iris counts three capturing times, even if for a different card. Two case studies were attempted to achieve the highest accuracy, the first case was using the Chinese Academy of Sciences' Institute of Automation V1.0 (CASIA-IrisV1) dataset using the Cosine Distance. The second one was using the Indian Institute of Technology Delhi (IITD) dataset using k-Nearest Neighbors (KNN) and Histogram of Oriented Gradient (HOG) techniques together reaching 100% accuracy.**

Keywords—Automated Teller Machines (ATMs); digital banking; image processing; iris recognition; One Time Password (OTP); machine learning; fraud detection; fraud prevention; biometrics; security; banking

I. Introduction

Automatic Teller Machines (ATMs) provide a non-stopping banking services without any time or place limitations [1, 2], which gives it this huge importance worldwide. It allows cash withdrawal, cash deposits, checking the account balance, paying bills and many other banking services over 24 hours / 7 days.

Despite all these advantages, ATMs are a very risky banking channels if they are not provided with the right security methods [3]. The current ATM framework was designed to avoid this risk, the current framework is that ATMs are designed with the Personal Identification Number (PIN) as the main authentication factor and some monitoring cameras to record all the daily interactions.

However, this design does not provide the required protection as the PIN has not become a very safe authentication technique [4], as when ATM cards are lost or stolen, an unauthorized user can get and enter the correct PIN and access all the clients' accounts and money [5]. In addition, this monitoring tool is insufficient because of the lack of security guards and because the human factor is the only monitoring factor, this security design is not helpful for detecting or preventing ATM fraud. This can be helpful after a fraud occurs.

The current – after fraud - scenario is that the client receives an SMS from the bank saying that he made a withdrawal with a specific amount, then the client begins to realize that he is a fraud victim and starts to report this fraud and asks for this video to check who is the criminal. In most of these cases, clients cannot get their money back or find the criminal. As the number of ATM users is growing daily because of the digital transformation awareness and the high increase in the number of deployments of new ATMs in addition to the increasing economic impact of the banking services [6]. So, detecting the fraud or the criminal is not enough as a preventive action all the time. As the same criminal can do this fraud in many other places with many different clients easily without detecting that he is a recorded criminal.

In this paper, a framework is proposed by using the iris recognition for the authentication of ATMs which can automatically detect and prevent the known as well as the unknown attacks on ATMs. Iris recognition is an advanced biometric technology that is used for detecting and identifying human iris from an image or video. It has many benefits that make it a perfect solution for the ATMs authentication. One of these benefits is that they are stable and unique over the whole life.

The biometric authentication became an important concern for many researchers because of the huge continuous wave of ATMs attacks worldwide. It is the process of identifying whether a specific person is the authorized person or not using a unique biological characteristic such as the fingerprint, face recognition, Iris recognition, voice recognition, behavior authentication and many other types [7, 8]. It works by comparing the enrolled biometric in the database with the person's captured biometric to authenticate. That is what makes it very helpful in the fast transactions-based authentications, as it is fast, accurate and not forgettable.

Iris recognition is an advanced biometric technology that is used for detecting and identifying human iris from an image or video. It has many benefits that make it a perfect solution for the ATMs authentication. One of these benefits is that it is stable and unique over the whole life [9]. The biometric authentication has been a very important concern for many researchers due to the huge continuous wave of attacks all over the world [10]. Biometric authentication is the process of identifying whether a specific person is the authorized person or not using a unique biological characteristic such as the fingerprint, face recognition, Iris recognition, voice recognition, behavior authentication and many other types [11]. It works by comparing the enrolled biometric in the database with the person's captured biometric to authenticate. That is what makes it very helpful in the fast transactions-based authentications, as it is fast, accurate and not forgettable [12].

Our paper is organized as the following: Section I which is an introduction of our paper including all the related topics of our framework. Followed by Section II, which gives a background about fraud and some biometric technologies with a comparison of how much they are effectively works to prevent any fraud. Then Section III, which includes a sample of other similar researches that were taken as a reference while our study. Then Section IV, which proposes our framework with two case studies to achieve the highest accuracy, followed by Section V which presents the structure of the database of our proposed framework. Then Section VI provides our experimental setup showing how our framework was implemented to get the case studies' results. Then Section VII, which presents the research contribution showing how our workflow overcomes the limitations of the other proposed solutions. Then in Section VIII we will present our results. And finally, Section IX concludes the paper.

II. Background

Fraud has many increasing techniques when it is related to the banking sector. It may be direct to the banking channels by stealing the card itself, the client's credentials, and many other direct ways. Or through any other way like the social media for example, which has been increasing and by sequence affects the banking sector which makes it a must to consider the information credibility as a very high concern to be considered at any fraud detection and prevention solution including all its perspectives [13]. It had been noticed also that the gap that allows the fraud to increase is the spread of using the technology by all its applicable tools without giving an attention to the relation between the more advanced the current technologies are and the greater the risk of the leakage of our data security and privacy [14].

For the example of social media, we are currently facing a very increasing phenomenon of customizing fraud campaigns over the social media and SMSs using some fake information and news to be able to steal the clients' banking data, which leads to being able to attack their banking channels and take their money [15, 16].

Noting that the fraud process is not necessary to start from the attacker's side, as sometimes the user is the initiator of this fraud, by listening to the spreading social media fake news (specially the Facebook as it is the most influencing social media application) and aim to gain more money and benefits then enters his banking or financial data to an untrusted source [17, 18].

There are various techniques that can be used to authenticate using biometrics. Below is a comparison in Table I:

TABLE I. COMPARISON OF THE BIOMETRIC TECHNOLOGIES

Biometrics	Cost	Accuracy	Performance	Flaws	Stability
Iris	High	High	High	Lighting	High
Retina	High	High	High	Glasses	High
Face	Medium	Medium	Medium	Beard, Glasses, Age	Medium
Fingerprint	Low	Medium	Medium	Dirt, Dryness	High

III. Literature Review

In this section we will provide a view of the historical researches about the iris authentication and how researchers used it to detect the ATM fraud actions and enhance the ATM security.

After reviewing several studies, we found that some researchers used only the iris recognition as a single authentication technique, while some of them used it in cooperation with other techniques also.

Some researchers used the multi-factor authentication approach, Akinola Kayode E. and his colleagues, (2019) proposed in their paper they used the iris recognition with the PIN to obtain the benefit of both the accuracy, the low cost (compared to the other approaches), the small size of its tool, the easiness of its programming language, and to avoid the risk of using only the PIN. The results of their paper were that the Fake Acceptance Rate (FAR) was 0% while Fake Rejection Rate (FRR) was found to be 99.94% which means that it was not possible for any fraudster to match the identity of another user in the database. There was 1.6% of the authentic users got denied access, which is small amount. ATM users should be security focusing while withdrawing money to prevent forced withdrawals. However, using the PIN with the iris is useless as a security with, it is just making the ATM journey timing longer which is against the purpose of the ATMs [19].

Other research such as Joyce Soares and A.N.Gaikwad, (2016) didn't only decide to replace the current ATM system with another biometric system using the iris recognition and the fingerprint to authenticate. But also protected the ATMs terminals from the thieving attacks and from the fire danger by making provisions of the pump motor and a direct current (DC) motor for rolling the shutter. Their system uses two techniques each for each recognition type. The Circular Hough Transform for iris recognition and the minutiae matching algorithm for fingerprint recognition. From the technical perspective, they used the ARM7 (a processor) based LPC2148 (a microcontroller) controlling to make the accessing process easy and smart. Their system's results provide the average accuracy of the overall system is 91.6% and the of these biometric technologies: average equal error rate is 0.076 in addition to securing from the fire and thief attacks. It also shows that the taken time for whole the ATM transaction is less than 10 seconds per user. After analysis, they mentioned that the accuracy and the security of this system is maximum and reaches up to 95%. However, they lost the main purpose of the

ATMs, which is the fast timing of making financial banking interactions. Also, if the user used the choice of the fingerprint, he/she will face a hygienic risk [20, 21].

Mohamed A. Kassem and his colleagues, (2014) noticed the high risk of attacks on the ATMs. So, they decided to make a framework that is secured an also fast using the multimodal biometrics. But to choose the right biometrics to be used they followed some criteria like the universality, uniqueness, permanence, measurability, performance, acceptability, and the circumvention. The main purpose of this proposed system is to reach a higher performance than using only a single biometric system. After passing the above-mentioned criteria to choose the right biometrics, they decided to use the fingerprint and the iris together as they are having the most acceptance of people than face recognition for example and based on the availability of their integration devices. However, they lost the main purpose of the ATMs, which is the fast timing of making financial banking interactions. In addition, if the user used the choice of the fingerprint, he/she will face a hygienic risk [22].

N.Geethanjali and K.Thamaraiselvi, (2013) proposed a system that is not only based on the multimodal biometrics, but also on the two levels of authentication in the ATMs. The system provides three choices of the multimodal biometrics during the authentication: Fingerprint and Iris, Iris and Face, Face and Fingerprint. The user can choose any system of them based on the biometrics that he wants to enroll for the verification to be authenticated. If the user failed to authenticate because of any reason, the user will be directed to a second choice of verification using another two biometrics. This will make the false acceptance rate (FAR) and the false reject rate (FRR) decrease and ensure a high level of security. However, they lost the main purpose of the ATMs, which is the fast timing of making financial banking interactions. Also, if the user used the choice of the fingerprint, he/she will face a hygienic risk [23].

Other research used only the iris recognition technology, like Pratiksha, and her colleagues, (2020), they used the iris recognition as it offers a new solution for identifying, authenticating and securing the user by analyzing the random pattern of the iris. Their iris system works by recognizing the person from an eye image and comparing it to the human iris pattern that is already stored at the template database. They used CASIA database at their paper and applied their project using MATLAB. Their results after using 20 images for training, 10 images for testing to calculate some features such as the contrast, the energy and the homogeneity were that their proposed system ad recognition rate of 94.6 % using the probabilistic neural network (PNN) [9].

Abiodun Esther Omolara and his colleagues, (2019) proposed a system that solves the ATMs fraud problem using the FingerEye. Their proposed system passes with three phases. The FingerEye is a strong system that is integrated with the iris scanning authentication. They register the users' iris at the profile creation stage and analyze it then convert it into a binary code then store it at the bank database. Their target was not only to prevent the ATM fraud, but also to design a new solution that helps the clients with disabilities as the blind clients to use ATMs' services. The results were saying that the proposed solution has a competitive advantage than the other proposed solutions as it does not only mitigate the Shoulder-surfing attacks, but prevents all the possibilities of shoulder-surfing, eavesdropping, and man-in-the-middle attacks. They also found that they improved the efficiency of the system by making the average authentication time to be 1.4 seconds instead of the current timing which is 6.5 seconds (using the bin or the password). They were unable to test this solution on a blind client, but they concluded that the authentication will be also secured and faster. However, the proposed module is really a difficult & complicated workflow, as they are depending on many processes and tools to implement the framework. So, it loses the main purpose of the ATMs, which is the fast timing of making financial banking interactions [24].

Komal Marathe and Hemant Mande, (2019) decided to develop a system to protect the ATMs' consumers from any fraud. They proposed an application called "Face Recognition System" (FRS), which can identify the client from a captured digital image or even from a video. The normal technique of this system is to match the captures photo's facial features with the stored one at the database. But that is not everything, if they availed a strong lighting and learning, the future authentication trials and transactions will have a wide base with boarders to compare with in case of failing at the original account image comparing. In their system, when the face image gets captured, the face gets located, then the iris gets detected and scanned then compared with the captured image at the database. At the end, they found that using a 2D and 3D technology had protected the authentication security level of the ATM strongly [25].

S. Koteswari and his colleagues, (2012) applied the concept of visual cryptography (VC) in the iris recognition by implementing the cryptographic software using Matlab 7.9.A modified version which is a method of maintaining the security of the captured images. That happens by dividing the image into a random share with encrypting it using a key. And it will be decrypted also using the same key. Their proposed method focuses on protecting the iris templates that are saved at the database. They divided their proposal into two phases. The enrolment phase and the authentication phase. As a result of their proposed system, this identification system is quite simple requiring few components and is effective enough to be integrated within security systems that require an identity check. The errors that occurred can be easily overcome by the use of stable equipment. Judging by the clear distinctiveness of the iris patterns we can expect iris recognition systems to become the leading technology in identity verification in ATM banking [26].

IV. The Proposed Framework

After passing with all the previous papers, we can start with our proposed framework. In this paper we are proposing a multi-authentication framework that detects and prevents the fraud actions on the ATMs, that will be applied through using the iris recognition biometric technology at the authentication phase at the ATM with the One Time Password (OTP) as a second step authentication to allow the client to access his/her accounts. The following figure represents the proposed framework (see Fig. 1):

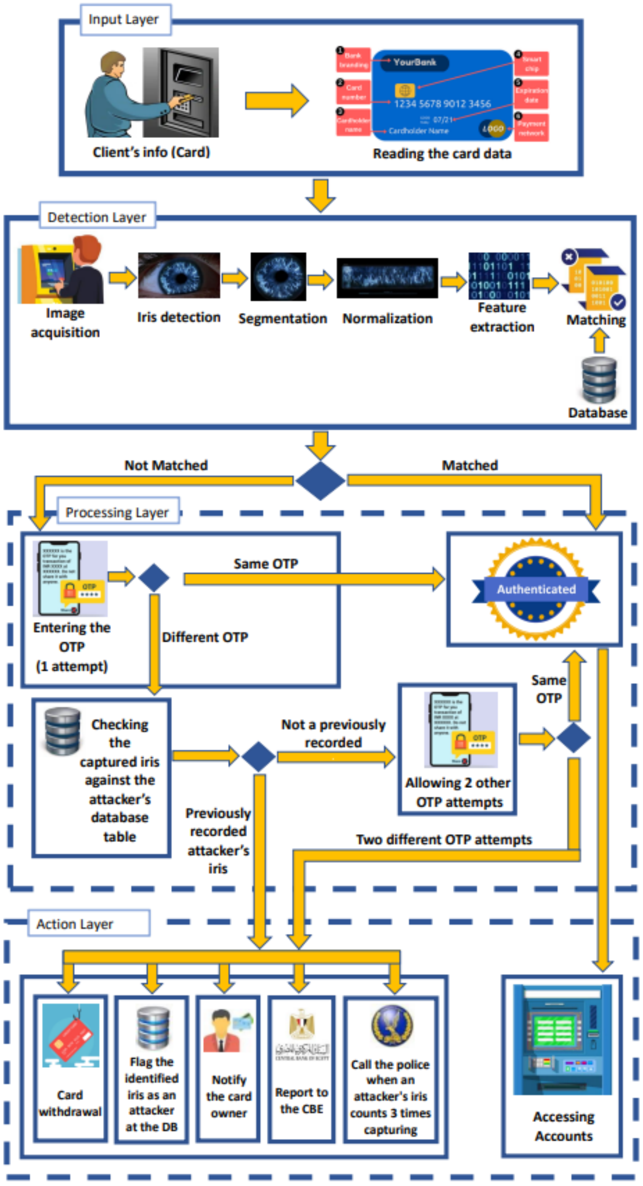

Fig. 1. The proposed framework.

In order to achieve the goal of our framework, we have gone through two case studies with two different techniques and datasets which gives us the ability to discover the most efficient and effective technique to achieve our main goal with this framework.

1) Case study (1): Our framework contains four layers (see Fig. 5), the input layer (see Fig. 2), the detection layer, the processing layer, and the action layer. It starts with the input layer, in which the client enters his card into the ATM, then the ATM starts reading the card data which includes the bank branding, the card number, the cardholder's name, a smart chip, an expiration date, and the payment network.

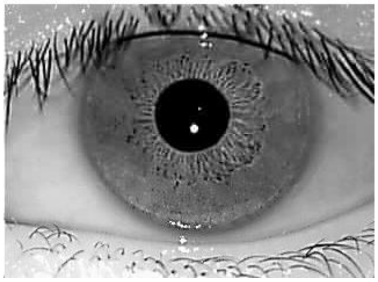

Fig. 2. The input layer.

Then it moves to the second layer, which is the detection layer, it includes the iris recognition cycle which starts with the user's image acquisition, and then it automatically detects the user's iris. After detecting the iris, this detected iris goes through another three steps before being matched with the database:

- Segmentation: In which the iris region gets isolated from the whole eye (see Fig. 3).

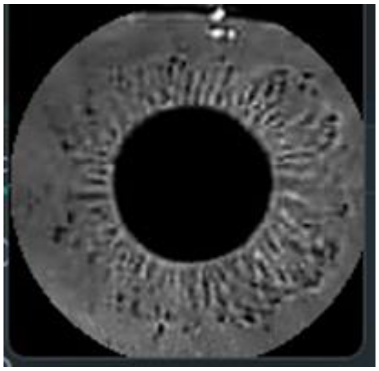

Fig. 3. The segmentation layer.

- Normalization: In which the segmented iris image gets transformed into a fixed size and dimensions to be ready for the next step (see Fig. 4) which is the feature extraction step. The below formula [27] is the normalization formula which was used at our framework:

$$\begin{gathered} I_n(X,Y) = I_o(x,y) \\ x = x_p(\theta) + \left(x_i(\theta) - x_p(\theta)\right)\frac{Y}{M} \\ y = y_p(\theta) + \left(y_i(\theta) - y_p(\theta)\right)\frac{Y}{M} \\ \theta = 2\pi X/N \end{gathered} \tag{1}$$

where, I_n is a $M \times\ N$ (64× 512 in our experiments) normalized image, $x_p(\theta)$, $y_p(\theta)$, and $\left(x_i(\theta) - y_p(\theta)\right)$ are the coordinates of the inner and outer boundary points in the direction θ in the original image I_0 [27].

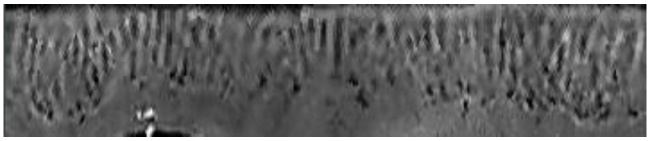

Fig. 4. The normalization layer.

- Feature Extraction: In this step, the normalized iris image gets converted to a set of parameters (mathematical parameters) to be ready to be easily matched with the database at the next step. The below formulas [27] are the feature extraction formulas which were used at our framework:

$$G(x,y,f)=\frac{1}{2\pi\delta_x\delta_y}exp\left[-\frac{1}{2}\left(\frac{x^2}{\delta_x^2}+\frac{y^2}{\delta_y^2}\right)\right]M_i(x,y,f),$$
$$i=1,2.$$
$$M_1(x,y,f)=\ cos\left[2\pi f\left(\sqrt{x^2+y^2}\right)\right] \qquad (2)$$
$$M_2(x,y,f)=\ cos[2\pi f(xcos\theta+ysin\theta)]$$

where, $M_1(x,y,f)$ denotes the modulating function, M_1 and in M_2 are the modulating function of the defined filter and Gabor filter, respectively, f is the frequency of the sinusoidal function, δ_x and δ_y are the y axis, respectively, the θ denotes the orientation of Gabor filter [27].

$$m=\tfrac{1}{n}\textstyle\sum_{\omega}|F_i(x,y)|\,,\quad \sigma=\tfrac{1}{n}\textstyle\sum_{\omega}\big||F_i(x,y)|-m\big| \qquad (3)$$

where, w is an 8 × 8 block in the filtered image, n is the number of pixels in the block w, and m is the mean of the block ω [27].

$$F_i(x,y)=\ \iint I(x_1,y_1)\,G_i(x-x_1,y-y_1\,)dx_1dy_1;$$
$$i=1,2 \qquad (4)$$

where, G_i is the ith channel of the spatial filters, $I(x,y)$ denotes the ROI, and $F_i(x,y)$ is the filtered image [27].

The last step at the iris recognition cycle and the detection layer is the matching step, in which the extracted feature gets compared to the stored one at the database during the enrolment phase to see if it is the cardholder or not. The following formula [27] is the matching formula which was used in our framework:

$$d_3(f,f_i)=1-\frac{f^T\quad f_i}{\|f\|\ \|f_i\|} \qquad (5)$$

where, f and f_i are the feature vector of an unknown sample and the i th class, $d_n(f,f_i)$ denotes the similarity measure, d_3 is the L1 distance measure, L2 distance measure (i.e., Euclidean distance) and cosine similarity measure, respectively. The feature vector f is classified into the mth class, which is the closest mean, using the similarity measure $d_n(f,f_i)$ [27].

It leads us to the next layer, which is the processing layer, in this layer; we will have two possible options: the first one is that the captured iris and the stored iris at the database are matched, and the second option is that they are not matched.

1) *If* matched, the user will authenticate normally and will be able to move to the action layer to access his/her accounts.

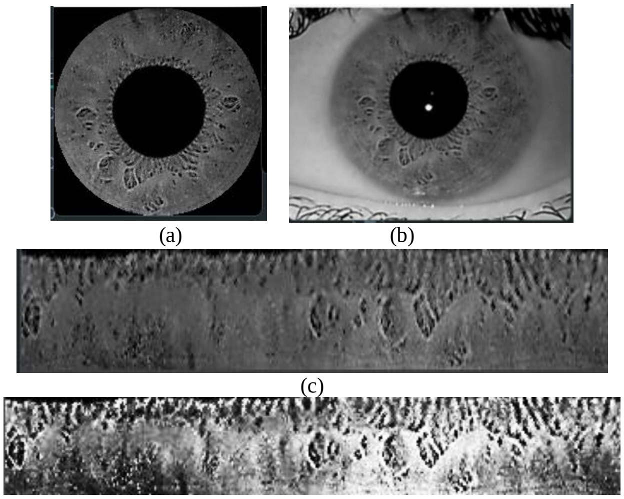
2) *If* not matched, the user will receive an SMS with an OTP on his/her mobile and will be asked to enter it into the ATM for a just one attempt. If it was the same OTP, then he/she will authenticate normally and will be able to move to the action layer to access his/her accounts. But if it is not the same OTP, then the system will start checking the captured iris against the attackers database table to check if it is a previously recorded attacker's iris or not.

If his/her iris got matched with any attacker's iris, then the system will move to the action- layer to take the below actions on the user as he/she will be detected as an attacker:

1) *Card* withdrawal.
2) *Flag* the identified iris as an attacker at the DB.
3) *Notify* the card owner.
4) *Report* to the CBE.
5) *Call* the police when an attacker's iris counts three times capturing, even if for a different card.

If not matched, then the user will receive another SMS with an OTP and will be asked to enter this OTP with only two attempts. If he/she entered the same OTP, then he/she will authenticate normally and will be able to move to the action layer to access his/her accounts. But if he/she entered a wrong OTP at the two attempts, then the system will move to the action layer to take the below actions on user as he/she will be detected as an attacker:

1) *Card* withdrawal.
2) *Flag* the identified iris as an attacker at the DB.
3) *Notify* the card owner.
4) *Report* to the CBE.
5) *Call* the police when an attacker's iris counts three times capturing, even if for a different card.



(a) (b)

(c)

(d)

Fig. 5. Image pre-processing (a) The original image (b) The segmented / localized image (c) The normalized image (d) The normalized image after enhancement.

2) *Case study (2):* Our framework at this case contains a pre-processing stage, which is the Image Pre-processing stage, as we are using here Indian Institute of Technology Delhi (IITD) dataset, which contains eyelashes and eyelids and are in many different sizes which affects the results efficiency. So, we will go through the Image Resizing to unify the iris images and make sure these are all with the same dimensions and suitable for the framework's best results by allowing it to get the same number of features from all the dataset's iris.

Considering also that there is a relation between decreasing the image’s size and the processing time [28] so, the images sizes became (200×200 pixels) after this stage.

The second stage is the Segmentation stage, at this stage the mission is to remove the non-useful surrounding regions of the iris by detecting the boundaries of both the iris and the pupil automatically which ease the feature extraction process of these images. As an output of this stage, we should have a ready image for the next stage which is the Feature Extraction stage. In this case study, we are using the Daugman‘s Integro-Differential operator technique for the iris segmentation which works by dividing the eye into two circles, the pupil and the iris, then detecting the center and radius of the pupil and the iris. The circle on the pupil explains the distance between the pupil and the iris then the circle on the iris shows the distance between the iris and the other parts of the eye. The third stage is the Feature Extraction, which is the most important stage and in which the needed and important features get extracted from the image and un-needed features are excluded. In our framework we will use Histogram of Oriented Gradients (HOG) for the feature extraction stage. In which the image gets divided into some cells, and each cell into some pixels. Now, we have arrived to the last stage at our framework which is the Classification stage, at this stage we have user K-Nearest Neighbor (k-NN) algorithm to be able to obtain the highest accuracy which works by finding the nearest neighbor object at the extracted feature space then gives an output that the entered iris belongs to which group of features.

V. Structure of Database

Fig. 6 shows the Entity Relation Diagram (ERD) that represents our proposed framework, it contains all the related parties of our framework and explains the relation between them. The “Attackers History” table includes all the history of any detected attacker, which has a many-to-one relation with the “Attackers” table, which counts the iris’s capturing time as an attacker. It also has all the required tables with all the data that helps at the fraud detection, prevention, reporting to the central bank of Egypt (CBE), and taking the right legal action.

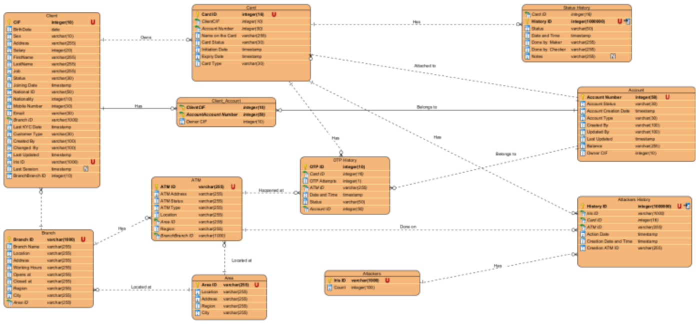


Fig. 6. Database Entity Relation Diagram (ERD).

VI. Experimental Setup

Due to the difficulty of implementing the proposed model at this stage in the real life because of its very high-cost hardware requirements, we decided to simulate the ATM device currently by a Graphical User Interface (GUI) that describes the customer interactions with the ATM into our framework. Below we will attach some highlights of our framework:

1) The main step that appears to the customer to enter his Card ID and the ID of the ATM he is acting with is a simulation to the physical card entering to the ATM and to upload his Iris as a simulation to the live scanning of his iris, then the client clicks on “Enter” (see Fig. 7):

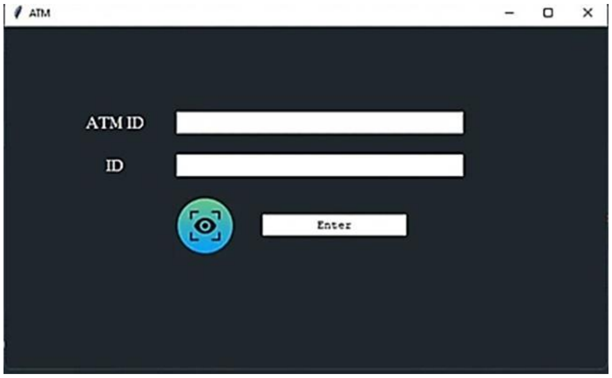

Fig. 7. The first step at our proposed system.

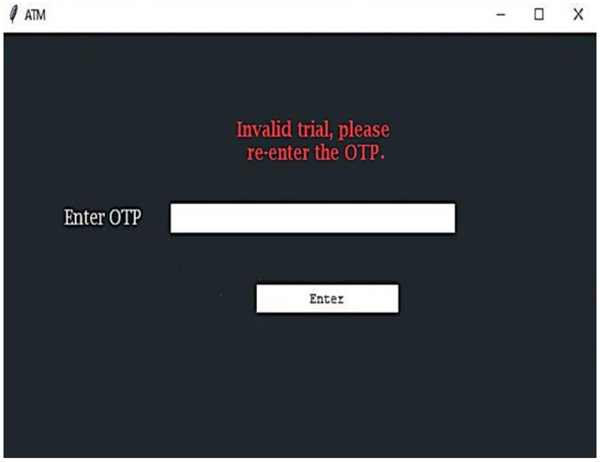
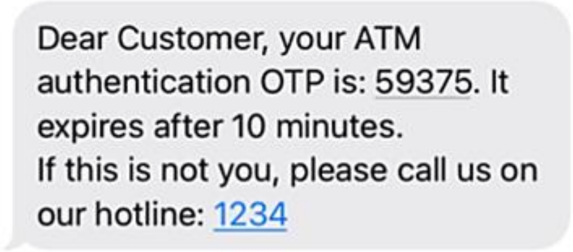
2) In case if the captured Iris was a wrong iris (not the iris of this card), then the client will be asked to enter the OTP the was sent to the mobile number of his card. So, the below screen simulates this step to allow the client to enter his OTP (see Fig. 8):



Invalid trial, please
re-enter the OTP.

Fig. 8. Case of capturing a wrong iris.

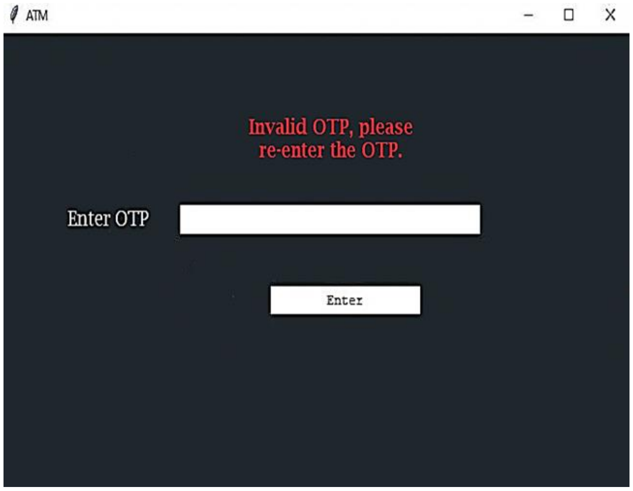
3) The OTP SMS that will be delivered to him from the SMS gateway with a random OTP (see Fig. 9):



Dear Customer, your ATM authentication OTP is: 59375. It expires after 10 minutes.
If this is not you, please call us on our hotline: 1234

Fig. 9. First OTP SMS

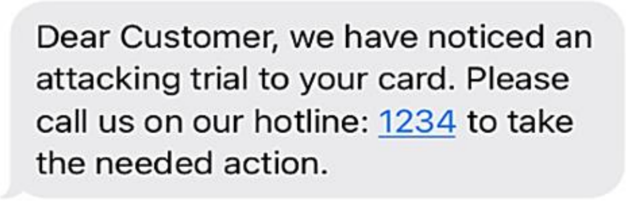
4) In case of entering a wrong OTP, the system will verify the captured iris against the attackers table first, then if it does not match with any attacker's iris, another OTP attempts will be allowed to him with two different SMSs (The third SMS will be sent to him only in case of entering a wrong OTP for the second time). The below screen shows the screen that asks the client to re-enter the OTP (see Fig. 10):



Invalid OTP, please
re-enter the OTP.

Fig. 10. Case of entering a wrong OTP.

5) *In* case of entering a wrong OTP for three times (even if in a different periods or ATMs), the card will be withdrawn, and the customer will receive the below SMS at the mobile number of his card (see Fig. 11):



Dear Customer, we have noticed an attacking trial to your card. Please call us on our hotline: 1234 to take the needed action.

Fig. 11. Case of entering a wrong OTP for three times.

VII. Research Contribution

Our workflow overcomes the limitations of the other proposed solutions as shown in the below Fig. 12, at this part we will explain all our contribution points in details:

1) Suitable to all cultures, as it does not need a specific level of knowledge, age, education or a specific culture to be used, it is just following the signs on the ground of the ATM to be able to allow the iris to be captured.

2) Achieves the main purpose of ATMs, which is making some banking transactions in a short time: as this framework balances between the high security and the effectiveness at the same time, as it is not complicated and does not take much time to authenticate with.

3) Prevents ATMs fraud, not just detects it: as the main idea of our framework is to prevent the attacker from making any fraud on the card without limiting the client's needs from the service. So, in case of noticing any abnormal behavior, the card will be withdrawn, and a legal action will be taken with the attacker and his data.

4) Hygienic way to authenticate: as it is touchless, so, no way to transfer any virus or disease while authenticating.

5) Ensures a high level of security: as it uses the two factors authentication technique to make sure that if the iris recognition failed according to any surrounding reason, the OTP will pass.

6) In case of detecting a fraud action, the card will be withdrawn: to ensure the safety of clients' data and money, our framework will prevent the attacker from keeping the client's card with him, to avoid being used at any suspicious website that does not require an OTP.

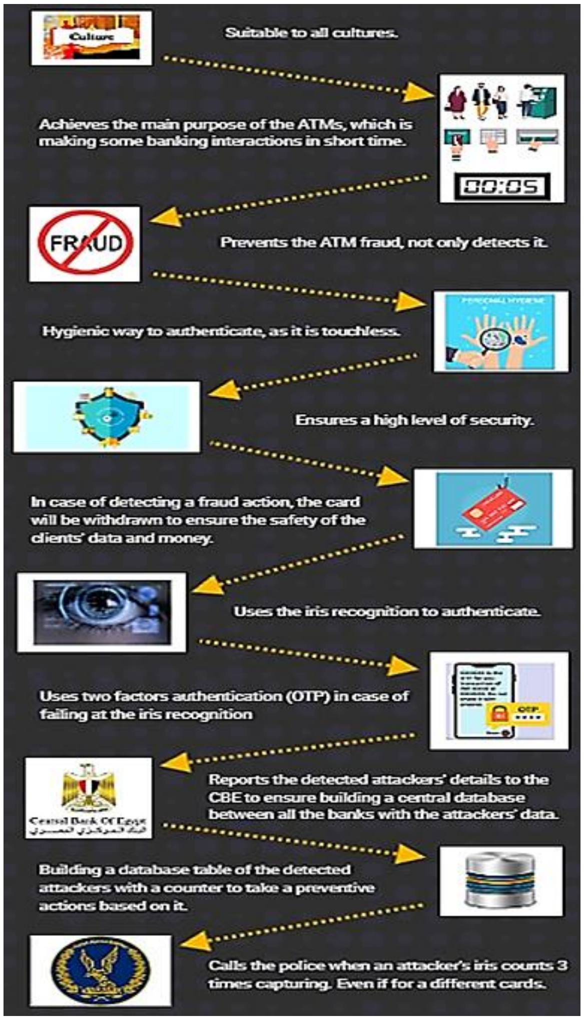
7) Using the iris recognition to authenticate: as this technique is highly secured, unique, and can't be affected by age or illness. It avoids the weakness of the PIN and face recognition, avoids the complication of the other high-level biometric security techniques like the retina, and avoids the high hygienic risk of the fingerprint.

8) Uses the two factors authentication in case of failing at the iris recognition: this point achieves the required balance between making the business process runs smoothly and normally and ensuring a high level of security. As we always give the client another chance to validate that he is the card owner, not an attacker.

9) Reporting the attackers' details to the CBE: as this step ensures having a centralized database between all the banks and the governmental institutions with the attackers' data, which accelerates and facilitates avoiding any upcoming attacks and taking the right legal action in case of facing any attack.

10) Building a database table of the detected attackers with a counter: this step facilitates taking the right preventive action with the captured attackers and prevents the fraud from happening next time.

11) Calling the police when the attacker's iris counts three times capturing; this step will be an instant action to prevent the attacker if it was faster than the attackers' trials.



Culture
Suitable to all cultures.
Achieves the main purpose of the ATMs, which is making some banking interactions in short time.
00:05
FRAUD
Prevents the ATM fraud, not only detects it.
PERSONAL HYGIENE
Hygienic way to authenticate, as it is touchless.
Ensures a high level of security.
In case of detecting a fraud action, the card will be withdrawn to ensure the safety of the clients' data and money.
Uses the iris recognition to authenticate.
Uses two factors authentication (OTP) in case of failing at the iris recognition
OTP
Central Bank Of Egypt
البنك المركزي المصري
Reports the detected attackers' details to the CBE to ensure building a central database between all the banks with the attackers' data.
Building a database table of the detected attackers with a counter to take a preventive actions based on it.
Calls the police when an attacker's iris counts 3 times capturing. Even if for a different cards.

Fig. 12. Workflow overcomes the other solutions' limitations.

VIII. Results

For the case study (1), we selected to use the Chinese Academy of Sciences' Institute of Automation V1.0 (CASIA-IrisV1) [29] dataset currently at our module. It consists of 756 iris images from 108 eyes. For each eye, there are seven images captured in two sessions and stored in bitmap (BMP) format with a resolution of 320*280 pixels.

These 756 irises are specified as two main groups, the first group is for the iris that was captured at the first session, they are three images and used as a training dataset. While the second group is for the iris that was captured at the second session, they are 4 images and used for testing.

Using CASIA-IrisV1 dataset, we applied our framework on two different cases and ways.

1) The first one is using the original CASIA-IrisV1 dataset normally, where each folder contains the training and testing iris for the same person. In this case, the recognition results using Different Similarity Measures are as provided in Table II:

TABLE II. The Recognition Results Using the Original Dataset

Similarity Measures		Correct Recognition Rate (CRR) %	
		Original Feature Set	Reduced Feature Set (107)
1	**L1**	60.87963	66.203704
2	**L2**	54.398148	73.611111
3	**Cosine Distance**	54.398148	75.925926

We decided to work with the Cosine Distance as it provides the highest accuracy as shown above 75.925926%.

Which means that out of 107 irises, there are around 81 irises got matched successfully. However, there are 26 irises didn't get matched successfully due to many environmental factors.

Noting that reducing the feature set to "107" resulted into a higher accuracy and a lower computational power, as this reduction had reduced the confusion of comparing across many features.

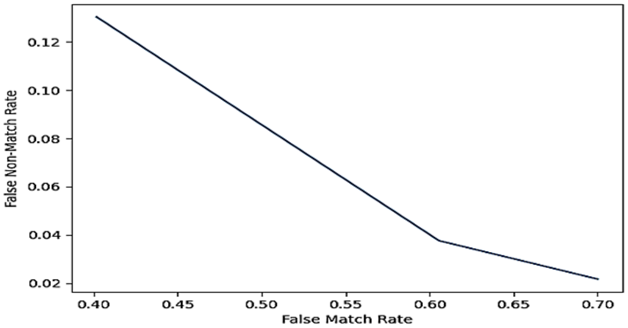


Fig. 13. Recognition results using cosine distance.

This graph in Fig. 13 describes the relation between the false non-match rate (FNMR) and the false match rate (FMR), the FNMR is when we compare the iris of someone to his other iris during the testing phase, and the results became another one's iris. So, it is a false non-match result. During the FMR is when we compare two different iris of two different people at the testing phase, and it results as the same iris. So, it is a false matching result. So, it is an inversely proportional relation between them as shown at the graph. The relation of coaptation (ROC) is calculated as: FMR/1-FNMR. At this case, the FMR and the FNMR are the percentage of the non-accurate results of the framework, this percentage of non-accuracy can be treated by the data augmentation. By increasing the training dataset, the module will be more trained and will have the ability to reach more accuracy and avoid any FMR or FNMR.

At each iris, we can extract many features to be used at detecting the iris owner, which takes a very high computational power. So, we reduced the taken features to be just 107 features. This graph in Fig. 14 shows that when we reacted 40 features extracted, we got the highest accuracy we need. So, at this point, we can close the program and get enough results. However, if we completed 107 features, we would reach highest accuracy that we can get using the extracted features, which is: 75.925926%.

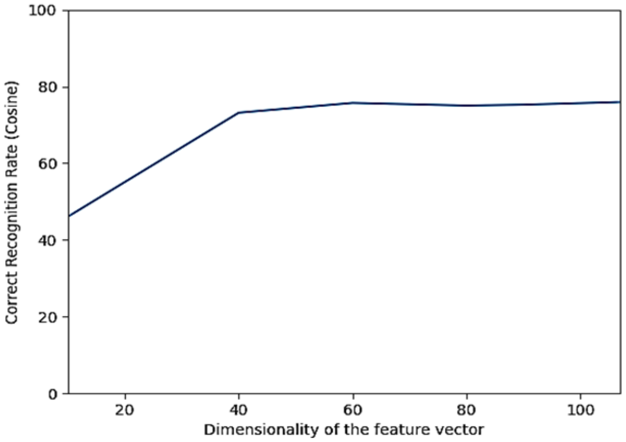

Fig. 14. Receiver Operating Characteristic Curve (ROC).

2) The second one is using CASIA-IrisV1 dataset but with applying some changes on it, by replacing the testing iris of each folder with another person's iris to check if it will be matched normally or not. In this case, the recognition results using Different Similarity Measures are as provided in Table III:

TABLE III. THE RECOGNITION RESULTS USING THE NEGATIVE DATASET

Similarity Measures		**Correct Recognition Rate (CRR) %**	
		Original Feature Set	**Reduced Feature Set (107)**
1	**L1**	1.388889	0.462963
2	**L2**	1.388889	0.462963
3	**Cosine Distance**	1.388889	0.462963

As shown at the above table, the resulted CRR is 0.46%, this very low accuracy rate is due to some human errors during capturing the iris dataset, which led to a FMR and FNMR by this percentage. So, we do recommend availing this framework at a very suitable environment by applying the ATMs shields as what is already happening at most of the banks, that will lead to getting the highest results and accuracy from the module.

For the case study (2), we have decided to use IITD (IIT Delhi [30] dataset using k-Nearest Neighbors (KNN) and Histogram of Oriented Gradient (HOG) techniques. We have selected to use the Indian Institute of Technology Delhi (IITD) database, this database is a bitmap format image database which was collected from the students and the staff of the Indian Institute of Technology Delhi (IITD) at July 2007 using JIRIS, JPC1000, and digital CMOS camera which consists of 2240 images from 224 different groups of users who are between 14-55 years (176 males and 48 females) 10 images gets registered for each user in an indoor environment. The resolution of each image is 320 x 240 pixels. The results of this combination were great! as it reached 100% accuracy with seven images for training and 3 images for testing as in Table IV:

TABLE IV. TESTING RESULTS OF USING (HOG) + (KNN)

Images Numbers Per Person	Training: 7 images Testing: 3 images	Training: 3 images Testing: 2 images	Training: 2 images Testing: 3 images	Training: 1 image Testing: 4 images
Accuracy %	100%	99.33%	98.21%	96.31%

IX. CONCLUSION

The technique of using the iris recognition combined with the OTP as a second step authentication is a reliable technique to secure the ATMs, as it provides a highly secured system with a fast timing to complete any financial transaction. In addition to our proposed model, which does not only succeed in achieving this security at a fast time, but also enhanced its prevention by providing a table of the attackers and the suspected attackers with a counter and a preventive action (notifying the user, notifying the bank, reporting to the CBE to centralize & share these data with the other banks, and reporting to the police). We also recommend by the end of our paper to use k-Nearest Neighbors (KNN) and Histogram of Oriented Gradient (HOG) techniques together to reach the highest accuracy (100%).

In the future, it is noted that the larger the dataset size we use, the better the accuracy we get. So, we are planning to use the other mentioned sources of data in our module to achieve the needed level of accuracy and to use the deep learning technology: Convolutional Neural Network (CNN). It is necessary to plan to enhance this model by cancelling the use of any cards to authenticate and by providing a suitable system for the users with disabilities to be able to do all their financial actions through the ATM normally.

***Abstract*—The liver is one of the most important organs in the human body. The liver's proper function is critical for overall health, and liver diseases or disorders can have serious consequences. Liver cancer is also known as hepatic cancer, which is divided into various types of cells that belong to the cancer. The most common type of liver cancer is hepatocellular carcinoma (HCC). HCC is one of the most common types of liver cancer that can affect up to 85% of people worldwide. Early detection of liver cancer is essential in healthcare because it increases the chances of successful treatment and patient outcomes. Many researchers have developed models that help detect and diagnose liver cancer. The first step in detecting liver cancer is identifying people at a higher risk. Chronic hepatitis B or C infection, cirrhosis, heavy alcohol use, obesity, and exposure to certain chemicals and toxins are all risk factors. This paper is mainly focused on detecting the cancer-affected regions that occur in the liver. In this paper, a combined ensemble model (CEM) for a liver cancer detection system is developed to find and detect liver cancer and liver disorders in their early stages. A pre-trained model, RESNET50 with transfer learning, is used to obtain the features from the pre-trained model—an advanced preprocessing technique involved in filtering the noise from input CT scan images. A hybrid feature extraction (HFE) technique also gets significant elements from the input CT scan images. Finally, the proposed CEM combines an Extreme Gradient Boosting (EGB) algorithm with a Recurrent Neural Network (RNN) that focuses on detecting the abnormal cancer cells present in input CT scan images. The performance of the CEM shows a high accuracy of 98.48% with a 10% high detection rate. Previously, it was 88.12%.**

Keywords*—Liver Cancer; Hepatocellular Carcinoma (HCC); Combined Ensemble Model (CEM); RESNET50; Extreme Gradient Boosting (EGB); Recurrent Neural Network (RNN)

I. INTRODUCTION

Cancer is a most complex diseases characterized by unrestricted cell growth and division in the body [1]. It is a significant public health concern worldwide and can affect almost any body part. Cells in the body normally grow, divide, and die in a controlled manner [2]. The body's genetic instructions tightly control this process. When this control is disrupted, cells can divide and grow uncontrollably, forming a tissue mass called a tumor. Tumors of two types, such as benign or malignant, Benign is non-cancerous, which is not more dangerous than malignant. Malignant is more dangerous because it is cancerous and spreads very quickly to all the body parts [3] [4]. The process of converting healthy cells into cancerous cells is known as carcinogenesis. Usually, it involves DNA alterations in the cell. These alterations can be brought on by a genetic predisposition, viral infections, to carcinogens (such as tobacco smoke or certain chemicals). The kind and stage of a cancer diagnosis can have a significant impact on the symptoms. Common symptoms include sudden weight loss, exhaustion, pain, skin changes, chronic coughing or hoarseness, lumps or masses, and altered bowel or bladder habits [5] [6]. Physical examinations, imaging tests, and laboratory testing are commonly used to diagnose cancer. Effective therapy depends on early discovery.

Image processing is an essential domain in detecting and diagnosing liver cancer. These models assist medical professionals in early cancer detection and treatment planning by extracting meaningful information from CT scans, MRIs, or ultrasound images [7]. Medical imaging, blood tests, and sometimes tissue biopsy are used to detect liver cancer. Early detection is critical for successful treatment and outcomes. A complete medical history taking into account risk factors such as alcohol use, hepatitis infection, and family history. They will also conduct a physical exam to look for signs of liver abnormalities like enlargement or tenderness [8] [9]. Several tests are available to aid in detecting and diagnosing liver cancer cells in CT scan images [10] [11]. Deep Learning (DL) is essential in detecting complex cancer patterns in liver CT scan images. Fig. 1 shows the sample liver lesions present in CT scan images.

This paper introduced the pre-trained model, such as ResNet-50, extracts accurate features from CT scan samples. Transfer learning with pre-trained models can significantly improve the proposed model's performance, particularly for limited labeled data. Denoising techniques are used in many image processing techniques to process CT scan images. In conjunction with various denoising filters, this paper removes noise from input CT scan images. Gray-level run-length Matrix (GLRLM) and region-based features were used to improve feature extraction.

A. *Contributions of this Work*

1) By integrating the distinct models, CEM is usually higher in forecasting because it consists of many basic models. Every model used in this work offers benefits while working on the proposed approach.

2) Complex interactions between many clinical and genetic variables are frequently involved in identifying liver cancer. CEM can more accurately forecast outcomes by capturing these complex interactions by combining many modeling methodologies.

3) The proposed model uses the Pre-trained model RESNET50 to get the accurate cancer disease patterns in the given samples.

4) An interesting features are obtained by using the hybrid feature extraction (HFE) that helps to improve the performance of final outcomes.

II. Literature Survey

Kim et al. [12] proposed a one-sided ANOVA approach for extracting the feature set for accurate disease detection using a feature (aptamer) array. For 80 liver cancer patients and 310 healthy people, the proposed approach combined AI with 10-fold cross specifications verified by aptamer array response. The proposed ANOVA approach has an accuracy of about 93.6% for ten features, which is 3.51% higher than the single-way method. Ahmad et al. [13] proposed a new approach called DBN-DNN, which can fine-tune the proposed DNN approach. An advanced pre-processing technique improves performance by employing an active contour technique based on liver features that store memory and measure time. The evaluation result shows that the proposed approach's performance on test images achieved a Dice score of 95.34%, which is high, compared to existing models. Balagourouchetty et al. [14] developed a CAD system for diagnosing liver diseases. The proposed method uses an ensemble FCNet classifier to classify hepaticae lesions based on several significant factors obtained from GoogleNet-LReLU transfer learning approaches. The proposed approach is a fully connected layer that includes classification and extraction using the inception layer and is combined with the ReLU activation function. Finally, the variety is based on six different types of liver diseases, and it is highly accurate. Yamakawa et al. [15] developed a new model for detecting tumors in the liver. The proposed method combines CNN with VGGNet to classify the four types of tumors based on the affected regions. The dataset contains 988 images representing various cases. When combined with CADx, the proposed method predicts liver cancer tumors with an accuracy of 94.56%, which is a high detection rate. Aslam et al. [16] presented an integrated learning model that combines image processing techniques and deep learning (DL) approaches to detect early-stage liver cancer tumors. The proposed model also employs the ResUNet, the most advanced model, to achieve better results. The dataset includes 100 CT scan liver tumor images from various patients. Finally, the proposed approach's accuracy is around 99.67%, and its F1-score is 94.8%, which is high compared to other systems in this paper. Shukla et al. [17] presented the automated liver tumor detection model from MRI scan images. The proposed approach divides the concave surfaces combined with geodesic active contour. The author introduced the Cascaded Fully CNN approach to segment the tumor region from the input sample. The training process reduces the error rate for liver segmentation. The final liver tumor analysis for the proposed approach is to obtain 94.56% accuracy and 88.89 Sec for computation of liver analysis. Sanyal et al. [18] presented a new model for detecting NAFLD based on the stage of liver disease. The proposed approach provided clear information about the liver status and stage in the early stages of the disease. As a result, this approach offers the default disease information that aids in detecting and diagnosing NAFLD. Li et al. [19] investigated NAFLD using various methodologies. Zhou et al. [20] proposed NAFLD for the detection of liver cancer. The author discussed about various models that helps to diagnose the cancer cells in liver. Marengo et al. [21] presented a new model for detecting HCC, a type of common liver cancer. Other factors, such as type 2 diabetes, NAFLD, and obesity, contribute to the rapid growth of HCC. It is a rapidly spreading cancer in the general population that should be detected in its early stages. The author discussed several techniques and methods for treating HCC and devised a limited solution. Sun et al. [22] talked about a variety of liver diseases. The author concentrated on detecting obesity-related health issues and their consequences. According to epidemiological studies, obesity is the root cause of various cancers. Obesity is strongly linked to other liver diseases such as NAFLD, NASH, and cancer. Kwon et al. [23] introduced a method for segmenting liver CT scan images using DL. The author wishes to identify additional factors influencing liver cancers based on human activities and habits. Manjunath et al. [24] presented a DL approach for detecting liver disease based on tumors growth. The tumor images are collected online and classified into Metastasis and Cholangiocarcinoma. The proposed approach gets better accuracy with 97.89% and a dice score of 98.23%. Lakshmipriya et al. [25] compared various DL algorithms based on classification, segmentation, and medical details of liver diseases. The author discussed different DL algorithms and found new challenges from the existing algorithms. Piyush Kumar Shukla et al. [26] presented an automated liver disease detection system that finds the tumors and lesions in the MRI images belonging to abdomen images that are gathered from 3D-related abhorrent and shape-based model results. The proposed approach combined with geodesic active contour analysis to find the different liver regions in the body. Finally, the training approach reduces the error rate by using the CFCNs to detect the segmented tumor image. In the final step, the segmentation approach obtained a tumor detection accuracy of 94.67% with a computation time of 17 seconds for one photo. The DL technique, which identifies liver tumors from CT scan pictures, was first presented by Heng Zhang et al. [27]. The CNN model was employed to segment CT scan images. Based on experimental results, comparisons between several segmentation approaches are presented. The automated KMC method, which offers a region-based growth strategy to locate the tumor region and display tumor grades, was proposed by Liping Liu et al. [28]. The deficiencies belong to blood vessels in the portal venous phase (PVP) based on the poor density of the liver CT scan pictures. In the last stage, patients with 26.67% having low blood deposition effect and 54.34% having high blood were discovered. Nayantara et al. [29] introduced the effective segmentation that detects liver diseases accurately on CT scan images. The author analyzed several DL algorithms that find liver diseases accurately. Zhang et al. [30] presented the diagnosis of liver diseases using Dl algorithms. Mubashir Ahmad et al. [31] developed the patch-based DL algorithm that segments the liver CT scan images using SAE. The proposed approach processes every pixel of the image and finds the accurate patches of initialize the liver disease-affected regions. The preprocessing method improved the images and created overlapping patches from each one, which were then fed into the SAE to extract features. In the last step, the classification is used to classify the affected regions based on the feature extraction. The proposed approach obtained the dice score similarity up to 97.23%, which shows high accuracy. Manoj Kumar et al. [32] proposed a comparative study that finds the overall liver disease patients based on three stages. The preprocessing technique min-max normalization is applied, and in the second step, the PSO feature extraction is used to extract the significant data from the input CT scan images and improve the disease detection rate. Li et al. [33] proposed a novel approach that detects liver cancer from liver CT scan images. Two datasets, such as MICCAI 2017 and 3DIRCADb data sets, are used for evaluation. The proposed approach focused on detecting the cancer-affected regions by using segmentation with the FCNN model and UNet (H-DenseUNet) that effectively extract the hybrid feature fusion layer. The comparison between several algorithms shows the proposed approach obtains good outcomes. Amita Das et al. [34] introduced the WGDL approach for detecting cancer lesions using CT scan images. The input CT scan images are separated using watershed segmentation and GMM to divide the cancer lesion. Finally, the DNN is used for classification based on segmentation outcomes. Anandan et al. [35] presented the enhanced filtering approach called NMADF that helps filter the input CT scan images. The proposed approach uses the two-fold segmentation that segments the liver cancer images. The canny edge detection approach is used as a preprocessing technique—finally; the improved DNN approach is used to classify liver cancer images. The results show the better performance of the proposed approach compared with existing models.

A. Limitations of Existing Models

1) The existing model requires massive training data to solve the sample imbalance.

2) There needs to be more accurate classification of normal and cancerous samples.

3) The existing models require high-quality images to detect accurate results.

4) There must be more issues in finding the accurate affected region in the given sample.

III. Dataset Description

The dataset was obtained from Kaggle and contains CT scan images related to contrast and patient age. The default viewpoint is to find various image textures tested for analyzing trends in CT scan images and statistical patterns. It features strongly correlated with these traits and possibly builds simple tools for automatically classifying these images when they have been misclassified. The total images used for training is 500 and testing is 500 CT scan liver images. The size of image in dataset is 500 x 500 width and height and size is 5-6 MB. The sample datasets with different types of images are shown in Fig. 1. All the images are in same size and pixel rate.

A. RESNET50 (Pre-Trained Model)

A common and practical approach in medical image analysis is the ResNet-50 model for cancer cell detection. ResNet-50 is deep convolutional neural network (DCNN) architecture with great success in image classification and object detection. When used to detect cancer cells, it can aid in identifying and classifying cancerous cells in medical images such as histopathology slides or radiological scans. ResNet-50 comprises 50 Convolutional layers connected by skip connections (residual blocks). The ResNet-50 weights were fine-tuned on a liver cancer cell dataset using popular deep-learning libraries such as TensorFlow. On the training data, train the ResNet-50 model with appropriate loss functions such as binary cross-entropy or focal loss for binary classification (cancerous or non-cancerous). To attain the highest validation set performance, track and modify hyper parameters like learning rate and batch size. To avoid over-fitting, techniques such as early stopping are used. If necessary, the post-process approach is used to predict to remove noise or refine the detected cancerous regions. The overall architecture of RESNET 50 is explained in Fig. 3. The input image and final output is obtained after processing all layers.

B. Pre-processing and Noise Removal

Pre-processing is essential in removing noise from input liver CT scan images. This paper combines an advanced pre-processing technique with Iterative Reconstruction (IR) and Anisotropic Diffusion (AD). It is beneficial for removing noise and improving image quality and diagnostic accuracy in CT (computed tomography) scan images. Various noise reduction techniques can be used depending on the specific noise characteristics and the image processing goals. Fig. 2 and Fig. 5 shows the input and output of the image selected from dataset.

C. Iterative Reconstruction (IR)

Iterative reconstruction is a computational technique used in medical imaging to improve image quality and reduce radiation exposure, particularly in CT (computed tomography) scans. It is an alternative to traditional filtered back projection (FBP). It is a simpler and faster method but may result in lower-quality images, mainly when data is limited, or measurements are noisy. Iterative reconstruction algorithms can address these issues by refining the vision iteratively based on the acquired data and a mathematical model of the imaging process. A CT scanner captures a series of X-ray projections as it rotates around the patient. These projections are different angles of CT-Scan attenuation through the patient's body. The iterative reconstruction process estimates the patient's internal structures, usually a simple or uniform image. The initial image generates CT-Scan projections as if the image were actual. This step uses a mathematical model that accounts for the CT-Scan attenuation properties of the tissues being imaged.

x: The true underlying image we want to reconstruct.

y: The acquired data (e.g., projection data in CT imaging).

R: The reconstruction operator that maps the image x to the acquired data y.

ϵ: The noise or error in the data.

The iterative reconstruction process can be represented mathematically using the following equation:

$$y = R(x) + \in$$

The goal is to find the best estimate x_k of the true image x iteratively minimizing the variance among the acquired and estimated data $R(x_k)$. this is typically done by solving the optimization issue at every iteration:

$$x_{k+1} = \mathrm{argmin}_x\{||y - R(x)||^2 + \leftthreetimes \Phi(x)\}$$

$||y - R(x)||^2$Represents the data fidelity term, $\Phi(x)$ is a regularization term that enforces some desired properties on the reconstructed image, such as smoothness or sparsity.

$\leftthreetimes$ is a regularization parameter that controls the trade-off between data fidelity and regularization.

D. Anisotropic Diffusion (AD)

Anisotropic Diffusion (AD) is a method for edge-preserving smoothing in image processing. When used to enhance or denoise photos while maintaining structural integrity, it is especially helpful. AD can be used in the context of medical imaging to enhance the visibility of pertinent features, such as scans showing malignancy. Anisotropic diffusion is based on the principle of performing diffusion in a way that is less noticeable in homogenous regions and more evident along the image's borders. This reduces noise while maintaining significant edges and structures.

The AD equation is represented as:

$$\frac{\partial I}{\partial t} = \nabla.(c(||\nabla I||)\nabla I)$$

I is the image intensity

∇ is the gradient operator

$||\nabla I||$ is the magnitude of the gradient,

$c(||\nabla I||)$ is the diffusion coefficient.

t is the time.

Based on the gradient's magnitude, the diffusion coefficient $c(||\nabla I||)$ is a function that establishes the appropriate amount of diffusion at each location. The role that is applicable as:

$$c(||\nabla I||) = e^{-(\frac{||\nabla I||^2}{K^2})}$$

The amount of diffusion is controlled by the parameter K in this case. Greater diffusion is permitted by smaller K values, while greater K values better maintain edges. Iteratively solving the equation over the image is done until the desired degree of smoothing is attained. The goal of the procedure is to maintain edges and fine structures while smoothing the image more over homogeneous areas. Anisotropic diffusion can be used to improve the visibility of significant characteristics in cancer images, which will facilitate medical experts' analysis and interpretation of the images.

E. Gray-Level Run-Length Matrix (GLRLM)

A popular texture analysis technique in medical image processing is the GLRLM. CT scan images are analyzed for a variety of purposes, including cancer detection. GLRLM provides texture pattern information by quantifying the distribution of grey-level runs in an image. The GLRLM describes the correlations between pixel intensities along various directions and is commonly obtained from the co-occurrence matrix. Features that characterize an image's texture can be extracted using the GLRLM and used for classification or other analysis purposes.

1) Run-Length Matrix (RLM): The RLM $P(a, b)$ is calculated by counting the number of consecutive pixels with intensity a and length b in a specified direction. Let N be the number of gray levels.

$$P(a, b) = \sum_{x=1}^{N} \sum_{y=1}^{M} \delta(I(x, y) = i \text{ and } R(x, y) = j)$$

Normalized Gray-Level Run-Length Matrix (NGLRLM):

Normalize the RLM to obtain the NGLRLM:

$$P_{norm}(a, b) = \frac{P(a, b)}{\sum_{x=1}^{N} \sum_{y=1}^{M} P(a, b)}$$

2) Gray-Level Run-Length Matrix (GLRLM) Features: Several statistical measures can be computed from the GLRLM to extract features. Some of significant features are given below:

Short Run Emphasis (SRE):

$$SRE = \frac{\sum_{i=1}^{N} \sum_{j=1}^{M} \frac{P(a,b)}{j^2}}{\sum_{i=1}^{N} \sum_{j=1}^{M} P(a, b)}$$

Long Run Emphasis (LRE):

$$LRE = \frac{\sum_{i=1}^{N} \sum_{j=1}^{M} P(a, b) \cdot j^2}{\sum_{i=1}^{N} \sum_{j=1}^{M} P(a, b)}$$

Gray-Level Non-Uniformity (GLN):

$$\sum_{i=1}^{N} \sum_{j=1}^{M} P(a, b)^2$$

Run Length Non-Uniformity (RLN):

$$\sum_{i=1}^{N} \sum_{j=1}^{M} P(a, b)^2$$

F. U-Net Architecture

It is used for segmentation of cancer cells in given dataset images. The architecture consists of a contracting path, a bottleneck, and an expansive path.

1) Contracting path: It is responsible for capturing context and reducing the spatial resolution of the input image.

$$\mathrm{Conv}(x, \mathrm{filters}, \mathrm{kernel}_{size}, \mathrm{activation} =' \mathrm{relu}', \mathrm{padding} \\ = '\mathrm{same}'$$

x is the input tensor.

filters is the number of filters in the convolutional layer.

kernel_{size} is the size of the convolutional kernel.

activation is the activation function, typically ReLU.

padding is set to 'same' to maintain the spatial dimensions.

$$\mathrm{maxpool}(\mathrm{x}, \mathrm{pool}_{\mathrm{size}}, \mathrm{strides}$$

where,

$\mathrm{pool}_{\mathrm{size}}$ is the size of pooling window.

Strides is the stride of the pooling operation.

2) Skip connections: In order to concatenate feature mappings from the contracting path to the appropriate layer in the expansive path, the U-Net design uses skip connections.

$$\mathrm{concatenate}(\mathrm{conv}_{\mathrm{block}_{\mathrm{output}}}, \mathrm{corresponding}_{\mathrm{conv}_{\mathrm{block}_{\mathrm{output}}}})$$

3) Output layer: It is also a convolutional layer with a sigmoid activation function, producing the final segmentation map.

$$\mathrm{conv}(\mathrm{x}, 1, 1, \mathrm{activation} =' \mathrm{sigmoid}')$$

where:

1 is the number of filters (assuming binary segmentation, i.e., cancer cell or background).

1 x 1 convolutional kernel is used.

IV. Extreme Gradient Boosting (XGBoost)

In this paper, the Extreme Gradient Boosting (XGBoost) approach is used for the classification of input cancer and non-cancer images. Usually, a binary classification model with the target variable being a binary value indicating whether or not a patient has liver cancer is used to identify liver cancer using XGBoost. The two components of the XGBoost objective function are the regularization term, which penalizes the model's complexity in order to prevent over fitting, and the loss function, which calculates the difference between the true and predicted values.

$$\mathrm{Objective} = \sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{loss}(\mathrm{y}_{\mathrm{i}}, \hat{\mathrm{y}}_{\mathrm{i}}) + \sum_{\mathrm{k}=1}^{\mathrm{K}} \Omega\,(\mathrm{f}_{\mathrm{k}})$$

n -total training samples

y_{i} -True table for i^{th} sample.

$\hat{\mathrm{y}}_{\mathrm{i}}$ -predicted output for i^{th} sample.

K- Total trees ensemble.

$\Omega(f_k)$ Regularization term for the k^{th} tree.

1) Loss Function: In this scenario, the loss function which is used for classification of cancer images is logistic loss:

$$\mathrm{loss}(\mathrm{y}_{\mathrm{i}}, \hat{\mathrm{y}}_{\mathrm{i}}) = -[y_i \log(\hat{y}_i) + (1 - \mathrm{y}_{\mathrm{i}}) \log(1 - \hat{y}_i)]$$

y_{i} is the true label.

$\hat{\mathrm{y}}_{\mathrm{i}}$ Predicted probability of class 1.

2) Regularization term: These terms are used by XGBoost to regulate the total model's complexity as well as the complexity of each individual tree. The regularization term for the k^{th} tree is a sum of the leaf scores:

$$\Omega(\mathrm{f}_{\mathrm{k}}) = \gamma\mathrm{T} + \frac{1}{2} \curlywedge \sum_{\mathrm{j}=1}^{\mathrm{T}} \mathrm{w}_{\mathrm{j}}^{2}$$

T total leaves in the tree.

w_j score associated with the j-th leaf.

γ and $\curlywedge$ Regularization parameters.

3) Tree Building Process: XGBoost builds trees in an additive manner, where each new tree is trained to correct the errors of the combined existing ensemble. The update at each step is given by:

$$\hat{\mathrm{y}}_{\mathrm{i}}^{(\mathrm{t}+1)} = \hat{\mathrm{y}}_{\mathrm{i}}^{(\mathrm{t})} + \eta \cdot \mathrm{f}_{\mathrm{t}}(\mathrm{x}_{\mathrm{i}})$$

The final equation classifies the input liver sample as tumor affected or not. The final architecture is given in Fig. 4 with step-by step approaches used to obtain the better output.

V. Performance Metrics

This section focuses mainly on showing the effectiveness of the proposed approach based on the outcomes. The performance metrics are obtained by using the proposed approach. The count values are obtained by the proposed classification approach. XGBoost is the classification model implemented by using the Python language with potential libraries. There are several libraries that help provide accurate results with the particular libraries. The performance is measured by using the following metrics. The count values are measured from the proposed approach. Fig. 6 shows the attributes of performance measures based on confusion matrix.

$$\mathrm{Precision} = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FP}}$$

$$\mathrm{Accuracy} = \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{TN} + \mathrm{FP} + \mathrm{FN}}$$

$$\mathrm{Recall} = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}}$$

$$\mathrm{Specificity} = \frac{\mathrm{TN}}{\mathrm{TN} + \mathrm{FP}}$$

$$\mathrm{F1-Score} = 2 * \frac{(\mathrm{Precision} * \mathrm{Recall})}{(\mathrm{Precision} + \mathrm{Recall})}$$

A. Experimental Results

This section mainly focused on analyzing the performance of the proposed approach is compared with several existing models. This section focused on providing the analysis of every parameter that shows the huge impact on output. It includes the training and testing loss and training and testing accuracy for the given pre-trained model. Also, this consists of comparative performances of several existing algorithms compared with the proposed algorithm.

The training loss measures the performance of model on training data. It initializes the error between the estimated output and original output at the time of training phase. In this paper, the loss is minimized by updating the model parameters by using several optimization algorithms. Testing loss mainly generalizes the model performance on new and unknown data. It is evaluated on a different dataset that the model has not seen during training. The proposed model shows the better performance by showing the balanced outcomes. The performance metrics based on the reduced testing and training loss are displayed in Fig. 7. It shows the proportion of successfully predicted instances to all instances in the dataset and is commonly stated as a percentage. There are two main types of accuracy: training and testing accuracy. Training accuracy gives an indication of how well the model has learned the training data. High training accuracy does not, however, guarantee that the model will perform well when applied to novel or unidentified data. The model's accuracy on a different dataset that it was not exposed to during training is known as testing accuracy. Since testing accuracy shows how well the model is likely to function on unknown data, it is a more significant parameter. Fig. 8 shows the performance of training phase testing phase.

Table I shows the performance of ML algorithms without using any ensemble techniques or pre-trained models. It is the classification models obtained by the implementation of ML algorithms. Fig. 9 shows the comparisons between ML algorithms.

TABLE I. THE PERFORMANCE OF VARIOUS ML MODELS

Parameters	Random Forest (RF)	CNN	XGBoost
Precision	73.23	76.23	86.56
Accuracy	74.53	80.34	88.12
Recall	75.12	81.23	89.23
Specificity	71.23	83.56	90.34
F1-Score	73.34	84.23	91.34

Table I shows the obtained results that are obtained by using existing algorithms such as RF, CNN and XGBoost. Among all these algorithms the XGBoost gained the better classification results compared with existing approaches. The traditional XGBoost obtained the high performance in terms of accuracy of 88.12%, precision of 86.56%, recall of 89.23, Specificity of 90.23 and F1-Score of 91.34.

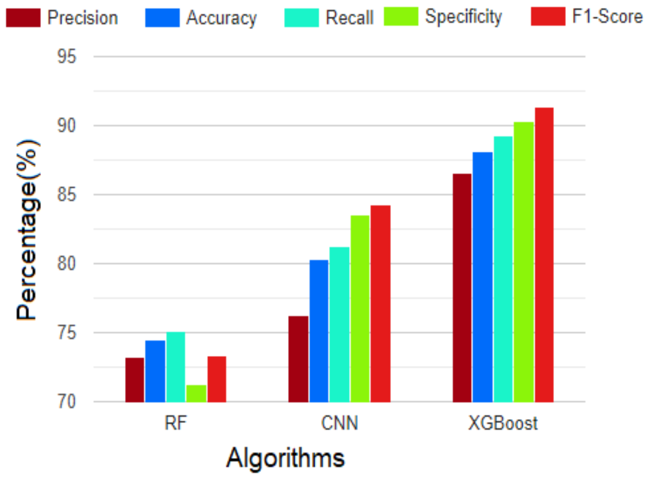

Fig. 9. The comparative performances of various ML algorithms.

TABLE II. THE OVERALL PERFORMANCE OF ALL THE ADVANCED ALGORITHMS THAT EVERY ALGORITHM IS COMBINED WITH VARIOUS PREPROCESSING AND FEATURE EXTRACTION TECHNIQUES

Parameters	Random Forest (RF)	CNN	Combined Ensemble model (CEM)
Precision	83.45	88.23	97.81
Accuracy	84.23	89.34	98.48
Recall	85.12	90.23	98.65
Specificity	81.23	90.56	98.45
F1-Score	82.87	91.23	98.19

Table II shows the comparison between traditional and Ensemble Algorithms that shows the high performance in terms of various parameters. The proposed CEM is the ensemble algorithm that combines with the U-Net and XGBoost. It achieved the high accuracy of 98.48% based on correctly classified outcomes. The remaining parameters are also shows the high rate. Finally, Fig. 10 shows the overall performances of existing and proposed algorithms.

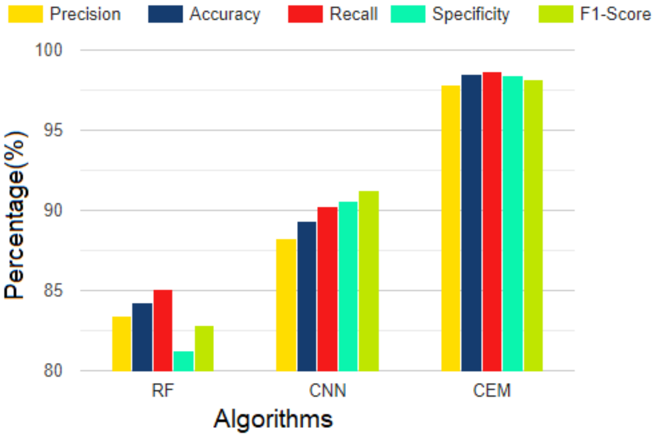

Fig. 10. The overall performances of existing and latest algorithms.

VI. Conclusion

In this work, we looked into the use of a Combined Ensemble Model (CEM) in liver cancer diagnosis. Utilizing each model's unique characteristics to improve overall forecast accuracy and reliability was the main goal. Our results show that the CEM technique has the potential to enhance liver cancer diagnostic skills. The ensemble model performed better than the individual models alone. It was created by combining many algorithms, such as [list of individual models]. By combining several algorithms, the constraints of using a single model were effectively mitigated and a more reliable and accurate prediction of liver cancer was made. Furthermore, the CEM demonstrated enhanced generalization capabilities, suggesting its potential applicability to diverse patient populations and datasets. The ensemble approach not only improved sensitivity and specificity but also provided a more comprehensive understanding of the complex patterns within the data. While the CEM outperformed individual models, it is crucial to acknowledge the importance of continuous refinement and optimization. Future work should focus on fine-tuning the ensemble model, exploring additional algorithms, and incorporating new features to further enhance its diagnostic capabilities. The implications of our study extend beyond the realm of liver cancer diagnosis. The success of the CEM approach highlights the value of ensemble techniques in medical decision-making, emphasizing the significance of model diversity and collaboration. This research contributes to the growing body of evidence supporting the use of ensemble models in healthcare applications. Finally, the Combined Ensemble Model presents a promising avenue for improving the accuracy and reliability of liver cancer diagnosis. As we move forward, it is essential to continue refining and validating the model on larger and more diverse datasets, ultimately paving the way for its potential integration into clinical practice.

Abstract—**Air quality is of great importance due to its direct impact on the environment, human health, and quality of life. It could be affected negatively by the presence of dust particles in the atmosphere. Thus, it is vital to purify air from dust and mitigate its impact on air quality. In this regard, dust sensors play a vital role in monitoring and measuring airborne dust particles. They utilize various techniques, such as optical scattering, to detect and quantify the concentration of dust in the air. Microcontrollers are powerful and versatile devices, which have been widely used in many Internet of Things (IoT) applications. They process the collected data from sensors and react accordingly by controlling the operation of IoT devices. Accordingly, the primary goal of this paper is to develop a model for reducing the amount of dust and other particulates in the air to improve its quality. In addition to the microcontroller, which controls the overall operation of the proposed model, two other main components are utilized: a sensor and a sprinkler. The results of the model have shown that it can successfully reduce the dust concentration and suppress the dust intensity to less than 0.1%. The result concluded that the proposed model achieved its primary goals by integrating sensors and sprinkler into an intelligent dust removal model.**

Keywords—Dust Suppression; dust elimination; digital dust sensor; humidifier; dust intensity

I. Introduction

Because oxygen is supplied to our lungs, blood, and other organs through the air we breathe, it crucial for it to be as pure as possible to ensure a healthy life for humans. A vital component of environmental health is air quality. One of the biggest environmental hazards to human health is air pollution. As of 2019, 99% of people on Earth reside in places where air quality standards set by the World Health Organization (WHO) were not achieved. Each year, the poor air quality results in millions of deaths. Globally, ambient (outdoor) air quality is thought to have contributed to 4.2 million preventable deaths in 2019 [1, 10]. Surprisingly, multiple WHO's studies reveal that indoor air quality is five to ten times worse than outside air quality, especially in urban regions. The environment and human health are seriously threatened by air pollution, which is brought on by a variety of pollutants, including dust particles in the atmosphere [1, 3].

Poor air quality has a negative impact on the quality of life for individuals. Air pollutants have the potential to cause irritation. Many studies have demonstrated the link between specific air pollutants and lung cancer as well as respiratory ailments. The quality of the air both indoors and outdoors is vital. Common outdoor air contaminants include particulate matter, allergens, and ground-level ozone. Common indoor air contaminants include mold, radon, secondhand smoke, and dust [8].

Dust particles in the air are one of the main causes of air pollution [7] that could cause serious health hazards to humans. These particles can come from natural processes including wind erosion, vehicles emissions, construction sites, and industrial activity. High dust exposure can cause allergies, respiratory disorders, and other health concerns [4]. The issue with airborne dust is caused by the presence of rock dust in the atmosphere. Pneumonia is a potentially dangerous occupational lung illness that can be brought on by this dust. Statistics show that there are about 500 new cases of pneumonia detected yearly, which suggests that more work needs to be done to treat lung cancer and pneumonia [9].

In semi-arid environment, sandstorms frequently occur, especially in the summer. These sandstorms, which occur when strong winds swirl sand about and propel it into the air, may make it difficult for people to see far, and they also make driving more dangerous. The difficulty for drivers to spot other vehicles is a hazardous consequence, which raises the chances of accidents. Furthermore, breathing in dust might be harmful when traveling or working in factories that produce construction waste [2, 11, and 12].

In order to establish a sustainable ecosystem, it is essential to develop a model aimed at reducing the concentration of dust in the atmosphere. To lessen the severity of the dust and enhance the quality of the air, this study suggests a prototype that can be used to detect and reduce dust in the atmosphere. Thus, the goal of the paper is to create a dust removal system that employs intelligent control and hardware components to effectively minimize airborne dust particles.

Dust sensors greatly aid the monitoring and measurement of airborne dust particles. They use various techniques, such as optical scattering, to identify and measure the amount of dust in the atmosphere. Real-time data from these sensors makes it possible to evaluate the quality of the air and identify any possible health hazards. Therefore, the proposed model uses a dust sensor to continuously monitor dust levels in the air and start the necessary dust removal activities [5].

ESP32 microcontrollers are powerful and adaptable microcontrollers, which have been extensively utilized in Internet of Things (IoT) applications. Wi-Fi and Bluetooth are only two of the many communication capabilities provided by these controllers. They also have the processing capacity to manage sensor data and operate auxiliary devices. As the central nervous system of the dust removal system, the ESP32 microcontroller facilitates data processing, communication among hardware elements, and decision-making based on gathered sensor data. Existing methods of dust removal typically involve passive techniques such as air filters and ventilation systems [13]. While these methods can provide some level of dust reduction, they often have limitations in terms of efficiency, scalability, and real-time monitoring. Thus, the proposed model aims to overcome these limitations by developing an active and responsive system that can detect elevated dust levels and initiate immediate dust suppression measures [6, 8].

The remaining of this paper is organized as follows. Section II discusses the related work, Section III illustrates the methodology. Section IV presents the dust mitigation prototype. Section V presents experimental setup of the proposed model and results. Section VI presents the discussion and conclusion.

II. Related Work

According to the Energy Progress Report published in 2022 by the International Energy Agency (IEA), International Renewable Energy Agency (IRENA), World Bank, and World Health Organization (WHO), the United Nations Sustainable Development Goals (SDGs), which include improving air quality, are largely dependent on sustainable energy solutions [1]. The report evaluates the state of the world's efforts to achieve SDG 7, which is to guarantee that everyone has access to modern, affordable, dependable, and sustainable energy by 2030. It assesses advancements in energy efficiency, renewable energy, and the availability of clean cooking fuels and electricity. The proposed dust reduction system, which uses information technology to reduce air pollution, is in line with these objectives. The report offers a comprehensive discussion about the need to design creative solutions for monitoring air and reducing air pollution.

An annual report on the primary technical and natural dangers associated with hard coal mining has been made available [14], with a focus on the industry's need for efficient dust control. This report lists several coal mining dust emission sources, such as loading, blasting, drilling, and transportation. It also covers a number of dust control techniques used in the sector, including ventilation, water spraying, and the application of personal protection equipment. It is crucial to continuously monitor and control dust levels in order to lower the hazards related to dust exposure.

Controlling dust concentration in a hard coal mine processing plant's workplace was the subject of another investigation, which found that the spraying system, called New Environmentally Friendly and Efficient Pulverization Technology for Underground Mining (NEPTUN), significantly decreased dust levels [3]. The researchers measured the dust concentration before and after installing the NEPTUN system at various workstations using a dual-channel laser dust monitor. The results of the investigation showed that the processing plant's dust concentrations were considerably lower because of the NEPTUN spraying system, which suppresses dust using high-pressure water spraying. The results also showed that larger nozzle diameters and higher water pressure enhanced the system's efficiency.

A comprehensive review of many types of sensors, their operational mechanisms, and their uses in a variety of industries, including biomedical engineering, automotive systems, and environmental monitoring, was provided in [15]. The study covered the most recent developments in sensor technology, including wireless sensor networks and the IoT, which make it possible to gather and interpret vast amounts of sensor data for sophisticated applications. Furthermore, an overview of the several kinds of sensors—physical, chemical, and biological—as well as their uses in a range of industries, including agriculture, health care, and environmental monitoring, were given [16]. This study underlined how crucial it is to choose the right sensors for a given application based on factors like sensitivity, specificity, and operating principles. This discussion of the different sensor technologies provided insightful information that was useful for the creation and incorporation of sensors in the proposed dust reduction system.

The authors in [17] described multisensory data fusion and filtering for vehicle’s safety systems, which provide insightful information for the integration of several sensors in the suggested dust reduction system. They presented a number of data fusion methods that may be used to integrate and merge data from many sensors in order to enhance system performance, including Bayesian networks, particle filtering, and Kalman filtering. Furthermore, it emphasized the significance of sensor fusion in vehicles’ applications, including autonomous vehicles and driver assistance systems, where it is necessary to integrate data from several sensors to produce precise and trustworthy information for decision-making. The study underlined how important it is to take sensor fusion techniques into account when developing the suggested dust reduction system since it is likely to need information from several sensors in order to monitor and regulate the dust levels.

The use of big data and IoT technology in air quality monitoring was examined in [18], which offered insightful information for the suggested dust reduction system. The authors suggested an IoT-based air quality monitoring system that gathered data in real time from air quality sensors placed around different areas. Big data analytics techniques were used to process the gathered data in order to find trends, patterns, and anomalies and produce insights that decision-makers could use. The adoption of IoT and big data technologies in air quality monitoring presents a number of potentials and problems, including data security, privacy, and system scalability, all of which were covered in this study. The study emphasized how IoT and big data technologies might provide continuous, real-time monitoring of air quality, which could be essential for the successful installation of the suggested dust reduction system.

An automated cleaning method for removing dust from solar PV modules was demonstrated in study [19]. They discovered that automated cleaning solutions can enhance the performance of solar panels and are more effective and efficient than hand cleaning. The proposed model's dust removal component may benefit from the knowledge gained from this investigation.

In study [20], a smart dry fog technology for controlling fugitive dust emissions was introduced. The system is composed of a dry fog generator, a control unit, and a network of sensors. A thorough analysis of dust suppression systems was given in [21], which also assessed in applying this technology in different industries as well as their limitations and effectiveness. The efficiency of several dust suppression techniques, including ventilation, chemical treatment, and water spraying, in reducing dust emissions from various sources was covered by the authors. They also emphasized the significance of taking into account the unique properties of dust particles, such as their size, shape, and moisture content, when choosing the best dust suppression methods. The paper stressed on the importance of continuously monitoring and controlling dust levels in order to guarantee efficient dust control. A further study put forth a framework for incorporating sensors into an IoT platform [22]. A methodical approach to sensor integration—which encompasses sensor selection, data collection, processing, fusion, and visualization—was put forth by the authors. The framework highlighted the factors that should be taken into account when choosing the right sensors for a certain application type. These factors include cost, accuracy, and dependability. The authors also covered the opportunities and difficulties of integrating sensors into IoT platforms, including system scalability, data security, and privacy [23]. In conclusion, previous studies have shown that there is still room to develop novel approaches with even higher precision than those used previously in order to reduce or suppress dust particles in the ambient air.

III. Methodology

The proposed prototype for dust reduction includes five key components which are, the dust sensor, ESP32 microcontroller, sprinkler controlled by a spray module, TFT screen, and water level sensor. These components work together in a coordinated manner to achieve the goal of dust removal.

The dust sensor is responsible for detecting and measuring the concentration of dust particles in the air. It uses a digital dust particle sensor that can identify air dust aerosols greater than 0.8 μm in diameter. The sensor continuously monitors the ambient air and provides real-time data on the dust concentration. The ESP32 microcontroller acts as the central control unit of the system. It receives data from the dust sensor and processes it to determine if the dust concentration exceeds a predefined threshold. When the threshold is exceeded, the microcontroller triggers the spray module to initiate the dust suppression process. The spray module is designed to release a fine mist or water spray into the air to effectively reduce the dust concentration. It is comprised of a pump, nozzles, and a plumbing system that distributes the water evenly. The microcontroller controls the activation of the spray module based on the inputs received from the dust sensor. The TFT (Thin Film Transistor) screen, with its 3.5-inch display, serves as the user interface of the system. It provides real-time visual feedback to users, displaying the current dust concentration level, water tank level, and other relevant information. The TFT screen enhances user interaction and allows for monitoring and control of the system's operation. To ensure proper functioning of the system, a water level sensor is integrated to monitor the water tank level. It accurately measures the water level and provides feedback to the microcontroller. This allows the system to optimize water usage and prevent interruptions in the dust removal process.

By integrating and coordinating the functions of the above discussed components: dust sensor, ESP32 microcontroller, spray module, TFT screen, and water level sensor, the proposed prototype creates an intelligent and responsive dust removal system. The cooperative functioning of these components ensures efficient and effective dust suppression, leading to improved air quality and a healthier environment.

A. *Proposed Model Architecture*

The software system architecture encompasses the design and structure of the software system components that enable the coordination and functionality of the hardware tools. It involves the implementation of various software modules and their interactions to achieve real-time dust monitoring, automatic dust suppression, and user interface capabilities. The components contribute to the overall software architecture are:-

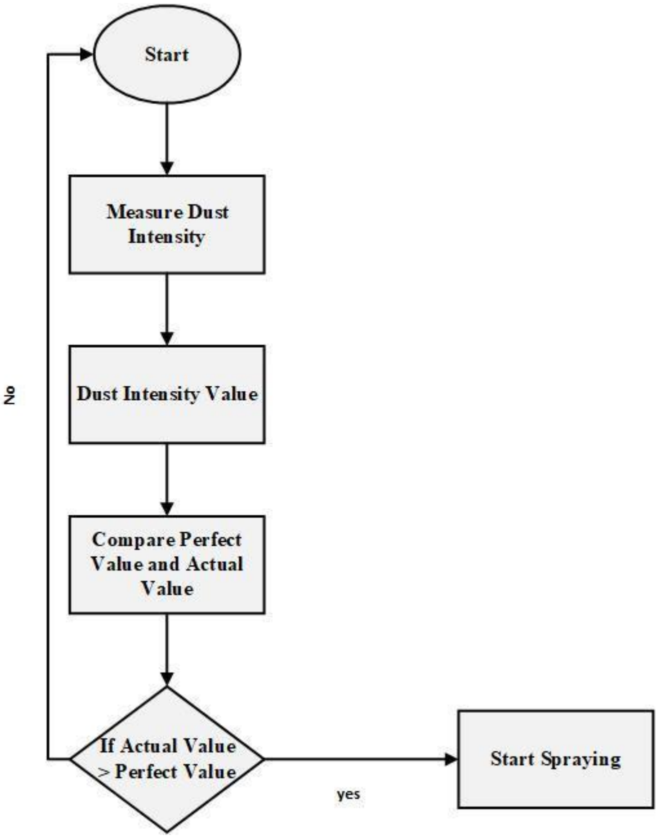
- Firmware for ESP32:- The ESP32 microcontroller requires firmware that serves as the foundation of the system. This firmware includes the necessary drivers and libraries to interface with the hardware components, such as the dust sensor, water level sensor, TFT screen, and spray module. It also manages communication between the different components of the system using protocols, such as Wi-Fi and Bluetooth, to facilitate data exchange and connectivity.

- Dust Monitoring and Control: The software architecture incorporates two modules for dust monitoring and control. The dust monitoring module reads the data from the dust sensor in real-time and processes it to determine the current dust concentration. Based on predefined thresholds, the control module initiates actions to activate the spray module for dust suppression. These modules work together to continuously monitor the air quality and respond accordingly.

- User Interface: The user interface module provides a visual representation of the system's status and enables user interaction. It utilizes the TFT screen to display real-time information, including the dust concentration level and water tank level. The user interface module allows users to monitor the system, adjust settings, and view historical data. It provides a user-friendly and intuitive interface to enhance user experience and system control.

- Data Storage and Analysis: This module captures and stores relevant data, such as dust concentration readings, system status, and user settings. It enables historical data analysis, trend identification, and performance evaluation of the dust removal system.
- Communication and Connectivity: The software architecture system includes modules for communication and connectivity. These modules enable the system to transmit and receive data from external sources, such as remote monitoring systems or control interfaces. Communication protocols like Wi-Fi or Bluetooth are utilized to establish connections and exchange information with other devices or systems. This enables remote monitoring, control, and integration with larger networks or cloud-based platforms.

The software architecture of the system ensures the seamless integration of the various software components with the hardware tools. It enables real-time monitoring, automatic control, user interaction, data storage, and connectivity functionalities. Through a well-designed software architecture, the dust removal system can effectively detect elevated dust levels, initiate appropriate actions for dust suppression, provide visual feedback to users, and facilitate data analysis for system optimization and performance evaluation.



Start
Measure Dust Intensity
Dust Intensity Value
Compare Perfect Value and Actual Value
If Actual Value > Perfect Value

No

Fig. 1. Flowchart of the proposed system mechanism.

The flowchart in Fig. 1 represents a simplified process for an automatic dust reduction system. The purpose of this system is to measure the dust intensity in the environment and determine if it is necessary to start spraying to reduce the dust levels. The steps of this dust reduction system are as following:-

1) Start: The process begins by initializing the automatic dust reduction system.

2) Measure dust intensity: The system measures the current dust intensity in the environment using dust sensors.

3) Dust intensity value: The measured dust intensity value is obtained from the sensors.

4) Compare threshold value and actual value: The system compares the actual dust intensity value with a predefined (acceptable) value. This value represents the maximum of dust intensity level in the environment, where below this value no dust suppression action is needed. The system checks if the actual dust intensity is greater than the threshold value. If the actual value is greater than the threshold value, it indicates that the dust levels in the environment are too high and require intervention to mitigate the dust. If the actual value is less than the threshold value, the system returns to the "Measure dust intensity" step, and continue monitoring the dust levels in the environment.

5) Start spraying: If the actual dust intensity value is higher than the threshold value, the system initiates the spraying process to reduce dust levels in the environment. After spraying, the system returns to the "Measure dust intensity" step to reassess the dust levels and determine if additional spraying is necessary.

IV. DUST MITIGATION PROTOTYPE

In the proposed system, the ESP32 microcontroller serves as the central control unit, managing the TFT display, dust sensor, water level sensor, and spray module. The system is powered by a Li-ion battery, which is charged using a charger. A voltage booster is connected between the battery and the ESP32 to ensure a stable voltage supply for the microcontroller and its connected components. Fig. 2 illustrate the different components of the system and the connections between these components.

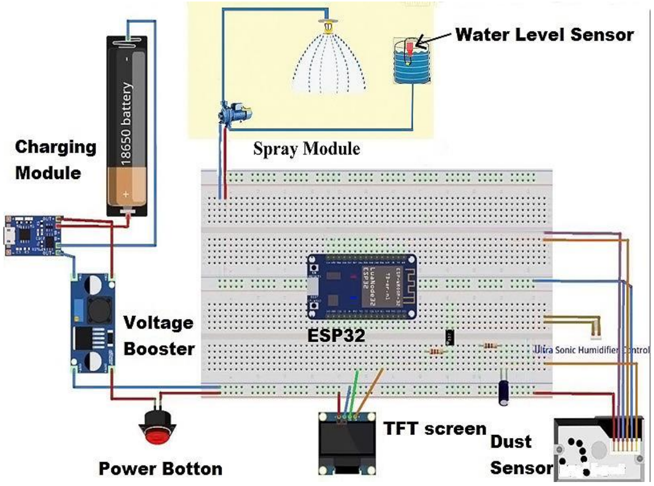

Fig. 2. Prototype components and connections.

In the followings, the role of each component is described:

- Charger Module and Li-ion battery: The charger provides power to the Li-ion battery, ensuring it remains charged and ready to supply energy to the system. The battery's role is to store energy and provide a stable power source for the entire system.
- Voltage booster: Connected between the Li-ion battery and the ESP32, the voltage booster steps up the battery's voltage to a suitable level for the microcontroller and its connected components. This ensures consistent performance and helps prevent under-voltage issues.
- ESP32 microcontroller: The ESP32 serves as the brain of the system, controlling and processing data from the sensors, managing the spray module, and displaying information on the TFT screen. It receives power from the voltage booster and communicates with each component through defined pin connections.
- TFT display: The TFT display is connected to the ESP32 and displays dust and water level readings, as well as warning messages when needed. It provides a user-friendly interface for monitoring the system's status.
- Dust sensor: The dust sensor is connected to the ESP32 through an analog input pin (A0). It detects dust levels in the environment and sends the readings to the microcontroller for processing. If the dust level exceeds the predefined threshold, the ESP32 activates the spray module.
- Water level sensor: The water level sensor is connected to the ESP32 through another analog input pin (A1). It measures the water level in the water tank used for the spray module. If the water level falls below a certain threshold, the ESP32 displays a warning message on the TFT screen.
- Spray module: Controlled by a servo motor connected to the ESP32, the spray module is responsible for releasing water to reduce dust levels when needed. The servo motor opens and closes the spray module based on commands from the ESP32.

The proposed dust reduction system is a cohesive unit that combines various sensors and components under the control of the ESP32 microcontroller. The system monitors dust and water levels, activating the spray module when necessary to mitigate dust levels, and alerts the user if the water level is low. The Li-ion battery supplies power, while the charger and voltage booster ensure stable and consistent performance (see Fig. 3).

V. EXPERIM ENTAL SETUP AND RESULTS

This section presents the test setup of the proposed prototype for dust mitigation. It includes the test setup, evaluation experiments, and the obtained results. The testing phase involved a comprehensive evaluation of the dust removal system to assess its functionality, performance, and effectiveness in reducing dust levels in the air. The testing phase aimed to validate the system's capabilities and ensure its reliable operation in real-world scenarios. The test was done in a controlled environment designed by the researcher. The system was implemented in a Plexiglass acrylic box measuring 15cm x 7cm x 20cm to simulate a controlled environment as seen in Fig. 4. Plexiglass acrylic is a transparent, lightweight, and durable material, making it suitable for creating a test chamber. The testing phase aimed to validate the system's capabilities and ensure its reliable operation in real-world scenarios. A controlled test environment was created, simulating different dust concentrations within the Plexiglass acrylic box. The test chamber was prepared with a calibrated dust source to generate consistent dust levels for evaluation. The system was calibrated and configured to establish baseline measurements and define the threshold for dust concentration. This calibration ensured accurate detection and appropriate response to elevated dust levels. Different evaluation setups were examined to test the proposed prototype:

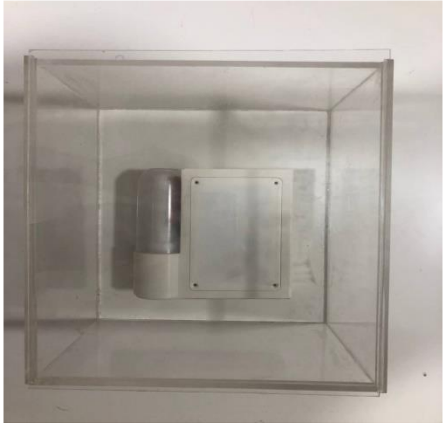

Fig. 4. Plexiglass acrylic box.

1) Evaluation No. 1: Evaluation Objective: Verification of the Activation and Efficiency of the Spray Module in Response to elevated dust levels. This Evaluation Procedure is as following:

- Initialize the Dust Reduction System.
- Set the initial dust concentration to 350 micrograms/m3.

Anticipated Outcome: The TFT display should accurately reflect the concentration of dust present in the immediate environment. With the initial concentration set at 350 micrograms/m3, the ESP32 microcontrollers expected to initiate the spray module, thus mitigating dust levels as shown in Table I.

TABLE I. THE PARAMETER OF EVALUATION NO. 1

parameter	values
The initial dust concentration	350 micrograms/m3
The final dust concentration	150 micrograms/m3
time	10 minutes

Documented Result: The TFT display displayed the correct initial dust concentration of 350 micrograms/m3. As anticipated, the ESP32microcontroller successfully initiated the spray module.

Evaluation status is successful, and the spray module effectively reduced the dust concentration from 350 micrograms/m3 to approximately 175 micrograms/m3 within a span of 10 minutes, which demonstrates a significant decrease of approximately 50% in dust levels.

2) Evaluation No. 2: Evaluation Objective: Examination of the Water Level Monitoring Mechanism and Warning Functionality Based on the Moisture Indicator. This Evaluation Procedure is as following:

- Initiate the Dust Reduction System.
- Deliberately allow the water reservoir to dry up, causing a change in the moisture indicator status from "moist" to "dry."

Anticipated Outcome: The TFT display should present the accurate status of the water level in the reservoir by displaying either "moist" or "dry." In the event that the water level descends to the "dry" status, a warning message "Low Water Level!" should be distinctly exhibited on the TFT display.

Documented Result: The TFT display successfully indicated the change in moisture status from "moist" to "dry." As soon as the moisture indicator switched to "dry," the ESP32 microcontroller successfully triggered the "Low Water Level!" warning message. The status of the evaluation is successful.

3) Evaluation No. 3: Evaluation Objective: Performance Analysis of the Dust Reduction System under Optimal Operational Conditions. The evaluation procedure is as shown:-

- Initiate the Dust Reduction System with the initial dust concentration set at 350 micrograms/m3 and the water level indicated as "moist."
- Monitor the system's performance in reducing dust levels.

Anticipated Outcome: The TFT display should correctly indicate both the dust concentration and the moisture status. With the initial dust concentration set at 350 micrograms/m3, the spray module should be initiated by the ESP32 microcontroller and effectively reduce dust levels.

Documented Result: The TFT display accurately demonstrated the dust concentration and moisture status. With the initial dust concentration set at 350 micrograms/m3, the spray module was successfully initiated by the ESP32 microcontroller, thereby reducing the dust levels. The status of the evaluation is successful.

The evaluation on effectiveness shows that the system exhibited high effectiveness as it reduced the dust concentration from 350 micrograms/m3 to around 175 micrograms/m3 within a 10-minute duration. This signifies a notable decrease of approximately 50% in dust concentration levels. Therefore, the system proves to be highly efficient in maintaining optimal dust levels in the environment.

The main difference between Evaluation No.1 and Evaluation No.3 lies in the specific objectives and conditions under which the Dust Reduction System is evaluated. Evaluation No. 1 concentrated on the system’s response to elevated dust levels and Evaluation No. 3 emphasized the overall performance under optimal conditions, including moisture status monitoring.

4) Evaluation No. 4: Evaluation Objective: Assess the Dust Reduction System's Performance in a Larger Test Environment (4m x 4m). Set up the Dust Reduction System in a controlled test environment designed by the researcher, a 4m x 4m room, simulating a larger workspace.

- Initiate the Dust Reduction System with the initial dust concentration set at 350 micrograms/m3 and the water level indicated as "moist."

- Monitor the system's performance in reducing dust levels in the larger test environment.

Anticipated Outcome: The TFT display should correctly indicate both the dust concentration and the moisture status. With the initial dust concentration set at 350 micrograms/m3, the spray module should be initiated by the ESP32 microcontroller and effectively reduce dust levels.

Documented Result: The TFT display accurately demonstrated the dust concentration and moisture status in the larger test environment. With the initial dust concentration set at 350 micrograms/m3, the spray module was initiated by the ESP32 microcontroller. However, the dust reduction performance was not as effective in the larger room compared to the smaller test environment.

The status of the evaluation is partially successful. Some technical issues were encountered during the test, which include uneven spray distribution and reduced spray coverage. These issues were attributed to the larger room size, which affected the spray module's ability to efficiently reduce dust levels throughout the entire space. Regarding the evaluation of the system's effectiveness in reducing the dust levels, the system has reduced the dust concentration from 350 micrograms/m3 to approximately 225 micrograms/m3 within a span of 10 minutes, which demonstrates a decrease of about 36% in dust levels.

In comparison to the previous evaluations conducted in the smaller test environment, the effectiveness of the system in the larger test environment was lower. This highlights the need for further optimization and adaptation of the system for larger spaces to achieve more efficient dust reduction. To enhance the system's effectiveness in larger environments, further research and development should focus on improving the spray module's coverage and distribution capabilities. This could involve modifying the nozzle design, optimizing the spray pressure, and incorporating additional spray units to ensure more uniform dust reduction throughout the entire space.

VI. Discussion

The proposed prototype for dust mitigation incorporated five components, which are a digital dust sensor, an ESP32 microcontroller, a water spray module, a TFT display, and a water level sensor to create a responsive and intelligent dust reduction system. The dust sensor monitored dust levels continuously, while the spray module suppressed dust when dust concentrations exceeded a pre-specified threshold. Together, all the system components have been utilized to reduce the environmental dust load.

The performance evaluation revealed that the combined dust sensor and sprinkler module system successfully reduced dust levels. In about 10 minutes, the system reduced dust intensity by up to 50% in a controlled test environment. This indicates that the proposed model achieved its objective of reducing airborne dust concentrations by integrating digital technologies.

The TFT screen displayed real-time dust levels and water tank measurements, allowing for system status monitoring. The warning feature alerted users when water levels were low, ensuring operation reliability. Thus, the screen provided visual feedback on the performance of the system and served as an effective user interface.

While the system performed well in a small test box, its effectiveness was reduced when operating the prototype in a larger room due to spray distribution and coverage issues. This demonstrates the need for further design optimization of the spray module in order to increase the effectiveness of dust control in spacious areas.

VII. Conclusion

In conclusion, the Automatic Dust Reduction System achieved its primary goals by integrating sensors and actuators into an intelligent dust removal model. The prototype successfully reduced the dust concentration in a small area. Nevertheless, for large-scale dust control, spray coverage and distribution must be optimized. Overall, the project demonstrates the feasibility of combining innovative technologies to develop an IoT intervention for enhancing air quality. With the appropriate modifications and enhancements, the proposed dust removal system could be implemented on a larger scale to assist in mitigating the serious threats posed by dust pollution. Future work for the dust reduction system involves several key areas of improvement and expansion. Additionally, enhancing the efficiency of the spray module is crucial. This can be achieved by optimizing the nozzle designed spray pressure, adding more spray nozzles to ensure adequate dust suppression, and implementing an adaptive spraying system that adjusts spray patterns based on room size and dust levels.

Q-KGSWS: Querying the Hybrid Framework of Knowledge Graph and Semantic Web Services for Service Discovery

Pooja Thapar, Lalit Sen Sharma
Department of Computer Science and IT, University of Jammu, J&K, India

***Abstract*—In the era of big data, Knowledge Graphs (KGs) have become essential tools for managing interconnected datasets across various domains. This paper introduces a novel RDF (Resource Description Framework) based Knowledge Graph of Semantic Web Services (KGSWS), designed to enhance service discovery. Leveraging the versatile SPARQL query language, the framework facilitates precise querying operations on KGSWS, enabling customized service matching for user queries. Through comprehensive experimentation and analysis, notable improvements in accuracy (69.75% and 90.01%) and rapid response times (0.61s and 1.57s) across two semantic search levels are demonstrated, validating the efficacy of the approach. Furthermore, research questions regarding the interlinking of ontologies, methods for formulating automatic queries, and efficient retrieval of services are addressed, offering insights into future avenues for research. This work represents a significant advancement in the domain of semantic web services, with potential applications across various industries reliant on efficient service identification and integration. Future phases of research will focus on logical inference and the integration of machine learning-based graph embedding models, promising even greater strides in knowledge discovery within the KGSWS framework, thus reshaping the domain of semantic web services.**

Keywords—Ontologies; knowledge graph; semantic web services; SPARQL query language; OWLS; data integration; service discovery

I. Introduction

In today's rapidly changing computing environment, the fundamental paradigm of Service Oriented Architecture (SOA) is supported by core engineering principles of Reusability, Discoverability, and Interoperability. These principles provide a robust framework for orchestrating communication in distributed computing environments characterized by services encapsulated in discrete units. SOA leverages standardized interfaces and protocols, enabling seamless integration and communication between heterogeneous systems, thereby fostering a modular and extensible architecture [1]. Web Services (WS), the embodiment of SOA, play a pivotal role in contemporary enterprise solutions by enabling the integration of systems across organizational boundaries. WS, being self-described and disseminated by organizations, facilitate interoperable, machine-to-machine interactions and promote code reusability across networks. The orchestration of this integration relies on the convergence of components such as WSDL (Web Service Description Language), UDDI (Universal Description, Discovery and Integration), and SOAP (Simple Object Access Protocol), including the Service Consumer, Service Registry, and Service Provider. These components empower manual examination of WS within the UDDI repository, enabling users to identify services based on their specific functionalities [2] . However, the use of XML as the standard language for describing WS capabilities, while crucial for service description, introduces ambiguity in keyword-based matchmaking due to the absence of machine-understandable semantic information. This challenge in the software landscape necessitates the introduction of formal knowledge representation—a shared, universally harnessed resource within intricate software engineering systems [3] [4].

Semantic Web Services (SWS) build upon the foundation of WS by incorporating semantic extensions through metadata vocabularies from the Semantic Web. These extensions are either realized through semantic annotations known as SAWSDL (Semantic Annotations for WSDL) or by employing domain ontologies rooted in description logic, as seen in OWL-S. Ontologies, acting as metadata vocabularies, provide a formal, machine-understandable representation of concepts and their relationships within a domain, enhancing knowledge comprehension. Among the conceptual models defining SWS, OWL-S distinguishes itself through the integration of domain ontologies into WS descriptions. This integration enables logical reasoning, facilitating more precise and automated service discovery. Rules and constraints, defined on the concepts and properties of domain ontologies, serve as reference points for logical inference, fortifying specification, consistency, and conceptualization during service discovery. It, therefore empower domain experts to navigate knowledge contexts across domains with unambiguous precision. However, the intricacies of description logic formalism within domain ontologies, and the proliferation of SWS services have presented efficiency challenges for industries and organizations in terms of service discovery [5-7].

This paper confronts these challenges by leveraging the burgeoning paradigm of Knowledge Graphs (KGs). The unique capability of KGs to incorporate semantic metadata descriptions of entities makes them a prime candidate for complex querying through semantic web technologies, particularly SPARQL querying [8] [9]. This work introduces a pioneering approach: the creation of an RDF-based Knowledge Graph of Semantic Web Services (KGSWS) for service discovery, empowered by SPARQL-based question answering. At its core, this approach centers on generating interlinked data from domain ontologies to significantly augment service discovery accuracy. By employing advanced KG techniques and querying methodologies, SPARQL queries utilize the knowledge encapsulated in OWL-S service descriptions and their linked ontologies from KGSWS to address queries based on diverse user input/output requests. In essence, KGSWS uncover the hidden correlations between service descriptions and domain ontologies; and provide insightful recommendations to refine the user experience effectively and thereby serving as a bridge between the realm of SWS and KGs.

The paper's structure unfolds as follows: Section II delves into the Background elements and techniques underpinning this research. Section III explores related work, elucidating the context that motivated our research endeavor. Section IV frames the research questions to be in the proposed work. Section V meticulously details the proposed methodology, laying out the innovative approach that unifies SWS ontologies and KGs. Following this, Section VI unveils our experimental results, providing a comprehensive comparative analysis with related work. Finally, in Section VII, we conclude and outline future avenues for this research, illuminating the potential for further advancements in the domain of semantic web services.

II. Background

This section lays the groundwork for understanding the key components and concepts that underpin our research:

A. Semantic Web

Semantic Web is an advancement to the existing Web 2.0, designed to enable machines to process information intelligently, akin to human reasoning. This capability is achieved through the strategic use of semantic tags, imbuing data with what we call "Semantic Metadata." To exemplify, consider the concept of a "Service" in our context. Semantic Metadata goes beyond the term itself, distinguishing between a "Web Service" as a functional software component and a "Semantic Web Service" as a service enriched with semantic information, by providing specific details about its functionalities, inputs, and outputs, thereby facilitating precise and automated discovery. Structured Linked Open Data (LOD) is represented as a graph, interconnecting data across servers via Universal Resource Identifiers (URIs). RDF (Resource Description Framework) leverages URIs to denote relationships within this graph. In this structured environment, edges serve as the conduits for relationships between two resources, culminating in triplets within a directed graph. Ontologies, integral to the Semantic Web stack, enhance data within specific domains with semantic metadata. These ontologies furnish explicit, machine-understandable descriptions of concepts and their relationships, thus deepening data comprehension. OWL (Web Ontology Language), a logic-based language, forms the foundation of these ontology models, empowering RDF triple stores with rigorous constraints. The presence of OWL reasons ensures not only logical consistency but also real-time computation of inferred knowledge, thereby propelling data automation and interoperability. Incorporating Knowledge Graphs and the SPARQL Query language into the Semantic Web framework enhances our methodology for precise service discovery [10-13].

B. Knowledge Graph (KG)

Knowledge Graphs (KGs) are intricate representations of real-world entities as interconnected nodes, serving as central hubs for information retrieval and complex web searches. Their significance in encapsulating machine-understandable contextual information within heterogeneous environments has spurred intensive research in semantic matching. In 2012, Google pioneered the concept with its Google Knowledge Graph, featuring an impressive array of 570 million entities [14]. Subsequently, KGs such as Geonames, FactForge [15], Yago [16], Wikidata [17], and more have been carefully built, containing a lot of Linked Open Data (LOD). Across various domains, including retail, entertainment, healthcare, finance, and more, KGs have revolutionized question answering and knowledge discovery, underlining their versatility. KGs typically adopt either the subject-property-object (s,p,o) notation or the entity-relation-entity representation. Formally, a KG is defined as a subset of $(\mathcal{E} \times R \times \mathcal{E}) \cup (\mathcal{E} \times L_r \times L)$, where:

- $\mathcal{E}$ refers to the set of entities.
- R signifies the set of relations between entities.
- L_r signifies the set of relations linking entities with object of literals.
- L refers to the set of literals.

In semantic network modeling, triplets (s,p,o) denote metadata statements resulting from the mapping of subject (s) and object (o) to nodes or entities and their associated properties (p) to links or relations. In this structured framework, $\mathcal{E}$ must be a URI or a blank node representing the subject, while R and Lr must be URIs, and the object entity can be a URI, blank node, or literal. In the context of SWS discovery, KGs herald a transformative shift from big data discovery to intelligent data discovery. Knowledge integration from domain ontologies plays a pivotal role in this transformation [18].

C. SPARQL Query

SPARQL Protocol and RDF Query Language (SPARQL) stands as the preeminent query language for Semantic Web data, providing a means to interrogate extensive RDF-based KGs. Unlike SQL, tailored for relational databases, SPARQL caters to NoSQL graph databases like KGs, enabling the integration of knowledge from diverse sources to derive new insights. Built on the HTTP transport layer protocol, SPARQL facilitates querying information from multiple KGs via federated queries. It employs graph pattern matching, represented as subject, predicate, and object (s,p,o) triple patterns, to uncover solutions. SPARQL supports four query types: ASK, SELECT, CONSTRUCT, and DESCRIBE, each designed for specific querying purposes [19]. By harnessing the capabilities of SPARQL, our methodology transcends conventional querying techniques, providing a sophisticated means to navigate and utilize the rich semantic information encapsulated within the KG.

III. Related Work and Motivation

Over the past decade, substantial research efforts have been dedicated to enhancing the efficiency of Semantic Web Services (SWS) discovery algorithms. These algorithms aim to facilitate the discovery, selection, composition, classification, and ranking of SWS based on various functional and non-functional parameters. Numerous matchmaking algorithms have been devised, leveraging both logical and non-logical functional parameters of SWS. These algorithms enhance the selection and recommendation process for SWS. Initial variant of OWLS-M0 [20] used only logic based semantic similarity measure on I/O for service discovery. However, the other variants in [20] and notable work by [21, 22] employed hybrid matchmakers that consider logical and non-logical parameters from OWL-S and WSMO services. Semantic similarity metrics such as cosine similarity, loss-of-information, and Jensen-Shannon divergence were employed to assess the compatibility of services. One challenge encountered in this context is the time-consuming creation of matchmaker ontologies, particularly when handling a substantial number of services. To address this, [23, 24] introduced a caching-based mechanism called Service Discovery Caching (SDC). SDC involves the construction of a graph to cache frequently used services, thereby mitigating the time overhead. Another line of research [25] employed First Order Logic (FOL) to formally describe service capabilities. The study utilized SPARQL 1.0 for querying services based on their descriptions, particularly in cases where services provided Preconditions and Effects (PE) descriptions. Although promising, this method was constrained by the limited availability of services with PE descriptions in the dataset, limiting its generality. Efforts to reduce the problem space of service searching led to prefiltering mechanisms [26-28]. These mechanisms were designed to enhance existing matchmaker engines using SPARQL queries, significantly improving response times. Nevertheless, the challenge of semantic matching persisted, particularly for complex concepts and relations within domain ontologies. Working on the same OWL-S dataset, the work in [29] have used unsupervised learning methods like DBSCAN clustering to cluster the services semantically closed and thereby finding the semantically closed cluster to user requirement using Latent Semantic Analysis (LSA). An ensemble model based approach in [30] use decision tree and logistic regression for service classification and recommendation of top-10 services. However, none of these works implemented the concept of KGs in the domain of SWS. The work cited in study [31] [32] employed machine learning methodologies; specifically K-Means clustering was used in [31] to generate a Service Ontology from SWS corpus. Results demonstrated that the generated ontology can be used for the discovery mechanism. Later work in [32] utilized first K-Means clustering and then K-Nearest Neighbors (KNN) for classification. This analysis yielded a noteworthy accuracy rate of 89.28%. However, it's essential to emphasize that this algorithm was rigorously tested within a restricted range of domains. Another work in [33] used part of OWL-S dataset i.e. 30000 triplets to add domain knowledge in KG and also for training and testing purpose of user’s intent. However, with advanced machine learning methods, the overall accuracy of SWS discovery has improved. However, most of these works [29-32] focused on a subset of domains within the OWLS collection, and none of the works have implemented an automatic querying method for user queries. Instead of using the relevance file provided for OWLS-TC as per user queries, different methods have been employed to compute evaluation metrics.

In parallel with advancements in SWS discovery, Knowledge Graphs (KGs) have emerged as a powerful tool for representing and retrieving knowledge from large interlinked datasets. These KGs integrate domain ontologies at a universal level, creating extensive graphical representations of interlinked data that support complex queries and unified knowledge discovery. Recent work on KGs has generated KGs in different domains whereas some works perform querying over the existing KGs to improve the tasks like recommendation systems, link prediction, node classification, and knowledge discovery [34-36]. Another line of works in [37-40] generate SPARQL queries from natural language for existing KGs like DBpedia, Wikidata for complex querying. Furthermore, Graph Neural Network-based learning models have been employed to enhance KGs' performance in tasks such as link prediction and multihop querying [41-43]. Our motivation for this research stems from the intersection of SWS discovery and KGs. Both domains utilize ontologies as a foundation, making them amenable to integration. While previous works have primarily focused on matchmaking within SWS or querying KGs independently, there is a notable gap in seamlessly integrating SWS discovery with Knowledge Graphs (KGs) specific to our domain of SWS for service discovery. This is the key motivation behind our research. We aim to bridge these domains by creating a Knowledge Graph of Semantic Web Services (KGSWS). This integrated approach enables enhanced SWS discovery using KG-based querying techniques.

IV. Research Questions

The motivation for this proposed work arose from an extensive review of related research papers and the challenges discussed in the field. Our objective is to establish a centralized Knowledge Graph (KG) for Semantic Web Services (SWS) and address the following research questions:

1) How can ontologies from different domains be interlinked to form an extensive Knowledge Graph enriched with semantic metadata thereby enhancing the discovery of SWS?

2) What methods can be used to formulate the automatic queries on the KG, aligned with varying numbers of inputs-outputs for effective querying purposes?

3) How can we efficiently retrieve SWS from big KG that precisely matched the user requirements for service discovery? Additionally, how can we identify the closely related services when an exact match is not available, maintaining the integrity of the user's query?

V. Proposed Approach

In this section, the detailed experimentation done to design a framework for discovery of relevant services across KGSWS has been discussed. The framework includes the steps required to create, visualize, and query the KGSWS as shown in Fig. 1. The detailed insights to these steps have been discussed in Phase 1 and Phase 2 of the framework. Phase 3 discussed the validation process of the results.

A. *Phase 1: Preprocessing Phase to Generate Knowledge Graph*

The core step of our approach is the creation of a Knowledge Graph designed explicitly for Semantic Web Services (KGSWS). This phase describes the steps involved in constructing the KGSWS from the OWL-S service descriptions and their associated domain ontologies with an example. Through this, semantic metadata was integrated with KGSWS that forms the backbone of the proposed approach.

1) OWL-S service descriptions and KGSWS Construction: OWL-S services are based on frameworks that add semantic extensions to non-semantic web services using domain ontologies. In OWLS approach, Service Profile describes the capabilities of the service and refer as the upper ontology, Service Modelling demonstrates data flow and control flow within the services and Service Grounding specify the procedure of interaction with these services using protocols and message formats. OWL-S service description is mainly provided by the upper ontology Service Profile where different terms describe the inputs, outputs, preconditions, and their effects (IOPE); postconditions, assumptions based on the transition rules, if required. Once the service based on the brief description of IOPE concepts in the Profile is selected; Process Model related with Service Profile is used for further interaction with these services by linking them to their domain ontologies. For instance, consider the Profile and Process Model in the Service Description of finding author of the book as shown in Fig. 2(a). In the Profile of the service <profile:serviceName>, <profile:textDescription>, <profile:hasInput> and <profile:hasOutput> provides the information of the book whereas the <process:

parameterType> in the process model linked the I/O concepts “Book” and “Author” to the ontology “books.owl” for the semantic matching of the concepts. In order to construct KGSWS from of these services, these I/O terms are referred as entities and their associated properties and restrictions form the relations are then mapped to literal or another entity. Since these I/O concepts refer to some domain ontologies description in the Process Model, these ontologies are also linked in KGSWS by extracting an interoperable definition of each concept from their properties and restrictions from domain ontology. This was done by first serializing the service descriptions concepts and their associated ontologies to Triple Notation (Turtle Notation. ttl). Apache Jena Fuseki was used for integration, thus all the OWL mappings, alignment axioms that indicate equivalence or relationships between terms were preserved. Afterwards, KGSWS graph was created using network and rdf based libraries like rdflib, networkx in Python which consists of 1,21,542 Triplets. Fig. 2(b) shows the snippet of turtle representation for example shown in Fig. 2(a).

(b)

Fig. 2. (a) Example of service description structure [42]. (b) Shows the snippet of turtle notation for above service description example used to construct KGSWS.

B. *Phase 2: Discovery Phase*

The main objective of this phase was to perform queries over KGSWS created in phase 1 of the proposed framework.

1) Querying and Searching from KGSWS: KGSWS, generated in Phase 1, comprises millions of entities and their attributes represented as nodes and edges. To query such specialized KGs, specialized knowledge of the querying language and a deep understanding of the underlying structure are required. Addressing the challenge of searching for relevant services based on the I/O concepts mentioned in the user request, we automated the generation of SPARQL queries based on the OWL-S service description model. These queries are then executed across the KGSWS to search and retrieve relevant services. The proposal used SPARQL 1.1 query due to its efficient results in pre filtering of domain wise services [28] and recommendation by W3C for querying over graphical databases. However, the work lacked its own matchmaker and has not integrated different domain ontologies to create big KG due to which services based on equivalent concepts were not retrieved. For instance, to find the name of books giving title or other information as input retrieve the service no.1 and 2 with output concept “Book” from “books.owl” domain ontology as valid services as shown in Table I. In the given query, the service no. 3 having interface description “Publication-number” as input and “Book” as output concept from “univ.owl” is also valid due to equivalence relation of “books:Book ≡ univ:Book” where books and univ are namespaces for “books.owl” and “univ.owl” ontologies respectively.

As show in Fig. 3(a) of “books.owl” ontology, the “Book” concept was used to describe information of different types of books and in Fig. 3(b) of “univ.owl”, the same highlighted concept was added as a subclass of “Publication” concept. To query the KGSWS, two methods were implemented with a view to include different degree of semantic matching.

2) Semantic matching: To evaluate the performance of different degree of semantic match of concepts during discovery of services from their knowledge graph, two methods namely Method 1 and Method 2 were used to generate query wise relevant list. These two matchmaking algorithms focus solely on the input and output parameters of the service and employ two levels of semantic concept matching, namely ‘Q_{each}’ and ‘Q_{few}’ as outlined in Table II. This is followed by the pseudocodes for both discovery methods. The Phase 1 of constructing KGSWS is followed by the process of parsing I/O concepts based on user requests. Subsequently, a SPARQL query, guided by steps 9-12, was executed to retrieve a list of relevant services using Select, Where, Filter, Bind, Regular expressions options in the query. For the determination of services using "Q_{each}," each concept in the user request was considered, and services aligned with equivalent concepts in other ontologies within the same domain were retrieved through the 'owl:equivalentClass' restriction. Additionally, for "Q_{few}," beyond the steps involved in "Q_{each}," a 'UNION' operation in the SPARQL query was introduced to filter out entirely irrelevant services.

TABLE I. SOME RELEVANT SERVICES TO FIND THE BOOK NAME FROM ITS GIVEN INFORMATION

S.No.	WSName	Textual Description of the Functionality	Interface Description	
			Input	Output
1.	BookFinder.owls	The services retrieves the book information having title as input	books:Title	books:Book
2.	BookSearchService.owls	Search engine for book	books:Title	books:Book
3.	Publication_book_service.owls	The service retrieve the book name with given publication number	niv:Publication	univ:Book

TABLE II. DEMONSTRATED THE METHODS FORMULATION IN DESCRIPTION LOGIC

Method No.	Method Name	Description Logic Representation	Description
Method 1	Q_{each}	If $I_{concept}(S) \equiv I_{concept}(R_q)$ ^ $O_{concept}(S) \equiv O_{concept}(R_q)$	Service S concepts are semantically equivalent to R_q Concepts
Method 2	Q_{few}	If $I_{concept}$ $(R_q) \subseteq I_{concept}$ (S) ^ $O_{concept}(R_q) \subseteq O_{concept}(S)$	R_q concepts matched to some concepts of service S
where $I_{concept}(S)$, $I_{concept}(R_q)$, $O_{concept}(S)$, and $O_{concept}(R_q)$ represents the inputs/outputs concepts of advertised and request services respectively			

Pseudocode for Method 1: Q_{each}

```
Input:
Given user query refer to required $Q_{input}$ and $Q_{ouput}$ where:
        $Q_{input}$: List of required input concepts in the query
        $Q_{ouput}$: List of required output concepts in the query
Output:
                RSL: Relevant Service List
Local Resources:
KGWS = Knowledge Graph of Services
and their Ontologies
For each query, Parse $Q_{input}$ and $Q_{output}$
Parse the TDB knowledge graph of services
Check if the predicate of the triplet is service:Service
For each service, retrieve the process Input and Output tags
from the triplet
Retrieve <process:parameterType> tags of process Input
and Output to retrieve domain ontology
Apply filters for semantic matching of "each" concept of
$Q_{input}$ and $Q_{ouput}$.
Generate RSL($Q_{input}$, $Q_{ouput}$, RSL- Relevant Service List)
Repeat
```

Pseudocode for Method 2: Q_{few}

```
Input:
Given user query refer to required $Q_{input}$ and $Q_{ouput}$ where:
        $Q_{input}$: List of required input concepts in the query
        $Q_{ouput}$: List of required output concepts in the query
Output:
                RSL: Relevant Service List
Local Resources:
KGWS = Knowledge Graph of Services
and their Ontologies
For each query, Parse $Q_{input}$ and $Q_{output}$
Parse the TDB knowledge graph of services
Check if the predicate of the triplet is service:Service
For each service, retrieve the process Input and Output tags
from the triplet
Retrieve <process:parameterType> tags of process Input
and Output to retrieve domain ontology
Apply filters for semantic matching of "few" concepts of
$Q_{input}$ and $Q_{ouput}$.
Generate RSL($Q_{input}$, $Q_{ouput}$, RSL- Relevant Service List)
Repeat
```

C. Phase 3: Parsing of Relevance File

In this phase, the list of services generated in Phase 2 was validated against the services in the relevance file provided by domain experts for "OWL-TC4."

The file features a <binaryrelevanceset> root tag containing <request>, <name>, and <uri> tags for each service request, as shown in the above structure of XML relevance file. These tags were employed to assign a unique ID to each request, with service request names based on the requested service's functionality. The <uri> tag contains a unique address to identify the request on the web. Furthermore, each <request> has a <ratings> tag containing multiple <offer> tags specifying the <name>, <uri>, and binary relevance in the <relevant> tag of the service. These requests have been parsed and the relevant information was stored in a CSV relevance file using Python libraries for hierarchical structures as shown in pseudocode. The service list from Phase 2 was compared with this relevance file to determine the key parameters of the model, as discussed in the next section.

Pseudocode: To Parse XML DOM

```
1. Import the XML libraries and other hierarchical libraries
2. Parse the relevance file 'owls-tc4.xml'
3. Get the root of the structure
   //To match the name and uri of each query request given by the user
4. For each user request as child in xml file
5. Retrieve the name and uri of the request
   //Find the name, uri, and relevance value of services for particular request
6. For each item offer giving the details of the service
7. Retrieve the service name, uri and its relevance value.
8. Append the results in data frame //As hierarchical structure
9. Export the results as "outputxml.csv"
```

Structure of the XML Relevance File

```
<binaryrelevanceset> //for the binary relevance sets
<request ...>
<name ... />
<uri .../>
<ratings>
<offer ...> //each request contains multiple offers
<name ... />
<uri .../>
<relevant>value</relevant>
//here the value can be either 0 or 1
</offer>
...
</ratings>
</request>
...
</binaryrelevanceset>
```

VI. Results and Discussion

In this section, a comprehensive analysis of the performed experiments has been discussed to assess the performance and efficiency of our proposed framework. The section commenced by describing the experimental scenario and the dataset used for testing. Following this, an in-depth analysis of the results has been done to emphasize significant observations and comparisons between our approach and baseline methods.

A. *Experimental Scenario*

In order to test the performance of our proposal, ontology based SWS test collection OWLS-TC v4 [44] was used to create KGSWS. As shown in Table III, the collection contains 1083 services from nine domains namely Education, Medical Care, Food, Travel, Communication, Economy, Weapon, Geography, and Simulation. These services were based on 48 domain ontologies. KGSWS consists of 1,21,542 triplets generated from the integration of these 1083 service descriptions and their corresponding 48 domain ontologies. Further, 38 test queries with varying number of input output concepts based on the domains were executed against KGSWS using two different SPARQL query methods.

TABLE III. Domain Names and Number of Services in each Domain

S.No.	*Domain*	*No. of Services*
1	*Education*	279
2	*Medical Care*	73
3	*Food*	34
4	*Travel*	197
5	*Communication*	59
6	*Economy*	325
7	*Weapon*	40
8	*Geography*	60
9	*Simulation*	16
	Total	*1083*

B. *Analysis of Results*

In this subsection, we provide a comparative analysis of our proposed methods i.e. Method 1 (Q_{each}) and Method 2 (Q_{few}), against baseline approaches. The key parameters that were used to compare the performance of these methods are given below in Table IV [45]. The Macro-Averaged Precision Recall metrics was used to give equal relevance to each test query and its value lies in the range [0, 1]. The relevance file provided for OWLS-TC (as discussed in Phase 3) was utilized to compute the key parameters of the methods in the proposed framework.

1) Analysis of method 1 results: As discussed, Method 1 employed each concept matching approach, aligning service requests with the concepts within the KGSWS. This precision-oriented method demonstrated noteworthy results as shown in Fig. 4(a) and Fig. 4(b). It retrieved fewer or zero irrelevant services, leading to significantly higher precision in most cases. Also, Method 1 exhibited an average query response time of a mere 0.61 seconds, showcasing its efficiency. However, this method faced challenges in test cases 8, 17 and 22, where it failed to locate any relevant service matching each concept, leading to a precision value of zero and due to equal importance of each query it dropped the overall precision value even if in most of the cases the values reaches 1 as shown in Fig. 4(a). Furthermore, the proposed model did not include logical inferred "subclass" concepts during the matchmaking of each concept. Due to this, all the relevant services having input-output concepts as direct subclass concepts of requested concepts in the query were not retrieved dropping the macro-averaged recall value to 49.14%. But, the overall accuracy of the model is 69.75% better than one of the existing work [20].

TABLE IV. KEY PARAMETERS USED FOR THE PERFORMANCE EVALUATION OF THE MODEL

Precision	Precision in case of SWS is defined as the number of relevant services out of the total number of services retrieved by the framework. Mathematical equation to calculate the Precision value is given as follows: $\frac{S_{relevant}}{S_{relevant} + S_{irrelevant}}$ where, $S_{relevant}$ gives the number of relevant services retrieved, and $S_{irrelevant}$ gives the number of irrelevant services retrieved
Recall	Recall is computed by taking the fraction of relevant services retrieved out of the total relevant services given in the relevance file by domain expert. Mathematical equation to calculate the Recall value is given as follows: $\frac{S_{relevant}}{S_{relevant} + S_{relevantNR}}$ where, $S_{relevant}$ gives the number of relevant services retrieved, and $S_{relevantNR}$ gives the number of relevant services not retrieved by the framework
Macro-Average Precision	Macro Average Precision is used to compute the arithmetic mean of the precision of each test query in case of multiclass classification. $\sum_{q=1}^{N} \frac{Precision}{N}$ where, q represents the number of test queries and $Precision_q$ gives the precision value of q^{th} query
Macro-Average Recall	Macro-Average Recall is used for multiclass classification and is computed by taking arithmetic mean of each test query recall value. $\sum_{q=1}^{N} \frac{Recall_q}{N}$ where, q represents the test query and takes values up to N, and $Recall_q$ gives the recall value of q^{th} query
Accuracy	Accuracy provides the overall performance of the model by computing the ratio of correct predictions out of total predictions done by the model.
Average Query Response Time	Average Query Response Time (Avg. Q_{rt}) is computed by taking the average of total response time taken to execute all the test queries.

- Logical Inferencing over KGSWS

The incorporation and interconnection of ontologies within KGSWS not only enhance the outcomes, as discussed in the previous section, but also pave the way for easier reasoning, composition, and classification in the future. Reasoning over KGSWS involves incorporating logically inferred concepts through the "subclass" symmetric relation. For example, when searching for services that provide the price of a given book, services that yield "MaxPrice" or "RecommendedPrice" as output, with "book" as input, are also deemed relevant. This relevance stems from their subclass relationship with the "Price" concept. However, the proposal did not account for the addition of logically inferred subclass concepts from the given concepts, leading to a decrease in the overall accuracy of Method 1.

2) Analysis of Method 2 results: Method 2, characterized by looser restrictions on the semantic match of I/O concepts, yielded contrasting results as shown in Fig 4(c) and Fig 4(d). This enhancement allowed the automatic retrieval of services sharing subclass relationships with some concepts of user concepts thereby capturing more closely related services. This flexibility leads to improved recall values, as Method 2 can identify a broader range of relevant services. This method proved beneficial in the worst cases of Method 1, where it retrieved some relevant services and achieved non-zero precision. However, this came at the trade-off of retrieving some irrelevant services, resulting in a decrease in average precision. This highlights the potential of Method 2 for more comprehensive service discovery, albeit at the expense of precision. Table V demonstrates the macro-averaged results, accuracy and average Q_{rt} of the two methods.

3) Comparison with existing frameworks: Comparing our experimental results with some published results of other existing works on the same dataset (see Table VI), it was observed that our proposed method demonstrated superior performance in terms of average response time and accuracy. Notably, the two-step approach in [28] involving prefiltration and subsequent matchmaking incurred a higher average query response time compared to our approach. This is a significant achievement, considering that our search was conducted over the integrated KGSWS, underlining the efficiency and swiftness of our approach. Moreover, the matchmakers of [20] exhibited longer response times, primarily attributable to the addition of concepts to a new matchmaker ontology for each request. In contrast, our approach, which seamlessly integrates the advantages of in depth querying over Knowledge Graph, overcame this bottleneck, leading to a more streamlined and efficient service discovery process. An important observation in our results was that while some subsequent studies [29-32] explored machine learning-based classification techniques, none had harnessed the potential of the Knowledge Graph within this domain.

(d)

Fig. 4. (a) Macro-averaged precision recall of method 1. (b) Query wise accuracy of method 1 and the dotted redline shows the macro-averaged accuracy of the model. (c) Macro-averaged precision recall of method 2. (d) Query wise accuracy of method 2 and the dotted redline shows the macro-averaged accuracy of the model.

TABLE V. KEY PARAMETERS RESULTS GIVEN BY TWO METHODS "Q_{EACH}" AND "Q_{FEW}"

Key Parameters	Method 1	Method 2
Macro-Averaged Precision	0.9036	0.9388
Macro-Averaged Recall	0.4914	0.8614
Accuracy	0.6975	0.9001
Average Query Response Time (in s)	0.61 s	1.57s

C. Discussion

The proposed work, used the advanced potential of KGs for semantic enrichment and querying, overcomes the limitations of previous approaches by introducing an integrated composite schema known as KGSWS for querying. This schema allows Method 1 and Method 2 to incorporate more relevant services within the same domain using different levels of filtering and regular expressions during the discovery process. The integration of domain ontologies and service descriptions in KGSWS enables the alignment of heterogeneous concepts within the same domain with user-requested concepts, thereby increasing the accuracy of both Method 1 and Method 2. However, as the work does not include logical reasoning over KGSWS, the performance metrics of Method 1 experienced a decline to 69.75% due to the matching of each concept of the user-requested query. Additionally, while Method 2 benefits from the inclusion of more equivalent concepts within the same domain, allowing for the automatic inclusion of more relevant services with loose concept matching using filters and regular expressions, this also entails the inadvertent inclusion of some irrelevant services. Compared to previous approaches, our proposed framework offers a comprehensive querying solution rather than relying on pre-filtering through querying on exiting matchmakers [28], which can lead to increased response times. Furthermore, unlike existing methods [20] that create matchmaking ontologies for discovery, our approach does not require such intermediary steps. For validation purposes, our work utilized the relevance file provided for the OWLS dataset in Phase 3 instead of employing alternative methods [29-33] to find relevant services, thereby enhancing the reliability of the framework. Additionally, we considered the complete OWLS-TC dataset rather than using its subset to generate KGSWS and further for service discovery. The framework also allows for the automatic generation of queries based on user-requested concepts, offering a generic and streamlined approach to querying.

TABLE VI. COMPARISON OF ACCURACY AND QUERY RESPONSE TIME OF EXISTING FRAMEWORKS WITH THE PROPOSED FRAMEWORK

	Accuracy (%)	Average Q_{rt} (in sec.)
Method 1	69.75	0.61 s
Method 2	**90.01**	**1.57s**
OWLS-M0 [20]	49.55	57.33s
OWLS-MX3 (M3) [20]	82.96	58.46s
SPARQLent [28]	72.02	55.00s
HELSWSR [30]	85.60	-
-[29]	83.09	-
- [32]	89.28	-

VII. CONCLUSION AND FUTURE SCOPE

In this paper, we have presented a framework for the automatic discovery of SWS through the use of SPARQL querying over KG. By introducing the KGSWS framework, a paradigm shift has been made by offering more precise and machine understandable context during automatic matchmaking of services. The integration of domain ontologies in KGSWS introduces a new level of semantic richness that effectively resolved the ambiguity associated with keyword-based matchmaking of WS. In conclusion, our work contributes to the field of SWS discovery by efficiently retrieving the relevant services aligned with the concepts in user request. Our approach also addresses several research questions discussed at the outset of this work.

A. Addressing Research Questions

1) How can ontologies from different domains be interlinked to form an extensive Knowledge Graph enriched with semantic metadata thereby enhancing the discovery of SWS?

Our framework successfully accomplished this by constructing the KGSWS from OWL-S service descriptions and their associated domain ontologies that forms a centralized repository of semantic metadata to enhance the discovery process of services.

2) What methods can be used to formulate the automatic queries on the KG, aligned with varying numbers of inputs-outputs for effective querying purposes?

Our experiments demonstrated the effectiveness of our approach in generating and executing general-purpose queries over KGSWS. The capabilities of two semantic matching methods namely "Q_{each}" and "Q_{few}," have been evaluated in answering user queries based on varying input/output parameters.

3) How can we efficiently retrieve SWS from big KG that precisely matched the user requirements for service discovery? Additionally, how can we identify the closely related services when an exact match is not available, maintaining the integrity of the user's query?

The semantic matching methods provide a practical solution to this challenge. The "Q_{each}" method excels in retrieving precisely matched services whereas the "Q_{few}" method retrieved closely related services when exactly matched services are not available.

B. Future Scope

While our proposed work has achieved promising results, several avenues for improvements and future research exist:

1) Logical inference: In future work, the inclusion of logical inferencing techniques in Q_{each} semantic matching can enhance the macro-averaged recall and thereby accuracy of our framework.

2) Scalability and machine learning based models: As the number of SWS and their associated ontologies continues to grow, scalability remains a critical concern. The incorporation of machine learning based graph embedding models can efficiently handle large KGs and also enable more accurate service recommendations.

VIII. DECLARATIONS

Author contribution P.T and L.S conceived the idea. P.T executed the experiments and wrote the article. L.S did edition and corrections.

Rural Revitalization Evaluation using a Hybrid Method of BP Neural Network and Genetic Algorithm Based on Deep Learning Model

Songmei Wang*, Min Han
School of Marxism, Zhengzhou Technical College, Zhengzhou, Henan 450121, China

***Abstract*—The rural revitalization strategy is a comprehensive plan for supporting rural revival in the new development stage while prioritizing agricultural and rural area development. Establishing a rural revitalization evaluation model will help monitor and guide the development of rural revitalization strategies and comprehensively deepen rural reforms. This research combines the benefits of the BP neural network with the genetic algorithm, introduces the genetic algorithm in optimizing the weights and thresholds of the BP neural network, and develops a GA-BP neural network model to evaluate and predict rural rejuvenation. The research findings demonstrated that the GA-BP neural network model possesses rapid convergence, accuracy, and stability in assessing and predicting rural revival and can evaluate and predict rural revitalization well.**

Keywords*—The rural revitalization strategy; deep learning model; the GA-BP neural network; evaluation model

I. Introduction

The rural revitalization strategy marks that China has entered a new era in solving the “three rural” issues [1]. It will be significant for governments at all levels to understand the implementation process of rural revitalization, implement targeted policies, and give full play to the ingenuity, enthusiasm, and creativity of the country’s cadres and the masses [2].

The evaluation of rural revitalization might establish objectives and requirements. The general conditions for rural rejuvenation were described as “prosperous industries, livable ecology, civilized rural customs, effective government, and rich life” [3]. To make the general demands of the rural revitalization strategy and the “three-step” objective concrete and executable, an evaluation system for rural revitalization must be developed. Rural revitalization evaluation is conducive to an intuitive description of the overview of rural revitalization and construction, drawing a blueprint for the future vision of rural revitalization so that decision-makers, commanders, and builders of rural revitalization have a clear direction and goal of efforts and have a clear vision for rural revitalization [4]. Rural revitalization evaluation can keep track and make adjustments to the strategy’s progress. Using the rural revitalization evaluation model, it is possible to track the development of the rural revitalization strategy, including whether progress has been made in the five areas of “prosperous industry, livable ecological, civilized rural traditions, efficient governance, and prosperous life.” Through monitoring the rural revitalization process, the problems existing in the rural revitalization process can be found in time to implement targeted policies and correct the deviations in the development. Rural revitalization evaluation helps classify and guide rural revitalization strategies in various regions. The rural revitalization strategy must proceed from the actual situation of each region, and it needs to be promoted according to local conditions and classified. The rural revitalization evaluation can rank the existing rural conditions according to the index evaluation scores of various regions to scientifically measure the progress and grasp the actual situation of rural revitalization in various regions [5].

BP neural network, a multi-layer feedforward network trained through backpropagation algorithm, and genetic algorithm, a search algorithm that simulates natural selection and genetic mechanisms. This hybrid method can more effectively solve complex problems in rural revitalization evaluation. There are certain limitations in the evaluation of rural revitalization in existing research. Some studies may rely solely on traditional statistical methods or a single machine learning algorithm, which may not fully address the complexity and non-linear relationships in rural revitalization evaluation. By introducing a hybrid method of BP neural network and genetic algorithm, we can better capture these complexity and nonlinear relationships, thereby providing more accurate and comprehensive evaluation of rural revitalization.

II. Literature Review

A. Rural Revitalization Strategy

1) Rural revitalization strategy: The proposed and improved rural revitalization strategy is based on rural construction theory and practice [6]. Regarding national development, the stance of “agricultural, rural areas, and farmers” must be spelled out. The peasant masses are crucial to the process of national revolution, construction, and development, and peasant masses must constantly be taken into account in national development [7]. “Three Rural” work is not only related to rural areas’ development but also to social stability and the realization of national goals. The government should give political guarantees for the healthy growth of “agricultural, rural areas, and farmers” and should direct the development and construction of rural areas. The government should emphasize agricultural production and policy reform, promote agricultural and rural modernization, and improve the training of rural grassroots party groups and talent management [8].

2) The scientific connotation of a rural revitalization strategy: They were all development plans put forth by the state in reaction to the current domestic situation at the time, and the “rural revitalization strategy” was founded on “creating a new socialist countryside” [9]. The introduction of the rural revitalization plan is a necessary condition for the growth of the times, indicating that rural development has reached a new stage and that a new era based on the strategy is about to begin [10].

Rural revitalization is a three-dimensional security strategy that encompasses economic, ecological, cultural, social governance, and other components of the entire revitalization rather than just one or a few areas of revitalization [11]. First is adhering to the policy orientation of prioritizing the development of agriculture. Agricultural development must focus on high-quality development requirements, stabilize grain production, and ensure the absolute security of national rations. Agricultural development must adhere to the word “excellent” and quality first. Social development cannot simply pursue scale and speed but should seek sustainability. The level of development varies greatly in different regions. It is necessary to respect the differences, diversity, and regional characteristics of agricultural and rural development, implement classification, and adapt to local conditions [12]. Whether the prerequisites for the priority development of agriculture and rural regions can be accomplished in practice depends on whether the objectives of agricultural and rural modernization and national modernization can be achieved. Second, clarifying the general guidelines for the rural rejuvenation approach is the second step. Third, industrial revitalization is the focal point and critical component of rural revitalization. Developing modern agriculture, promoting the integrated growth of primary, secondary, and tertiary industries, and establishing a rural industrial system is crucial for the success of rural industries. The country needs to keep developing agriculture that is good for the environment now and in the future. Fourth, comprehensively deepening rural reforms are necessary for rural rejuvenation. Reform is necessary for rural revival to promote vitality. Further adjustments are required to ensure the agricultural structure is optimized and to assume the integrated growth of primary, secondary, and tertiary industries in rural areas.

B. Deep Learning Model

1) Deep learning: Deep learning, a machine learning algorithm, makes multiple multilayered, nonlinear modifications to data to abstract it [13]. A multi-level machine learning approach called “deep learning” is built on learning representations to model the intricate relationships between data [14].

Deep learning builds a hierarchical model structure matching the human brain (attribute categories or features) by modeling the brain's nervous system with a rich hierarchical structure and extracting the input data level by level to construct more abstract higher-level representations [15].

2) BP Neural Network Model

a) Structure and characteristics of BP neural network: A BP neural network is constructed with an input layer, several hidden layers, and an output layer [16]. The output signal from the second layer serves as the input signal for the third layer, the excitation mode unit of each node output by the input layer serves as the input for the first hidden layer, etc. [17]. Fig. 1 depicts a BP neural network with a three-layer design and one hidden layer.

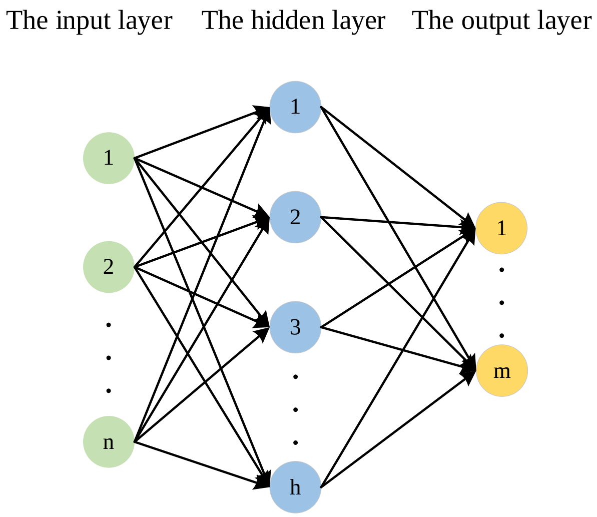

Fig. 1. Three-layer BP network model structure.

b) BP neural network learning algorithm: The mathematical relationship between signals of each layer is [18]:

$$o_k = f(net_k), k = 1,2,\ldots,l \quad (1)$$

$$net_k = \sum_{j=0}^{m} w_{jk}\, y_j, k = 1,2,\ldots,l \quad (2)$$

$$y_j = f(net_j), j = 1,2,\ldots,l \quad (3)$$

$$net_j = \sum_{i=0}^{n} v_{ij}\, y_i \quad j = 1,2,\ldots,m \quad (4)$$

The derivatives of *f(x)* in the above equations are all S-functions, and the derivatives of *f(x)* are:

$$f'(x) = f(x)[1 - f(x)] \quad (5)$$

The mean square error of the actual output of the network to the desired output is:

$$E = \frac{1}{2}\sum_{k=1}^{l}(d_k - o_k)^2 \quad (6)$$

Then, the amount of weight adjustment in the output and hidden layers of the network is:

$$\Delta w_{jk} = \eta(d_k - o_k)o_k(1 - o_k)y_j \quad (7)$$

$$\Delta v_{ij} = \eta(\sum_{k=}^{l} \delta_k^o w_{jk})y_j\ (1 - y_j\ )x_i \quad (8)$$

$$\delta_k^o = (d_k - o_k)o_k(1 - o_k) \quad (9)$$

The η is the scaling factor, which represents the learning rate in the network training.

Supposing the BP network has *m* implicit layers. In that case, the number of nodes in the implicit layer is represented by m_1, m_2 ,..., m_h, and the output of the hidden layer is represented by y_1, y_2,..., y_h, then the amount of weight adjustment for each layer is:

Output layer: $\Delta w_{jk}^{h+1} = \eta(d_k - o_k)o_k(1 - o_k)y_j^h \quad j = 0,1,2,\dots,m_h; k = 1,2,\dots,l$; the h-th hidden layer: $\Delta v_{ij}^h = \eta(\sum_{k=1}^{l} \delta_k^o w_{jk}^{h+1})y_j^h(1 - y_j^h)y_i^{h-1} \quad i = 0,1,2,\dots,m_{h-1}; j = 1,2,\dots,m_h$; first hidden layer: $\Delta v_{pq}^1 = \eta(\sum_{r=1}^{m_2} \delta_r^2 w_{qr}^2)y_q^1(1 - y_q^1)x_p \quad p = 0,1,2,\dots,n; q = 1,2,\dots,m_1$

From the previous, it can be observed that in the BP learning algorithm, the input signal of each layer, the error signal of each layer's output, and the learning rate all influence how much the weights of each layer are adjusted [19].

C. *Genetic Algorithm*

1) Basic concept of genetic algorithm: A method for global optimization known as a "genetic algorithm" was developed by mimicking biological processes like genetic evolution [20]. It is characterized by group search and mutual exchange of information between groups. The genetic algorithm search does not depend on the gradient problem. So, it has excellent robustness and a capability for worldwide search. Additionally, complex nonlinear problems that are challenging to solve using conventional search techniques can be solved using evolutionary algorithms. Genetic algorithms use many concepts in biology, such as gene chain code, population, crossover, variation, fitness, and selection [21].

2) Flow of genetic algorithm: Like neural networks, genetic algorithms are capable of nonlinear mapping and can solve complex optimization problems, such as multi-objective and nonlinear optimization problems. In addition, a genetic algorithm is an approximation algorithm. The mathematical model of the genetic algorithm is shown in Fig. 2.

3) Design and implementation of genetic algorithm

a) Coding method: Genetic algorithms operate on individuals in a population to accomplish optimization, and they can only deal with individuals through gene chain codes [21]. Therefore, individuals need to be transformed into the form of gene chain codes before using the genetic algorithm. This process is called coding. When designing the encoding scheme, three issues are often considered.

Completeness: All points in the problem space can be found in the expression space, i.e., all possible solutions in the problem space can be transformed into gene chain codes. Soundness: all points in the expression space find their counterparts in the problem space, i.e., each gene chain code corresponds to a possible solution. Non-redundancy: there should be a one-to-one correspondence between the problem and expression spaces.

b) Design of fitness function: The fitness function's design is the foundation for the genetic algorithm's optimization search and directly impacts how well it works. The design of the fitness function is dictated by how the problem will be solved, and it must have a positive outcome. The following three aspects of the fitness function are explained from the fitness function's design method, the fitness function's adjustment, and the influence of the fitness function on the genetic algorithm [22].

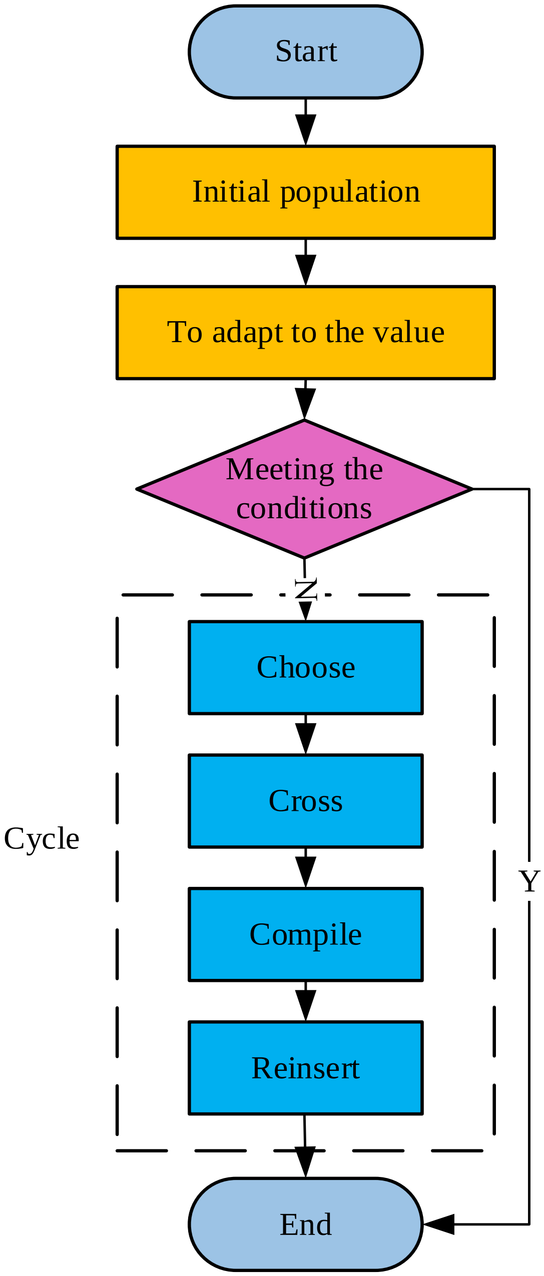

Fig. 2. Mathematical model of genetic algorithm.

i) The fitness function's design process. The fitness function's design must take into account two factors. First, the genetic algorithm seeks the smallest value rather than looking for the most significant value of the goal function of g(x). Second, the genetic algorithm ranks the individual's fitness based on this to determine the selection probability so that the fitness function must be positive. How to map the objective function into the maximum form and ensure the non-negativity of the fitness function is the key to the design of the fitness function. The function can be multiplied by -1 to transform the minimum value problem into a maximum value problem. However, this does not guarantee the non-negativity of the fitness function. For this case, the following approach can be taken to transform the objective function *g(x).*

$$f(x) = \begin{cases} C_{max} - g(x), & g(x) < C_{max} \\ 0, & others \end{cases} \quad (10)$$

The C_{max} in the above formula is usually taken as the maximum value of *g(x)* in the process of evolution. If *g(x)* is a non-negative function, *f(x)=1/g(x)* conversion can also be used.

When the genetic algorithm finds the maximum value of the objective function *g(x),* to ensure the non-negativity of the fitness function, the conversion can also be performed:

$$f(x) = \begin{cases} C_{min} + g(x), & C_{min} + g(x) > 0 \\ 0, & others \end{cases} \quad (11)$$

In the above formula, C_{min} is usually taken as the evolutionary process's minimum value of *g(x).*

ii) Adjustment of the fitness function. Some abnormal individuals often appear when using the genetic algorithm to optimize the population. When the number of abnormal individuals is too much, the more competitive they will be, which will lead to the phenomenon of convergence before the optimization is full. Therefore, it is crucial to reduce the competitiveness of these abnormal individuals. Reducing the competitiveness of abnormal individuals can be achieved by deflating the fitness function, and this deflation becomes the adjustment of the fitness function. The adjustment of the fitness function is the key to ensuring that good individuals are selected, and the commonly used adjustment methods are linear adjustment and power function adjustment.

The following formula can express linear adjustment:

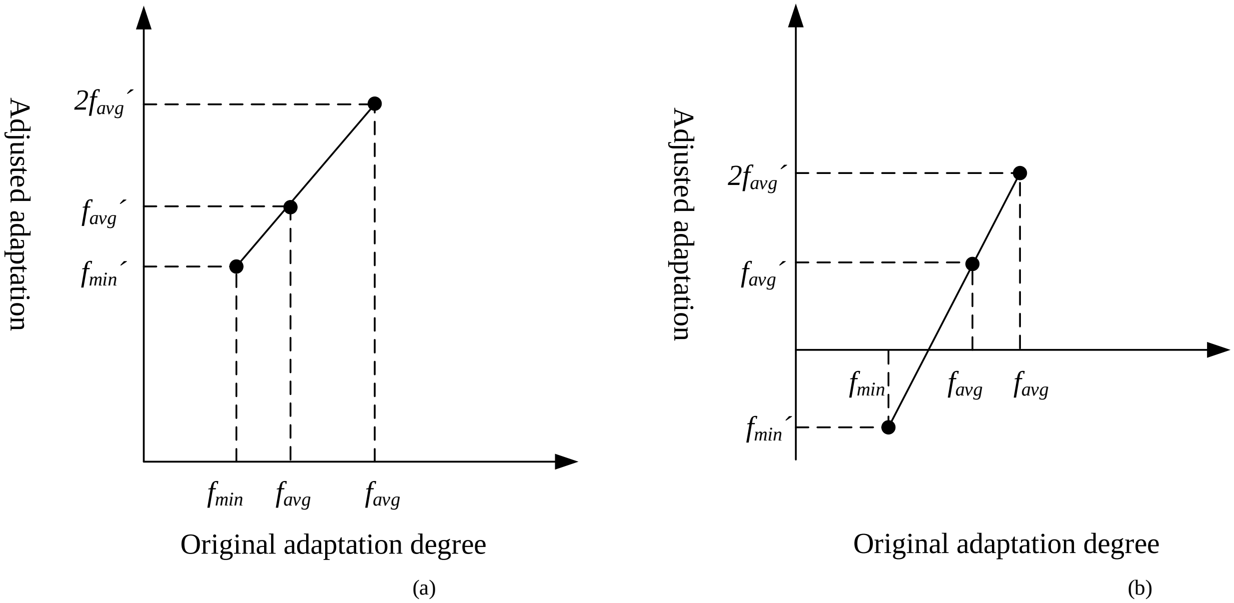
$$f(x)' = af(x) + b \quad (12)$$

In the formula above, *f(x)* represents the original fitness function, *f(x)'* represents the modified fitness function, and the coefficients a and b are selected to satisfy the following conditions: (1) The adjusted fitness must have the same mean value as the original fitness. (2) The highest value of the modified fitness function must be a predetermined multiple of the original fitness function's mean value. That is,

$$f_{max}(x)' = Cf_{avg}(x) \quad (13)$$

The *C* is a replication number set to obtain the optimal individual, and usually, *C* can take a value between 1.2 and 2.0.

Condition (1) is proposed to ensure that, on average, individuals in each population can produce the desired offspring in subsequent selection treatments. The proposed Condition (2) would limit the number of offspring generated by the person with the highest initial fitness. It should be noted that the adjusted fitness values may have negative values. The excessive scaling of coefficient C mainly causes the negative value to the original fitness function. Fig. 3(a) shows the result of the standard adjustment, in which the fitness values of a few abnormal individuals are scaled down, and the others are scaled up, and there are no negative fitness values. Fig. 3(b) shows the unreasonable adjustment. The fitness of abnormal persons is significantly lower than the mean value of fitness $f_{avg}(x)$ and the maximum value of fitness f_{max} *(x).* When the linear adjustment is used to pull apart $f_{avg}(x)$ and $f_{max}(x)$, there will be negative fitness values. When the coefficient *C* cannot meet the requirement of fitness adjustment, the original fitness minimum $f_{min}(x)$ can be mapped to the adjusted fitness minimum and make $f_{min}(x)' = 0$, provided that $f_{avg}(x) = f_{avg}(x)'$ is still guaranteed.



(a) (b)

Fig. 3. (a) Result of standard adjustment. (b) Unreasonable adjustment.

Power adjustment: The adjustment is to do k times power treatment on the original fitness function *f(x)*, that is, *f(x)' =f*$_k$*(x)*, and the value of *k* is related to the solution of the problem to be solved, and it can be corrected on demand in the process of the algorithm.

iii) The influence of the fitness function on the genetic algorithm

First, the genetic algorithm's selection operation directly affects how the fitness function is designed. Second, the fitness function specifies the genetic algorithm's iteration stopping condition. There is no specific theory about the genetic algorithm iteration stopping condition. Generally, the iteration stopping condition is when the fitness function reaches the maximum or suboptimal value. However, the maximum and suboptimal values are uncertain in many optimization problems. In such cases, the algorithm iteration is usually terminated when the evolution of the population of individuals tends to a steady state.

c) Selection of genetic operators: The genetic algorithm makes up of three fundamental operators—selection, crossover, and mutation. The selection operator plays a crucial part in the genetic algorithm, with the fitness proportion technique and the expectation value method constituting the most overall selection strategies [23]. The most used selection algorithm is the fitness proportion technique. Each person's fitness in this approach relates to how likely they will be chosen. If the starting population size is n and each individual's fitness score is f_i, the likelihood that an individual will be chosen is P_i.

$$P_i = \frac{f_i}{\sum_{j=1}^{n} f_i} \tag{14}$$

The expectation ratio method calculates the number of individuals' next generation expected to survive based on their fitness values. This method can avoid the phenomenon that good individuals are eliminated and abnormal individuals are selected in the fitness proportion method. The following formula can describe the expected value proportion method.

$$M = \frac{f_i}{\bar{f}} = \frac{nf_i}{\sum f_i} \tag{15}$$

The *f* is the fitness function's average value.

D. Optimization of Neural Networks by Genetic Algorithm

1) Optimizing network connectivity: The BP learning method is the most traditional way to gain the connection rights of the BP neural network. This algorithm's drawbacks include sluggish training speed and frequent slips into local minima. This issue can be significantly resolved by employing the genetic algorithm. The steps of the genetic algorithm to improve the connection rights of the BP neural network are as follows.

a) Determining the encoding scheme. The encoding method has binary encoding and real encoding. Binary coding is simple but not intuitive, and the accuracy is not high; Real coding is very intuitive and accurate. Therefore, the real coding method is commonly used to encode the connection weights.

b) Determining the fitness function. In genetic algorithms, fitness functions can be defined as f= C-e, where C is a constant and e is the sum of the squares of errors. There are many ways to select the fitness function, including the relationship with energy function, evolution time, and network complexity, as long as the fitness function is non-negative.

c) Genetic manipulation. In a genetic algorithm, genetic operation mainly refers to selection, crossover, and variation. The advantage of genetic operation is that it can realize a global search for complex nonlinear functions. However, when gradient functions are easy to obtain, they should be used as much as possible. The local optimization capability of the BP algorithm is relatively robust. Thus, adding a genetic algorithm with global optimization capability can modify the BP algorithm's flaws.

2) Optimizing network structure: The connection patterns and weights between the nodes are the two primary components of a neural network's structure. The following are the main steps in the genetic algorithm optimization of the neural network structure.

a) Randomly generate n different structures and encode each structure. Different codes correspond to different structures.

b) Training the structures in the individual set with different initial weights.

c) Determining the fitness of individuals with the results of training.

d) Selecting the individuals with higher fitness for the next generation.

e) Crossover and mutation of the population to produce a new generation.

f) Repeat the process of (2)-(5) until the network structure meets the requirements.

E. Establishment of the GA-BP Model

Optimizing BP networks with genetic algorithms mainly includes three aspects: optimizing connection weights, optimizing network structure, and optimizing learning rules [24]. However, the theory of network structure optimization and learning rule optimization is still immature and difficult to implement. This paper focuses mainly on the research and implementation of genetic algorithms to improve the weights and thresholds of BP networks [25].

A genetic algorithm encodes the connection weights and thresholds in the BP network in order to maximize the neural network's connection weights. Finally, genetic operators are employed, including selection, crossover, and variation [26]. The genetic output results are utilized as the initial weights and thresholds of the BP network to generate the GA-BP prediction model, and the GA-BP model is trained to attain the needed level of accuracy [27]. The specific operation flow is shown in Fig. 4.

III. Method

A. Establishment of Rural Revitalization Evaluation Index System

This paper establishes the following evaluation index system based on the Specification for the Construction of Beautiful Countryside in the New Era. There are four primary indicators and 15 secondary indicators. The primary indicators are the basis of industrial development, ecological environment, civilization management, and living standards.

B. Determination of the Evaluation Level of Rural Revitalization

This paper uses the Delphi technique to measure how rural revitalization has affected the research object to measure the situation accurately. The Delphi technique is simply a confidential letter consultation process. Generally, it involves gathering expert opinions on the problems that need to be forecasted, sorting, induction, and statistics, followed by anonymous feedback to the experts. This process is repeated until all expert opinions are in agreement.

C. Construction of GA-BP neural network model

1) Determination of the number of neurons in the input and output layers: The contribution of the BP network to this experiment is the second indicator of the rural revitalization evaluation index. Therefore, there are fifteen neurons in the input layer and one neuron in the output layer, which reflect the assessment value of the results of rural revitalization.

2) Determination of the number of hidden layers and the number of neurons: Nonlinear recognition capabilities of the BP network are caused mainly by the existence of one or more hidden layers between the input and output layers. Through the addition of more hidden layers, accuracy can be enhanced and error reduced. However, it also increases the network’s complexity and training time, as well as the training error of the network weights. Consequently, there are two methods for improving accuracy: increasing the number of hidden layers and the number of hidden layer neurons. The optimal number of neurons for the buried layer cannot be calculated with absolute confidence on a theoretical level. The selection of the number of inferred layer neurons is also compatible with specific empirical formulations, such as Formula (16). The estimated number of implied layer neurons derived from the formula can serve as the starting point for the trial-and-error process.

$$m = \sqrt{n+1} + \alpha \tag{16}$$

Fig. 5 shows the correlation coefficients and mean square error (MSE) obtained by training the three-layer BP neural network with the number of neurons in the hidden layer ranging from 5 to 15.

According to this study, when there are 12 neurons in the hidden layer of a three-layer BP network, the correlation coefficient is at its highest, and the MSE is at a more desired level. The correlation coefficient is at its lowest when the number of neurons in the hidden layer is 13, and the correlation coefficient is even negative during training. Theoretical investigation indicates that the average number of neurons in the buried layer is between 1 and 2. After repeated training, two BP number neural networks were initially identified: BP networks with one hidden layer and two hidden layers. Fig. 6 depicts the output of the correlation coefficients and mean square error (MSE) after training these two networks ten times.

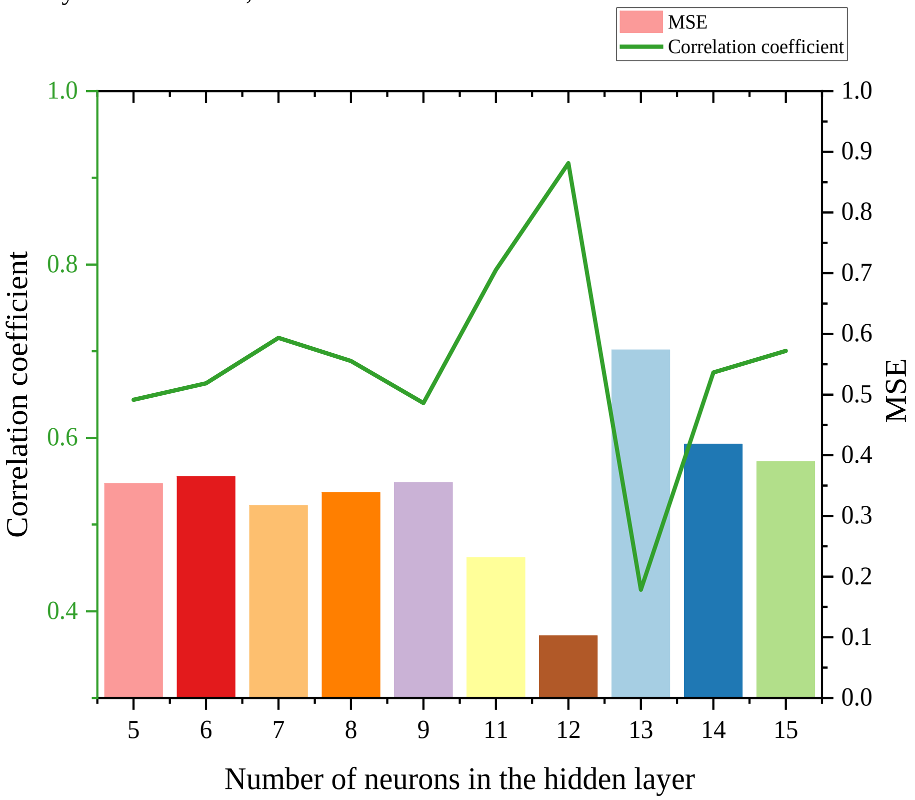

Fig. 5. Training of three-layer BP neural network.

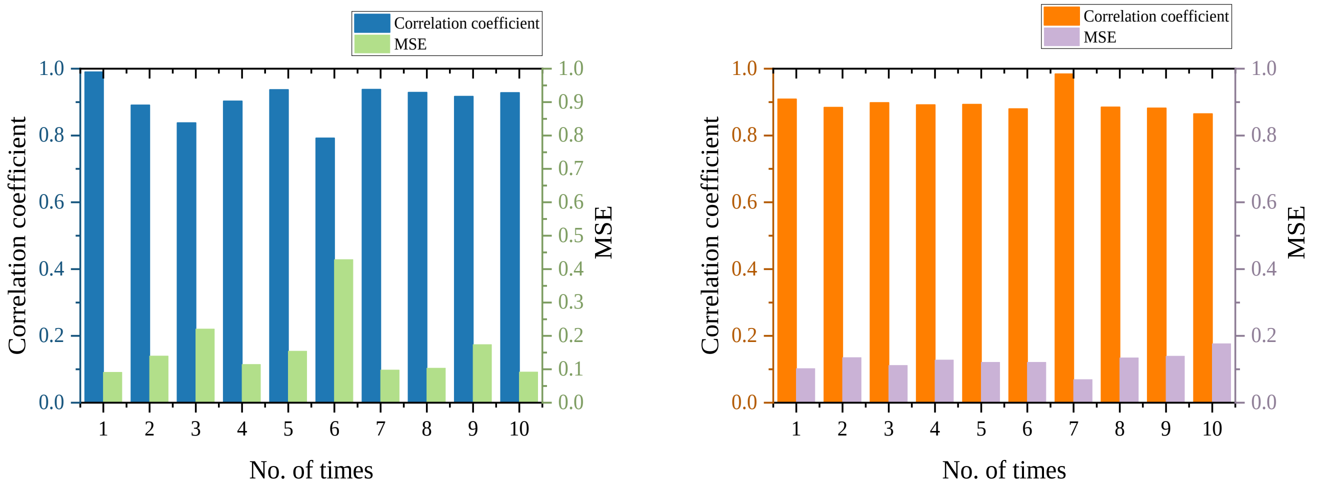

One hidden layer of BP neural network

Two hidden layers of BP neural network

Fig. 6. Correlation coefficients and MSEs of BP networks with different numbers of hidden layers.

The unpredictability of the BP network's initial weights is evident in the fact that the outcomes of each training are not the same and that there is a significant amount of variability in the training results. It is found that the differences in training error, correlation coefficient, and MSE between the BP network with one hidden layer and the BP network with two hidden layers are not much. Moreover, compared with the BP network with one hidden layer, the network structure with two hidden layers is more complex and takes longer to train. The fact that the results of each training are different and that there is a sizable level of variability in the training results shows how unpredictable the starting weights of the BP network are.

D. Optimization of Weights and Thresholds by Genetic Algorithm

1) Determining the genetic algorithm population: In genetic algorithms, the size of the population directly affects the global optimization characteristics of the genetic algorithm. In general, the larger the population size, the higher the diversity of the population, and the less likely the algorithm will fall into local minima during optimization. The population size is generally set between tens and hundreds. The calculation speed is also considered in the selection of population size. Combining these two factors, in this experiment, the number of genetic algorithm populations is 40.

2) Determining the genetic algorithm variation probability: In the genetic algorithm, the variation probability's size directly affects the algorithm's convergence and the final solution's performance. The larger the variation probability, the higher the diversity of individuals, but an increase in the variation probability reduces the convergence of the network, leading to a reduction in the final solution's performance. In engineering applications, the variation probability size usually ranges from 0.001 to 0.1. In this experiment, the probability of the genetic algorithm was determined to be 0.05.

3) Training of the genetic algorithm: The fact that each training produces a new set of outcomes and a considerable degree of variability in the training results demonstrates how unpredictable the BP network's beginning weights are. The genetic algorithm of this experiment is selected 100 times, and the MATLAB genetic algorithm toolbox is applied to train the samples. The error sum of the squares curve and fitness value curve during training are shown in Fig. 7. With the increase in training times, the sum of error squares becomes smaller and smaller, and the fitness value increases gradually. The larger the fitness value, the higher the sample's fitness to the environment is.

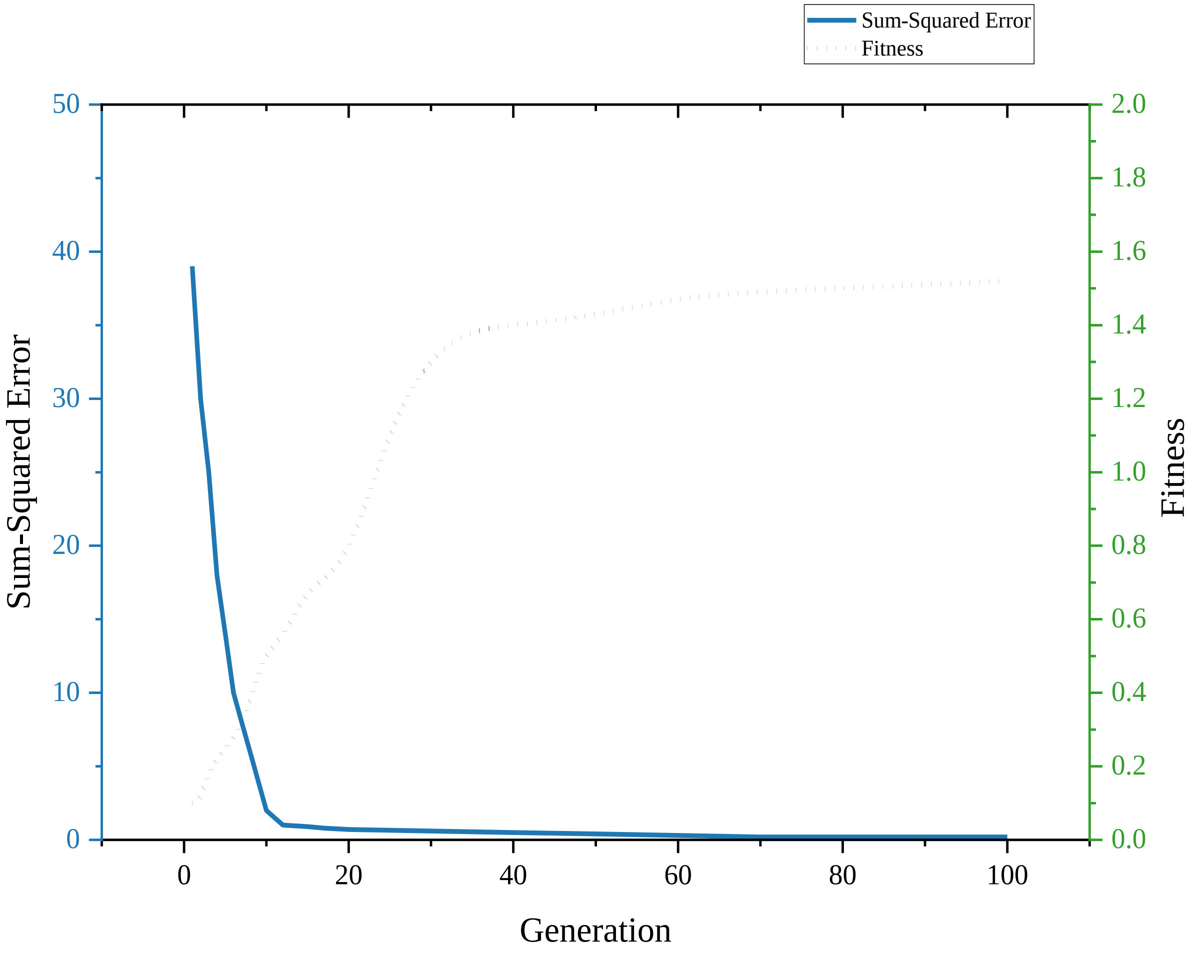

Fig. 7. Error sum-of-squares curve and fitness curve.

IV. Results

A. Selection of Training Samples

In this work, 30 samples were selected: 20 were used for training the GA-BP model, and 10 were used as test samples. The evaluation indexes in the samples were used as the input of the GA-BP model, and the model's output was the prediction of the rural revitalization evaluation at this time. Finally, the prediction accuracy of the GA-BP model could be obtained by comparing the predicted value with the actual value.

B. Evaluation of GA-BP Prediction Model

This paper used three indicators of convergence, accuracy, and stability. Convergence was judged based on the number of Epochs of steps in the network training process to determine the convergence speed. Different networks converge faster with fewer steps when they reach the same training goal; conversely, convergence is slower with more steps. Accuracy was determined by the relative error between the test simulation output value and the desired output value of different networks to determine the accuracy of the output results obtained by testing the trained network. Where, relative error = (test simulation output value - desired output) / desired output × 100%. The stability of the network was further judged from the macroscopic point of view by calculating the mean square error (MSE) of the test output of different networks based on the error between the test simulation output and the expected output.

The convergence curves of the GA-BP prediction model are shown in Fig. 8. It can be found that the loss function of the GA-BP prediction model converges to stability and achieves the training goal after 400 times of training.

In this article, the GA-BP network model was evaluated, and the test simulation output results are depicted in Fig. 9. It can be seen that the GA-BP prediction model can reduce the percentage error of predicted samples to less than 4% and that the prediction error of some samples is nearly zero.

The GA-BP prediction model was trained ten times, and the percentage error, correlation coefficient, and mean square error (MSE) of the test samples are output, as shown in Fig. 10.

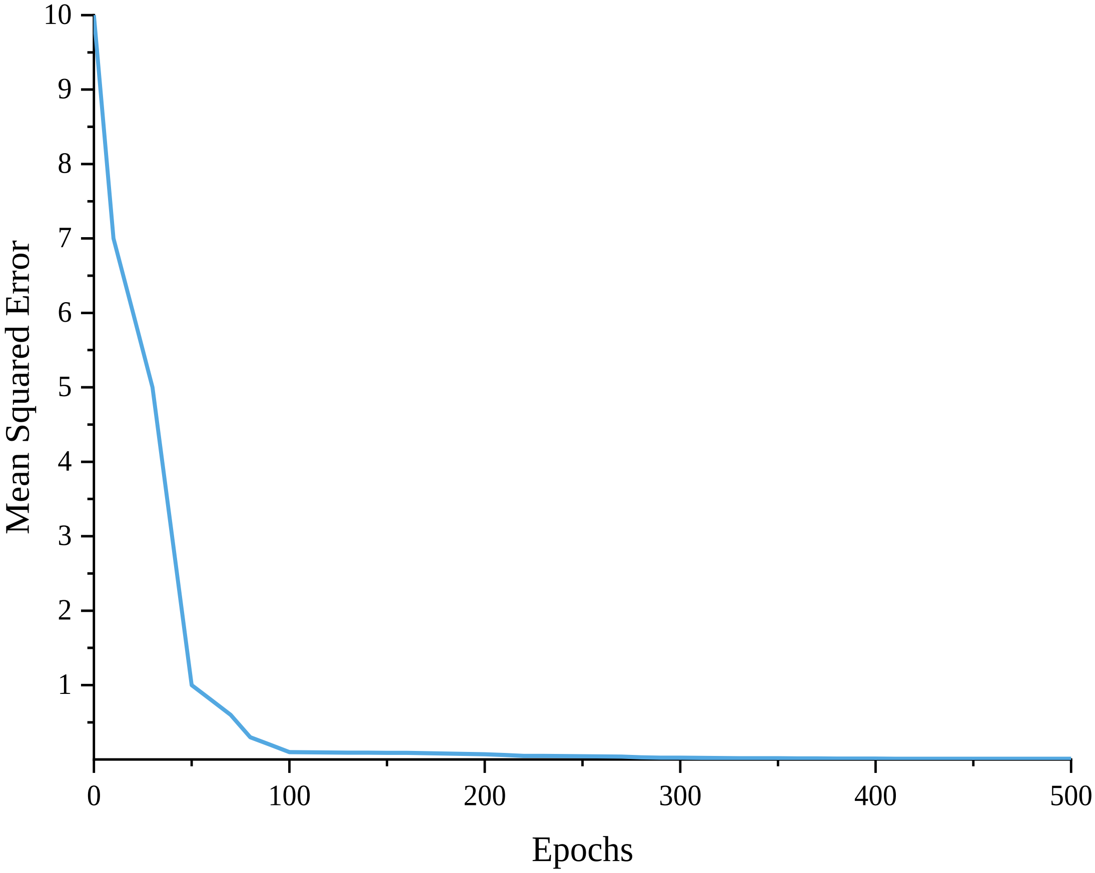

Fig. 8. Convergence of the GA-BP prediction model.

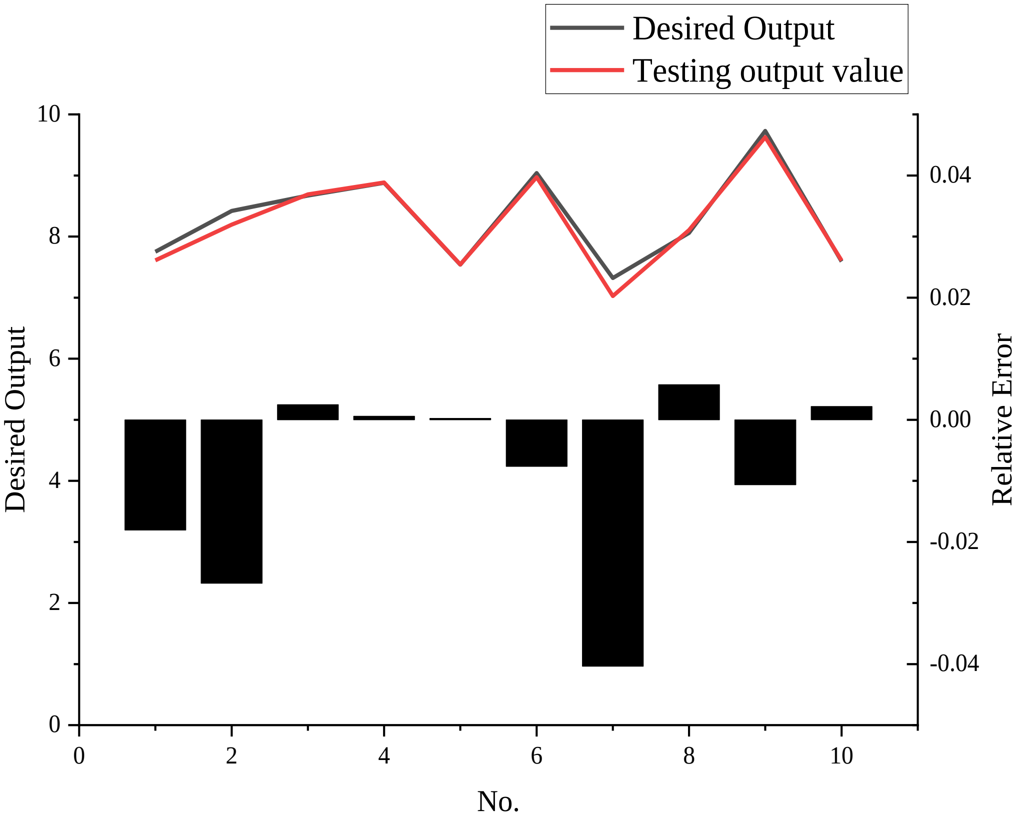

Fig. 9. Simulation results of GA-BP neural network for test sample data.

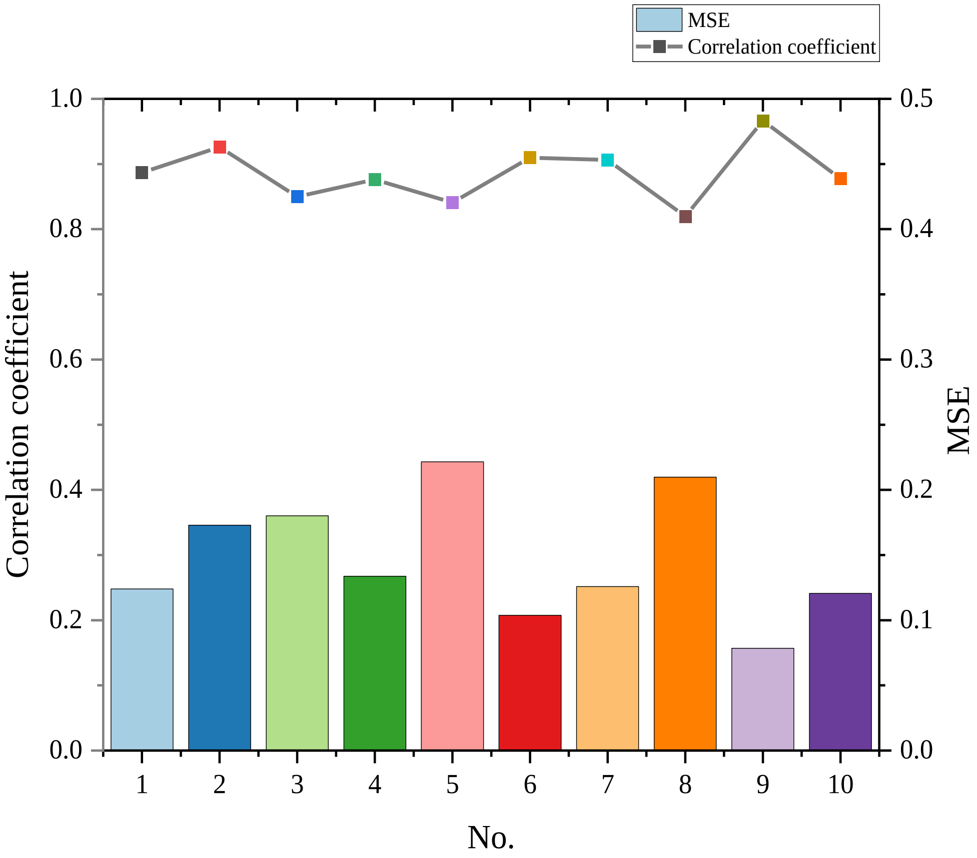

Fig. 10. Prediction of samples by GA-BP model.

V. Discussion

There are many factors affecting rural revitalization, and this paper only designs the evaluation index system based on the existing policy situation and literature research in China. The relevance and applicability of the evaluation indexes and the allocation of index weights are issues that need further study in evaluating rural revitalization. In addition, due to the difficulty of obtaining evaluation data, this paper only selects relevant subjective evaluation data obtained in actual work to train and test the neural network, which is insufficient in the sample data. The information reflected by the sample is not comprehensive enough. Further research is needed to find a general, efficient, or accurate parameter setting method; for the shortcomings of the traditional genetic algorithm, which is prone to premature maturity and slow convergence, other methods can be used to improve the traditional genetic algorithm.

VI. Conclusion

This research conducted an extensive and systematic study on the evaluation of rural revitalization by the consultation of several pieces of literature, given the circumstances of rural revitalization strategy. This article established the rural revitalization evaluation index system according to pertinent policies and documents. The GA-BP neural network model was built using deep learning theory. The GA-BP neural network model addressed the BP neural network's training process drawbacks, including its slow pace, ease of dipping below the local minimum value, and reliance on the initial weight. The rural revival was assessed and predicted using the GA-BP neural network model. The findings demonstrated that the GA-BP neural network model had rapid convergence, accuracy, and stability in rural rejuvenation's evaluation and prediction abilities, demonstrating its high applicability in these areas.

Sound Classification for Javanese Eagle Based on Improved Mel-Frequency Cepstral Coefficients and Deep Convolutional Neural Network

Silvester Dian Handy Permana[1], T.K. Abdul Rahman[2]
Informatics Engineering, Universitas Trilogi, Jakarta, Indonesia[1]
School of Science and Technology, Asia e University, Shah Alam, Malaysia[2]

***Abstract*—The Javanese Eagle is a rare and protected animal in Indonesia. These animals only live in a few species and are threatened with extinction. These birds need to be bred to avoid extinction. One form of communication between the Javanese eagles and each other is the sound of their tweets. These tweets can be studied and classified to conserve endangered animals. This study will classify the sound of the Javanese Eagles for the benefit of animal conservation. Data in the form of voice tweets will be classified. This classification uses algorithms from improved MFCC (Mel-Frequency Cepstral Coefficients) and Deep Convolutional Neural Network. The result of this study was to classify the sound of the Javanese Eagle from the lack of food or drink, the normal tweets state of the bird, and to find out the Javanese Eagle in finding a partner. This research has been carried out by comparing the CNN architecture with AlexNet and VGGNet models and various combinations of training, validation, and test data. The best model dataset underwent division into 80% for training, 10% for validation, and 10% for testing. Training and testing of both IMFCC and VGGNet models occurred using the same dataset. During training, VGGNet achieved 100% accuracy, while testing yielded 99%. ROC Curve: 'Normal' AUC 0.996, 'Looking for Partner' AUC 1.000, 'Looking for Food' AUC 0.996. This study aids Javanese Eagle conservation, crucial for preventing extinction at conservation sites.**

Keywords*—Improved MFCC; deep convolutional neural network; Javanese eagle sound; sound classification

I. Introduction

The Javanese Eagle (*Nisaetus Bartelsi*) is a rare and protected animal in Indonesia. The Javanese Eagle existence is increasingly rare because of the eruption of Mount Merapi, which caused the death of many Javanese Eagles and it only lays 1 to 2 eggs per year. In addition, many illegal hunters hunt these birds to sell and make a profit [1]. Even though in 1990, eagles were protected by the government, there are still many who trade eagles illegally [2]. These animals only live a few species globally and are threatened with extinction [3, 4]. The Javanese Eagle is one of the animals that are conserved in zoos and nature reserves. These birds need to be bred to avoid extinction [5]. Especially in zoos, caretakers need to pay attention to the needs of these birds, especially in maintaining a balance nutrition. Because, balanced nutrition will keep Javanese eagles to survive. However, sometimes they cannot understand the Javanese Eagle's needs quickly. Javanese eagles usually use their tweet to code their environment to find food or before eating other animals. From the tweet sound, it can be identified the conditions and needs of the Javanese Eagles. The voice of this tweet is very distinctive and very specific which can be heard [6, 7].

In helping to preserve the Javanese Eagle, research is needed to identify the needs of the Javanese Eagles. The chirping sound of this Javanese Eagle can be studied and classified to help in the conservation of endangered animals. With the tweets studied by the proposed technique and verified by experts, can know the basic needs of the bird especially in searching for prey. This research will develop a Javanese Eagle’s sound classification technique that will classify the sound of the Javanese Eagle into lack of food or drink, knowing the Javanese Eagle in search of partner, and normal state of bird tweets through combination of algorithms from Mel-Frequency Cepstral Coefficients (MFCC) [8] and Deep Conventional Neutral Network [9, 10, 11, 12, 13]. The data from this study were taken from zoos and nature reserves in Indonesia such as the Ragunan Zoo, PSSEJ, and the Bogor Botanical Garden. The sound that was taken and use as a data are validated by experts. Data in the form of voice tweets will be classified.

MFCC is a feature extraction that produces features in the form of cepstral coefficient parameters. Feature extraction Mel Frequency Cepstral Coefficient (MFCC) converts sound waves into several types of parameters such as the cepstral coefficient which represent the audio file. In addition, Improved MFCC generates feature vectors that convert voice signal into several vectors for speech recognition. This signal is known as spectrogram. Convolutional Neural Network (CNN) is the development of Multilayer Perceptron (MLP) which is designed to process two-dimensional data. CNN is included in the type of Deep Neural Network because of its high network depth and widely applied to image data. The sound image formed from the MFCC model can provide a specific picture so that CNN can train properly so as to produce an accurate model. Before being processed using CNN, the Javanese eagle’s sound needs to be converted to a spectrogram first. The existence of this spectrogram provides a significant difference from the presence of audio in a tweet. Spectrograms provide higher accuracy in training that audio signals trained in digital form. The Improved MFCC and followed by CNN in deep learning architecture was designed to classify the Javanese Eagle’s voice. Javanese eagle sound classification was used to identify whether the Javanese eagle is lacking of food or drink, finding a partner, or it is a normal tweet of bird. The result of this research was used to help the bird's caretaker to better understand the basic needs of the Javanese Eagle.

The combination of signal processing and deep learning has the potential to reveal the complex layers of meaning hidden within the vocal repertoire of the Javanese Eagle. By combining different methodologies, the objective was to classify the tweets of the Javanese eagle into specific categories: regular sounds representing their daily activities, sound indicating their hunger and search for food and sound expressing their desire for a mate, reflecting the intricate social dynamics of these magnificent birds of prey.

The output of this research has helped to protect Javanese eagle birds from extinction. In this research, the needs of Javanese eagle can be identified from the sound of their chirping. This research created an application that can differentiate the sound of the tweets of the Javanese eagle. This research is expected to have a major impact in the caring for the existence of the Javanese eagle by providing what is needed quickly. By providing caretakers and conservationists with a tool to swiftly identify and respond to the needs of the Javanese Eagle, the study contributes to the ongoing efforts to protect this species from extinction. Developing an application capable of distinguishing between different tweet sounds holds significant promise for enhancing the management and conservation of the Javanese Eagle population. Ultimately, by leveraging advancements in signal processing and deep learning, this research underscores the importance of interdisciplinary collaboration in safeguarding Indonesia's biodiversity and preserving the ecological balance of its natural habitats.

II. Literature Review

In this section discussed about the Javanese eagle, animal sound and the voice of the Javanese eagle's tweet. And a quick overview of literature review on previous research about classification of animal's sounds, MFCC, and CNN deep learning.

A. Javanese Eagle

The Javanese Eagle, scientifically classified as *Spizaetus bartelsi*, represents a distinctive species within the medium-sized bird category. Endemic to the lush landscapes of Java Island, this avian species thrives in the verdant forest that adorn the highlands and mountain slopes. Regrettably, the very existence of the Javanese eagle faces a precarious future, imperiled by the relentless march of time and insidious encroachment of illegal deforestation, which threaten to drive this rare species to the brink of extinction [14]. Historically, the Javanese eagle was a prominent inhabitant of Java Island's forests and mountainous terrains. Yet, in the wake of anthropogenic activities and environmental transformations, the once-thriving population has witnessed a distressing decline. This medium-sized eagle exhibited a body ranging from 60 to 70 cm, measured from the beak to the tip of the tail [15]. The Javanese eagle eats various types of small birds and other poultry, small mammals such as mice, squirrels, rabbits, to medium-sized one such as monkeys. This bird also eats various types of small reptiles such as lizards, monitor lizards, and snakes. This bird lives on the slopes of mountains and hills. Now its existence is only in the rain forest alone. This animal is endemic to the island of Java [16].

B. Animal Sound

Sound is a form of energy that always propagates in all directions in the form of longitudinal waves. Sound can be heard if there is a sound source, medium or intermediary to propagate, as well as an object to listen to / which is used to capture the sound signal. A signal is a variation of variables such as the pressure wave of sound, the color of an image, the depth of a surface, the temperature of a body, the voltage or current of a conductor or biological system, light, radio electromagnetic signals, the price of goods or the volume and weight of an object. It can be said that a signal is a medium to carry information about the past, present and future state of a variable [17].

C. Classification of Sounds

Environmental Sound Classification (ESC) is one of the most challenging tasks in forensic digital signal processing and machine learning. Many methods have been proposed to perform ESC, one of which is self-supervised learning (SSL) for ESC. SSL is a model used to study unsupervised representations by completing pretext tasks and using them to perform downstream task such as classification or regression [18]. This study uses the ESC-10 and DCASE 2019 Task-1(A) datasets. The first dataset used is the ESC-10 containing 400 signals from 10 different types of environmental sounds. 10 types of sounds from the ESC-10 dataset: Dog Barking, Baby Cry, Clock Tick, Fire Cracking, Helicopter, Person Sneezing, Rain, Rooster and Sea Waves. The test signal contains 10 different types of environmental sounds including Airport, Bus, Metro Station, Metro, Park, Public Square, Shopping Mall, Street Pedestrian, Street Traffic and Trams [19]. In this study the model developed uses a spectrogram image as its input, in the early stages of extracting the spectrogram signal. This research discusses the evolution of object detection, highlighting the shift from traditional methods reliant on handcrafted features to deep learning approaches. It emphasizes the advantages of deep learning in learning semantic, high-level features and explores various architectures, training strategies, and optimization functions. The paper provides a comprehensive review of deep learning-based object detection frameworks, covering both generic and specific detection tasks such as salient object detection, face detection, and pedestrian detection. Experimental analyses are conducted to compare methods and suggest future directions for research in object detection and neural network-based learning systems [20]. In this research discusses about an audio extraction technique using MFCC, LPC and DTW and use CNN methods for training and classification process. It develop a hardware module to collect the audio data and sent to the server and used data from online source. The hardware module can function well to classify and send audio signal to the cloud server and store. The audio signal in the cloud server can be reused for the training phase. The highest accuracy obtained reached 91.3% [21].

D. Classification of Animal's Sounds

Research on the classification of animal sounds were carried out by [22, 23]. Reference [22] took the theme of classifying animal sounds using the Convolutional Neural Network method. In this study, the problem of classifying animal sounds using deep learning was investigated and a system based on a convolutional neural network was proposed. The result obtained from this study are unsatisfactory where the highest accuracy is only up to 75% which in the confusion matrix gives the result 4 bird sound are misclassified as cats. While reference [23] took the theme of an IoT-based sound classification system. In this study a well-known feature extraction technique called Mel Frequency Cepstral Coefficient (MFCC) is used to extract features from a given audio clip, send it to the CNN architecture. The result obtained from the research after the dataset test was run on the model, the best accuracy was obtained by AdaDelta, Gradient Descent, and RMSProp optimizer, which was 91.3%, and the worst accuracy was obtained by Momentum optimizer which was 82.6%. Research conducted by [24], with the theme Workflow for automatic identification of animal sounds. In this study, the development and application of a convolutional neural network for the automatic detection of 14 birds and mammals adapted in the forest by classifying spectrogram images generated from short audio clips were explained. The result of this study was stored after Epoch 100 with a training loss of 0.0182, validation loss of 0.0139, training accuracy of 0.9954, and validation accuracy of 0.9969. Research conducted by [25] with the theme of differences between MFCC and IMFCC for the classification of bird sounds. In this study a comparison between MFCC and IMFCC features for automatic bird species recognition systems was carried out with the aim of validating the use of IMFCC features as features that can also be extracted for bird species recognition and the method of bird sound classification system used in this study using Hidden Markov Models (HMM) for data training needs. To compare the efficiency of the features of MFCC and IMFCC with the proposed algorithm using the TAR and TRR performance. Based on the TAR and TRR performance on *Automolus rubiginosus*, *Synallaxis erythrothorax*, *Cardinalis*, *Cercomacra Tyrannina*, and *Myiozetetes Similis* the result of the IMFCC method provide a percentage increase than MFCC. Finally, study conducted by [26], with the theme of a forest fire early warning system with the sound of birds. In this study, the bird data used in the form of recordings of bird sounds from four bird species. The four bird species used in this study were Cipoh, Prenjak, Merbah Cerucuk and Pleci. The result of this study obtained a test accuracy value of 96.45% based on the results of the testing process carried out on the experience of the system program. At this stage it can be concluded that the proposed method is able to classify bird sounds based on the condition of the two birds with an accuracy of 96.45%.

E. Mel Frequency Cepstral Coefficients (MFCC)

MFCC is a method that is quite good and the most widely used in the field of speech recognition. MFCC is a feature extraction that produces in cepstral coefficient parameters. Feature extraction MFCC converts sound waves into several types of parameters, such as the cepstral coefficient, which represent the audio file. In addition, MFCC produces feature vectors that convert voice signals into several vectors for speech feature recognition [27]. MFCC has seven stages, namely pre-emphasis, frame blocking, windowing, Fast Fourier Transform (FFT), Mel Frequency Wrapping (MFW), Discrete Cosine Transform (DCT) and cepstral lifting, which produces parameters like features, namely frames and cepstral coefficient. The final result of MFCC method will improves the quality of the speech recognition, it can be seen using plot from cepstral lifting stage [28].

F. Convolutional Neural Network (CNN) Deep Learning

Convolutional Neural Network (CNN) is one of the deep learning algorithms included in the feed forward class method that is inspired by the visual cortex of the brain. However, to be able to predict well, CNN must be designed with a more complicated architecture. As a result, CNN training is very computationally expensive and has implementation because of its slow speed. CNN has several models in the training process where the method has a different architecture according to the problem. The training model is used in accordance with the state of the object of identification because CNN has several layers implemented at the training stage. The modern CNN discovered by LeChun has seven layer structures (not including the input layer) namely LeNet-5 which has the following structures C1, S2, C3, S4, C5, F6 output [29]. Example of case studies in image recognition on CNN have three stages, namely the input, CNN, and output stages [20]. Input layer is the stage for inserting images into the program and further be processed by changing the image into a binary form so that it can be process at the CNN stage [30]. The CNN algorithm develops multi-layer perceptron (MLP) to process data, one of which is two-dimensional image data, for example images. This CNN algorithm classifies labeled data using the supervised learning method, namely, targeted data and the appropriate variables. Convolutional Neural Network (CNN) has five stages, namely (a) convolution, (b) ReLu layer, (c) max pooling, (d) flattening, and (e) full connection.

III. Methodology

It is not an easy task to extract sound features, recognize them and classify them from various short audio clip. This was due to background noise, very short sound intervals, and fast clip changes. These things interfere with the recognition process carried out by artificial intelligence. Therefore, the recognition of the input voice is very important and affects the result of the voice classification. The system must distinguish the sound that it wants to process and which sound it does not want to process. As a result, the voice data obtained needs to be processed first before entering the voice classification model for processing. The research flow can be seen in Fig. 1.

A. Develop a Data Set of Sounds of Javanese Eagle

The data used in this study is data in the form of recordings of the sound of birds chirping which is captured by recording on the spot or looking for it in the datasets that are already available. The dataset was divided into two consisting of a true dataset containing the sound of an eagle and a noise dataset. The sounds of the birds used are the sounds of the Javanese eagle so that the sounds of other birds were included in the noise dataset. These two types of data sets were further divided into two, namely the dataset used in the training process and the dataset used in the testing process. The self-collected bird sound clips are short audio clips containing only one tweet. The steps of the Development Data Set for Javanese Sound flow are shown in Fig. 2 below.

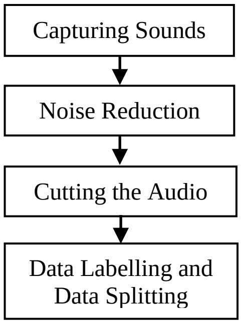

Fig. 2. Development data set for Javanese sound flow.

The preprocessing phase plays a crucial role in the successful identification of Javanese Eagle's primary needs using the hybrid improved Mel-Frequency Cepstral Coefficients (MFCCs) and Deep Convolutional Neural Network (CNN). This phase involves two key steps: Capturing Sounds, noise reduction and cutting audio, and Data Labelling and Data Splitting. The data for Capturing sounds phase are gathered from three specific locations: Taman Safari, PSSEJ and Ragunan Zoo with a total 300 samples for the dataset. After that, to enhancing the signal component the unwanted background noise from the audio signal were attenuate or eliminate using the noise reduction phase [31]. Then the audio data is dissected into individual syllable segment to separate each distinct syllable inside cutting audio phase. After that, the data is assigned with labels and split into three distinct subsets known as training data, validation data and testing data.

B. Develop an Improved Mel Frequency Cepstral Coefficients (MFCC) Technique for Converting the Javanese Eagle Tweet into Spectogram

At this stage, will convert the sound image into the form of a spectrogram using the Improved Mel Frequency Cepstral Coefficients (IMFCC), which will extract the sound features using an artificial intelligence model. The sound spectrogram example is shown in Fig. 3 below.

In order to obtain an effective feature representation for the sound detection of the Javanese eagle, in this study, an improved MFCC-based feature extraction algorithm is proposed. Improved MFCC using Constant-Q (CQT) and Mel Spectrogram. Constant-Q Transform (CQT) is an algorithm that can efficiently compute the Fourier transform. The improved MFCC has two stages before using MFCC itself. The first step is Implementation of Constant-Q Transform (CQT) and the second is Implementation of Mel-Spectrogram. The steps of the improved MFCC flow are shown in Fig. 4 below.

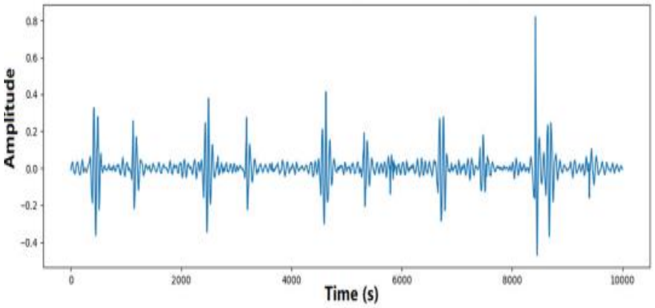

Fig. 3. Sound spectrogram.

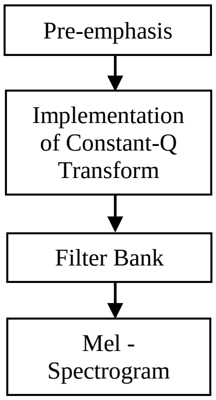

Fig. 4. Improved MFCC.

The audio signal is one-dimensional data, so to convert the audio data it is necessary to convert the audio signal to a log scale time frequency using Constant-Q Transform (CQT). The CQT transformation can be seen in Eq. (1).

$$X[k,n] = \sum_{q=n-\lfloor Nk/2\rfloor}^{n+\lfloor Nk/2\rfloor} x(q)\, a_k^*\left(q - N + \frac{Nk}{2}\right) \tag{1}$$

where, k = 1,2 …, K indexes the catch-frequency coefficient of CQT. Shows a_k^*(n). The basic function of a_k^*(n) is a waveform with complex values. Then in the atomic Eq. (2) the time frequency is defined as follows:

$$a_k(n) = \frac{1}{Nk}\,\omega\left(\frac{1}{Nk}\right) exp\left(-j2\pi\frac{f_k}{f_s}\right) \tag{2}$$

The value fk is the storage centre frequency k, and fs denotes the sampling rate, and w (t) is a continuous window function sampled at the point determined by t. Nk is the length of the window which is inversely proportional to fk in order to achieve the same Q-factor for all k containers. The center frequency fk is defined as Eq. (3) follows:

$$f_k = f_1\, 2^{\frac{k-1}{B}} \tag{3}$$

where, f_1 is the middle frequency of the lowest frequency container, and B is the coefficient to determine the number of containers per octave. In the process, B is an important parameter to make choices when using CQT, because it determines the time-frequency resolution considerations of CQT. The IMFCC consist of four stages, namely: pre-emphasis, implementation of Constant-Q Transform, filter bank and mel- Spectrogram.

C. *CNN for Classification of Eagle's Tweet*

In this study, the classification model used is Convolutional Neural Network (CNN) which consists of three stages, namely: convolution, Rectified Linear Unit (ReLu), and pooling. The CNN training itself will be carried out by repeating the convolution and ReLu stages using the training dataset that has been prepared. CNN itself is used because it has the characteristics of sparse interaction, parameter sharing, and equivalent representation. The steps of the CNN Model are shown in Fig. 5 below.

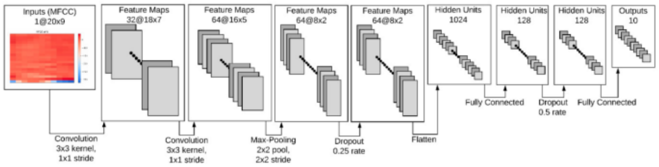

Fig. 5. CNN model.

Introducing a Comparative Analysis: AlexNet and VGGNet for Sound Recognition. Two such seminal architectures, and VGGNet and AlexNet, have etched their names in the annals of deep learning, each characterized by its unique design and contributions. To compare AlexNet and VGGNet effectively, several factors need to be considered, such as model complexity, adaptability to temporal data, and computational efficiency. AlexNet's deep architecture and local response normalization can be modified to accommodate the temporal characteristics of sound, while VGGNet's uniform structure may be better able to capture diverse temporal features. A nuanced approach is necessary to evaluate these architectures, with adaptations and optimizations being crucial to realizing the full potential of both AlexNet and VGGNet in sound classification tasks. AlexNet's architecture is characterized by its depth, large convolutional filters, ReLU activation, and hierarchical feature extraction. The utilization of convolutional layers, max-pooling, and fully connected layers in the architecture of AlexNet facilitated the attainment of cutting-edge performance in picture classification tasks. While, the VGGNet architecture is characterized by its simplicity, regularity, and deep stack of convolutional layers. This design philosophy allows the network to learn hierarchical features of increasing complexity from the input image, making is effective for image classification tasks. The AlexNet CNN and VGGNet Model Architecture are shown in Fig. 6 and Fig. 7 below:

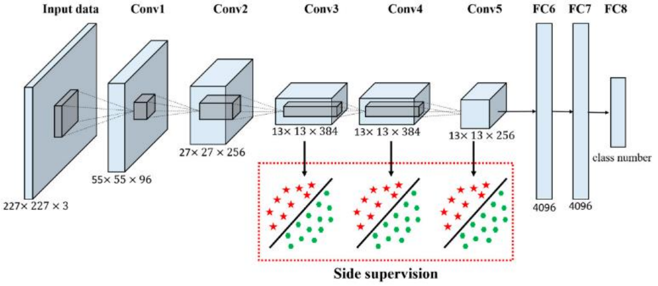

Fig. 6. AlexNet CNN model architecture.

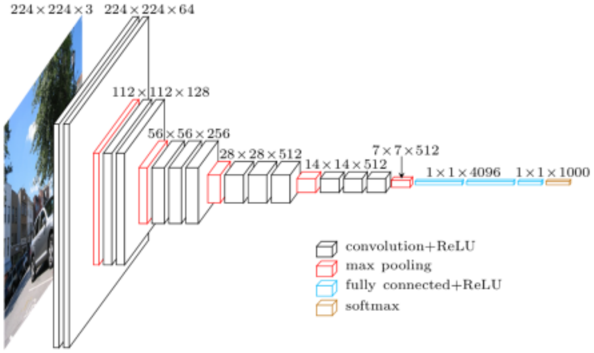

Fig. 7. VGGNet CNN model architecture [32].

1) Convolutional: CNN is a neural network model designed to process data in a grid-like structure. Therefore, the MFCC input in the form of these images will be entered into a matrix that contain the pixel values in the existing image. After that the image map will be multiplied by a matrix that we call the kernel model, for each pixel value of the image matrix. It is this kernel model that the model will study and create. This stage uses mathematical equations such as Eq. (4)

$$S(i,j) = (I * K)(i,j) = \sum_m \sum_n I(m,n)K(i-m,j-n) \quad (4)$$

At the end of the image matrix itself will be filled by an auxiliary variabel with a value of 0. The kernel model will also move by shifting it according to a predefined value, which can call stride. These three parameters are very important at this stage.

2) Rectified Linear Units (ReLu): The result of the image matrix that have been multiplied by this kernel model will be normalized so that negative values in the image matrix must be removed. On CNN, a thresholding process will be carried out, which changes the negative value to zero, using ReLu. ReLu itself has similarities as in equation 3.19 whose activities can be seen in Fig. 10 below.

3) Pooling: After the pixel values have been convoluted and denormalized, the CNN matrix will be reduced in size so that the calculation and classification process become faster and more precise using the pooling method [33]. There are many pooling methods, in this study using the max-pooling method which is very commonly used in CNN and also easy. Basically max-pooling works by grouping the CNN matrix into small matrices and then taking the highest value from the small matrix.

4) Fully connected layer: The CNN matrix values that have gone through the three stages will then proceed to the last stage, namely Fully Connected Layer. At this stage the data obtained from the CNN matrix will be combined and flattened into a one-dimensional layer containing the values from the CNN matrix. This process is often called the flatten process [33]. After completing the flattening stage, the spectrogram image value data that has been generated by CNN will be classified using the SoftMax classifier function.

D. Analysis of Result

To determine the success or failure of this study, it is necessary to Testing data or test data. Tests on learning outcomes are carried out to assess the level of success they have. The success in the test is presented in the form of a percentage, such as the following equation. The results of the test are decisions that were the result from the classification carried out. Testing can be done by using the Correlation coefficient (R), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), and Mean Square Error (MSE). The equation for the correlation coefficient (R) uses the Eq. (5) as follows:

$$R = \frac{\sum_{i=1}^{N}(x_i - \bar{x})\,(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{N}(x_i - \bar{x})^2 \sum_{j=1}^{N}(y_i - \bar{y})^2}} \quad (5)$$

Furthermore, to calculate the Mean Absolute Error (MAE) can use the Eq. (6) follows:

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|x_i - y_i| \quad (6)$$

Then to calculate the Mean Absolute Percentage Error (MAPE) you can use the Eq. (7) follows:

$$MAPE = \frac{1}{N}\sum_{i=1}^{N}\frac{|x_i - y_i|}{x^i} \,.\, 100\% \quad (7)$$

And lastly, to calculate the Mean Square Error (MSE) you can use the Eq. (8) follows:

$$MSE = \frac{1}{N}\sum_{i=1}^{N}(x_i - y_i)^2 \quad (8)$$

where, x; y is the target value and predicted value, and N is the number of sample data.

The Confusion Matrix is an indispensable tool for understanding the strengths and weaknesses of a classification model. It allows researchers and practitioners to pinpoint specific areas of improvement, assess the model's robustness, and make informed decisions about model refinement or optimization based on real-world implications. The matrix comprises four essential components: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). True Positive (TP) represents instances correctly classified as positive by the model. True Negative (TN) denotes instances accurately identified as harmful. False Positive (FP) signifies instances wrongly classified as positive, and False Negative (FN) includes instances incorrectly identified as harmful.

When the model accurately identifies positive audio samples associated with Javanese eagles, it is denoted as True Positive (TP). On the contrary, True Negative (TN) arises when the model correctly rejects audio samples unrelated to Javanese eagles. False Positive (FP) instances occur when the model incorrectly identifies negative audio samples as positive for Javanese eagles. Finally, False Negative (FN) incidents happen when audio samples relevant to Javanese eagles are incorrectly classified as irrelevant by the model.

Comprehending these concepts aids in evaluating the reliability of the model or system in predicting Javanese eagle sounds. The quantification of TP, TN, FP, and FN counts facilitates the calculation of evaluation metrics such as precision, recall, and F-Score. Precision is the ratio of true positives to the sum of true and false positives, reflecting the accuracy of optimistic predictions. Recall, also known as sensitivity or true positive rate, is the ratio of true positives to the sum of true positives and false negatives, indicating the model's ability to identify all relevant instances. F1-score, a harmonic mean of precision and recall, provides a balanced assessment of the model's overall performance. A confusion matrix is typically presented in a Table I format with rows and columns corresponding to the actual and predicted classes, respectively. Here's a simple representation:

TABLE I. REPRESENTATION OF CONFUSION MATRIX

	Predicted Positive	**Predicted Negative**
Actual Positive	TP	FN
Actual Negative	FP	TN

E. Validation on Expert Verification

Validation through expert verification is a crucial component of this research, ensuring the robustness and reliability of the developed sound classification system for Javanese eagles. Pusat Suaka Satwa Elang Jawa (PSSEJ) serves as the primary domain for this validation process. The expertise of caretakers at PSSEJ plays a pivotal role in assessing the accuracy and effectiveness of the developed system. Their extensive experience caring for Javanese eagles equips them with a nuanced understanding of the eagles' vocal expressions corresponding to distinct needs and providing a real-world evaluation that aligns with the practical aspects of eagle care and conservation efforts. Their validation ensures that the developed system aligns with scientific precision and integrates seamlessly into the context of caretaking at PSSEJ.

IV. RESULT AND DISCUSSION

The outcomes and discussions of the study on sound classification for identifying the primary needs of the Javanese Eagle are presented, employing a hybrid approach of improved Mel-Frequency Cepstral Coefficients (MFCC) and Deep Convolutional Neural Network (DCNN). The section commences with a concise overview of the research objectives and methodology, followed by an elaborate account of the utilized dataset, encompassing the recording process, data pre-processing, and feature extraction.

A. Development of Data Set for Sounds of Javanese Eagle

Data on Javanese eagle sounds were gathered from three separate sites. A bidirectional microphone was used to record audio, which was then saved in uncompressed WAV format with a sampling rate of 44.1 kHz and a resolution of 16 bits. Our machine learning algorithm was trained using the training set, and its performance was assessed using the testing set. Eighty percent of the dataset (240 sound samples) was used for training, and the remaining twenty percent (60 sound samples) was used for testing. The sound clips were pre-processed to remove any background noise, normalize the amplitude, and cut them to a set length of a syllable. The steps in this phase are:

1) *Capturing sound:* The data-gathering process involved recording the sounds produced by Javanese Eagles in their

natural habitat within the park. The recordings were made using a high-quality microphone and a digital audio recorder and conducted during the daytime when the Javanese Eagles were most active and vocal. This study used a bidirectional microphone to record the sounds of Javanese eagles. A bidirectional microphone, also known as a figure-eight microphone, captures sound from two opposing directions while denying sound from other approaches. Using a bidirectional microphone, the sounds of Javanese eagles can be accurately recorded.

2) Noise reduction: The sound data collected has gone through pre-processing once the Javanese eagle's sound was recorded. Pre-processing was the process of cleaning and filtering recorded audio to eliminate distracting elements like background noise. A crucial first step in employing sound classification to determine the main requirements of Javanese Eagles has been data pre-processing. To achieve accurate sound categorization findings, pre-processing has consisted of multiple phases aimed at cleaning and filtering the collected audio data.

This study has made use of spectral subtraction to separate the desired eagle vocalizations from the unwanted background noise present in the audio files. By applying noise reduction to the audio files, undesired background noise has been successfully removed, increasing the sound categorization process' accuracy and precision. Prior to conducting spectral reduction, it has been necessary to apply a High Filter to the sound data. The High filter has served to discriminate between low-frequency sounds and high-frequency sounds.

3) Cutting the audio: Efficient techniques for audio translation were crucial in comprehensively studying and evaluating the noises emitted by Javanese eagles, thereby enhancing our understanding of their behavior and communication. The aim of this method has been to analyze Javanese eagle audio recordings by segmenting them into syllabic units, known as "syllables" in the field of phonetics, with a minimum duration of 0.5 seconds. Additionally, to achieve the best possible outcome, the audio cutting process has utilized the noise-free audio sound.

B. Converting Javanese Eagle Sound into a Spectogram Using Basic Mel Frequency Cepstral Coefficients (MFCC) Technique

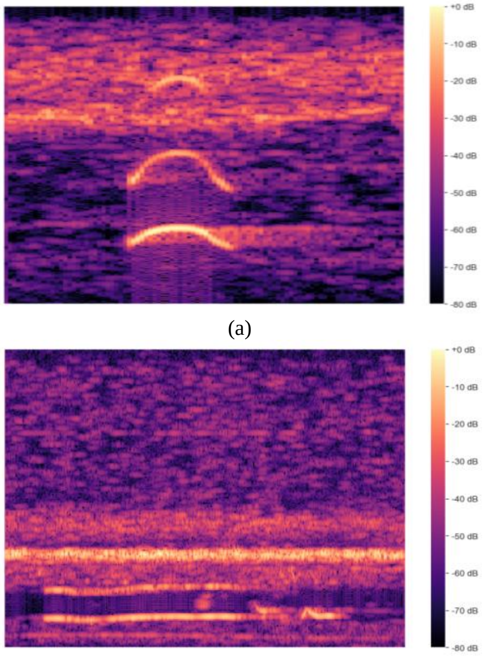
Converting Javanese eagle sounds into spectrograms involves using the basic technique of Mel Frequency Cepstral Coefficients (MFCC) as the primary method. The MFCC method serves as the foundation for generating spectrograms from Javanese eagle sounds, enabling a detailed visual representation of the frequency and energy components of each sound segment.

The MFCC technique involves several crucial steps. First, the sound signal is divided into small time intervals known as frames. Each frame is then analyzed to extract important features encompassing frequency and sound energy information. The next step involves applying Fourier transformation to each frame to convert it from the time domain to the frequency domain. In the MFCC technique, this transformation is typically done using the Short-Time Fourier Transform (STFT). After the transformation, a filter bank is applied to the frequency spectrum to capture more relevant information in the audio spectrum.

1) Pre-emphasis of audio signal: Pre-emphasis is an audio signal processing technique that enhances sound characteristics by emphasizing high frequencies in the signal. This results in a clearer representation of acoustic details and an overall improvement in sound quality.

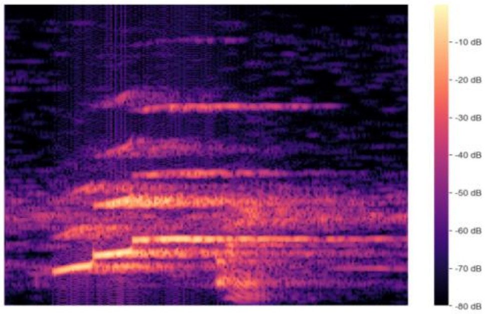
Implementing pre-emphasis on each syllable could enhance comprehension of the acoustic properties of that sound. Additionally, pre-emphasis could mitigate the presence of noise in a speech signal, thereby yielding a more pristine rendition of the sound. The pre-emphasis was implemented on sound signals at the syllable level.

2) Implementation of Short-Time Fourier Transform (STFT): STFT is used to analyze how the frequency of an audio signal changes over time. This technique divides the audio signal into small segments called frames and then performs Fourier transformations on each of these frames. The STFT process enables us to observe how the frequency in an audio signal changes over time, thereby generating a spectral representation of the signal. STFT is employed after obtaining the audio signal that has undergone pre-emphasis. The implementation of STFT in this study, the configuration used includes a NFFT of 512, a window length of 256, a hop length of 128, and the use of a 'hamming' window. The effect of applying the Short-Time Fourier Transform (STFT) on syllables explained in Fig. 8. Fig. 8(a), (b), and (c) depict the STFT representations.



(a)

(b)



(c)

Fig. 8. (a) STFT on normal tweets, (b) STFT on looking for food tweets, (c) STFT on looking for partner tweets.

3) Filter bank implementation for STFT representation: This Filter bank operates by segregating the frequency signal into smaller sub-bands. By applying Filter bank to STFT, frequency information from the audio signal can be more effectively separated, allowing for a more detailed analysis of each frequency sub-band. Each filter within the Filter bank responds to specific frequency ranges. The fusion of STFT and Filter bank has enabled the creation of Mel Spectrogram, facilitating the analysis of Javanese eagle vocalizations within a frequency range similar to human auditory perception and sound processing. This aids in understanding significant changes in the acoustic characteristics of Javanese eagle sound. The resulting Mel Spectrogram serves as a visualization of frequency representation in the form of a spectrogram derived from employing Filter bank techniques on the STFT output.

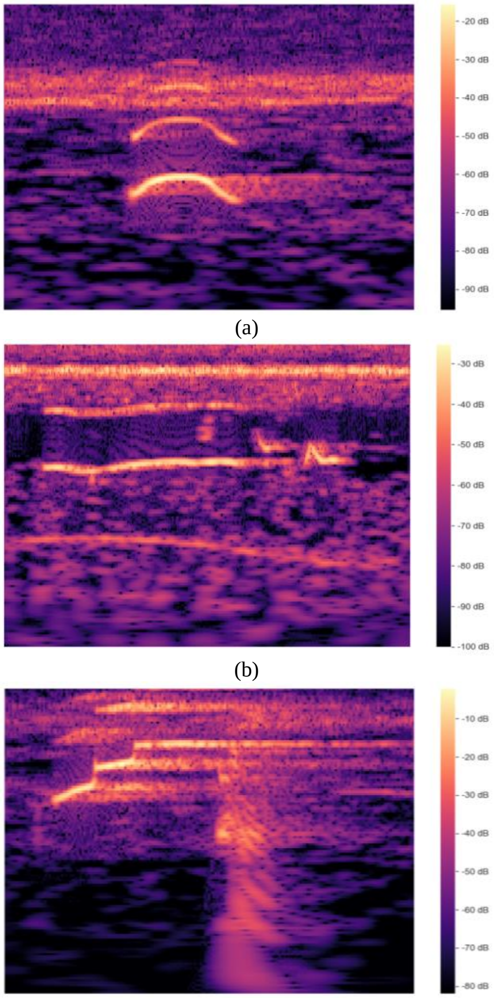
4) Converting a normalized Mel Spectrogram to an image representing the audio: The representing Javanese eagle sound were transformed into a visual image from a standard Mel Spectrogram. The aim is to illustrate audio data in an easily comprehensible visual format, aiding in a simpler understanding of the vocal attributes of the Javanese eagle. The initial step in this study involves normalizing the Mel Spectrogram. Normalization is a crucial procedure to convert spectral data into a standardized format suitable for analysis. The normalization of the Mel spectrogram function balanced the spectrum and increased the Signal-to-Noise Ratio (SNR).

C. Converting Javanese Eagle Sound into a Spectrogram Using Improved Mel Frequncy Cepstral Coefficients (IMFCC) Technique

The objective of this study was to provide a novel method for assessing the noises produced by Javanese eagles by transforming them into a visually informative representation known as a spectrogram. The Improved Mel Frequency Cepstral Coefficient (Improved MFCC) technique was employed, involving the substitution of the Short-Time Fourier Transform (STFT) with the Constant-Q Transform (CQT). This research utilizing Javanese eagle vocalizations that had been divided into syllabic segments. Segmentation facilitated the detection of variations in the vocalization of the Javanese eagle, such as alterations in pitch or rhythm that might have been present within each syllable.

1) Pre-emphasis of audio signal: Applying pre-emphasis to each syllabic segment holds the potential to enhance understanding of the acoustic characteristics of that sound. This process aids in distinguishing sounds with high intensity at high frequencies from those with a more balanced frequency range. Additionally, pre-emphasis can reduce noise in speech signals, resulting in a cleaner and clearer representation of the sound.

2) Implementation of Constant-Q transform: The CQT setup we used to comprise multiple essential settings. The hop length was configured at 128, and the transformation process employed 'hamming' windows. By utilizing CQT with this particular configuration, it was expected that a more accurate and informative spectral representation of the Javanese eagle's vocalizations could be obtained at the syllable level. The effects of applying the Constant-Q Transform (CQT) on syllables that had undergone pre-emphasis in the preceding sub-chapter are depicted in Fig. 9 below. Fig. 9(a), (b), and (c) depicted a CQT representation, which provided information about energy levels across different frequencies during a certain period of time.



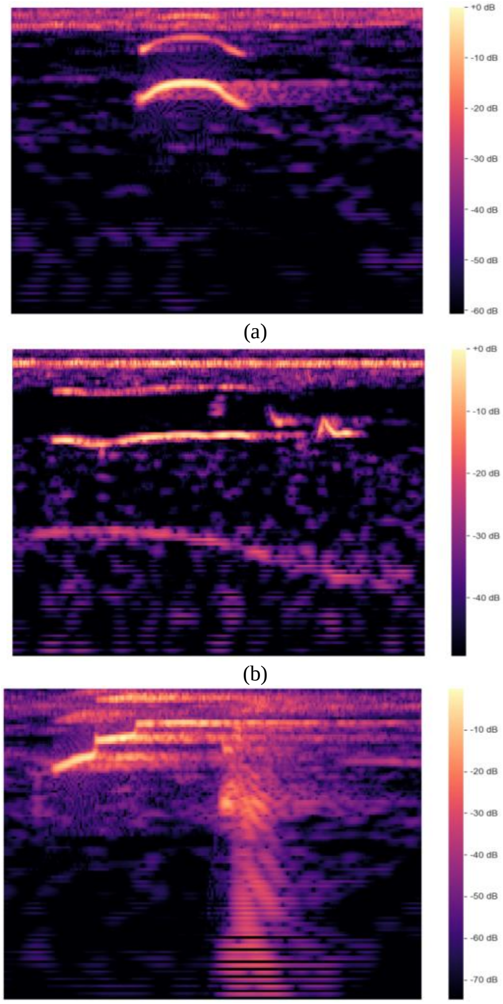
(a)

(b)

(c)

Fig. 9. (a) CQT on normal tweets, (b) CQT on looking for food tweets, (c) CQT on looking for partner tweets.

3) Filter bank implementation for CQT representation: This study involved the creation of a novel technique for evaluating the sounds of Javanese eagles. It achieved this by combining Filter bank with the Constant-Q Transform (CQT) output to generate a more detailed spectral representation called the Mel Spectrogram. The fusion of Constant-Q Transform (CQT) and Filter bank has enabled the generation of a Mel Spectrogram, which facilitated the examination of the vocalizations of the Javanese eagle in a frequency domain that closely aligns with human auditory perception and sound processing. This has aided in comprehending significant alterations in the acoustic properties of sound. The outcome of applying Filter bank to the CQT output has yielded a Mel Spectrogram, as seen in Fig. 10 below. Fig. 10(a), (b), and (c) depicted a Mel Spectogram representation.



(a)

(b)

(c)

Fig. 10. (a) Normal tweets, (b) Looking for food tweets, (c) Looking for partner tweets Mel spectrogram.

4) Converting a normalized Mel Spectrogram to an image representing the audio: The representing Javanese eagle sound were transformed into a visual image. The first phase in this investigation involved normalizing the Mel Spectrogram. Normalization was a crucial procedure for transforming spectral data into a standardized format suitable for analysis using mean normalization approach to normalize the data, resulting in a spectral average of zero and decreased data variability. The normalization of the Mel spectrogram function balanced the spectrum and increased the Signal-to-Noise Ratio (SNR).

D. Convolutional Neural Network (CNN) Deep Learning for Classifying the Tweets of Javanese Eagle Spectrogram

Convolutional Neural Networks (CNNs) have been a potent category of deep learning models that have demonstrated remarkable efficiency in many picture and signal processing applications, including the classification of spectrograms, such as those depicting the tweets of the Javanese Eagle. Spectrograms are graphical depictions of audio signals, illustrating the variations in frequency components as they evolve over time. By utilizing a Convolutional Neural Network (CNN) and providing it with a dataset of categorized Javanese Eagle tweets, the network has acquired the ability to identify and differentiate unique auditory patterns linked to other categories, such as diverse calls or behaviors exhibited by the eagles.

1) Data Validation and Image Pre-processing: Data validation was crucial in the context of training Convolutional Neural Networks (CNN) on Javanese Eagle sound spectrograms to ensure the dataset's trustworthiness. Spectrogram picture data was considered valid only if it had a file extension of png, jpg, or bmp. This approach guaranteed that only image data adhering to the required format was used for training, preventing any compatibility problems that might have arisen and led to errors during the preprocessing and model training stages.

After completing the data validation stage, the subsequent step involved image preprocessing. This procedure involved modifying the dimensions of the spectrogram image to fulfill the specifications of the CNN model. the spectrogram image underwent a conversion process to either a size of 227 x 227 or 224 x 224. Therefore, the picture preprocessing procedure readied the dataset in a suitable format and ensured the data was prepared for utilization in CNN training for the interpretation of Javanese Eagle sound spectrograms.

2) Data splitting and data labelling: Data labeling and data splitting were two crucial stages in data preprocessing for training and assessing Convolutional Neural Network (CNN) models. Data labeling involved assigning a specific label or category to each individual data instance inside a dataset. Labels were crucial for CNN models to acquire knowledge and comprehend the correlation between characteristics (attributes) and intended outputs. In an image classification task, each image had to be assigned a label that indicated the object or category seen in the image.

Data splitting entailed the partitioning of a dataset into three distinct subsets, commonly known as training data, validation data, and testing data. The objective was to partition a subset of data for the purpose of training a Convolutional Neural Network (CNN) model, referred to as the training data.

Subsequently, data that had not been previously encountered during training was employed to evaluate the CNN model's ability to generate precise predictions, known as the test data. Validation data was employed throughout the training process to oversee and enhance the model. The data splitting are shown in Table II below.

TABLE II. DATA SPLITTING

Experiment	Data	Training	Validation	Testing
Experiment I	900	630 (70%)	90 (10%)	180 (20%)
Experiment II	900	630 (70%)	180 (20%)	90 (10%)
Experiment III	900	720 (80%)	90 (10%)	90 (10%)

3) CNN Architecture Model: The Convolutional Neural Network (CNN) architecture has served as the fundamental framework in image processing and has consisted of multiple layers that collaborated to achieve a profound comprehension of picture data. The method commences with convolution layers, where tiny filters or kernels are employed to extract distinctive features like edges, textures, and patterns from the image. The outcome is a feature map that accentuates significant details within the image.

Max Pooling layers have typically succeeded convolution layers, serving to reduce data dimensionality and computational complexity by selecting the highest value within an overlapping region. Subsequently, a Flatten layer is employed to transform the three-dimensional feature map into a singular, one-dimensional vector. A Dense layer is a type of neural network layer characterized by having every neuron connected to every neuron from the previous layer. This means that there is a full and direct connection between all neurons in the layer and the neurons in the previous layer. The ReLU (Rectified Linear Unit) activation function is applied to each neuron in the Dense and convolution layers to introduce non-linearity to the model, aiding in acquiring more intricate features. The Softmax activation function computes the probabilities for each distinct class, and the class with the highest probability is selected as the final prediction of the model.

Apart from that, two architectures have been employed, namely Alex Net and VGGNet-16. The architectures were used in the training, testing and evaluation process for experiments 1, 2, and 3 that have been carried out. Model summary of Alex Net and VGGNet-16 were displayed in Fig. 11.

4) Training and testing CNN model: Assessing the performance of a Convolutional Neural Network (CNN) model during training is crucial. This involves tracking loss function values and accuracy to gauge the model's success in categorizing the training data. Choosing the appropriate number of epochs is important, with 25 epochs being ideal to ensure the model converges well. Evaluating the model's performance is done through experiments on the dataset, with results providing valuable insights into the impact of validation and testing dataset sizes and the proportion of training data. After training, the model is tested on never-before-seen testing data to evaluate its ability to generalize learned information. Evaluation metrics such as accuracy, precision, recall, F1-score, Confusion Matrix, and AUC-ROC curve offer valuable insights into the model's effectiveness in classifying previously unseen new data.

(b)

Fig. 11. Model summary of (a) Alex net, (b) VGGNet-16.

Experiment 1: The trained MFCC with AlexNet model achieved 97% accuracy in identifying Javanese Eagle's sound patterns. However, the testing showed a slightly lower accuracy rate of 95% with some identification failures in specific categories, indicating the need for further improvement.

Experiment 2: The trained MFCC with VGGNet Model showed stable accuracy despite a significant increase in loss. Testing showed an accuracy rate of 94% with some identification failures in specific categories. The early stopping method was effective in optimizing the training process.

Experiment 3: The trained MFCC with AlexNet Model achieved 97% accuracy in identifying Javanese Eagle's sound patterns. However, the testing showed a slightly lower accuracy rate of 93% with some identification failures in specific categories, indicating the need for further improvement.

Experiment 4: The trained MFCC with VGGNet model on a 70:20:10 dataset split achieved 97% accuracy during training. However, there was a significant increase in loss values during epochs 15-20. The early stopping method was implemented at epoch 20 and proved successful. The model's ability to classify spectrogram images remained highly reliable during testing.

Experiment 5: The trained MFCC with AlexNet model achieved 98% accuracy during training, showcasing exceptional ability to capture the patterns and characteristics within the spectrogram data. The model's performance during testing remained highly accurate.

Experiment 6: The trained MFCC with VGGNet model achieved 98% accuracy during training, showcasing exceptional ability to capture the patterns and characteristics within the spectrogram data. The model's performance during testing remained highly accurate.

Experiment 7: A CNN with AlexNet architecture was trained to learn the IMFCC spectrogram of Javanese Eagles. The model achieved an accuracy rate of 99% during training. In testing, it achieved an accuracy rate of 98% with some identification failures.

Experiment 8: A CNN with VGGNet architecture was trained to learn the IMFCC spectrogram of Javanese Eagles. The model achieved an accuracy rate of 97% during training. In testing, it achieved an accuracy rate of 97% with some identification failures.

Experiment 9: A CNN with AlexNet architecture was trained to learn the IMFCC spectrogram of Javanese Eagles. The model achieved an accuracy rate of 97% during training. In testing, it achieved an accuracy rate of 97% with some identification failures.

Experiment 10: The results of training a CNN with VGGNet architecture to learn the IMFCC spectrogram of Javanese Eagles are not provided in the given text.

Experiment 11: The IMFCC and AlexNet models were trained and tested for the 80:10:10 dataset. The AlexNet architecture recognized and learned the sound patterns of Javanese Eagles with high precision, achieving an accuracy rate of 98% during training. Testing involved classification analysis, Confusion Matrix, and ROC Curve, with an overall accuracy rate of 97%.

Experiment 12: The IMFCC and VGGNet models were trained and tested for the same dataset. The VGGNet architecture achieved a peak accuracy rate of 100% during training and an accuracy rate of 99% during testing. The ROC Curve showed an area under the curve of 0.996 for the 'Normal' category, 1.000 for 'Looking For Partner', and 0.996 for 'Looking For Food'.

Improved Mel Frequency Cepstral Coefficient (IMFCC). The CQT approach in IMFCC was found to be more precise that the Short-Time Fourier Transform in MFCC. In experiment 12, the CNN model based on the VGGNet-16 architecture achieved 99% accuracy. The resulting AUC value shows an Average Recall of 0.89, an Average Specificity of 0.965, and an Area under Curve (AUC) value of 0.93. The MAPE value for the LookingForFood class is 0.006; for the LookingForPartner class, it's 0.315; and for the Normal class, it's 0.045. The average MAPE value can be calculated by adding the MAPE values for each class and dividing the result by the number of classes. In this case, the average MAPE value is (0.006 + 0.315 + 0.454) / 3 = 0.141. Precision for LookingForFood was 0.93, for LookingForPartner it was 1.00, and for Normal, it was 0.95. The F-Score values for the classes were 0.96 for LookingForFood, 0.81 for LookingForPartner, and 0.97 for Normal. These values calculate the average F-Score as (0.96 + 0.81 + 0.97) / 3 = 0.91. This results show that the purposed method is suitable for detecting real-time Javan Hawk-Eagle sounds.

5) CNN model validation: The evaluation process begins by considering the complexity of analyzing real-time sound recordings of the Javan hawk-eagle. The CNN model, utilizing the VGGNet-16 architecture, undergoes rigorous testing, analyzing the intricate vocalizations of these birds within audio frames. The raw dataset, consisting of the model's predictions, acts as a preliminary insight into the model's performance. Instances where the Javan hawk-eagle sounds are correctly identified with confidence reflect the model's accuracy. The VGGNet-16 architecture-based CNN model achieved 99% accuracy in experiment 12, making it suitable for detecting real-time Javan hawk-eagle sounds.

Metrics like the Area under Curve (AUC), Mean Absolute Percentage Error (MAPE), and F-Score are pivotal in this evaluation to measure the model’s performance. The evaluation csv file contains authentic sound recordings, labels, and tweet counts directly obtained from the Javanese Eagle conservation site. It provides a deep understanding of the Javan hawk-eagle sound detection balance between precision and recall, aiding in refining and enhancing the accuracy and reliability of the model for better practical applications in sound detection in natural environments.

The prediction results were processed to compare the predicted data with the actual data, which can be observed in the actual and predicted tweet sounds image. The Confusion Matrix generated from the prediction outcomes for each audio file in Evaluation.csv provides a detailed breakdown of the model's performance in classifying different sound categories from the audio files in the evaluation dataset. Lastly, the metrics TP (True Positive), TN (True Negative), FP (False Positive), and FN (False Negative) derived from the Confusion Matrix present a detailed account of the model's performance in accurately identifying each class and its corresponding errors or correct identifications.

The Area under Curve (AUC) is a performance metric used to measure the reliability of classification models in distinguishing between different classes. AUC measures how well the model recognizes instances of a class and separates that class from others. The average Recall and Specificity values for each class are then computed to calculate the AUC, which ranges from 0 to 1. A high AUC value signifies that the model exhibits proficiency in distinguishing between behaviors.

The Mean Absolute Percentage Error (MAPE) is a metric used to measure the relative error in a model's predictions. It is crucial in evaluating the accuracy of the model's prediction for each behavior class of Javanese eagles. MAPE is computed by averaging the absolute percentage errors between the actual and predicted values. Lower MAPE values indicate the model's ability to accurately predict eagle behavior, while higher values signify a greater level of inaccuracy.

The F-Score is an essential metric for evaluating the performance of classification models in identifying Javan Hawk-Eagle behaviors. It combines Precision and Recall to provide an overview of how well the model can differentiate between LookingForFood, LookingForPartner, and Normal behaviors based on the observed sounds. Precision measures the accuracy of the model's predictions for a specific class, while Recall evaluates how well the model can identify all instances of that class.

V. Conclusion and Future Works

In conclusion, the research presented a novel approach, combining Improved Mel Frequency Cepstral Coefficients (IMFCC) with Deep Convolutional Neural Networks (CNN), to decode the intricate vocalizations of the Javanese Eagle. The research aimed to decode the Javanese Eagle's vocalizations by combining Improved Mel Frequency Cepstral Coefficients (MFCC) with Deep Convolutional Neural Networks (CNN), promising enhanced comprehension and species conservation. Using IMFCC, experiment 12 achieved 99% accuracy with VGGNet-16 architecture, showing significant promise in real-time sound detection. The method achieved high accuracy rates, demonstrating its suitability for real-time sound detection. With an Average Recall of 0.89, an Average Specificity of 0.965, and an AUC value of 0.93, the study's findings underscore the effectiveness of the proposed technique in understanding and classifying Javanese Eagle sounds.

Moving forward, future research avenues include exploring alternative machine learning models such as Recurrent Neural Networks (RNNs) and Convolutional Recurrent Neural Networks (CRNNs) to improve temporal analysis. Additionally, investigating advanced feature extraction techniques beyond IMFCCs, like Hybrid Cepstrum Analysis (HCA) or Mel-Spectrograms, could provide deeper insights. Further exploration of evaluation metrics focusing on temporal accuracy and ethical considerations surrounding model deployment in natural environments will enhance the robustness and applicability of sound detection and recognition systems.

Ethnicity Classification Based on Facial Images using Deep Learning Approach

Abdul-aziz Kalkatawi, Usman Saeed
Dept. of Computer Science and Artificial Intelligence-College of Computer Science and Engineering,
University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—Race and ethnicity are terminologies used to describe and categorize humans into groups based on biological and sociological criteria. One of these criteria is the physical appearance such as facial traits which are explicitly represented by a person’s facial structure. The field of computer science has mostly been concerned with the automatic detection of human ethnicity using computer vision-based techniques, where it can be challenging due to the ambiguity and complexity on how an ethnic class can be implicitly inferred from the facial traits in terms of quantitative and conceptual models. The current techniques for ethnicity recognition in the field of computer vision are based on encoded facial feature descriptors or Convolutional Neural Network (CNN) based feature extractors. However, deep learning techniques developed for image-based classification can provide a better end to end solution for ethnicity recognition. This paper is a first attempt to utilize a deep learning-based technique called vision transformer to recognize the ethnicity of a person using real world facial images. The implementation of Multi-Axis Vision Transformer achieves 77.2% classification accuracy for the ethnic groups of Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White.**

Keywords—Vision transformer; deep learning; ethnicity; race; classification; recognition

I. Introduction

The terms race and ethnicity are often used interchangeably which leads to misconception in some circumstances. The word race is used to categorize humans into groups biologically based on physical appearance traits inherited from the ancestors [1], whereas the term ethnicity is used to categorize humans into groups ethnographically based on geographic regions, language, cultural tradition, and shared ancestry which could refer to the similar physical appearance traits inherited but not inclusively [2].

Racial categories were first proposed in 1779s by Johann Friedrich Blumenbach, these categories were Ethiopian-black race, Caucasian-white race, Mongolian-yellow race, American-red race, and Malayan-brown race [3]. A commonly adopted racial categorization is proposed by the U.S. Census Bureau where they categorize race into White, Black or African American, American Indian or Alaska Native, Asian, Native Hawaiian and Pacific Islander [4]. The White race represents the ethnic groups originating in Europe, the Middle East, and North Africa. The Black race represents the ethnic groups originating in South Africa, Nigeria, Ghana, Kenya, etc. The American Indian or Alaska Native race represents the ethnic groups originating in North and South America also including Central America. The Asian race represents the ethnic groups originating in East or Southeast Asia, and the Indian subcontinent. The Native Hawaiian and Pacific Islander race represent the ethnic groups originating in Hawaii, Guam, Samoa, and other Pacific Islands [5].

The human face conveys a set of semantic traits; these traits can be used to conclude several attributes for a person such as identity, gender, age, race or ethnicity, and expressions [6]. The human face is the area from the upper edge of the forehead to the chin and from the left ear to the right ear. The structure of the facial area is represented in three main regions which are superior, middle, and inferior. The superior region describes the shape of the forehead, eyebrows, and eyes. The middle region describes the shape of the nose, cheeks, and ears. The inferior region describes the shape of the lips, chin, and jawline [7]. Thereby, the shape of the facial structure provides discriminant appearance traits from one person to another's. In facial recognition systems based on computer vision techniques the shape of the facial structure is referred to as facial features. The complexity of facial recognition systems lies in the process of transformation from visual facial features to a quantitative representation of the data.

Majority of the proposed methods are based on facial features descriptors where pre-defined procedures are performed to capture and analyze facial images to construct a geometry map of facial traits such as the shapes of the mouth, nose, eyes and facial landmarks or image texture such as skin color. Then the extracted features are encoded into a feature vector to be used in a classifier [8]. However, recent methods are mainly based on the automation of feature extraction using deep learning such as convolutional neural network (CNN) models, which have achieved better accuracy and generalization results when trained with a sufficient amount of representative data [8].

The lack of exploitation of deep learning techniques other than CNN motivated the study of deep learning techniques that can model the facial features for ethnicity recognition. This paper employs the deep learning model Multi-axis Vision Transformer (MaxViT) proposed by Google research team [9] for the purpose of image-based classification. The objective is to test the capability of MaxViT to recognize cognate facial features that implicitly represent the discriminative appearance traits which distinguish one ethnic group from other using facial images. The proposed model is trained on a database created by merging three different ethnicity datasets namely FairFace [10], UTKFace [11], and Arab face dataset [12]. The main contribution is that the proposed model achieves better generalization capabilities compared to other models with an accuracy of 77.2% for classifying six ethnic groups i.e., Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White. The utilization of deep learning techniques such as MaxViT would significantly improve the current state of the art for ethnicity recognition with implication for various fields such as human computer interaction and video surveillance.

II. Related Work

A. Databases

One of the crucial factors for the advancement in the scope of race or ethnicity recognition in computer vision is the availability of a large and diverse dataset that provides reliable annotated facial images based on racial or ethnic categories. However, the research area of ethnicity recognition is still lacking in this factor, as no dataset that represents all the racial or ethnic groups is available. One of the most recently proposed datasets is called FairFace [10] consisting of 97,698 images for seven ethnic groups (Black, East Asian, Indian, Latino Hispanic, Middle Eastern, Southeast Asian, and White) labeled by age, gender, and ethnicity. Another dataset proposed in the field of ethnicity recognition by Zhifei Zhang et al. [11] called the UTKFace dataset consists of 20,000 images for five ethnic groups (Asian, Black, Indian, White, Others) labeled by age, gender, and ethnicity. The dataset proposed by Ziwei Liu et al. [13] called Labelled Faces in the Wild (LFW) consists of 13,233 images for three ethnic groups (Asian, Black, White) labeled by gender, and ethnicity. MORPH dataset proposed by Karl Ricanek et al. [14] consists of 55,134 images for five ethnic groups (African, European, Asian, Hispanic, Others). BUPT-BALANCEDFACE dataset proposed by Mei Wang et al. [15] consists of more than one million images for four ethnic groups (Asian, African, Indian, and Caucasian). BUPT-GLOBALFACE dataset proposed by Mei Wang et al. [16] consists of two million images for four ethnic groups (Asian, African, Indian, and Caucasian). Mivia Ethnicity Recognition (VMER) dataset composed from VGG-Face2 dataset [8,17] and consisting of more than three million images for the ethnic groups (African American, East Asian, Caucasian Latin, and Asian Indian). There are many other facial datasets such as Diversity in Faces (Dif) [18], IMDB-WIKI dataset [19], and Cross-Age Reference Coding (CARC) dataset [20], these datasets are not optimally oriented toward ethnicity recognition.

B. Conventional Feature Extraction

This section summarizes the methods that have been commonly used for facial features extraction using computer-vision techniques for race or ethnicity recognition.

A study conducted by L. Farkas [21] which is based on the relations between well-defined facial landmarks in terms of the Euclidean distance between two points, the angle formed by a point and two other points, and the perpendicular distance from a point to the straight line between two other points. This study shows that these relations can be used to distinguish the differences in facial features of different ethnic groups. Therefore, the use of geometric facial features to classify ethnic groups is applicable. On the other hand, Xiaoguang et al. [22] used appearance-based approaches that extract facial features based on the pixel intensity values in a black-and-white image of the face. This method achieved high accuracy when implemented to classify between two ethnic groups Non-Asian, and Asian, however, this method may be insufficient to classify between more specific ethnic groups because it can vary significantly based on images quality factors such as resolution, viewing angles, and illumination. Another appearance-based approach proposed by G. Zhang et al. [23] which is based on the invariant of monotonic transformation in the grayscale images using Local Binary Pattern histograms to describe the texture and shape variations. S. Hosoi et al. [24] extracted ethnic facial features using Gabor Wavelet Transformation besides Retina sampling. Their proposed method achieved a high accuracy relative to the number of ethnic groups concluded in the experiment. An approach proposed by N. Narang et al. [25] to extract facial features from images by locating eye centers using manual annotation and affine transformation to construct a geometric representation of face images. Kazimov T. et al. [26] proposed a method to define ethnic features based on the Euclidean distance between 30 geometric landmarks. H. Ding et al. [27] proposed an approach based on 3D face models where ethnic features are extended using Oriented Gradient Maps. M. A. Uddin et al. [28] proposed an integrated approach to classify the ethnicity of Caucasian, African, and Asian based on texture and shape features using a histogram of oriented gradients and Gabor filter to extract features from a grayscale image, and then combining both feature vectors into one.

C. Deep Learning-based Feature Extraction

This section summarizes the deep learning approaches that have been proposed previously for feature extraction for ethnicity recognition.

Marwa Obayya et al. [29] used a fusion of three pre-trained CNN models as feature extractors, namely VGG16, Inception v3, and capsule networks. And a bidirectional long short-term memory model as a classifier, the model is trained using VMER dataset and achieves an accuracy of 70% for classifying four ethnic groups of African American, East Asian, Caucasian Latin, and Asian Indian. Gurram Sunitha, K. et al. [30] used a pre-trained Xception CNN model as a feature extractor and kernel extreme learning machine model is used as classifier. The model is trained using the BUPT-GLOBALFACE dataset and achieves an accuracy of 97% for classifying four ethnic groups of Asian, African, Caucasians, and Indian. Norah A. Al-Humaidan et al. [12] used a pre-trained ResNet50 CNN model as a feature extractor and a fully connected layer for classification. The model is trained on a sub-ethnic group of Arabs dataset consisting of 5,598 images of Gulf Cooperation Council (GCC) countries people, 1,665 images of Levant people, and 1,555 images of Egyptian people. The model achieved 76% classification accuracy. Heng Zhao et al. [31] proposed ethnicity recognition framework by utilizing a CNN model, Content-Based Image Retrieval model (CBIR), and Support Vector Machines (SVM) classifier. A VGG-16 CNN model is used for feature extraction and a Bag-of-Words model is used as CBIR, a combination of CNN feature and ranking feature are used to train SVM model for classification. The model is trained using a dataset consisting of 1,000 images of Bangladeshi people, 1,520 images of Chinese people, and 1,078 images of Indian people. The model achieved 95%

classification accuracy. Hu Han et al. [32] used a modified AlexNet CNN model with batch normalization layers for feature extraction and two fully connected layers for classification. The model is trained on MORPH-II dataset achieving 96% classifying accuracy for three ethnic groups of Black, White, and Other. Anwar Inzamam et al. [33] used a pre-trained VGG-Face CNN model for feature extraction and a SVM model as a classifier. The model is trained on ten different databases, using ten-fold cross-validation where nine databases are used for training and one for testing. The model achieved 98% average classification accuracy over all databases for three ethnic groups of Asian, White, and Black. Amr Ahmed et al. [34] used a Feed-Forward based CNN model and max pooling layer for classification. The model is trained using Face Recognition Grand Challenge dataset achieving 93% classifying accuracy for three ethnic groups of Asian, White, and Other.

A summary of related work based on deep learning approach is shown in Table I, describing the model used, the number of ethnicity groups classified by the model and accuracy achieved by the model compared to the proposed model.

TABLE I. A SUMMARY OF RELATED WORK BASED ON DEEP LEARNING APPROACH

Author	Method	Ethnicity groups	Accuracy
Marwa Obayya et al. [29]	Fusion of VGG16, Inception v3, and capsule network CNN models	African American, East Asian, Caucasian Latin, and Asian Indian	70%
Gurram Sunitha, K. et al. [30]	Xception CNN model	Asian, African, Caucasians, and Indian	97%
Norah A. Al-Humaidan et al. [12]	ResNet50 CNN model	GCC people, Levant, and Egyptian	76%
Heng Zhao et al. [31]	VGG-16 CNN model	Bangladeshi, Chinese, and Indian	95%
Hu Han et al. [32]	AlexNet CNN model	Black, White, and Other	96%
Anwar Inzamam et al. [33]	VGG-Face CNN model	Asian, White, and Black	98%
Ahmed et al. [34]	Feed-Forward based CNN model	Asian, White, and Other	93%
Proposed model	MaxVit vison transformer model	Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White	77%

III. PROPOSED METHOD

This section describes the proposed approach for ethnicity recognition using computer-vision techniques based on deep learning. There are two main limitations of the existing techniques described in the literature review section. First, most of the proposed techniques are limited to classifying up to four ethnic groups. Secondly, the proposed techniques are limited to the utilization of CNN models for the purpose of feature extraction. Thus, this paper proposes a model for classifying six ethnic groups i.e., Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White by employing the MaxViT model which is a hybrid Vision Transformer based model capable of feature extraction and classification.

A. *Multi-Axis Vision Transformer (MaxViT)*

Initially transformers were proposed for the task of natural language processing [35], the prime feature of transformers is the self-attention mechanism which is the ability to capture semantic relations between data segments in a sequence. However, recently in the scope of computer-vison transformers have attracted considerable interest in the research community and several approaches have been proposed for image classification, segmentation, object detection, and generation. Thereby, Zhengzhong Tu et al. [9] proposed a Self-Attention mechanism named multi-axis self-attention (Max-SA) which can capture both local and global semantic relations between data segments. This is accomplished by decomposing the self-attention mechanism into window attention for local interaction and grid attention for global interaction. The Max-SA mechanism is a stand-alone attention module which can be adopted in any network architecture. Thus, The Max-SA module is the backbone structure of MaxViT model (see Fig. 1) coupled with Inverted Residual Block (MBConv) [36]. The model is available on Google Colab notebook (https://colab.research.google.com/drive/1UvseIP7zvFiysagSp4zfvt9f9ErHu-lo?usp=sharing).

MaxViT module uses the relative positional multi-head attention mechanism. The basic concept of an attention mechanism is to estimate the relevance of one data token to other data tokens in a sequence. In self-attention layer there are three trainable weight matrices (W^Q, W^K, W^V) from which three variables are generated by performing dot-product multiplication of the initial input variable (X_i) with learnable matrices represented as $(Q = XW^Q, K = XW^K, V = XW^V)$, from which attention layer output is represented as in Eq. (1), where d_k is input size [37].

$$Attention(Q, K, V) = sofmax\left(\frac{QK^t}{d_k}\right)V \qquad (1)$$

As for multi-head attention which is an extension of self-attention where the input is first partitioned into several segments and each segment is processed in parallel by a separate attention layer from which the output of each layer is considered as an attention head. Hence, multiple attention heads are aggregated as the final output allowing the model to capture various feature aspects of the input. As for the relative positional self-attention, an additional bias is concatenated with the output of the attention layer which incorporates positional importance of data tokens in a sequence.

The MaxViT module is composed of three main blocks. First, the MBConv with Squeeze-and-Excitation (SE) [38] block, window attention block, and grid attention block. The MBConv with SE is utilized to enhance the model efficiency and generalization, where MBConv are used to scale the model depth wise allowing it to capture complex features, and SE are used as channels wise self-attention mechanism that capture interdependencies between channels. The window attention block transforms the input feature map into non-overlapping windows to represent a confined attention by reshaping it $\left(\frac{H}{P} \times \frac{W}{P}, P \times P, C\right)$ where P is the window size. The grid attention block transforms the input feature map into uniform grid to represent a sparse attention by reshaping it $\left(G \times G, \frac{H}{G} \times \frac{W}{G}, C\right)$ where G is the grid size. Each of the attention blocks outputs are reshaped back to the initial input shape and passed through a multi-Layer perceptron block is illustrated in Fig. 1.

Fig. 2. Architecture of MaxVit model.

The MaxViT model architecture is shown in Fig. 2. The MaxViT model architecture can be described as follows. First, the input layer which takes an input feature map of size (C, H, W) where C depicts the feature map channels/depth, H the feature map height, and W the feature map width. The stem layer uses convolutional layers to extract low-level features from the input and reduce its spatial dimensionality. Thus it reduces the computational complexity of the model. The MaxVit block which is composed of sequentially staked MaxViT modules where each block outputs half the resolution of the prior block with a doubled channels size. Finally, the classifier which transforms the multi-dimensional output into one-dimensional i.e., a feature vector. From then the feature vector is passed to a fully connected layer which performs linear transformation and outputs a prediction.

IV. Experiment and Results

This section describes the datasets used for model training and testing, the experiment conducted, and the results obtained. The experiments were implemented using PyTorch (2.0.0+cu118) for Python (3.10.5) and executed on a computer with Intel Core i7-6700 processor with 16 GB RAM, and RTX 3080 with 10-GB VRAM GPU.

A. Dataset

The experiments were conducted on a database created by merging three datasets FairFace [10], UTKFace [11], and Arab face dataset [12]. Dataset is described in Fig. 3 composed of six classes with sample sizes of 15,937 for Asian, 18,589 for Black, 18,074 for Indian, 14,988 for Latino Hispanic, 15,188 for Middle Eastern and 28,645 White, with a total of 111,421 samples split into 101,474 samples for training and 9,947 samples for testing. The ratio of training samples to testing samples per class is shown in Fig. 4. Random samples from each dataset are shown in Fig. 5.

B. Experiment

This section describes the configuration and hyperparameters used for the proposed model. The objective of this experiment is to employ the MaxVit transformer-based model for ethnicity recognition using facial images. The experiment utilizes transfer learning technique to reduce computational complexity and training time by reusing the pre-trained parameters of all the model layers excluding the classifier head which were modified to an output size of 6 hence the initial model is trained on ImageNet dataset [39] for object classification with an output size of 1000. Also, in the experiments all of the pre-trained model layers parameters are retrained.

Data Preprocessing: Typically, when utilizing transfer learning data must follow the same preprocessing pipeline used for training the initial model. Thus, for data preprocessing the first step is to resize the image to 224 × 224 pixels with center crop applied, and then a random horizontal flip of the image is applied with probability of 80% as a data augmentation. Next, image pixels values are converted from 0 to 255 to be between 0.0 and 1.0, where each of the color channels values represented as (Red, Green, Blue) are normalized by a mean of 0.485, 0.456, 0.406 and standard deviation of 0.229, 0.224, 0.225, which can enhance the model's learning process by standardizing the input. The specific values are often determined empirically based on the dataset being used. In this case, these values are used when trained on ImageNet dataset.

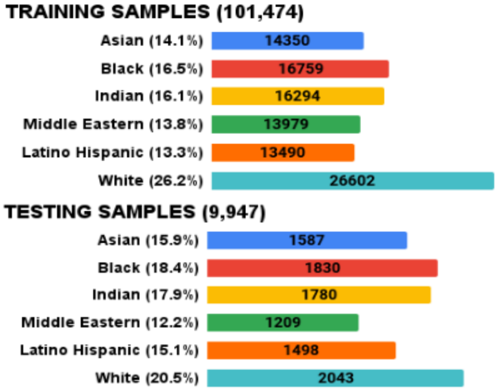

Fig. 3. Dataset overview.

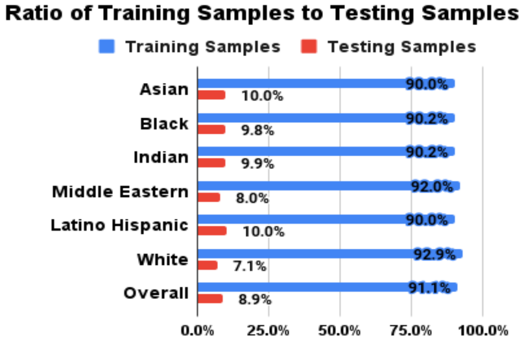

Fig. 4. Data split ratio.

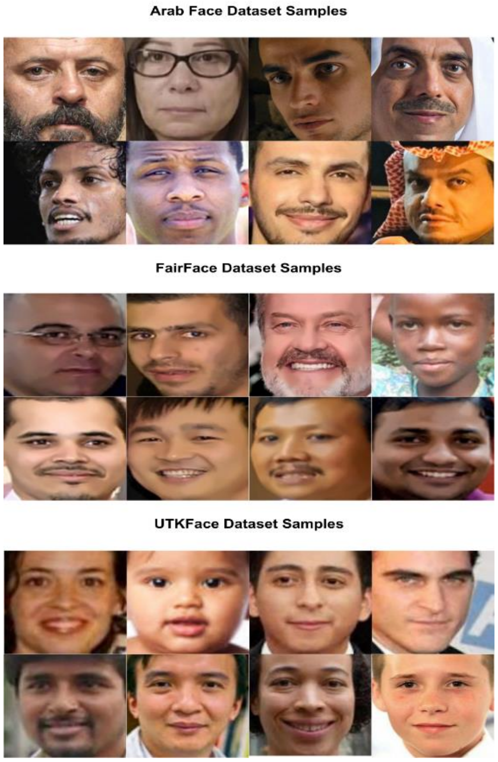

Fig. 5. Samples overview from each dataset.

Model hyperparameters: The model takes an input tensor shape of (B, C, H, W) where B stands for batch size and has the value of 20 images, C for color channels which is 3 for each image, H for the pixel height of each image that is 224, and W for the pixel width of each image that is 224. Based on the experiment an optimal batch size is between 16 and 20, thus for the purpose of reducing training time and fully utilizing hardware capacity the batch size is set as 20 images. A head dimension of 32 is used to represent the output feature map of the attention layers with partitioning size of 7 × 7 for both window and grid attentions, for the purpose of reusing the pre-trained parameters. Cross-entropy loss is used as a loss function to measure the dissimilarity between predicted probabilities and the actual targets. As for model parameters optimization the Adadelta algorithm is implemented with a learning rate of 0.1. Adadelta is an adaptive learning rate technique [40] which dynamically and automatically adjusts the learning rates on a per-parameter level, thus based on the experiment with Adadelta optimizer the learning rate value does no substantial impact on the learning process unless extreme values are used.

C. Results

In the main experiment the model was trained for 15 epochs achieving the highest classification accuracy of 0.772 for classifying six ethnic groups of Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White. Additional experiments are conducted for a comparison in which four CNN models are trained using the same dataset. These models are a pre-trained VGG-Face model based on Vgg-16 architecture [41] which is developed for face recognition with over two million faces images. A pre-trained VGG-Face2 model based on ResNet-50 architecture [17] which is also developed for face recognition but with over three million faces images. A pre-trained EfficientNet-V2 model [42] for object classification is also based on MBConv. Additionally for the purpose of testing MaxVit model scalability an experiment is conducted by training the proposed model on three ethnic classes i.e., Black, White and others which is a merged class of all the remaining categories. For training the sample sizes used are 17,015 samples for Black, 17,099 samples for White, and 18,458 samples for the merged class. For evaluation the sample sizes used are 1,300 samples for black, 1,300 samples for white and 1,500 samples for the merged class. The model achieved a classification accuracy of 0.835. Lastly for comparison the same experiment is conducted with three classes using the AlexNet model [32] which achieved the classification accuracy of 0.782. The results are shown in Fig. 6. Additionally, the classification accuracy of top two predicted classes is shown in Fig. 7 where the proposed MaxVit model achieves the highest score of 91.3%. A comparison of model size in terms of parameters size is shown in Fig. 8, where the proposed MaxVit model being the smallest model in terms of parameters size. Hence, in terms of performance smaller models require lower computational capacity thus being more efficient in terms of speed and size on disk. Confusion matrices are shown in Fig. 9 describing the models classification performance of 9,947 samples for six classes.

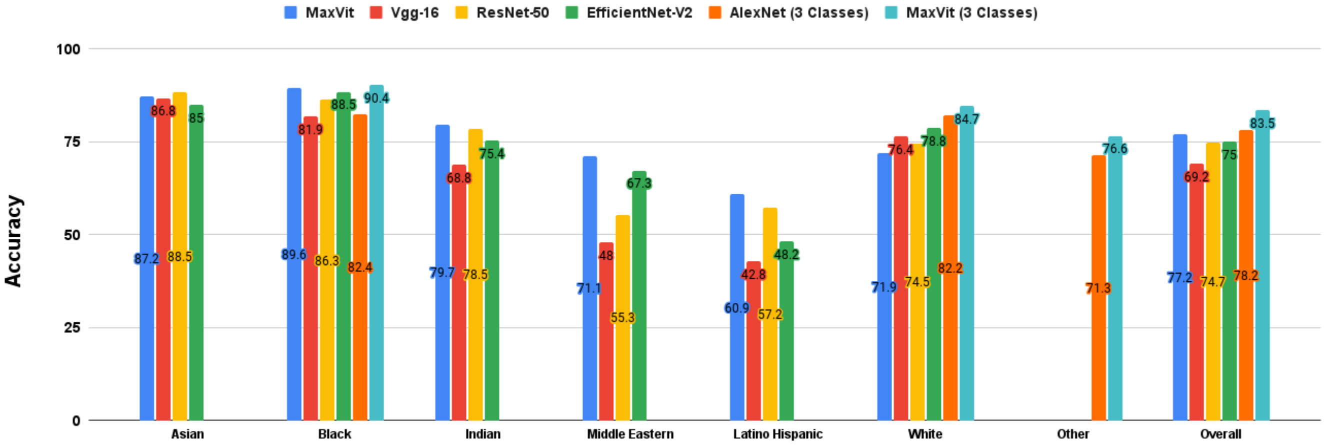

Fig. 6. Models classification accuracies.

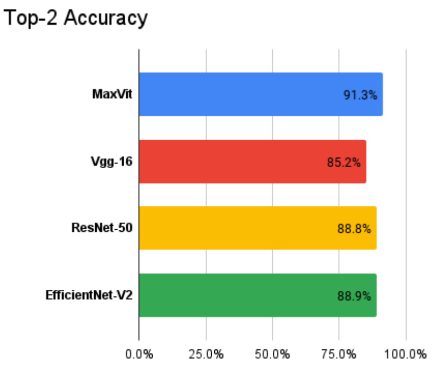

Fig. 7. Top two predicted classes accuracy scores.

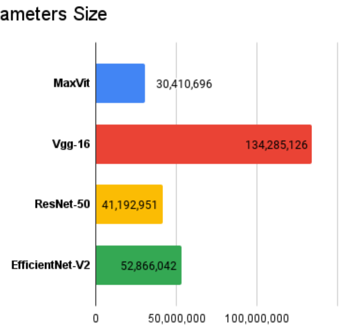

Fig. 8. Models parameters size.

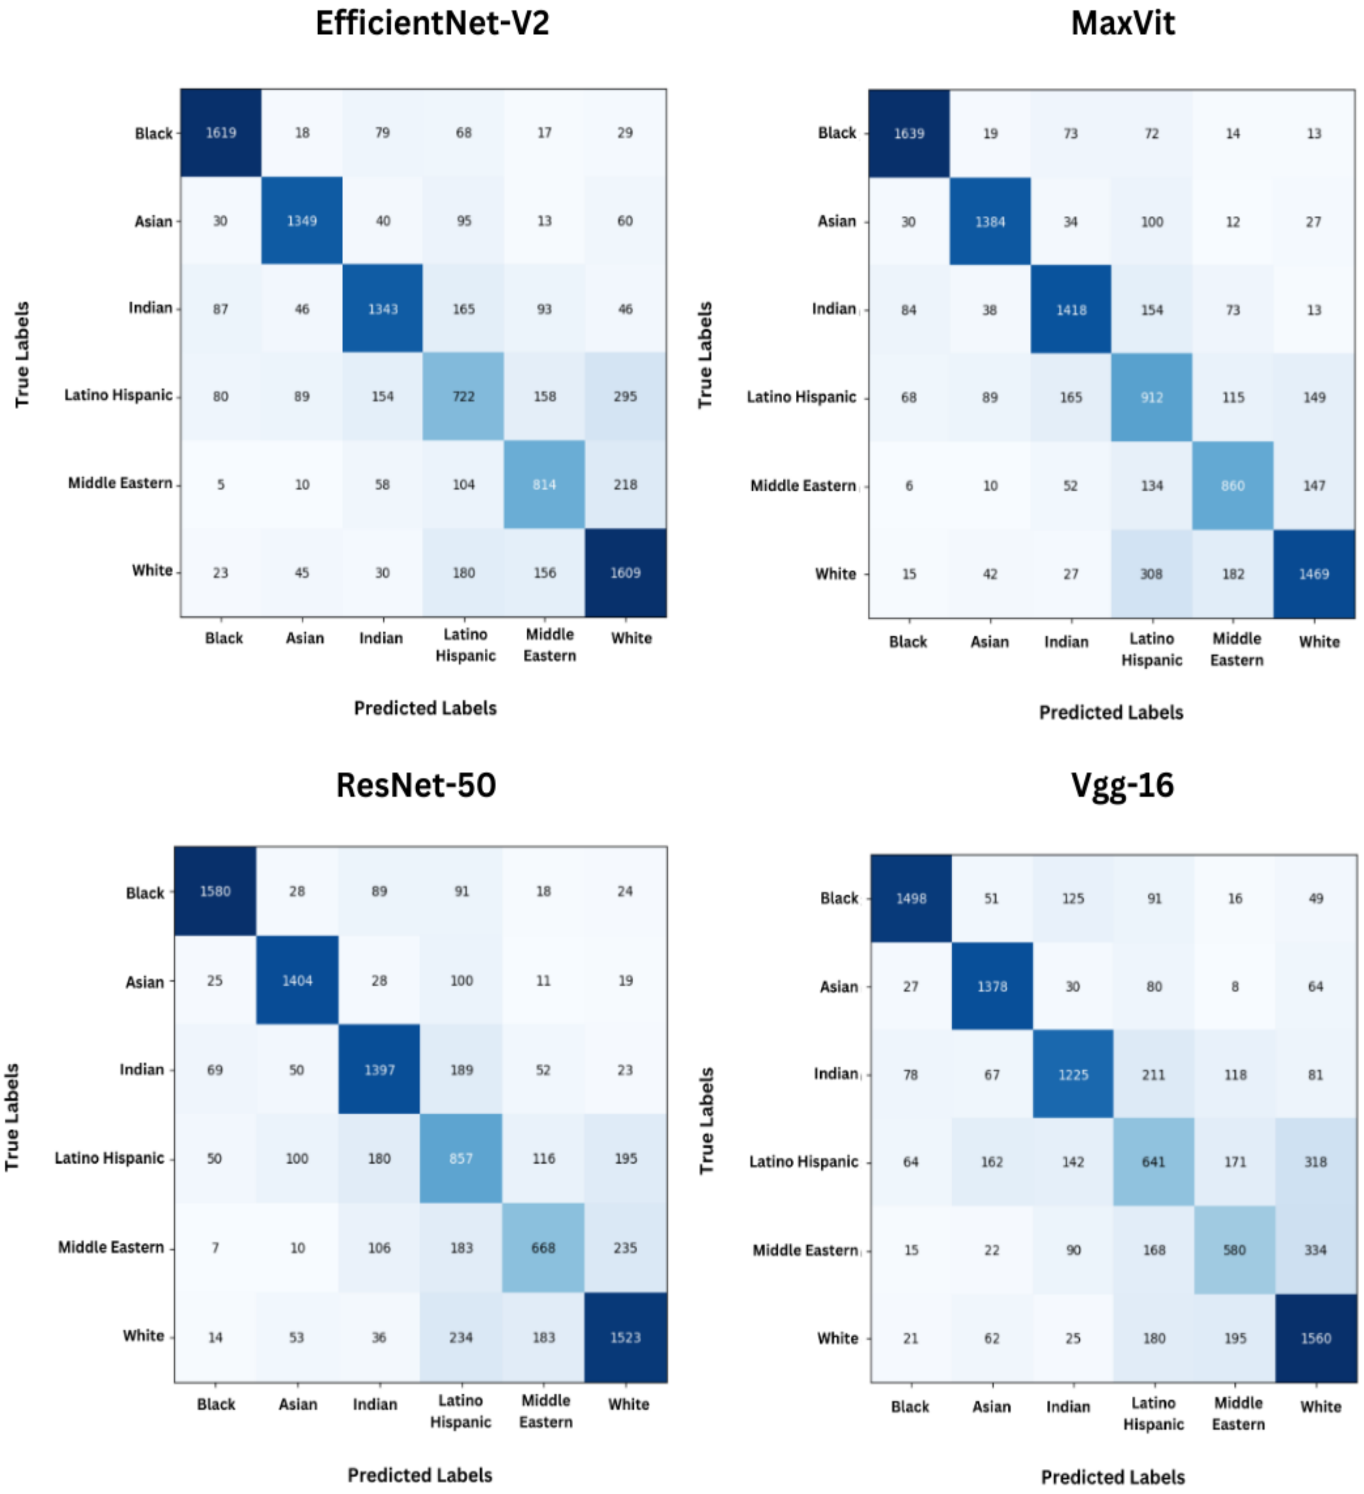

Fig. 9. Confusion matrices.

Based on observation, the model’s misclassification for both of Latino Hispanic, and Middle Eastern is noteworthy. This due to the high overlapping diversity between the three ethnic groups of White, Latino Hispanic, and Middle Eastern which are merely considered multiracial groups [43]. Thus, considerable efforts are required for the creation of a representative dataset for such ethnic groups, which certainly could improve the performance of ethnicity recognition models. However, in the conducted experiments the proposed MaxVit model achieves better generalization compared to other models.

V. Conclusion

This paper addresses the two common limitations of research in the field of race recognition. First, a large database has been created with six racial categories i.e., Asian, Black, Indian, Latino Hispanic, Middle Eastern, and White. Second, it has proposed the usage of a vision transformer named MaxVit as an ethnicity recognition model using facial images. It achieves a classification accuracy of 77.2% and better generalization than other recent works.

The research area of race and ethnicity recognition is still unsaturated, mainly from the aspect of racial or ethnic groups diversity, as the number of pre-defined racial categories is limited by the available datasets. This could be particularly problematic for individuals who have mixed racial backgrounds, thus multiracial classification is noteworthy as racial facial traits are noticeably overlapped for most of population individuals. Therefore, a considerable effort should be devoted towards such aspects, which certainly contribute to the advancement of the research area.

***Abstract*—Drivable area or free space detection is an essential part of the perception system of an autonomous vehicle. It helps intelligent vehicles understand road conditions and determine safe driving areas. Most of the driving area detection algorithms are based on semantic segmentation that classifies each pixel into its category, and recent advances in convolutional neural networks (CNNs) have significantly facilitated semantic segmentation in driving scenarios. Though promising results have been obtained, the existing CNN-based drivable area detection methods usually process one local neighborhood at a time. The locality of convolutional operation fails to capture long-range dependencies. To solve this problem, we propose an improved Swin Transformer based on shift window, named Multi-Swin. First, an improved patch merging strategy is proposed to enhance feature interactions between adjacent patches. Second, a decoder with upsampling layer is designed to restore the resolution of the feature map. Last, a multi-scale fusion module is utilized to improve the representation ability of global semantic and geometric information. Our method is evaluated and tested on the publicly available Cityscapes dataset. The experimental results show that our method achieves 91.92% IoU in road segmentation detection, surpassing state-of-the-art methods.**

Keywords—CNNS; driving area detection; multiscale fusion; semantic segmentation; Swin Transformer

I. INTRODUCTION

With the rapid development of computer technology, autonomous driving has entered into real life. Driving area detection aims to accurately determine the current accessible area of vehicles in complex road environments using relevant technologies, which is a critical research area within the field of autonomous driving. Given the crucial role of the drivable area detection algorithm in ensuring the safety and efficiency of vehicle driving on the road, there is an urgent need to improve the accuracy of road detection.

The existing driving area detection methods can be divided into traditional methods and learning-based methods. Traditional methods use the pavement features of 2D images to segment roads. For example, Shi et al. [1] use the road color characteristics and vanishing points to detect the road boundary. Some researchers use edge detection operators to extract the edge boundary of the road and segment the road surface [2], [3]. Though traditional methods can detect driving areas in real time, they are not suitable for complex situations where the road surface features are not obvious.

Learning-based methods typically rely on semantic segmentation to achieve their goals. Semantic segmentation is a pixel-level technology that acts on each pixel of an image to predict its category. This prediction preserves the edge and semantic information of the original image, which is beneficial for enabling autonomous vehicles to understand the scene. As an exemplary approach, ERFNet [4] has demonstrated remarkable performance in road segmentation by incorporating residual layers and decomposition convolutions. Additionally, SNE-RoadSeg [5], data fusion CNN architecture, leverages RGB images and inferred surface normal information to accurately detect driving areas. Despite the success of existing learning-based techniques, the convolutional feature extraction is often criticized for its inability to capture long-range dependencies, which can impede the semantic segmentation performance.

Compared to convolution-based feature extraction methods, Transformer [6] can learn the relationship between global pixels, rather than just their local neighborhood. Additionally, the number of operations required to calculate the correlation between two positions is independent of the distance. For instance, the Swin Transformer [7] has achieved impressive results in image classification, object detection, and semantic segmentation thanks to its window attention and layered design. However, Transformer has not yet been applied to driving area detection. It should also be noted that the current fusion strategy reduces the information interaction between adjacent patches during the down sampling process.

This paper aims to address the limitation of convolution in capturing long-range dependency information. To achieve this, a pure attention model is proposed to replace the convolution operation with a gradually decreasing spatial resolution. To be specific, the input image is first divided into patches of the same size and the corresponding position encoding for each pixel is generated using a linear embedding layer. An encoder composed entirely of Swin Transformer is used to process the patches and a new patch fusion strategy is proposed to improve the information interaction between adjacent patches in the same window. A multi-scale fusion module is then employed to enhance the expression ability of the global semantic and geometric information of the feature map obtained from the encoder. Finally, a decoder with an up-sampling operation is designed to restore the resolution of the feature map and complete pixel-level segmentation prediction. The road segmentation experiment is conducted on

publicly available Cityscape dataset [8], and the experimental results prove the effectiveness of the proposed method.

II. Related Works

A. Semantic Segmentation

Convolution neural network (CNN) [9] is a kind of feedforward neural network with convolution computation and depth structure, which was originally designed for image classification tasks. In 2015, Long et al. [10] first applied convolution operations to semantic segmentation tasks in FCN. They use 1x1 convolution to replace the full connection layer in the convolutional network. And the feature map is upsampled to achieve end-to-end network segmentation. U-Net [11] adopts a fully symmetrical encoder-decoder structure on the basis of FCN, and deepens the decoder by stacking convolutional layers. It effectively improves the performance with only a small amount of training data. SegNet [12] transfers the maximum pooling index to the decoder, which improves the segmentation resolution and shows better performance than FCN. Furthermore, the emergence of the residual layer [13] can avoid the degradation of the deep network and achieve very high accuracy with network that stack a large number of layers [14]. DANet [15] uses the Xception network as the backbone, and adds a full connection module based on the attention mechanism at the end to retain the more receptive field. SENet [16] automatically obtains the importance of each channel by explicitly modeling the interdependence between feature channels and divides the attention mechanism into two very key operations, Squeeze and Excitation. While decreasing the number of parameters and computational requirements, the accuracy of the algorithm is improved.

B. Multi-Scale Fusion

Recently, several approaches have been presented to tackle the limited receptive field problem in FCNs and their variations. DeepLab [17] applies atrous spatial pyramid pooling (ASPP) in the spatial dimension and leverages conditional random fields (CRFs) to refine the output results. FPN [18] asserts that small targets require the use of larger-scale feature maps due to inadequate resolution information provided by smaller ones, but downsampling losses in deeper images lead to excessive information loss, potentially disregarding small target details. Zhao et al. [19] propose utilizing dilated convolutions to augment the ResNet architecture. Their PPM module facilitates multi-scale feature fusion by acquiring diverse background information across regions. DeepLabV3+ [20] builds on an enhanced Xception [21] backbone and incorporates the decoder module from DeepLabV3 [22], further integrating low-level and high-level features to improve segmentation boundary accuracy. Qin et al. [23] introduce an autofocus convolutional layer, an attentive variant of ASPP, to enhance multi-scale feature extraction capabilities. This layer dynamically learns the weights of different branches via an attention mechanism, adapting the receptive field size for effective multi-scale feature extraction. Gu et al. [24] utilize dual parallel encoders to extract information at varied scales, subsequently merging them using a decoder. With a UNet backbone, each encoder processes images of dissimilar resolutions to acquire feature maps at differing scales.

C. Vision Transformer

ViT [25] uses Transformer for vision tasks for the first time. The 2D image is divided into patches of the same size and expanded into 1D sequences by pixels. The position coding of each pixel is obtained through the linear embedding layer and then input into the encoder. It shows the great potential of Transformer in the field of vision. However, ViT must first be pretrained on a large-scale dataset. Different from ViT, DEiT [26] uses an appropriate training method and distillation technique to solve this problem. DEiT can learn inductive biases based on CNN thanks to the distillation principle, which enhances its capacity to interpret image-type data. SETR [27] achieves excellent semantic segmentation performance with three optional decoding algorithms and a Transformers-based encoder.

The global attention used in Transformer requires a lot of computing resources. Swin Transformer adopts sliding window and layered architecture to solve this problem. The sliding window restricts the attention calculation to one window, introduces the locality of CNN convolution operation and reduces the amount of calculation. It achieves the impressive results on multiple tasks in the visual field. SegFormer [28] combines Transformer encoder and MLP decoder. The position encoding will result in performance degradation because the testing and training resolution are different. To address this issue, SegFormer utilizes a 3x3 deepwise convolutional layer to transmit positional information. The proposed MLP decoder is utilized to combine local and global attention by aggregating the multi-scale features of the encoder output.

D. Driving Area Detection

The existing driving area detection methods can be divided into traditional methods and deep learning-based methods. The information about the pavement features in the 2D image is extracted and segmented by the conventional driving area detection technique. For example, Shi et al. [1] identified road borders using vanishing points and road color attributes. Gao et al. [29] proposed a real-time vision technique based on the color cue training model of continuous frames to identify the driving area in the presence of shadows, lane markers, or unstable lighting. Yao et al. [30] identify drivable area with Support Vector Machine (SVM) and achieve 82.51% F1-score on KITTI dataset [31]. Deep learning driving area detection makes use of semantic segmentation as a key tool. A multitask CNN network was introduced by Pizzati et al. [32] to determine the available space in each lane. The network can operate in real-time thanks to ROS-based calculation. Qiao et al. [33] built the architecture using the characteristic pyramid network and the spatial pyramid pool module based on the ResNet network. It was able to achieve 84.58% IoU on the BDD100K datasets. Choi et al. [34] proposes a network using accumulated decoder features, called ADFNet, which operates using only decoder information, with no skip connections between encoder and decoder. Han et al. [35] proposed a new partitioned network, EdgeNet. It includes a class aware edge loss module and a channel attention mechanism. More than

70% of IoU was obtained on the Cityscapes dataset. In order to overcome the issues of limited anti-noise ability and inadequate segmentation of small-scale objects, Dong et al. [36] proposed an approach using a generative adversarial network (GAN [37]) in conjunction with an ERFNet model.

While these approaches have yielded good experimental results in the drivable area detection domain, they do not address the problem of poor long-range information reliance due to convolutional kernel restrictions.

III. METHOD

A. Architecture Review

The architecture of the driving area algorithm of the improved Swin Transformer proposed in this paper is shown in Fig. 1, which is composed of an encoder, a decoder, and a multi-scale fusion module. The network processing flow is as follows： First, the RGB input images are separated into identically sized, non-overlapping patches. Second, linear embedding layer generates patch embedding. Then, the encoder takes these embeddings as input to generate feature maps. Next, a multi-scale fusion module is introduced between the encoder and decoder to improve the representation ability of the feature map. After that, the decoder restores the original image resolution. Finally, pixel-level segmentation prediction is produced via a 1x1 convolutional Layer. Below, we'll go into more depth about each module.

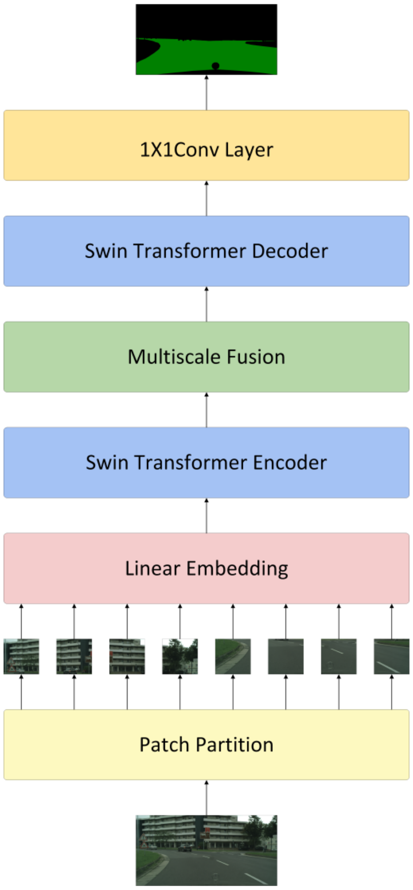

Fig. 1. Network structure.

B. Preprocessing

The input of multi-head self-attention (MSA) is 1D sequence, but there is a mismatch between 2D image and 1D sequence. The input image needs to be sequentialzed. Expanding the image pixel values into a 1D sequence is a direct way. However, the computing complexity increase sharply if the input is a high-resolution image. To solve this problem, we divide the input images into size 4X4, non-overlapping patches, which is similar to prior works [7], [21]. By further mapping each vectorized patch into a C dimensional embedding space with a linear embedding layer, we obtain a 1D sequence of patch embeddings for an input image.

C. Encoder

As shown in Fig. 2, the encoder consists of Swin Transformer blocks and patch merging layers. The supplied image is split into 4X4 patches. The Swin Transformer blocks perform feature representation learning on the input images, and generate a feature map. The patch merging layers down sample the received feature map to expand the receptive field. The layer processing of our proposed encoder is shown in Table I.

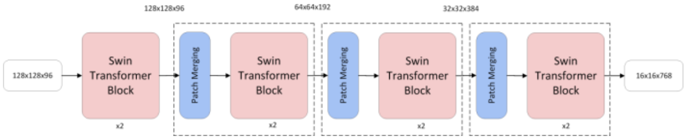

Fig. 2. Detailed display of encoder.

TABLE I. LAYER DISPOSAL OF OUR PROPOSED ENCODER

Layer	Type	Out-F	Out-Res
1	Patch Partition	48	$\frac{H}{4}$ x $\frac{W}{4}$
2	Linear Embedding	C	$\frac{H}{4}$ x $\frac{W}{4}$
3-4	Swin Transformer Block	C	$\frac{H}{4}$ x $\frac{W}{4}$
5	New Patch Merging	2C	$\frac{H}{8}$ x $\frac{W}{8}$
6-7	Swin Transformer Block	2C	$\frac{H}{8}$ x $\frac{W}{8}$
8	New Patch Merging	4C	$\frac{H}{16}$ x $\frac{W}{16}$
9-10	Swin Transformer Block	4C	$\frac{H}{16}$ x $\frac{W}{16}$
11	New Patch Merging	8C	$\frac{H}{32}$ x $\frac{W}{32}$
12	Swin Transformer Block	8C	$\frac{H}{32}$ x $\frac{W}{32}$

1) Swin Transformer block: Fig. 3 illustrates the structure of Swin Transformer block. It is consisted of LayerNorm layer (LN), multi-head self-attention (MSA), residual connection, and MLP layer with nonlinear GELU. As indicated in Fig. 3, Swin Transformer block is computed as follows:

$$\hat{y}^{l} = W - MSA(LN(y^{(l-1)})) + y^{(l-1)} \tag{1}$$

$$y^{l} = MLP(LN(\hat{y})) + \hat{y}^{l} \tag{2}$$

$$\hat{y}^{(l+1)} = SW - MSA(LN(y^l)) + y^l \tag{3}$$

$$y^{(l+1)} = MLP(LN(\hat{y}^{(l+1)})) + \hat{y}^{(l+1)} \tag{4}$$

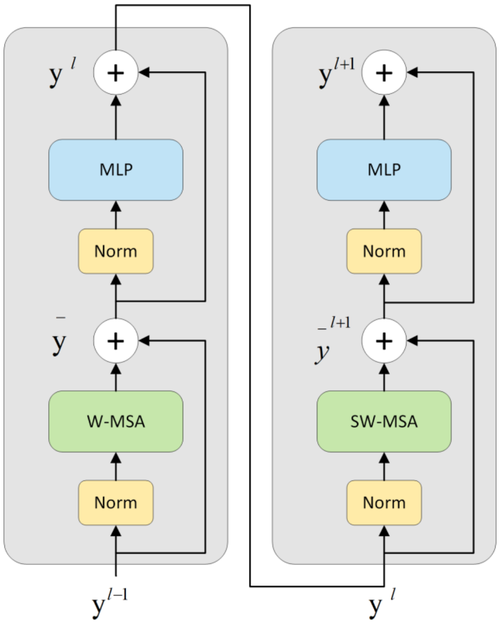

Fig. 3. Illustration of Swin Transformer block inside encoder and decoder.

where, ŷ is the output after (S) W-MSA, and y is the output after MLP. Instead of global attention, the window attention mechanism is used to reduce computational complexity. Compared to the quadratic complexity of global attention, the computational complexity of the small window grows linearly. The window-based multi-head self-attention (W-MSA) and shift window-based (SW-MSA) are utilized to improve cross-window connection. Self-attention formula is as follows:

$$Attention(Q,K,V) = SoftMax(\frac{QK^T}{\sqrt{d}} + B)V \tag{5}$$

where, Q, K, and V represent query, key, and value matrix, d represents dimension, and B represents offset. Attention is shown in Fig. 4.

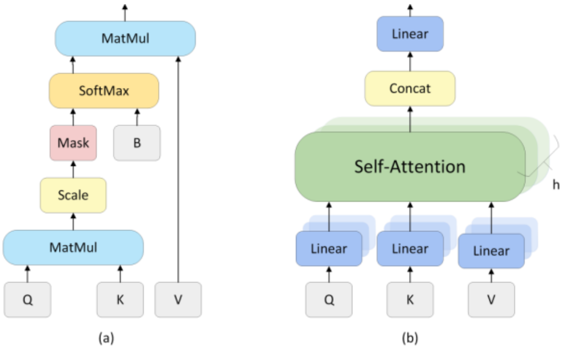

Fig. 4. (a) Self-Attention. (b) Multi-Head self-attention.

2) New patch merging: The patch merging process is shown in Fig. 5. This module aims to down sample the feature map received from the Swin Transformer blocks. It reduces calculation, and realizes hierarchical design. After the merging layer, the resolution of feature map becomes half of the original. First, the pixel values are taken at intervals in the row and column directions of the feature map to form four new tensors. As indicated in Fig. 5, two adjacent pixels on the new feature map are not adjacent in the original feature map, which reduces information interaction during fusion. To improve the interaction between adjacent pixel points, we add a pooling layer in the fusion stage. A new tensor with a channel dimension of 5C is created by concatenating the output of the pooling layer and the feature maps generated from the down sampling. The resolution of the feature map is finally changed using the fully connected layer. The problem of lack of information interaction caused by capturing pixels at intervals is relieved since the feature map produced by the pooling layer has the global features of the input.

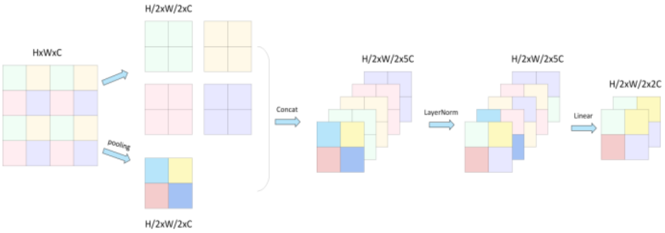

Fig. 5. The process of patch merging.

D. Multi-scale Fusion

The objects in the image are range in size, and each object has a unique set of features. Shallow features can be used to differentiate simple objects, while deep features can be used to separate complex targets. Combining data from various levels is better suited for complicated tasks since the shallow network prioritizes details while the high-level network prioritizes semantic information. In order to improve the capacity to convey global semantic and geometric information, we design a multi-scale fusion module. It combines the output of each group of Swin Transformer Blocks between the encoder and decoder. The multi-scale fusion module is shown in Fig. 6. Given four feature maps produced by Swin Transformer blocks at different stages, the down sampling operation is first performed on the three feature maps with high-resolution. Secondly, 1x1 conv layer is used to map the feature maps of different dimensions to the same dimension. Finally, four groups of feature maps are concatenated to form a new feature map. The obtained feature map has stronger representation ability because it fuses feature information from different levels.

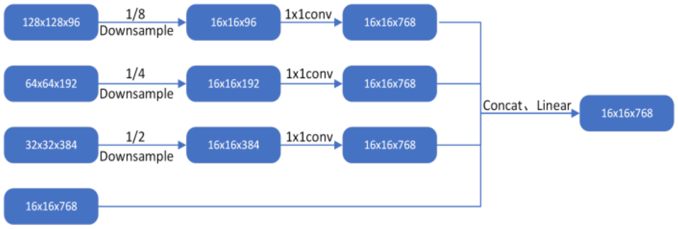

Fig. 6. Details of multi-scale fusion.

E. Decoder

Similar to the encoder, the decoder is composed of Swin Transformer blocks and patch extension layers. Fig. 7 depicts details of the decoder. Among them, the Swin Transformer block is consistent with the encoder, and the patch expansion layer upsamples the feature maps. It has been suggested by SETR that restoring the resolution to its original size in one-step might be interfered by noise. Instead of one-step upscaling, we consider a progressive upsampling technique. Each time a patch expansion layer is applied, the input feature map is increased to 4x resolution. Then feature map resolution is restore to its original size using a 2X upsampling layer at the end of the decoder. To output pixel-level segmentation prediction, a 1x1 convolutional layer is employed. Table II shows the layer processing of our proposed decoder.

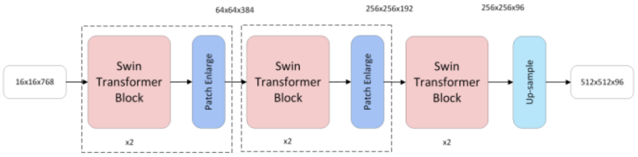

Fig. 7. Detailed display of decoder.

IV. EXPERIMENT

A. Dataset and Experimental Setup

The dataset chosen for this study is Cityscapes. The primary goal of Cityscapes dataset is to provide an image segmentation dataset in an unmanned driving environment, so that researchers can evaluate the performance of algorithms to understand the semantic information of the urban environment. Cityscapes provides 5000 fine annotation images and 20,000 rough annotation images, with a total of 33 categories of annotation items, including 50 street scenes of different cities in various scenarios, backgrounds, and seasons. There are 19 commonly employed categories. Drivable area detection aims to identify the driving area on the road, so we only use the datasets that contain annotations about the road. As a result, there are only two categories in this experiment: drivable area and background. Fig. 8 displays cityscape datasets. There are fine-labeled and coarse-labeled images in the Cityscapes dataset. Although the segmentation accuracy of coarse labeled images is not as good as that of fine labeled images, they still contribute to model training. Therefore, we train the ADE20K pretrained model released by Swin Transformer on roughly labeled Cityscapes images. And use it as a pre-trained model to train fine-label dataset.

Python 3.8 and Pytorch 1.12.1 are used to implement the model. The window size based on shift window attention is set to be 7, the patch size is set to 4, and the input image size is set to 512x512. We trained our model on a NVIDIA RTX2080Ti GPU. Our backpropagation model is optimized using the AdamW optimizer with a momentum of 0.9 during training. The batch size is 8 and the learning rate is 1e-4.

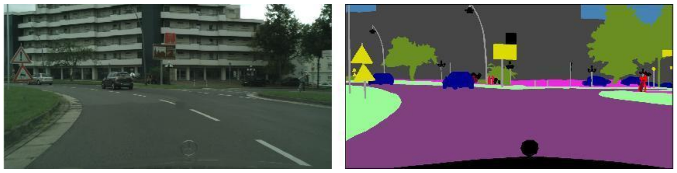

Fig. 8. Cityscapes datasets.

B. Evaluation Metrics

The commonly used Intersection over Union (IoU) [38] index, pixel level accuracy, and precision are used to evaluate the experimental results. We use the pixel level for the three test indicators. IoU is the ratio of the intersection sum of the predicted result and the true value:

$$\mathrm{IoU} = \frac{TP}{TP + FP + FN} \tag{6}$$

Pixel level accuracy is the ratio of correctly classified pixels to the total number of pixels in the image:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{7}$$

The precision rate is the probability that all predicted positives are actually positives:

$$\mathrm{Pr}\,ecision = \frac{TP}{TP + FP} \tag{8}$$

where, TP, TN, FP and FN represent the pixel level true positive, true negative, false positive and false negative indicators,respectively. Positive refers to the labeled part (driving area), while negative refers to the part of the non-object label (which can be directly understood as the background).

C. Performance Evaluation

In this section, we qualitatively compare our proposed model with state-of-the-art semantic segmentation models. Each model was trained for about 200 epochs until convergence of the loss function. Evaluation was performed on the Cityscapes test set, consisting of 1525 images, at a resolution of 512x512. Experimental results for the Cityscapes dataset are shown in Table III. Our method demonstrates superior performance in category IoU when compared to HRNet [39] and U-Net, and excels in pixel-level accuracy and precision over other models. Specifically, it outperforms HRNet by 0.2%, 0.9%, and 0.63% in these metrics, and has a 0.15%, 0.88%, and 0.44% advantage over U-Net. Despite having a minor disadvantage in the IoU metric against DeepLabV3+, our method ranks first in the other two metrics with respective leads of 0.26% and 0.16%. These results support our claim that our method improves classification accuracy.

The semantic segmentation outcomes on the Cityscapes dataset are depicted in Fig. 9, where (a) is Original driving scene images, (b) is Ground truth annotations, (c) is Road segmentation results of our model. (d) Road segmentation results of DeepLabV3+, (e) is Road segmentation results of HRNet and (f) is Road segmentation results of UNet. The segmentation results reveal that our approach can accurately demarcate the road and surrounding objects within the driving region. In contrast to other techniques, our method provides better predictions for the edges of the drivable area and background. This superiority can be attributed to the fact that the attention mechanism captures long-range semantic information, achieving better performance than convolutional networks in edge detection. Hence, our method excels in learning edge pixels, resulting in higher pixel prediction accuracy and overall performance than other networks.

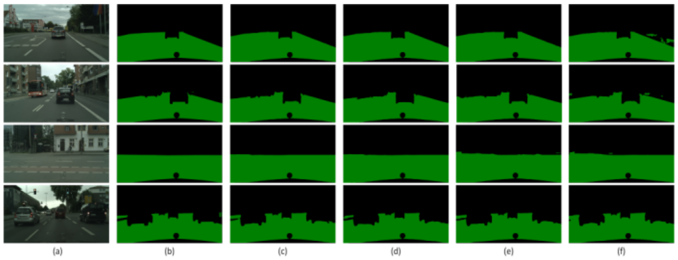

Fig. 9. Examples of road segmentation results on cityscapes dataset.

TABLE III. EVALUATION RESULTS ON THE CITYSCAPES TEST SET FOR ROAD SEGMENTATION

Models	IoU (%)	PA (%)	Precision (%)
Multi-Swin	91.92	**96.79**	**96.19**
HRNet	91.72	95.89	95.56
DeepLabV3+	**92.25**	96.53	96.03
U-Net	91.77	95.91	95.75

D. Ablation Study

In this section, we conduct ablation experiments on our proposed driving area detection algorithm to verify the effectiveness of different modules. From the perspective of patch fusion strategy, multi-scale fusion module and decoder, we conduct comparative experiments.

1) New patch merging: To substantiate the efficacy of the suggested patch fusion strategy, we replaced the patch merging layers with those from the original Swin Transformer, leaving the remaining networkarchitecture unmodified. The experimental outcomes are outlined in Table IV. From the data presented in Table IV, one can observe that our method surpasses the original Swin Transformer patch merging technique in all three examined metrics, resulting in improvements of 0.31%, 0.12%, and0.27%, respectively. This modification mitigates the insufficiency of information interaction during the fusion procedure to some degree, ultimately improving road segmentation accuracy.

TABLE IV. EXPERIMENTAL RESULTS OF FUSION STRATEGY

Models	IoU (%)	PA (%)	Precision (%)
Multi-Swin	**91.92**	**96.79**	**96.19**
Swin	91.61	96.67	95.92

2) Multi-scale fusion module: Our multi-scale fusion module's effectiveness is proven throughseveral experiments, including: a) substituting the proposed module with alternative multi-scale fusion techniques like ASPP and PPM, and b) removing the fusion module entirely. ASPP relies on multiple parallel dilated convolutional layers operating at varying dilation rates to extract features at different scales, which are then processed independently and merged into the final result. By constructing convolutional kernels with varying receptive fields through different dilation rates, ASPP captures object information across scales. On the other hand, PPM is designed to gather background information from multiple regions, addressing the lack of effective strategies to exploit global context in feature fusion. The experimental results are displayed in Table V. As illustrated in the table, our method yields the most favorable outcomes across all three metrics. Relative to ASPP, our fusion module shows significant improvement across all three metrics with gains of 0.51%, 1.28%, and 0.86%, respectively. When comparing against PPM, our fusion module exhibits performance advantages of 0.87%, 1.53%, and 1.21% for the same three metrics. Therefore, our proposed multi-scale fusion module aligns better with our network's design and enhances the accuracy of drive area detection.

TABLE V. EXPERIMENTAL RESULTS OF MULTI-SCALE FUSION MODULE

Models	IoU (%)	PA (%)	Precision (%)
Multi-Swin	**91.92**	**96.79**	**96.19**
Detachment	90.85	94.89	94.63
ASPP	91.41	95.51	95.33
PPM	91.05	95.26	94.98

3) Network structure: Swin Transformer Blocks serve as the primary components of both the encoder and decoder. To assess the effectiveness of our decoder, we substituted it with a Multi-Layer Perceptron (MLP), which includes an input layer, output layer, and several hidden layers. The MLP decoder utilizes GELU as a nonlinear activation function and restores the resolution of the input feature map to its initial dimensions. Results presented in Table VI reveal that our method outperforms MLP decoders across all three tested metrics, yielding boosts of 1.89%, 1.46%, and 2.05% for IoU, PA, and Precision, respectively. This validates the efficacy of our proposed decoder.

TABLE VII. EXPERIMENTAL RESULTS OF DECODER STRUCTURE

Models	IoU (%)	PA (%)	Precision (%)
Multi-Swin	**91.92**	**96.79**	**96.19**
MLP	90.03	95.33	94.14

E. Discussion

This paper presents the outcomes of four distinct experiments: a comparison test using cutting-edge techniques, as well as three separate sets of experiments employing the suggested drivable region recognition algorithm for purposes of elimination. These experiments show that our proposed algorithm achieves exceptional results in the realm of detecting drivable areas, with measurements such as Precision and PA reaching high levels of 96.19% and 96.79%, respectively, placing them at the forefront of comparable efforts. Additionally, the value of IoU was determined to be 91.92%. The experiments carried out for the purpose of eliminating variables confirmed the effectiveness of the various components put forth in this paper. Specifically, the novel patch fusion strategy served to enhance the interplay between neighboring points of interest, the multi-scale fusion module successfully combined more contextually relevant semantic information, thus increasing the expressiveness of feature maps, and lastly, the decoder employed in this work effectively restored the resolution of the feature map layer by layer, thereby mitigating any potential interference caused by noise and better suiting the overall architecture of the network described in this paper. Ultimately, these findings suggest that the methodology introduced in this study improves upon the accuracy of detecting drivable regions and could play a valuable role in furthering the application of deep learning within the domain of autonomous driving.

V. CONCLUSION

In this paper, an enhanced Swin Transformer based semantic segmentation algorithm is proposed. The proposed method is based on encoder-decoder framework. Different from other semantic segmentation networks, we use Swin Transformer as the main body of encoder and decoder. It is applied to the field of drivable area detection for the first time. Meanwhile, the patch merging strategy is improved to enhance the feature interaction between adjacent patches. We design a decoder with an upsampling layer to recover the resolution of the feature maps. Finally, a multi-scale fusion module between the encoder and decoder is used to optimize the expressiveness. We use the publicly accessible Cityscapes dataset for training and testing, and compare our algorithm with state-of-the-art semantic segmentation networks to demonstrate the feasibility and usability of the proposed method. Experimental results indicate that the enhanced Swin Transformer-based method outperforms other well-known algorithms in terms of IoU metrics, achieving higher levels of pixel level accuracy and precision.

Even while the Multi-Swin method has produced ground-breaking results in terms of the accuracy of drivable area recognition, it still has several issues that need to be fixed. In particular, compared to conventional convolutional networks, the use of attention mechanisms places a greater demand on processing power when handling high-resolution pictures. Consequently, future research priorities will be on efficiently lowering the computational complexity and resource usage of the method without compromising or improving detection accuracy. Moreover, this paper's suggested modifications mostly focus on improving the accuracy of the model's predictions, leaving unexplored the possibility of improving the model's real-time responsiveness. The only static images in the training dataset at this time are two-dimensional ones, which is different from the dynamic visual information found in real-world application situations. Thus, future research must immediately focus on improving the algorithm's real-time performance optimization. Concurrently, in order to make sure that the model can better respond to the real-time decision-making requirements in real-world autonomous driving scenarios, video sequences or continuous dynamic picture data must be added for training.

Sky Pixel Detection in Outdoor Urban Scenes: U-Net with Transfer Learning

Athar Ibrahim Alboqomi, Rehan Ullah Khan
Department of Information Technology, College of Computer, Qassim University, Buraydah, Saudi Arabia

***Abstract*—The sky depicts a high visual importance in outdoor scenes, often appearing in video sequences and photos. Sky information is crucial for accurate sky detection in several computer vision applications, such as scene understanding, navigation, surveillance, and weather forecasting. The difficulty of detecting is clarified by variations in the sky's size, weather and lighting conditions, and the sky's reflection on other objects. This article presents a new contribution to address the challenges facing sky detection. A unique dataset was built that includes scenes of distinct lighting and atmospheric phenomena. Additionally, a modified U-Net architecture was proposed with pre-trained models as encoder VGG19, EfficientNetB4, InceptionV3, and DenseNet121 for sky detection to solve outdoor image limitations and evaluate the influence of different encoders when integrated with the U-Net, aiming to identify which encoder describes features of the sky accurately. The proposed approach shows encouraging results; as it presents improved performance over the adjusted U-Net architecture with inceptionv3 on the proposed dataset, achieving mean Intersection over union, dice similarity coefficient, recall, precision, and accuracy of 98.57 %, 99.57 %, 99.41 %, 99.73%, and 99.40 %, respectively. At the same time, the best loss was achieved in U-Net with VGG19 equivalent of 0.09.**

Keywords*—*Computer vision; transfer learning; semantic segmentation; sky detection; U-Net; machine learning

I. Introduction

Sky has received remarkable interest over the past few years as a robust indicator of outdoor scenes. The scene’s environmental information the sky provides is more significant than other scenes’ components. Therefore, sky detection is considered a crucial preprocessing step in various vision applications, such as weather classification [1], image or video editing [2], and navigation [3]. Moreover, the sky mask can be used to evolve the accuracy of object detection and tracking algorithms. Given its significance, sky detection research became one of the active topics in the computer vision field. This segmentation task is dedicated to identifying and isolating the sky region within a scene from other objects. However, the complexity of sky regions poses a significant challenge, owing to the vast range of pixel intensities and the notable variations in sky tone across different weather conditions and times of day. Semantic segmentation techniques represent the ideal solution for this task.

Semantic segmentation is one of the leading computer vision tasks where the object boundaries are delineated precisely. Segmentation tasks usually need complex, advanced techniques and high-quality data.

In addressing these challenges, semantic segmentation techniques have emerged as the preferred solution for accurate sky detection. By employing advanced algorithms capable of understanding the semantic meaning of image pixels.

The research community proposed two different approaches to solve the problem of sky segmentation. The first approach was the traditional approach where researchers tend to use certain methods like color-based, edge-based and region-growing.

Another approach is the usage of Machine learning. In this approach, some researchers tended to use traditional machine learning models e.g., Support vector Machine (SVM), K-means, and Logistic regression (LR). Others used more advanced techniques such as Deep learning (DL), e.g., CNN. More details about these methods will be discussed in the literature review section.

The article is arranged as follows: Section II is literature review Section III details the proposed method and dataset followed by preprocessing; Section IV explain network architecture. Section V discusses the experimental results, Section VI is discussion and finally, the paper concludes in Section VII.

II. Literature Review

Two main approaches for semantic segmentation techniques are used in sky detection tasks: the traditional-based approach and the deep learning-based approach. Firstly, traditional methods, such as edge, colour, and region-based techniques, have been introduced [4]. These traditional-based methods mainly rely on manually engineered features, such as color, texture, edges, or shape information, to identify the objects in images. The traditional methods are simple, fast, and computationally effective; however, their dependency on low-level hand-crafted features leads to low segmentation performance. On the other hand, deep learning-based methods such as U-Net [5], FCN[6], or Mask R-CNN [7] are considered end-to-end techniques [8]. These methods utilize the convolutional neural network (CNN) to extract features automatically. Although deep learning techniques need powerful hardware and extensive data, they are more robust to noise originating in sky regions from weather variations.

In the past few years, extensive research has been focused on sky and ground segmentation. Yehu Shen and Qicong Wang [9] proposed a technique based on gradient information to detect the horizon line. This method defined the border point in each column all over the image and then defined the region above these border points as the sky region. The previous method didn't detect the sky regions occluded by foreground objects. Zhao Zhijie et al. handled this challenge [10] by using color and gradient features to detect multiple border points in each column. The horizon-based approaches lost their detection efficacy as the complexity of scenes increased. Subsequently, classification-based approaches were introduced where the classifiers depend on the handcrafted features to detect the sky. Xiuzhuang Zhou et al. [11] proposed a novel technique that combines the advantages of superpixels and context inference. This method used features like lines, texture, color, position, and shape to train a Support Vector Machine (SVM) as a local superpixel classifier. Then, the conditional random field (CRF) was implemented as a contextual inference model to refine the segmentation. Additionally, Fl´avia de Mattos et al. [12] utilized eleven whiteness indexes as extracted features to feed (SVM) classifier. Yingchao Song et al. [13] proposed a novel model with two imbalanced SVM classifiers trained on several haze-relevant features. This model was trained on a hazy sky dataset with 500 annotated hazy images and divided the image into three areas: high confidence of being the sky regions with high confidence of not being the sky, and uncertain regions. In addition to the supervised traditional approach, cluster-based methods can be used in sky segmentation. Chao Fang et al. [14] deploy the K-mean clustering method to segment the sky regions based on pixels' brightness. Additionally, Yin et al. presented an innovative method called Sky-GVINS for achieving precise positioning in densely built environments and open sky areas with GNSS measurements [15]. This method relied on a lightweight sky segmentation, utilizing a global threshold technique to distinguish sky and non-sky regions in fish-eye sky-pointing imagery. The experimental dataset comprised 500 images representing diverse conditions, such as occlusions in the sky presented by buildings and trees.

Traditional machine learning techniques based on hand-crafted features adapted poorly to the variational complex sky appearance. Therefore, computer vision scientists have directed their attention to end-to-end deep learning techniques that extract features automatically using CNN to handle sky segmentation tasks. Yi-Hsuan Tsa [16] proposed a sky segmentation model based on FCN. This model was trained on 15,000 images from the LMSun dataset and achieved 94 %-pixel accuracy. Radu P. Mihail et al. [17] created a new dataset called Sky Finder and evaluated three approaches for sky segmentation in natural outdoor scenes. The results argued poor performance due to local lighting and weather conditions. Then, a new deep ensemble method that combined the output of existing methods with raw image data using rCNN was proposed and shown to improve performance with an MCR of 12.96%. Zou et al.'s study presented a novel approach to sky segmentation, combining computer vision and deep learning [18]. They proposed a new computer vision-based "flow propagation" method for robust background motion and feature estimation. These features were fed into a customized deep CNN model ResNet-50 based for training. The networks can be effectively trained on videos without using external data annotations. The proposed method was tested on BDD100k datasets. This innovative blend of handcrafted and CNN features demonstrates a unique strategy in sky segmentation research. The method is designed to operate on trained data; therefore, it does not work on different datasets. Wang et al. introduced a real-time sky segmentation method formulated for mobile augmented reality based on a deep semantic network called FSNet [19]. The authors designed the method for efficient segmentation under varied weather conditions, validated through extensive testing on a substantially large dataset. For refining the segmented regions, sky-aware constraints were included, which considered factors such as color, the sky's position, and temporal coherence across neighbouring frames. Extensive qualitative and quantitative analysis testing demonstrated that the proposed method surpasses other leading methods in real-time performance. The result's accuracy was gauged using the mean intersection over union (mIOU) metric, achieving 90.17%. However, the method showed limitations and did not perform efficiently for heterogeneous skies, such as during sunsets. Recently, U-Net has been one of the most commonly developed deep learning algorithms, especially for biomedical segmentation tasks. Due to its efficiency, U-Net architecture was widely implemented in all segmentation applications, including sky segmentation. Liba and colleagues introduced a precise method for sky optimization aimed at enhancing the sky's appearance in images, including sky segmentation [20]. They constructed a dataset of sky masks utilizing partially annotated images that were painted and refined using a modified weighted guided filter. Moreover, they trained a U-net neural network to conduct sky segmentation on RGB images by predicting the sky probability for each pixel. The Morph-Net method was employed to optimize performance and minimize network size. In their work, Kuang et al. proposed an innovative framework for segmenting sky and ground in the visual navigation of planetary rovers [21]. The study introduced a U-shaped neural network entitled NI-U-Net and incorporated a conservative annotation method to minimize human interference. Augmented results were exhibited through a pre-training process across complex scenarios using the Skyfinder dataset, a well-acknowledged benchmark. The framework was evaluated based on seven metrics, achieving high results.

Although deep learning-based segmentation models such as U-Net have achieved high performance, the requirement of huge high-quality labelled data and large costly computation power for model training limit their implementation in practical systems. Training CNN-based models from scratch is an impractical time-consuming technique as it takes a long time for the model to converge. The transfer learning approach was introduced as an ideal solution to overcome these challenges where the model uses prior information in a new task. The pre-trained weights learned from tasks that are not completely relevant to new tasks are more useful than randomly initialized weights.

In this work, the main objective is to remarkably enhance the sky segmentation task in adverse weather and lighting conditions by a modified U-Net architecture with pre-trained models as encoder VGG19, EfficientNetB4, InceptionV3, and DenseNet121 for sky detection to solve outdoor image limitations and evaluate the influence of different encoders when integrated with the U-Net, aiming to identify which encoder describes features of the sky accurately. The reason behind choosing the U-Net architecture is that it outperformed other architectures used in most of the research works. The integration between UNet architecture and transfer learning allows us to handle sky segmentation tasks effectively with high segmenting performance while saving computation power.

III. Proposed Methodology

The goal in this proposed approach is to simplify image segmentation and develop efficient, robust algorithms for sky segmentation. The methodology showed in Fig. 1. forms the basis of our approach, ensuring that the outcomes are trustworthy and valid. The widely used U-Net architecture was modified by adapting different backbones as an encoder path, which improved the depth of the network and produced better results. The model was tested using collected dataset and found that our approach outperformed existing methods in terms of capabilities. The overall approach is given in Fig. 1.

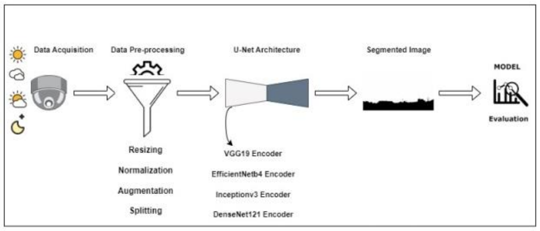

Fig. 1. Proposed methodology.

A. DataSet Acquisition

Data was systematically collected to capture different aspects of the sky. This data was collected at various times and in diverse weather conditions. To ensure comprehensive collection, stationary outdoor cameras were strategically placed in 11 specific urban locations in the Kingdom of Saudi Arabia. These regions were chosen based on their varied urban landscapes, allowing for expansive sky views to be captured.

The dataset incorporates different periods of the day (morning, midday, and evening) as well as various weather conditions (sunny, cloudy, partly cloudy). This comprehensive dataset allows for a wider range of image variations. In this research work, special care was taken to ensure that the photos collected were high quality and free from any unwanted elements or issues such as artifacts, noise, repeated images, or spots on the lens. The resulting dataset consists of RGB images that brightly represent the dynamic nature of the sky in these areas. In total, the dataset consists of 1691 diverse images captured. It's important to note that all images in the dataset contain both sky and non-sky areas. Sample images from each location are presented in Fig. 2.

B. Ground Truth

To enhance the accuracy of the dataset even further, a specialized computer vision annotation tool called CVAT was utilized. Manual annotations were made for each image through this tool by creating binary mask segmentations. These masks specifically separate regions into two categories: sky and non-sky. The definition of "sky" includes sky and other elements commonly found in skies, like clouds, sun, or moon. Conversely, "non-sky" consists of all other areas that do not fall under this sky category. These masks are ground truth.

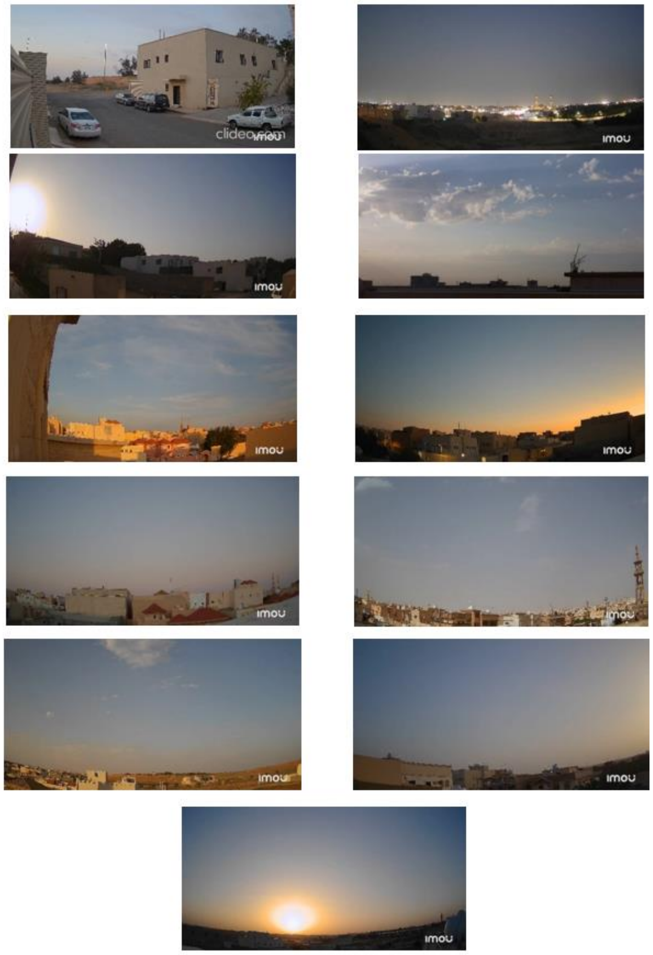

Fig. 2. Sample images from different locations.

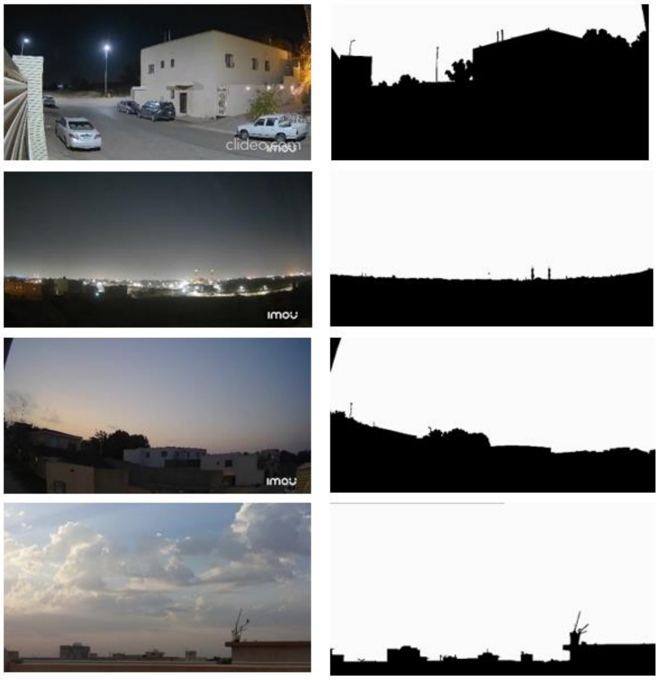

Fig. 3. Some of the data samples with ground truth.

Ground truth masks are an essential element for any machine learning application. They provide an essential reference or benchmark for algorithm training in image processing tasks, hence the term 'ground truth' [22], as they provide a standard against which the outcomes of the algorithms can be measured. Ground truth masks were generated for each image. These are binary masks, where 0 represents the sky region, and 1 represents the non-sky regions. Fig. 3 provides samples from dataset and their corresponding ground truth masks.

C. Data Preprocessing

Data pre-processing was carried out to increase computational performance and have efficient processing. First, the images were resized to 256×256 pixels. Additionally, the data normalization was also carried out by normalizing each pixel value of the data. By dividing each pixel value by 255, all data values fall within a range from 0 to 1. This normalization process is beneficial as it improves both the speed and accuracy of convergence during further calculations. Furthermore, masks (which indicate specific areas) were converted into binary format for more accessible analysis and understanding. To ensure accurate and reliable results, the images in the dataset were carefully divided into two separate datasets: the training dataset and the validation dataset. The training dataset accounts for 80% of collected data, while the remaining 20% is allocated to the validation dataset, allowing the algorithm to familiarize itself with various patterns and features within the images.

To address the issue of insufficient data and overcome hardware constraints, a solution was implemented using the ‘ImageDataGenerator’ class from the Keras framework, augmented images were generated on the fly during each epoch of training. This ensured that the model received diverse new variations in each iteration, effectively enhancing its ability to learn and generalize patterns. This strategy helps mitigate overfitting issues that often arise when working with small datasets. The augmentation techniques for this research include random rotation, horizontal and vertical shifts, shear transformation, and zoom. Fig. 4 presents a selection of samples that demonstrate the effects of these augmentation techniques on images in dataset.

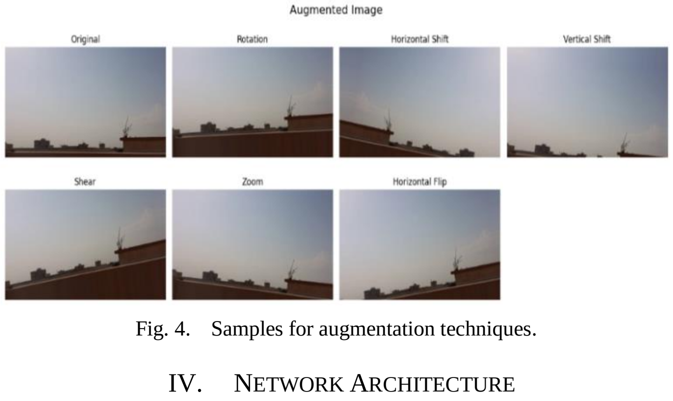

Fig. 4. Samples for augmentation techniques.

IV. Network Architecture

The illustration in Fig. 5 demonstrates the working of the proposed architecture for an RGB input image with dimensions 256×256×3. The segmented output map with dimensions 256×256×1 using the U-Net [5] network is received at the output. It is observed that there is no reduction in size between the input and output.

Four different deep learning-based networks are proposed as alternatives to the contracting path for the U-Net. These encoders are VGG19 [23], EfficientNetb4 [24], InceptionV3 [25], and DenseNet121 [26] to extract deep features, both height and width progressively decreasing while channel numbers increase. This channel augmentation enables capturing higher-level features as information flows through this pathway. The model undergoes a final convolution operation at the bottleneck, resulting in a feature map of size 16×16×1024. The expansive path then reconstructs an image of the exact dimensions as the original input from this feature map. Up-sampling layers are employed to increase spatial resolution while reducing channel count. The decoder layers utilize skip connections from the contracting path to locate and enhance features in the image. Ultimately, each pixel in the output image represents a label corresponding to the class in the input image. In this case, the output is a segmentation map, distinguishing between foreground and background regions for each pixel. The foreground represents the sky region, and the background represents the non-sky regions.

The crucial hyperparameters necessary for the convergence of the proposed models were identified. This includes batch size was set to 32 for all models, 100 epochs, AdamW optimizer selection, and learning rates set to 0.00001. The loss function applies the binary cross-entropy.

The framework for statistically evaluating the efficacy of the models for sky segmentation is one of the key points of emphasis in the research. A suite of metrics is selected to quantify the performance of the models. The work leverages mean Intersection over Union (mIoU), Dice Similarity Coefficient (DSC), precision, recall, and accuracy, as critical metrics for this study.

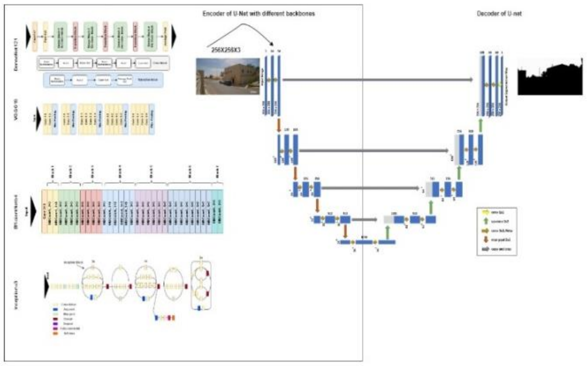

Fig. 5. Demonstratration of the working of the proposed architecture.

V. Results

The operating system of this work is Windows 11, the deep learning environment is Keras and TensorFlow, and the programming language is Python. The hardware configuration is an Intel Core i7-2.80 GHz CPU and 16.0 GB RAM.

In this research study, the proposed novel deep learning algorithm for sky segmentation was evaluated by utilizing various encoders within the U-Net architecture and subjecting it to critical analysis.

After several experiments, models that consist of the encoder employing VGG19, EfficientNetB4, InceptionV3, and DenseNet121 were compared, InceptionV3 U-Net showed the best performence, obtaining remarkable mIOU and DSC scores as high as 98.57% and 99.57% respectively. mIOU stands for mean Intersection over Union while DSC stands for Dice Similarity Coefficient which tells us how great the proposed model can perfectly draw the Sky region in the images. Such high scores are indicative of the model's robust performance in capturing the intricate details of the sky, laying the foundation for applications such as obstacle detection and path planning for autonomous vehicles.

Table I depicts the model’s performance concisely, measuring the Recall, precision, accuracy, and F1 score. Embodied in the table is not only the performance of the Inceptionv3 U-Net but also its other architectures, the VGG19 U-Net, the DenseNet121 U-Net, and the Efficientnetb4 U-Net. Though the VGG19 U-Net, the DenseNet121 U-Net, and the Efficientnetb4 U-Net all offer comparable results, their scores are slightly less in comparison to the Inceptionv3 U-Net. The high performance that is demonstrated by all models serves as a testament to the ability of different encoders to amplify the U-Net architecture where sky segmentation is concerned.

TABLE I. PERFORMANCE EVALUATION FOR SKY SEGMENTATION MODELS

Evaluation	**Models**			
	VGG19 U-Net	***Densenet121 U-Net***	***Efficientnetb4 U-Net***	***Inceptionv3 U-Net***
mIoU	98.46 %	98.48 %	98.45 %	98.57 %
DSC	99.53 %	99.54 %	99.53 %	99.57 %
Recall	99.36 %	99.73 %	99.33 %	99.41 %
Precision	99.71 %	99.35 %	99.72 %	99.73 %
Accuracy	99.35 %	99.36 %	99.34 %	99.40 %
Loss	0.09	0.11	0.14	0.11

A further illustration of training and testing curves is shown in Fig. 6 and Fig. 7. In Fig. 6, the upper row corresponds to the InceptionV3 U-Net model, revealing its superior performance compared to the lower row representing the DenseNet121 U-Net model. Similarly, Fig. 7 presents the learning trajectories of the VGG19 U-Net and EfficientNetB4 U-Net models, offering nuanced perspectives on their adaptability and convergence. The models have performed consistently well over both the training and validation sets, hence no signs of overfitting. In addition to the numerical metrics, it can be seen that the loss value during training is consistently low, again reaffirming the robustness of training procedures. Moreover, it can be concluded the models with high accuracy scores can do pixel classification in the sky region very well, which indicates the models are good enough even in discerning subtle details.

The attainment of high learning due to the decrease in loss curves indicates the learning models’ saturation. Conversely, the rise in accuracy and IOU curves shows that the model is still learning, which means that the learning phase is not over. Both curves are proposed to be well-balanced so as to enable the learning process to be terminated.

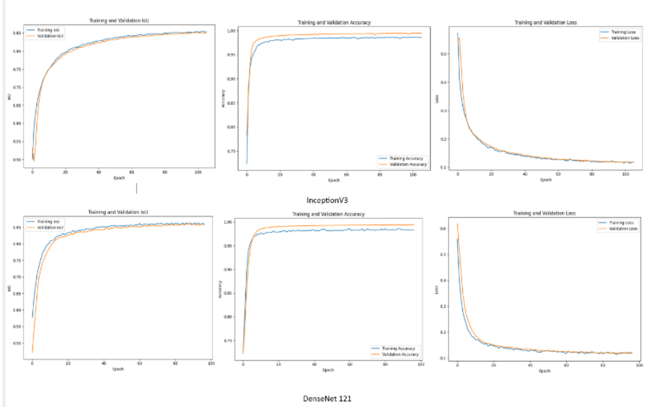

Fig. 6. The performance curves of the inceptionv3 U-Net and Densenet121 U-Net.

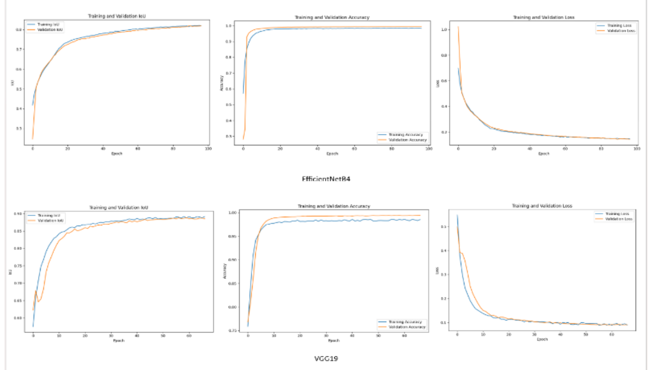

Fig. 7. The performance curves of the Efficientnetb4 UNet and VGG19 Unet.

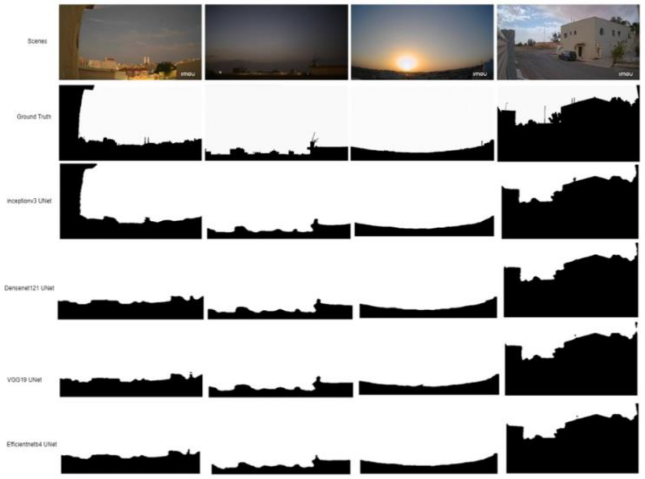

Fig. 8. Samples of prediction of the models.

The qualitative assessment of model predictions is presented next in Fig. 8. This includes visual samples of the models’ predictions on various scenes in different weather conditions and times of the day. The examples show that the models perform well in challenging setups such as back illumination or low light. This preliminary qualification holds true across the U-Net architecture and for the different backbone encoders, where it is evident that all models very accurately detect sky and ground pixels in various scenes.

VI. Discussion

The proposed models are able to perform with a relatively high degree of accuracy. In particularly hard scenarios, such as night scenes, the results are outstanding. They have done quite well in the task of distinguishing sky- and non-sky regions. And have done much better than other systems to avoid misclassifications such as white buildings as clouds, with a significantly greater precision.

However, the models' limitations become apparent in more complex scenarios, such as scenes with intricate structures like trees or poles on buildings. In these instances, the models struggle to accurately detect sky areas, revealing areas that might benefit from further refinement. This acknowledgement of limitations is crucial for guiding future iterations of the models.

This project opens avenues for future research, outlining potential directions to enhance the model's capabilities and address identified limitations. As a future work, various complex sites will be incorporated to train models robustly in the future by increasing dataset used in this project. Additionally, assessing how the model performs on different datasets to assess its adaptability to different scenarios and datasets. Moreover, this study will be expanded by focusing on a specific challenge, e.g., in weather phenomena, such as dust or rain and how to detect the sky.

VII. Conclusion

The finalization of this work throws light on the significant achievements that have been made in the field of Semantic Sky Segmentation. Initially, the main aim was to search for the most suitable encoder that could capture all the details of the sky, ideally during the segmentation process, to get very accurate results. The whole project was carried out in a series of different stages where alterations were made to the U-Net Architectures that employed several other encoders such as VGG19, EfficientNetB4, InceptionV3, and DenseNet121. The end-to-end binary segmentation model was a key stage in the proposed approach. The project's foundation rested on various steps, from comprehensive data preparation to the advanced image processing steps. The choice of the Keras framework facilitated a simplified model construction process, allowing for essential data augmentation to increase the dataset and enhance the model's overall performance.

Model evaluation was accomplished with the help of metrics like mIOU, Accuracy, Precision, Recall, DSC, Loss, etc. The results were as follows: the mean Intersection over Union, Dice similarity coefficient, recall, precision, and accuracy scores of 98.57%, 99.57%, 99.41%, 99.73%, and 99.40%, respectively. Additionally, it's noteworthy that the U-Net with VGG19 equivalent achieved the best loss of 0.09, underscoring its effectiveness in minimizing error.

This comprehensive approach of the evaluation process helps to understand the various aspects of the models. The InceptionV3 UNet model was identified as the most robust performer among the models tested over this dataset. Thus, the extended view of performance metrics for the different models validated the precision of the model's segmentation.

The success of this project lies not only in the numbers but the proof lies in models' improved perception of complex scenes and their ability to work more effectively with applications. These have done well with an ability to tell sky pixels away from the ground.

In conclusion, the outcomes of these experiments not only contribute to the growing body of knowledge in computer vision but also pave the way for practical applications where precise sky segmentation holds significant importance.

Abstract—**Plant diseases are a persistent threat to the global agricultural economy, compromising food supply and security. Accurate and early diagnosis is vital for effective agricultural management. This study addresses this gap by introducing a better approach for identifying plant diseases in leaves: the Integrated Hybrid Attention-Based One-Class Neural Network (ABOCNN) System. The system uses deep learning and domain-specific information, as well as powerful neural networks and attention processes, to extract features unique to a certain ailment while excluding irrelevant data. By dynamically focusing on prominent areas in leaf images, the proposed methodology obtains an impressive 99.6% accuracy, beating both traditional approaches and cutting-edge deep-learning approaches by an average of 12.7%. The practical use of this strategy has a significant influence on crop yield and agricultural sustainability. Attention maps increase interpretability and help individuals comprehend more fully how decisions are made. The system, written in Python, is precise, scalable, and adaptable, making it a helpful tool for a wide range of agricultural applications combining multiple plant species and disease classifications. With an incredible 99.6% accuracy rate, the Integrated Hybrid ABOCNN Technology provides an innovative method for diagnosing plant diseases, outperforming conventional approaches by 12.7%. Attention maps increase interpretability and give important information about the model's decision-making processes.**

***Keywords*—Convolutional Neural Network (CNN); attention model; leaf disease detection; attention-based one-class neural network; crop production**

I. Introduction

Plant leaf detection refers to the process of identifying and analyzing the characteristics of leaves in plants. Leaves are vital components of plants, playing a crucial role in photosynthesis, respiration, and transpiration. By detecting and understanding various leaf attributes, such as shape, size, color, and texture, researchers, botanists, and agriculturalists can gain valuable insights into plant species identification, health assessment, disease detection, and growth monitoring. Leaf detection has traditionally been a manual and time-consuming task, requiring experts to visually inspect and classify leaves based on their features [1]. However, automatic leaf recognition is now more practical and precise because to developments in neural networks, algorithmic learning, and computational imaging methods. By utilizing sophisticated algorithms and neural networks, leaf detection systems can analyze digital images or live video feeds to identify and segment leaf regions from complex backgrounds. These systems can also extract relevant features from the detected leaves, enabling further analysis and classification [2]. The applications of plant leaf detection are diverse and impactful. In agriculture, leaf detection can aid in crop management, enabling early detection of diseases, nutrient deficiencies, or pest attacks. It can assist in optimizing irrigation, fertilization, and overall plant health monitoring. Additionally, leaf detection has significant implications in environmental conservation, as it can aid in species identification, biodiversity assessment, and ecosystem monitoring [3]. Overall, plant leaf detection offers an efficient means to study and understand the characteristics of leaves, providing valuable insights into plant health, growth, and species identification. With continued advancements in technology, this field holds great potential for revolutionizing plant science, agriculture, and ecological research [4].

A cutting-edge method for automatically identifying and detecting leaves from plants is foliage identification using deep learning, which makes use of the capabilities of networks. Deep learning models, especially CNN, have demonstrated outstanding ability in image analysis and identification, which makes them suitable for jobs requiring the detection of leaves. In order to distinguish leaf in the foreground and correctly identify their existence in an image, the subject learns to identify patterns, characteristics, and architectures that are exclusive to leaves. Intricate nuances and changes in leaf attributes, like as form, texture, venation patterns, and color, may be captured by deep learning models since they are excellent at autonomously generating hierarchical representations of data. They can handle complicated leaf shapes and identify between many plant species quite effectively [5]. The key benefit of leaf identification using deep learning is its ability to generalize well to unseen data. Once trained, the model can efficiently process new leaf images and accurately identify leaves even in diverse environments and under varying lighting conditions. The applications of deep learning-based leaf detection are vast. It can assist botanists and researchers in plant species identification, enabling quick and reliable classification of leaves. It also plays a crucial role in plant disease diagnosis and monitoring, as the detection of abnormal leaf patterns or discoloration can indicate potential health issues [6]. Additionally, deep learning-based leaf detection contributes to precision agriculture by enabling automated crop monitoring, yield estimation, and targeted interventions for optimizing plant health and growth. However, it's important to note that deep learning-based leaf detection requires a large and diverse dataset for training the model effectively. The initial training dataset's reliability and accurate representation have an important effect on the model's accuracy and generalizability. Plant leaf diseases represent a severe threat to crop production, efficiency in agriculture, and the availability of food [7]. These illnesses need to be correctly recognized and categorized early on in order to receive quick therapies and effective management techniques. Due to their shown high effectiveness in image recognition tasks, algorithms that utilize deep learning are especially well-suited for the diagnosis and classification of diseases of plant leaves. A sophisticated hybrid approach called ABOCNN has been created in this situation, fusing the benefits of several deep learning architectures [8].

The ABOCNN framework integrates the power of CNN and attention-based mechanisms to enhance disease detection and classification accuracy. CNNs are recognized for their capacity to autonomously acquire and extract significant characteristics from images. Attention mechanisms concentrate on critical regions, allowing the network to give better consideration to disease-specific patterns in leaf images [9]. The key advantage of the ABOCNN framework lies in its ability to handle complex and diverse disease patterns, including subtle variations in leaf textures, discoloration, lesions, and other disease-related characteristics. By integrating CNNs' feature extraction capacities with attention processes, the framework may efficiently collect both global and local disease-related information, permitting precise and accurate plant leaf disease diagnosis [10]. The suggested paradigm has important effects on crop management, farming, and the pathology of plants. It provides a quick and automated method for identifying and categorizing plant leaf diseases, enabling early intervention with targeted therapies. In turn, this aids agronomists and farmers in making educated choices, allocating resources efficiently, and reducing crop losses. In conclusion, the ABOCNN framework provides a cutting-edge method for the identification and categorization of plant leaves using deep learning. It improves the dependability and precision of disease identification by merging CNNs and attention processes, which helps to create more efficient and environmentally friendly agricultural practices [11].

The key contributions of this paper are as follows:

- With a sophisticated hybrid ABOCNN architecture as the foundation, the study introduces a revolutionary deep learning technique that results in a significant increase in accuracy.
- The Attention Mechanism enhances the capacity of the model to identify disease-specific characteristics in leaf images. The method enhances accuracy and making decisions by constantly attributing significance to geographical elements.
- Attention maps enhance the comprehensibility of the suggested method. These maps provide users with useful knowledge into the procedure and enable them to better understand the procedure for making decisions.
- The hybrid ABOCNN model is adaptable and scalable, making it suitable for usage with a wide range of plant species and diseases. Because of its adaptability, it may be employed in a variety of agricultural applications.
- The finding signifies a substantial advancement in the treatment of agricultural conditions using deep learning. The hybrid ABOCNN approach has the capability to significantly enhance agricultural results by transforming plant disease detection and intervention techniques.

The approached paper's manuscript is structured as follows: Several similar works are reviewed in Section II. Information on the problem statement is given in Section III. The planned ABO-CNN is detailed in depth in Section IV. In Section V, research findings are shown, reviewed, and a thorough assessment of the suggested strategy in comparison to current standards is presented. The paper's conclusion is presented in Section VI.

II. Related Works

Lu et al. [12] proposed utilizing a CNN to classify disease of plant leaf. They examined the most recent CNN networks that were relevant to classifying plant leaf diseases in their article. Additionally, they outlined the DL concepts involved in classifying plant diseases and provided the CNN methodologies used in the process. Additionally, it summarized various issues with the DL utilized for classifying plant diseases based on extrinsic and intrinsic characteristics, as well as the accompanying remedies. Inadequate datasets in terms of number and variety are the main issue with CNN-based DL's application to the categorization of plant diseases. This condition contributes to some extent to all the other issues that have been raised. The practical application is significantly influenced by adequate datasets. However, external factors like seasonality and climate may readily alter data collection, and image labelling is often a time-consuming and hard operation. These elements make it very challenging to create an effective dataset.

Sen et al. [13] proposed classifying leaf disease using the EfficientNet network. Considering the reality that the raw image size had to be restricted due to hardware constraints, the EfficientNet architecture provided superior outcomes than previous CNN algorithms that had been fed images as inputs with higher dimensions. When the initialization times of each model per session were looked at, AlexNet showed less overall accuracy and precision than the other models. It took 310 and 352 s in both the initial and augmented datasets, respectively. The dataset on plant leaf disease can be expanded, though. This will aid in the creation of models that can anticipate outcomes more accurately under challenging circumstances. Pathologists for plants and producers are going to be able to promptly identify diseases of plants and implement necessary precautions by utilizing these enhanced techniques in mobile situations.

Hassan et al. [14] suggested the use of transfer-learning and neural algorithms, researchers improved the identification of plant-leaf illnesses. They switched from standard suppression to depth-separable inversion in this study, which minimizes the amount of work of the computations. The models were trained on a dataset comprising 14 distinct species of plants, 38 different types of diseases, and healthy foliage from plants. Other parameters, such as the overall amount of sections, being abandoned, and the quantity of epochs, were used to evaluate the models' effectiveness. The created models fared better in terms of overall accuracy rates for sickness categorization than traditional handmade based on features methods. In comparison to earlier deep learning techniques models, the newly constructed model behaved more effectively while requiring less training time. The CNN-based deep learning techniques architecture has certain limitations even though it has excellent detection rates for identifying plant diseases. The disadvantages of them are that whenever there doesn't seem sufficient noise in the collection of photographs, the deep-learning model may be misclassified.

Zhou et al. [15] KNN Classifier is proposed for the proposed Color and Material Based Methodology for the Identification and Diagnosing the Leaf Disease. In the current study, the K-nearest neighbor classifier was recommended as a method for classifying and identifying leaf diseases. For categorization, the leaf disease images textural characteristics are retrieved. In this study, a KNN classifier will be used to categorize numerous plant species' illnesses. The suggested method has a 96.76% accuracy rate for correctly identifying and diagnosing the chosen illnesses. However, there are disadvantages and difficulties, including high computing costs, sluggish performance, memory and storage problems for huge datasets, sensitivity to metric selection and distance, and vulnerability to the plague of dimensionality.

Sibiya et al. [16] advocated the use of CNN in order to distinguish healthy leaves from leaves with illnesses on maize. To create a collection of networks for illness image recognition and classification, this study uses CNN aided principles. The CNN network was trained using Neuroph to identify and categorize images of the wheat diseases of the leaves that were gathered using a mobile device's camera and exercise. Three different forms of wheat leaf diseases could be distinguished by the created model from healthy leaves. This study focused on the ailments that cause the most harm to Southern Africa's maize crops, widespread rust and grey leaf spot. The calculation length and sensitivity to outliers of the procedure are both rather high.

Lv et al. [17] recommended using Feature Enrichment Based Maize Leaf Disease Detection and DMS-Robust Alexnet. They initially developed an architecture for leaf maize characteristic augmentation in order to improve the qualities of wheat in a complicated environment. Then, a special neural network called DMS-Robust Alexnet is developed. It is based on the core Alexnet architecture. The DMS-Robust Alexnet uses dilatation of conjunction and multiple scales conjunction to boost the effectiveness of feature extraction. proposed using DMS-Robust Alexnet and Feature Enhancement Based Wheat Leaf Disease Diagnosis. They initially built an infrastructure for leafy wheat characteristic augmentation to increase the attributes of wheat in a complicated environment. This DMS-Robust Alexnet, a one-of-a-kind neural network, is then developed. It is based on Alexnet's core framework. The DMS-Robust Alexnet improves feature extraction efficiency by utilizing multi-scale merging and synthesis dilation.

The literature review points out several shortcomings in the current methods of plant leaf disease classification, including the inability and difficulty of gathering sufficient data, hardware limitations, high computing costs, sensitivity of metric selection, and vulnerability to dimensionality constraints. These limitations make it more difficult to identify plant diseases accurately and effectively. The proposed solution uses an advanced hybrid ABOCNN deep learning strategy to tackle these problems. This method enables accurate disease diagnosis by dynamically focusing on relevant portions of leaf pictures using one-class neural networks and attention techniques. This strategy not only outperforms CNN-based and conventional methods in terms of operation, but it also enhances interpretability through attention maps, making it a viable substitute for improved agricultural outcomes. Feature Enrichment Based Maize Leaf Disease Identification with DMS-Robust Alexnet, CNN-based models, KNN Classifier, transfer learning, and Efficient Net are some of the approaches that have been assessed.

III. Problem Statement

The literature review, which emphasizes the major impact of diseases of plant leaves on agriculture and food security, serves as the foundation for the current study [18]. It is obvious that existing plant disease detection methodologies may not be able to deliver the level of accuracy and repeatability required for effective preventive and remedial interventions. This conclusion underscores the critical requirement for advances in plant disease detection systems, stimulating the development and research of a more precise and reliable techniques for dealing with the challenges these agricultural threats provide. The work intends to solve the identified challenges in plant disease diagnosis by developing a more complicated hybrid deep learning architecture and using a dependable strategy. The research aims to improve the capacity and understanding of the disease detection process while acknowledging the limitations of traditional approaches and CNN-based techniques in terms of consistency and accuracy. The goal is to increase disease detection efficacy by deleting unnecessary information and dynamically concentrating on disease-specific regions in plant leaf images utilizing one-class neural networks as well as attention procedures. This method attempts to advance disease detection approaches, resulting in more accurate and reliable outcomes in the natural setting of plant pathology [19].

IV. Proposed Advanced Hybrid ABOCNN Framework

The proposed methodology for revolutionizing plant disease detection in leaves, named the Hybrid ABOCNN Framework, comprises multiple stages and processes designed to enhance the accuracy and efficiency of identifying diseases in rice leaves. The dataset used consists of 5932 images of rice leaves with diseases like brown spot, bacterial blight, blast, and tungro, which were obtained from fields in western Odisha. These images underwent augmentation, increasing the number of images by six times. The pre-processing stage involves applying a Gaussian filter to remove noise and blur, followed by feature extraction using the CNN approach. The CNN is a complex network consisting of inversion, pooling, and fully connected layers, which are trained using the VGG-16 structure. The incorporation of the Attention Mechanism enhances the CNN's performance by assigning weights to important spatial features, thereby improving disease detection and classification accuracy. The proposed Attention-CNN model combines the benefits of both CNN and the Attention Mechanism. Training is performed using the Adam optimization method with cross-entropy as the loss function. The overall methodology, from data collection and pre-processing to feature extraction and classification, aims to create a robust and accurate framework for identifying plant diseases in rice leaves, ultimately contributing to more efficient agricultural practices. Fig. 1 shows the proposed ABOCNN framework.

Pre-processing using Gaussian Filter
Feature Extraction using CNN
Classification of Plant Disease using ABOCNN Method
Performance Evaluation

Fig. 1. Proposed hybrid ABOCNN framework.

A. Dataset

The collection comprises 5932 images of leaves of rice with diseases such as brown spot, bacterial blight blast, and tungro. The original images were taken using an exceptional grade of several fields of rice in western Odisha. The diseased areas in patches were obtained from the large original images. The patches were subsequently processed as samples of data after being converted to 300 300 pixels. Out of the 800 total images in the initial collection, 200 images from every group were picked for testing. The remaining 5132 images were augmented using the collection. Simple rotation and flipping operations were conducted to all photographs as part of the augmentation process, including revolve left 90 degrees, revolve right 90 degrees, flip vertically, flip horizontally and rotate 180 degrees. Consequently, including the upgraded images, the overall amount of images increased by six times. The more improved photographs there are, the more likely it will be that the camera system will pick up the proper qualities. Table I contains a list of the experiment's images by name and number. The data sample are allocated at randomly in amounts of 80:20 for both validation and training. Evaluation along with training samples are randomly selected for each execution [20].

TABLE I. TRAINING AND VALIDATION OF THE DATA SAMPLES

Leaf disease	Number of images used of augmentation	Number of original images	Number of images used for Training and validation	Number of images used for Testing
Bacterial Blight	1384	1584	8304	200
Tungro	1108	1308	6648	200
Brown Blast	1400	1600	8400	200
Blast	1240	1440	7440	200
Total	5132	5932	30,792	800

B. Pre-processing using Gaussian Filter

The process of separating features necessitates the transformation of unorganized information into quantitative qualities in order to capture and keep the specifics of the very beginning of data. Each patient processes information in a different way, and these traits are determined from the entire set of representations that were collected. To identify, the number of dimensions associated with the representation must be reduced, whereas the overall size of the representation increases throughout testing. In order to remedy this problem, features are removed. The GLCM is utilized during the feature extraction procedure. By producing several sets of images with specific values, it shows the graphical representation's structure of hierarchy. The GLCM displays the intensity of the displayed pixels by using the appropriate grayscale. The quantity of energy, comparison, connection, entropy, homogeneity, and other properties of the second-degree representation are evaluated in order to eliminate the statistically significant texturing feature. The first stage is image pre-processing. A Gaussian filter with a smoothed method is applied to the leaf during the pre-processing stage to minimize noise and eliminate blur from the image to increase the enhancement of the leaf image. The representation of this filter is defined in Eq. (1),

$$G(u,v) = \frac{1}{2\pi}(\varphi^2)\left(e^{-\left(\frac{u^2+v^2}{2e^2}\right)}\right) \tag{1}$$

Intensity gradient of the image is found out as given below in Eq. (2)

$$N(v,v) = \sqrt{g_u^2(u,v) + } g_v^2(u,v) \tag{2}$$

Edge thinning occurs when the gradient's degree is determined based on the strength of the edges. To eliminate the visible edge pixels caused by noise in the image, edge pixels with inadequate gradient values are deleted, while those with large gradient values are retained. a technique for computing texture and color information simultaneously. The texture of leaf images is often inconsistent, making it difficult to recognize textural patterns. Furthermore, typical techniques lose chromatic information, preventing them from supplying the key texture feature. In this study, we offer a novel technique in which the input image is completely enclosed by a circular window that travels over it [21].

The coordinates of the point (x, y) is home to the shade vector of characteristics (u, v). The supplied dimensions for (u, v) are (q cos t, q sin t), where u is equal to q cos θ and v is equal to q sin θ. The location of the starting point of these orientations is the circular window's centroid. The t(r) represents the color-texture translation of the provided two-dimensional images D (u, v) at r radius. This may be calculated through calculating the mean of D (q cos θ, q sin θ) within a particular region of r. It is expressing itself as Eq. (3):

$$t(r) = \frac{1}{2\pi r}\int_0^{2\pi} D(qcos\theta, qsin\theta)d\theta \tag{3}$$

C. Feature Extraction Using CNN

CNN are an appropriate strategic option for feature extraction in such circumstances because of their exceptional ability to extract discriminative and hierarchical characteristics from images. CNNs are appropriate for extracting disease-specific properties from plant leaf images because they are exceptionally effective at automatically learning and identifying complicated patterns. CNNs are advantageous because they are capable of transforming raw pixels into significant characteristics by reducing the dimensionality of images while maintaining essential information. It leads to more accurate and dependable identification of diseases by expediting the following process of categorization and improving the model's capacity to recognize small modifications and disease-related patterns. CNNs are a significant tool in the field of agricultural disease diagnostics because of their well-known versatility and scalability, which allow them to handle a wide range of plant species and diseases.

CNN are complex networks, and how effectively the network functions depend on how it is built. Its three component parts are the inversion layer, pooled layer, and the fully associated layer. While the initial two layers together constitute the extractor of features, the last layer acts as classifiers. The subsequent layer of pooling reduces the geographic extent of the properties that the previous layer of inversion recovered. The layer with all connections, followed by softmax, classifies the images using the feature that was extracted. The converging part of the method takes the raw image and extracts its properties using a set of adaptable filters. By doing a window that slides between the dot based on every filter and the original image pixel, a 2-D map of features is created. The total area of the feature map is decreased via a subsampling layer termed max pooling. The layer of data that is entirely interlinked is then used to link the developed feature map to each of it completely. Softmax constructs a multiclass problem and gives every category a decimal probability in order to categorize the images.

The VGG-16 structure is a large convolutional network with parameters that have previously been taught on the over three million clearly annotated images in the ImageNet Database. To acquire the categorizations, this data set is utilized to train and improve the earlier trained VGG-16 model [22]. After synchronizing the attributes from the source images, each image's input pixel is increased by the relevant characteristic pixels in the convolutional layer. Divide the outcome by the total amount of pixel in the characteristic after adding all the pixel values. The calculated values have been added to reflect the feature map, causing the enhancement to be utilized on the total image. Each calculated value occupies a space on the characteristic map. As a result, all of the characteristics are processed and multiple characteristic maps are created. The Eq. (4) to obtain the convolutional layer is the following,

$$v_{lmn} = \sum_{B=0}^{B-1}\sum_{C=0}^{C-1}\sum_{f=0}^{C-1} s_{l+c,m+f,K^c cfbn}^{(l-1)} + f_{imn} \tag{4}$$

where, f_{imn} is generally set to which is not contingent on the image's component position. $K^c cfbn$ as an identical value of weight. After repeatedly applying the layers of convolution to the input images, a collection of feature maps may be obtained. Let D_i represent the characteristic map of the ith layer in CNN, then the D_i can be generated as in Eq. (5)

$$D_i = \rho(D_{i-1}V_i + k_i) \tag{5}$$

where, D_i is the characteristic mappings of the presently active layer of networks and D_{i-1} is the convolution characteristic of the preceding layer. The rectification functional is represented by ρ (·), the i-th layered offsets matrix is called k_i, and the layer's weighting is called V_i. The purpose of layered pooling is to decrease the overall quantity of distance, which can lower the processing expense and consequently lower the risk of excessive fitting. During (6), at the k-th layer of pooling, a corresponding distinct on the ith isolated reactive fields is found.

$$v_i^k = down(v_i^{k-1}, r) \tag{6}$$

where, down (·) demonstrates the actions for down-sampling, v_i^{k-1} is the characteristic vectors in the preceding layer, and r is the pooling size. The Softmax function is represented in Eq. (7)

where, r is the pooled dimensions, v_i^{k-1} is the characteristic vectors from the preceding layer, and down (·) is the down-sampling value. Multiple fully connected (FC) layers can occur after a combination of pooling and convolutional layers. These layers utilize the gathered characteristics to categorize images. The Soft max operates is commonly utilized for category predictions using the features obtained from the previous layers. Eq. (7) represents the Softmax function.

$$Softmax(k) = e^{ij} \setminus \sum_{l=1}^{l} e^{il} for(j = 1, \ldots\ldots. l) \tag{7}$$

where, K represents the dimension of the z vector [23].

D. Attention Mechanism Integration

The main goal of the suggested method is to improve CNN's performance by employing the Attention Mechanism to assign importance and selectively focus on aspects in images that are important concentrate situation. The main benefit of the Attention Mechanism is that it can dynamically assign weight to different spatial properties in characteristic maps, which helps the model make better decisions. Through this technique, the Attention-CNN model develops flexibility in collecting complex information and adapting to varied datasets, which eventually leads to greater illness detection. It also improves classification accuracy. An essential part of the suggested deep learning approach for the precise recognition and identification of plant leaf diseases is the Attention Mechanism, which is crucial in improving the model's accuracy and interpretability.

By keeping the context-relevant properties, the CNN is enhanced by the attention model. Each block's characteristics are combined with those from the layer above it in the prior based model. In this manner, all characteristics gathered from the prior CNN blocks are given equal weight. Important features from the preceding blocks must be weighted highly in relation to other features in order to learn accurate feature values. As a result, a mechanism for attention was added to the CNN architecture to enable learning and selection of standout characteristics from earlier blocks. This model generates an attention mask that equalizes the relative importance of spatial characteristics at that feature map. Using a method for paying attention between blocks, the CNN framework learns the weighted utility for simulating the responses from the prior blocks. The relationships from the previous blocks which were skipped had been graded across the dimension axis for all pixels in that layer's spatial range [24].

The outcome of the convolutional layers 'x' in both the initial and subsequent blocks is directed through two functional channels, H(x) and I'(x). H(x) represents the set information procedures that were used to take 'x' and feed it forward in a straightforward feed-forward fashion to the following block. I'(x) denotes the collection of procedures that skip 'x' across convolutional and maximum-pooling layers and are weighted with attention. The output U(x) from a CNN block is produced using the weighted summation is represented in Eq. (8)

$$U(X) = H(X) + I'(X) \tag{8}$$

The functional path I'(x) is computed as in Eq. (9)

$$I'(X) = I'(X) * \varphi \tag{9}$$

where, 'φ' is a matrix containing attention weights with dimensions that match those of I(x)'s dimension in space. The attention weight matrix 'φ' ' is point-wise amplified over the relevant cross-section of I(x) and disseminated along the entire depth. By incorporating a mechanism for attention into CNN, the network may use the input from the present instant and the output from the previous moment to adaptively distribute the weighting for the data of the whole network. To increase the classification's accuracy and flexibility, significant details of the image might be concentrated on. Based on this, the CNN's attention concept is added to form the Attention-CNN model. Every inversion layer of the four stages that make up a single layer of convolution is followed by a layer of attention in order to successfully accomplish the weight transportation. The convolution kernels for each layer are 8x3x3, 16x 5, 32x 3, and 32x 3, respectively. The initial and final convolution layers are joined by a pooling layer. The maximum amount of nodes in the full interconnections layer is set to 64, and the output of the layer that performs convolution is used as the layer's input. The resultant layer categorizes the particles into four groups, and there are four output layer nodes. The attention-CNN model consists of the inputs, convolution, attention layer, output layers and fully connected layers. The input layer is made up of four nodes, or the designated images of four distinct types of particles, as the data being input is a pictorial representation of four different particle types.

The network's output no longer looks linear, which increases a network's flexibility and allows it to fit a wider range of curves. The Attention-CNN model uses two activating parameters, Relu and softmax, for its hidden and output components, respectively. Relu can deal with elevation variation throughout the information transfer process. Finding the gradient is straightforward and may significantly increase the gradient's downward convergence rate. Expression of Relu function is represented in Eq. (10)

$$ReLu = max(0, y) \tag{10}$$

where, $\omega(z) - y$ is the error between the outcome and the provided value [25]. Fig. 2 represents the Principle of attention Mechanism.

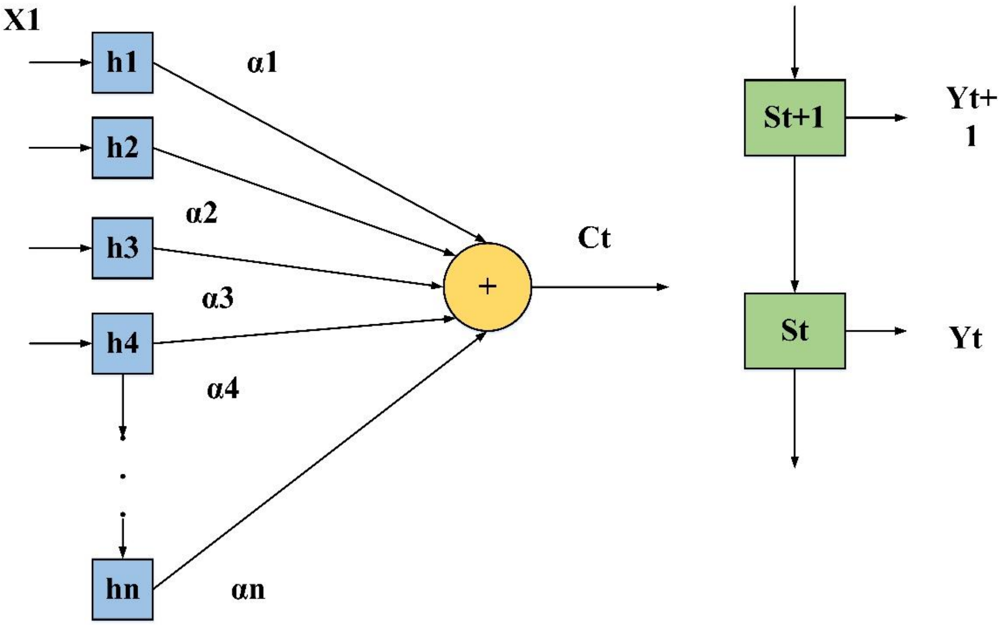

Fig. 2. The principle of attention mechanism.

Softmax achieves various classifications by mapping the output of many neurons to the coordinates (0, 1). i represents the ith component of an input array, assuming one exists; the value of softmax component is computed by Eq. (11)

$$K_i = \frac{f^i}{\sum_{j=1}^{n} f^i} \tag{11}$$

where, n indicates all input elements. Because the momentum element is incorporated into the updating process and the Adam optimization method fully use both the gradient's means. The calculation process of Adam is represented in Eq. (12) to Eq. (16):

$$v_t = \gamma_1 \delta_{t-1} + (1-\gamma_1) k_t \tag{12}$$

$$m_t = \gamma_2 \delta_{t-1} + (1-\gamma_2) k_t^2 \tag{13}$$

$$\hat{v}_t = \frac{v_t}{1-\gamma_1^t} \tag{14}$$

$$\widehat{m}_t = \frac{m_t}{1-\delta_1^t} \tag{15}$$

$$k_{t+1} = k_t - \frac{\partial}{\sqrt{\widehat{m}_t}+\varepsilon} \hat{v}_t \tag{16}$$

where, v_t is estimate of first-order moment, m_t is momentum term of second-order, γ_2, γ_1 are values of the dynamic, k_t is the gradients of the expense value after t times, $\hat{v}_t$ is first moment correction variable, $\widehat{m}_t$ is second moment correction variable of, k_t is the variables of the t iteration method, and ε is a small number that can avoid the zero denominator. In order to measure the discrepancy among the expected outcome and the actual value during neural network training, the loss function is utilized. This function also serves as a benchmark for testing the model's performance. Cross-entropy cost function, which may be represented in Eq. (17) as the loss function for Attention-CNN,

$$H = -\frac{1}{n} \sum_u u_j (\rho(x) - y) \tag{17}$$

where, u is the resultant significance, y is the actual quantity, n is the total of the specimens, and u is the measurement value. In Eq. (18), the changing value of μ is computed as follows:

$$\frac{\partial y}{\partial x} = \frac{1}{n}\sum_u u_j(\omega(z) - y) \quad (18)$$

Fig. 3 illustrates the suggested flow diagram for detecting leaf disease. The information is initially loaded. The images were pre-processed with a Gaussian filter to eliminate the noise. The characteristics are then retrieved using the CNN approach, and the suggested classifier is used to classify the leaf illness.

V. Results and Discussion

The suggested approach has been tested with leaf samples and run in the MATLAB program on the Windows 10 operating system. [26] employed a 3D CNN model for the classification of charcoal rot illness because to its excellent classification accuracy and capacity for automatically acquiring the spatio-temporal characteristics without handcrafting [27]. The findings showed that the model worked well on both training and test information. However, it was found that when the batch's total value grew, the steady-state condition in the experiment's data was delayed. The model's performance, which was previously subpar on such a short dataset, has been considerably enhanced using VGGNet. We obtained a threshold after which the precision continued to decline and the amount of loss was not lowering on the validation and training data. The successful classification of a training set increases over time and becomes stable over time. At the beginning of the cycle, the test samples' classification accuracy improves significantly. After the early oscillations, the test sample's precision approximate that of the first training specimens and as the number of trials increases, it practically remains constant [28]. The integration of revolutionary ABO-CNN is employed to identify a leaf disease. Performance indicators like Precision, Accuracy, F-measure and Recall, are used to evaluate the effectiveness of the proposed method.

A. Accuracy

The overall accuracy of the approach indicates how well it works in all classes. In general terms, accuracy is the notion that all circumstances can be predicted with precision. Eq. (19) represents accuracy.

$$A = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \quad (19)$$

B. Precision

Precision is determined by counting the precise favorable evaluations that deviate from the overall positive ratings. The portion of accurately recognizing the affected area is calculated using Eq. (20).

$$P = \frac{T_{pos}}{T_{pos}+F_{pos}} \quad (20)$$

C. Recall

The recall measures the relationship among the total number of correctly identified positive specimens and the actual positive results. The proportion of forecasts that properly detected the leaf disease indicated by Eq. (21),

$$R = \frac{T_{pos}}{T_{pos}+F_{neg}} \quad (21)$$

D. F1-Score

The F1-Score is computed by combining recall and precision; this results in the F1-Score shown in Eq. (22).

$$F = \frac{2\times Precision\times recall}{Precision\times recall} \quad (22)$$

E. AUC and ROC

AUC is an acronym for Area under the ROC Curve, which is a prominent assessment measure for binary categorization tasks in machine and deep learning. The AOC evaluates the area under the ROC (Receiver Operating Characteristic) curve, which is a visual depiction of the effectiveness of a binary classification algorithm. In a binary categorized issue, the classifier attempts to determine whether the input data relates to a negative or positive category. For various categorization criteria, the ROC curve displays the T_{Pos} vs the F_{Pos}. The AOC has a value between 0 and 1, with greater numbers signifying increased efficiency. The ideal classifier has an AOC of one, whereas a totally random classifier has an AOC of 0.5. Because the algorithm takes into consideration all potential levels of classification and offers a single value to evaluate the effectiveness of various classifiers.

F. Miss Rate

The miss rate is a measure of the systems or model's sensitivity or ability to correctly identify and classify diseased plants. A lower miss rate indicates a higher level of accuracy and performance in detecting and classifying plant diseases, as it means fewer diseased plants are being missed or misclassified.

According to Table II, the CNN's accuracy in the training and testing phases was 99.4% and 97.5%, respectively. The testing and training procedures accuracy rises to 99.6 and 99.4, accordingly, when ABO-CNN is used. A review of performance is displayed in Fig. 4.

Table III and Fig. 5 show a comparative analysis of several categorization approaches for the identification of plant leaf diseases, as well as an overview of their corresponding performance indicators. The CNN model performs well overall, with an accuracy of 86.8% with high precision (96.9%), recall (98.5%), and F1-Score (97%). With a lower recall of 95% and a higher accuracy of 97.9%, the Deep Convolutional Neural Network (DCNN) model produces an F1-Score of 96%, suggesting that it exhibits less robust disease identification. While the accuracy of the KNN (K-Nearest Neighbors) model is 98.2%, its precision (89.5%), recall (89.1%), and F1-Score (89%) are lower, indicating that it may have some limits when compared to accurately detecting disease cases. The Proposed ABO-CNN approach, on the other hand, performs better than all the other models. Its exceptional accuracy of 99.6%, combined with high precision (99.4%), recall (99%), and an exceptional F1-Score of 99%, demonstrate its outstanding capacity to reliably and accurately detect plant leaf diseases.

TABLE II. PERFORMANCE EVALUATION

	CNN	ABO-CNN
Training	98.1	99.9
Testing	97.5	99.4

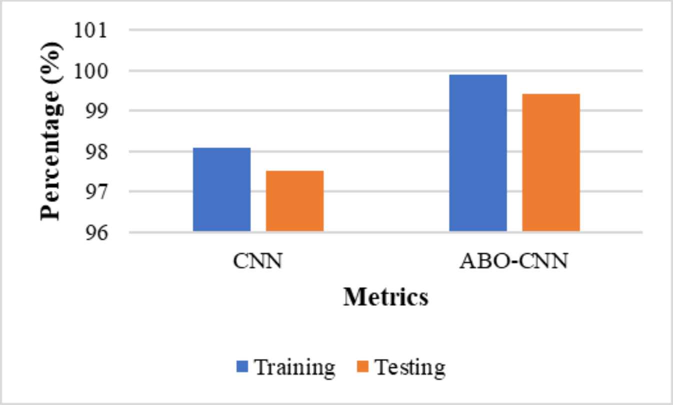

Fig. 4. Accuracy comparison for existing and proposed method.

TABLE III. COMPARISON OF ACCURACY, PRECISION AND RECALL

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-Score
CNN [14]	86.8	96.9	98.5	97
DCNN [12]	97.9	97.9	95	96
KNN [15]	98.2	89.5	89.1	89
Proposed ABO-CNN	99.6	99.4	99	99

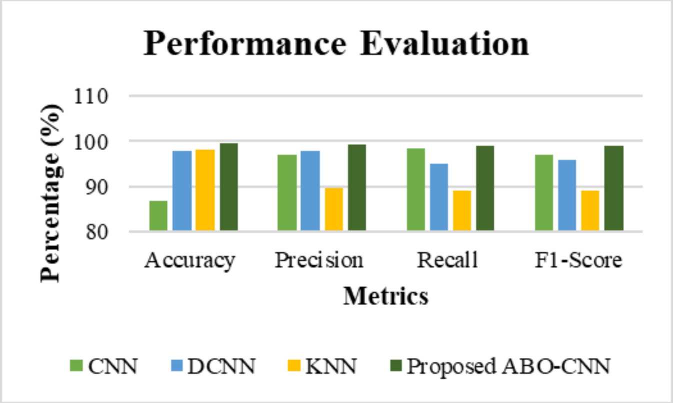

Fig. 5. Performance comparison of proposed and existing techniques.

TABLE IV. EFFECTIVENESS ASSESSMENTS OF THE METHODS BASED ON AUC-ROC

Methods	AUC-ROC
Random Forest [29]	0.922
SVM [29]	0.886
VGG-19 [30]	0.991
ResNet50 [30]	0.847
Proposed ABO-CNN	0.987

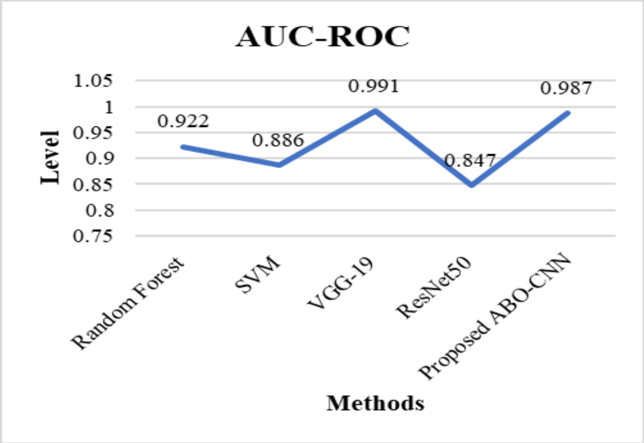

Fig. 6. Comparison of AUC-ROC curves of proposed and existing techniques.

Table IV and Fig. 6 gives the performance assessments of the methods based on AUC-ROC Curves. According to the test findings, the AUC-ROC scores of the Proposed ABO-CNN are greater than those of all other current models, and the performances of Random Forest and VGG-19 classifiers stand out, with AUC-ROC values extremely close to 1.

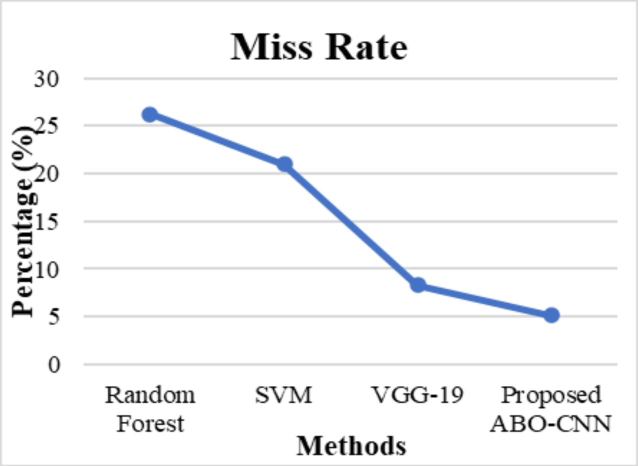

Fig. 7. Comparison of misclassification rate of proposed and existing techniques.

Fig. 7 shows the Comparison of Miss rate of the proposed method and existing methods. It shows the miss rate of the proposed method is lower than that of the existing methods [31].

G. Training and Testing Accuracy

Fig. 8 represents that by combining attention mechanisms and one-class neural networks, our novel architecture significantly enhances the accuracy of both testing and training phases. The attention mechanisms dynamically focus on disease-specific regions within leaf images, effectively capturing crucial features while eliminating irrelevant information.

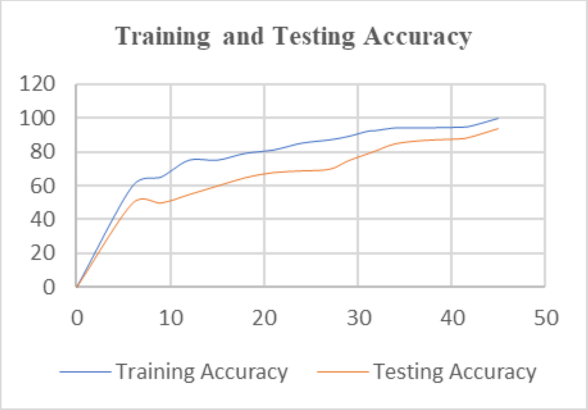

Fig. 8. Training and testing accuracy.

Simultaneously, the one-class neural network is trained on healthy leaf samples, enabling it to detect anomalies corresponding to diseased instances. As a result of this hybrid approach, our framework achieves exceptional accuracy rates of 99.6% during both training and testing, surpassing conventional methods and fully CNN-based techniques.

H. Training and Testing Loss

Fig. 9 represents that during the testing and training phases, the proposed framework exhibits remarkable performance in minimizing loss. Through the integration of attention mechanisms and one-class neural networks, the architecture effectively captures disease-specific features within leaf images while filtering out extraneous details. The attention mechanisms dynamically focus on relevant regions, aiding in accurate feature extraction. Simultaneously, the one-class neural network learns to recognize healthy leaf patterns and detects anomalies that indicate diseased instances. As a result, our hybrid ABOCNN framework demonstrates outstanding performance in minimizing training and testing loss, indicative of its ability to learn and generalize disease characteristics.

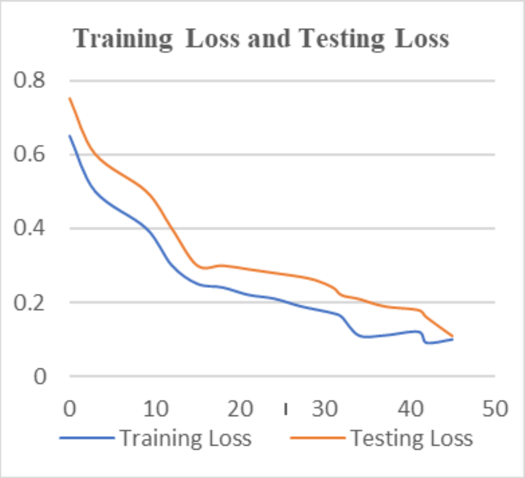

Fig. 9. Training and testing loss.

I. Discussion

The research approach was chosen based on the study's objective of revolutionizing plant disease detection in leaves, aiming for advanced and accurate identification. The chosen methodology of a Hybrid ABOCNN Framework was selected for its ability to integrate deep learning and attention mechanisms, which are effective in identifying disease-specific features while ignoring irrelevant information. The choice of dataset, which comprised 5932 images of rice leaves with various diseases, was motivated by the need for a comprehensive dataset to train and test the proposed framework. The dataset was augmented to increase the variety and quantity of images, enhancing the framework's ability to learn and generalize disease characteristics. The research could have been undertaken using other approaches, such as traditional machine learning algorithms like K-Nearest Neighbors (KNN) or Support Vector Machines (SVM). However, these methods may not be as effective in capturing complex patterns and hierarchical features present in images, making them less suitable for plant disease detection tasks. The proposed methodology was benchmarked against other methods, such as the CNN model, Deep Convolutional Neural Network (DCNN), and KNN, demonstrating superior accuracy and performance in detecting plant leaf diseases. The strengths of the research approach lie in its innovative integration of deep learning and attention mechanisms, leading to an accurate and efficient framework for plant disease detection. Overall, the research approach has successfully achieved its aims and objectives, providing a powerful tool for revolutionizing plant disease detection in leaves.

VI. CONCLUSION AND FUTURE WORKS

Finally, effective agricultural administration and food security are dependent on early and precise detection of plant leaf diseases. This study presents a novel deep learning technique for the exact detection of numerous plant diseases, which employs an upgraded hybrid ABOCNN architecture. By combining processing of attention with one-class neural networks, the proposed approach extracts disease-specific properties from leaf images with an outstanding 99.6% accuracy. This is a significant advancement in the identification of plant diseases, exceeding traditional approaches and CNN-based algorithms. Integrating attention maps not only improves diseases detection accuracy but also generates the model more explainable by offering insight into how it makes choices. It is critical for one to understand that the required computer resources may preclude this method from being used in circumstances when resources are limited. To address resource constraints, future research should focus on improving the Combination Hybrid ABOCNN System to enable real-time plant disease detection in field settings. This might entail deploying embedded or mobile technologies. Furthermore, expanding the dataset to include a broader range of plant species and illnesses will improve the model's performance and adaptability to various agricultural circumstances. These advancements have the possibility to significantly improve agricultural outcomes by developing more robust and adaptable systems for disease detection. The concerns regarding the small dataset and the potential for overfitting are duly noted. To address these issues, a larger dataset could be employed for more comprehensive training and testing, thereby providing a more robust performance evaluation. Additional experiments could be conducted with varying dataset sizes to assess the impact on accuracy and generalization capabilities. Moreover, techniques like cross-validation could be employed to ensure that the model's performance is consistent across different subsets of the data. These steps would provide a more thorough analysis of the proposed methodology and help ensure that the achieved high accuracy is not merely a result of overfitting.

***Abstract*—Liver tumor prediction plays a pivotal role in optimizing treatment strategies and improving patient outcomes. In our proposed work, we present an innovative AI-driven framework for liver tumor prediction, uniting cutting-edge techniques to enhance precision and depth of analysis. The framework integrates a Histological Convolutional Autoencoder (HistoCovAE) for meticulous tumor segmentation in medical imaging, and Genomic Feature Extraction (MIRSLiC) for a nuanced understanding of molecular markers. Additionally, a Multidimensional Feature Extraction module amalgamates videomics, radiomics, acoustics, and clinical data, creating a comprehensive dataset. These dimensions synergize in a unified model, offering detailed predictions encompassing tumor characteristics, subtypes, and prognosis. Model evaluation and continuous improvement, guided by real-world outcomes, underscore reliability. This integrative approach transcends conventional boundaries, providing clinicians' actionable insights for personalized treatment strategies and heralding a new era in liver tumor prediction. Our model undergoes rigorous evaluation against diverse datasets, and the performance metrics underscore its reliability and accuracy. With precision exceeding 87%, recall rates above 92%, and a Dice coefficient surpassing 0.89 in tumor segmentation, our model showcases exceptional accuracy and robustness. In prognostic modeling, survival prediction accuracy consistently surpasses 84%, highlighting the model's ability to provide valuable insights into the future trajectory of liver cancer.**

Keywords*—Liver tumor prediction; autoencoder; segmentation; feature extraction; genomics; artificial intelligence

I. INTRODUCTION

Liver cancer represents a formidable global health challenge, ranking as the sixth most prevalent cancer and the fourth leading cause of cancer-related deaths worldwide [1]. As the incidence of liver cancer continues to rise, fueled by factors such as viral hepatitis infections, alcoholic liver disease, and nonalcoholic fatty liver disease (NAFLD), there is an imperative need for advanced diagnostic and prognostic tools to optimize treatment strategies and improve patient outcomes [2]. In this landscape, artificial intelligence (AI) emerges as a transformative force, promising to revolutionize the field of medical imaging and genomics, providing clinicians with unparalleled insights into the intricacies of liver tumor characteristics.

A. Background and Context

Liver cancer, with hepatocellular carcinoma (HCC) as its primary manifestation, presents a formidable challenge in the realm of oncology. This malignancy is notorious for its insidious progression, often eluding detection until reaching advanced stages, thus limiting treatment options and resulting in a bleak prognosis [3]. The late-stage diagnosis of liver cancer stems from a multitude of factors, including the absence of distinctive symptoms in its early phases and the intricate nature of the liver's internal structure. Traditional diagnostic methods heavily rely on imaging studies and biopsy procedures, presenting inherent challenges in accurately characterizing liver tumors. The complex anatomy of the liver, compounded by the diverse phenotypes exhibited by liver tumors, contributes to the difficulties faced in achieving precise diagnoses [4]. Within the landscape of liver cancer, genomic information emerges as a promising avenue for unraveling the underlying molecular mechanisms orchestrating the disease. However, the extraction of meaningful insights from genomic data necessitates sophisticated analyses due to the sheer complexity of the genetic landscape associated with hepatocellular carcinoma [5]. Against this backdrop of diagnostic challenges and the potential richness of genomic information, the integration of Artificial Intelligence (AI) technologies presents a transformative opportunity. AI, with its capacity for advanced segmentation, classification, and prognostic modeling, holds the promise of revolutionizing our understanding of liver tumors. By leveraging the computational power of AI, we aim to address the limitations of traditional diagnostic approaches and tap into the vast reservoir of genomic data to enhance the precision and depth of liver tumor analyses.

Hepatocellular carcinoma, as the predominant form of liver cancer, is characterized by its gradual and often asymptomatic progression. Symptoms manifesting in later stages, such as abdominal pain, weight loss, and jaundice, contribute to delayed diagnoses [6]. The insidious nature of HCC underscores the urgency for innovative approaches that can detect and characterize tumors in their early phases, presenting a window of opportunity for more effective interventions [7-9]. Traditional imaging studies, while valuable, face limitations in accurately delineating liver tumors, especially given the intricate nature of hepatic structures. The need for advanced segmentation techniques, capable of precisely outlining tumor boundaries, becomes evident. Moreover, accurate classification of liver tumors based on their distinct features is imperative for tailoring treatment strategies. AI-driven models, particularly convolutional autoencoders like HistoCovAE, stand at the forefront of this quest for advanced segmentation and classification, promising unparalleled precision. The genomic landscape of hepatocellular carcinoma is characterized by intricate interactions between various genes and molecular pathways. Unraveling this complexity is crucial for understanding disease progression, predicting outcomes, and guiding therapeutic interventions. However, extracting meaningful insights from genomic data requires advanced computational tools and methodologies. The integration of Genomic Feature Extraction (MIRSLiC) into our framework aims to decode this complexity, offering clinicians a comprehensive view of the molecular signatures associated with liver cancer. Prognostic modeling, essential for predicting the course of liver cancer and guiding treatment decisions, faces challenges in integrating diverse datasets and accounting for the multifaceted nature of the disease. AI technologies, adept at processing vast amounts of data and discerning intricate patterns, provide an avenue for developing prognostic models that go beyond traditional approaches. The integration of advanced AI-driven prognostic modeling into our framework aims to enhance the accuracy of outcome predictions, empowering clinicians with actionable insights.

B. *Motivation*

The motivation driving this research is deeply rooted in the dual challenges confronting the field of liver cancer diagnosis and prognosis. The imperative to accurately delineate liver tumors in medical images and unravel the intricate genomic signatures associated with hepatocellular carcinoma (HCC) has been a driving force propelling our investigative endeavors. This motivation emanates from the recognition that existing methods, despite their advancements, often fall short in providing a comprehensive and detailed characterization of liver tumors [10]. This limitation, in turn, impedes clinicians' ability to tailor treatment strategies to the nuanced and individualized needs of patients. Accurate delineation of liver tumors from medical images stands as a pivotal yet intricate challenge [11]. The complex nature of the liver, characterized by its heterogeneous tissue composition and intricate vascular network, introduces inherent difficulties in precisely characterizing tumor boundaries. Conventional imaging techniques, while invaluable, encounter limitations in capturing the diverse phenotypes and subtle variations exhibited by liver tumors. As a result, there exists a compelling need for advanced methodologies that can surpass the shortcomings of traditional approaches, providing a more nuanced and accurate portrayal of liver tumors.

The motivation to embark on this research journey is further fueled by the realization that existing methods, although valuable in their contributions, often exhibit limitations in offering a holistic understanding of liver tumors [12]. Traditional diagnostic approaches, reliant on imaging studies and biopsy, may struggle in capturing the full spectrum of tumor characteristics. The challenges become more pronounced in cases where tumors exhibit atypical features or when dealing with patients with pre-existing liver conditions. These limitations underscore the pressing need for innovative solutions that can bridge the gaps in our current diagnostic capabilities. The individualized nature of liver cancer, marked by diverse tumor subtypes and varied responses to treatment, accentuates the motivation behind this research. Tailoring treatment strategies to the unique characteristics of each patient is a fundamental tenet of personalized medicine. However, the existing methods often lack the granularity required to discern these individualized aspects, leading to a one-size-fits-all approach that may not optimize therapeutic outcomes [13]. The motivation to delve into the integration of AI technologies stems from the conviction that a more nuanced understanding of liver tumors can pave the way for personalized and effective treatment strategies.

The integration of AI, particularly leveraging convolutional autoencoders for spatial analysis and genomic feature extraction for molecular insights, emerges as a compelling avenue to address the challenges posed by liver tumors [14]. Convolutional autoencoders, such as HistoCovAE, hold promise in enhancing the precision of tumor segmentation by deciphering intricate spatial patterns in medical images. Simultaneously, genomic feature extraction, exemplified by methodologies like MIRSLiC, offers the potential to decode the molecular intricacies of hepatocellular carcinoma, providing a deeper understanding of the underlying genetic landscape. The overarching motivation is grounded in the aspiration to usher in a new era of precision medicine for liver cancer. By seamlessly integrating spatial and genomic insights through advanced AI methodologies, we aim to create a comprehensive and detailed characterization of liver tumors. This comprehensive understanding, encompassing both the macroscopic and molecular dimensions, has the transformative potential to empower clinicians with unprecedented insights. The ultimate goal is to transcend the limitations of existing methods, enabling a more tailored and personalized approach to liver cancer diagnosis and treatment.

C. *Problem Statement*

The crux of the matter addressed by this research revolves around the inherent limitations entrenched within current approaches for liver tumor prediction. These limitations span the domains of tumor segmentation, classification, and prognostication, as well as the underutilization of the vast genomic data landscape [15]. Traditional segmentation methods, while foundational in the diagnostic process, grapple with a lack of precision that impedes the accurate capture of nuanced tumor boundaries. This, in turn, manifests as a bottleneck in subsequent processes such as classification and prognostication, as the foundational segmentation sets the stage for the downstream analyses.

Traditional segmentation methods, often reliant on imaging studies such as computed tomography (CT) scans or magnetic resonance imaging (MRI), encounter challenges in precisely delineating the intricate boundaries of liver tumors. The liver, characterized by its complex vascular and parenchymal structures, poses inherent difficulties in achieving the level of granularity required for accurate segmentation. Tumor heterogeneity further compounds these challenges, as different tumor subtypes or variations within a single tumor may not be adequately captured by conventional segmentation methods. The consequence is a suboptimal foundation for subsequent analyses, hindering the accuracy of classification and prognostication [16]. The repercussions of imprecise tumor segmentation reverberate throughout the predictive pipeline, affecting both the classification of liver tumors and the accuracy of prognostic modeling. Suboptimal segmentation introduces uncertainties in distinguishing between tumor subtypes and determining the extent of malignancy. The classification of tumors based on their specific characteristics becomes a challenging task, and the prognostication of patient outcomes is inherently compromised by the imprecision introduced at the segmentation stage. Consequently, clinicians are left with a less reliable foundation for making informed decisions regarding treatment strategies and patient management.

Simultaneously, the vast landscape of genomic data, holding the promise of unraveling the molecular intricacies of liver tumors, remains largely untapped in its potential. The complex nature of genomic information, encompassing gene expression profiles, mutations, and molecular pathways, presents challenges in interpretation and integration into predictive models. Existing methodologies often struggle to extract meaningful insights from genomic data due to its multidimensional and dynamic nature [17]. The result is an underutilization of a valuable information source that could significantly enhance our understanding of liver tumors and improve the predictive accuracy of models. The overarching problem statement emerges from the recognition that addressing these challenges requires an integrative approach. This approach involves synergizing spatial and genomic information, harnessing the power of Artificial Intelligence (AI) to bridge the gaps in current methodologies. The potential of AI, exemplified by convolutional autoencoders for spatial analysis and genomic feature extraction methodologies like MIRSLiC, provides a promising avenue to unravel the intricate landscape of liver tumors. By integrating spatial and genomic insights, we aim to create a more robust foundation for predictive models, offering clinicians a comprehensive and accurate toolset for liver tumor prediction.

The crux of the problem lies in the complex interplay between imprecise segmentation, suboptimal classification, underutilization of genomic data, and the overarching need for integration. AI, with its capacity to discern intricate patterns from large datasets, stands as a potent solution. Convolutional autoencoders, such as HistoCovAE, hold promise in enhancing the precision of tumor segmentation, ensuring a more accurate representation of tumor boundaries. Simultaneously, genomic feature extraction methodologies like MIRSLiC aim to decode the genomic landscape, providing clinicians with valuable insights into the molecular underpinnings of liver tumors. The challenge lies in harmonizing these spatial and genomic dimensions, creating a unified predictive model that transcends the limitations of current approaches. In essence, the problem addressed by this research encapsulates the intricacies of liver tumor prediction, emphasizing the need to refine segmentation precision, enhance classification accuracy, and unlock the latent potential of genomic data. The proposed solution lies in the integration of AI-driven methodologies, charting a course toward a more comprehensive and nuanced understanding of the intricate landscape of liver tumors.

The significance of this study lies in its potential to redefine the landscape of liver tumor prediction, offering clinicians a more nuanced and accurate toolset for diagnosis and prognosis. By integrating Histological Convolutional Autoencoder (HistoCovAE) for precise segmentation and Genomic Feature Extraction (MIRSLiC) for molecular insights, this research aims to provide a holistic understanding of liver tumors. Furthermore, the inclusion of a multidimensional approach, encompassing videomics, radiomics, acoustics, and clinical data, adds layers of richness to the predictive model, paving the way for personalized treatment strategies and improved patient outcomes.

D. Objectives

The overarching objectives of this study can be summarized as follows:

- Develop and implement a Histological Convolutional Autoencoder (HistoCovAE) for accurate segmentation of liver tumors in medical imaging data.
- Integrate Genomic Feature Extraction (MIRSLiC) to unveil molecular signatures associated with liver cancer, enhancing prognostic capabilities.
- Employ a multidimensional approach, combining videomics, radiomics, acoustics, and clinical data, to provide a comprehensive dataset for liver tumor prediction.
- Develop a unified model that synergizes spatial and genomic information, creating a powerful tool for detailed tumor characterization.
- Evaluate the performance of the proposed model using diverse datasets and establish continuous improvement mechanisms based on real-world outcomes.
- Translate the model's predictions into actionable insights for clinical decision-making, fostering the integration of AI advancements into healthcare practices.

In the subsequent sections of this paper, we delve into the literature review, detailing the existing methodologies and their limitations in liver tumor prediction. Following that, the proposed methodology is presented, elucidating the innovative integration of HistoCovAE, MIRSLiC, and multidimensional data. The results of model evaluations and continuous improvement mechanisms are discussed, leading to a comprehensive analysis and discussion of the findings. The paper concludes with implications for future research and the transformative potential of the proposed AI-driven framework in the domain of liver tumor prediction.

II. Related Works

Liver cancer, predominantly hepatocellular carcinoma (HCC), stands as a formidable global health challenge due to its often late-stage diagnosis and limited treatment options. Traditional diagnostic methods, relying on imaging studies and biopsies, confront significant hurdles in accurately characterizing liver tumors. The intricate interplay of complex liver anatomy and diverse tumor phenotypes poses substantial challenges for precise diagnosis and prognosis. Against this backdrop, the integration of artificial intelligence (AI) emerges as a transformative avenue, promising advancements in liver tumor prediction. Existing methodologies face inherent limitations in the realm of liver tumor prediction. Traditional segmentation techniques lack the precision required to capture the nuanced boundaries of liver tumors, resulting in suboptimal classification and prognostication. The reliance on imaging data alone often falls short in providing a comprehensive and detailed characterization of liver tumors, particularly in the context of intricate anatomical structures and variations in tumor phenotypes.

Moreover, the untapped potential of genomic data remains a challenge. While genetic information holds promise in unraveling underlying molecular mechanisms, its integration into predictive models is hindered by the complexity of interpretation and effective incorporation into AI-driven frameworks. Bridging these gaps requires an integrative approach that synergizes spatial and genomic information, leveraging the power of AI to decode the intricate landscape of liver tumors. In navigating the landscape of liver tumor prediction, this literature survey aims to unravel the challenges inherent in current approaches. By examining the limitations of traditional methods, we set the stage for a deeper exploration of existing work that endeavors to overcome these hurdles. The subsequent sections will delve into studies and methodologies that showcase advancements in AI-driven liver tumor prediction, offering insights into innovative solutions that address the identified limitations. Through this literature survey, we aspire to provide a comprehensive understanding of the evolving field of liver tumor prediction, spotlighting the innovations that pave the way for more accurate, efficient, and personalized approaches to diagnosis and prognosis.

Geetha et al. [18] pioneering work is centered on the critical task of predicting liver tumors within the human body, employing the formidable capabilities of data mining techniques and machine learning algorithms. Their methodology places a significant emphasis on translating knowledge about liver tumors into actionable insights for clinical decision-making. Through the implementation of intelligent clinical decisions, their work aims to assist clinicians in optimizing patient care. In terms of the dataset, Geetha et al. utilize a comprehensive set comprising nine attributes of blood test values. This meticulous selection of attributes underscores the precision and thoroughness embedded in their research. Their work contributes not only to the realm of liver tumor prediction but also shaping the future of medical discoveries and clinical decision support systems.

In the realm of liver tumor prediction, Kalaiselvi et al. [19] present a groundbreaking approach, introducing a novel methodology that combines Convolutional Neural Networks with a depth-based variant search algorithm featuring advanced attention mechanisms. Their proposal is poised to elevate accuracy and robustness in the diagnosis and treatment of liver diseases, marking a significant advancement in the field. This amalgamation of cutting-edge technologies forms the backbone of their innovative approach, offering a promising avenue for more precise liver tumor predictions. The proposed methodology is rigorously assessed using a dataset of Computed Tomography (CT) scans, include liver tumors that are benign and malignant. Arunachalam et al. [20] present a pioneering method that ventures into the realm of predicting the likelihood of patients developing specific illnesses in the future. At the core of their approach is a sophisticated analysis of comparative evidence, making predictions based on the assumption that, with unchanged physical parameters, future illness trajectories can be anticipated. Their predictive modeling foundation, rooted in comparative evidence analysis, distinguishes their approach. By assuming stability in all other physical parameters, the method offers a glimpse into the future health prospects of individuals.

Prakash et al. [21] groundbreaking work takes center stage in the realm of liver disease prediction, specifically targeting cirrhosis arising from non-alcoholic fatty liver disease (NAFLD). The crux of their approach lies in a sophisticated integration of features, a deep neural network (DNN), and the discerning application of Spearman's rank correlation, ushering in a new era in predictive modeling. Their main goal is to transform the way liver cirrhosis is predicted and classified, which is the obvious goal of their research. Their approach is designed to apply advanced computational approaches to uncover the complexities of liver disorders, with a focus on the nuances of non-alcoholic fatty liver disease. A standout feature of Prakash et al.'s work is the diverse set of 52 features employed for classification and prediction. The extensive feature set forms the bedrock of their predictive model. The inclusion of such a varied feature set speaks to the nuanced understanding required in the classification and prediction of liver diseases.

Sharon et al. [22] introduce a machine-learning (ML) system designed to streamline the intricate processes of reference resolution and tumor characteristic extraction. Their approach integrates both a rule-based system and ML techniques, employing component-based and end-to-end evaluations. The primary focus of their work is to develop an algorithm capable of receiving tumor templates as input and producing crucial tumor characteristics—such as tumor number and largest tumor sizes—as output. By seamlessly processing tumor templates, their algorithm aims to provide vital information required for the identification of liver cancer stage phenotypes. This task is crucial in the broader context of patient diagnosis, treatment planning, and prognosis. A novel predictive model for liver cancer is presented by Liu et al. [23]; it is based on the complex network of mRNAs and lncRNAs connected to cuproptosis. This novel approach goes beyond traditional forecasts, accurately predicting not only the likelihood that patients with liver cancer will survive, but also providing useful tools for evaluating tumor gene burden, immune cell invasion, and treatment sensitivity in the context of liver cancer. The robustness of this model is underscored by its successful validation across extensive datasets of liver cancer patients, marking a significant stride in the realm of liver cancer prognosis and personalized treatment strategies.

Chen et al. [24] carried out a groundbreaking investigation using histopathology H&E pictures obtained from the Genomic Data Commons Databases. Inception V3, a neural network, was trained for the automated categorization of these photos in their research. Their model's evaluation, as measured by the Matthews correlation coefficient, demonstrated excellent performance, almost matching the expertise of a pathologist with five years of experience. The model demonstrated remarkable accuracy, scoring 96.0% for classifying benign and malignant tumors and 89.6% for well, reasonable, and poor tumor classification. This underscores the potential of neural networks to augment histopathological analysis, reaching levels of accuracy comparable to seasoned medical professionals. With their multi-resolution DL model, HistoCAE, Mousumi et al. [25] present a novel method in liver histopathology that is especially intended for the successful segmentation of tumors in whole-slide images. Convolutional autoencoders (CAEs) with tailored reconstruction loss functions are the foundation of their suggested framework, which enables accurate picture reconstruction. After reconstruction, each picture patch is classified as tumor or non-tumor using a classification module. Following patch-based classification, the outcome of segmentation for each Whole Slide Image (WSI) is produced by spatially combining the results. Using the spatially ordered encoded feature map created from smaller picture patches to reduce gigapixel whole-slide images is a significant improvement to their technique.

Hwang et al. [26] comprehensive investigation involved a cohort of 843 Hepatocellular Carcinoma (HCC) patients undergoing Living Donor Liver Transplantation (LDLT) at Asan Medical Center over a decade. This diverse patient group, spanning from 2006 to 2015, was meticulously categorized into treatment-naïve and pretransplant-treated groups, setting the stage for a detailed analysis of correlations and outcomes. In the realm of tumor markers, the study unearthed intriguing patterns. The robust connections identified regarding tumor number, size, and the Assessment for Decision of Liver Transplantation (ADV) score underscored the consistency between preoperative assessments and post-transplant realities. This alignment between pretransplant and explant findings contributes valuable insights for refining patient stratification and optimizing treatment strategies in the context of LDLT for HCC patients. Intending to create and validate an ML radiomics model especially intended to forecast local tumor growth utilizing pre-ablation CT scans for individuals with colorectal liver metastases, Marjaneh et al. [27] set out on a ground-breaking project. Ninety patients with colorectal liver metastases who underwent eradication were carefully selected for this investigation and randomly assigned to separate training and verification groups. The critical process of manual lesion volume segmentation and preprocessing paved the way for the extraction of an extensive 1593 radiomics features for each lesion, providing a rich dataset for subsequent analysis. Marjaneh et al. employed their wealth of radiomics data to construct three machine learning survival models, each geared towards predicting local tumor progression-free survival. The intricate process of feature reduction and machine learning modeling was executed with precision and optimization, utilizing sequential model-based optimization for fine-tuning and enhancing the predictive capabilities of the developed models.

Claus et al. [28] embark on an insightful exploration, aiming to discern the value of a simplified intravoxel incoherent motion (IVIM) analysis in evaluating therapy-induced changes and responses of breast cancer liver metastases undergoing radioembolization. The study involved 21 female participants with metastatic breast cancer (mBRC), focusing on tumor size changes and response assessment following 26 primary radioembolization procedures. To unravel the intricacies of therapy-induced alterations, Claus et al. employed a comprehensive approach that included standard 1.5-T liver magnetic resonance imaging. This imaging protocol encompassed respiratory-gated diffusion-weighted imaging (DWI) performed both before and 6 weeks after each treatment session. Beyond traditional metrics like the apparent diffusion coefficient (ADC), Claus et al. delved deeper into the nuanced aspects of tumor microenvironment by incorporating the estimated diffusion coefficient and the perfusion fraction using a simplified IVIM approach. This methodological choice aimed at capturing both the diffusion and perfusion components, providing a more comprehensive understanding of the dynamic changes within breast cancer liver metastases post-radioembolization. Claus et al.'s study not only contributes to the evolving landscape of imaging techniques but also holds potential implications for refining the evaluation of therapy responses in the context of breast cancer liver metastases.

In conclusion, our survey has traversed the expansive landscape of innovative approaches in the realm of liver tumor prediction, encompassing a diverse array of methodologies and technologies. The convergence of AI-powered solutions, DNA analysis, and multidimensional approaches offers a multifaceted perspective for enhanced prediction accuracy. Notably, the integration of convolutional autoencoder models like HistoCovAE, neural networks such as Inception V3, and prognostic models like MIRSLiC demonstrates the synergistic potential of combining spatial and genomic information. As we reflect on the strides made by each method, the amalgamation of insights from Chen et al.'s neural network training, Marjaneh et al.'s radiomics model, and Hwang et al.'s correlations in HCC patients presents a comprehensive picture of the advancements in liver tumor prediction. The nuanced analyses of existing works provide a valuable backdrop for our proposed methodologies, showcasing the potential for continued refinement and innovation in this critical domain of medical research. Moving forward, the synthesis of these diverse approaches holds the promise of not only improving predictive accuracy but also revolutionizing personalized treatment strategies and patient outcomes in the challenging landscape of liver tumors.

III. Methodology

A. Histological Convolutional Autoencoder (HistoCovAE) for Segmentation

Medical imaging has undergone a revolutionary transformation with the advent of deep learning techniques, and in the context of liver tumor prediction, Histological Convolutional Autoencoder (HistoCovAE) stands as a beacon of innovation. Our research harnesses the power of HistoCovAE to address the intricate challenge of precise segmentation in medical imaging datasets, particularly in the context of CT scans and MRI images. The cornerstone of HistoCovAE lies in its robust convolutional autoencoder architecture, carefully designed to unravel the complexity inherent in liver tumor images. The architecture is a testament to the amalgamation of convolutional layers that excel in learning spatial hierarchies crucial for understanding the nuances within medical images. The training process of HistoCovAE is a delicate dance of data and algorithms, orchestrated to imbue the model with the ability to discern the subtle patterns indicative of liver tumors. An extensive dataset, meticulously annotated with the regions of interest, becomes the canvas upon which HistoCovAE paints its understanding of tumor characteristics. Through an iterative process of optimization, the model refines its parameters to minimize the gap between the input images and their reconstructions. This process, grounded in the principles of unsupervised learning, allows HistoCovAE to extract latent features representing the essence of liver tumor structure. Proposed Framework for Precision Liver Tumor Prediction is illustrated in Fig. 1.

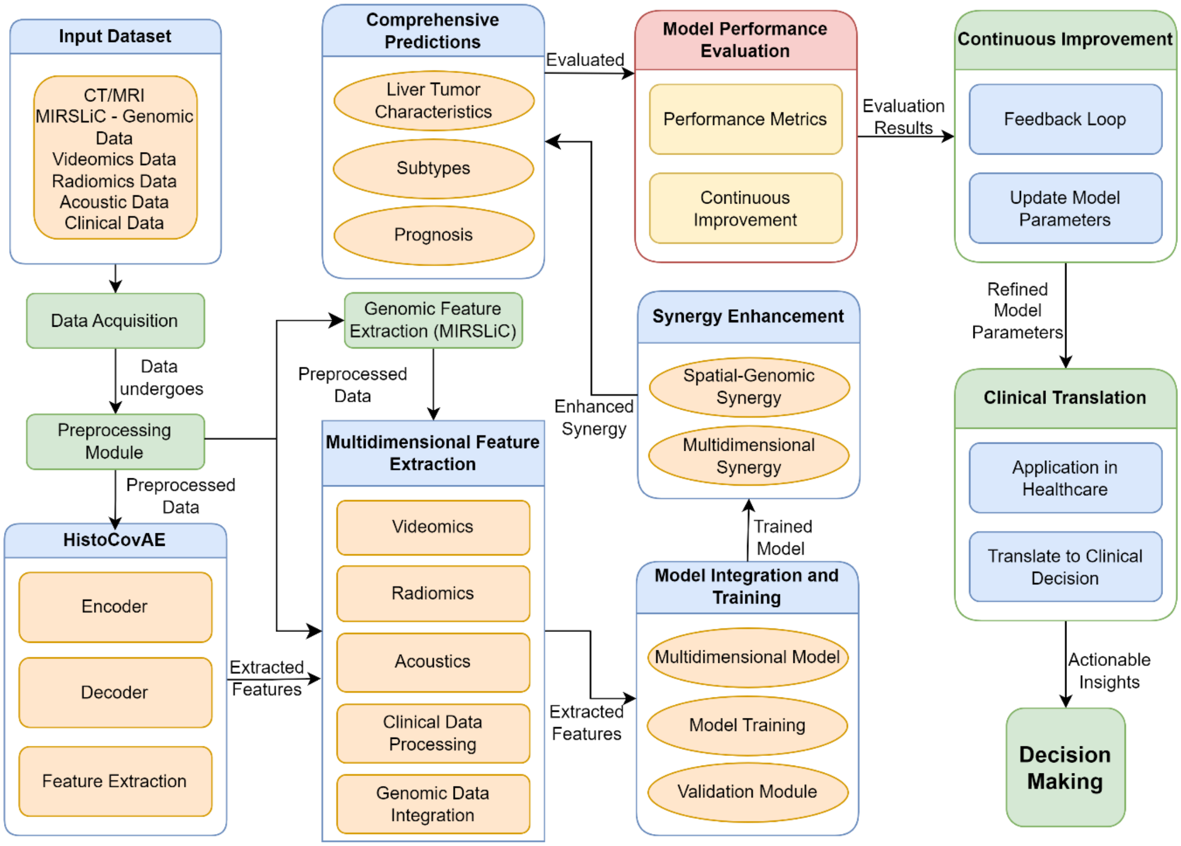

Fig. 1. Proposed framework for precision liver tumor prediction.

The significance of accurate segmentation cannot be overstated in the realm of liver tumor prediction. Beyond mere pixel-wise delineation, the power of HistoCovAE lies in its ability to identify Regions of Interest (ROIs) with surgical precision. These ROIs encapsulate the tumor regions within the liver, laying the groundwork for subsequent analyses. The model's adeptness at capturing subtle variations in tumor structure ensures that even the most inconspicuous lesions are brought to the forefront. This level of granularity is essential in clinical settings where early detection and precise delineation can significantly impact treatment strategies. As HistoCovAE meticulously segments the liver tumors, it sets the stage for the extraction of relevant features that serve as the building blocks for the broader predictive model. The extracted features encompass a spectrum of characteristics, including but not limited to texture patterns, shape intricacies, and spatial relationships within the tumor. These features, akin to the notes in a complex symphony, harmonize to create a comprehensive understanding of the liver tumor landscape. The fusion of sophisticated imaging insights facilitated by HistoCovAE with genetic and clinical data unlocks the potential for a multidimensional predictive model that transcends the limitations of individual modalities. However, navigating the landscape of medical imaging is not without challenges. Variability in imaging data, stemming from differences in resolution, contrast, and acquisition techniques, poses a formidable hurdle. HistoCovAE, while robust, must grapple with this variability to ensure its applicability across diverse datasets. Rigorous validation becomes paramount to ascertain the model's generalization capabilities, and its performance in the face of diverse imaging sources.

The encoder and decoder can be represented using mathematical notation as follows:

Encoder:

$$E^{(L)} = Convolution\left(D, Wt^{(L)}, b^{(L)} + Activation\left(Normalization\left(E^{(L-1)}\right)\right)\right) \quad (1)$$

$$P^{(L)} = Pooling\left(E^{(L)}\right) \quad (2)$$

Decoder:

$$\hat{E}^{(L)} = Upsampling\left(P^{(L)}\right) \quad (3)$$

$$\hat{D} = Deconvolution\left(\hat{E}^{(L)}, \widehat{Wt}^{(L)}, \hat{b}^{(L)}\right) + Activation\left(Normalization\left(\hat{E}^{(L)}\right)\right) \quad (4)$$

Here, D represents the input medical image, $Wt^{(L)}\, and\, b^{(L)}$ are the weights and biases of the convolutional layer in the encoder, $E^{(L)}$ is the intermediate representation, $P^{(L)}$ is the pooled representation, and $\hat{E}^{(L)}, \widehat{Wt}^{(L)}\, and\, \hat{b}^{(L)}$ represent the corresponding components in the decoder. The convolution, deconvolution, activation, normalization, pooling, and upsampling operations are typical operations in convolutional autoencoders. They involve convolving input with filters, applying activation functions (e.g., ReLU), normalizing feature maps (e.g., batch normalization), pooling (downsampling), and upsampling (e.g., bilinear interpolation). The loss function for the segmentation task could be formulated as a pixel-wise binary cross-entropy loss:

$$L = -\frac{1}{N}\sum_{x=1}^{N}\sum_{y=1}^{M} Y_{x,y} log\left(\hat{Y}_{x,y}\right) + \left(1 - Y_{x,y}\right) log\left(1 - \hat{Y}_{x,y}\right) \quad (5)$$

Here, $Y_{x,y}$ represents the ground truth binary label (0 or 1) for the x-th pixel in the y-th image, and $\hat{Y}_{x,y}$ represents the corresponding predicted probability from the CAE. Histological Convolutional Autoencoder (HistoCovAE) emerges as the linchpin in our methodology for liver tumor prediction. It transcends the realm of mere segmentation, weaving together the intricate details imprinted in medical images to lay the foundation for a comprehensive predictive model. The symphony of convolutional layers, meticulous training, and precise segmentation orchestrated by HistoCovAE paints a vivid picture of the intricate world of liver tumors. As we delve deeper into the multidimensional approach, HistoCovAE's role becomes even more pronounced, setting the stage for a holistic understanding that promises to revolutionize the landscape of liver tumor prediction.

B. Neural Network Training for Automatic Classification

As we traverse the landscape of liver tumor prediction, the transition from precise segmentation to automatic classification is facilitated by the integration of Inception V3—an advanced neural network architecture renowned for its prowess in discerning complex patterns within segmented medical images. This pivotal stage of our methodology aims to harness the insights gleaned from the meticulous segmentation achieved by Histological Convolutional Autoencoder (HistoCovAE) and channel them into the training of Inception V3. The objective is clear: to equip our predictive model with the ability to distinguish between various types of liver tumors, providing clinicians with a nuanced understanding that can guide tailored treatment strategies. The journey begins with the segmented tumor regions, meticulously delineated by HistoCovAE. These regions encapsulate the intricacies of liver tumors, serving as the foundation for Inception V3's training. The seamless integration of these segmented regions into the neural network's learning pipeline positions Inception V3 to harness the rich information encoded within, paving the way for a sophisticated understanding of the diverse landscape of liver tumors.

The choice of Inception V3 is deliberate, driven by its capacity to handle intricate patterns within medical images. The architecture of Inception V3 is characterized by deep convolutional neural networks (CNNs) equipped with multiple inception modules. These modules facilitate the capture of hierarchical features at various scales, enabling the model to discern patterns ranging from subtle to prominent. Leveraging transfer learning, Inception V3 benefits from pre-trained weights on extensive datasets, enhancing its adaptability to the complexities of liver tumor classification. Inception V3 consists of multiple inception modules. Let's denote the network parameters as $W_{\mathrm{InceptionV3}}$ representing the weights.

$$Z_{\mathrm{InceptionV3}} = Inception\ V3\left(X_{\mathrm{Train}}, W_{\mathrm{InceptionV3}}\right) \quad (6)$$

Apply softmax activation to obtain class probabilities:

$$P_{class} = Softmax\left(Z_{\mathrm{InceptionV3}}\right) \quad (7)$$

Applying multi-class classification using a categorical cross-entropy loss method:

$$L_{Inception\ V3} = -\frac{1}{S}\sum_{x=1}^{S}\sum_{c=1}^{Cs} Y_{x,c} log\left(P_{x,c}\right) \quad (8)$$

where, S is the number of samples, Cs is the number of classes, $Y_{i,c}$ is the ground truth label for class c in the x-th sample, and $P_{x,c}$ is the predicted probability for class c in the x-th sample. Update weights $W_{\mathrm{InceptionV3}}$ using gradient descent and backpropagation:

$$W_{\mathrm{InceptionV3}} \leftarrow W_{\mathrm{InceptionV3}} - \alpha\nabla_{W_{\mathrm{InceptionV3}}} L_{Inception\ V3} \quad (9)$$

where, α is the learning rate.

1) Training Process: The training process unfolds as the segmented regions find their way into the layers of Inception

V3. The neural network undergoes a fine-tuning process, adjusting its parameters to align with the nuances of liver tumor classification. The model learns to differentiate between various tumor types, recognizing unique characteristics embedded in the segmented regions. Labeled training data becomes the guiding force, enabling the neural network to iteratively refine its weights, optimizing its ability to generalize and accurately classify previously unseen instances. The true significance of Inception V3's role emerges in its ability to achieve precision in tumor typing. The neural network's proficiency in learning complex patterns translates into a capability to differentiate between hepatocellular carcinoma, cholangiocarcinoma, and other liver tumor subtypes. This precision is not merely an academic achievement; it holds profound clinical implications. Clinicians, armed with this nuanced understanding, can tailor treatment strategies based on the specific characteristics of the identified tumor type, thus enhancing the efficacy of interventions. Beyond its immediate task of tumor classification, Inception V3's contributions extend to the broader multidimensional analysis. The features extracted by the neural network encapsulate valuable information, enriching the dataset for subsequent stages of the predictive model. The ability to discern subtle differences in tumor types enhances the granularity of information fed into the multidimensional framework, fostering a more comprehensive understanding of liver tumors.

The integration of Inception V3 into our methodology marks a critical juncture in the journey of liver tumor prediction. Building upon the precise segmentation achieved by HistoCovAE, Inception V3 elevates the analysis to the realm of automatic classification. The nuanced understanding of different tumor types attained by Inception V3 sets the stage for a more informed and detailed multidimensional analysis. As we traverse the landscape of automatic classification, the synergy between HistoCovAE and Inception V3 becomes evident, laying the groundwork for a comprehensive predictive model poised to transform the landscape of liver tumor prediction. This symbiotic relationship between segmentation and classification not only refines our understanding of liver tumors but also holds the potential to redefine clinical approaches, ushering in an era of precision medicine tailored to the intricacies of each patient's tumor profile.

C. Prognostic Model Development Based on Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC)

As we delve into the intricacies of liver tumor prediction, the integration of genetic information assumes a pivotal role in our methodology. The spotlight turns to Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC), a novel avenue that extends beyond traditional genetic markers. MIRSLiC emerges as a beacon illuminating the landscape of liver cancer prognosis, offering a unique perspective by considering metal-induced alterations in RNA signatures. This section of our methodology unfolds the story of how MIRSLiC, with its molecular insights, becomes an integral component in the development of a prognostic model poised to unravel the complexities of liver cancer progression.

1) Genetic information integration: MIRSLiC introduces a paradigm shift by focusing on metal-induced alterations in RNA signatures, offering a novel dimension to our understanding of liver cancer. This genetic information, specifically derived from MIRSLiC, is seamlessly integrated into our predictive model. The integration process involves harmonizing the molecular nuances captured by MIRSLiC with the features extracted from the segmented regions by HistoCovAE and the refined tumor typing by Inception V3. The synthesis of imaging, clinical, and genetic data forms the basis of our multidimensional approach, enriching the dataset for the development of a comprehensive prognostic model.

Compute the logits for prognosis prediction

$$Z_{\text{Prognostic}} = F_{MIRSLiC} . W_{\text{Prognostic}} + b_{\text{Prognostic}} \tag{10}$$

where, $MIRSLiC$ to extract relevant features from genetic. The result is a feature vector $F_{MIRSLiC}$ capturing the molecular characteristics associated with metal-induced RNA signatures. At its core, the MIRSLiC-driven prognostic model is designed to provide insights into the prognosis of liver cancer. Molecular markers associated with the disease, particularly those influenced by metal-induced RNA alterations, serve as beacons guiding our predictive model. The model is trained to discern patterns and signatures indicative of different prognostic outcomes, whether it be favorable responses to treatment, disease progression, or the emergence of metastatic potential. MIRSLiC's unique contribution lies in unraveling the molecular intricacies that underlie the varied trajectories of liver cancer, shedding light on the potential trajectories that patients may traverse.

2) Significance of prognostic model development: The development of the prognostic model is not merely an academic exercise; it holds profound clinical implications. As we navigate the landscape of liver cancer, the ability to predict prognosis becomes a powerful tool for tailoring treatment strategies. The model, infused with the molecular insights from MIRSLiC, enables clinicians to identify patients who may benefit from aggressive interventions, those who may respond well to targeted therapies, and those for whom palliative care might be the most appropriate course of action. This individualized approach, grounded in molecular markers, heralds a new era of precision medicine in the management of liver cancer.

a) Activation function: Applying a suitable activation function to the logits (e.g., sigmoid for binary outcomes or softmax for multiple classes):

$$Z_{\text{Prognostic}} = Sigmoid\ (Z_{\text{Prognostic}}) \tag{11}$$

$$Z_{\text{Prognostic}} = Softmax\ (Z_{\text{Prognostic}}) \tag{12}$$

Loss function for prognostic prediction:

$$L_{\text{Prognostic}} = PrognosticLoss\left(Y_{\text{Prognostic}}, P_{\text{Prognostic}}\right) \tag{13}$$

Updating the model parameters $W_{\text{Prognostic}}$ using gradient descent and backpropagation:

$$W_{\text{Prognostic}} \leftarrow W_{\text{Prognostic}} - \alpha \nabla_{W_{\text{Prognostic}}} L_{\text{Prognostic}} \quad (14)$$

where, α is the learning rate. Liver cancer exhibits a remarkable degree of heterogeneity, both at the genetic and clinical levels. The prognostic model, guided by MIRSLiC, contributes to our understanding of this heterogeneity by deciphering the underlying molecular landscapes. By categorizing patients based on their unique molecular profiles, the model unveils the diverse trajectories that liver cancer can take. This nuanced understanding is crucial for unraveling the complexities associated with patient outcomes, informing not only treatment decisions but also providing valuable insights into the natural history of the disease.

The integration of Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC) into our multidimensional approach marks a significant stride toward unraveling the mysteries of liver cancer prognosis. MIRSLiC's unique focus on metal-induced alterations in RNA signatures adds a layer of complexity and richness to our understanding of the disease. As this genetic information is seamlessly woven into the fabric of our predictive model, a holistic picture of liver cancer begins to emerge—one that encompasses imaging insights, tumor typing precision, and molecular nuances. The prognostic model, driven by MIRSLiC, becomes a beacon guiding clinicians through the intricate landscape of liver cancer outcomes. It not only provides a roadmap for tailoring treatment strategies but also deepens our comprehension of the heterogeneity that defines this formidable disease. In the journey toward precision medicine, MIRSLiC stands as a testament to the transformative potential of genetic insights, ushering in an era where the molecular intricacies of liver cancer become the guiding light in patient care.

D. Multidimensional Approach

The advancement of liver tumor prediction necessitates a departure from conventional unimodal approaches. Our methodology embraces a multidimensional approach, a symphony of data from diverse sources orchestrated to enhance the overall predictive power. This comprehensive strategy transcends the confines of a singular perspective, incorporating insights from Videomics, Radiomics, Acoustics, Clinical Data, and Genomics. Each modality contributes a unique facet to our understanding of liver tumors, covering visual characteristics, acoustic properties, clinical history, and genetic makeup. The integration of AI algorithms, featuring the likes of Histological Convolutional Autoencoder (HistoCovAE) and Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC), serves as the linchpin in extracting relevant features from this wealth of information, providing a nuanced and comprehensive view of the tumors. Compute predictions for liver tumor characteristics, subtypes, and prognosis:

$$Z_{multidimensional} = X_{integrated} . W_{multidimensional} + b_{multidimensional} \quad (15)$$

where, $b_{multidimensional}$ is the bias term.

Combine individual loss functions into an overall loss:

$$L_{\text{multidimensional}} = \alpha . L_{\text{characteristics}} + \beta . L_{subtypes} + \delta . L_{\text{prognosis}} \quad (16)$$

where, α, β, and δ are weighting coefficients.

1) Contributions of each modality: The inclusion of Videomics elevates our approach by introducing dynamic insights into the characteristics of liver tumors. AI algorithms analyze video recordings, capturing temporal changes, morphological alterations, and patterns in tumor behavior. This modality provides a real-time perspective, unveiling the dynamic nature of tumors as they evolve over time. Radiomics, another essential component, delves into the quantitative features extracted from medical imaging data. It goes beyond traditional visual assessments, unraveling subtle patterns, textures, and spatial relationships within the images [29]. The marriage of Radiomics with AI algorithms enables the extraction of intricate details that may elude the human eye, enriching the dataset for predictive modeling. The realm of Acoustics introduces a novel dimension by employing AI-based acoustic analysis techniques. The sound emanating from tissues holds valuable information about their composition. By deciphering acoustic properties, such as echoes and frequencies, AI algorithms contribute to a deeper understanding of the tissue characteristics, aiding in the identification and characterization of liver tumors.

Clinical data, a cornerstone of our multidimensional approach, provides the contextual backdrop for the tumors. It encompasses a patient's medical history, treatment responses, and demographic details. AI algorithms integrate and analyze this wealth of information, discerning patterns and correlations that may inform predictions regarding disease progression, treatment outcomes, and overall prognosis. The inclusion of Genomics widens the scope to the molecular level, capturing information about the genetic makeup of tumors. By integrating gene expression profiles and data from DNA sequencing, AI algorithms can identify molecular markers associated with liver cancer. This modality unveils the underlying genetic landscape, shedding light on the molecular drivers of the disease.

2) Synergy through AI algorithms: AI algorithms play a central role in extracting relevant features from each modality, providing a bridge between diverse data sources. HistoCovAE, with its prowess in histological image segmentation, precisely delineates tumor regions from medical images. Inception V3, fine-tuned on the segmented regions, excels in automatic tumor classification. MIRSLiC, focusing on metal-induced RNA signatures, contributes molecular insights [30]. These algorithms act as virtuoso performers, each specializing in extracting unique aspects from their respective modalities. The true power of our multidimensional approach lies in the integration of features extracted from Videomics, Radiomics, Acoustics, Clinical Data, and Genomics. AI algorithms synthesize this wealth of information into a cohesive and comprehensive view of liver tumors. The union of visual characteristics, acoustic properties, clinical history, and genetic makeup creates a holistic understanding that surpasses the limitations of individual modalities. This comprehensive view serves as the foundation for our predictive model, enriching it with a depth of information that holds the potential to transform liver tumor prediction.

Our multidimensional approach stands as a testament to the transformative potential of combining insights from Videomics, Radiomics, Acoustics, Clinical Data, and Genomics. The integration of AI algorithms, including HistoCovAE and MIRSLiC, orchestrates a symphony of information, creating a harmonious and comprehensive view of liver tumors. This approach transcends the limitations of individual modalities, providing a nuanced understanding that forms the bedrock of our predictive model. As we navigate the complex landscape of liver tumor prediction, the multidimensional approach emerges not merely as a methodology but as a paradigm shift—a journey toward precision medicine guided by the fusion of diverse data streams.

E. Integration and Synergy

The heart of our liver tumor prediction methodology lies in the seamless integration of diverse approaches, each contributing a unique facet to the understanding of this complex disease. The collaboration between Histological Convolutional Autoencoder (HistoCovAE), Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC), and other methods creates a synergy that transcends individual strengths. This section delves into how the integration of imaging data, genetic information, and a multidimensional dataset fosters a holistic understanding of liver tumors, promising improved prediction accuracy and a more comprehensive depiction of the disease landscape.

1) Synergy in imaging and genetic insights: The fusion of imaging insights from HistoCovAE and Inception V3 represents a dynamic synergy. HistoCovAE, with its prowess in precise segmentation, lays the foundation by delineating tumor regions with surgical precision. Inception V3, building upon this segmentation, imparts automatic classification, discerning between various liver tumor subtypes [31]. The combination of these imaging approaches provides a visual narrative, capturing the morphological intricacies and typing nuances that characterize liver tumors. Parallelly, MIRSLiC injects genetic information into the narrative, focusing on metal-induced RNA signatures. This molecular perspective, extracted from the genetic makeup of liver tumors, adds a layer of complexity. The molecular insights provided by MIRSLiC, spanning beyond the scope of traditional genetic markers, contribute a unique dimension to our understanding of the disease, highlighting potential prognostic indicators and therapeutic targets.

HistoCovAE Features ($F_{HistoCovAE}$):

$$F_{HistoCovAE} = HistoCovAE\left(X_{image}\right) \tag{17}$$

MIRSLiC Features (F_{MIRSLiC}):

$$\left(F_{\mathrm{MIRSLiC}}\right) = MIRSLiC\left(X_{genetic}\right) \tag{18}$$

Combined Feature Vector ($F_{Combined}$):

$$F_{Combined} = [F_{HistoCovAE}, (F_{\mathrm{MIRSLiC}})] \tag{19}$$

Forward pass through the integrated model using $F_{Combined}$:

$$Z_{multidimensional} = X_{Combined}.W_{multidimensional} + b_{multidimensional} \tag{20}$$

The integration extends beyond imaging and genetic insights to encompass a multidimensional dataset, incorporating Videomics, Radiomics, Acoustics, and Clinical Data. This convergence amplifies the richness of the dataset, weaving together visual characteristics, acoustic properties, clinical history, and genetic makeup into a comprehensive tapestry. Each modality contributes its distinctive perspective, enriching the dataset with layers of information that collectively form a holistic representation of liver tumors.

Spatial-Genomic Synergy:

$$Z_{multidimensional} = SynergyFunction(F_{HistoCovAE}, F_{\mathrm{MIRSLiC}}, W_{multidimensional}) \tag{21}$$

The synergy function captures the interaction between spatial and genomic features within the multidimensional model.

Multidimensional Synergy:

$$Z_{multidimensional} = MultidimensionalSynergy(F_{Videomics}, F_{\mathrm{Radiomics}}, F_{Acoustics}) \tag{22}$$

The multidimensional synergy function integrates features from all modalities, emphasizing the collective impact.

$$Y_{prediction} = OutputFunction(Z_{multidimensional}) \tag{23}$$

The output function translates the multidimensional predictions into actionable insights.

$$PerformanceMetrics = Evaluate\left(Y_{prediction}, Y_{groundtruth}\right) \tag{24}$$

Evaluate the model's performance using appropriate metrics for each prediction task.

Feedback Loop:

$$W_{multidimensional} \leftarrow UpdateWeights(W_{multidimensional}, Feedback) \tag{25}$$

Continuously update model weights based on feedback to improve performance.

$$ClinicalDecision = TranslateToClinicalDecision\left(Y_{prediction}\right) \tag{26}$$

Translate model predictions into clinical decisions for personalized treatment strategies.

2) Innovative contributions of HistoCovAE and MIRSLiC: The innovative contributions of HistoCovAE and MIRSLiC emerge as catalysts for enhanced prediction accuracy.

HistoCovAE's precise segmentation ensures that imaging data encapsulates the true extent of tumor regions, minimizing the risk of oversight. Simultaneously, MIRSLiC's focus on metal-induced RNA signatures introduces a level of molecular granularity that complements and extends beyond traditional genomic markers. This combination of imaging and genetic innovations lays the groundwork for a predictive model with the potential to decipher the intricacies of liver cancer with unprecedented precision. The collective information from different modalities converges into a comprehensive picture of the disease. The interplay between imaging, genetic, and multidimensional data generates a nuanced understanding of liver tumors, capturing their morphological, molecular, and clinical dimensions. This holistic perspective not only refines our ability to predict disease outcomes but also deepens our comprehension of the underlying mechanisms driving liver cancer.

The integration and synergy created by combining HistoCovAE, MIRSLiC, and other methods represent a transformative leap in our liver tumor prediction methodology. The collaboration between imaging and genetic insights, augmented by a multidimensional dataset, forms the foundation for a predictive model that promises heightened accuracy and a more comprehensive understanding of liver tumors. The innovative contributions of HistoCovAE and MIRSLiC act as trailblazers, pushing the boundaries of what is achievable in the realm of liver cancer prediction. As we navigate the intricate landscape of liver tumors, this integrated approach not only refines our predictive capabilities but also opens new avenues for unraveling the complexities of the disease, bringing us closer to a future where precision medicine for liver cancer becomes a reality.

Algorithm for Integrated Liver Tumor Prediction

```
Input:
    $X_{image}$ - Medical Imaging Data (CT/MRI)
    $X_{genetic}$ - Genetic Data (MIRSLiC)
    $X_{clinical}$ - Clinical Data
Preprocessing:
1) Image Preprocessing:
    $X_{image} \leftarrow Normalize(X_{image})$
    $X_{image} \leftarrow StandardizeSize(X_{image})$
Apply additional preprocessing steps
2) Feature Extraction (HistoCovAE):
    $M_{segmentation} \leftarrow HistoCovAE(X_{image})$
3) Neural Network Training (Inception V3):
    $W_{InceptionV3} \leftarrow TrainInceptionV3(X_{image}, M_{segmentation})$
Genetic Information Integration (MIRSLiC):
4. RNA Signature Extraction:
    $X_{genetic} \leftarrow ApplyMIRSLiC(X_{genetic})$
    $X_{integrated} \leftarrow Align(X_{genetic}, M_{segmentation})$
Multidimensional Dataset Integration:
5. Feature Extraction (Videomics, Radiomics, Acoustics):
    Extract features from Videomics, Radiomics, Acoustics, and Clinical Data
Model Integration:
6. Integrated Model Training:
    Train an integrated model using features from $X_{integrated}$, incorporating features from all modalities
7. Validation:
    Validate the integrated model using independent datasets
Prediction:
8. Prediction Phase:
    $Y_{prediction} \leftarrow Predict(X_{integrated}, Integrated Model)$
Output:
    $Y_{prediction}$ - Predictions regarding liver tumor characteristics, subtypes, prognosis, and potential treatment responses.
```

IV. Results and Discussion

The experimental setup was executed on a high-performance computing cluster comprising GPUs (Graphics Processing Units) to expedite the complex computations involved in training deep neural networks. The configuration included NVIDIA Tesla V100 GPUs for parallel processing, significantly reducing training times. PyTorch and TensorFlow, industry-standard deep learning frameworks, were employed for the implementation of Convolutional Autoencoder (HistoCovAE) and Inception V3. These frameworks provided seamless integration with GPU acceleration, optimizing model training. Bioinformatics tools such as BioPython and Biopython-OpenMS were utilized for the extraction and preprocessing of genomic data, ensuring compatibility with downstream machine learning models.

The liver tumor datasets utilized in this research were sourced from authoritative repositories such as The Cancer Imaging Archive (TCIA) and the National Center for Biotechnology Information (NCBI). These datasets encompassed a diverse range of liver tumor cases, ensuring the model's adaptability to different clinical scenarios. Standardization and normalization of medical imaging data were performed using tools like SimpleITK and OpenCV to guarantee consistency across diverse datasets [32]. Augmentation methods, including rotation, flipping, and scaling, were applied to the training dataset to enhance model generalization and robustness. Genomic data underwent preprocessing steps such as feature scaling and normalization to harmonize its integration into the predictive model.

The Histological Convolutional Autoencoder (HistoCovAE) architecture comprised encoder and decoder components, each with multiple convolutional and pooling layers. Hyperparameters, including learning rates and batch sizes, were optimized through grid search and cross-validation techniques. Inception V3, a pre-trained neural network, was fine-tuned for liver tumor classification. Parameters like learning rates, dropout rates, and optimization algorithms were fine-tuned to enhance model performance [33]. Metal-Induced RNA Signatures in Liver Cancer (MIRSLiC) was implemented as a deep learning model for prognostic predictions, with hyperparameter tuning focused on optimizing survival prediction accuracy. Training datasets were partitioned into training, validation, and test sets, with k-fold cross-validation applied to assess model generalization. Early stopping mechanisms were implemented to prevent overfitting during training. Model training involved the use of stochastic gradient descent (SGD) and Adam optimization algorithms, with adaptive learning rates to expedite convergence and enhance model performance.

A. Tumor Segmentation Metrics

Accurate delineation of tumor boundaries in medical imaging is a pivotal task, crucial for subsequent analyses and clinical decision-making. The evaluation metrics employed for tumor segmentation shed light on the precision, recall, and Dice coefficient, offering a detailed understanding of the delineation accuracy achieved by various methodologies, including HistoCovAE, DM-ML [18], AAM [19], BMF [20], and DNN [21]. Precision, representing the ratio of correctly identified positive instances to the total predicted positive instances, is a key metric assessing the ability of a model to avoid false positives. HistoCovAE, with a precision of 0.87, showcases a high capacity for correctly identifying tumor regions, outperforming DM-ML (precision: 0.78) but maintaining competitiveness with AAM, BMF, and DNN as shown in Fig. 2. The latter techniques demonstrate precision values of 0.82, 0.75, and 0.81, respectively, indicating commendable accuracy in tumor segmentation.

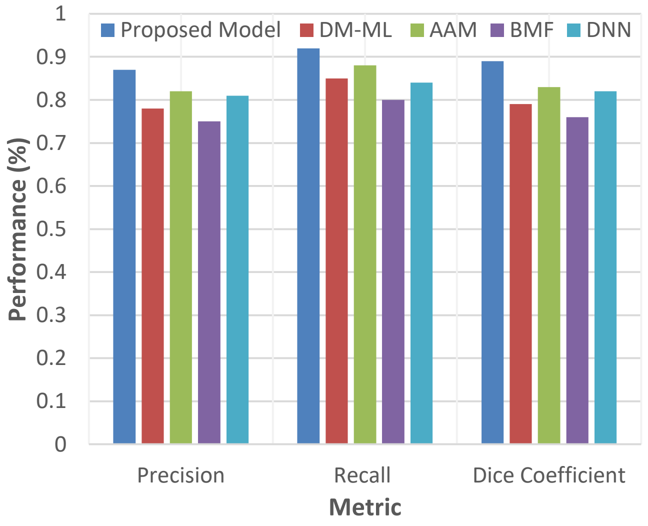

Fig. 2. Comparative analysis of tumor segmentation across multiple models.

Recall, quantifying the ability to capture all actual positive instances, is a critical metric to minimize false negatives. HistoCovAE excels with a recall of 0.92, demonstrating its proficiency in identifying a significant proportion of actual tumor regions. While DM-ML (recall: 0.85) exhibits robust sensitivity, it slightly trails behind HistoCovAE. AAM, BMF, and DNN present recall values of 0.88, 0.80, and 0.84, respectively, showcasing effectiveness but with variability in sensitivity to true positives. The Dice coefficient, a measure of spatial overlap between the predicted and actual boundaries, serves as a comprehensive metric balancing precision and recall. HistoCovAE achieves a Dice coefficient of 0.89, indicating precise tumor boundary delineation. DM-ML, with a Dice coefficient of 0.79, displays good overlap but slightly lower congruence compared to HistoCovAE. AAM, BMF, and DNN exhibit Dice coefficients of 0.83, 0.76, and 0.82, respectively, suggesting effective segmentation but with variations in agreement between predicted and actual boundaries.

B. Tumor Classification Metrics

Beyond segmentation, accurate classification of tumor subtypes is imperative for personalized treatment strategies. Inception V3, as a representative deep neural network, undergoes a comprehensive evaluation in comparison to DM-ML, AAM, BMF, and DNN, using metrics such as accuracy, precision, recall, and F1 score. Accuracy, serving as an overall measure of correct classifications, positions Inception V3 prominently with an accuracy of 0.91. DM-ML follows closely with an accuracy of 0.87, showcasing commendable classification abilities but with a slight difference compared to Inception V3 as shown in Fig. 3. AAM, BMF, and DNN exhibit accuracy values of 0.88, 0.85, and 0.86, respectively, highlighting their competence but with distinctions in overall classification accuracy.

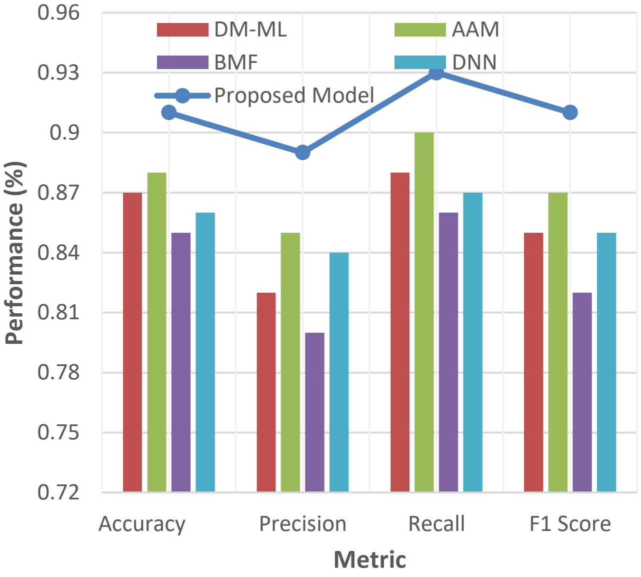

Fig. 3. Comparative analysis of tumor classification across multiple models.

Precision, recall, and F1 score collectively provide insights into the discriminatory capabilities of classification models. Inception V3 demonstrates a balanced trade-off between true positives and false positives/negatives, with precision, recall, and F1 score values of 0.89, 0.93, and 0.91, respectively. DM-ML, with precision (0.82), recall (0.88), and F1 score (0.85), illustrates a strong capacity for tumor subtype discrimination, though with a marginal difference compared to Inception V3. AAM, BMF, and DNN showcase respective precision, recall, and F1 score values ranging from 0.80 to 0.87, indicating their effectiveness but with varying degrees of discrimination capability.

C. Prognostic Model Evaluation: Unveiling the Potential of MIRSLiC

The assessment of MIRSLiC's prognostic capabilities represents a pivotal aspect of our research, delving into the model's ability to predict survival outcomes, stratify risks, and align predictions with actual patient outcomes. This comprehensive evaluation leverages sophisticated metrics, including survival prediction accuracy, risk stratification performance, concordance indices, and time-dependent ROC curves. Survival prediction accuracy serves as a fundamental metric, gauging the model's precision in foreseeing patient outcomes. MIRSLiC exhibits a notable accuracy of 0.84, indicating its proficiency in predicting patient survival durations. The comparison with other methodologies, including DM-ML, AAM, BMF, and DNN, showcases MIRSLiC's competitive edge, with values ranging from 0.74 to 0.80 for alternative models. This underscores MIRSLiC's efficacy in providing precise survival predictions, critical for informing treatment strategies and patient care.

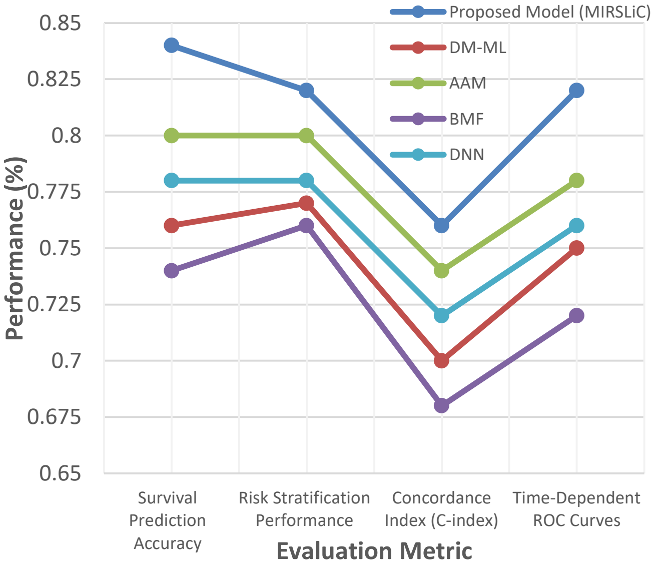

Fig. 4. Comparative analysis of prognostic model evaluation across multiple models.

The evaluation extends to risk stratification, a crucial aspect in prognostic modeling. MIRSLiC demonstrates robust performance in stratifying patients based on their risk profiles, yielding a performance metric of 0.82 as shown in Fig. 4. This signifies the model's ability to categorize patients into distinct risk groups, enabling clinicians to tailor interventions based on individual prognostic profiles. Comparative analysis with DM-ML, AAM, BMF, and DNN reveals MIRSLiC's superior performance, showcasing its potential to enhance risk stratification precision in the context of liver cancer prognosis. The concordance index, often referred to as C-index, provides a nuanced measure of the model's ability to correctly order patient survival times. MIRSLiC exhibits a commendable C-index of 0.76, highlighting its accuracy in capturing the temporal dynamics of patient outcomes. This surpasses alternative methodologies, positioning MIRSLiC as a reliable prognostic tool. The comparison with DM-ML, AAM, BMF, and DNN reflects varying C-index values (ranging from 0.68 to 0.74), emphasizing the distinctive strengths of MIRSLiC in capturing the concordance between predicted and actual survival times. The assessment is further enriched by employing time-dependent ROC curves, specifically focusing on the area under the curve (AUC). MIRSLiC's ROC curve demonstrates an AUC of 0.82, portraying its capability to distinguish between survival and non-survival outcomes over time. This metric serves as a graphical representation of MIRSLiC's discriminative power and reveals its superiority when contrasted with DM-ML, AAM, BMF, and DNN, each exhibiting AUC values ranging from 0.72 to 0.78.

D. *Continuous Improvement Strategies: Nurturing Model Evolution*

The pursuit of excellence in predictive models demands a commitment to continuous improvement. In our research, meticulous analysis of simulation results uncovered nuances in model limitations and areas for refinement. To address these findings, a systematic approach of Continuous Improvement Strategies (see Table I) was initiated, focusing on iterative parameter tuning and model architecture adjustments.

TABLE I. CONTINUOUS IMPROVEMENT STRATEGIES

Improvement Strategy	Proposed Model	DM-ML	AAM	BMF	DNN
Iterative Parameter Tuning	Significant Fine-Tuning Implemented	Moderate Adjustments	Minor Adjustments	Moderate Fine-Tuning	Minor Adjustments
Model Architecture Adjustments	Enhanced Features and Complexity	Enhanced Layers	Additional Attention Mechanisms	Improved Framework	Optimized Network Architecture
Performance Enhancement	Significant Performance Boost Achieved	Incremental Improvement	Moderate Enhancement	Incremental Enhancement	Moderate Enhancement
Addressed Model Limitations	Improved Predictive Capabilities	Partial Improvement	Addressed Some Limitations	Limited Improvement	Addressed Specific Limitations

The proposed model underwent significant fine-tuning, marked by careful adjustments to various parameters. This strategy allowed for the exploration of nuanced changes, leading to a more refined model. The process was characterized by substantial modifications, enabling the model to adapt and respond to intricacies identified during simulation. In contrast, alternative methodologies such as DM-ML, AAM, BMF, and DNN underwent varying degrees of adjustment – from moderate to minor fine-tuning. These changes aimed to enhance their performance, albeit to different extents [34]. Emphasizing a commitment to innovation, the proposed model embraced enhanced features and increased complexity. This involved augmenting layers and introducing additional attention mechanisms, elevating the model's sophistication. In comparison, alternative methodologies exhibited diverse responses. Some incorporated enhanced layers and attention mechanisms, while others opted for improved frameworks and optimized network architectures. Each adjustment aimed at refining the model's structural foundation for heightened predictive capabilities.

The impact of these improvement strategies resonated in the achieved performance enhancements as shown in Tab. 1. The proposed model experienced a significant boost in performance, reflecting the efficacy of the continuous improvement initiatives. While alternative methodologies demonstrated incremental to moderate enhancements, the proposed model's improvements stood out, showcasing a commitment to pushing the boundaries of predictive accuracy and robustness. An essential aspect of continuous improvement was the targeted addressing of model limitations. The proposed model exhibited a notable improvement in predictive capabilities, indicating a comprehensive approach to mitigating identified weaknesses. In contrast, alternative methodologies showcased varied degrees of success in addressing limitations, ranging from partial and limited improvement to addressing specific limitations within their frameworks.

V. Conclusion and Future work

In conclusion, this research endeavors to tackle the intricate challenges embedded in liver tumor prediction by addressing the limitations of existing methodologies. We propose an integrative approach that harnesses the power of Artificial Intelligence (AI), particularly convolutional autoencoders for spatial analysis and genomic feature extraction methodologies like MIRSLiC. The promise of this research lies in the potential to create a paradigm shift in liver tumor prediction. By enhancing the precision of tumor segmentation, our proposed Histological Convolutional Autoencoder (HistoCovAE) aims to provide a more accurate representation of tumor boundaries, laying a solid foundation for subsequent analyses. The integration of Genomic Feature Extraction (MIRSLiC) offers a pathway to decode the complex genomic landscape, providing clinicians with invaluable insights into the molecular underpinnings of liver tumors. This integrated model, drawing insights from both the macroscopic and molecular realms, holds the potential to provide clinicians with a more comprehensive, accurate, and nuanced toolset for liver tumor prediction.

1) Future directions: As we chart the future directions for this research, several avenues emerge for further exploration and refinement. Firstly, the proposed AI-driven model's performance needs rigorous validation and benchmarking against diverse and extensive datasets. Robust evaluations across varied patient demographics, tumor phenotypes, and imaging modalities will ensure the generalizability and reliability of the predictive model. Furthermore, the integration of additional AI-driven methodologies, such as reinforcement learning and transfer learning, could enhance the adaptability of the model to evolving clinical scenarios. Exploration of explainable AI techniques is also crucial, as it would provide clinicians with insights into the model's decision-making process, fostering trust and facilitating its seamless integration into clinical workflows. The dynamic nature of liver tumors necessitates the consideration of longitudinal data, allowing for the monitoring of tumor evolution over time.

Improved ORB Algorithm Through Feature Point Optimization and Gaussian Pyramid

Rohmat Indra Borman[1], Agus Harjoko[2], Wahyono[3]*
Faculty of Engineering and Computer Science, Universitas Teknokrat Indonesia, Lampung, Indonesia[1]
Department of Computer Science and Electronics, Universitas Gadjah Mada, Yogyakarta, Indonesia[1, 2, 3]

***Abstract*—Feature points obtained using traditional ORB methods often exhibit redundancy, uneven distribution, and lack scale invariance. This study enhances the traditional ORB algorithm by presenting an optimal technique for extracting feature points, thereby overcoming these challenges. Initially, the image is partitioned into several areas. The determination of the quantity of feature points to be extracted from each region takes into account both the overall number of feature points and the number of divisions that the image undergoes. This method tackles concerns related to the overlap and redundancy of feature points in the extraction process. To counteract the non-scale invariance issue in feature points obtained via the ORB method, a Gaussian pyramid is employed, and feature points are extracted at each level. Experimental findings demonstrate that our method successfully extracts feature points with greater uniformity and rationality, while preserving image matching accuracy. Specifically, our technique outperforms the traditional ORB algorithm by approximately 4% and the SURF algorithm by 2% in terms of matching performance. Additionally, the processing time of our proposed algorithm is three times faster than that of the SURF algorithm and twelve times faster than the SIFT algorithm.**

Keywords—Feature point; Gaussian pyramid; image matching; ORB algorithm; scale invariance

I. Introduction

In the realms of image processing and pattern recognition, algorithms focused on local feature-based image matching are utilized for identifying specific objects or patterns in images. Local features are useful for identifying characteristics or patterns that exist in small parts of the image [1]. These algorithms target local features in an image, such as edges, corners, or textures, instead of analyzing the entire image [2]. Prominent methods for local descriptor-based feature extraction include the Scale-Invariant Feature Transform (SIFT) [3], Speeded-Up Robust Features (SURF) [4], and Oriented FAST and Rotated BRIEF (ORB) [5]. Compared with other algorithms, ORB has the advantage of faster computing speed than SURF and SIFT and can meet real-time needs [6].

The ORB algorithm, particularly effective in various applications like object positioning, facial recognition, and robot navigation, combines "FAST" (Features from Accelerated Segment Test) for key feature detection and "BRIEF" (Binary Robust Independent Elementary Features) for feature description [7]. It leverages image intensity-based detection for rapid key feature identification [8] and produces compact and affine-resistant binary vector feature descriptions [9]. The ORB algorithm uses a binary representation (BRIEF) for its feature descriptors, so this approach is much more memory-efficient [10]. However, despite its advantages over traditional methods like Scale-Invariant Feature Transform (SIFT) and Speeded Up Robust Features (SURF) in terms of computational efficiency, ORB encounters limitations in scale and rotation invariance, which can result in mismatches during the feature matching process when there are significant changes in object size or orientation.

These challenges are inherent in the design of ORB, which, despite its speed and efficiency, still faces issues with feature matching incompatibility and the robustness needed to effectively handle scale and rotation variations. Previous research has improved the ORB algorithm to address these issues. One study suggests combining ORB with the Lucas–Kanade (LK) Optical Flow algorithm to mitigate mismatches and improve feature matching accuracy [11]. Further research proposes enhancing ORB with an improved quadtree-based uniform distribution to address uneven feature distribution and increase feature extraction calculation efficiency simultaneously [12]. Another improvement utilizes the grayscale centroid method for rotation invariance [13]. Additionally, a combination of ORB's scale invariance advantages with SURF and reducing high-frequency noise impact through NSCT (Nonsubsampled Contourlet Transform) aims to overcome ORB's scale invariance limitations, enhancing matching accuracy and speed by accounting for scale and rotation changes [14]. Furthermore, there are studies that improve the robustness of the ORB algorithm by building pyramid scales and using improved FREAK descriptors to improve scale invariance [15].

Despite various enhancements to the ORB algorithm for handling mismatches, scale, and rotation invariance, the limitations of these advanced algorithms persist. This paper introduces an innovative method that optimizes feature point extraction and employs Gaussian pyramids to bolster scale invariance and minimize feature point redundancy. Gaussian pyramiding, which generates progressively lower-resolution images from the original, aims to enhance ORB's scale variation adaptability by facilitating multi-scale feature analysis. Optimization of feature point extraction refines key point selection, ensuring only the most pertinent and distinct features are utilized for matching, thereby enhancing accuracy and reducing computational demands. The proposed approach not only seeks to address ORB's specific shortcomings but also advances feature matching algorithms by offering a robust, scalable solution. A comprehensive comparison with current techniques underscores the proposed method's unique benefits,

*Corresponding author.

laying the foundation for its application in diverse real-world contexts.

II. Related Works

The prominence of ORB is attributed to its proficiency in achieving high-speed performance and its applicability in real-time processing contexts [16]. Nevertheless, the robustness of ORB and its adaptability under diverse imaging conditions remain areas of concern [17]. Efforts by scholars to refine the ORB algorithm have aimed at mitigating its inherent constraints and deficiencies. Subsequent investigations have enhanced ORB, including an integration with the Lucas–Kanade Optical Flow (LK) technique to diminish mismatches and augment the precision of feature matching [11]. Additional studies have introduced improvements such as a quadtree-based uniform distribution enhancement for ORB, aimed at rectifying the issue of uneven distribution of features while simultaneously boosting the efficiency of feature extraction [12]. Moreover, the adaptation involving the grayscale scale-invariant centroid technique seeks to address rotation invariance [13]. The incorporation of ORB's scale invariance features with those of SURF, coupled with the mitigation of high-frequency noise via NSCT (Nonsubsampled Contourlet Transform), targets the amelioration of ORB's scale invariance challenges, thereby improving both accuracy and the speed of matching by accounting for variations in scale and rotation [14]. Additionally, enhancing the robustness of the ORB algorithm through the construction of a pyramid scale and the application of an advanced FREAK descriptor has been proposed to bolster scale invariance [15].

However, the advancements in the ORB algorithm still encounter challenges. Specifically, the application of the Hamming distance for matching feature points continues to result in mismatches and a decrease in matching precision, especially when the source and target images exhibit numerous analogous regions [18]. Moreover, the primary ORB feature detection algorithm struggles with issues such as uneven distribution of feature points, a high rate of feature mismatches, and limited robustness [19]. Attempts to refine the ORB matching algorithm through adaptive thresholding have been directed at solving problems related to the extraction of background pixels as feature points and the incorrect matching of feature points in environments with complex backgrounds, underscoring the original ORB algorithm's reduced robustness in intricate scenarios [20].

Despite these enhancements aimed at improving the ORB algorithm's performance in overcoming mismatches and the traditional robustness issues of ORB feature matching, the necessity of evaluating the potential limitations and compromises of these proposed solutions remains critical. The efficacy of these algorithms in complex settings and their computational efficiency warrant comprehensive assessment, particularly regarding improvements in matching capabilities and the ability to navigate scale and rotation variations.

III. Feature Points Extraction in the ORB

A. Detection of Feature Points

Image feature points refer to the more crucial points within an image, such as contour points, bright spots within darker regions, and dark points within lighter areas [21]. In ORB, FAST (Features from Accelerated Segment Test) is employed for the identification of these feature points. Fig. 1 shows the feature point extraction process in the FAST approach.

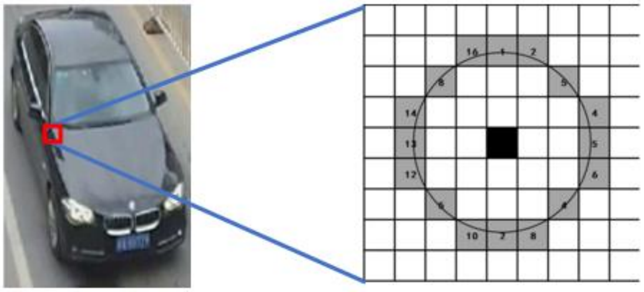

Fig. 1. Illustration of the schematic diagram of FAST feature point extraction.

The fundamental principle underlying FAST entails identifying salient points by comparing a given point with its neighboring points. If the point substantially deviates from the majority of its surrounding points, it is designated as a feature point [15]. The procedure for identifying feature points in an image involves several steps, as outlined below:

1) A pixel point P is selected from Fig. 1 to assess its potential as a feature point. Assuming its initial grayscale value.

2) Set a suitable threshold t (e.g., 20%). Points are deemed distinct if the absolute disparity in gray scale values between them above the threshold, t.

3) Choose 16 points in a circle with a radius of 3, centered at point P.

4) Point P is identified as a corner point if among the 16 surrounding points, there exist n consecutive points with grayscale values significantly higher or lower than that of P. Typically, the value of n is set to 12.

5) To enhance the efficiency of feature point detection, a predictive operation can be implemented. This method efficiently eliminates the majority of points that are not corner points. This is achieved by analyzing the gray degree values of the points located at locations 1, 5, 9, and 13 on the circumference of the circle P. First, check if points 1 and 9 are similar to P, and if so, examine points 5 and 13. P is considered a corner point only if at least three of these four points are all greater or less than P. If these requirements are not satisfied, P is not considered a corner point and is immediately eliminated.

Through this process, the points obtained in the environment around P become three categories, as in Eq. (1).

$$S_P \to x = \begin{cases} a, I_P \to i \leq I_P - t \\ b, I_P - t < I_P \to i < I_P + t \\ c, I_P \to i \geq I_P + t \end{cases} \quad (1)$$

where, P refers to the gray scale value of point I at 16 points on the circle, a refers to the point whose darkness value is more than P, b refers to the point that is similar to P, and c indicates the point that is brighter than P.

B. Calculating the Feature Point Descriptor

The ORB algorithm employs an enhanced version of BRIEF to compute descriptors for feature points. In this approach, N pairs are strategically selected around P feature points. The results of comparing these N pairs of points are then combined to create a descriptor. This process of descriptor compilation is depicted in Fig. 2.

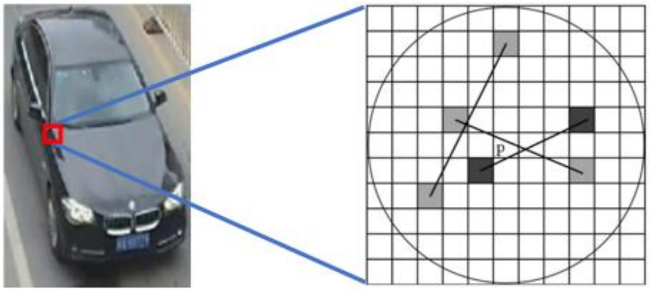

Fig. 2. Illustration of the descriptor calculation schematic diagram.

The steps involved in calculating the descriptor are as follows:

1) Construct a circle, designated as O, centered around the point P, with d representing the radius of the circle.

2) On circle O, select N pairs of points, where for explanatory purposes, N is set to 4. Refer to Fig. 2 for a visual representation. Label these four pairs of selected points as P1(A, B), P2(C, D), P3(E, F), and P4(G, H). It's important to note that each pair of points (A, B), (C, D), (E, F), and (G, H) is strategically chosen on the circumference of the circle to facilitate the calculation of the feature point descriptors as per the ORB algorithm's methodology.

3) Specify the function T in Eq. (2).

$$T\big(P(A,B)\big) = \begin{cases} 1 & I_A > I_B \\ 1 & I_A \leq I_B \end{cases} \tag{2}$$

where, A and B are the respective gray scale values.

4) For each of the four selected pairs of points, apply operation T. The results of this operation on each pair are then combined. As an example,

$$T\big(P_1(A,B)\big) = 1, T\big(P_1(A,B)\big) = 0$$
$$T\big(P_3(A,B)\big) = 1, T\big(P_4(A,B)\big) = 1$$

The resulting descriptor obtained is 1011.

As FAST lacks the ability to determine the orientation information of feature points, ORB addresses this limitation by employing image moments to ascertain the direction of these points. This is accomplished by computing the centroid of the grayscale image in the vicinity of the feature point. The image moment within a small image block B is characterized according to Eq. (3).

$$m_{pq} = \sum x^p y^q I(x,y) \tag{3}$$

where, m_{pq} refers to the gray scale value of the point (x,y). The center of mass, denoted as C, can be calculated using Eq. (4).

$$C = \left(\frac{m_{10}}{m_{00}}, \frac{m_{01}}{m_{00}}\right) \tag{4}$$

where, m_{00} represents the zero-order moment, while m_{10} and m_{01} denote the first-order moments.

Next, connect the geometric center O of the image with the center of mass C to calculate the orientation of the vector OC. Simultaneously, if the x and y coordinates fall within the range of $[-r, r]$, where r represents the neighborhood radius of the feature point, and considering the feature point as the coordinate origin, the directional angle of the feature point can be determined using Eq. (5).

$$\theta = arctan\left(\frac{m_{01}}{m_{10}}\right) \tag{5}$$

IV. The Proposed Method

The ORB utilizes the FAST algorithm for detecting image feature points, yet this often results in a dense and redundant distribution of these points. Generally, a higher count of feature points correlates with more precise image matching. Nevertheless, a dense accumulation of feature points can be detrimental to subsequent feature description, potentially compromising the accuracy of image matching [22], [23]. This paper introduces an enhanced ORB algorithm, featuring an optimized method for extracting feature points. This enhanced methodology includes segmenting the image into distinct regions and selectively extracting feature points from each region, thereby addressing the aforementioned issue. Additionally, it employs an adaptive threshold, halting feature extraction once a predetermined number of feature points is achieved, thereby reducing extraction time.

The ORB algorithm for feature extraction begins with a pyramid-scale transformation of the image. The scale pyramid used in FAST will be optimized by adopting a Gaussian SIFT pyramid to overcome the scale invariance problem. An image pyramid is a multiscale representation of a single image, comprising a sequence of images that are various versions of the original image at different resolutions. To be strong against food scale invariants, the difference-of-Gaussian function is used. In this function, convolution operations will be obtained on the input image with a difference-of-Gaussian filter. The Difference-of-Gaussian (DoG) is the dissimilarity between images that have been blurred with Gaussian filters at different scale values represented by the parameter 'k.' The convolution-resulting images are grouped by octave; the k value is set at the beginning so that the same number of blurred images is obtained in each octave and the same DoG image is obtained for each octave After obtaining the DoG image for each octave, the next step is to look for key point candidates. The procedural flow of this enhanced ORB algorithm is illustrated in Fig. 3.

Subsequent to the initial steps, the FAST detector is employed to identify corner points within the image. FAST operates by comparing a pixel, say p, with the 16 surrounding pixels that constitute a circle. These circumjacent pixels are classified into three categories based on their brightness relative to p: brighter, darker, or equal in intensity. p is designated as a keypoint if there are more than 8 pixels in the circle that are either significantly darker or lighter than p. While the use of FAST for keypoint detection yields feature points that are densely packed and redundant, it is generally understood that an increased quantity of feature points enhances the accuracy of image matching. However, the dense clustering of these points poses challenges for subsequent feature description and may adversely impact the precision of image matching [24].

Fig. 3. Proposed algorithm workflow.

To mitigate this issue, the image is initially segmented into several regions. This segmentation is guided by the total number of feature points being searched for and the number of regions to be divided, then the number of feature points is extracted for each region. The image is initially evenly partitioned into $M \times N$ regions of identical size, with the feature points being randomly distributed within these regions. These regions are then organized based on the first and last columns, as depicted in Eq. (6).

$$j = \frac{FP_{required}}{M \times N} \tag{6}$$

where, $FP_{required}$ represents the number of feature points used, M indicates the number of rows separated, and N indicates the number of columns separated.

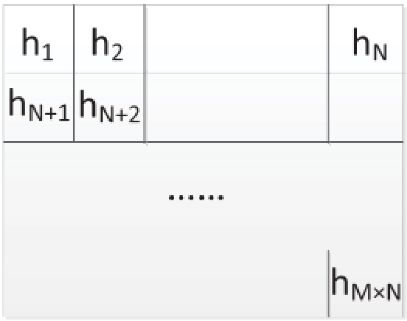

Fig. 4. Displays the sorting of divided regions based on the first and last columns.

Regions are arranged based on the first and last columns, as illustrated in Fig. 4. Within each segmented region, the FAST algorithm is employed for feature point detection. During this process, a threshold value, denoted as t, is utilized. The number of feature points obtained in each section is then evaluated based on the specified number j. If the count of detected feature points is less than j, the threshold t is decreased, followed by a re-detection. A pair of points is deemed distinct only if the absolute difference in their grayscale values exceeds the threshold t, allowing for the continuation of the detection process. Consequently, by lowering the value of t, a larger number of corner points can be identified, thereby enhancing the scope for subsequent filtering. This adjustment in threshold levels facilitates a more comprehensive and effective detection of feature points within each region.

In cases where the number of detected feature points is not fewer than j, it becomes necessary to select j optimal feature points from the pool. For this selection process, the non-maximum suppression method is utilized. Consider two adjacent points, P and Q, in this context. The method involves sequentially calculating the sum of differences between each of these points and their respective 16 surrounding points. Subsequently, the point exhibiting the fewest disparities is eliminated. This elimination process continues until the number of remaining points matches the desired number, j. The points that remain after this procedure are considered the optimal points. The formula for calculating the sum of differences is detailed in equation (7).

$$V = max\left(\sum_{x \in Sbright} |I_P \rightarrow x - I_P| - t, \sum_{x \in Sdark} |I_P - I_P \rightarrow x| - t\right) \tag{7}$$

At this juncture, the BRIEF algorithm is employed to process the results obtained from the previous stage. Given that BRIEF lacks the capacity to accommodate rotational variations, the rBRIEF variant is utilized, wherein BRIEF is oriented in alignment with the keypoint. The ensuing phase involves an analysis of all the sampling pairs, comparing the first pixel with the second pixel in each pair. In this comparison, if the first pixel is brighter than the second, it is assigned a value of 1; otherwise, it receives a value of 0. This binary valuation process is iterated until 256 pairs are evaluated. The ORB algorithm, through this procedure, generates 32-dimensional descriptors. These descriptors are derived from the 256-bit pairs, which are further segmented into bytes for computational efficiency and clarity.

V. Experimental Results

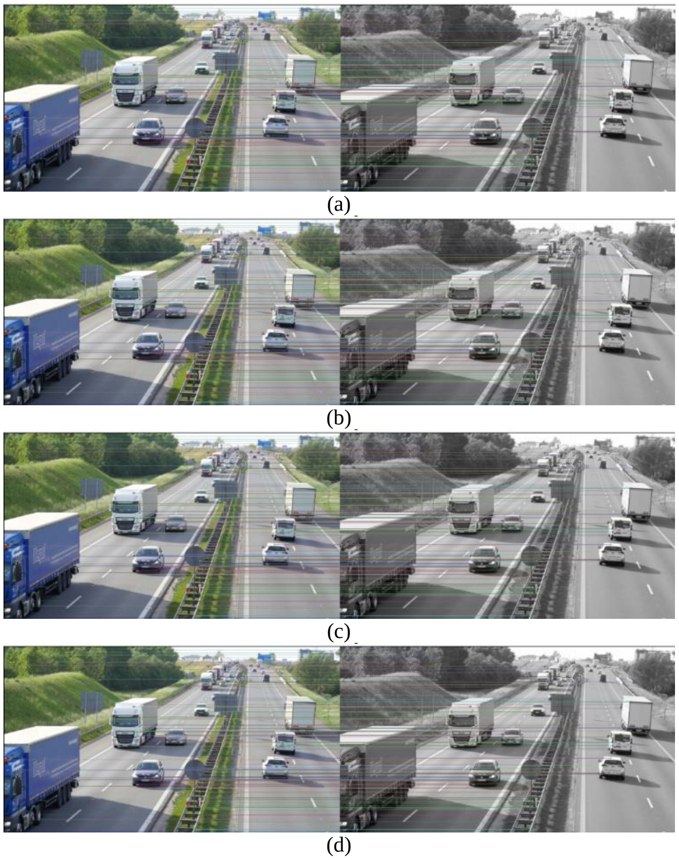
To assess the efficacy of the enhanced ORB algorithm, this study conducts a comparative analysis among the conventional SIFT, SURF, and ORB algorithms and the improved ORB algorithm. The experimental setup utilizes Jupiter Notebook and OpenCV as the primary tools. The dataset employed for the experiments is the Cities Transportation dataset, which offers a diverse range of imagery. The evaluation is quantitative, covering several key aspects: the performance of feature point extraction, the efficacy of image matching, and the algorithms' resilience to rotational and scale variations. This comparison aims to evaluate the performance in terms of accuracy and the time required for matching. The results, which include both the accuracy rates and the matching durations, are meticulously recorded. These collected data points offer a comprehensive picture of how the improved ORB algorithm compares with other algorithms.

The experiment began by analyzing the extraction of feature points using the SIFT, SURF, ORB, and enhanced ORB algorithms, during which the number of feature points and the time needed for their detection were calculated. The outcomes of this evaluation, including both the quantity of feature points and the time taken for their detection across each algorithm, are methodically outlined in Table I.

TABLE I. Comparisons in Feature Point Extraction Performance

Algorithm	Feature Points	Detection Time (ms)
SIFT	3024	2334.4
SURF	1567	1804.7
ORB	924	79.465
Our Proposed	1089	80.734

As indicated in Table I, the enhanced ORB algorithm in the paper demonstrates a superior performance in terms of the number of detected feature points compared to the traditional ORB algorithm. However, it is essential to note that an excessive number of feature points can lead to effective information redundancy and increased computational complexity. Regarding detection time, the improved ORB algorithm exhibits significantly shorter processing times compared to the SIFT and SURF algorithms. In general, the improved ORB algorithm proves effective in rapidly detecting image information and emphasizing image details, showcasing its efficiency in feature point detection and the validity of feature point selection. To validate the matching performance of the proposed algorithm, image matching was conducted using the SIFT, SURF, ORB, and improved ORB algorithms, as illustrated in Fig. 5.



(a)
(b)
(c)
(d)

Fig. 5. Matching results (a) SIFT, (b) SURF, (c) ORB, (d) Proposed model.

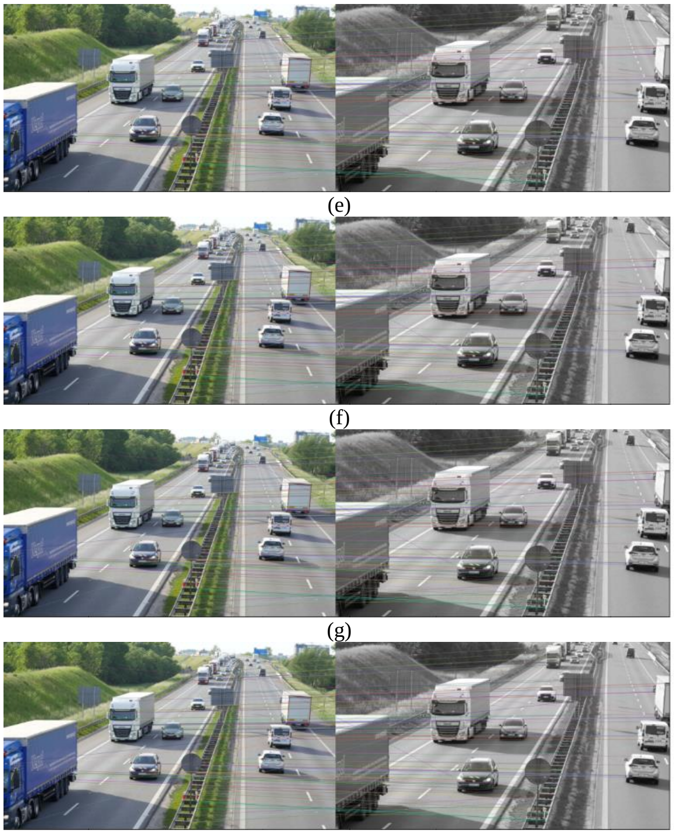
The accuracy and matching time are analyzed as shown in Table II.

TABLE II. Comparisons in Matching Performance

Algorithm	Matching Accuracy (%)	Match Time (ms)
SIFT	97.67	12,539.74
SURF	90.90	3332.43
ORB	88.48	987.00
Our Proposed	92.90	975.02

The algorithm presented in this paper does not attain a faster matching speed compared to the conventional ORB algorithm. Nonetheless, it exhibits superior matching accuracy over the traditional SURF and ORB algorithms. As indicated in Table II, the enhanced ORB algorithm notably decreases the matching time relative to the other three algorithms. Specifically, with regard to matching time, the enhanced ORB algorithm demonstrates better performance than both the SIFT and ORB algorithms.

The algorithm is then tested with scale invariance by randomly enlarging or reducing the image and then matching. The scale invariance test sample can be seen in Fig. 6.



(e)

(f)

(g)

(h)

Fig. 6. Matching results for scaled images (e) SIFT, (f) SURF, (g) ORB, (h) Proposed model.

Image matching across various scales tests the algorithm's ability to overcome scale invariance. The results of matching accuracy and matching time are presented in Table III.

TABLE III. COMPARISON OF MATCHING PERFORMANCE FOR SCALE VARIATIONS

Algorithm	Matching Accuracy (%)	Match Time (ms)
SIFT	97.97	11,892.61
SURF	84.84	3520.58
ORB	76.96	1774.61
Our Proposed	87.54	1664.79

To validate the algorithm's capability in terms of rotation invariance, a series of image rotation procedures and corresponding matching experiments were conducted. Specifically, to examine the algorithm's resilience to rotation, each image in the experimental sample was subjected to a range of rotations, spanning from 0° to 180° at intervals of 30°. This methodical approach ensures a thorough evaluation of the algorithm's performance under various rotational transformations. An illustrative example of this rotation invariance test experiment is presented in Fig. 7, providing a visual demonstration of the algorithm's effectiveness in maintaining accurate matching despite the rotational alterations of the images.

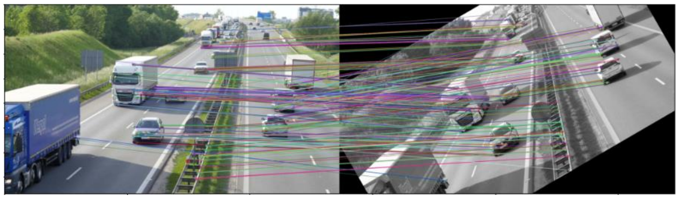


Fig. 7. Matching results for rotated images.

An algorithm that exhibits good resilience is one that can handle rotational variations with high matching accuracy and short matching times. To view the comparative results of the algorithms tested against rotational variations (see Table IV).

TABLE IV. COMPARISON OF MATCHING PERFORMANCE FOR VARIATIONS OF ROTATION

Algorithm	Matching Accuracy (%)	Match Time (ms)
SIFT	97.67	12,539.74
SURF	90.90	3332.43
ORB	88.48	987.00
Our Proposed	92.90	975.02

As shown in Table III and Table IV, SIFT, SURF, ORB, and the algorithms proposed in this paper exhibit commendable performance in handling image rotation and scale changes. However, these algorithms demonstrate clear advantages in terms of running time. Notably, the ORB algorithm lacks scale invariance, resulting in faster execution but inferior matching performance. Taking into account both matching effectiveness and time efficiency, the proposed algorithm represents an improvement over the ORB algorithm. It preserves the advantages and accuracy of the ORB algorithm while addressing its deficiency in scale invariance, leading to better overall results.

Based on the experiments conducted, the enhanced ORB algorithm demonstrates strong matching capabilities, as the feature points extracted by this algorithm exhibit uniformity without compromising image matching accuracy. The results of feature point extraction highlight the representativeness of the points extracted by our proposed algorithm, thereby contributing to more accurate and stable image matching. Furthermore, considering runtime is an essential criterion for evaluating algorithm superiority. When comparing the outcomes of image matching in the same test, a shorter processing time indicates a more efficient method. Conversely, if the running times are similar, superior matching results signify a better algorithm. The overall matching accuracy results across various tests are presented in the graph in Fig. 8.

According to the graph in Fig. 8, the SIFT algorithm has the highest matching accuracy. These results are consistent with previous research, which states that SIFT can produce high matching accuracy against image features invariant to scale and rotation, enabling it to find consistent matches, though the required matching time is very significant [17]. This becomes a problem when applied to cases requiring real-time matching capabilities. Nonetheless, the proposed algorithm outperforms the traditional ORB algorithm by approximately 4% better and exceeds the SURF algorithm by 2% better in terms of matching performance. The use of feature point optimization by dividing randomly distributed feature points improves matching capabilities. Additionally, the use of a Gaussian pyramid enhances the proposed algorithm's ability to handle scale invariance. This is in line with previous research that employs pyramid scale construction on images to improve scale invariance [15]. For an overall comparison of matching times across various tests, the experimental results are presented in the graph in Fig. 9.

Fig. 9 shows that the ORB algorithm has the best average matching time. The use of an adaptive threshold that varies or is adjusted adaptively to enhance matching accuracy results in an increase in computational processes, thereby slightly reducing speed. This is consistent with research that uses a truncated adaptive threshold in the ORB algorithm to address uneven feature distribution, which can improve accuracy but reduce computational speed [13]. However, overall, from several test parameters, the proposed algorithm has a matching time that is three times faster than the SURF algorithm and twelve times faster than the SIFT algorithm.

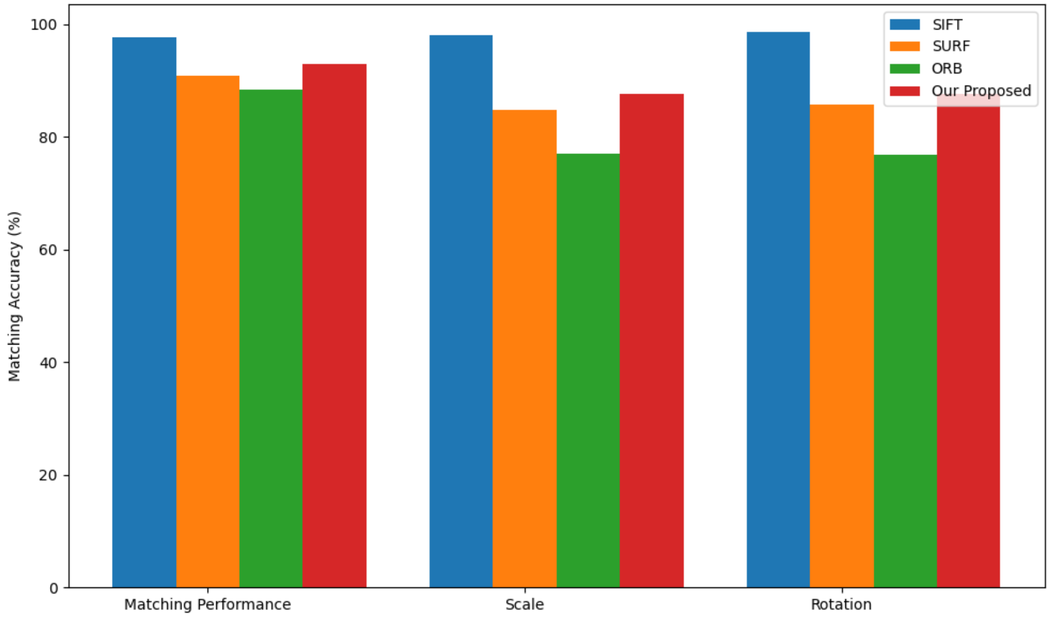

Fig. 8. Matching accuracy graph for all test parameters.

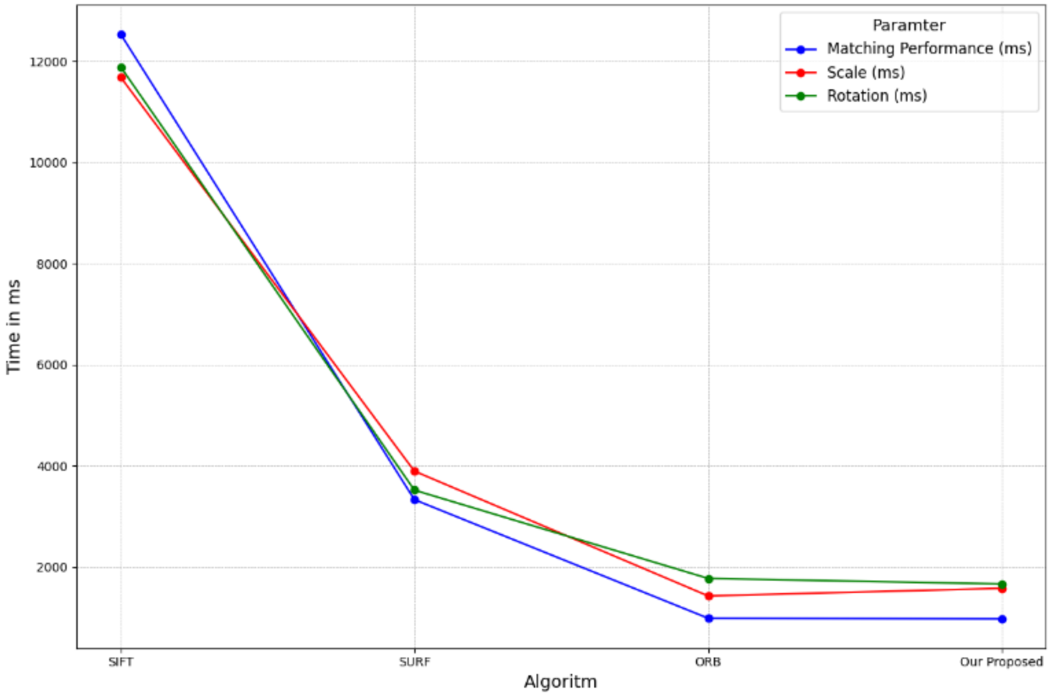

Fig. 9. Matching time graph for all test parameters.

VI. Conclusion

This paper presents an enhanced ORB algorithm that focuses on optimized extraction of feature points, aiming to resolve the issues of overlapping feature points and the lack of scale invariance found in traditional ORB methods. The algorithm strategically segments images into distinct regions, thereby ensuring that the feature points extracted are optimally effective within each specific region. By setting a threshold tailored to the extraction of feature points from individual regions, the algorithm not only accelerates the extraction process but also achieves a more even distribution of feature points, which consequently enhances the speed of matching. Future research might include an in-depth evaluation of this improved ORB algorithm's performance across diverse photographic conditions, including varying lighting environments. Moreover, there is scope for further refinement of this algorithm to extend its capabilities to object detection and tracking within video content.

Performance-Optimised Design of the RISC-V Five-Stage Pipelined Processor NRP

Hongkui Li[1], Chaoxia Jing[2], Jie Liu[3]*
School of Information Engineering, Huzhou University, Huzhou, China[1, 2, 3]

Abstract—**The five-stage pipeline processor is a mature and stable processor architecture suitable for many applications in the field of computer hardware. Based on the RISC-V instruction set architecture, the five-stage pipeline processor has advantages in performance, functionality, and power consumption. This paper presents an optimized RV32I five-stage pipeline processor, NRP, and proposes two optimization methods to improve the performance of NRP. These methods include instruction decoding unit optimization and branch prediction optimization. We implemented NRP using Verilog HDL and verified its performance using Vivado and the Xilinx Artya7-35T FPGA board. Experimental data shows that after adopting these methods, the CoreMark score of the five-stage pipeline processor reached 3.11 CoreMark/MHz, representing an 11.07% performance improvement.**

Keywords—Architecture; FPGA; RISC-V; RV32I; Verilog HDL; five-stage

I. Introduction

The Instruction Set Architecture (ISA) is the foundation of computer architecture. Existing ISAs (such as X86, ARM, etc.) have hindered the advancement and proliferation of technology through patent protection [1]. In 2010, the University of California, Berkeley, first released the RISC-V Instruction Set Architecture [2]. RISC-V is an open and free ISA.

In recent years, research on the RISC-V ISA has become a major focus. For example, Alibaba's Xuantie-910 [4, 5], Western Digital's SweRV [3], UC Berkeley's Rocket [6,7], IIT Madras' SHAKTI project [8], ETH Zurich's Pulpino [9-11], the open-source processor mriscv [12], and VexRiscv [13].

This paper presents an optimized five-stage pipeline RV32I scalar processor, NRP (New RISC-V Processor). The main contributions of this paper are as follows:

- To improve performance, we modified and optimized the ID and EX stages of the processor, reducing the negative impact of dependency conflicts on the processor.
- We implemented these optimizations using Verilog HDL and evaluated hardware resource utilization and processor performance. From the evaluation results, we found that this processor outperforms the classic five-stage pipeline processor.

II. Related Works

Dependency conflicts are an important factor affecting the performance of a five-stage pipeline processor. Dependency conflicts refer to the data dependency, control dependency, and structural dependency between instructions, which can lead to instruction hazards in the pipeline, thereby affecting the processor's performance.

In study [14], the authors designed and implemented a Tournament Branch Predictor, which improved the accuracy of branch prediction and enhanced the processor's efficiency. In reference [15], the authors combined the instruction fetch stage with the pre-fetch stage into a two-stage pipeline, resulting in a 17.6% improvement in processor performance. In reference [16], the authors proposed reducing hazards through the use of techniques such as data forwarding and branch prediction, leading to a 7.82% increase in processor performance. In reference [17], the authors optimized the instruction fetch unit, ALU, and data memory, increasing the processor's operating frequency.

The optimization strategies in references [14, 15] resulted in significant performance improvements but increased the complexity and hardware resources of the branch predictor. The optimization strategies in references [16, 17] had lower hardware overhead but led to smaller improvements in processor performance. This paper comprehensively compares these optimization strategies and proposes a new optimization strategy that achieves performance improvements with minimal hardware overhead.

III. The Design and Implementation of the NRP

A. Processor Architectures

The NRP processor adopts a five-stage pipeline design. As shown in Fig. 1, instructions undergo the following five stages during execution: Instruction Fetch (IF), Instruction Decode (ID), Execute (EX), Memory Access (MEM), and Write Back (WB) [18]. The design of the ID and EX stages in the NRP processor differs from that of the classic five-stage pipeline processor. The ID stage of the NRP processor consists of both the instruction decode unit and the decode execute unit, whereas the classic five-stage pipeline processor only has the instruction decode unit. The EX stage of the NRP processor consists of the execute unit and the branch prediction auxiliary unit, while the classic five-stage pipeline processor only has the execute unit.

B. Instruction Execution Process

This paper categorizes all instructions in RV32I into special instructions and regular instructions. Branch jump instructions and instructions similar to branch jump instructions in terms of computational operations are defined as special instructions. The computational operations of special instructions, originally executed in the EX stage, are now completed in the ID stage.

*Corresponding Author.

Special instructions include ADD, ADDI, SUB, SLT, SLTU, SLTI, SLTIU, BEQ, BNE, BLT, BGE, BLTU, BGEU, JAL, JALR, LB, LH, LW, LBU, LHU, LWU, SB, SH, SW. The ID and EX stages of the NRP processor differ from those of the classic five-stage pipeline processor, resulting in differences in the execution process of instructions in the ID and EX stages. Fig. 2 illustrates the main execution process of instructions in the ID and EX stages.

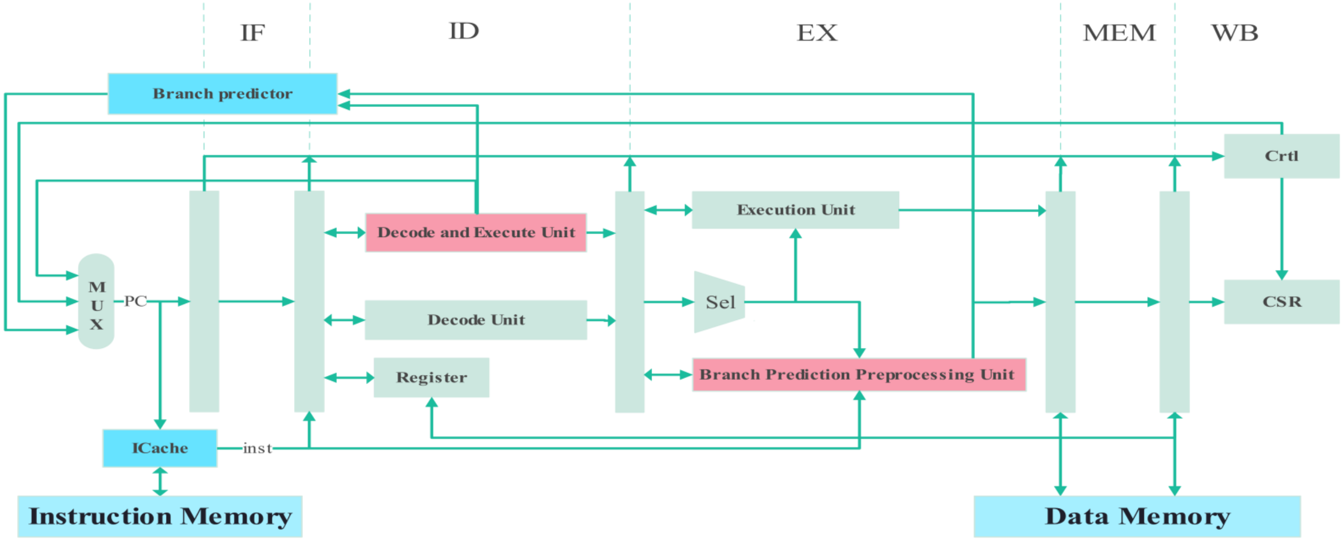

Fig. 1. A block diagram of the five-stage pipelined processor NRP.

The ID stage of the NRP processor consists of the instruction decode unit and the decode execute unit, with each functional unit's decoder responsible for decoding a portion of the instructions. In the ID stage, the execution logic of special instructions involves first decoding the instructions by the decode execute unit and then completing the computational operations required by the instruction opcode within this module. The instruction decode unit is responsible for decoding regular instructions and forwarding the instruction decode information and source operands to the next stage. If an unsolvable data dependency conflict occurs during the execution of a special instruction in the ID stage, the instruction is flagged and then resolved through data forwarding in the EX stage.

The EX stage of the NRP processor consists of the execute unit and the branch prediction auxiliary unit. The execute unit performs operations based on the type of instruction, including regular instructions and flagged special instructions. The branch prediction auxiliary unit is responsible for handling unflagged special instructions and generating branch prediction auxiliary information.

IV. The Optimization Design in NRP

Correlation conflicts are a significant factor affecting the performance of a five-stage pipelined processor. These conflicts can lead to pipeline stalls, reducing the processor's performance. The optimization idea proposed in this paper aims to minimize the negative impact of correlation conflicts on processor performance. In this section, we describe the design and implementation of optimization strategies for the NRP processor.

A. Optimization Design of the Decoding Stage

The control dependency conflict in a five-stage pipelined processor refers to the situation where the conditional result of a branch instruction is not yet determined, potentially allowing subsequent instructions to enter the pipeline. If the branch prediction fails, the pipeline needs to be flushed and restarted, causing a stall and impacting processor performance.

The optimization design in the ID stage of the NRP processor aims to reduce the pipeline stall time caused by control dependency conflicts. In a classic RISC-V five-stage pipelined processor, when a branch prediction fails, a stall of two clock cycles is required for pipeline flushing. This paper introduces an additional decode and execute unit in the ID stage of the NRP processor, reducing the stall to just one clock cycle in the event of a branch prediction failure.

The optimization design in the ID stage allows branch instructions to know the branch prediction result and determine if there will be a control dependency conflict. The execution process of special instructions in decode and execute unit is illustrated in Fig. 3. Firstly, the decoder decodes the instruction to obtain instruction information. Then, based on the instruction opcode, it generates a 2-bit enable signal to activate the corresponding arithmetic unit. The arithmetic unit performs operations on the source operands and communicates using shared data. Finally, the instruction operation result and related information are passed to the EX stage, and the branch prediction result is transmitted to the branch predictor. In the event of a branch prediction failure, the correct PC is passed to the IF stage, and the pipeline pause signal is transmitted to the Ctrl module.

Decode and execute unit consists of a special instruction decoder, an adder, and a comparator. In the implementation process, we virtually divide the full instruction decoder into a special instruction decoder and a regular instruction decoder. When the instruction decoder decodes a special instruction, decode and execute unit is activated. When the instruction decoder decodes a regular instruction, the decode and execute unit does not activate. The primary hardware costs in our optimization design in the ID stage are the adder and the comparator.

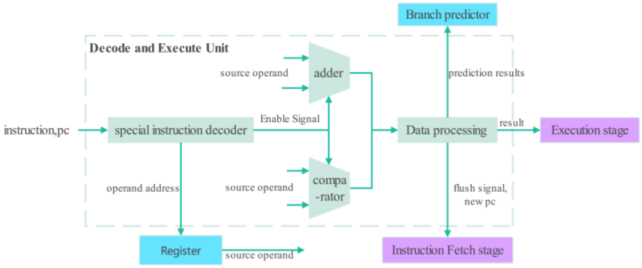

Fig. 3. Decode and execute unit.

B. Branch Predictor Optimization

The branch predictor used in this paper is based on SonicBoom's NLP (Next-Line Predictor), consisting of BHT (Branch History Table), BTB (Branch Target Buffer), and RAS (Return Address Stack). We have optimized the BHT.

Traditional BHT records the state of each branch instruction based on its historical execution results. When a branch instruction is executed for the first time, it defaults to not taken due to the lack of historical execution results. The design proposed in this paper allows obtaining the opcode and the target address of the instruction before its first execution, causing the branch instruction to default to taken upon its first execution. JAL and JALR, as direct jump instructions, always cause a jump upon each execution, which cannot be accommodated by the traditional BHT design.

The workflow of the BHT designed in this paper is as follows: When a branch instruction is first recorded in the BHT, the value of the corresponding two-bit saturating counter table (2BC) is set to 2. If the branch instruction indeed jumps during execution and the jump target address is correct, the value of the two-bit saturating counter table is incremented by 1. If the branch instruction does not jump during execution, then the value of the two-bit saturating counter table is decremented by 1. If the value of the two-bit saturating counter table for the branch instruction is greater than or equal to 2, it is predicted that the instruction will jump.

The branch prediction auxiliary module is crucial for implementing the BHT optimization design, as it allows obtaining the opcode and the target address of the instruction before its execution. The NRP processor classifies instructions into regular and special instructions. Special instructions are decoded and executed in the ID stage, so when a special instruction reaches the EX stage, an idle clock cycle is generated. The branch prediction auxiliary module utilizes this idle clock cycle to perform simple decoding of the instruction and generate data for updating the branch predictor.

The branch prediction auxiliary module consists of a branch instruction decoder and an adder, and its specific workflow is illustrated in Fig. 4. Firstly, the branch instruction decoder in the branch prediction auxiliary module decodes the instruction currently in the cache. If the instruction is a branch instruction, its instruction type and immediate value are obtained after decoding. Then, the PC value and the immediate value of the instruction are sent to the ALU for addition to obtain the jump target address. Finally, the PC value, instruction type, and jump target address of the instruction are sent to the branch predictor.

The primary hardware costs in the branch prediction optimization design are a branch instruction decoder and an adder, with the branch instruction decoder supporting only the decoding of branch instructions.

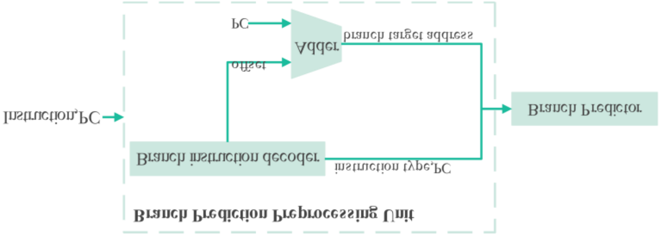

Fig. 4. The branch prediction auxiliary module.

C. Optimization of Dependency Conflict

The Fig. 5 illustrates how a classic five-stage pipelined processor uses data forwarding, pipeline stalling, and branch prediction to resolve various dependency conflicts and their resulting impacts.

In Fig. 5, we can observe the following scenarios. Firstly, the classic five-stage pipelined processor utilizes data forwarding to forward data from the EX stage and MEM stage to the ID stage to resolve non-load instruction-induced data dependency conflicts, and a combination of pipeline stalling and data forwarding is used to resolve load instruction-induced data dependency conflicts. Secondly, the classic five-stage pipelined processor executes branch instructions in the EX stage, and in the event of a branch prediction failure, it requires flushing the pipeline for two clock cycles. Lastly, the unoptimized branch predictor defaults to not taking a branch on the first prediction of a branch instruction, so when the processor executes an immediate jump instruction for the first time, a branch prediction failure and pipeline flush are inevitable.

Fig. 5. Methods for handling dependency conflicts before optimization.

The Fig. 6 illustrates how the NRP processor uses data forwarding, pipeline stalling, and branch prediction to resolve various dependency conflicts and their resulting impacts.

In Fig. 6, we can observe the following scenarios. Firstly, in the NRP processor, the use of data forwarding is more extensive, including between ID and EX, ID and MEM, and EX and MEM. Secondly, the NRP processor executes branch instructions in the ID stage to obtain the branch prediction result, so in the event of a branch prediction failure, it requires flushing the pipeline for one clock cycle. Lastly, the NRP processor employs an optimized branch predictor, so when executing an immediate jump instruction for the first time, it correctly takes the jump, avoiding pipeline flushing.

V. Experiment and Analysis

A. Functional Test

The COMPLIANCE TEST officially released by RISC-V can test whether the design of a RISC-V core complies with the RISC-V standard [19]. In this paper, joint simulation tests were conducted using Vivado and modsim, and the test results indicate that the NRP complies with the standard of RISC-V core design. Fig. 7 and Fig. 8 show the simulation test results for the ADD instruction and the JAL instruction, respectively.

B. Performance Test

CoreMark is a straightforward yet sophisticated benchmark designed specifically to evaluate the performance of a processor core. In this paper, the CoreMark program and the NRP processor core were ported to Xilinx's ARTYA7-35T development board using Vivado, and the clock function and serial print function were rewritten. The main frequency of the NRP processor core was set to 50MHz for testing, and the results were transmitted to a PC for display via a serial tool. Fig. 9 presents the serial print results, showing that the NRP processor achieved a final CoreMark score of 3.11 CoreMark/MHz.

C. Experimental Analysis

We implemented various versions of the NRP processor in Verilog HDL and evaluated their performance on Xilinx's ARTYA7-35T development board. Based on the optimization level of the NRP processor, we categorized it into three versions. The version without any optimization design is defined as NRP-Original, the version with optimization design only in the decode stage is defined as NRP-OptID, and the version with simultaneous optimization design in the decode stage and branch predictor is defined as NRP-Final.

Fig. 10 displays the CoreMark scores for each version of the NRP processor. After optimizing the design of the ID stage and the branch predictor, the performance of the NRP processor improved by 11.07%.

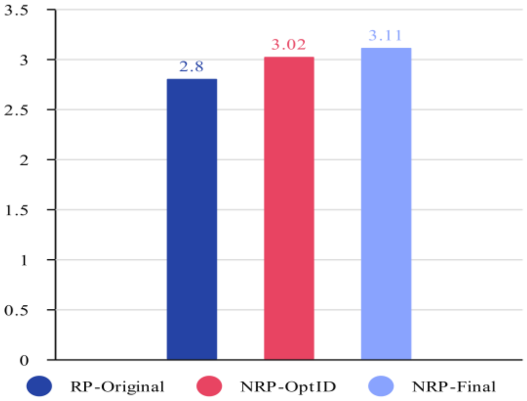

Fig. 10. Performance test results of different versions of NRP.

Fig. 11 presents the CoreMark test results for other open-source processors, showing that the performance of the NRP processor is significantly better than that of other processors [21]-[27].

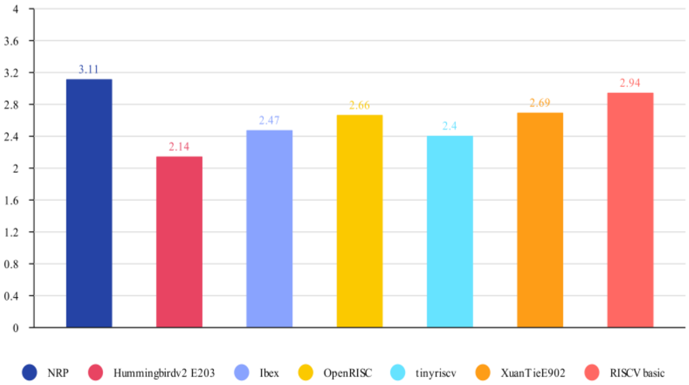

Fig. 11. Performance comparison of different open-source processors.

VI. Conclusion

We have proposed a five-stage pipelined processor based on RISC-V architecture. In this processor, we have employed instruction decoding unit optimization and branch prediction optimization as effective methods to improve operating frequency. We implemented the proposed processor in Verilog using Vivado and conducted tests and evaluations on the processor's performance and hardware resource consumption. The CoreMark test results for the NRP processor after adopting optimization strategies show a score of 3.11 CoreMark/MHz, representing an 11.07% improvement over the non-optimized design.

This research improves the performance of the five-stage pipeline processor based on RISC-V, which can improve the application range of the five-stage pipeline processor and promote the development of the community ecology of RISC-V instruction set architecture. In the future work, we will extend the design of this paper to the five-stage pipeline design of out-of-order execution, and reduce the impact of correlation conflicts on processor performance in out-of-order execution.

Enhancing Thyroid Cancer Diagnostics Through Hybrid Machine Learning and Metabolomics Approaches

Meghana G Raj
Department of School of Computer Engineering,
Kalinga Institute of Industrial Technology (Deemed to be University), Bhubaneswar, India

***Abstract*—Thyroid cancer, a prevalent endocrine malignancy, necessitates advanced diagnostic techniques for accurate and early detection. This study introduces an innovative approach that integrates hybrid Machine Learning (ML) algorithms with metabolomics, offering a novel pathway in thyroid cancer diagnostics. Our methodology employs a range of hybrid ML models, combining the strengths of various algorithms to analyze complex metabolomic data effectively. These models include ensemble methods, neural network-based hybrids, and integrations of unsupervised and supervised learning techniques, tailored to decipher the intricate patterns within metabolic profiles associated with thyroid cancer. The study demonstrates how these hybrid ML algorithms can efficiently process and interpret metabolomic data, leading to enhanced diagnostic accuracy. By leveraging the distinct characteristics of each ML model, our approach not only improves the detection of thyroid cancer but also contributes to a deeper understanding of its metabolic underpinnings. The findings of this study pave the way for more personalized and precise medical interventions in thyroid cancer management, showcasing the potential of hybrid ML models in revolutionizing cancer diagnostics. Our system analyzes thyroid cancer metabolomic data using ensemble methods, neural network-based hybrids, and unsupervised and supervised learning integrations. The research shows hybrid ML models may revolutionize cancer diagnoses by improving accuracy. LSTM+CNN, LSTM+GRU, and CNN+GRU have high accuracy rates, helping us comprehend thyroid cancer's biochemical roots. Hybrid ML models enhance thyroid cancer diagnosis and management, enabling more tailored and accurate medical treatments. The hybrid machine learning models like LSTM+CNN, LSTM+GRU, and CNN+GRU beat CNN, VGG-19, Inception-ResNet-v2, decision support, and random forests (99.45%).**

***Keywords*—Thyroid cancer; hybrid ML models; metabolomics; diagnostic accuracy**

I. Introduction

AI improves diagnosis, treatment, and care. AI's pattern recognition, predictive analysis, and decision-making skills enable computers to analyze complicated medical data with unprecedented precision and scale [1, 2]. This discovery enhances early sickness detection, precise diagnosis, and individualized therapy. AI technologies enhance hospital operations, predict disease outbreaks, and significantly improve patient outcomes. AI is critical to provide equitable access to high-quality treatment across geographic boundaries. As AI advances, it will improve global health outcomes with increasingly complex healthcare applications. However, healthcare AI adoption is hard. User adoption of AI-driven help requires trust. Studying security, risk, and trust on healthcare, AI adoption shows that trust is crucial. Oncology's leading killer affects several organs [3, 4]. Thyroid carcinoma is a prevalent endocrine malignancy worldwide. The sixth most prevalent cancer in women aged 15–49 is thyroid cancer, hence better identification and treatment are needed (see Fig. 1). Thyroid cancer is becoming more common, and machine learning and metabolomics may enhance detection and therapy [5, 6, and 7].

Thyroid cancer has increased in recent decades, with the American Cancer Society expecting 43,800 new cases and 2,230 fatalities in 2022 [8]. Thyroid cancer develops as a nodule at the throat's base when cells proliferate rapidly and escape the immune system. Unregulated cell reproduction spreads rogue cells into surrounding tissues. About 95% of thyroid malignancies are follicular or papillary. Effective management and damage reduction require early discovery and treatment of malignant thyroid nodules. Early thyroid cancer screening detects cancerous nodules. Neck palpation during physical examinations and ultrasonography, which may detect nodules smaller than 1 cm, are the main detection modalities. Ultrasonography helps distinguish benign from malignant nodules by their features [9].

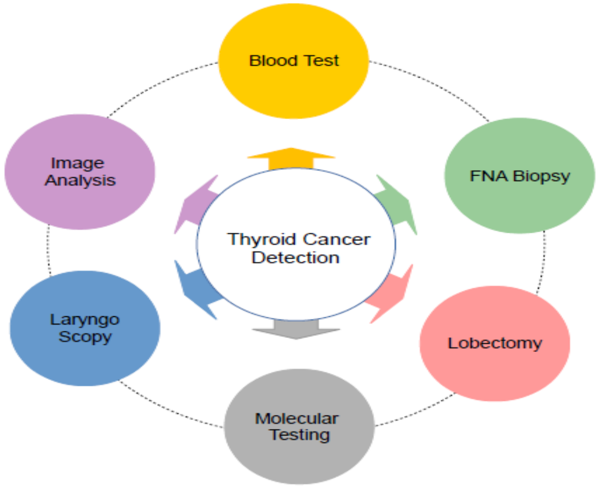

Fig. 1. Various methods for detection of thyroid cancer.

Automated thyroid nodule identification using computer-aided diagnostic (CAD) has evolved in recent years [10]. CAD tools using artificial intelligence analyze ultrasound features more intelligently, accurately, and consistently. This helps decrease needless biopsies. Machine learning and deep learning, key components of AI-based CAD systems, have changed medicine. These approaches use expert knowledge to choose important attributes from predetermined region-of-interest criteria. Margin, form, echogenicity, calcifications, and composition in thyroid ultrasound images have helped build CAD systems. Support vector machines, GoogLeNet, and CNNs have transformed thyroid nodule detection, according to previous studies. Machine learning and AI have greatly improved the use of CAD tools in clinical practice [11].

In thyroid cancer, early and accurate detection may save lives. This cancer survives better with early detection and treatment [12]. Early detection may reduce benign tumor treatment costs and stress. Doctors can enhance patient care with fast and appropriate treatment. Cancer detection employs image processing, deep learning, and AI, notably in medical imaging. Reduce noise in ultrasound images to identify thyroid cancer. Next, segmentation separates cancer-prone regions. Cancerous or benign nodules are determined by these sites. First, gather ultrasound images, then segment them to focus on the affected area. These segments' attributes constitute a predictive model, and a classifier predicts [13]. The neck gland's thyroid carcinoma is treated better with early detection. Healthcare professionals use machine learning algorithms to handle pandemics and natural disasters [14]. These algorithms help physicians identify and treat patients by analyzing enormous medical data. Thyroid CAD systems must be precise to minimize delays or unnecessary treatments. Deep learning-enhanced ultrasonography detects thyroid cancer using complex acoustic features. CAD and AI enhance thyroid cancer diagnosis. They simplify ultrasound-based risk categorization and enhance thyroid nodule identification and assessment. Traditional diagnostic methods like FNAB are 20% incorrect. Machine learning improves insights and judgments using probability and statistics. ML-based classification models using large image datasets are promising for study. Progress is shown by statistical pattern identification and quantification algorithms in thyroid node categorization systems like AmCAD-UT [15].

In this paper, the advent of deep learning models, particularly Long Short-Term Memory (LSTM), Gated Recurrent Units (GRU), Convolutional Neural Networks (CNN), and their hybrid combinations like LSTM+CNN, LSTM+GRU, and GRU+CNN, presents a transformative approach in thyroid cancer diagnostics. These advanced computational models offer unparalleled precision in analyzing complex medical data, significantly enhancing our ability to detect and diagnose thyroid cancer early and accurately. As we continue to integrate these sophisticated AI methodologies into medical practices, the potential for improving patient outcomes and revolutionizing the field of oncology is immense.

II. Related and Recent Work

AI has substantially improved medical diagnostics, notably tricky thyroid disorders. Improved ultrasound picture interpretation and quicker processing are the main reasons. Ultrasonography, FNA, and thyroid surgery now utilize deep learning (DL) and machine learning (ML) to classify thyroid nodules automatically [16]. Many research have shown AI's potential in cancer detection, where data volume and classification accuracy are critical. Ultrasound, CT, MRI, radioactive iodine, and histopathology diagnosis thyroid cancer. Many research have built AI-based CAD models to detect thyroid abnormalities in ultrasound and histopathological pictures. Xu et al. created a contrast-enhanced thyroid ultrasound diagnostic model using CNN feature extraction and LSTM classification. Zhao et al. offered CNN-extracted characteristics and image texture for ultrasonography thyroid classification [17]. CNNs classify thyroid and breast cancer ultrasound images, whereas U-Net models segment thyroid ultrasounds. Additionally, multi-scale region-based detection networks like Resnet50 and ZFnet are more accurate. Transfer learning reduces overfitting in thyroid nodule classification models employing inception networks, VGG16, and GoogLeNet. Using simple CNN models and spatial and frequency domains, Nguyen et al. categorized the TDID dataset using voting ensemble [18]. In ensemble learning, hunger games search algorithm and D-CRITIC TOPSIS model ranking educated deep vision Transformer and Mixer models. Sun et al. employed the TC-ViT model, a vision transformer with contrast learning, to classify thyroid imaging data by TI-RADS scores [19].

New AI technologies may standardize and enhance uncertain thyroid nodule categorization. Digital thyroid fine needle aspiration biopsy images are employed in these studies. EfficientNetV2-L image classification works in thyroid fine needle aspiration cytology, according to Hirokawa et al [20]. Kezalarian [21] studied AI's role in follicular cancer vs. adenoma, whereas Alabrak et al. proposed a CNN model with good accuracy, sensitivity, specificity, and AUC-score [22].

AI-based thyroid pathology whole slide image analysis utilizing modified QUADAS-2 was evaluated by Girolami et al [23]. Using numerous histopathology pictures, Wang et al. trained VGG-19 and Inception-ResNet-v2 models to diagnose thyroid diseases [24]. Chandio et al. suggested a CNN-based MTC detection decision support system. Hossiny et al. correctly identified thyroid tumors using cascaded CNN and split classification [25]. Do et al.'s thyroid cancer MI Inception-v3 model improved classification accuracy [26]. Bohland et al. found feature-based and deep learning-based thyroid carcinoma classification equivalent [27]. Transformer and Mixer models improve vision, but thyroid feature extraction is uncertain. Vector redundancy may cause feature extraction overfitting. Espadoto et al.'s dimensionality reduction survey was impressive [28]. Meta-heuristic feature selection approaches like moth flame and cuckoo optimization are common for high-dimensional datasets. In data-limited medical disciplines, ensemble techniques using numerous weak learners increase classification model accuracy. The weighted average ensemble technique is intriguing, but weight selection is tricky. FOX optimization, which performs well in traditional benchmarks, holds potential in feature selection and ensemble learning but has not been implemented [14].

TABLE I. COMPARATIVE STUDY ON VARIOUS METHODS FOR DETECTION OF THYROID CANCER

Authors	Method	Accuracy	Key Contributions
Alabrak et al. 2023 [22]	CNN model	78%	Proposed a CNN model to classify thyroid cancer with good accuracy, sensitivity, specificity, and AUC-score.
Wang et al. 2019 [24]	VGG-19 and Inception-ResNet-v2 models	97.34% and 94.42%	Trained models to diagnose thyroid diseases using histopathology images.
Chandio et al. 2020 [39]	CNN-based decision support system	99.00%	Suggested a system for detecting medullary thyroid cancer using CNN.
Hossiny et al. 2021 [25]	Cascaded CNN and split classification techniques	98.74%	Identified thyroid tumors with high accuracy.
Bohland et al. 2021 [27]	Feature-based and deep learning-based models	89.70% (feature-based), 89.10% (deep learning-based)	Comparison of thyroid tumor classification models.
Kouznetsova et al. (2021) [34]	ML model using saliva metabolites	Not Specified	Differentiated between malignant oral lesions and periodontitis.
Cai et al., 2015 [35]	Random forest ML model	86.54%	Classified lung cancer using DNA methylation markers.

The American Thyroid Association endorsed intraoperative frozen sections (FSs) for classical papillary thyroid cancer detection in 2015. However, onsite pathologists may struggle to detect rare cancers and poorly prepared specimens using paraffin sections. PTC is one of the most frequent thyroid cancer, although follicular, medullary, and undifferentiated carcinomas stain poorly. Rare lung and breast cancers are hard to diagnose. Diagnostic discrepancies and CNN model building are difficult due to the lack of pathological imaging data from uncommon cancers [29]. Computational pathology must find rare or intermediate groupings. Deep learning in several fields, including CNNs and RNNs, has led to computer-aided histopathological diagnostic systems. Digital pathology allows histopathological diagnosis using deep learning algorithms. Thanks to CAMELYON16 and the TCGA, patch-based CNNs for whole-slide images (WSIs) have improved cancer histology [30]. CNN methods for breast cancer lymph node metastatic diagnosis are examined. InceptionV3, utilizing CAMELYON16, achieves 98.6% AUC and 87.3% FROC. WSI patch image analysis using Resnet and conditional random fields was also helpful [31]. CNNs are cancer-trained and tested. On TCGA non-small cell lung cancer histopathology pictures, InceptionV3 and pathologists fared similarly. Deep learning model interpretability has improved with new bladder cancer and other cancer screening methods. Positive pathologist diagnostic accuracy comparisons [32].

ML has been used for about two decades to diagnose and track cancer. Cancer diagnosis has relied on decision trees and ANNs since the mid-1980s [33]. Age, health, sickness kind, location, tumor grade, and size affect cancer prognosis. ML predicts nodes and patient severity using this data. Protein markers and microarray data are used in breast and prostate cancer research to identify cancer types, predict risk, and test patients. Diagnostics improve using ML models for CT scans and cancer image projection. ML models to aid doctors in these imaging methods were recognized by the NCI (2022). Metabolomics has been used in cancer research. Research into cancer metabolites has advanced. In bladder cancer (BCa) studies, ML compared metabolite patterns at different stages. Metabolites in healthy and oral cancer patients are linked via these pathways. Using ML, Kouznetsova et al. (2021) distinguished malignant from periodontitis oral lesions using saliva metabolites [34]. Genomic data was used by ML-based classifiers to construct a lung cancer DNA methylation indicator panel. A random forest ML model diagnosed lung cancer with 86.54% accuracy by Cai et al., 2015 [35]. These results show ML's growing role in cancer diagnostic accuracy and efficiency, paving the way for future research (see Table I).

III. METHODOLOGY

A. Long Short-Term Memory (LSTM)

The Recurrent Neural Network (RNN) LSTM may learn long-term data sequence relationships. This is valuable in medical diagnostics, as patient data covers extended periods and includes important sequential patterns. The input, forget, and output gates make up LSTM. These gates regulate cell state information flow, enabling the network to remember or forget [36, 37]. This approach uses LSTMs to evaluate and understand complicated metabolic data and other temporal information. Metabolic marker alterations, thyroid symptom progression, and diagnostic data integration are included. The input, forget, and output gates of LSTM control information flow, making it effective. These gates determine what data to keep or discard as the data sequence proceeds, allowing the model to keep important data and forget non-essential data [40].

Equations for LSTM:

Forget Gate selects cell state data to discard. It examines the previous state (h_{t-1}). The program produces a value between 0 and 1 for each cell state (C_{t-1}) and current input (x_t).

$$f_t = \sigma(W_f[h_{t-1}, x_t] + d_f)$$

Input Gate: A sigmoid layer chooses values to update while a tanh layer creates a vector of candidates.

$$i_t = \sigma(W_i.[h_{t-1}, x_t] + b_i)$$
$$C'_t = \tanh(W_C[h_{t-1}, x_t] + b_C)$$

The previous cell state is updated to the new one.

$$C_t = f_t * C_{t-1} + i_t * C'_t$$

Output Gate: It selects the next hidden state representing prior inputs.

$$O_t = \sigma(W_o.[h_{t-1}, x_t] + b_o)$$
$$h_t = O_t * \tanh(C_t)$$

LSTM can analyze consecutive metabolic profiles and historical patient data to capture temporal relationships needed for thyroid cancer diagnosis and prognosis. Combining LSTM with additional machine learning methods like CNNs for image analysis improves thyroid cancer diagnosis.

B. Gated Recurrent Units (GRU)

GRUs are Recurrent Neural Networks (RNNs) intended to analyze data sequences. It is fewer gates and are simpler and more efficient in certain cases. Medical diagnostics use GRUs to capture temporal connections in sequential data. GRUs might assess time-dependent changes in metabolites, hormone levels, and other biochemical indicators of thyroid disorders to diagnose thyroid cancer [38].

Integrating the “forget and input” gates into one GRU simplifies RNNs "update gate." They also use a "reset gate." These two gates in GRUs control the information flow within the unit, which is essential for maintaining relevant information over different time steps.

Equations for GRU:

Update Gate: Determines how much previous knowledge to pass on.

$$z_t = \sigma(W_z[h_{t-1}, x_t])$$

Reset Gate: Decides how much of the previous knowledge to forget.

$$r_t = \sigma(W_r[h_{t-1}, x_t])$$

Current Memory Content: **Creates** the candidate which will be used to update the cell state.

$$h'_t = \tanh(W.[r_t.h_{t-1}, x_t])$$

Final Memory at Current Time Step: **Combines** the old state with the new candidate state

$$h_t = (1 - z_t) * h_{t-1} + z_t * h'_t$$

GRUs' basic design lets them store key data from prior data points and reject irrelevant data, improving their sequential data prediction abilities. Instead of update and reset gates, GRUs use a simpler gating method. The gates regulate how much previous knowledge to pass on to the future, improving sequential data learning. For a complete examination, we will use GRUs and other machine learning methods like CNNs.

C. Convolutional Neural Networks (CNN)

CNNs are powerful deep neural networks for visual analysis. They excel in automatically detecting and learning spatial hierarchies of characteristics from pictures, which is essential for thyroid cancer detection in medical imaging [39]. Convolutional, pooling, and fully linked layers make up a CNN. The output of a convolution process is sent to the next layer. The network builds a learnt feature hierarchy this way.

Equations for CNN:

Convolution Operation:

$$F_{ij} = \sum_m \sum_n I_{(i+m)(j+n)} K_{mn}$$

where, F_{ij} is the output feature map, I represents the input image, and K is the kernel or filter applied to the image.

Activation Function (ReLU): $f(x) = \max(0, x)$ used to provide the model non-linearity to learn more complicated patterns.

Pooling Operation (Max Pooling): $P_{ij} = max(I_{(i:i+p)(j:j+p)})$ where P_{ij} is the output after pooling, and I the input feature map, and p the pooling window size. As in ordinary neural networks, neurons in the final layers are completely coupled to all activations in the preceding layer. This part is typically used to classify features learned by the CNN into different categories.

This approach analyzes thyroid ultrasound pictures using CNNs. Their capacity to extract and learn key elements from these photos is critical for thyroid cancer detection. CNN and LSTM or GRU will evaluate non-imaging data together. CNNs extract features from pictures, whereas LSTM/GRU models analyze consecutive patient histories and metabolic profiles. This integrated strategy improves thyroid cancer diagnosis and monitoring accuracy and efficiency.

D. Hybrid model LSTM+CNN

The hybrid LSTM-CNN model is crucial. LSTM and CNN models work well together to analyze complicated sequence and picture datasets. This hybrid technique combines LSTM sequential data processing with CNN spatial feature extraction. It is suitable for diagnostic situations that need both time-series data (like metabolic profiles) and imaging data (like ultrasound pictures).

Equations for LSTM+CNN:

CNN Layer:

$$F_{ij} = \sum_m \sum_n I_{(i+m)(j+n)} K_{mn}$$

where, F_{ij} is the output feature map, I represents the input image, and K is the kernel or filter applied to the image. This equation represents the convolution operation in the CNN layer, crucial for extracting spatial features from images.

LSTM Layer:

$$h_t = O_t * \tanh(C_t)$$

where, h_t is the output of the LSTM cell at time t, O_t is the output gate, and C_t is the cell state. This LSTM equation is responsible for processing sequential data, maintaining important information over time.

Thyroid ultrasound pictures are processed by CNN to extract essential details. The LSTM component receives extracted characteristics. This section of the model handles time-series data like metabolic marker changes and symptom development. The temporal interpretation of these traits by the LSTM layers provides crucial information regarding thyroid cancer growth and status. Combining ultrasound pictures with patient history and metabolic data makes this hybrid model useful for thyroid cancer diagnosis. It provides a complete knowledge of the condition, which may improve diagnosis and therapy. LSTM and CNN work together in this hybrid model to record and evaluate spatial and temporal patterns.

E. Hybrid model LSTM+GRU

To handle and comprehend complicated sequential data, a hybrid model uses LSTM networks and GRUs. This hybrid model combines LSTM and GRU capabilities. GRUs change network information flow, whereas LSTMs remember information over extended durations. This combination improves the model's sequential data processing, which is useful for medical diagnostics time-series data analysis.

Equations for LSTM+GRU:

LSTM Layer

$$h_t = O_t * \tanh(C_t)$$

where, h_t is the LSTM cell output at time t, O_t is the output gate, and Ct is the cell state. This equation is essential for the LSTM to retain important information over time..

GRU layer:

$$h_t = (1 - z_t) * h_{t-1} + z_t * h'_t$$

where, h_t is the output at time t, z_t is the update gate, h'_t is the candidate activation, and h_{t-1} is the previous output. This equation helps the GRU balance old and new data. The model's LSTM component captures patient data's long-term dependencies and correlations by processing sequential data. GRU processes the LSTM layer output. It changes information flow to concentrate on the most important parts for the diagnostic job. The hybrid model is ideal for analyzing complicated medical data over time because it uses LSTM's capacity to recall information over longer sequences and GRU's efficiency in updating the hidden state. This LSTM+GRU hybrid model is ideal for assessing sequential medical data like metabolic alterations and thyroid disease development. For accurate thyroid cancer detection and progression, the model incorporates long-term and short-term data dependencies using LSTM and GRU. A more detailed examination using the hybrid method may lead to more accurate diagnosis and targeted therapy.

F. Hybrid model CNN+GRU

A CNN-GRU hybrid model is used. This combo processes imaging and sequence data to diagnose thyroid carcinoma comprehensively. This model combines CNN spatial feature extraction with GRU sequential data processing. CNNs thrive in imaging data analysis and interpretation, while GRUs excel at time-series data analysis, making this hybrid model ideal for medical applications that need both.

Equations for CNN+GRU:

CNN Layer:

$$F_{ij} = \sum_m \sum_n I_{(i+m)(j+n)} K_{mn}$$

where, F_{ij} is the output feature map, I represents the input image, and K is the kernel or filter applied to the image. This equation represents the convolution operation in the CNN layer, crucial for extracting spatial features from images.

GRU layer:

$$h_t = (1 - z_t) * h_{t-1} + z_t * h'_t$$

where, h_t is the output at time t, z_t is the update gate, h'_t is the candidate activation, and h_{t-1} is the previous output. This GRU equation manages the flow of information, balancing the retention of previous state information with new inputs Thyroid ultrasound pictures are processed by the CNN component to extract important spatial characteristics. The GRU component receives extracted characteristics. The GRU analyzes time-series data like metabolic marker changes and patient symptoms. CNN and GRU help the model gain insights from static pictures and dynamic sequential data, improving diagnostics. For various data analysis in thyroid cancer diagnosis, the CNN+GRU hybrid model is powerful. CNNs analyze ultrasound pictures to find thyroid cancer indicators, whereas GRUs evaluate patient-specific temporal data for a more accurate diagnosis. This method should enhance thyroid cancer identification and therapy.

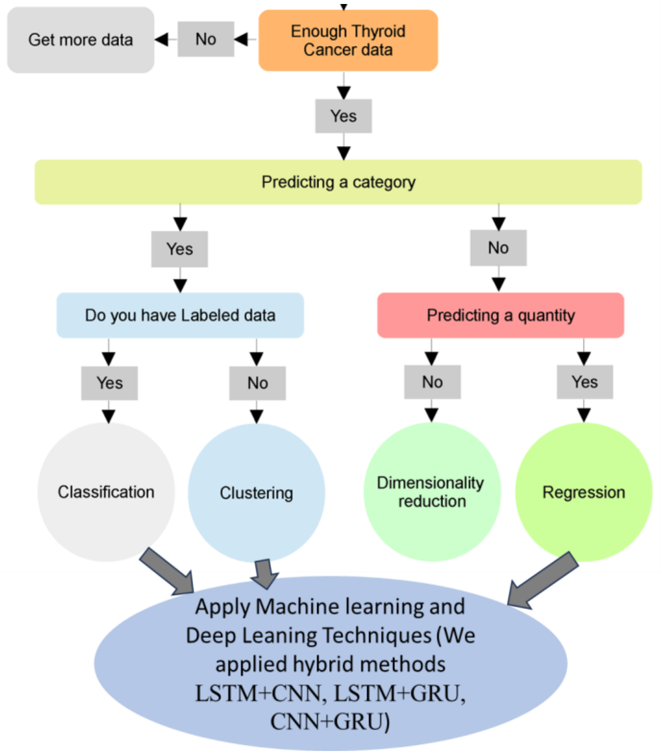

Fig. 2. Implementation process for predicting thyroid cancer.

This study reviews AI-based thyroid gland (TG) cancer diagnostic methods. Fig. 2 proposes categorizing AI-based thyroid cancer diagnostic methods. Considering tumor size, location, and patient age, and health, thyroid carcinoma categorization is crucial for appropriate treatment techniques. AI and machine learning have improved thyroid cancer classification automation and accuracy. CNNs and the U-Net architecture are increasingly employed for thyroid cancer segmentation because to their capacity to learn and generalize from big datasets. Applied Machine Learning and Deep Learning Techniques, such as LSTM+CNN, LSTM+GRU, and CNN+GRU, improve thyroid cancer detection.

IV. DATASET DETAILS

The Thyroid Disease dataset, graciously contributed on December 31, 1986, includes 10 Garavan Institute datasets. This multivariate, domain-theory dataset is for categorization in health and medicine. This dataset contains category and actual characteristics with various information. A unique dataset with 7200 occurrences and five characteristics is available for investigation. The Garavan Institute in Sydney, Australia, created six databases with 2800 training and 972 test examples each. These databases have several missing data points and 29 Boolean or continuously-valued features. In addition to the Sydney databases, Ross Quinlan's hypothyroid, data and sick-euthyroid, data present corruption concerns. Despite this, their format matches other databases. Another thyroid database by Stefan Aeberhard contains three classes, 215 instances, and five attributes without missing values (see Fig. 3).

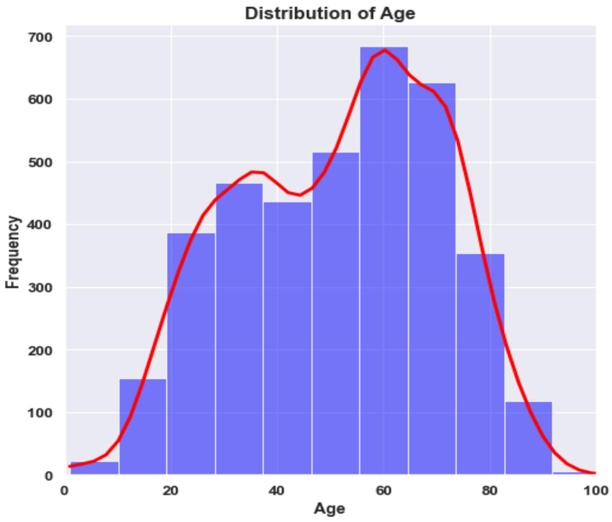

Fig. 3. Distribution of age for dataset.

The dataset contains several factors that may be used for thyroid analysis. The dataset's 'age' attribute is a significant demographic component. The variable'sex' shows gender distribution, revealing thyroid-related parameter gender differences. 'On thyroxine', 'query on thyroxine', 'on antithyroid medication','sick', 'pregnant', 'thyroid surgery', 'I131 therapy', 'query hypothyroid', 'query hyperthyroid', 'lithium', 'goitre', 'tumor', 'hypopituitary', and 'psych' are important binary variables These binary indicators reveal the presence or absence of certain illnesses or treatments, providing a complete health picture. The collection comprises thyroid hormone readings and levels. Variables like 'TSH measured', 'TSH', 'T3 measured', 'T3', 'TT4 measured', 'TT4', 'T4U measured', 'T4U', 'FTI measured', 'FTI' quantify thyroid-stimulating hormone (TSH), triiodothyronine (T3), thyroxine (TT4), and other These measures are essential for thyroid function testing. The dataset also includes 'TBG measured' and 'TBG' thyroxine-binding globulin readings. These measures add complexity to the dataset, enabling more detailed thyroid function evaluations (see Fig. 4).

The variable' referral source' indicates the participant's referral source, giving context for the data. Finally, the target variable 'binaryClass' indicates a thyroid-related condition's existence or absence. This prospective study monitored 383 patients for at least 10 years over 15 years. We aimed to predict recurrence in this patient cohort. The 13 clinicopathologic variables were extensively examined to predict recurrence. Patients in the study had a wide demographic, with a mean age of 40.87 ± 15.13 years. The population was 81% female. Gender distribution may alter sickness patterns and consequences, contextualizing the study's findings. A decade and 15 years of study revealed recurrence's temporal dynamics. Capturing complicated health histories with several clinicopathologic parameters created a sophisticated recurrence prediction model.

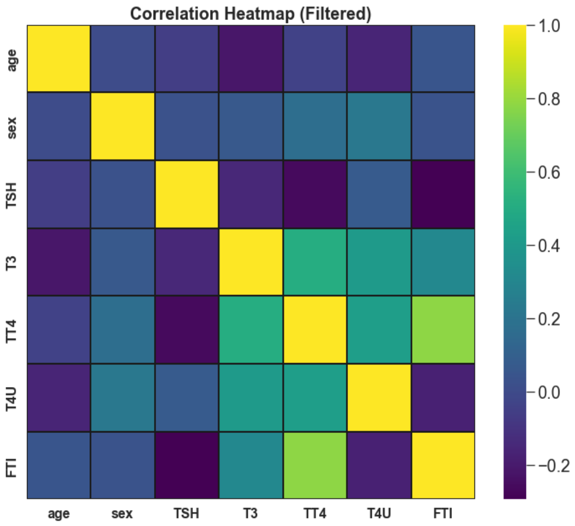

Fig. 4. Correlation matrix for dataset.

With its lengthy observation period and detailed clinicopathologic examination, this rigorous cohort study can evaluate and predict recurrence in a diverse patient population. Age and gender increase the dataset and enlighten sickness recurrence studies. The dataset employed in this research work encompasses a variety of clinical and demographic features crucial for evaluating the likelihood of thyroid cancer diagnosis. These features include mean radius, texture, perimeter, area, and smoothness, providing insights into the physical characteristics, structural properties, and extent of thyroid growths. The dataset's target variable, diagnosis, categorizes individuals into "benign" and "malignant" classes, serving as the label for machine learning predictions. This comprehensive dataset enables a thorough analysis for predicting thyroid cancer diagnoses based on diverse patient attributes.

V. RESULTS AND DISCUSSIONS

Thyroid cancer is a worldwide health issue that requires novel diagnostic methods. We build a powerful hybrid model using machine learning and metabolomics to handle this challenge. These methods attempt to improve thyroid cancer diagnostic accuracy and reliability, improving patient outcomes. After analyzing the complete dataset, specific indicators predicted thyroid cancer recurrence.

TABLE II. ANALYSIS OF DIFFERENT ML METHODS WITH FIVE FOLDS

Method	Fold	Accuracy	Precision	Recall	F1 Score
CNN	1	97.35	86.78	87.67	79.91
	2	97.68	87.67	88.36	80.63

	5	98.34	89.23	90.12	82.89

We observe that structurally incomplete treatment response (score = 0.843), gender (0.014), low-risk category (0.054), age (0.072), Hurthel cell pathology (0.013), and outstanding treatment response (0.004) were significant predictors. Since there were no node or partitioning depth limits, decision tree models could dynamically alter and capture complex patterns. Our study's accuracy and F1 score values for various approaches at different folds provide exciting new information about the hybrid models' performance. Famous models include the Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), Bidirectional LSTM (Bi-LSTM), Gated Recurrent Unit (GRU), and CNN+GRU, LSTM+CNN, and LSTM+GRU.

The discussion discusses our findings and each hybrid model's merits and weaknesses. Metabolomics data and machine learning methods help us grasp thyroid cancer's molecular landscape. Given the variability of thyroid cancer patients, the observed changes in accuracy and F1 score among folds suggest a nuanced approach. We also found that our hybrid models can capture complicated data linkages better than individual models. Metabolomics data and machine learning algorithms give a comprehensive view of thyroid cancer, possibly revealing novel biomarkers and diagnostic methods. Our results may be translated into clinical settings for more accurate and individualized thyroid cancer diagnosis.

In Table II, the comprehensive results, detailed in the table below, provide a nuanced understanding of each method's accuracy, precision, recall, and F1 score across different folds. The Hybrid LSTM+CNN Model performed well across folds. The model has consistent and strong prediction skills with an accuracy of 97.35% to 98.57%, precision of 86.78% to 89.56%, recall of 87.67% to 90.67%, and F1 Score of 79.91% to 83.12%. It may improve thyroid cancer diagnosis by merging LSTM and CNN architectures. The Hybrid LSTM+GRU Model also performed well in thyroid cancer diagnoses. The model had accuracy scores of 97.89% to 99%, precision of 87.78% to 92.34%, recall of 88.56% to 93.78%, and F1 Score of 80.67% to 87.78% across folds. The model's promising performance shows the benefits of merging LSTM and GRU architectures. In addition, the CNN+GRU Model consistently predicted thyroid cancer in the study. The model is predictively reliable with accuracy values of 97.89% to 98.68%, precision of 88.45% to 90.12%, recall of 89.23% to 91.01%, and F1 Score of 82.56% to 83.78%. CNN and GRU architectures help the model handle thyroid cancer diagnostic complexity. The Hybrid LSTM+CNN, Hybrid LSTM+GRU, and CNN+GRU Models, under the study subject, have promising predictive skills and integrate multiple machine learning architectures to improve thyroid cancer diagnosis. These results aid thyroid cancer diagnostic accuracy efforts.

The Fig. 5 shows accuracy trends throughout folds for the study's machine learning approaches. CNN, LSTM, Bi-LSTM, GRU, LSTM+CNN, LSTM+GRU, and CNN+GRU are illustrated with unique lines to compare performance. Folds (1–5) on the x-axis represent the model's assessment across varied datasets. On the y-axis, accuracy percentages demonstrate each method's predictive power. As compared to individual architectures, the Hybrid LSTM+CNN and GRU models are consistently more accurate. Although significantly varied among folds, the CNN+GRU model has comparable accuracy. Fig. 5 shows that hybrid machine learning methods combined with metabolomics data may improve thyroid cancer diagnosis. The figure's intricate patterns and trends aid thyroid cancer detection technique development.

In the pursuit of advancing thyroid cancer diagnostics, our research employs a hybrid approach, integrating machine learning methodologies with metabolomics techniques. Fig. 6 illustrates the F1 score across different folds for various methods employed in our study, encompassing Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), Bidirectional LSTM (Bi-LSTM), Gated Recurrent Unit (GRU), as well as hybrid models such as LSTM+CNN, LSTM+GRU, and CNN+GRU. Each method is represented with distinct markers and lines, showcasing their performance variability across different folds. The F1 score trends show how well these hybrid machine learning models improve thyroid cancer diagnosis.

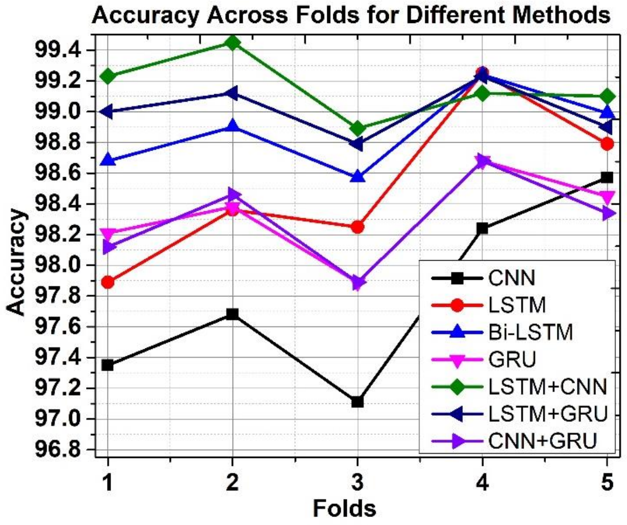

Fig. 5. Comparative analysis of accuracy with various ML methods and hybrid ML algorithms.

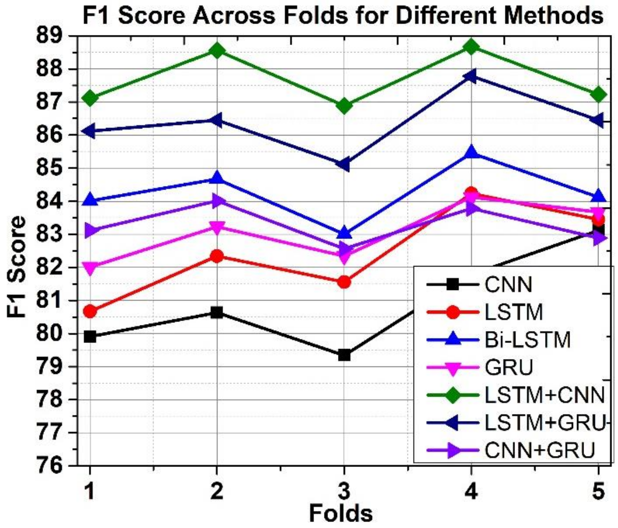

Fig. 6. Comparative analysis of F1 score with various ML methods and hybrid ML algorithms.

Our research compared hybrid machine learning models coupled with metabolomics data to improve thyroid cancer diagnosis. The table shows each method's accuracy, precision, recall, and F1 score across folds. The Convolutional Neural Network (CNN) reliably identified thyroid cancer patterns with 98.57% accuracy. LSTM+CNN and LSTM+GRU hybrid models outperformed standalone models, demonstrating the benefits of joining neural network architectures. Nuanced analysis showed surprising dynamics, with Bi-LSTM balancing accuracy and recall and LSTM+CNN excelling in F1 score. GRU models regularly outperformed 98%, demonstrating the synergy between recurrent neural networks and metabolomics data. LSTM+GRU was a standout hybrid model, outperforming across criteria. Finally, this comparison study helps physicians and researchers use machine learning and metabolomics to diagnose thyroid cancer more accurately.

A. Comparative Study with our Proposed Methods

Comparing hybrid machine learning and metabolomics approaches to thyroid cancer diagnosis examines the performance of different authors' methods. Alabrak et al. [22] used a CNN model and achieved 78% accuracy, demonstrating convolutional neural networks' potential. Wang et al. [24] found 97.34% and 94.42% accuracy in VGG-19 and Inception-ResNet-v2 models, demonstrating the usefulness of sophisticated neural network architectures (see Table III).

TABLE III. COMPARE DIFFERENT RECENT ML METHODS WITH OUR PROPOSED METHODS

Authors	Method	Accuracy
Alabrak et al. 2023 [22]	CNN model	78%
Wang et al. 2019 [24]	VGG-19 and Inception-ResNet-v2 models	97.34% and 94.42%
Chandio et al. 2020 [39]	CNN-based decision support system	99.00%
Hossiny et al. 2021 [25]	Cascaded CNN and split classification techniques	98.74%
Cai et al., 2015 [35]	Random forest ML	86.54%
Proposed model in this paper	Hydrid ML methods (LSTM+CNN, LSTM+GRU, CNN+GRU)	99.1%, 99.12% and 99.45%

Chandio et al. [39] developed a CNN-based decision support system with 99.00% accuracy for thyroid cancer diagnosis. Hossiny et al. [25] achieved 98.74% accuracy using cascaded CNN and split classification. Ensemble learning approaches are versatile, as Cai et al. [35] used a random forest machine learning model to achieve 86.54% accuracy. The hybrid machine learning techniques (LSTM+CNN, LSTM+GRU, CNN+GRU) in our study outperform these models with 99.45% accuracy. This shows that hybrid models, which include LSTM, CNN, and GRU, are better for thyroid cancer diagnosis. The suggested thyroid cancer diagnostic model outperforms individual models and state-of-the-art techniques, indicating clinical applicability and additional study.

VI. CONCLUSIONS AND FUTURE DIRECTIONS

We demonstrated that hybrid machine learning models like LSTM+CNN, LSTM+GRU, and CNN+GRU work. Hybrid models beat CNN, VGG-19, Inception-ResNet-v2, decision support, and random forests (99.45%). According to studies, metabolomics data and advanced machine learning enhance thyroid cancer detection. The hybrid models' high performance exhibits LSTM, CNN, and GRU synergies. These models may enhance thyroid cancer diagnosis and treatment, making them more effective and efficient. Future research should broaden the dataset to ensure model generalizability across patient categories. Exploring hybrid models' interpretability and discovering key qualities that allow correct diagnosis will enhance current methodologies' clinical applicability. Real-world clinical data and healthcare facility validation may further validate the provided models. Scalability and computational efficiency must be evaluated for clinical application of hybrid models. Metabolomics and machine learning should be used to improve thyroid cancer diagnosis models. The combination machine learning-metabolomics research improves thyroid cancer detection. The promising findings might revolutionize the field, boosting patient diagnosis and efficiency.

Future thyroid cancer detection utilizing hybrid machine learning and metabolomics covers several important research topics. First, healthcare organizations must cooperate to gather more and diverse datasets. This cooperation makes models generalizable across demographic groupings and therapeutically useful. Interpretability is crucial for healthcare machine learning model adoption. Further research should enhance hybrid model interpretability to highlight diagnostic patterns. Interpretability helps healthcare practitioners detect thyroid cancer biomarkers and gain confidence. For clinical usage, hybrid models must be scalable and computationally efficient. These models should be optimized for healthcare settings with varying computational resources. Adding the models to healthcare operations may boost acceptability. Metabolomics and machine learning models must evolve to stay ahead. Future research should create methods to benefit hybrid models using metabolomics and machine learning. Multimodal data integration research, encompassing omics and clinical data, is promising. Different data sources may help us comprehend thyroid cancer and build more precise and personalized diagnostic approaches.

Precision Insulin Delivery: Predictive Modelling for Bolus Insulin Injection in Real-Time

V.K.R. Rajeswari Satuluri, Vijayakumar Ponnusamy*
Department of ECE, SRM Institute of Science and Technology, Kattankulathur, Tamil Nadu, India

***Abstract*—Insulin is recommended for patients with Diabetes Mellitus (DM). It is challenging for doctors to prescribe accurate bolus insulin before every meal due to real-time factors such as the size of the meal, skipping a previous meal, and physical activity, which can risk the patient towards hyperglycemia or hypoglycemia. Previous studies executed insulin predictions where the methods did not consider the cases of controlled glucose levels, type of insulin prescribed, time of insulin-induced, and data detersion that can alter the predictions. To address these problems, our work has proposed an insulin predictive model from the integration of Internet of Things (IoT) devices, i.e., Continuous glucose monitoring (CGM) sensor and insulin pumps with rapid-acting insulin type where the insulin dosage with corresponding Current Blood Glucose levels (CBG) and improved Next Blood Glucose levels (NBG) are chosen. The dataset is subjected to data detersion where pre-processing, Exploratory Data Analysis (EDA), and Feature Selection is performed. Machine Learning (ML) models are applied on curated dataset where Decision Tree (DT)-Bagging algorithm, performed the best with a Mean Absolute Error (MAE) of 1.54 and a Mean Square Error (MSE) of 4.15. Performance metrics of the current study imply its suitability in medical applications for accurate prediction of real-time insulin dosage.**

I. Introduction

DM is an abnormality where irregular blood glucose levels arise due to the inadequacy of insulin secretion from the pancreas, insulin action in the body, or both [1]. Prediction of insulin is important for making informed decisions to maintain blood glucose levels [2].

A. Background

Previous methods of predicting insulin dosage based on invasive blood glucose collection methods have not considered the type of insulin which varies for every person that can alter the readings [3-4]. Other challenges are fluctuating glucose levels with respect to lifestyle factors such as skipping the previous meal, meal size, uncontrolled food habits, or physical activity. Prescribed insulin dosage may lead to overdosage and underdosage in these cases. Therefore, there is a need of a prediction model for insulin dosage in real-time which can be achieved from IoT devices by acquiring real-time blood glucose from CGM sensor and an insulin pump data to deliver accurate insulin dosages.

A study implemented a Gradient-boosting classifier to predict diabetes and linear regression for predicting insulin dosage from the Pima diabetes dataset and University of California (UCI) insulin dataset. An accuracy of 100% with the Gradient-boosting classifier and 78% with linear regression is achieved [5]. Deep reinforcement learning is implemented for bolus insulin advisors. It is observed that Time in range (TIR) increased for volunteers with bolus insulin advisor from TIR=74.1%±8.4% to 80.9% ± 6.9%, 54.9% ±12.4% to 61.6 ±14.1 [6]. A study discussed predicting insulin levels from 36 months of patient data by implementing Recurrent Neural Network (RNN)-Long Short-Term Memory (LSTM) and Artificial Neural Network (ANN) with an accuracy of 90% [7]. In a similar study of obtaining high MAE on predicting insulin dosage based on predicted glucose levels, Support Vector Regression (SVR) provides MAE of 28mg/dL on CBG, 21mg/dL on average daily glucose levels, and 3.8mg/dL on insulin required in next 24hrs. The study concludes that predicting accuracy is hard because glucose and insulin are highly erratic [8]. A study attempted to predict the initial inpatient Total Daily Dose (TDD). Ensemble learning model, i.e., Ridge regularization, Lasso regression, Random Forest, Gradient boosted DT is implemented where an Area Under Receiver Operating Curve (AUROC) of 0.85 and Area Under Precision-Recall Curve (AUPRC) of 0.66 is achieved [9]. Another study proposed glucose prediction with an accuracy of 98.7% and insulin dosage delivery prediction by employing an ANN. MSE calculated for ANN is 5.79. Feature Selection is carried out to identify the best features for insulin prediction. Data is set to zero when the patient takes no insulin during data processing. This may result in input data variation due to incorrect data patterns [10]. A dataset containing full CBG and insulin-prescribed information is vital for predicting insulin dosage. Other essential parameters, such as carb ratio, Body Mass Index (BMI), and correction factor, must be considered for predicting insulin dosage. In a similar study of initial insulin estimation during hospital admission, an ensemble algorithm with regression, Random Forest (RF), and gradient boosting is applied to classify patients who require more than six units of insulin and TDD. Receiver operating characteristic curve (ROCC) of 0.84 with 95% confidence interval (CI), Area under the curve (AUC) of 0.65 with a 95% CI, and MAE with 12 units of insulin is achieved [11]. MAE obtained is too high for insulin dosage prediction. In a study of gestational diabetes for predicting insulin levels, the Oral Glucose Tolerance Test (OGTT) was considered an independent predictor. Area Under the Curve (AUC) for the prediction of insulin treatment was found to be 0.77[12]. The algorithm can predict insulin and glucose levels by considering other parameters such as BMI, PBG, NBG, and CBG. Weight, fasting blood glucose, and gender are fed into an ANN algorithm for predicting insulin dosage, where an average accuracy of 96.5% and an average prediction error of 4% are achieved [13]. A neural network (NN) based bolus insulin prediction is attempted in a study from CGM. The NN is trained to learn Standard Formula (SF) parameters by examining the Blood Glucose Risk Index (BGRI). The parameters chosen are the Optimal bolus insulin calculator (SF-OPT), found to be 0.40, and the Neural Network Correction factor (SF-NNC), 0.37. Optimal-Neural network corrector (OPT-NNC), i.e.,0.30, Scheiner -Neural network corrector (SC-NNC), i.e., 0.23, Pettus and Edelman (PE-NNC) which is found to be 0.20[14].

The research gaps identified from the above literature are as follows:

1) The existing methods have predicted insulin by considering blood glucose values and their prescribed insulin dosage. The methods haven't focused on evaluating the cases of improved blood glucose levels w.r.t the prescribed insulin dosage. Therefore, the prediction may not be accurate in real-time.

2) Existing literature hasn't focused on the data detersion process [5-14]. Data detersion is vital for fixing ambiguities, errors, and any irrelevant data that may contribute to weakening the model. It is required for generating reliable visualizations and accurate models.

3) Various types of insulin are suggested for patients such as short-acting, ultra short-acting, intermediatory and long-acting insulin with different onset or peak times. The existing methods haven't focused on the type of insulin for predicting insulin dosage. As every type of insulin varies, the predictions are inaccurate and prone to hyperglycemia or hypoglycemia in real-time.

4) Meal intake is a potential discrepancy that influences the prescribed insulin dosage. Existing methods haven't focused on considering meal intake before the prescribed insulin regimen for accurate prediction of insulin dosage.

There is a need to create a multidisciplinary approach for predicting bolus insulin dosage by considering the parameters, i.e., insulin type, meal influence, CBG, improved NBG, and the corresponding insulin dosage. This attempt trains the model accurately by considering the suitable insulin dosages w.r.t the CBG. Data detersion is required to ensure that the reliability and accuracy is achieved by removing the outliers, inconsistencies to avoid skewed results by improving the quality of data for insightful information. This is our rationale to implement an advanced method of insulin prediction based on CBG and NBG [15] and data detersion methods. To our knowledge, this work is the first attempt from the existing literature to apply various methods of data detersion and prediction of bolus insulin from CBG and NBG levels, i.e., blood glucose recorded after half an hour of inducing bolus insulin. The outcome of the prediction is applicable in making informed clinical decisions, treatment titrations, changes in lifestyle habits, evidence-based dosage recommendations based on the patient's historical data, treatment outcomes, and the patient's response to the drug and clinical trials of insulin drug dosage. The novel contribution of the work is as follows:

1) The novelty of the proposed work is to create a prediction model from CBG and improved NBG for predicting accurate bolus insulin dosage.

2) Among all ML models, a striking improvement with 39.7% (from 3.12 to 1.88) in MAE and 72.7% (from 17.52 to 4.78) in MSE with ANN is achieved after applying Feature Selection.

3) After applying data detersion, the datasets improved the performance with 47.4% (from 3.12 to 1.64) in MAE and 76.2% (from 17.52 to 4.16) in MSE with the ANN model.

4) Bagging and boosting enhanced the performance of the dataset when compared with non-bagging and non-boosting models. An improvement of 35.5% in MAE (from 2.39 to 1.54) and 78.1% MSE (from 18.96 to 4.15) with DT-Bagging is achieved. Similarly,10% in MAE (from 2.39 to 2.13) and 56.6% MSE (from 18.96 to 8.22) with DT-Boosting is achieved.

The proposed work is organized as follows: Section II presents Material and Methods where data collection and cohort, data preparation, and data detersion are carried out. Data pre-processing, EDA, and feature selection are employed in data detersion method. Section III presents the Results and Discussion section, where bolus insulin prediction, predictive analysis, and validation of the DT-Bagging model are executed. The paper ends with Section IV, an exposition on the conclusion.

II. Materials and Methods

This section presents the experimental workflow, starting with data collection, as illustrated in Fig. 1. In data preparation, essential features and a dataset are extracted from the CGM sensor. The procedures and processes for data detersion i.e., data pre-processing, EDA, feature selection, are executed.ML algorithms are applied on the data detersion applied datasets for validation.

A. Data Collection and Cohort

Ethical clearance was obtained from the SRM Medical College Hospital and Research Centre, Kattankulathur-603203, Tamil Nadu, India (Ethical clearance number:-8274/IEC/2022). A publicly available 'closed-loop control to range system' public dataset was obtained from JCHR-JAEB center for health research which was coordinating center. The study was carried out in seven clinical centers (Sansum Diabetes Research Institute; USA, Montpellier University Hospital; France, Shafer Institute for Endocrinology and Diabetes; National Centre for Childhood Diabetes; Schneider Children's Medical Centre of Israel; Sackler Faculty of Medicine; Israel, Barbara Davis Centre for Childhood Diabetes; Colorado) where ethical clearance was approved by respective review boards. The written informed consent was obtained from each patient or parent, with assent obtained as required. The full protocol is available online (www.clinicaltrials.gov/ct2/show/NCT01271023).The study is designed and conducted according to ethical principles that comply with in the Declaration of Helenski. In this work, patient data anonymization was strictly performed by omitting the patient's name, address, and other personal details. The dataset for the proposed work was created considering the datetime and glucose values. Following are the study protocols followed by JDRF and the proposed work:

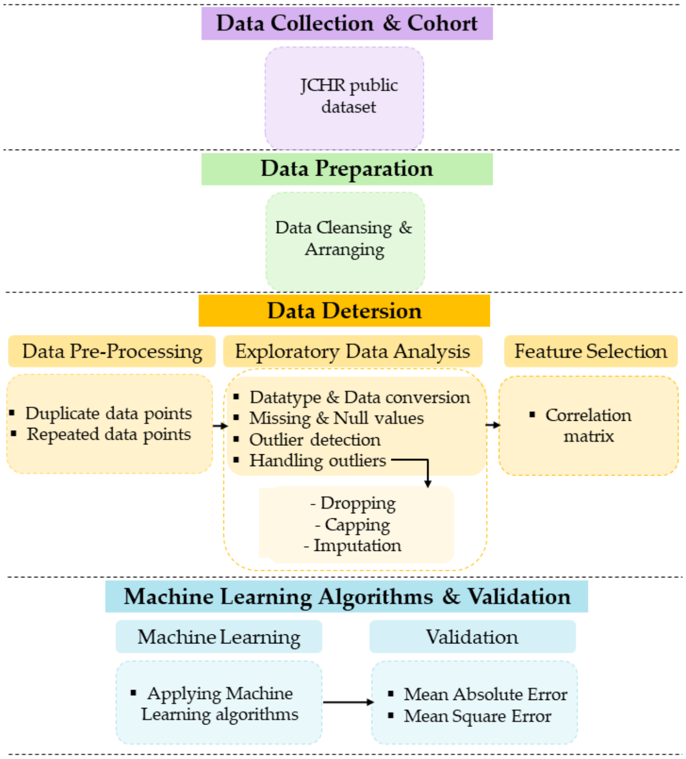

Fig. 1. Flow chart of data analyzation.

1) Eligibility: Clinically diagnosed T1DM patients for at least one year and using insulin pumps for at least six months are chosen for this study because the majority of TIDM patients are required to be on insulin pumps on a daily basis whereas T2DM and Gestational DM patients consume oral medications for regulating blood glucose levels. Patients with proper mental health and cognition for the study are chosen.

2) Sample size: In this work, sample size is chosen based on the patients whose blood glucose levels were improved. Many studies have chosen sample sizes of 13,20,25,56 [6,10,16-18] to predict insulin dosage. Therefore, glucose values at the time of bolus infusion, meal time, and amount of insulin dosage given are focused on a total sample size of 60 patients.

3) Inclusion and exclusion criteria: The inclusion criteria for this study are male and female groups aged 12 to 63 years who were on insulin pumps and CGM sensors without any break. Other age groups discontinued the treatment, and few were from the exclusion criteria. Pregnant and lactating women are excluded. Patients with diabetic ketoacidosis in the last six months, patients with Hypoglycemic episodes with unconsciousness, seizure disorder, and patients who have Coronary artery disease, active infection, muscular condition, and Cystic fibrosis are excluded due to the possibility of potential bias. The patient's name, address, and other personal particulars are entirely omitted.

B. Data Preparation

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations. Data from rapid-acting insulin type is considered in this work. A similar meal size is given to all the patients during lunch, breakfast, and dinner time. Bolus insulin dosage is given before 15 minutes of meal intake. Blood glucose levels are noted. In data preparation, features required for this work are selected from Dataset1. An instance of Dataset1 is presented in Table I. The dataset consists of P.ID, Age, Sex, BMI, CBG, bolus insulin given, bolus date time (Bdt), NBG, CR, CF, and Basal Infusion (BI) as features. NBG is the blood glucose value collected after 30 min and 60 min of bolus infusion. NBG and CBG are noted for every mealtime, i.e., breakfast, lunch, and dinner time. The shaded portion in the table depicts a record of a patient whose condition improved after bolus insulin treatment. The records where the blood glucose levels are improved (all shaded portion of the dataset) after 30 min of bolus infusion are chosen and created in a separate dataset, i.e., Dataset 2.A total of eight features, i.e., Age, Sex, BMI, CBG, bolus infused, NBG, CR, and CF, are selected from Dataset1 and created into Dataset2. The features are selected based on the previous works [5, 10-11,13-14,17-18] that align with predicting bolus insulin dosage for further processing.

C. Data pre-processing, Exploratory Data Analysis, and Feature Selection

Data pre-processing, EDA, and feature selection are executed on Dataset2 by implementing Python software.

1) Data pre-processing: Data pre-processing is the next step after data collection [19,20-21]. At this step, duplicate/repeated data points are removed. In this work, Dataset 2 is checked for duplicate and repeated values at each row. No duplicates or repeated values are found in Dataset2. Therefore, EDA is applied to the dataset.

2) Exploratory data analysis: ML models perform best after applying EDA on the dataset [19,22-23]. Therefore, in this work, EDA is considered the next step after data collection and pre-processing. The primary objective of EDA is to test the data for the nature of data distribution, outliers, anomalies, and complexity. It is a tool to visualize the data for manipulation. It helps in developing parsimonious models and implements clinically relevant variables [19,22]. EDA is applied on Dataset2, where the following steps are implemented:

TABLE I. AN INSTANCE OF DATASET1 CONSTRUCTED

P.ID	Age	Sex	BMI	Bolus Insulin at Breakfast					Bolus Insulin at Lunch					Bolus Insulin at Dinner					Carbohydrate Ratio	Correction Factor
				CBG	Bolus	Bdt	NBG (30min)	NBG (60min)	CBG	Bolus	Bdt	NBG (30min)	NBG (60min)	CBG	Bolus	Bdt	NBG (30min)	NBG (60min)		
4	39	M	33.7564	154	4.25	07-05-2011 9:47:35	110	92	200	2.35	07-05-2011 11:10:42	262	270	145	3.55	07-05-2011 19:07:41	134	129	7	90
12	*40*	*F*	*27.8896*	*134*	*11.25*	*14-06-2012 8:59:46*	*174*	*217*	*379*	*0.35*	*14-06-2012 13:07:10*	*298*	*200*	*110*	*11*	*14-06-2012 19:10:23*	*119*	*110*	*13*	*27*
25	*32*	*M*	*21.9612*	*128*	*4.4*	*01-04-2012 9:00:19*	*115*	*166*	*185*	*4.3*	*01-04-2012 13:01:06*	*182*	*195*	*130*	*4.25*	*01-04-2012 19:01:16*	*119*	*110*	*12*	*20*

P.ID=patient ID;BMI=body mass index;CBG=current blood glucose;Bdt=bolus datetime;NBG=next blood glucose;

a) Datatype and data conversion: The 'Sex' attribute is converted into an integer for ease of analysis. The data type and description of the dataset are thoroughly visualized. The dataset consists of float64 and int64 datatypes suitable for further processing.

b) Identifying missing / null values: The dataset was created by eliminating inactive sensor readings; therefore, null values are not found in the dataset. If a dataset consists of null values, they must be filled by calculating the mean for numerical data and mode for categorical data.

c) Detecting outliers: Outliers are data entry errors, measurement errors, experimental errors, and sampling errors. Outliers are detected using the Interquartile range (IQR) visualization method [24-25]. The Dataset2 is checked for outliers for each feature. Outliers are found at NBG and CBG values. Boxplots for CBG and NBG are depicted in Fig. 2. Outliers detected are detailed in Table IV. It can be observed from Fig. 2(a) that CBG consists of five outliers with a max outlier value of CBG at 383 for patients aged 52 and a min outlier value of CBG at 280 for patients aged 45 as detailed in Table II. It can be observed from Fig. 2(b) that NBG consists of four outliers with a max outlier value of NBG at 370 for a patient aged 52 and a min outlier value of NBG at 268 for a patient aged 12 as detailed in Table II.

IQR is calculated as,

$$IQR = Q3 - Q1 \tag{1}$$

where,

IQR=Interquartile range, Q3=third quartile representing 75th percentile, Q1=first quartile representing 25th percentile

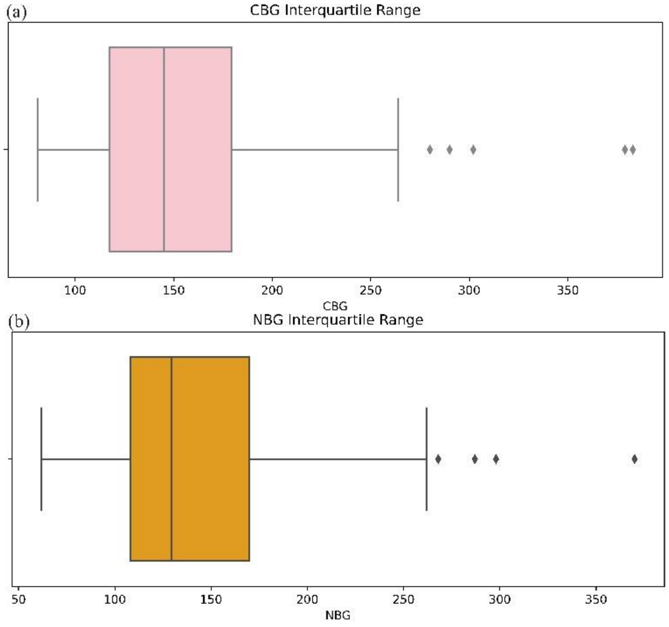

Fig. 2. Outlier detection using the IQR method. (a) Outlier detection in the CBG; (b) Outlier detection in the NBG.

The formula for the outer boundary limit is calculated as,

$$UBL = Q3 + (1.5 \times IQR) \tag{2}$$

$$LBL = Q1 - (1.5 \times IQR) \tag{3}$$

where,

UBL= Upper Boundary Limit, LBL= Lower Boundary Limit,1.5 is the decision range closer to the Gaussian distribution of outlier detection [30].

TABLE II. OUTLIER DETECTED FROM THE DATASET2

Attribute	No.of outliers	Max outlier value	Min outlier value
CBG	5	383 at age 52	280 at age 45
NBG	4	370 at age 52	268 at age 12

CBG=current blood glucose; NBG=next blood glucose

- Handling the outliers: The outliers are handled by considering the lower limit and upper limit boundaries from Eq. (6) and Eq. (7). The outliers are handled by three methods, i.e., dropping the outliers, capping the outliers, and imputing the outliers [26-27]. All approaches are applied on the Dataset2.
- Dropping the outliers: Outliers are dropped in this method. It is done by replacing outliers with a null value to differentiate from other data, and the null values are dropped. In this work, the outliers in the Dataset2 are first transformed into null values. The null values are then dropped from the dataset. A separate dataset ' droppedDataset2' file is created.
- Capping the outliers: The outliers are capped by setting a limit in the dataset. Capped values replace outliers identified above the upper limit and below the lower limit. The upper limit and lower limit is calculated from Eq. (4) and Eq. (5) as,

$$CUL = M + (3 \times SD) \tag{4}$$

$$CLL = M - (3 \times SD) \tag{5}$$

where,

CUL= Capping Upper Limit, CLL=Capping Lower Limit, M=Mean

Capped values on Dataset2 are detailed in Table III. It can be observed from Table III that on Dataset2, the lower limit for capped value is -41.69 for CBG and -46.69 for NBG. Any value falling below the lower limit will be capped at -41.64 for CBG, and -46.69 for NBG. Similarly, any value falling above the upper limit is capped at 362.67 for CBG 341.14 for NBG. The outliers from Dataset2 are capped, and a separate dataset is created as 'cappedDataset2'.

TABLE III. CAPPING OUTLIERS ON DATASET2

Attribute	Capped lower limit value	Capped upper limit value
CBG	-41.64	362.67
NBG	-46.69	341.14

CBG=current blood glucose; NBG=next blood glucose

- Imputing the outliers: The imputation of outliers is carried out by identifying the upper and lower limits in the dataset. The mean value of the feature in the dataset replaces outliers found above the upper limit and below the lower limit. The upper limit and lower limit is calculated from Eq. (6) and Eq. (7) as,

$$UL = Dataset2 > [Q3 + (1.5 \times IQR).max()] \tag{6}$$

$$LL = Dataset2 > [Q3 - (1.5 \times IQR).min()] \tag{7}$$

where,

UL=Upper Limit, LL=Lower limit

TABLE IV. IMPUTING OUTLIERS ON DATASET2

Attribute	Mean value
CBG	140.35
NBG	126.86

CBG=current blood glucose; NBG=next blood glucose

Imputed values from Dataset2 can be observed in Table IV. It can be inferred from Table IV that any value falling above the upper limit and below the lower limit is imputed by mean value, i.e., 140.35 for CBG and 126.86 for NBG. A separate dataset 'imputedDataset2' file is created.

Further analysis is carried out on the three separately created datasets, i.e., droppedDataset2, cappedDataset2, and imputedDataset2.

Feature Selection: After applying EDA on droppedDataset2, cappedDataset2, and imputedDataset2, important features are chosen to increase the performance of a model. At this step, features are selected by implementing a heatmap correlation matrix. This work implements a correlation matrix for finding the related features and patterns in a dataset. The features are highly correlated if the heatmap value is close to 1 [28]. It can be visualized from Fig. 3(a), 3(b), and 3(c) that CBG and NBG are highly correlated, whereas bolus is the target variable. Hence, CBG, NBG, and bolus are selected features from the correlation matrix and CR from [10]. ANN is applied to the dataset to test the correlation matrix's performance. It can be observed from Table V that before using feature selection, MAE of 3.12 and MSE of 17.52 were obtained with ANN. Similarly, after applying feature selection, an MAE of 1.88 and MSE of 4.78 are achieved. An improvement of 39.7% on MAE and 36.9% is observed on the dataset after applying Feature selection. The droppedDataset2, cappedDataset2, and imputedDataset2 are refined by dropping uncorrelated features, i.e., Age, Sex, BMI, CF, and by selecting CBG, NBG, Bolus, and CR.

3) Choosing the Machine Learning Model: In a few studies, LR and logistic regression are implemented [29,12], whereas other notable models such as SVR, RF, RR, LAR, and gradient boosting are explored [5,9,11,29]. Some literature has explored ensemble methods, i.e., bagging, boosting, and DT [10] and ANN [10,12,13,14]. It was inferred from the studies that the performance of the ML algorithm depends on the type of the dataset and methodologies [5-14]. Therefore, in this proposed work, k-NN, k-NN bagging, k-NN boosting, DT, DT bagging, DT boosting, and ANN are compared for validation.

TABLE V. PERFORMANCE METRICS OF ARTIFICIAL NEURAL NETWORKS BEFORE AND AFTER FEATURE SELECTION ON DATASET2

Dataset	MAE	MSE
Before Feature Selection	3.12	17.52
After Feature Selection	1.88	4.78

MAE=mean absolute error; MSE=mean squared error

III. RESULTS AND DISCUSSION

This section presents the results for predicting bolus insulin by applying ML algorithms on curated datasets, i.e., droppedDataset2, cappedDataset2, and imputedDataset2.

A. *Bolus Insulin Prediction Based on Current Blood Glucose and Improved Next Blood Glucose Levels*

The process flow of the work is depicted in Fig. 4. All three datasets are subjected to different ML algorithms for predicting bolus insulin. The models are validated by evaluating MAE and MSE. The performance of each dataset is compared with a recent work carried out to predict insulin [10].

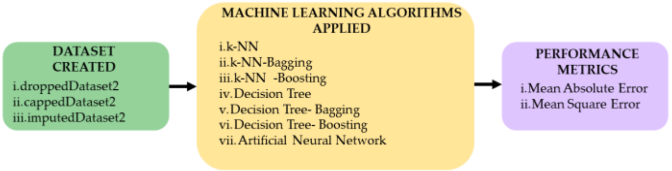

Fig. 4. Illustration of pipelines from dataset, machine learning algorithms and performance metrics.

1) Performance Metrics on Data Detersion Applied Models: Metrics implemented to measure the curated models are MAE and MSE. Absolute Error (AE) is the difference between the target and the predicted value, as mentioned in Eq. (8). MAE is an average of AE, as mentioned in Eq. (9). Squared error (SE) is the difference between the square of the target and the predicted value. MSE is the average mean of SE as mentioned in Eq. (10). The performance metrics are given as,

$$AE = \left|BI_{pred} - BI_{tgt}\right| \tag{8}$$

$$MAE = \frac{1}{M}\sum_{I=1}^{M}\left|BI_{pred} - BI_{tgt}\right| \tag{9}$$

$$MSE = \frac{1}{M}\sum_{i=1}^{M}\left|BI_{tgt} - BI_{pred}\right|^{2} \tag{10}$$

where,

BI =Bolus insulin, M = number of observations, BI_{pred}= predicted bolus insulin level, BI_{tgt}= target bolus insulin level.

2) Predictive Analysis: The dataset consists of 60 samples where CR, CBG, NBG, and Bolus Insulin are considered as input features. The ML models are trained by splitting the dataset into 80% for training and 20% for testing. ML algorithms are applied to the dataset before and after implementing feature selection. It can be inferred from Table VI that the performance metrics are high before feature selection, and the dataset performed the best with an MAE of 1.88 and MSE of 4.78 after feature selection.

K-NN is a regression algorithm where the predicted dependent variable is the average of k-nearest neighbors [30]. k-NN is applied to the curated datasets. Total neighbors, i.e., n_neighbors=21, are considered with 'uniform weights, 'brute' algorithm, and 'Minkowski' tree metric with power 'p=2'. imputedDataset2 performed best with MAE as 2.43 and MSE as 7.40 when compared with droppedDataset2 where MAE as

2.40, MSE as 8.08, and cappedDataset2 with MAE as 2.61, MSE as 10.47 is achieved. A difference in the trend of target and predicted bolus insulin can be observed in Fig. 5(a). Therefore, the model cannot be recommended for prediction of bolus insulin.

Fig. 5. Target and predicted bolus insulin from different models, I.E., (a) K-NN (b) K-NN Bagging (c) K-NN Boosting (d) DT (e) DT-Bagging (f) DT-Boosting (g) ANN.

K-NN with the Bagging-Ensemble algorithm combines two or more models [30]. A bagging regressor is applied on k-NN where the dataset is divided into many subsets, and the model is fitted on each subset independently. Predictions are made by aggregating individual predictions on the subsets [31-32]. K-NN is the base estimator with n_estimators=20. K-NN Bagging is applied on the curated datasets where droppedDataset2 performed best with MAE of 2.34, MSE of 6.53 when compared to the cappedDataset2 with MAE of 2.63, MSE of 10.10 and imputedDataset2 with MAE of 2.63, MSE of 9.73. droppedDataset2 performed best among curated datasets and even with comparison to recent work on predicting insulin [10]. The pattern of target and predicted bolus insulin on droppedDataset2 with k-NN Bagging can be observed in Fig. 5(b). It can be inferred that with an MAE of 2.34 and MSE of 6.53, the pattern of k-NN bagging is similar to k-NN with a decrease of 0.1 in MAE and a 0.87 increase in MSE. Differences can be observed between target and predicted bolus insulin. Therefore, this model cannot be recommended to predict bolus insulin.

K-NN with Boosting is an ensemble learning model learned from previous mistakes of weak classifiers sequentially [30]. The advantage of the model is to tune the weak into a robust model. It is an iterative method of increasing the efficiency of binary classifiers [31-32]. The base estimator is k-NN with n_estimators=100, a learning_rate of 0.3, and a 'square' loss. k-NN Boosting is applied on the curated datasets where imputedDataset2 performed best with MAE of 2.33 and MSE of 7.25 when compared to droppedDataset2 with MAE of 2.33, MSE of 7.48, and cappedDataset2 with MAE of 2.80, MSE of 10.28. The imputedDataset2 performed best in MAE with an increase of 0.9 in MSE when compared to [10]. The trend of target and predicted bolus insulin on imputedDataset2 can be observed in Fig. 5(c), where the pattern of target and predicted bolus insulin is similar to k-NN and k-NN Bagging. Therefore, this algorithm cannot be suggested for the prediction of bolus insulin.

DT model utilizes a set of binary rules to evaluate target value. Each tree has a simple model with branches, nodes, and leaves [33]. DT is applied on the curated datasets, i.e., where droppedDataset2 performed the best with MAE of 2.39, MSE of 18.96, and imputedDataset2 with MAE of 2.04, MSE of 9.13. droppedDataset2 performed best when compared to [10]. It can be inferred from Fig. 5(d) that the pattern of target and predicted bolus insulin performed better than other datasets. Therefore, it can be considered for the prediction of bolus insulin.

DT Model with Bagging is an ensemble model with DT as the base estimator where n_estimators=20.Bagging is applied on the curated datasets where the cappedDataset2 performed the best with MAE of 1.54 and MSE of 4.15 when compared to droppedDataset2 with MAE of 2.10 and MSE of 7.16 and imputedDataset2 with MAE of 2.12 and MSE of 7.51. Curated datasets performed the best compared to recent work on predicting insulin [10]. It can be inferred from Fig. 5(e), with MAE of 1.54 and MSE of 4.15, that the target and predicted bolus insulin follow a pattern. DT model with bagging can be implemented for predicting real-time insulin levels. This prediction is supportive of insulin pump therapy with minimum error.

DT Model with Boosting is an ensemble model with DT as the base estimator where n_estimators=20. Boosting is applied on DT to the curated datasets where capped Dataset2 performed best with MAE of 2.13 and MSE of 8.22 when compared to droppedDataset2 with MAE of 2.19 and MSE of 9.67, and imputedDataset2 with MAE of 2.22 and MSE of 10.26. The curated dataset performed better when compared to recent work [10]. It can be inferred from Fig. 5(f) that the model has a similar pattern to DT-Bagging, with an increase of 0.59 in MAE and 4.07 in MSE. As the former model, i.e., DT-Bagging, performs better than DT-Boosting, the former model can be considered for bolus insulin prediction.

ANN is applied where input dimensions of four, kernel initializer as 'normal' and 'relu' activation layer is considered. Hidden layers of 10 are considered with an epoch of 1000, batch size of 50, and verbose of 1. ANN is applied on the curated datasets where MAE and MSE obtained on droppedDataset2 are 1.64 and 4.16, performing the best compared to recent work [10]. MAE, MSE obtained on droppedDataset2 is 3.65, 18.69, and MAE, MSE obtained on imputedDataset2 is 2.75, 11.75. It can be observed from Fig. 5(g) that droppedDataset2 performed best when compared with cappedDataset2 and imputedDataset2. Due to the higher MAE and MSE of the ANN algorithm than DT with bagging, this model cannot be implemented for real-time prediction of bolus insulin.

DT with bagging performed the best with an MAE of 1.54 and MSE of 4.15. This model is recommended for predicting bolus insulin in real time. The findings of the proposed work are: (i) Feature selection plays a significant role in enhancing the performance of the dataset. An improvement of 39.7% (from 3.12 to 1.88) in MAE and 72.7% (from 17.52 to 4.78) in MSE with ANN is achieved after applying Feature Selection. (ii) The model's performance is enhanced with the data detersion process, where an improvement of 47.4% (from 3.12 to 1.64) in MAE and 76.2% (from 17.52 to 4.16) in MSE with the ANN model. (iii) Applying bagging and boosting enhanced the dataset's performance compared to non-bagging and boosting models. An improvement of 35.5% in MAE (from 2.39 to 1.54) and 78.1% MSE (from 18.96 to 4.15) with DT-Bagging is achieved. Similarly, 10% in MAE (from 2.39 to 2.13) and 56.6% MSE (from 18.96 to 8.22) with DT-Boosting is achieved. Therefore, it can be implied that the integration of AI and data science for the data detersion process boosts the performance of the models. The validation of the DT-Bagging model on cappedDataset2 is presented in the further section.

3) Validation of DT- Bagging Model: Bagging is an ensemble method combining several decision trees to optimize performance. DT with bagging architecture is presented in Fig. 6. The training dataset 'T_r'is divided into several subsets of data, i.e., $T_{1......}$ T_n which can be chosen randomly with replacement. Multiple learning models are generated by training each learner in the ensemble structure with the subsets. The subset of data is implemented for training the decision tree. Prediction from each DT model, i.e.,

$DT\ Model_1\ DT\ Model_n$ are aggregated, and insulin dosage is finally predicted. DT-Bagging is derived in Eq. (11).

$$p(o) = \frac{1}{B_P}\sum_{n=1}^{B_p} p_n\,(o) \qquad (11)$$

where,

$p(o)$ =predicted output, B_P =bootstrapping sets,$p_n(o)$=weak learners

The plot against the target and predicted bolus insulin is depicted in Fig. 7. The X-axis represents the target bolus insulin, whereas the Y-axis represents the predicted bolus insulin. It can be inferred that the target and predicted bolus insulin data points are closer to the trendline, defining a high correlation. DT-Bagging is validated by performing an error analysis. Error analysis evaluates MAE between the target and predicted insulin levels, as illustrated in Table VII. The model is tested with a new dataset of 20 samples where 13 samples are tabulated in Table VII. It can be inferred that the maximum variance achieved is 2.49, and the minimum variance is 0.08, falling under the tolerance limit of ±5 from IEC60601-2-12 of insulin pump protocol [34]. As the performance of the model with MAE of 1.50 is in the clinically acceptable range, the developed model is suitable for deploying insulin pumps.

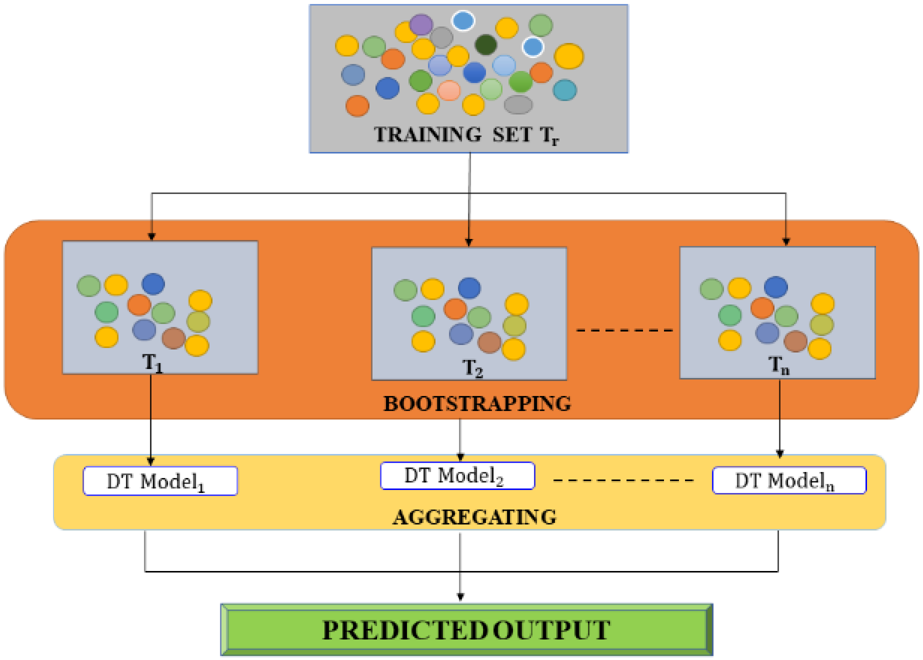

Fig. 6. Decision tree-bagging architecture.

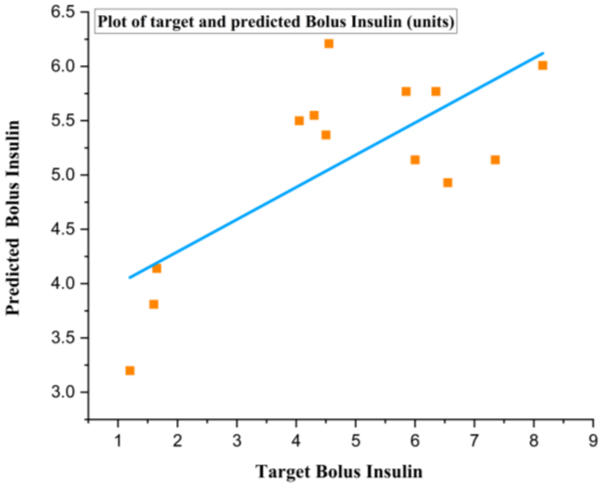

Fig. 7. The plot of target and predicted insulin levels on the proposed data detersion process on logcappeddataset2.

The proposed study is compared with previous approaches to insulin prediction in Table VIII. All the datasets curated from the data detersion process obtained the best performance with MAE and MSE compared to previous literature [9-11, 13].

The data detersion process proposed in the current work obtained the best performance with an MAE of 1.50 and MSE of 4.15.

The implications of the study outcomes are to make informed clinical decisions, treatment titrations, changes in lifestyle habits, and evidence-based dosage recommendations. It can be applied at the development stage of insulin clinical trials and drug dosage.

The model can be deployed in an insulin pump and can be integrated with the CGM device. Insulin dosage can be predicted in real-time based on blood glucose levels. The model can be deployed with a customized regimen considering an individual's health conditions and physical activity. The likelihood of successful outcomes due to improvement in treatment efficacy can be expected from the model's performance in bolus insulin prediction. Therefore, with the proposed work, adverse side effects such as hyperglycemia and hypoglycemia can be controlled, and balanced blood glucose levels can be achieved with better diabetes management.

IV. CONCLUSION

The strength of the proposed work is in (i) Bolus insulin prediction from CBG and improved NBG from previous literature are implemented in the current study [23]. (ii) Feature Selection is done to select correlating features between independent and dependent variables. An improvement of 37.9% is observed before and after applying Feature Selection on MAE and MSE from the DT-Bagging algorithm. (iii) Implementing Bagging on DT has improved the performance by 15% in both MAE and MSE, thus enhancing the model's performance. To understand the performance of the original dataset, ML algorithms are applied after which feature engineering is implemented. This attempt was to analyze if feature engineering could make any improvement in the prediction. To improve the performance after feature engineering, the original dataset was subjected to three ways of data detersion process to cure the data on which ML algorithms are applied. The limitation of the proposed work is the size of the dataset created. As CBG and improved NBG are considered from the dataset of 24,170 rows of bolus infusion, only 60 data showed improvement in NBG levels. Therefore, the model is built on a small dataset of size 60. To deploy the algorithm in a real-time scenario in an insulin pump, uncertainties and artifacts such as integration with CGM device and other health complications. The study is conducted only on T1DM with insulin pumps of at least six months and excluded patients with Diabetic and Coronary disease complications, making the proposed study less generalizable to a large population. Future work is to create a model on the massive dataset by considering CBG and improved NBG levels from different public datasets and predict bolus insulin dosage.

ACKNOWLEDGMENT

The authors are grateful and want to thank the JDRF Artificial Pancreas Project Consortium-Public dataset archive, for allowing them to use the datasets and giving the consent to publish research findings from the study.

Funding: This research received no external funding

Data Availability Statement: The data that support the findings of this study are openly available as ‘Inpatient Evaluation of an Automated Closed-Loop Control-to-Range System (CTR)’ in [JCHR] at [https://public.jaeb.org/datasets/diabetes][35].

Conflicts of Interest: The authors declare no conflict of interest.

Cross-Modal Video Retrieval Model Based on Video-Text Dual Alignment

Zhanbin Che, Huaili Guo*
College of Computer, Zhongyuan University of Technology, Zhengzhou, Henan 450007, China

***Abstract*—Cross-modal video retrieval remains a major challenge in natural language processing due to the natural semantic divide between video and text. Most approaches use a single encoder to extract video and text features separately, and train video-text pairs by means of contrastive learning, but this global alignment of video and text is prone to neglecting more fine-grained features of both. In addition, some studies focus only on profiling the video description text, ignoring the correlation relationship with the video. Therefore, this paper proposes a video retrieval method based on video-text alignment, which realizes both global and fine-grained alignment between video and text. For global alignment, the video and text are aligned by a single encoder and after linear projection; for fine-grained alignment, the video encoder is trained to align the video and text by masking some semantic information in the text. By experimentally comparing with multiple existing methods on MSR-VTT and MSVD datasets, the model achieves R@1 (recall at 1) metrics of 51.5% and 52.4% on MSR-VTT and MSVD datasets, respectively, which indicates that the proposed model can improve the efficiency of cross-modal video retrieval.**

Keywords—Video-text alignment; cross-modal; contrastive learning; similarity measure; feature fusion

I. INTRODUCTION

With the proliferation of mobile devices and high-speed networks, network resources predominantly manifest in textual and video formats. Video's formidable capacity for conveying information confers upon it a distinct advantage, rendering it more popular among users. Video retrieval not only reduces costs but also fosters innovation, enhances the quality of life, and generates economic value in diverse fields such as education, military, and healthcare. Consequently, the demand for precision in video content retrieval is escalating, making the enhancement of video retrieval efficiency a formidable research pursuit. Within the realm of video comprehension, a natural semantic gap exists between the various modalities of video. Solely extracting semantic features from videos is susceptible to yielding sparse feature representations, consequently diminishing the accuracy of video retrieval. Consequently, numerous scholars have endeavored to represent video features through multiple modalities to augment the precision of video retrieval, yielding noteworthy results. Current models such as Frozen [1], CLIP4Clip [2], and Clipbert [3] use contrast learning to achieve semantic alignment and interaction of cross-modal features, where features from different modalities are extracted and then mapped into the same space, enabling global alignment of video with video description text.

The semantic alignment strategy for unimodal encoders in comparative learning typically involves the integration of features from video description text and video features to calculate their similarity. However, this approach often overlooks the association between the local features of the two modalities, resulting in asymmetry in their representation and impacting the efficiency of cross-modal retrieval. In addressing these issues, some researchers employ lexical embedding [4] to achieve fine-grained retrieval by leveraging the relationship between different lexemes. Chen et al. [5] introduced a hierarchical graph inference model to generate text embeddings using an attention-based graph inference mechanism, capturing global-to-local feature associations. Notably, this model primarily focuses on text comprehension and neglects alignment with video content. To address this limitation, HANet [6] enhances the alignment between video and text by introducing a word-level attention mechanism. This mechanism calculates the importance of each word in the video representation and weights the text representation accordingly. However, the computational complexity of HANet is high due to the incorporation of a multi-level attention mechanism.

Upon a thorough examination of relevant research, it becomes evident that video retrieval models should prioritize video sub-regions closely associated with a given video summary. This entails employing cross-modal reasoning between video summaries and video frames to identify the most semantically relevant segments in both, thereby achieving alignment between the video and the summary text. However, prevailing video retrieval models frequently rely on global features of videos, utilizing mean pooling or self-attention methods. Unfortunately, these approaches fall short in effectively integrating the concept of cross-modal reasoning in practical applications. Consequently, the lack of fine-grained semantic attention to both video and summary text within the global alignment model hinders the encoding of localized visual information in the video. This deficiency subsequently leads to a degradation in retrieval performance.

In this paper, we introduce a dual video-text alignment model that aims to narrow the semantic gap between video and text at a finer granularity, thus improving the efficiency of video retrieval. Initially, a conventional methodology is employed to map features from both the video and the summary text into a shared space. This facilitates the computation of contrast loss, thereby achieving global alignment between the video and the text. Subsequently, we concentrate on the actions or scenes involving entities in the video, aligning them with the nouns and verbs present in the

*Corresponding Author.

textual description. This dual-pronged approach not only establishes global alignment but also enables more refined local alignment. The result is a comprehensive interaction between video and text, enhancing retrieval performance.

II. Related Works

This section provides an overview of related work on video retrieval methods and the video-text alignment method used in this paper, where exploring a new video retrieval method is the target task of this paper, and the study of the video-text alignment method is the focus of this paper.

A. Video Search Methods

Video-text alignment methods are more commonly used in video retrieval tasks. In their earlier work, Kaufman et al. [7] focused on pre-training by designing cross-modal fusion mechanisms, utilizing large-scale multimodal data for pre-training, and fine-tuning in downstream tasks. However, these approaches usually focus only on the global alignment of video and text, ignoring the interaction of local representations and affecting the retrieval efficiency.

Currently, popular methods encode video and text into feature vectors that are projected into a common space for matching by means of a dual-encoder structure of a text encoder and a video encoder. These methods utilize dot product operations to compute the global similarity and thus achieve alignment between video and text. For example, Bain et al. [1] proposed an end-to-end model that utilizes the ideas of ViT [8] and Transformer [9] to achieve a common representation of video and text. Luo et al. [2] utilized the knowledge migration of CLIP [10] to match the feature vectors of the video and the text in the common space and retrieve them by using the similarity between the vectors. Li et al. [11] matched multiple encoders in a specific common space, avoiding the dominant role of a single encoder and failing to fully utilize the visual information within the video, relying too much on textual information. In addition, methods based on graph neural networks [12], which represent video and text as graph structures; utilize graph neural networks for information dissemination and fusion. However, these methods still have some problems:

1) Global similarity may not adequately capture the complex relationships between video and text. Since video and text have different structures and semantics, relying only on global similarity may ignore the interaction of local representations.

2) Inconsistency in the length of video and text may lead to information loss. In a dual-encoder architecture, the output of the text encoder is usually truncated to fit the input of the video encoder. This truncation may lead to loss of textual information during the encoding process, thus affecting retrieval.

3) Imbalance of training data may lead to model overfitting. In video-text retrieval tasks, the training data is usually unbalanced, which may lead to overfitting of the model to local similarities during the training process, while ignoring the importance of global similarities.

To address these problems, researchers have proposed some improvement strategies, such as introducing an attention mechanism and utilizing methods such as contrast learning to capture local and global representations between video and text, which can effectively improve the performance of video-text retrieval tasks.

B. Video-Text Alignment Methods

Video-text alignment is commonly used in application domains such as video retrieval, video annotation, and video quizzing, and using features and objects in the video to match with the text is a common alignment method. Some work relies on the attention mechanism to extract information from videos [13], which is then used in downstream tasks such as video quizzing. Wang et al. [14] utilized multiple pre-trained experts to extract multimodal information and use it as an anchor point for alignment with text. Dong et al. [15] designed dual coding networks to perform multilevel coding of video spatial and temporal information with text. Luo et al. [2] based on the inspiration of a large-scale pre-trained graphic-text matching model CLIP [10], migrated the image-text alignment method to video-text alignment to realize video text retrieval. However, all these alignment methods are global alignment on the whole of video and video description text, ignoring the finer-grained semantic information alignment between the two.

To solve the above problems, some works split text descriptions into semantic phrases, e.g., Yang et al. [16] construct a semantic tree representation of the text and use a temporal attention encoder to obtain a video representation. Wang et al. [17] manipulate a fine-grained comparison target by selecting video frames that are semantically equivalent to the text to better learn the representation of the video and the text. Chen et al. [5] extract the text from the sentence to extract verbs and nouns and project them into a shared space for fine-grained alignment. In addition, Li et al. [18] performed large-scale image-text comparison learning through the Twin Towers model, which aligns the visual information in images with the meaning of text masked words through Masked Language Model (MLM) and Image-Text Matching (ITM) to achieve image-text retrieval.

Synthesizing the research on video retrieval algorithms, this paper proposes effective solutions to the problems of the current methods in Section *A*, and the main contributions include:

1) A video-text dual alignment model is proposed to enhance the interaction of local representations by aligning the global and fine-grained features of video with those of text to capture the more complex semantic relationships between the two.

2) Using the Transformer-based dual encoder structure, text information can be encoded more comprehensively, reducing the missing information caused by truncated text features.

3) Using the contrast learning method, video features are fitted to sentence features with global and fine-grained similarity to increase the balance of the training data and improve the video retrieval accuracy.

III. Methodology

The video-text dual alignment method employs dual encoders to train video and text features, proposing a dual alignment model for both global and fine-grained alignment to enhance cross-modal alignment between videos and summary text for improved video retrieval accuracy.

In this section, Section *A* provides an overview of the model to illustrate its working principles and processes, Section *B* details how video and text features are extracted, Section *C* introduces the framework and working principles of the dual alignment network model, Section *D* outlines the model's training strategy. Finally, Sections *E* and *F* elaborate on the objective functions and pretraining datasets used in this approach.

A. Overview of the Model

As illustrated in Fig. 1, our model adopts a two-tower structure to capture semantic information from both video and text during the feature extraction phase, employing dedicated encoders for each modality. For a given set of videos, the TimeSformer [19] serves as the video feature encoder. The output features, denoted as x_i and v_i, plays crucial roles in the global and fine-grained alignment of video and text, respectively. In the case of video description text, two inputs are provided to the text encoder DistilBERT [20]: the sentence with deleted verbs and nouns, and the complete video text description. The extracted text features y_i and t_j are used for global alignment and fine-grained alignment, respectively.

During the video-text alignment phase, one branch focuses on global alignment, projecting global video and text features into a common space. This branch is trained using a contrastive learning method to attain comprehensive semantic alignment of features on a global scale. The other branch is dedicated to fine-grained alignment, achieving detailed alignment between video and text by training a multimodal encoder to acquire vector representations of deleted nouns and verbs in the video modality.

The model enhances its cross-modal alignment capability, specifically in video-text alignment, through the incorporation of a cross-modal attention mechanism. This mechanism projects both the video and text into an embedding space, where semantic similarity is maximized. Consequently, for a given text query, video retrieval is formulated as a cross-modal similarity metric, aiming to identify videos that exhibit semantic alignment with the query.

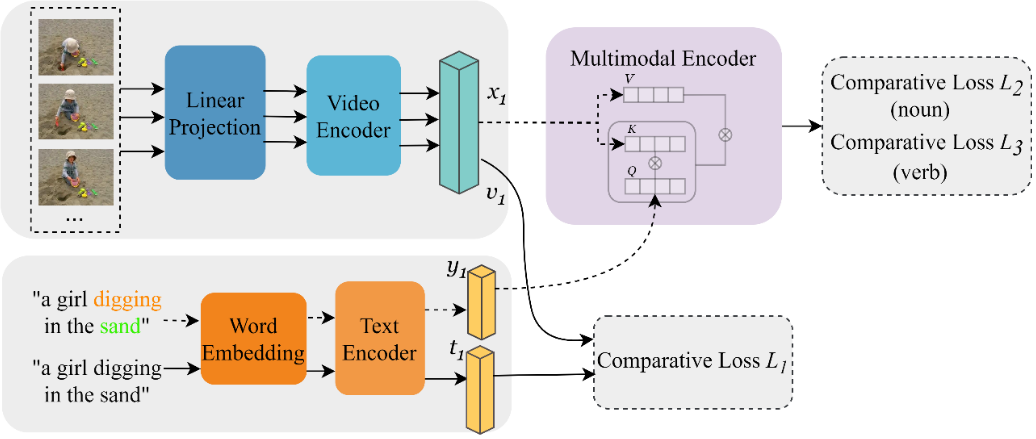

Fig. 1. Video-text dual alignment framework.

B. Feature Extraction

In this approach, both video and summary text undergo parsing using a video encoder and a text encoder. The distinct data modalities are then transformed into a unified numerical representation, yielding a sequence of feature representations for both. This facilitates alignment between the video and summary text on both a global and fine-grained level.

1) Video representation: This paper employs a dual encoder architecture for the extraction of video and text features. Specifically, TimeSformer is utilized to extract video features for each video. During the extraction of video features, as illustrated in Fig. 1, the M video frames of the clip are initially input into TimeSformer. Each video frame is then partitioned into P patches, which are subsequently fed into a linear projection header, spreading them into a series of tokens for the video. Following this, learnable $[CLS]$ tokens are affixed to the header of the sequence, enhancing our ability to learn sentence-level features for downstream tasks. Learnable positional embeddings are also introduced to the tokens. For each video frame feature $v_i \in R^{M\times P\times D}$, with D representing the feature dimension, TimeSformer applies the self-attention mechanism in both temporal and spatial dimensions, generating the final sequence of video frame embeddings $v_i = \{v_{cls}, v_1, v_2, ..., v_p\}$.

2) Text representation: For each of the N text descriptions associated with each video, this approach employs the DistilBERT model for feature extraction.

DistilBERT, being a lightweight BERT [21] model, is more suitable for deployment and operation under resource constraints due to its smaller size compared to the BERT model. DistilBERT produces a text embedding sequence, denoted as $t_j \in R^{N\times D}$, by tagging text description embeddings $[CLS]$ and positional tags, resulting in text features represented by $t_j = \{t_{cls}, t_1, t_2, ..., t_N\}$.

C. Model Framework

This paper centers on the examination of video-text alignment methods, emphasizing the double alignment of feature representations for both video and descriptive text at both global and fine-grained levels. This approach aims to enhance the overall understanding of the video and descriptive text, thereby improving the retrieval accuracy of the model.

1) Global alignment: In the context of global comparative learning, for a given video-text pair, subsequent to extracting features using two distinct encoders, the video embedding sequences and text embedding sequences are initially projected into a shared space through linear projection. Subsequently, all frames of each video undergo aggregation using mean pooling to obtain the average frame $\overline{v_i}$, $\overline{v_i} \in R^{1\times D}$. For each text, this paper extracts the representation by taking the first $[CLS]$ token, denoted as $\overline{t_j}$, $\overline{t_j} \in R^{1\times D}$. Finally, the method computes the similarity between them using the cosine similarity function denoted by $s(v_i, t_j)$. During training, the objective is to maximize the correct pairing of video-text pair comparisons while minimizing the remaining comparison targets that cannot be paired. The cosine similarity function is defined as shown in Eq. (1).

$$s(v_i, t_j) = \frac{\overline{v_i} \bullet \overline{t_j}^T}{\left\|\overline{v_i}\right\|\left\|\overline{t_j}\right\|} \qquad (1)$$

2) Fine-grained alignment: In the domain of video-text alignment, when given a video and its corresponding text description, this approach involves the removal of nouns from the text, utilizing the incomplete sentence with omitted nouns as the text to be aligned. The sentence then undergoes processing through a text encoder to obtain an intermediate text sequence representation $\{n\}_{n\_t}$. Simultaneously, the video is processed through a video encoder to acquire the intermediate video sequence representation $\{c\}_v$.

Subsequently, the linear transformation of the noun text sequence $\{n\}_{n\_t}$ is treated as the query (Q), and the linear transformation of the video sequence $\{c\}_v$ serves as keys and values (K,V). Through cross-modal attention using the Transformer, these are interacted to obtain vector representations of nouns that can be aligned in the video modal space. The nouns, removed from the text, are also processed through the text encoder to obtain a text space vector representation of the nouns, which are used to form positive and negative samples in the comparison target.

The video sequence representation and the noun sequence representation are projected through two separate linear layers into a common embedding space, and their similarity is computed using a cosine similarity function. The formulation of the cross-modal attention mechanism is depicted in Eq. (2):

$$Attention(Q,K,V) = Soft\max(\frac{QK^T}{\sqrt{d_k}})V \qquad (2)$$

where, Q denotes the text sequence originating from the deletion of the noun in the sentence, K and V denote the sequences originating from the video representation, and d_k denotes the dimension of K.

Similarly, the same operation is executed when removing a verb from a text as when omitting a noun. The sequence representation $\{v\}_{v\_t}$ of the sentence lacking the verb is derived, linearly transformed as a query (Q) in cross-modal attention, and interacted with the linear transformation of the video sequence representation $\{c\}_v$ to obtain the vector representation of the verb in the video modal space that can be aligned.

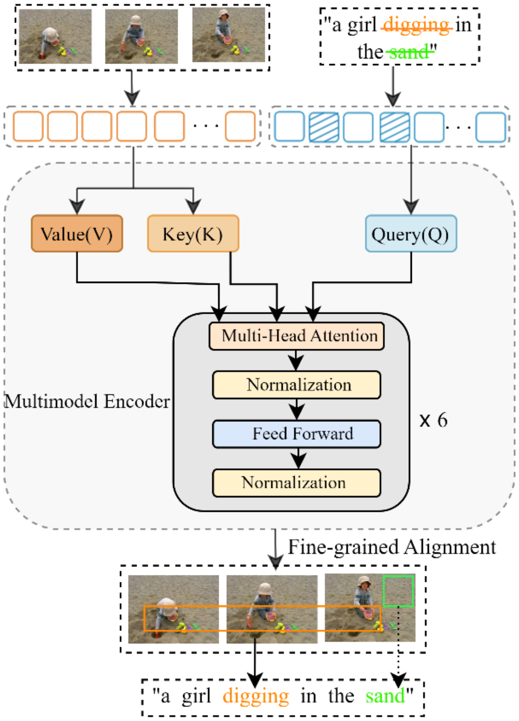

Fig. 2. Fine-grained alignment process.

The removed verbs also undergo processing through a text encoder to obtain a text space vector representation of the verb. The similarity is computed after passing these two representations through separate linear layers.

The fine-grained alignment process is depicted in Fig. 2, where this model linearly transforms the two modal features extracted from the video and the text, each with the noun or verb removed. The linearly transformed Q, K, and V are employed as inputs to the multimodal encoder, which captures cross-modal attentions between the video and the text through the multi-head attention module.

Following this, a contrast learning approach is utilized to maximize the similarity of correctly paired nouns or verbs and minimize the vice versa scenario. The training model is adept at extracting semantic information, such as scenes or actions, from the video content that aligns with the nouns or verbs in the text. This enables a higher degree of fine-grained alignment between the video and the text, consequently enhancing the efficiency of video retrieval.

D. Training Strategy

In the contrast learning model presented in this paper, it projects input samples into a low-dimensional vector space. The model undergoes initial training, ensuring that similar samples in the vector space are mapped to proximate locations, while dissimilar samples are mapped to distant locations. Specifically, for an input sample x_i and a positive sample y_i, the model is trained by maximizing their similarity. Simultaneously, within the same batch, unpaired samples are considered as negative samples. The objective is for the model not only to match positive samples but also to distinguish them from negative samples.

Throughout the training process, for the given video-text pairs, this paper employs comparison learning utilizing the loss function based on cosine similarity scores, as demonstrated in Eq. (3):

$$L_{nce} = -\sum_{i=1}^{N} log \frac{exp(\, s(x_i , y_i \,) / \tau \,)}{\sum_{i=1}^{N} exp((x_i , y_j \,) / \tau \,)} \tag{3}$$

where, $s(\, x_i , y_i \,)$ denotes the similarity score between input samples x_i and samples y_i, and N represents the batch size. The temperature coefficient τ is a hyperparameter that must be set to control how effectively the model discriminates between negative samples. The essence of this loss function lies in the fact that for each sample x_i, this paper normalizes its similarity score with the positive sample y_i by dividing it by the sum of the similarity scores between x_i and all the samples. This process yields a probability distribution, and the logarithm of this distribution is incorporated into the loss function, which is then averaged across all sample results. The objective of this loss function is to maximize the similarity of positive samples while minimizing the similarity with negative samples, aiming to learn a comprehensive feature representation.

In the global alignment comparison learning of video and text, the objective is to maximize the similarity of correctly paired video-text pairs and minimize the similarity of those that cannot be paired. Subsequently, the video and text representations $\overline{v_i}$ and $\overline{t_j}$ outlined, the contrast loss is computed as expressed in Eq. (4):

$$L_1 = -\sum_{i=1}^{N} log \frac{exp(\, s(\overline{\mathbf{v}}_i , \overline{\mathbf{t}}_i \,) / \tau \,)}{\sum_{j=1}^{N} exp((\overline{\mathbf{v}}_i , \overline{\mathbf{t}}_j \,) / \tau \,)} \tag{4}$$

In the context of finer-grained alignment, comparative learning is still employed to maximize the similarity between correctly paired nouns (pairs of nouns) and, conversely, minimize the similarity between nouns that cannot be correctly paired. The model aims to maximize the similarity between x_n and y_n while minimizing the similarity between x_n and y_n. Here, x_n represents the representation of nouns captured from the video space, y_n represents the representation of correctly extracted nouns from the text, and y_k represents the representation of the sequence of other nouns extracted from the same batch of text.

This approach trains the multimodal encoder by relying on the video sequence representations to identify correctly paired nouns, compelling the video encoder to precisely capture the spatial content. The representation of the loss function is shown in Eq. (5):

$$L_2 = -\sum_{i=1}^{N} log \frac{exp(\, s(x_n^i , y_n^i \,) / \tau \,)}{\sum_{j=1}^{N} exp((x_n^i , y_k^j \,) / \tau \,)} \tag{5}$$

where, x_n^i and y_n^i denote the ith paired sample (positive sample), y_k^j denotes the negative sample of the ith sample, and N denotes the batch size.

Similarly, comparative learning for paired verbs focuses on maximizing the similarity between the verb representation x_v in the video space and the verb representation y_v in the text space. Simultaneously, it aims to minimize the similarity between x_v and other verb representations y_v in the text space. The loss function is expressed in Eq. (6):

$$L_3 = -\sum_{i=1}^{N} log \frac{exp(\, s(x_v^i , y_v^i \,) / \tau \,)}{\sum_{i=1}^{N} exp(\, s(x_v^i , y_p^j \,) / \tau \,)} \tag{6}$$

where, x_v^i and y_v^i denote the ith paired sample and y_p^i denotes the jth negative sample of the ith sample.

E. Objective function

This model finds the optimal model parameters by minimizing the sum of the three losses in Section Ⅲ. *D*. The objective function is as in Eq. (7).

$$L = L_1 + L_2 + L_3 \tag{7}$$

F. Pre-training dataset

The video datasets employed for training this model are MSR-VTT [22] and MSVD [23], both comprising approximately 10K video data. To enhance the model's generalization, pre-training is conducted on the combined dataset of CC-3M [24] and WebVid-2M [1], resulting in approximately 5.5M video-text pairs after the merger.

IV. Experimental Setup

In this study, our experiments aim to investigate whether the dual video-text alignment model enhances video retrieval accuracy. Specifically, the model is anticipated to achieve improved accuracy by incorporating a more nuanced understanding of both the video and description text, in contrast to the prevalent utilization of global features. Ablation experiments are then conducted to discern whether the enhanced retrieval accuracy is attributed to the finer-grained comprehension of the video and description text.

In this section, we initially present the general information and implementation details of the dataset used in the experiment. The model's performance is evaluated by reporting R@K and MdR, and the efficacy of our method is established through comparisons with other video retrieval approaches. We also detail the process and results of the ablation experiments. Additionally, this paper utilizes Grad-CAM [25] for generating class activation maps showcasing model cross-modal attention, and concludes with a case study illustrating the retrieval results of the model.

A. Datasets and Evaluation Metrics

1) Datasets: To benchmark against advanced baseline models and assess the performance of our proposed model, we conducted experiments on two widely used public datasets. The details of the dataset sources and divisions are outlined below:

MSR-VTT is curated with 257 popular queries from a commercial video search engine, encompassing a diverse array of categories and video content. It comprises 10k video clips and 200k descriptions. In previous work [26], the training set consists of 9k clip-text pairs, with the remaining 1k pairs designated for evaluation. This model follows the same division for training and evaluation.

MSVD is selected from YouTube, where each video description is independent and not influenced by the vocabulary or word order choices in previous descriptions. The dataset comprises 1,970 videos, ranging in length from 1 to 62 seconds. Each video is associated with approximately 40 descriptions. The training, validation, and test sets consist of 1200, 100, and 670 videos, respectively. This model undergoes training and evaluation using this standardized partition.

2) Evaluation metrics: To assess the performance of the model proposed in this paper, we employ standard evaluation metrics for video retrieval tasks: K recall (R@K, with K values of 1, 5, and 10, higher being preferable) and median rank (MdR, lower being preferable). R@K calculates the percentage of test samples with correct results within the top-K retrieval points relative to the query samples. Calculated as in Eq. (8):

$$R@K = \frac{TP}{TP+FN} \tag{8}$$

where, TP (True Positives) denotes the number of relevant videos that were correctly retrieved in the first K retrieval results and FN (False Negatives) denotes the number of relevant videos that were not retrieved in the first K results.

MdR measures the median position of the correct option in the sequence, assessing the model's capability to rank relevant videos effectively in the retrieval task.

B. Experimental Details

To facilitate training, the video size is initially adjusted to serve as the original input. Frames are sampled from a video during training, where the size of each patch is set to 16×16. Consequently, each video frame corresponds to one patch with sequence dimensions. The temporal and spatial attention blocks in the TimeSformer are initialized using ViT [8] weights pretrained on ImageNet-21k. The text encoder employs the Transformer architecture with eight attention heads, and the dimension of the common feature space is set to 256. During the training phase, this model utilizes the AdamW [28] optimizer with a learning rate set to 3×10^{-5} and 10 training epochs. Multi-interval learning rate tuning is applied: [4, 8], and weights are decayed to 0.1 times their original values.

Building upon previous research, pre-training using image-text pairs proves effective in enhancing the model's representation of the video space. The images in CC-3M were replicated and transformed into static videos. Additionally, we opted for the WebVid-2M video dataset, featuring 2.5M videos, for joint pre-training alongside CC-3M. This was accomplished using the AdamW optimizer, where the learning rate was set to 1×10^{-4}, the number of epochs was 20, and multi-interval learning rate tuning was applied [12, 16]. The weights were attenuated by a factor of 0.1 times their original values.

V. Results and Discussion

To assess the impact of the video-text dual alignment model proposed in this paper on video retrieval accuracy, Tables I and II in this section present experimental results comparing this method with others on the MSR-VTT and MSVD datasets, with optimal results highlighted in bold. Through a comparison of evaluation metrics such as R@K and MdR, our method exhibits improvements in video retrieval task metrics over comparative models like X-CLIP and DCR.

A. Experimental Results

As depicted in Tables I and II, for the MSR-VTT and MSVD datasets, our method achieves a 1.3 percentage point increase in R@1 compared to previous state-of-the-art approaches. Notably, on the MSVD dataset, the improvement in R@1 is 2 percentage points. Simultaneously, there is a reduction in the MdR value in this task. This demonstrates that the incorporation of finer-grained alignment positively influences retrieval performance, underscoring the effectiveness of the proposed method.

The proposed method employs fine-grained alignment of words in text descriptions with actions or scenes in the video, leading to a more accurate alignment between video and text and improved modeling compared to the X-CLIP model, which outperformed other comparison models. While the ALPRO model introduces the concept of PEM for learning fine-grained region-entity alignment, the fine-grained alignment in our method is notably more pronounced for the retrieval task. Moreover, the Clover model also incorporates the idea of modal alignment to enhance cross-modal feature alignment and fusion. In contrast, our approach utilizes the simpler dual alignment to achieve superior performance while successfully meeting the objective of improving retrieval accuracy outlined in this paper.

B. Ablation Study

To assess the efficacy of the dual alignment module and evaluate the impact of various comparison modules on retrieval outcomes, ablation experiments were conducted on two datasets, MSR-VTT and MSVD. Results from the ablation experiments are presented in Tables III and IV, while Fig. 3 provides a visual depiction for a more intuitive understanding of the effects of different alignment modules.

Initially, when solely engaged in the global video-text alignment task L_1, the efficiency of video retrieval across all combinations remains relatively low. This suggests a noticeable semantic gap between the global features of video and text modalities. Subsequently, with the inclusion of fine-grained noun alignment or verb alignment tasks ($L_1 + L_2$ or $L_1 + L_3$), the R@1 values on the MSR-VTT dataset improved by 2.8 and 4.2 percentage points, respectively. This indicates that the combination of global alignment and fine-grained alignment contributes to performance enhancement, albeit not significantly.

TABLE III. ABLATION EXPERIMENT ON MSR-VTT UNIT：%

Method	R@1	R@5	R@10
L_1	40.6	67.4	80.5
L_1+L_2	43.4	72.5	84.9
L_1+L_3	44.8	73.1	83.4
L_1+L_2+L_3	**51.5**	**78.6**	**86.3**

TABLE IV. ABLATION EXPERIMENT ON MSVD UNIT：%

Method	R@1	R@5	R@10
L_1	43.6	69.2	83.6
L_1+L_2	46.5	74.8	85.3
L_1+L_3	45.2	73.5	84.9
L_1+L_2+L_3	**52.4**	**83.3**	**90.5**

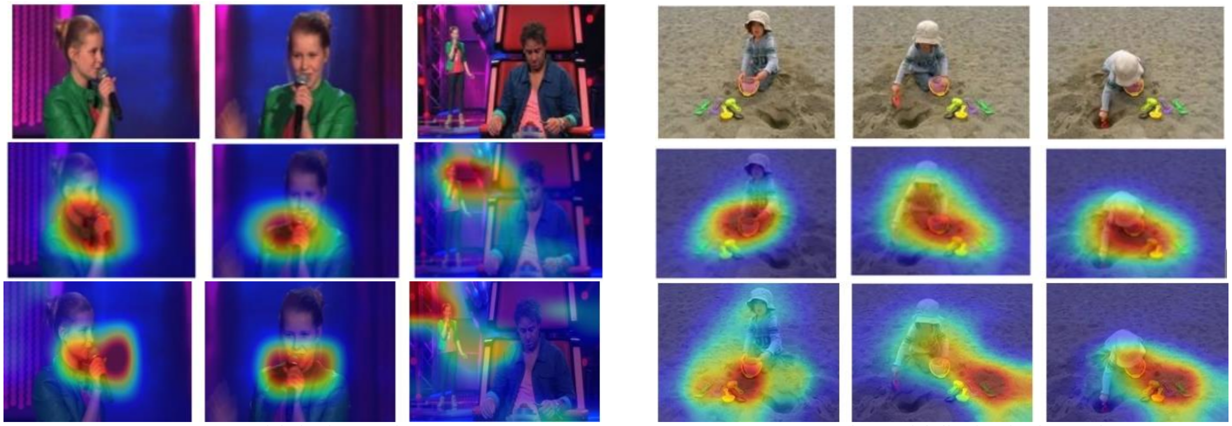
Ultimately, when integrating all three alignment tasks $L_1 + L_2 + L_3$, the model achieves optimal results on both datasets, as depicted in Fig. 3. The R@K values consistently rank highest when utilizing the three alignment strategies, reaching 51.5% and 52.4% at R@1 for the respective datasets. This underscores the effectiveness of combining three alignment strategies in improving retrieval efficiency. Attention Visualization

In the section on fine-grained video-text alignment, this model achieves a comprehensive understanding of the video content. Utilizing Grad-CAM, we generate class activation maps on the MSR-VTT dataset to visually represent the cross-modal attention between the video description and the video. This visualization aids in pinpointing corresponding regions in the video for the nouns or verbs mentioned in the text, showcasing the model's proficiency in fine-grained video-text alignment.

In this study, we employ Grad-CAM to visualize the third layer of the multimodal encoder. To enhance the presentation's clarity, we extract three frames from the video to illustrate the cross-modal attention between the verbs in the text and the video actions. We compare these results with the visualization outcomes of the X-CLIP model. In Fig. 3(a), depicting a scene where a girl sings on stage, our model's visualization captures the continuous focus on the girl's hand and face area, indicating alignment with the word "sing" in the text. Conversely, the X-CLIP model deviates from the girl's hand and face actions, favoring objects behind the girl. In Fig. 3(b), our model's visualization emphasizes the girl's hand movements corresponding to the word "digging" in the text, while the X-CLIP model seems more focused on objects beside the girl than her movements. This suggests that our model exhibits fine-grained cross-modal alignment capabilities compared to other models, emphasizing the importance of such alignment for improving retrieval results.

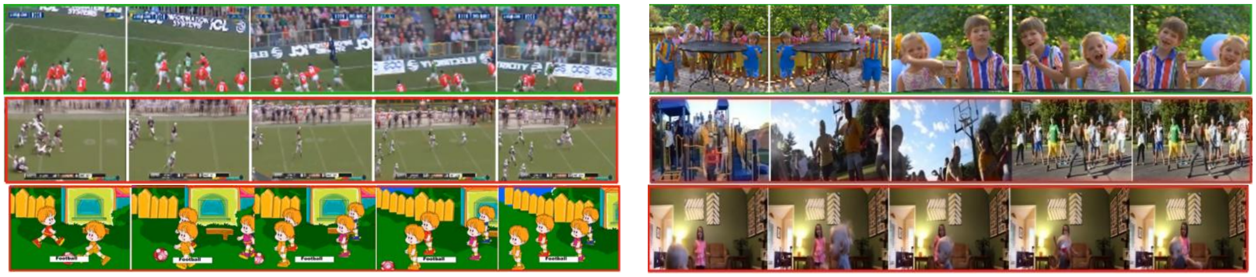
C. Video Retrieval Case

To demonstrate the retrieval effectiveness of the model, we visualize three examples of text retrieval on the test set of the MSR-VTT dataset, as shown in Fig. 4. In example (a), when searching for "two teams playing football," the model successfully retrieves scenes of people playing football, meeting the retrieval criteria. However, only one result is highlighted with a green box, as the model assumes one query corresponds to the optimal result. In Fig. 4(b), searching for "kids are singing by a table" yields the correct result in the first position. While other retrieval results are similar to the optimal one, they do not align with the scene described in the query. This highlights the model's ability to achieve fine-grained alignment between actions and scenes in the retrieval queries and video content, consequently enhancing retrieval efficiency.



(a) “a girl singing on the stage” (b) “a girl digging in the sand”

Fig. 3. Grad-CAM visualizes multimodal encoder cross-modal.



(a) Query: two teams playing football (b) Query: kids are singing by a table

Fig. 4. Text-video retrieval results example.

VI. Conclusion

This paper introduces an efficient video retrieval model through video-text alignment. The model uses TimeSformer and DistilBERT to extract unimodal feature representations from video and text, and performs global video-text alignment by linear projection and contrast learning. Subsequently, the local video information is compared and learned from the textual content by masking part of the textual information in order to achieve fine-grained video-text alignment. By enhancing the cross-modal training process and combining global and fine-grained alignment tasks, the model strengthens semantic associations between modal information, leading to improved alignment and enhanced video retrieval recall. Experiments on MSR-VTT and MSVD datasets validate the model's superiority and method effectiveness.

However, this method also has the non-negligible limitation that it takes a lot of time to perform video-text alignment, and it is also important to find a more efficient alignment.

In future work, we aim to delve deeper into exploring and integrating various modalities in videos, such as audio and subtitles, to further narrow the semantic gap between video and text and enhance the accuracy of video retrieval. Additionally, for the task of video retrieval, there is potential to train models tailored for retrieving videos in specific domains, making the models more specialized and efficient.

Abstract*—Exploring innovative pathways for non-invasive neural communication with language interfaces, this research delves into the interdisciplinary realm of neurolinguistic learning, merging neuroscience and machine learning. It scrutinizes the intricacies of decoding neural patterns associated with language comprehension. Leveraging advanced neural network architectures, specifically Deep Recurrent Neural Networks (RNN) and Gated Recurrent Units (GRU), the study aims to amplify the landscape of neuro-device interaction. The focus of Neurolinguistic Learning lies in extracting language-related brain signals without resorting to invasive procedures. Employing cutting-edge non-invasive methods and deep learning techniques, the research aims to elevate the capabilities of neural devices such as brain-machine interfaces and neuroprosthetics. A distinctive approach involves crafting a sophisticated Deep RNN-GRU model designed to capture intricate brain patterns linked to language processing. This architectural innovation, implemented in the Python software environment, harnesses the strengths of RNNs and GRUs to enhance language decoding. The study's outcomes hold promise for advancing non-invasive brain language decoding systems, contributing to the expanding knowledge base in neurolinguistic learning. The remarkable accuracy of the proposed RNN-GRU model, boasting a 90% accuracy rate, signifies its potential application in critical real-world scenarios. This includes assistive technologies and brain-machine interfaces where precise decoding of cerebral language signals is paramount. The research underscores the efficacy of deep learning methodologies in pushing the boundaries of neurotechnology. Notably, the model outperforms established techniques, surpassing alternatives like CSP-SVM and EEGNet by an impressive 30.4% in accuracy. The model's proficiency in deciphering topic words underscores its ability to extract intricate language patterns from non-invasive brain inputs.

Keywords*—Recurrent Neural Networks (RNN); Gated Recurrent Units (GRU); neurolinguistic learning; neural devices; brain machine interfaces

I. INTRODUCTION

Within the quickly developing field of neurotechnology, the goal of creating a seamless interface between the human brain and external devices has spurred innovative research efforts [1]. Neuro technology is advancing by developing neural-device interaction, an interdisciplinary field that combines neuroscience and engineering to improve two-way communication between neural systems and external devices, aiming to create a seamless interface [2]. Addressing fundamental issues and opening up new avenues for human-machine interfaces are the driving forces behind the advancement of neural-device interaction [3]. Conventional means of communication between neural devices and the brain frequently struggle with issues of signal integrity, bandwidth of information, and procedure invasiveness [4]. It is becoming increasingly important to overcome these obstacles as technology develops in order to improve our comprehension of neural processes and to use this knowledge for useful applications that help people with neurological disorders, disabilities, or those looking to enhance their cognitive abilities.

The understanding of neural signaling’ s complexity and the need for advanced models capable of real-time signal interpretation and deciphering are at the core of this research endeavor [5]. One promising approach is the use of deep reinforcement learning networks (DNRNNs) and GRUs. The dynamic information embedded in neural signals linked to different cognitive functions can be decoded by these models, which are excellent at capturing temporal dependencies and sequential patterns [6]. Learning more about neural-device interaction is important not only for academics and researchers, but also for a wide range of applications in human-computer interaction, rehabilitation, and healthcare [7]. More innovative assistive technologies, tailored therapeutic interventions, and more successful neuroprosthetics can all be made possible by improved neural-device interfaces [8].

Furthermore, these developments pave the way for revolutionary discoveries in areas like brain-machine interfaces, neuromodulation, and cognitive augmentation by facilitating a more intuitive and natural interaction between people and machines [9]. This research explores various methods for data collection and neural network architecture creation, emphasizing non-invasiveness. It describes a workflow for deep RNN-GRU-based neurolinguistic learning to improve neural-device interaction. The goal is to advance brain functions and foster a new era of human-machine cooperation [10].

A growing field identified as neurolinguistic learning has emerged from the dynamic intersection of neuroscience and artificial intelligence in an effort to understand the neural basis of language [11]. In an effort to uncover the mysteries buried in the neural code that underpins our capacity for language comprehension and production, this research explores the complex relationship between neural activity and language processing. Neurolinguistic learning aims to directly access the neural substrate of language, in contrast to traditional linguistic analyses, which rely on external behavioral measures. This approach provides a more nuanced and direct understanding of the cognitive processes involved. The realization that language, a distinguishing feature of human cognition, is not limited to observable behaviors or linguistic outputs is what spurred researchers to explore the field of neurolinguistic learning [12]. Rather, it is firmly anchored in the intricate and dynamic neural activity patterns that emerge inside the brain.

Specifically, non-invasive neural language decoding is the emphasis of this research, which is an important application of neurolinguistic learning [13]. Using invasive techniques like brain electrode implantation, the traditional methods for deciphering neural language patterns are frequently applied. Concerns about safety, ethics, and the need to create more widely available technologies, however, drive the search for non-invasive alternatives. Understanding neural language processes can be gained without invasive procedures by using non-invasive techniques like functional magnetic resonance imaging (fMRI) and electroencephalography (EEG). This work aims to apply deep learning models, namely Deep RNN and GRU, to advance the state-of-the-art in non-invasive neural language decoding. These architectures are especially well-suited to modeling the dynamic nature of language processing because they are good at capturing sequential patterns and temporal dependencies. Through the use of these sophisticated neural network architectures, the research hopes to shed light on the complexities of neural language representation and, as a result, improve our comprehension and decoding skills for the ideas encoded in neural language [3].

Non-invasive neural language decoding has potential to revolutionize assistive technology, neurorehabilitation, and communication technology. It can help people with communication impairments, offer new perspectives on cognitive processes, and create more user-friendly interfaces. This project combines linguistics, artificial intelligence, and neuroscience, transforming our understanding of language and the human mind. [14].Improving the smooth connection between neural devices and the complex processes of language expression and comprehension is one of the main issues in this field [1]. The need to overcome the drawbacks of the invasive procedures that are typically used in neural interface development is what drives this research [15]. Even though they work well, invasive techniques like implanting electrodes directly into the brain come with risks, such as tissue damage and infections. As a result, the search for non-invasive substitutes has taken center stage in the development of neural-device interfaces [16]. This project specifically focuses on leveraging advanced neural network architectures, namely Deep RNN and GRU, to decode neural language signals without resorting to invasive interventions.

Our main focus is on the field of neurolinguistic learning, which investigates the complex connection between language processing and brain activity. The complexity of language patterns is a challenge for traditional neural interfaces because of the difficulties in decoding the rich and dynamic information contained in neural signals. In this work, the author explore the potential of deep learning—more especially, RNN-GRU models—to non-invasively decipher the complex patterns related to language. RNN-GRU models were specifically chosen because of their demonstrated ability to handle sequential data and capture temporal dependencies. These architectures offer a sophisticated understanding of how neural signals encode linguistic information over time, making them well-suited to simulate the dynamic nature of language processing. Through these advanced neural network architectures, we hope to open up new possibilities for neural devices and usher in a new era of non-invasive neural language decoding.

The practical applications of this research have transformative potential and go beyond the domain of neuroscience. A successful implementation could transform augmentative communication technologies and make it possible for people with disabilities or communication disorders to express themselves with never-before-seen ease. Furthermore, our method's non-invasiveness reduces related health risks and encourages accessibility and broad acceptance.

The key contributions of the article is,

- The work proposes a non-invasive method for neurolinguistic learning that harvests language-related brain signals without necessitating invasive procedures. This is achieved by utilizing the most advanced deep learning algorithms, specifically Deep RNN-GRU.
- The study increases the possibility of neuro-device interaction by using complex neural network architectures, notably Deep RNN and GRU. This technology has significant promise for non-invasive neuro-communication applications in both ethical and helpful situations. The incorporation of these topologies facilitates the capture of complex brain patterns associated with language processing in the creation of neurotechnological interfaces.
- The real contribution is the development and use of the Deep RNN-GRU model, which is done using the

Python programming language. This well-designed architecture plays to the strengths of RNNs and GRUs while showcasing an advanced tool for improved language decoding, encouraging transparency and reproducibility within the scientific community.

- The work offers novel and analytical techniques for deciphering language-related brain signals, which significantly advances the rapidly expanding field of neurolinguistic learning. The exceptional accuracy and performance of the suggested RNN-GRU model demonstrate its potential as a revolutionary tool in the ongoing advancement of non-invasive neural language decoding systems.

The remainder sections of the article includes related works, problem statement, methodology and results in Sections II, III, IV and V respectively. The paper is concluded in Section VI.

II. Related Works

Dash et al. [17] proposed neural interpretation of speech in amyotrophic lateral sclerosis. A motor neuron-related illness identified as ALS can result in locked-in syndrome, which is total paralysis with awareness. Through brain computer interfaces, such as EEG spellers, which have a low communication rate, these locked-in patients can converse. Neural speech decoding paradigms that could lead to normal communication rates have been the focus of recent research. However, the focus of current neural decoding research is on typical speakers, and it is unclear how far these findings can be applied to a target population (such as those with ALS). The study examined the decoding of spoken and imagined phrases from non-invasive magnetic resonance imaging signals of individuals with ALS using seven machine learning decoders and multiple spectral characteristics (band-power of neural signals: delta, theta, alpha, beta, and gamma frequency ranges). The outcomes of the experiment showed that while ALS patients' decoding performance is considerably higher than chance, it is still lower than that of healthy individuals. For five imagined phrases and five spoken phrases from ALS patients, the best scores were 75% and 88%, respectively. As far, this is the first instance of neural speech decoding for a population with speech disorders. The disadvantage is that in order to confirm the study's effectiveness, analysis involving a greater number of individuals with more severe ALS and multiple sessions are required. Moreover, improved neurolinguistic comprehension of the imagining of speech would facilitate the development of algorithms for improved imagined speech decoding performance.

Cooney et al. [13] proposed an EEG-fNIRS bimodal deep machine learning design for overt and imagining speech decoding. Research on brain-computer interfaces is increasingly utilizing various characteristics of multiple signal modalities at the same time. The bimodal gathering procedures that integrate the temporal and spatial resolutions of electroencephalography and near-infrared spectroscopy require new decoding techniques. Present an EEG-fNIRS hybrid BCI that utilizes a unique bimodal in nature deep neural network design consisting of two convolutional sub-networks to decode both overt and imagined speech. Each subnet's features are fused before being further extracted and categorized. Classification accuracy using the hybrid approach showed substantial gains on EEG used independently for imagined speech ($p = 0.02$) and a tendency towards a significance for overt speech .The classification accuracy was 46.31% and 34.29%. Bimodal decoding produced significantly better results for both speech types when compared to fNIRS .While stimulus affected overt and imagined words in significantly different ways, deeper subnets improved performance. The bimodal approach performed significantly better than the unimodal results for several tasks. The results imply that neural signal decoding could be enhanced by multi-modal deep learning. With this novel architecture, speech deciphering from bimodal in nature neural signals can be enhanced.

Llanos et al. [18] proposed peripheral stimulation of nerves without invasive procedures improves speech in adults category learning. In animal models, vagus nerve stimulation has been demonstrated to prime adult sensory-perceptual systems towards plasticity. Accurate temporal integrating with auditory stimuli can significantly improve the specificity of auditory cortical representations. Here, the study investigated whether adult speech category learning is improved by sub-perceptual thresholds transcutaneous stimulation of the vagus nerve in conjunction with non-native speech sounds. To recognize non-native Mandarin tone categories, twenty-four native English speakers received training. The tVNS was matched with the tone groups that were either easier or harder to learn for each of the two groups. While receiving no stimulation, the control group used the same thresholding process as the intervention groups. Our findings showed that tVNS significantly improved learning and retention of accurate stimulus-response associations for speech categories, but only when stimulus was combined with categories that were simpler to learn. This effect manifested quickly, generalizing to new exemplars, and differed qualitatively from the typical individual variability seen in hundreds of learners completing the same task in the absence of stimulus. Before and after training, electroencephalography recordings showed no signs of tVNS-induced modifications to the sensation representations of auditory stimuli. According to these findings, paired-tVNS selectively improves both perception and consolidation of memories of intuitively salient categories by inducing a temporally exact neuromodulatory signal.

Feng et al. [19] proposed brain and language semantic alignment: a curriculum contrastive approach for electroencephalography-to-text generation. The tremendous potential for brain-computer interfaces has led to a growing interest in Electroencephalography-to-Text creation, which attempts to produce natural text from EEG signals. But a significant obstacle to this task is the striking difference between the semantic-dependent representation of text and the subject-dependent EEG representation. In order to address this, the study develops a Curriculum Semantic-aware Contrastive Learning approach that reduces the discrepancy by effectively recalibrating the subject-dependent EEG representation to the semantic-dependent equivalent. More precisely, semantically similar EEG representations are pulled together by our C-SCL, while dissimilar ones are pushed apart. Furthermore, carefully utilize curriculum learning to both craft and make the learning progressively meaningful contrastive pairs in order to incorporate more meaningful contrastive pairs. Numerous experiments on the ZuCo benchmark, and our approach, when combined with various models and architectures, achieve the new state-of-the-art while demonstrating steady improvements through three types of metrics. Additional research demonstrates not just its advantages in low-resource and single-subject settings, but also its strong generalizability in zero-shot scenarios.

Lee et al. [20] proposed deciphering language-specific imagined speech neural correlation through EEG signals. Degenerative diseases and brain lesions can cause devastating speech impairments. For people with severe speech deficits, the use of imaginary speech in brain-computer interfaces has proven to be an urging hope for reestablishing speech production nerve impulses. However, due to low signal-to-noise ratio and high variation in both temporal and spatial information, studies in the EEG-based simulated speech domain still have some limitations. In this work, the author examined the neural signals of two native speaker groups performing two tasks in separate languages like English and Chinese. The study postulated that the tonal and ideogram-based Chinese language and the non-tonal and phonogram-based English language would differ spectrally in how their brains computed speech. The results showed that, in some frequency band groups, Chinese and English had significantly different corresponding power spectral densities. Furthermore, native Chinese speakers in the theta band demonstrated distinct spatial evaluation during the imagination task. In order to decode the brainwaves of speech, this paper will therefore propose the essential the spectral and spatial data of word creativity with specialized language. The main flaw is that while the experiment's imagination tasks were designed to categorize words using machine learning algorithms, there hasn't yet been any evaluation of the classification performance.

Jensen et al. [21] proposed MVPA analysis of intertribal phase coherence of neuromagnetic responses to words reliably classifies multiple levels of language processing in the brain. One of the least understood aspects of the human brain is language's neural processing, yet a number of circumstances call for an objective, participant-friendly, and noninvasive assessment of the language function's neurocognitive state. A brief task-free recording of MEG reactions to a series of spoken language contrasts was suggested as a basis for a solution to this problem. Spoken stimuli with differences in lexicon, semantics, were used. The multivariate pattern analysis to investigate intertribal phase coherence in five canonical bands based on beam former source reconstruction is utilized. By employing this method, effectively distinguish between the brain responses to real words and pseudo words, between proper and improper syntax, and between semantic variations. The most accurate classification results showed dispersed activity patterns that were augmented by other regions while being dominated by the core temporofrontal language circuits. The neurolinguistic properties varied across frequency bands; broad γ was used to classify lexical processes, α and β was used to classify semantic distinctions, and low γ feature patterns were used to classify syntax. Importantly, every kind of processing started almost simultaneously 100 milliseconds after the auditory data made it possible to distinguish between spoken and written input. This demonstrates that distinct neuronal networks operating at different frequency bands are involved in individual neurolinguistic processes, which occur simultaneously. This gives rise to even greater hope that neurolinguistic processes in a variety of populations can be objectively and noninvasively evaluated using brain imaging. The disadvantage is that in order to determine whether this method can be used to identify linguistic abnormalities in different populations, it is necessary to fully comprehend the relationship between time courses, frequency bands, neuronal substrates, and neurolinguistic properties.

Time courses, frequency bands, neuronal substrates, and neurolinguistic properties interact in a way that necessitates a thorough comprehension of the approach being considered for detecting linguistic abnormalities in different populations. Although this has great potential, a major limitation is that the classification performance of the word categorization tasks created with machine learning algorithms is not evaluated. Nevertheless, more recent studies demonstrate the method's strong generalizability in zero-shot scenarios in addition to its benefits in low-resource and single-subject settings. Notably, despite subnets not being specifically designed for different data types and suboptimal fNIRS data timing, the dual network enhancement in the majority of subjects' results is a promising result. However, for wider application, resolving the method's drawbacks and carrying out a comprehensive assessment of its overall performance are still essential.

III. Problem Statement

Despite considerable progress in the development of neural-device interfaces, the seamless and efficient communication between the human brain and external technologies remains a formidable challenge. The limitations of current approaches, particularly the invasive nature of many brain interfaces, pose significant risks and hinder widespread adoption. This study addresses this pressing issue by proposing an advanced methodology employing Deep Recurrent Neural Networks (RNN) and Gated Recurrent Units (GRU) for neurolinguistic learning, aiming to provide non-invasive alternatives. The primary objective is to decode cerebral language signals in a non-intrusive manner, representing a crucial initial step towards enhancing the safety and usability of neural interfaces in applications such as assistive technologies, neuroprosthetics, and brain-machine communication. The existing landscape of non-invasive neural language decoding struggles to capture the intricate sequential patterns inherent in language processing. The complexity and dynamism of language-related brain signals pose challenges for conventional techniques. Consequently, the research advocates for the integration of deep RNN-GRU architectures, renowned for their proficiency in capturing sequential dependencies, into the neurolinguistic learning framework. The central challenge lies in designing and optimizing deep learning models to advance our understanding of non-invasive neural language decoding, thereby facilitating more effective and user-friendly neuro-device interactions [21].

IV. Proposed Deep RNN-GRU based Neurolinguistic Learning

The methodology advances non-invasive communication between brain devices and language interfaces by utilizing a multidisciplinary approach based in neurolinguistic learning. The study explores the complexities of deciphering language-related brain patterns, with a focus on the interface between neuroscience and machine learning. By utilizing cutting-edge neural network topologies, particularly Deep RNN and GRU, the study seeks to improve the capabilities of neuro-device interaction. Because the process is non-invasive, there is no need for intrusive procedures, which ensures both practical and ethical viability. A Deep RNN-GRU model is painstakingly built in Python to capture intricate brain patterns related to language processing. The model's ability to decipher complex language patterns, particularly for subject words, indicates its potential for practical uses such as brain-machine interfaces and assistive technologies. This represents a major advancement in the integration of neurolinguistic learning and neurotechnology. The proposed methodology is shown in Fig. 1.

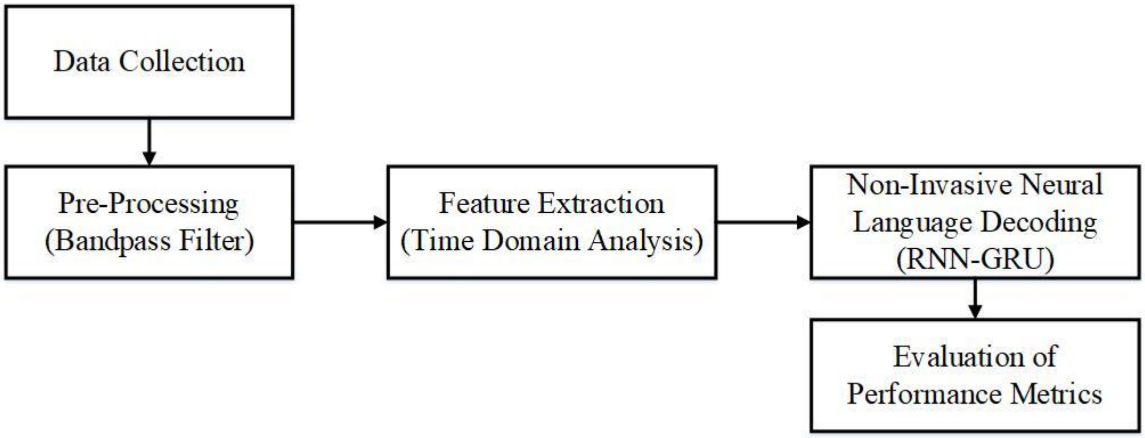
A. Data Collection

Eleven healthy volunteers within the ages of 20 and 34 were recruited for this study, six of them were male and five of them were female. Respondents were made aware of the methods, frameworks, and goals before to the study. Every participant provided written permission in accordance with the Declaration of Helsinki, and all research methods were approved by Korea University's Institutional Review Board. Eight terms that represent the subject, verb, and object parts of the sentence were selected for the experimental setting based on their applicability to natural human-machine interaction, particularly with neural mechanical arm control. The fundamental language was made up of these words, which included subjects like "I" and "partner," verbs like "move," "have," and "drink," and object terms like "box," "cup," and "phone." Every phrase was said by those taking part 25 times, and their audio cues were captured. Respondents wore 64-channel EEG actiCaps during the EEG monitoring session, and MATLAB 2020a software's BrainVision Recorder was used to record EEG signals. Respondents in the study completed speech imaging tasks for every single one of the three sub sessions that focused on subject, verb, and object terms, correspondingly. High signal quality was maintained during the entire trial by providing students with pauses to preserve their physical and mental health and by displaying illustrations on a monitor [22].

One method for transforming EEG signals into a format that is easier to analyze and understand is called spectrogram embedding. EEG data, which show the brain's electrical activity over time, are frequently intricate and provide important insights into cognitive functions. By converting the EEG signal into a spectrogram—a graphic depiction of the signal's frequency content across time spectrogram embedding is achieved. The first step in the procedure is to divide the EEG signal into smaller temporal chunks, or epochs. By doing this, the EEG signal is converted from the time domain to the frequency domain, displaying the various frequency components that are present. Following that, the data is usually shown as a two-dimensional picture with time on one axis and frequency on the other. The shading or color intensity of the image indicates the amplitude of each frequency at a certain moment in time.

B. Preprocessing using Bandpass Filter

The role of a Bandpass Filter is paramount in signal processing, serving to selectively permit a specified range of frequencies while attenuating frequencies outside this designated band. This filter is instrumental in various applications where isolating specific frequency components from a signal is crucial. In fields such as telecommunications, audio processing, and biomedical signal analysis, Bandpass Filters help extract relevant information by allowing only the desired frequency range to pass through. In the context of communication systems, Bandpass Filters aid in frequency division multiplexing, enabling multiple signals to coexist without interference. Moreover, in biomedical applications, Bandpass Filters are essential for isolating physiological signals of interest, such as detecting heartbeats in an ECG. Their versatility in isolating and enhancing specific frequency components makes Bandpass Filters indispensable tools in signal processing, facilitating accurate and targeted analysis across diverse domains.



Data Collection
Pre-Processing (Bandpass Filter)
Feature Extraction (Time Domain Analysis)
Non-Invasive Neural Language Decoding (RNN-GRU)
Evaluation of Performance Metrics

Fig. 1. Proposed methodology.

Applying a Bandpass filter to EEG signals during preprocessing is a crucial step in improving the specificity and quality of brain information derived from the raw data. By selectively allowing some frequencies and attenuating others, the bandpass filter helps to separate the brain oscillations of interest from possible noise and artefacts. One common option for EEG data linked to language activities is to apply a bandpass filter in a certain frequency range, this range has been deliberately selected to include the brain frequencies associated with cognitive functions such as language comprehension and speaking. Unwanted elements, including muscular artefacts or outside interference, are reduced by using the bandpass filter, which makes it possible to analyze the brain activity related to the experimental task more narrowly. Bandpass filtering is important for EEG preprocessing because it can increase the signal-to-noise ratio, which guarantees that the underlying brain signals are more accurately represented in the studies that follow. This specific stage is critical for reliably extracting features for applications requiring nuanced brain patterns, such as language decoding. By helping to improve the overall quality of the EEG data, bandpass filtering advances our knowledge of the brain mechanisms underlying language and communication by enabling more precise interpretations and insights into the neural dynamics linked to cognitive activities.

C. Feature Extraction using Time Domain Analysis

Feature Extraction using Time Domain Analysis serves a crucial role in the neuro-linguistic decoding framework presented in this article. It involves the identification and extraction of relevant features from temporal data patterns associated with neural language signals. By delving into the time domain, this technique enables the model to capture subtle variations and temporal nuances inherent in the non-invasive brain signals. This process enhances the discriminative power of the features fed into the subsequent RNN-GRU model, contributing to the accurate decoding of complex linguistic patterns. Essentially, Feature Extraction using Time Domain Analysis acts as a critical pre-processing step, facilitating the comprehensive representation of temporal information and thereby augmenting the overall effectiveness of the neuro-linguistic decoding system proposed in the study.

Time-domain analysis feature extraction turns out to be a crucial step in deciphering the temporal complexities of EEG signals related to language processing, which is important in the quest to advance neural-device interaction through deep RNN-GRU based neurolinguistic learning for non-invasive neural language decoding. Time-domain features provide a way to describe the dynamic interaction between language components and brain activity throughout the experimental tasks. These features are produced directly from the timing and amplitude information of EEG data. An important temporal aspect of this research is the examination of Event-Related Potentials (ERPs). ERPs are the mean brain responses that are time-locked to certain events, such words being presented in speech-imaging tasks. Researchers can learn more about how the brain responds to language inputs over time by extracting ERPs. The characteristics of ERP components, such as their peak amplitudes, latencies, and durations, offer a thorough description of the brain dynamics connected to various language components. The Mean Absolute Value (MAV) is given below,

$$\text{MAV} = \frac{1}{M}\sum_{j=1}^{M}|y_j| \tag{1}$$

The length of the sample is denoted by M.

When analyzing EEG data, zero crossing is an essential time-domain feature extraction technique, especially when trying to comprehend the temporal dynamics of brain activity. Finding the locations in the EEG signal where the amplitude crosses the zero axis is the goal of this approach. Zero crossing analysis offers important insights into the frequency and pattern of oscillatory variations in the EEG signal, providing information about the underlying brain processes connected to language-related activities in the context of neurolinguistic learning. Researchers can extract features that describe the frequency of transitions between positive and negative voltage values by measuring the number of times the EEG waveform crosses zero within a certain time interval. This characteristic is particularly relevant for identifying rhythmic neural patterns and can enhance the effectiveness of non-invasive neural language decoding techniques by providing a thorough grasp of the temporal dynamics of brain activity during language processing tasks.

$$\{y_j < 0 \text{ and } y_{j+1} > 0\} \text{ or } \{y_j > 0 \text{ and } y_{j+1} < 0\} \tag{2}$$

The consecutive samples are denoted as y_j and y_{j+1}.

To better clarify the timing elements of brain responses during language activities, the study may also concentrate on temporal features including signal length, rise time, and fall time. These behavioral characteristics add to our sophisticated knowledge of the brain's real-time processing of language data. Time-domain analysis is applied to both neural language pattern decoding and deep RNN-GRU model training, where it captures the sequential dependencies present in EEG data related to non-invasive language decoding. This methodological approach is in line with the overall objective of improving neural-device interaction, which will aid in the creation of more efficient and user-friendly brain-machine interfaces for a range of applications in assistive technologies, rehabilitation, and communication.

D. Deep RNN-GRU-based Neurolinguistic Learning for Non-Invasive Neural Language Decoding

RNN-GRU plays an important role in sequential data processing tasks, exhibiting distinct advantages in capturing and understanding temporal dependencies within input sequences. The GRU architecture, a variant of traditional RNNs, introduces gating mechanisms that enable more effective handling of long-range dependencies and mitigate issues like vanishing gradients. This makes RNN-GRU particularly well-suited for applications such as natural language processing, time series analysis, and speech recognition, where contextual information across different time steps is crucial. The inherent ability of RNN-GRU to selectively update and forget information, combined with its parallel processing capabilities, enhances its efficiency in modeling complex temporal patterns. These networks have proven instrumental in tasks requiring nuanced understanding of sequential data, making them a valuable asset in advancing various fields.

The development of deep RNNs and GRUs has led to major breakthroughs in neurolinguistic learning, a cutting-edge discipline at the nexus of neuroscience and linguistics. By non-invasively decoding cerebral language patterns, this novel method seeks to open up new avenues for comprehension of the complex interplay between language processing and brain activity. Deep RNN-GRU models are an advanced type of neural networks that are very useful for language decoding tasks since they are made to collect and analyze temporal connections in sequential input. Because of the GRU's capacity to store and update information selectively across long periods, the design makes it possible to represent language-related brain signals' fluctuations in time in a sophisticated manner.

The ability of deep RNN-GRU models to handle variable-length sequences present in natural language is a significant benefit in neurolinguistic learning. The network can learn hierarchical characteristics of language representation, from intricate syntactic patterns to subtle phonetic variations, thanks to its hierarchical structure. It is ideally suited for deciphering brain signals linked to different language processes because of its versatility. These models are very useful for non-invasive neural language decoding. Conventional approaches frequently entail intrusive techniques like brain electrode implantation, which restricts their application and raises ethical questions. However, non-invasive neuroimaging data, like electroencephalography (EEG), may be used to train deep RNN-GRU models, making this method more generally applicable and morally sound.

During the training phase, the model is exposed to language stimuli while brain activity is being recorded. The deep RNN-GRU continuously improves its capacity to decipher language-related information from brain signals by learning to associate particular patterns in the input data with matching linguistic qualities. The model will get more and more adept at capturing the complex links between brain activity and language representation thanks to this iterative learning process. Deep RNN-GRU-based neurolinguistic learning has a wide range of significant applications. In addition to basic studies on the neurological underpinnings of language, this method has applications in therapeutic situations. It may, for example, aid in the creation of assistive technology for people with communication impairments or function as a tool for tracking alterations in language-related brain activity in response to treatment measures.

Even with the advancements, deep neurolinguistic learning still faces several obstacles. Further work is needed to address ethical issues with permission and privacy, interpretability of learnt representations, and generalization of models across different populations. Interdisciplinary cooperation among neuroscientists, linguists, and machine learning specialists is becoming more and more important as the field develops in order to overcome these obstacles and realize the full potential of deep RNN-GRU-based neurolinguistic learning.

Eq. (3) represents the hidden state update h_t at time t in the RNN. Here, y_t is the input at time h_{t-1} is the hidden state from the previous time step, V^h is the weight matrix associated with the hidden state, and tanh is the hyperbolic tangent activation function. The tanh function introduces non-linearity, allowing the network to capture complex relationships and patterns in the data.

$$h_t = \tanh\,(V^h y_t + V^h h_{t-1}) \tag{3}$$

$$x_t = V^h h_t \tag{4}$$

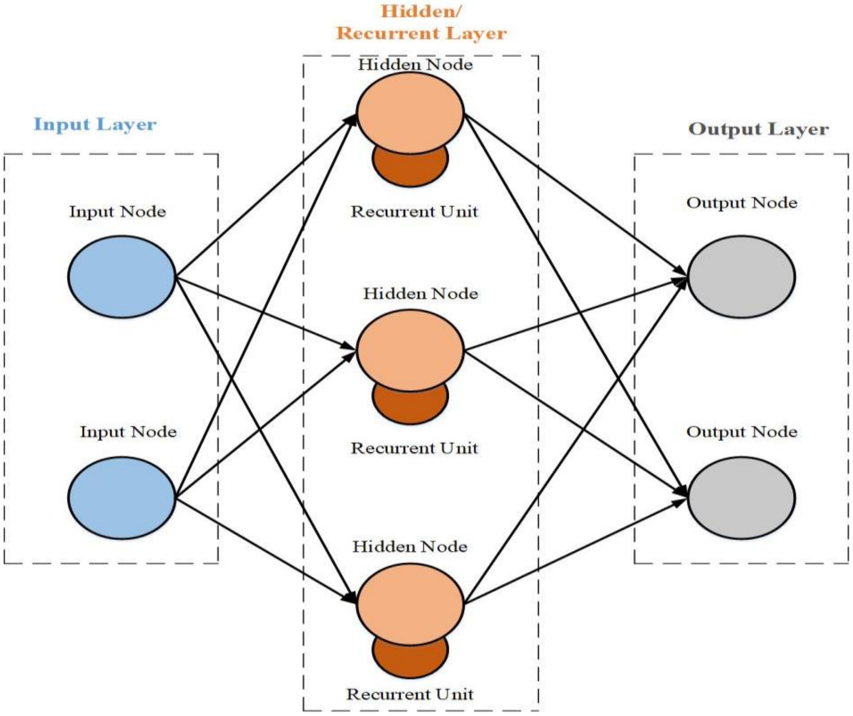


Fig. 2. RNN-GRU architecture.

Fig. 2 shows the architectural diagram of the RNN-GRU model. The above equations form the basis of a GRU, a kind of RNN architecture intended to effectively capture and handle sequential data. The update gate z_t and reset gate r_t, which are both triggered by the sigmoid function σ, are defined by Eq. (3). By deciding what to keep from the prior hidden state h_{t-1} and the current input y_t, these gates control the flow of information. Eq. (4) uses the tanh function to generate the candidate hidden state $\widetilde{h_t}$ and integrates the reset gate r_t to update the hidden state selectively. To provide a seamless transition between the past and current states, Eq. (5) finally combines the update gate z_t with the former hidden state and the candidate hidden state. All together, these formulas describe the complex dynamics of a GRU, which allows it to efficiently recognize and learn sequential patterns in a variety of contexts, including natural language processing and maybe neurolinguistic learning.

$$z_t = \sigma\ (y_t W^z + h_{t-1} V^z) \tag{5}$$

$$r_t = \sigma\ (y_t W^r + h_{t-1} V^r) \tag{6}$$

$$\widetilde{h_t} = \tanh\ (y_t W^h + (r_t * h_{t-1}) V^h) \tag{7}$$

$$h_t = (1 - z_t) * h_{t-1} + z_t * h_t \tag{8}$$

RNN-GRU Algorithm

```
Load and preprocess data      // Bandpass filter
Feature Extraction            // Time Domain Analysis
Define RNN-GRU model architecture
    Split data into training and testing sets
Train the RNN-GRU model
Evaluate the model on the test set
Make predictions on new data
Visualize results
```

V. Results and Discussion

With a foundation in neurolinguistic learning, the methodology advances non-invasive communication between language interfaces and brain devices through a multidisciplinary approach. Situated at the nexus of neuroscience and machine learning, the research delves into the complexities involved in deciphering brain patterns linked to language. The goal of the project is to improve neuro-device interface capabilities by utilizing cutting-edge neural network topologies, including Deep RNN and GRU. Because the approach is non-invasive, it ensures both ethical and practical feasibility by removing the need for intrusive operations. A Deep RNN-GRU model that is carefully designed to capture intricate brain patterns related to language processing is created using Python. The model represents a major advancement in the fusion of neurolinguistic learning and neurotechnology because of its ability to decode complex language patterns, particularly for subject words. This shows the model's potential for use in assistive technologies and brain-machine interfaces.

A. Model Loss

The model loss is a key metric of the model's performance during training. It is commonly expressed as a mathematical measure of the dissimilarity between expected and real neural language patterns. When the loss trend is trending downward, the model is doing a good job of reducing mistakes and modifying its parameters to better suit the training set. A steady decline in loss values across epochs indicates that the non-invasive brain signals have been successfully learned to recognize and adjust to. On the other hand, variations or plateaus in the loss trajectory call for further examination and may indicate that the model needs its hyper parameters adjusted or that overfitting or underfitting occurred. Moreover, comprehending the relationship between decoding accuracy and loss offers a thorough grasp of the model's generalization capabilities and clarifies how resilient it is when decoding a variety of neural language patterns. It is depicted in Fig. 3.

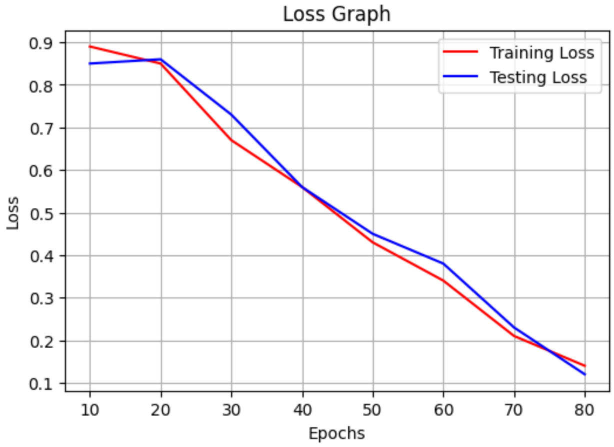

Fig. 3. Model loss.

B. PVC Performance

A statistic called Percent Valid Correct (PVC) performance is employed, especially in cognitive or behavioral studies, to measure the precision and dependability of a classification or prediction system. It shows the proportion of accurate answers or forecasts among all valid cases that were taken into account for a task or experiment. This statistic only looks at how well the system performs when a legitimate answer or forecast can be made; it ignores incorrect or ambiguous data items. This statistic offers a more focused evaluation of the system's effectiveness by highlighting its accomplishments particularly in situations where a significant answer or forecast is anticipated.

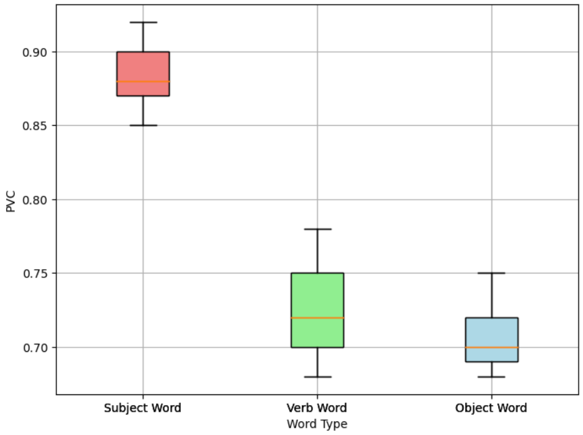

Fig. 4. PVC performance.

A thorough assessment of the model's capacity to decipher brain language patterns is provided by Fig. 4, which shows PVC Performance across many linguistic aspects, namely subject words, verb words, and object words on the x-axis. The way that PVC performance is distributed among various linguistic components provides information on how well the model can identify and anticipate different sentence structure components. Differences in the PVC performance of subject, verb, and object words might be a sign of various brain representations for these linguistic components or of varying degrees of complexity. Understanding the model's complex reactions to many aspects of language requires analyzing the PVC performance across these categories. Doing so may reveal brain activity patterns that alter according to grammatical functions. Furthermore, it offers useful data for adjusting the architecture and training strategies of the model to improve decoding accuracy across various linguistic components, which helps to improve neurolinguistic learning techniques in non-invasive neural language decoding paradigms.

C. Decoding Accuracy over Time

A statistic called decoding accuracy over time is used to evaluate how well a neural decoding model performs and changes over the course of an experiment or activity. This statistic assesses how well the model can predict and understand neural patterns linked to certain cognitive processes or stimuli throughout time. The decoding accuracy's dynamic nature over time offers valuable insights into the model's flexibility and learning dynamics, demonstrating its ability to grasp temporal variations in brain activity. Researchers can identify patterns, trends, or fluctuations in the model's performance by analyzing decoding accuracy at various time intervals. This provides a thorough knowledge of the model's ability to detect and adapt to temporal variations in cognitive or language processing. This measure is especially useful for research using time-series data, such EEG signals, since it offers a detailed assessment of the model's performance in real-time and its possible applications, such as brain-machine interfaces and neurolinguistic learning.

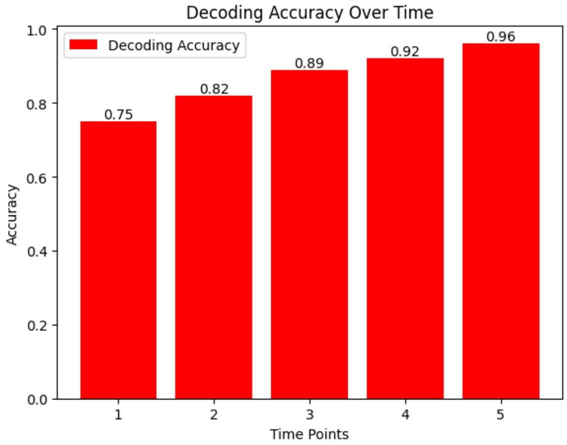

Fig. 5. Decoding accuracy over time.

A more comprehensive illustration of how the model's accuracy changes throughout the course of the task or experiment is given in Fig. 5. Decoding accuracy trajectory tracking over time can show learning, adaptation, or stabilization tendencies in response to changing cognitive demands. Accuracy peaks or troughs at particular times might be related to different stages of the experiment, such when stimuli are presented or when language tasks are performed. Determining the model's sensitivity to temporal changes in brain activity and maybe identifying crucial intervals for optimal performance require an understanding of the oscillations in decoding accuracy. Furthermore, this temporal analysis provides useful insights for improving the model, helping scientists adjust parameters or add adaptive techniques to improve accuracy at critical times. In the end, this helps develop more efficient and temporally-aware neural decoding systems for use in neuroscience and brain-machine interfaces.

D. PVC Distribution across Different Word Types for Various Methods

The pattern or spread of PVC performance across several categories or classes of words within a given dataset is referred to as the PVC distribution across various word kinds. This metric measures the precision of a classification or decoding system and evaluates its performance over a range of linguistic aspects, especially in the context of neurolinguistic learning or non-invasive brain language decoding. The distribution analysis seeks to identify any differences in the model's ability to decode various word kinds, including verb, object, and subject terms. Gaining an understanding of the PVC distribution allows one to assess the model's performance in a more complex way by gaining insight into how sensitive and flexible it is to different linguistic elements.

TABLE I. PVC DISTRIBUTION ACROSS DIFFERENT WORD TYPES FOR VARIOUS METHODS

Methods	Subject Word	Verb Word	Object Word
CSP-SVM [23]	0.60	0.52	0.48
EEGNet [24]	0.78	0.56	0.53
Proposed RNN-GRU	0.90	0.72	0.70

Table I presents the decoding accuracy ratings for the various techniques (CSP-SVM [23], EEGNet [24], and the suggested RNN-GRU model) for various linguistic components (verb, object, and subject words). Prominently, the suggested RNN-GRU model outperforms the other techniques in every category, with exceptional accuracy of 0.90 for subject words, 0.72 for verb words, and 0.70 for object words. This shows that in terms of collecting and interpreting neural patterns associated with various linguistic components, the RNN-GRU architecture—which was created for neurolinguistic learning in non-invasive neural language decoding performs better than more conventional techniques like CSP-SVM and EEGNet. The suggested RNN-GRU model's effectiveness in comprehending and decoding complex linguistic representations from non-invasive neural signals is highlighted by the notable accuracy improvement, especially in the decoding of subject words. This highlights the model's potential to advance the fields of neural-device interaction and neurolinguistic learning. It is depicted in Fig. 6.

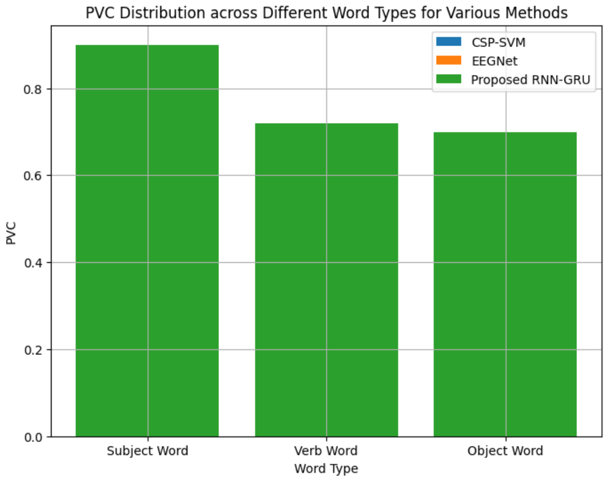

Fig. 6. PVC distribution across different word types for various methods.

E. Discussion

The study's findings, which are represented in the decoding accuracy scores for various techniques across subject, verb, and object words, offer important new information on the effectiveness of applied neurolinguistic learning strategies for non-invasive brain language decoding. Remarkably, the suggested RNN-GRU model demonstrates significant accuracy gains over conventional techniques like CSP-SVM [23] and EEGNet [24], especially in the decoding of topic words. This indicates how well the model is able to represent and decipher intricate brain patterns linked to various language components. The observed distribution of PVC performance over various word kinds clarifies the model's subtle competency and provides a thorough grasp of its flexibility to various language processing components. The area of neuro-device interaction has benefited greatly from these discoveries, which highlight the promise of deep learning techniques more especially, the suggested RNN-GRU model in improving the precision and usability of non-invasive neural language decoding systems.

The observed distribution of PVC performance over various word kinds clarifies the model's subtle competency and provides a thorough grasp of its flexibility to various language processing components. The area of neuro-device interaction has benefited greatly from these discoveries, which highlight the promise of deep learning techniques more especially, the suggested RNN-GRU model in improving the precision and usability of non-invasive neural language decoding systems. Overall, the results suggest potential directions for applications in neurotechnology and human-computer interaction, as well as advancing neurolinguistic learning approaches and laying the groundwork for future advancements in non-invasive cerebral language decoding.

VI. Conclusion and Future Scope

This research underscores the advancement possibilities in non-invasive neural language decoding through the application of a deep RNN-GRU-based neurolinguistic learning technique, thereby augmenting the capabilities of brain-device interfaces. The findings presented illustrate the superior aptitude of the proposed RNN-GRU model in capturing intricate linguistic nuances from non-invasive brain signals, outperforming traditional methods like CSP-SVM and EEGNet, particularly in decoding topic terms. The model's adaptability to diverse linguistic components is evident in the nuanced distribution of PVC performance across different word types, emphasizing its potential to enhance the accuracy and robustness of non-invasive neural language decoding systems. The flexibility of the model to various linguistic elements highlights its potential to improve the precision and resilience of non-invasive neural language decoding systems. For responsible implementation, it is imperative to handle constraints including generalizability, interpretability, and ethical issues. Neural patterns associated with language comprehension can vary across individuals, languages, and contexts. Thus, the model's performance might differ when applied to different populations or languages.

In order to further increase decoding performance, future research could concentrate on optimizing hyper parameters and fine-tuning the model for the proposed RNN-GRU architecture. Expanding the dataset to include more real-world scenarios and language components might improve the model's applicability and generalizability. Enhancing the model for real-time decoding and dynamic language processing tasks could increase its usefulness in applications like assistive technology and brain-machine interfaces. Furthermore, examining the interpretability of the model's learnt representations may yield further insights into the neurological underpinnings of language processing. It is still essential for responsible implementation to address ethical issues, such as participant privacy and the moral use of brain data.

Post Pandemic Tourism: Sentiment Analysis using Support Vector Machine Based on TikTok Data

Norlina Mohd Sabri*, Siti Nur Athira Muhamad Subki, Ummu Fatihah Mohd Bahrin, Mazidah Puteh
College of Computing, Informatics and Mathematics
Universiti Teknologi MARA Cawangan Terengganu, Kampus Kuala Terengganu, Malaysia

***Abstract*—The tourism industry is one of the hard hit businesses during the Covid-19 pandemic and has been struggling for backup ever since. However, nowadays the industry has started to bloom again with the lifting of all of the restrictions of Covid-19. This research aims to analyze the sentiments of the tourists using the Support Vector Machine (SVM) algorithm to know their views on the tourist spots after the pandemic. The scope of the research covers the state of Terengganu which is popularly known for its islands and unique culture on the east coast of Malaysia. TikTok data has been used as the source of data as social media currently has become one of the top mediums for reviewing, selling and promoting products and services. The objective of the research is to explore the SVM algorithm in the sentiment classification of tourist spots in Terengganu. This research is expected to help the Tourism Terengganu to improve their tourist spots and their services. The phases of the research include collecting data from TikTok, data pre-processing, data labelling, feature extraction, model creation using SVM, graphical user interface development and performance evaluation. The evaluation results showed that the performance of the SVM classifier model was good and reliable, with 90.68% accuracy. The future work would be collecting more data from TikTok regularly to further improve the accuracy of the algorithm.**

Keywords—Post pandemic tourism; support vector machine; sentiment classification; TikTok data

I. Introduction

The Covid-19 pandemic has once brought tourism to stop and become one of the hardest hit businesses in the global economy [1]. However, this industry is starting to bloom again with the lifting of all the Covid-19 restrictions and also the less severe effects of virus infections. In the early days of the opening of tourism, people have been educated about the new normal procedures such as wearing masks, social distancing and sanitizing hands [2]. Since then, people have not been afraid to go anywhere in the world for a holiday getaway. Tourism is now slowly recovering and is back again as one of the country's sources of economic growth. The outbreak of the Covid-19 virus is not the biggest concern nowadays since people can get treatment if infected [3].

Terengganu is one of the states in Malaysia, located on the east coast of the Malaysian peninsular. It is a coastal state, facing the South China Sea with diverse tourist attractions such as natural tourism, cultural tourism and marine tourism. Terengganu is renowned for its islands, stunning beaches, and abundant marine life. Since the opening of the tourism businesses, social media has grown to be a very powerful information source for tourists to share their experiences. Social media such as Facebook, TikTok, Twitter and Instagram allow tourists to describe their own experience with the hotel, restaurants, and other tourist attractions. These shared sentiments have a big impact on local tourism.

Sentiment analysis (SA), also known as opinion mining is the computation of people's opinions, judgments and emotions through entities, events and attributes held by the users [4]. Sentiment analysis or opinion mining uses natural language processing and text analytics to locate and extract subjective information from source materials. To determine whether a statement indicates a positive or negative opinion towards the subject, sentiment analysis is frequently used to extract sentiments, opinions, and subjectivity from texts [5].

The ability of locals and visitors to express their sentiments is essential for the development of tourism. The expressed opinions and emotions in the reviews from social media could be extracted and analysed for the improvement of the business. Summary findings from sentiment analysis will aid tourists in selecting their tour destination and itinerary [6]. Tourists may do an information search to select the right location, which can be difficult due to the abundance of options and information on the Internet [7]. Sentiment analysis could be used to gather feedback for any tourist spots, thus helping people to choose the right vacations for them.

Based on these motivations, this research has proposed the sentiment analysis for Terengganu tourist spots after the pandemic using TikTok data. TikTok has been chosen as it has become the top medium for today's online business and socialization. TikTok is one of the social media platforms that have the power to spread news and information. Moreover, many travel and tourism companies nowadays use TikTok to promote their tourist attractions or activities. Reviews from TikTok could be classified into positive or negative sentiments. This sentiment analysis is based on the machine learning approach and Support Vector Machine (SVM) has been chosen as the classifier. SVM has proven to be able to produce good performance in sentiment classification problems [8] [9] [10] [11]. The objective of the research is to explore the capability of SVM in the classification of Terengganu's tourist spot reviews after the Covid-19 pandemic using TikTok data. The analysis results are expected to help the Tourism Agency and also the tourists to know the current conditions of the tourist spots in Terengganu, especially after the Covid-19 pandemic. This paper is arranged into five main sections which are the Introduction in Section I, Brief Literature Review in Section II, Material and Method in Section III, Result and Discussion in

Section IV and finally paper is concluded in Section V. The Brief Literature Review section provides explanation on SVM, its advantage, limitation and the previous works that have implemented the algorithm.

II. Brief Literature Review

A. Support Vector Machine (SVM)

Support Vector Machine is a global classification algorithm under the supervised learning method. SVM uses the hyperplane, which separates new inputs and produces the output [12]. The basic concept of SVM is to identify the optimum hyperplane that divides two different classes which are positive and negative classes. A separator in a d-dimensional space known as a hyperplane has d-1 dimensions. The data points closest to the hyper-plane, known as support vectors, have an impact on the hyper-position planes and orientation. The margin, or the distance between the support vectors and the hyperplane, must be maximal for the hyperplane that has been chosen. The hyper-plane can be altered by even a slight interference in the location of these support vectors. There are different types of kernel functions in SVM. The kernel's job is to accept input data and transform it into the required shape. The kernels are Linear, Polynomial and Radial Basis Function (RBF). Each of the kernels has its formula based on their concepts [13].

The advantage of SVM is that the binary classifier SVM is very efficient and has the benefit of being able to categorize with a minimal amount of information [14]. However, SVM also has its limitations such as being time-consuming when used with big amounts of data. Also, this method must be modified to classify data into more than two classes since it was designed to classify with only two classes [15]. In this research, SVM has been selected due to its suitability to process an ample amount of data and only two classes are needed in the sentiment classification.

B. Implementation of SVM Algorithm in Various Problems

SVM has been implemented in various classification problems and the results have proven to be promising. Reference [16] uses SVM, K-Nearest Neighbour (KNN) and Naive Bayes algorithm in the classification of wheat grain. This study aimed to determine the most discriminatory features and a suitable classifier that may classify the given wheat sample into classes ‘fresh’ or ‘rotten’. Since wheat is the body's principal source of energy in the form of protein, it needs to be stored with a good storage management system. The results showed that the SVM classifier outperformed other classifiers by achieving an accuracy of 93%. Another implementation of SVM was the analysis of lung cancer classification using multiple feature extraction with SVM and KNN [17]. The lung cancer was a result from the unchecked cell proliferation in a lung area. This project aimed to classify the lung CT images as normal or damaged. The results showed that SVM has achieved the highest accuracy of 96.42%.

Reference [18] has conducted a research on movie recommendation and sentiment analysis using Naïve Bayes and SVM. This project aimed to perform sentiment analysis on the movie’s reviews and to deal with the vast volume of data. The overall accuracies have shown that SVM has achieved 98.63% whereas the accuracy of Naïve Bayes was 97.33%. Reference [19] has conducted a research on sentiment analysis based on the reviews of the smartphone. There are so many smartphone products on the market which provide high-efficiency features and customers were more likely to write reviews about them. The results of this research showed that SVM has produced 79.5% accuracy. Reference in [20] has conducted a research to classify the online class student feedback in new semester. An analytical approach is required to learn the feelings of the students as they begin the new semester with online learning. In the research, the SVM method has obtained a good accuracy of 84%. Based on the previous problems, SVM has generated good performance in sentiment classification problems. Based on the algorithm’s capability, it is worth exploring the algorithm in this classification problem.

III. Material and Method

A. Experimental Data

In this research, the TikTok application has been utilized to gather information for identifying tourist attractions in Terengganu. There are many tourist attractions in Terengganu such as the islands of Redang, Perhentian, Kapas, Tenggol and also on the mainland which are Pasar Payang, Taman Tamadun Islam, Batu Buruk Beach and the Terengganu State Musem. The data was collected from TikTok by using Chrome Developer Console and JavaScript has been used to automate data extraction from the TikTok website. The search keys were “Amazing Terengganu”, “Tourism Terengganu”, “Terengganu best places” and “Terengganu aesthetic”. All those keys were searched one by one, and the data scrapped was saved into the .csv file format. The data were scrapped from March to July 2023. A total of 1311 rows of reviews had been scrapped from TikTok and the data contained 11 attributes which are comment number (id), nickname, user@, user URL, comment, time, likes, profile picture URL, 2nd level comment, the user replied to and number of replies. Since this project was only focused on analysing the comments made by the user, all other attributes were discarded during the pre-processing stage.

B. Data Pre-processing

The data pre-processing is an essential part of natural language processing when it comes to text classification [21]. The unstructured data from TikTok were processed in the next stage via the data pre-processing techniques. The steps of the TikTok data pre-processing are removing duplicated data, lowercase conversion, removing TikTok mention and punctuation, tokenization and stop words removal, POS-tags labelling and lemmatization.

The first step is to remove the duplicated data from the raw dataset. The number of the raw data was 1311, which has been reduced to 1305 when all duplicated data were deleted. For lowercase conversion, the lower() method has been used to convert all of the comments to lowercase. After that, the hashtag symbol (#), user handles (@) and non-letter characters were then removed from the remark by replacing them with a blank string. These TikTok mentions and punctuation was eliminated to avoid interfering later with the main process. The next step is the tokenization and the stop words removal, which is necessary to improve the readability and transformability during feature extraction. Tokenization divides all text sentences into smaller pieces called tokens. Following tokenization, stopwords removal was applied to the clean dataset, removing stopwords from the NLTK package. The lambda function is used to eliminate the stopwords. Then, the POS tagging established the word class based on the word's placement in the sentences, indicating whether the word was a noun, adjective, verb, and so on, to allow for future lemmatization use. The POS tags of a word are necessary for correctly obtaining the word's lemma. Finally, the lemmatization step was applied to the dataset to produce meaningful root words. Lemmatization was chosen over stemming because it generated better results by analysing the word's portion and constructing actual dictionary words.

Fig. 1 shows the outcome of the data pre-processing steps, which demonstrates that most of the data have been adequately cleaned.

Fig. 1. Data pre-processing results.

C. Data Labelling

After data cleaning, the data must be labelled to train the classifier model. Textblob is used in this project to label the text polarity to determine the text sentiment. Positive sentiment and negative sentiment are the two sentiment classes that have been assigned to the user review data. The positive class classification was based on comments that have supportive, agreeable, and positive-sounding terms. The negative class was based on user complaints or unhappiness with the situation. The dataset has been cleaned up of neutral remarks and comments that have nothing to do with the application's opinion [21].

The polarity score ranges from [-1.0,1.0] where a negative statement receives a score of -1 and a positive statement receives a score of 1. The polarity value for this project was between 1 and -1, where 1 stands for "Positive" and -1 for "Negative". Table I shows the data labelling in this research. Fig. 2 shows the result of text labelling. After removing the neutral sentiment texts, the total number of data was reduced from 1304 to 1178. This numerical labelling was done to facilitate further processing that requires numerical labels instead of textual labels.

TABLE I. DATA LABELLING

Polarity	Data Labelling	Sentiment Class
More than 0	1	Positive Review
Equal or less than 0	-1	Negative Review

	lemmatized	label	polarity
0	['fun', 'long', 'beach', 'fireworks', 'show', ...	positive	0.18

Fig. 2. Sample of labelled dataset.

D. Feature Extraction

Feature extraction helps identify characteristic sentences in tourist attractions, review data and turn them into features. The ability to produce performance in machine learning is determined by the features employed, hence the feature extraction stage was regarded as being of utmost importance [22]. The technique used for feature extraction is the TF-IDF (Term Frequency-Inverse Document Frequency) score. The TF-IDF technique is an unsupervised feature extraction method that functions at the level of a language's words or lexicon. The review text's word items are converted into numerical data using TF-IDF, making it simple for the following machine learning approach to build the classification model [23]. The term frequency (TF), inverse document frequency (IDF), and the TF-IDF score are the three calculations used to assess the significance of each word inside the data. Eq. (1) to Eq. (3) represent the three equations respectively. The TF-IDF values for each word within the dataset are collected in the corpus, creating a vocabulary of unique words. Words with high TF-IDF values are considered more important and distinctive. These words are often indicative of the specific content or theme of a document. Identifying these key features helps in understanding the focus of each document. Fig. 3 shows the sample of words and their corresponding TF-IDF values.

- Term Frequency (TF)

Using TF, one may determine how many terms are contained in a document.

$$\textit{Term Frequency, TF} = \frac{\text{Frequency of word (W) appearing in a document (D)}}{\text{Total number of words (W) in document (D)}} \qquad (1)$$

- Inverse Document Frequency (IDF)

The Inverse Document Format Frequency (IDF) gives the text's uncommon words priority.

$$IDF = log_e \frac{\text{Total number of documents (D)}}{\text{Total number of document containing word (W)}} \qquad (2)$$

- TF-IDF Score

The TF-IDF score for each word is calculated. Higher-scoring words are thought to be more important, whereas lower-scoring words are thought to be less relevant.

$$TF\text{-}IDF\ (W) = \text{TF(W) x IDF (W)} \qquad (3)$$

Fig. 3. System architecture of SVM classifier model.

E. *System Architecture*

The phases of the research include collecting data from TikTok, data pre-processing, data labelling, feature extraction, model creation using the Support Vector Machine (SVM) method, graphical user interface development and performance evaluation. Fig. 4 depicts the system architecture for the SVM classifier model. The initial phase involves data collection, where data was collected from TikTok using the Chrome Developer Console. Data pre-processing requires several phases, which include duplicate data removal, case conversion, punctuation removal, word expansion, hashtag removal, short word removal, tokenization, stop word removal, POS tag labelling, and lemmatization. The next phase is the data labelling with Text Blob, where the entire dataset will be labelled as "Positive Review" or "Negative Review." Positive reviews are labelled with the value 1, while negative reviews are labelled with the value -1. In the feature extraction phase, the dataset will be vectorized using TF-IDF technique. This is to convert the text data into numerical form so that it can be processed by the algorithm. The dataset will then be separated into two datasets, training and testing using the hold-out method. The training data is used to train the SVM classifier, while the test data is used to evaluate the performance of the algorithm. The values of accuracy, recall, precision, F1-Score and AUC are measured during the performance evaluation. The classifier model is then integrated with the graphical user interface to be used by the end user. The graphical user interface enables the system to collect user input, process the text, classify the text using the model and display the output to the user.

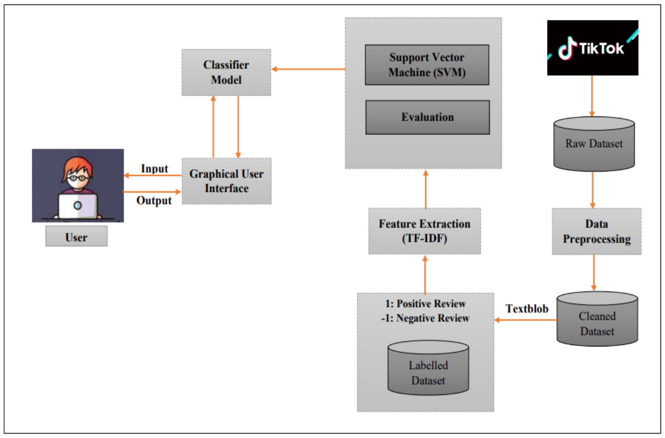

Fig. 4. System architecture of SVM classifier model.

F. *Performance Evaluation*

After building the classification model, it is important to undertake a performance evaluation to determine how accurately the suggested model produces the classification. To help the model perform better, several performance metrics could be applied. These sections explain the confusion matrix, which includes the F1 scores, accuracy, precision, recall, and ROC curve.

1) Confusion matrix: Accuracy, precision, recall, and F1 score values are computed using the confusion matrix. How accurately the model can classify objects is described by its accuracy. Precision is the proportion of correctly made positive forecasts to all correctly made positive predictions. The next step is to determine how many of the positive groups that were accurately predicted are supported by the data. The capacity to determine the number of data that would count positively for a certain attribute is known as recall. The harmonic mean between recall and precision is the definition of the F1 score. The F1 score is a statistical metric used to evaluate the average performance, depending on precision and recall [24]. A confusion matrix presents a matrix-style summary of the data set's entries based on the two standards of actual value and predicted value. The matrix's columns reflect the expected values, whereas the rows of the matrix represent the true values [25].

Confusion matrix is a technique for evaluating how well classifiers perform at each label level. It can compute the F1-measure, recall rate, precision, and accuracy rate [26]. True Positive (TP) represents the number of positive tourist attraction reviews that are correctly predicted while False Positive (FP) represents the number of positive tourist attraction reviews that are predicted as negative by the classifier. True Negative (TN) is the number of negative reviews correctly predicted and False Negative (FN) is the number of negative reviews predicted as positive by the classifier. Eq. (4) to Eq. (7) represents the Accuracy Rate, Precision, Recall Rate and F1-Measure.

- Accuracy Rate

The accuracy ratio is the number of correct samples divided by the total number of samples. The Eq. (4) below can be used to calculate the classifier's accuracy.

$$Accuracy= \frac{TP+TN}{TP+TN+FP+FN} \tag{4}$$

- Precision

Precision shows the percentage of predictions for this kind of result that were accurate. The accuracy of the model prediction increases with increasing value. The Eq. (5) below can be used to calculate the precision.

$$Precision= \frac{TP}{TP+FP} \tag{5}$$

- Recall Rate

Recall is calculated as the ratio of the number of positive predictions to the number of positive class values in the test data. The accuracy of the classifiers is measured by recall, and it can be calculated with Eq. (6).

$$Recall= \frac{TP}{TP+FN} \tag{6}$$

- F1-Measure

F1-Measure effectively communicates the harmony of memory and precision. The harmonic mean of recall and precision is known as the balanced F1-score. F1-Measure obtained from the Eq. (4) below:

$$F1\text{-}measure= \frac{2*Precision*Recall}{Precision+Recall} \tag{7}$$

2) Receiver Operating Characteristic (ROC): One of the model measurement metrics is the receiver operating curve or ROC. The AUC stands for the area under the ROC curve. The performance of the model is improved by a higher AUC. It utilizes positive and negative numbers, demonstrating its capacity for classification [27]. The corresponding coordinates for the threshold's highest value are (0, 0), and for the threshold's smallest value are (1, 1) [25].

IV. Result and Discussion

In this research, the first analysis conducted was the exploratory data analysis on the collected TikTok data. The second analysis was on the performance of the Support Vector Machine Classifier. The second analysis covers the accuracy, Confusion Matrix and ROC results.

A. Exploratory Data Analysis

The labelling of the data has resulted in more positive comments than negative ones. Fig. 5 shows the number of positive comments (773) is larger than the number of negative comments (407). Some of the positive comments include beautiful beaches, nice scenery and good food in Terengganu. The most mentioned tourist spots were Pulau Redang, Pulau Perhentian, Pantai Batu Buruk, Pasar Payang, Taman Tamadun Islam, Masjid Kristal, Kuala Ibai and Muzium Negeri. There were also comments on the improvement of some of the tourist spots after the Covid-19 movement control order. The negative comments were mostly about the cleanliness of certain areas of the tourist spots. At certain tourist spots such as beaches, some irresponsible tourists were being negligent on environmental cleanliness by throwing rubbish everywhere and dirtying the places. Overall, the tourists were happy to have their holidays at Terengganu. They seemed not bothered about the Covid-19 virus which still existed in this post-pandemic. This might be because people were tired and could not care less after being in the movement control order for almost two years and fortunately the virus had also evolved to be more benign.

After processing the numeric information in the dataset, word clouds were generated for two categories: positive and negative. Word clouds are commonly used to visualize and analyse qualitative data. In this case, the comment text from the "stopword_removed" column is utilized to create the word clouds. The purpose of these word clouds is to gain insights into the main topics being discussed. Fig. 6 shows the positive word cloud, highlighting the most prominent words mentioned in TikTok comments about tourist attractions in Terengganu. The keywords include "beautiful," "Terengganu," "place," "best," "clean," "beach," "good," "view," and "island." These words suggest that users frequently mentioned these positive aspects of the tourist attractions in Terengganu in their comments.

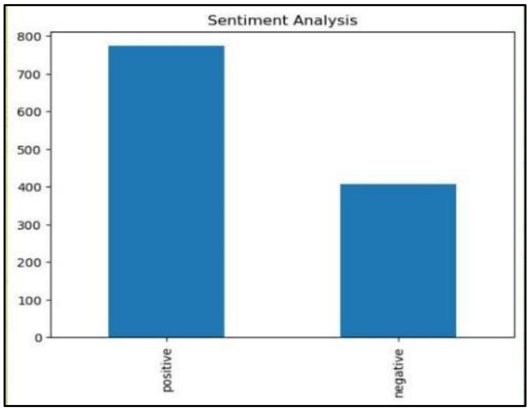

Fig. 5. Number of positive and negative comments.

On the other hand, Fig. 7 displays the negative word cloud. The words "dirty," "Terengganu",”place”, "beach," and "difficult" are considered negative, indicating that people were dissatisfied with the environmental conditions at some of the tourist attractions in Terengganu. Perhaps proper management of trash and also warning or fine should be imposed on tourists who throw rubbish at improper places.

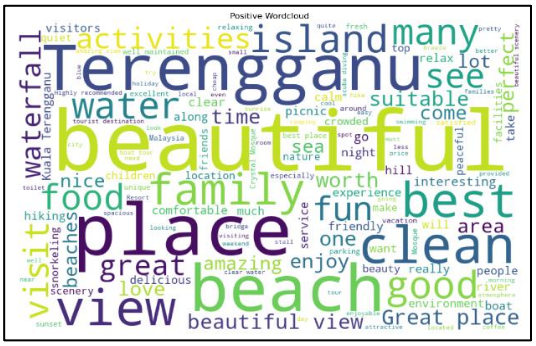

Fig. 6. Positive word cloud.

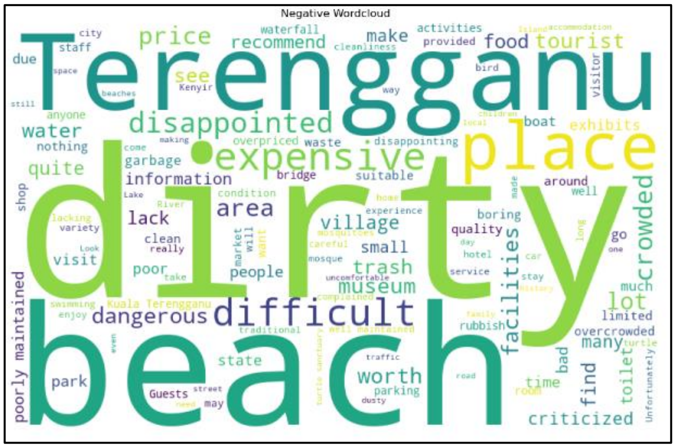

Fig. 7. Negative word cloud.

B. Support Vector Machine Classifier Performance Evaluation

This section provides the evaluation result for the performance of the Support Vector Machine (SVM) model that has been developed from scratch. The evaluation covers SVM accuracy, confusion matrix and the ROC curve.

1) SVM accuracy: In this research, the holdout method was used, and the dataset was split into the training and testing sets based on three different percentage splits: 80:20, 70:30 and 60:40. The accuracy results for each split are shown in Table II. Among the splits, the 80:20 split achieved the highest accuracy of 90.68%. Based on this result, the 80:20 split was selected for further model development since it produced the highest accuracy. Fig. 8 shows the comparison of accuracies among the data splits. In this research, the accuracy result was getting better with more data used for training. The accuracy result of 90.68% has shown that the SVM model is good and acceptable as the sentiment classifier. This is also on par with other SVM performances, as the results of SVM in other research have also produced more than 90% accuracy [16] [18] [17]. In future, the accuracy is expected to be improved if more data are scrapped and anayzed.

2) Comparison between the similar works: This section presents the accuracy of algorithms that have been implemented in similar works, which are tourism-related sentiment analysis. Table III shows the accuracy results for each of the research, using RNN, CNN, LTSM and the proposed SVM models. Based on the table, the proposed SVM model has achieved an accuracy of 90.68% which is higher than the reported RNN (80%) and LSTM (84%) accuracies. Based on this comparison, the accuracy result of the SVM model has proven to be good and able to achieve higher accuracy in its problem compared to certain deep learning models.

3) Confusion matrix: Fig. 9 shows the confusion matrix plot to illustrate the value of True Positive (TP), False Negative (FN), False Positive (FP), and True Negative (TN) for negative (0) and positive (1) labels. Confusion matrix is the calculation of the correct and wrong predictions, which gives an insight into the error made by the classifier model and the type of error being made. Based on Fig. 9, 73 is the value of TP, which indicates the number of positive tourist attraction reviews correctly predicted, while the FP is 13, which was the positive tourist attraction reviews predicted as negative by the classifier. The value of FN is 9, which is the number of negative reviews predicted as positive by the classifier. Lastly, the TN value is which indicates 141 the number of negative reviews correctly predicted by the prototype. From the results, it can be observed that the model has made 214 correct predictions out of 236 predictions made. From the confusion matrix plot, it could be seen that the model has succeeded in predicting 90.68% of data in this sentiment classification problem.

TABLE II. DATA SPLIT RESULTS

Data Split	Training Data	Testing Data	Accuracy (%)
60:40	708	472	88.35%
70:30	826	354	89.27%
80:20	944	236	90.68%

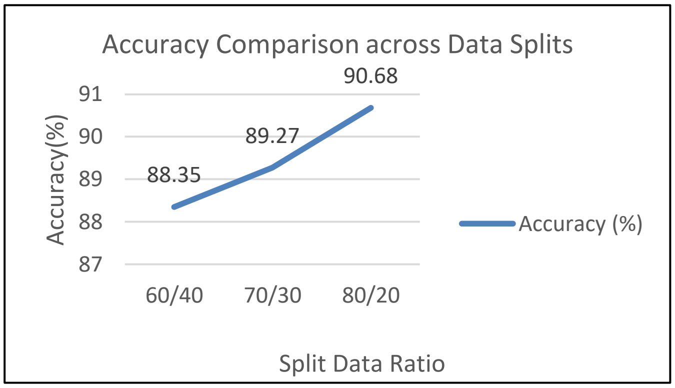

Fig. 8. Accuracy comparison among the data splits.

TABLE III. COMPARISON OF ACCURACY BETWEEN SIMILAR WORKS

Title	Algorithm	Accuracy	Reference
Sentiment Analysis in Reviews About Beaches in Bali on Tripadvisor Using Recurrent Neural Network (RNN)	Recurrent Neural Network (RNN)	80%	[28]
Convolutional Neural Networks for Indonesian Aspect-Based Sentiment Analysis Tourism Review	Convolutional Neural Network (CNN)	95.22%	[29]

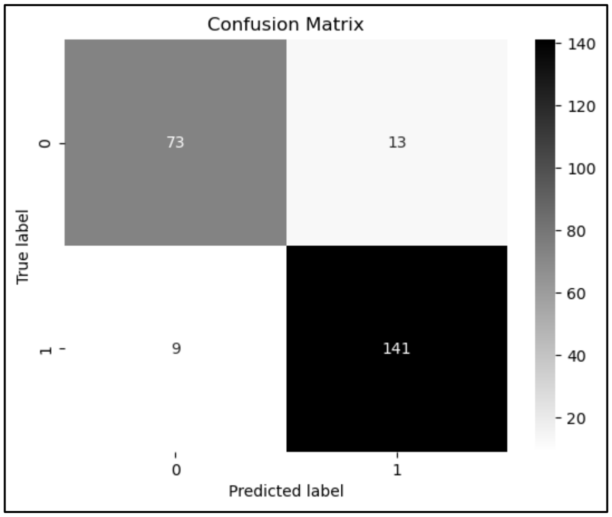

Fig. 9. Confusion matrix plot.

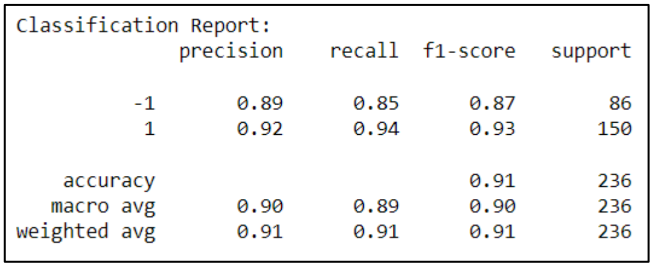
Fig. 10 shows the classification report of the accuracy, precision, recall and F1-score for the Support Vector Machine (SVM) classifier model. The average precision obtained was 0.92, which indicates how many instances the model correctly predicted out of all the instances. For recall, the average value is 0.94, indicating the instances that the model correctly predicted in the particular class. Finally, the average F1-score is 0.93, which represents the weighted average of precision and recall. The F1-score value has shown the good and acceptable performance of the model in correctly identifying both positive and negative instances.



```
Classification Report:
              precision    recall  f1-score   support

          -1       0.89      0.85      0.87        86
           1       0.92      0.94      0.93       150

    accuracy                           0.91       236
   macro avg       0.90      0.89      0.90       236
weighted avg       0.91      0.91      0.91       236
```

Fig. 10. Classification report.

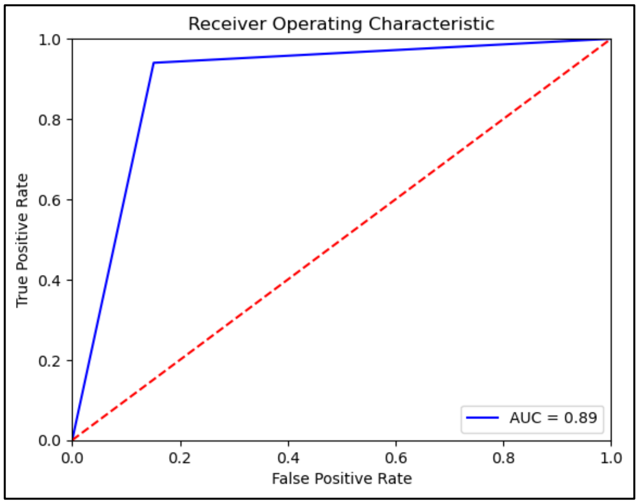


Fig. 11. ROC curve.

4) Receiver Operating Characteristic (ROC) Curve: Fig. 11 displays the ROC curve for the Support Vector Machine (SVM) classifier model. The ROC curve is created by plotting the true positive rate (TPR) against the false positive rate (FPR). The true positive rate represents the proportion of positive observations correctly identified as positive out of all positive observations (TP/ (TP + FN)). The ROC curve's position closer to the upper left corner indicates a more effective classification of data into categories by the model. To quantify the area covered by the curve, the AUC (area under the curve) value was used. For the SVM model, the AUC calculated was 0.89, which indicates a good performance in correctly classifying data points. The AUC value could be improved more with the improvement of the true positive rate.

V. CONCLUSION

This research has met its objective in exploring the capability of SVM in the sentiment classification of the tourist spots in Terengganu after the Covid-19 pandemic era. The SVM model has produced good and reliable performance in this sentiment classification problem with an accuracy of 90.68%. In this research, the SVM model has successfully classified the tourists' sentiments and it was found that the reviews from TikTok were mostly positive about the tourist spots in Terengganu in the post pandemic. People were not afraid anymore of the Covid-19 virus and were mostly positive about coming to Terengganu for getaways. The effects of the Covid-19 virus have gradually become mild and nowadays people can do their treatments if affected. The research findings can be used by the tourism industry in Terengganu to improve the tourist spots and their services. This research also provides informed decisions about which places to visit in Terengganu, enabling tourists to choose their ideal destinations and have a memorable vacation experience. Positive feedback could significantly influence users' final decisions and make their vacation planning process easier, ensuring a smooth and well-organized trip. The recommendation for future work is to establish automated data collection techniques. This would allow the system to regularly scrap the TikTok data, enabling the model to be trained with the latest and relevant data. It is expected that this future work could further improve the classifier accuracy in the sentiment classification of the tourist spots in Terengganu. Moreover, the SVM classifier performance would also be compared with other classification algorithms such as the Naive Bayes and other deep learning algorithms.

ACKNOWLEDGMENT

Special gratitude goes to Universiti Teknologi MARA for the support given towards the advancement of research in the university. This research is funded under the UiTM Geran Penyelidikan Myra Lepasan PHD (600-RMC/GPM LPHD 5/3 (068/2021).

ISSIEE lab, Department of Computer Science, ENSAM Casablanca, Casablanca, Morocco[2]

Abstract—**The proper allocation of data between training and testing is a critical factor influencing the performance of deep learning models, especially those built upon pre-trained architectures. Having the suitable training set size is an important factor for the classification model's generalization performance. The main goal of this study is to find the appropriate training set size for three pre-trained networks using different custom datasets. For this aim, the study presented in this paper explores the effect of varying the train / test split ratio on the performance of three popular pre-trained models, namely MobileNetV2, ResNet50v2 and VGG19, with a focus on image classification task. In this work, three balanced datasets never seen by the models have been used, each containing 1000 images divided into two classes. The train / test split ratios used for this study are: 60-40, 70-30, 80-20 and 90-10. The focus was on the critical metrics of sensitivity, specificity and overall accuracy to evaluate the performance of the classifiers under the different ratios. Experimental results show that, the performance of the classifiers is affected by varying the training / testing split ratio for the three custom datasets. Moreover, with the three pre-trained models, using more than 70% of the dataset images for the training task gives better performance.**

Keywords—Artificial intelligence; classification; MobileNetV2; ResNet50v2; sensitivity; specificity; train / test split ratio; VGG19

I. INTRODUCTION

In our daily life, we have a huge number of generated data of different forms: text, image and video obtained from cameras and sensors. This data can be analyzed efficiently by using the advanced techniques such as deep learning. In image classification, deep learning models are used to identify special features in the images characterizing a particular class and that will help the model to distinguish between different classes. They can reach the human level performance on several fields like classifying animals, different types of food, diseases.

When having a small dataset, the best way to classify images is by using the transfer learning approach. It uses one model's knowledge on a machine learning task and reuses it as a starting point for a different but a related task. The pre-trained neural network is fine-tuned to achieve the user's needs rather than being trained the model from scratch.

Using transfer learning on image classification was introduced in the literature in several areas:

- The authors in study [1] propose the use of VGG19 architecture as the base model and complement it with different state-of-the-art techniques to classify histopathological images into IDC and non-IDC classes, Invasive Ductal Carcinoma (IDC) is a type of breast cancer.
- To identify covid-19, pneumonia and lung cancer diseases using chest radiographs, researchers in paper [2] suggest the combination of VGG-19 and Convolutional Neural Networks (CNN) to improve the performance of the multi-class classification task.
- The study presented by [3] gives different fine-tuned pre-trained models such as VGG-19, ResNet50V2 and DenseNet-121 to predict sentiments using the Twitter-based images.
- Researchers in the paper [4] gave the performance evaluation of Resnet18, Resnet50, Alexnet, DenseNet121, DenseNet201 and VGG16 models in rating gravel road images obtained from self-recorded videos and from Google Street View.
- The classification of a forest fire imagery into forest fire and no-fire was introduced in the paper [5] using a new proposed approach based on the use of the VGG19 model.
- To improve the intention classification accuracy, researchers in the paper [6] used the knowledge of the ERNIE model (Enhanced Representation through Knowledge Integration) for both: the student and the teacher models.
- The paper in [7] presents image classification and image prediction for the ImageNet dataset using the pre-trained models: MobileNet, MobileNetV2, VGG16, VGG19 and ResNet50.
- For the land use and land cover classification, transfer learning was used in the study presented in the paper [8] to fine-tune the pre-trained models: VGG16 and WRNs (Wide Residual Networks). To compare the performance and computational time, some techniques were employed such as: gradient clipping, data augmentation and early stopping. The red-green-blue version of the EuroSAT dataset was used in this work.

- The paper in [9] presents a systematic review of the early detection of Alzheimer disease (AD) by using transfer learning and neuroimaging biomarkers. In this review, five datasets were used. The researchers in this paper confirm that, for the early diagnosis of AD, the use of transfer learning technique is beneficial to develop a more accurate model.

- Transfer learning studies that uses the non-medical ImageNet datasets for medical image analysis was systematically reviewed in the paper [10]. To approach medical tasks with a non-medical dataset, the researchers suggest the use of transfer learning with ImageNet dataset. They also approve that CNN model and transfer learning technique gave reasonable performance.

- To classify mangrove communities, the study presented in the paper [11] uses three transfer learning strategies and discuss the differences in the classification task. Different models were constructed with the three deep learning algorithms: DeepLabV3+, HRNet and MCCUNet,

- For Arabic tweet classification, a transformer-based model was proposed in the paper [12]. This model was constructed from a pre-trained BERT model given by the hugging face transformer library using custom dense layers. To categorize the tweets, a multi-class classification layer was built on the top of the BERT encoder. Five publicly datasets was employed to do this study.

- The paper in [13] presents a review of the diabetic retinopathy classification with deep learning models that use transfer learning technique. According to this work, transfer learning is useful with medical image classification due to the limited number of medical images.

- To perform urban sounds classification, the researchers in the paper [14] have applied transfer learning with three datasets: UrbanSound8k, ESC-10 and Air Compressor. The pre-trained models used in this study are: GoogLeNet, SqueezeNet, ShuffleNet, VGGish and YAMNet.

- The detection of the Covid-19 disease was done in the paper [15] using the transfer learning technique with a dataset formed by X-ray images. The dataset is divided in three folders: Covid-19, pneumonia and normal (healthy) cases. Although a small dataset was used, high accuracy is achieved over all the models. The proposed approach uses VGG16, VGG19 and ResNet101 architectures.

- To categorize various food products using transfer learning, a recognition model was introduced in the paper [16]. The dataset employed in this work is Food-101. The proposed model, that uses Efficientnetb0 architecture, reaches the accuracy of 80% which is the best accuracy compared to other state of the art models.

- The study presented in the paper [17] applied the transfer learning technique for classifying monkeypox skin lesions. Six different models were employed in this work: DenseNet201, InceptionResNetV2, EfficientNetB7, InceptionV3, ResNet50 and VGG16. The paper proposes also a fine-tuned version of the InceptionV3 model named PoxNet22. The proposed transfer learning-based model gives better performance in terms of accuracy, recall and precision.

- The paper [18] gives an evaluation of pre-trained models for the detection of osteoporosis which is a bone disease in knee radiographs. VGG16 and VGG16 with fine-tuning were used in this study. The models were evaluated using accuracy, sensitivity and specificity metrics. According to this study, fine-tuning improves the VGG-16 performance for the desired task.

- Different pre-trained models for bird image identification were studied and compared in the paper [19]. The models employed are: DenseNet201, InceptionV3, MobileNetV2 and ResNet52V2. The dataset contains 58388 bird images belonging to 400 spices. All the implemented models give good accuracy but DenseNet201 was the best network, according to the authors.

- The researchers in the paper [20] confirm that the VGG16 gives a good performance with all the nine different chest X-ray datasets used. The datasets have various sizes and different class labels.

While using the transfer learning technique, the obtained model's accuracy can exceed 90% even when using datasets with less than 100 images in each class [21] just by using the correct implementation of the pre-trained model.

In a previous work [22], a performance comparison of three pre-trained models on the classification task using a custom dataset was performed. The models were trained on 30 epochs with 10^{-3} and 20 as values for the learning rate and the batch size parameters respectively. VGG19 achieved the highest accuracy, precision, recall and f1-score.

This work follows the perspective of those researches, by proposing a study of variation impact of train / test split ratio on the performance of three fine-tuned pre-trained models (MobileNetV2, ResNet50v2 and VGG19), while using a new dataset never seen by the models.

This paper is organized as follows:

Section II contains a literature review on machine learning pre-trained models. Section III introduces the pre-trained models. Section IV contains the description of the three datasets used in this study. The preprocessing phase and evaluation metrics employed for the performance comparison are described in Section V. Results and discussion is given in Section VI. The conclusion is in Section VII.

II. Literature Review on Machine Learning Pre-Trained Models

Many researches try to understand how to enhance performance of ML pre-trained models. Here are some of those studies:

- The work presented in paper [23] gives a study of the effects of dataset size and training/testing split ratios on the performance of multiclass classifiers. The results demonstrate that XGBoost gives the best performance. The performance evaluation was done using 25 performance parameters.
- The paper in [24] presents a CNN-based automatic model for the identification of the strawberry leaf plant disease like: powdery mildew leaf, healthy leaf and caterpillar pests leaf. MobileNetV3-Large and efficientNet-B0 were implemented as architecture. The dataset contains 1336 images collected from the field and the data augmentation was applied to it.
- The paper in [25] proposed a deep learning method based on CNN architecture to classify six types of strawberry plants diseases. This study utilizes 4663 strawberry leaf disease images data.
- The work presented in the paper [26] demonstrates that the use of CNN models is useful than the non-Deep learning models to distinguish between infected and healthy strawberry leaves. Under the supervision of disease specialists, the dataset (1450 images) were collected from Balamore and Millen farms Ltd.AlexNet, SqueezeNet, GoogleNet, ResNet50, SqueezeNet-MOD1 and SqueezeNet-MOD2 were employed in this study.
- The paper [27] presents an evaluation of four ensemble learning algorithms (random forest, CatBoost, XGBoost and random forest) for the prediction of heart disease using different hyperparameter optimization techniques. Three kaggle datasets were combined which had features to augment the dataset size. Using 80% of the dataset images for training was useful because the proposed model gives better accuracy while working with the train / test split ratio of 80%-20%.
- The paper [28] studied the impact of different train / test split ratios on the model performance. The ratios: 50-50, 60-40, 70-30, 80-20 and 90-10 were used in this work. The authors recommend the use of different classifiers with different train / test split ratios.

III. Pre-trained Models

A. MobileNetV2

MobileNetV2 [29] is a CNN model based on an inverted residual structure where the residual connections are between the bottleneck layers. The architecture incorporates shortcut connections to aid in training deeper networks without vanishing gradients. To improve efficiency, the model uses depth-wise separable convolution which is independently performed for each input channel. Depth-wise separable convolution reduces the complexity cost and the pre-trained model size. Due to this, MobileNetV2 has higher accuracy, needs fewer operations and is much faster than the MobileNetV1 model. The MobileNetV2 architecture (see Fig. 1) consists of 17 building blocks in a row followed by 1x1 convolutional layer, global average pooling layer and classification layer. The expansion layer role is to expand the number of channels in the data. In the projection layer, high number of dimensions is reduced to a smaller one.

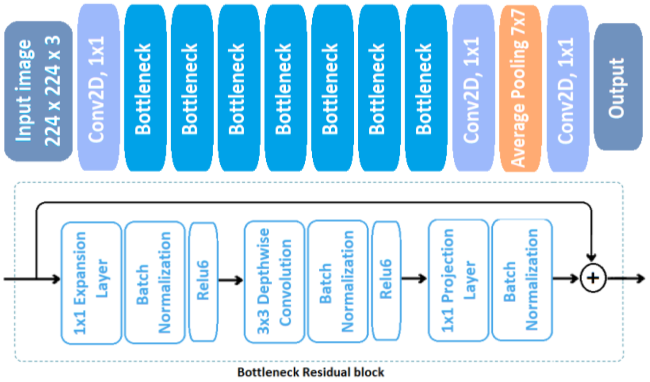

Fig. 1. MobileNetV2 architecture.

B. VGG19

VGG19 [30], part of the VGG family (Visual Geometry Group), is a CNN architecture with multiple layers. It was published by Simonya and Zisserman researchers from the Oxford University in 2014. It consists of 19 layers: 16 convolutional and three fully connected layers with a filter size of 3x3 (see Fig. 2). The number of parameters is reduced due to the small kernel size; it also enables them to cover the entire image. VGG19 was trained on the ImageNet database that contains more than 14 million images belonging to 1000 categories which helps the network to capture a diverse set of features, making it a powerful tool for the transfer learning task. For downsampling, VGG19 incorporates max-pooling layers and uses fully connected ones for classification.

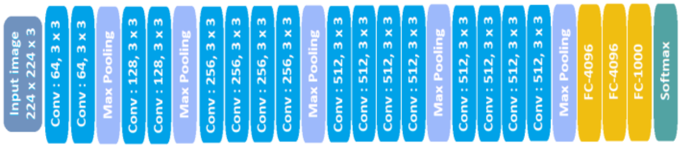

Fig. 2. VGG19 architecture.

C. ResNet50v2

ResNet50V2 [31], is a 50-convolutional neural network: 48 convolutional layers, one MaxPool layer and one average pool layer. It is known for its depth and skip connections which protect the model from vanishing gradient problem in much deeper networks. ResNet50V2 uses residual blocks which enhance the training efficiency in achieving both depth and accuracy in different tasks. To reduce the computational complexity and adjust the input layer to increase the performance of the network, ResNet50V2 utilizes batch normalization and bottleneck blocks. The ResNet50V2 architecture is shown in Fig. 3.

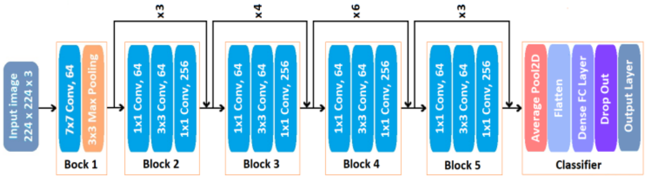

Fig. 3. ResNet50v2 architecture.

IV. Datasets

The balance (or imbalance) of the classes, which is the diversity of samples belonging to each class is a significant factor that affects the performance of classification models. Providing imbalanced data to the classifier may bias it towards the majority class because it lacks enough data to learn about the minority, which can cause false predictions. In this context, the study presented in this work was done with three balanced datasets each containing 1000 colored images divided into two classes: class_0 (500 images) and class_1 (500 images). The description of the three datasets is in Table I.

Some samples of images in the three datasets are shown in Fig. 4, Fig. 5 and Fig. 6.

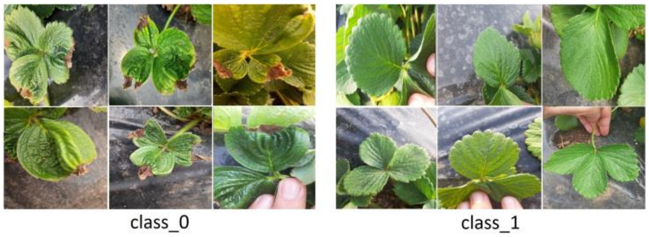

Fig. 4. Sample images from Dataset1.

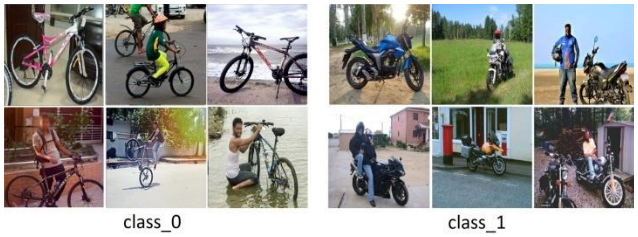

Fig. 5. Sample images from Dataset2.

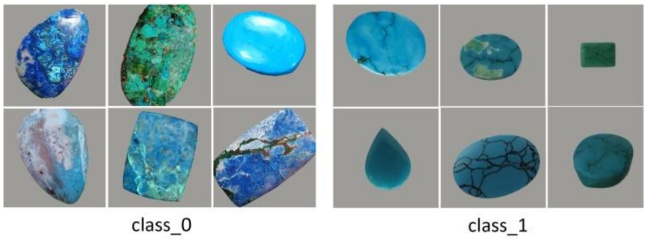

Fig. 6. Sample images from Dataset3.

TABLE I. Description of the Datasets

Dataset name	Description	Class_0 description	Class_1 description
Dataset1 (Fig. 4)	Formed from the kaggle dataset named 'Images of Strawberry Leaves for Tipburn Detection' [1]. It contains 1431 images divided into two classes: healthy (626 images) and calciumdeficiency (805 images).	Contains images of 500 images of leaves with calcium deficiency.	Contains images of 500 images healthy leaves.
Dataset2 (Fig. 5)	Formed from the kaggle dataset named 'Paribahan BD' [2]. It contains 7474 images divided into two classes: local-vehicles (7474 images grouped in 8 folders) and generated images (80 images grouped in 8 folders).	Contains 500 images of bicycles.	Contains 500 images of bikes.
Dataset3 (Fig. 6)	Formed from the kaggle dataset named 'Gemstones' [3]. It contains 6043 images divided into three classes: train (3043 images grouped in 6 folders), test and validation (each one contains 1500 images grouped in 6 folders).	Contains 500 images of turquoise gemstones.	Contains 500 images of fake-turquoise gemstones.

V. Preprocessing and Evaluation Metrics

A. *Preprocessing*

One of the major problems when training deep learning models is to have a large dataset which is not always an easy task. It is necessary to have a huge number of images in each class of several subjects of the classification. To expand the size of the three small datasets used in this work, it was beneficial to utilize the data augmentation process with the KerasImageDataGenerator class. The summarized data augmentation description is in Table II. The images have different dimensions, for this reason, they were rescaled to 224x224 pixel resolution to make them compatible with the pre-trained model's requirement.

B. *Evaluation Metrics*

In machine learning, the performance evaluation of classification models needs the use of some metrics to be able to solve real-world problems.

There are several measures to test the performance of classification results [32], the three following ones were considered in this study:

[1] https://www.kaggle.com/datasets/ercanavsar/images-of-strawberry-leaves-for-tipburn-detection

[2] https://www.kaggle.com/datasets/naifislam/paribahan-bd?select=generated_images

[3] https://www.kaggle.com/datasets/muhammadmuzamil5500/ gemstones

$$Sensitivity = \frac{TP}{TP + FN} \quad (1)$$

$$Specificity = \frac{TN}{TN + FP} \quad (2)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

TP: True Positive, TN: True Negative, FP: False Positive and FN: False Negative.

TABLE II. SUMMARIZED DATA AUGMENTATION DESCRIPTION

Name	Value / Description
Rotation_range	20
Zoom_range	0.15
Width_shift_range	0.2
height_shift_range	0.2
Shear_range	0.15
horizontal_flip	True
Fill_mode	‘nearest’

VI. RESULTS AND DISCUSSION

The pre-trained models were trained in Google Colab notebook with a learning rate of 10^{-3}, a batch size of 32 for 60 epochs. Graphics Processing Units (GPUs) was used as the model’s hardware platform.

Adam function is the simple and time-efficient optimizer for deep neural networks; thus, it has been employed for the compilation process.

The results discussed in this work are the best ones achieved from several experiments which were carried out for each case.

A. Dataset1

From Table III, it can be observed that the MobileNetV2 achieves the best sensitivity 100%) with the ratio 90%-10% and the best specificity (99%) with the ratio 80%-20%, but the best performance in terms of accuracy is obtained when using 70% of the dataset for training and 30% for testing (97.67%).

TABLE III. MOBILENETV2 EXPERIMENTATION RESULTS ON DATASET1

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	97	97.5	97.25
70% - 30%	96.67	98.67	**97.67**
80% - 20%	93	**99**	96
90% - 10%	**100**	94	97

Looking at the plot of confusion matrix (see Fig. 7), it can be seen that MobileNetV2 model accurately predicted 293 out of 300 total samples (train / test ratio: 70%-30%).

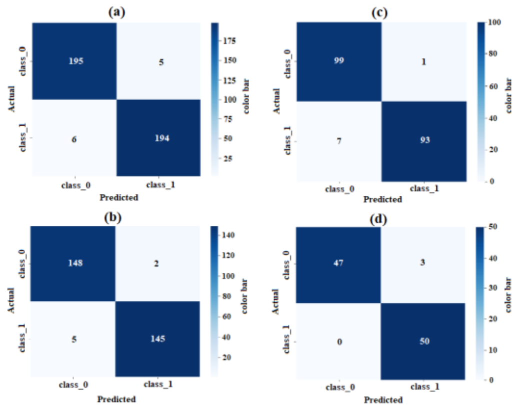

Fig. 7. Confusion matrices for MobileNetV2 with the ratios: (a) 60%-40%; (b) 70%-30%, (c) 80%-20% and (d) 90%-10%.

Resnet50V2 performs well with the Dataset1: the accuracy is greater than 97% with all train / test ratios (see Table IV). The best sensitivity score (99.5%) is observed when using 60% of the dataset for the training phase. The high specificity score (100%) is obtained with the ratio 90%-10%. But the best performance of the network is achieved with the ratio 70%-30% in terms of accuracy (98.5%).

TABLE IV. RESNET50V2 EXPERIMENTATION RESULTS ON DATASET1

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	**99.5**	96.5	98
70% - 30%	98.67	97.33	98
80% - 20%	98	99	**98.5**
90% - 10%	96	**100**	98

ResNet50v2 classifier gives better performance with the ratio 80%-20%: it predicted accurately 197 samples which represent 98.5% of the total samples (200 samples) (see Fig. 8).

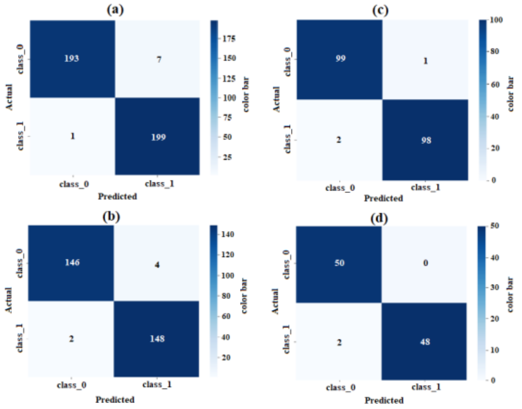

Fig. 8. Confusion matrices for ResNet50v2 (Dataset1).

Although the VGG19 classifier achieves the best sensitivity score (97%) with the ratio 80%-20% and the best specificity one (100%) with the ratio 90%-10%, the best performance of the network is observed while using 70%-30% as a train / test ratio. With this ratio (70%-30%), VGG19 reaches 97.33% for the accuracy metric (see Table V).

TABLE V. VGG19 EXPERIMENTATION RESULTS ON DATASET1

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	94	98	96
70% - 30%	96	98.67	**97.33**
80% - 20%	**97**	96	96.5
90% - 10%	88	**100**	94

The VGG19's confusion matrix, plotted in Fig. 9, shows that the model succeeds to classify 292 samples out of all samples while using the ratio 70%-30%.

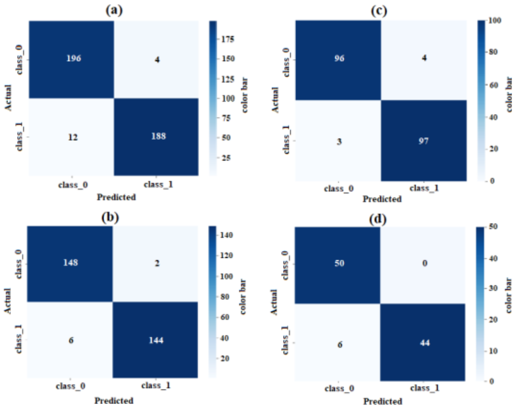

Fig. 9. Confusion matrices for VGG19 (Dataset1).

B. Dataset2

Out of all the train / test ratios, MobileNetV2 performs well with 80%-20% and 90%-10% in terms of sensitivity, specificity and accuracy with 100%, 98% and 99% respectively (see Table VI).

TABLE VI. MOBILENETV2 EXPERIMENTATION RESULTS ON DATASET2

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	99	96.5	97.75
70% - 30%	99.33	96.67	98
80% - 20%	**100**	**98**	**99**
90% - 10%	**100**	**98**	**99**

With the ratios 80%-20% and 90%-10%, MobileNetV2 classifies accurately 99% of all the samples which is the best result obtained by this network (see Fig. 10).

The network gives better sensitivity (100%) while working with 90% of the dataset for the training phase. The better specificity and accuracy were reached with the ratio 80%-20% with scores of 100% and 99.5% respectively (see Table VII).

ResNet50v2 classifier gives better performance with the ratio 80%-20%: it predicted accurately 199 samples which represent 99.5% of the total samples (200 samples) (see Fig. 11).

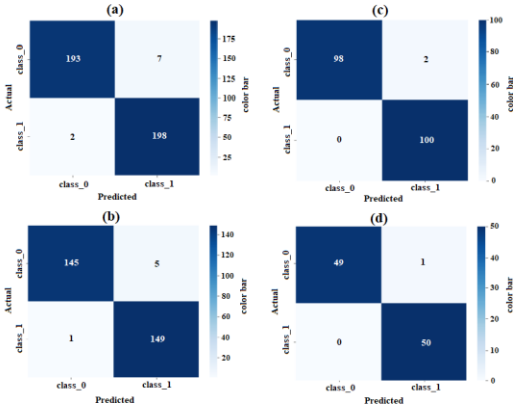

Fig. 10. Confusion matrices for MobileNetV2 (Dataset2).

TABLE VII. RESNET50V2 EXPERIMENTATION RESULTS ON DATASET2

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	99	98	98.5
70% - 30%	99.33	96	97.67
80% - 20%	99	**100**	**99.5**
90% - 10%	**100**	98	99

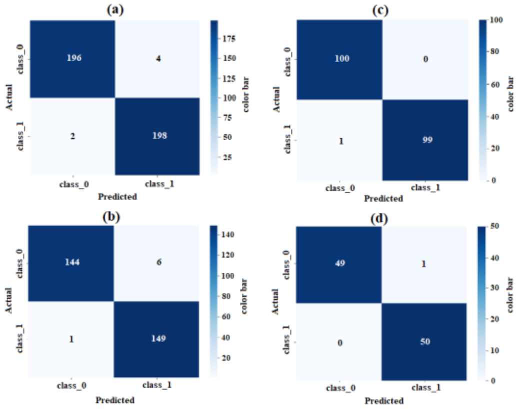

Fig. 11. Confusion matrices for ResNet50v2 (Dataset2).

The train / test ratio 90%-10% gives better sensitivity, specificity and accuracy with the score 100% for each one of them (see Table VIII).

TABLE VIII. VGG19 EXPERIMENTATION RESULTS ON DATASET2

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	99.5	96	97.75
70% - 30%	99.33	98	98.67
80% - 20%	99	99	99
90% - 10%	**100**	**100**	**100**

The pre-trained model succeeds to correctly classify all the samples while taking 90% of the dataset for training which represent a good result (see Fig. 12).

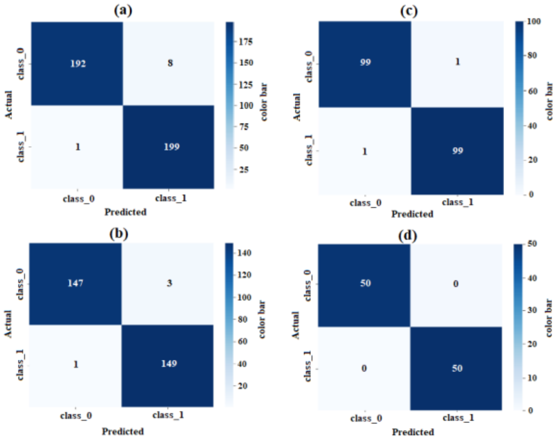

Fig. 12. Confusion matrices for VGG19 (Dataset2).

C. Dataset3

The MobileNetV2 model achieves better sensitivity (100%) with the ratios 80%-20%, and better specificity (100%) with the ratios 60%-40%. But out of all the train / test ratios, 80%-20% gives significantly better accuracy with a score of 99.5% which is a good result (see Table IX).

TABLE IX. MOBILENETV2 EXPERIMENTATION RESULTS ON DATASET3

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy %)
60% - 40%	98.5	**100**	99.25
70% - 30%	98.67	**100**	99.33
80% - 20%	**100**	99	**99.5**
90% - 10%	**100**	98	99

According to the confusion matrix of MobileNetV2 model with the ratios 80%-20%, it can be observed that the pre-trained model arrives to accurately predict 99.5% of all samples (199 samples of 200) (see Fig. 13).

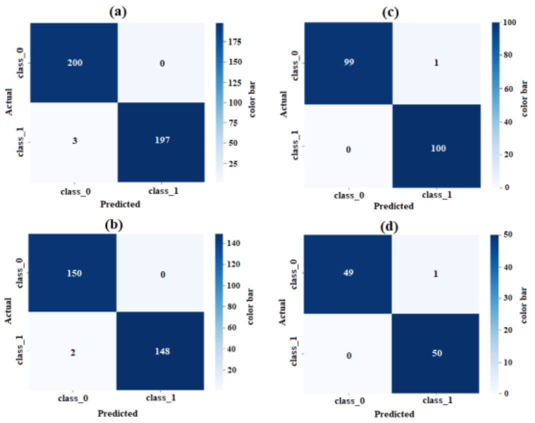

Fig. 13. Confusion matrices for MobileNetV2 (Dataset3).

With the Dataset3, the ResNet50V2 classifier achieves the perfect sensitivity, specificity and accuracy while working with 90% of the total dataset's samples for training and 10% for testing, with a score of 100% for each one of them. It also gives better specificity with the ratio 80%-20% (see Table X).

TABLE X. RESNET50V2 EXPERIMENTATION RESULTS ON DATASET3

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	99.5	97.5	98.5
70% - 30%	99.33	99.33	99.33
80% - 20%	98	**100**	99
90% - 10%	**100**	**100**	**100**

ResNet50v2 classifier gives better performance with the ratio 90%-10%: it predicted successfully all the samples (see Fig. 14).

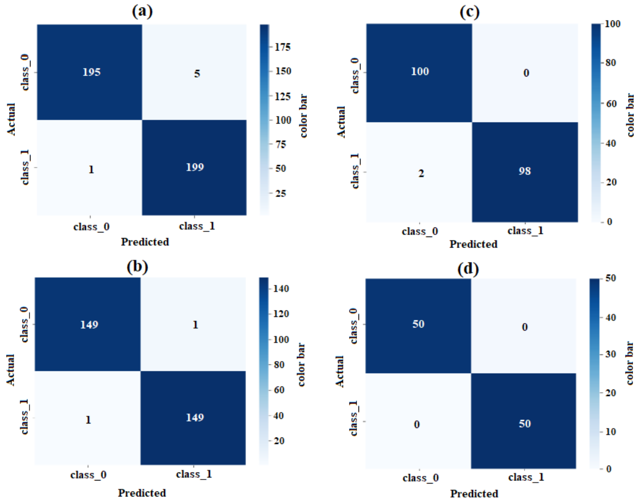

Fig. 14. Confusion matrices for ResNet50v2 (Dataset3).

With the train / test ratio 90%-10%, the VGG19 pre-trained model gives better performance in terms of sensitivity, specificity and accuracy with a score of 100% for each one of the metrics (see Table XI).

TABLE XI. VGG19 EXPERIMENTATION RESULTS ON DATASET3

Train / Test ratio	Sensitivity (%)	Specificity (%)	Accuracy (%)
60% - 40%	97.5	99.5	98.5
70% - 30%	98	99.33	98.67
80% - 20%	98	**100**	99
90% - 10%	**100**	**100**	**100**

The VGG19's confusion matrix, plotted in Fig. 15, shows that the model succeeds to classify correctly all the samples while using the ratio 90%-10%.

The results show that the best performance achieved with the networks was when using the train / test ratios 80%-20% and 90%-10%. While working with the ratio 60%-40%, all the classifiers couldn't give better scores in terms of sensitivity, specificity and accuracy, as well as the other ratios. The three networks need more than 70% of the dataset's samples for the training phase to give better results.

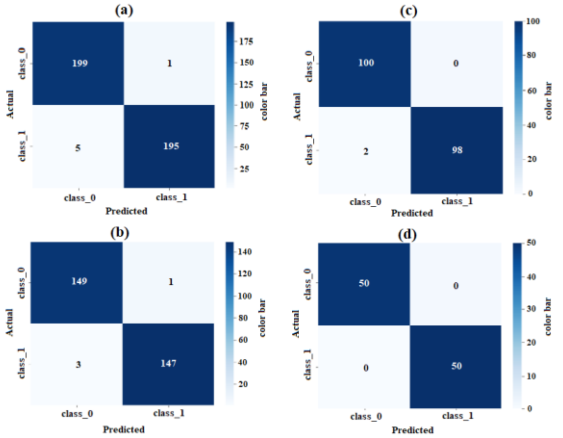

Fig. 15. Confusion matrices for VGG19 (Dataset3).

VII. Conclusion

This study was realized with three datasets never seen by the pre-trained models: MobileNetV2, ResNet50 v2 and VGG19. The datasets were divided in two classes (class_0 and class_1). For all experiences, the batch size was fixed at 32 and the learning rate at 10^{-3}. All the experiences were for 60 epochs. Analyzing the results, it can be observed that the train / test split ratio has a significant impact on the classification performance of the three pre-trained networks: MobileNetV2, ResNet50v2 and VGG19, the ratios 80%-20% and 90%-10% gives better results on the most cases.

All the pre-trained networks used in this study performs well with the Dataset3, this is due to its simplicity in comparison with the other datasets (Dataset2 and Dataset3). It has less features to be learned by the models which facilitate the learning process and enhance the classifier's performance.

In conclusion, increasing the size of the train data enhanced the performance of the three classifiers; more than 70% of the dataset's samples is required in the training phase to achieve better performance.

For future work, other datasets with different sizes will be studied using the three pre-trained models to have a more generalized conclusion concerning the impact of the train / test split ratio on the performance of the networks. Other architectures could be also added to the study. The impact of using several optimizers will be investigated for different pre-trained models and different datasets.

***Abstract*—Aiming at the problem that improper posture of basketball players leads to not obvious sports effects, the present paper proposes an action recognition method combining computer vision and big data technology and applies it to athletes' daily training and competition. Firstly, based on the current mainstream motion recognition models, 3D graph convolution are used to improve the original 3D convolution to promote the expression ability of spatial structure features and temporal features in skeleton sequences. Secondly, channel and spatial attention mechanisms are introduced to focus on the weight distribution of key points and strong features in different posture recognition processes. Finally, the proposed model is tested in real data, and the test results show that the model runs smoothly while maintaining high recognition performance. It can more effectively direct basketball players to implement comprehensive, systematic, and scientific teaching and training standards that directly support raising the game's general level of performance.**

Keywords—Action recognition; computer vision; big data technology; three-dimensional convolution; channel and spatial attention mechanisms

I. Introduction

Accurately identifying and evaluating athlete movements is crucial in basketball training. However, traditional action recognition methods often rely on manual observation or simple video analysis tools, which not only have low efficiency but also cannot guarantee accuracy. Basketball is a highly complex competitive sport that requires athletes to possess superb skills and tactical understanding. In order to achieve the best training results, coaches and athletes need a method that can accurately and efficiently identify and evaluate athlete movements. Traditional action recognition methods mainly rely on manual observation, which is not only time-consuming but also susceptible to subjective factors. With the development of big data technology, the accuracy and efficiency of machine learning and computer vision algorithms have been significantly improved, providing new possibilities for solving this problem. Due to the continuous development of the social economy and science and technology, intelligence has been more and more widely concerned about and studied and is gradually becoming a global trend. With the arrival of the information age, many intelligent devices have become accessible to people, which greatly facilitates people's lives and further promotes the development of relevant research fields. In recent years, research on artificial intelligence has made remarkable progress. Machine vision is the main branch of artificial intelligence, and human behavior recognition is one of the important research directions [1]. Visual human behavior recognition includes the following parts: Acquisition of human behavior video sequence, feature extraction of moving human body, learning and recognition of classifier, among which feature extraction and classification recognition is the main research content of human behavior recognition [2].

Visual human behavior recognition and analysis is a comprehensive research direction; from the theoretical level, human behavior recognition research involves a variety of theoretical disciplines, including pattern recognition, statistics, information processing, computer vision, and so on. The research significance of human motion behavior recognition is mainly reflected in its practical value. With the continuous progress of video acquisition sensors and information science and technology, the research of motion behavior recognition has gradually become a subject with wide application prospects in many fields. It has been successfully used in basketball training, football training, alpine skiing, running, and other sports movement recognition because of its portability, wireless, and easy-to-operate characteristics [3]. However, in competitive competition, the limitation of experimental conditions leads to great challenges in capturing the above movements. Because of the quick development of computer vision and big data technology, it is important to use the new technology to effectively capture the training movements of basketball and football players, help them improve their disharmonious movements quickly, and improve their comprehensive quality.

Recent advancements in computer vision-based motion capture technology have made it possible to recognize human activity in challenging environments. Unmarked motion capture was carried out by camera equipment to obtain kinematics information remotely in the competition. Based on computer vision machine learning algorithms, human actions are displayed as waveforms corresponding to specific actions that are downloaded to a computer terminal. Subsequently, the synchronous video analysis, information extraction, and quick feedback are finished. Motion analysis based on a computer vision image must first predict or estimate the target's position and direction within the image sequence. Real-time tracking and displacement parameter acquisition are then accomplished by locating the target in the continuous image that has the same or comparable features. The human body is typically represented in practical applications as a collection of rigid bodies joined by frictionless revolute joints because this makes machine recognition and tracking easier. However, because human movements involve soft tissues like tendons and ligaments, they are too complex to be fully understood by a rigid, simple body model. Thus, one of the challenges facing specialists in computer vision, machine learning, and sports science is precise tracking and measurement of dynamic human posture.

A deeper neural network model structure characterizes deep learning. The majority of the algorithms use manually labeled image data to train the neural network and then input the image or video into the trained network to estimate and recognize human posture, joint center, and bone position. In particular, skeleton behavior recognition technology is a method to understand and describe human behavior by extracting the action features in a skeleton sequence. Skeleton behavior recognition is one of the hot research directions in the field of machine vision. It can realize the accurate recognition of the motion of the target object by the computer, then analyze the motion of a human body in the video, and improve the dynamic perception ability of the computer. To evaluate the advantages of our method over existing methods, we conducted experimental comparisons on publicly available datasets. The results show that basketball training action recognition methods based on big data channels and spatial attention mechanism technology have significant advantages in accuracy, efficiency, and applicability to real-world scenarios. Compared with traditional methods based on manual observation or simple video analysis, our method greatly improves the accuracy and efficiency of recognition, reducing the need for manual intervention. Meanwhile, when compared with other deep learning models, our method better processes spatial information in videos by introducing spatial attention mechanisms, further improving the performance of action recognition. The basketball training action recognition method based on big data channels and spatial attention mechanism technology provides an efficient and accurate means of action evaluation for basketball training. This method can not only be applied in the field of basketball training, but can also be extended to other sports or general video action recognition tasks. Future work will further optimize the model structure, explore more effective attention mechanism methods, and apply this technology to practical training scenarios to verify its performance and effectiveness in the real world.

Section I of this article first analyzes the application background of machine learning and computer vision algorithms, which are of great significance for capturing the training movements of basketball players.   Section II analyzed the comprehensive temporal dynamic information of bone sequences under different attention mechanisms of network applications. Section III proposes a method for action recognition using computer vision technology and big data technology, and applies it to action recognition in basketball player training. Section IV uses a 3D graph convolution module to extract spatiotemporal information from the skeleton sequence. We have established an attention enhancement structure to help nodes focus on key action information and pay more attention to certain areas. Finally, a behavior recognition model was constructed by combining 3D convolution with attention enhancement structures. Section V summarizes the entire text. The P-R curves of the model in this article can all surround the P-R curves of the comparison model, indicating that the overall action recognition performance of the model in the current study has been improved to varying degrees after using 3D graph convolution and attention mechanism to improve the existing model.

II. Related Works

Human motion recognition research is getting more and more advanced as a result of the steady advancement of deep learning, machine learning, and other related technologies. The research and application of human motion recognition based on attitude sequence are different from tasks such as image recognition and target detection. The research on human motion recognition is related to time sequence. Input data includes spatial dimension and time dimension, so compared with other fields of computer vision, the difficulty and challenge of action recognition are greater.

A. *Motion Recognition Based on Human Bone Sequence*

Dynamic human skeletons often contain a wealth of information and best represent human movement and behavior. The motion recognition algorithms based on the human bone sequence are usually divided into four categories: manual feature-based method, RNN/LSTM-based method, CNN-based method, and graph convolutional Neural network (GCN) based method.

Using the geometric relationships found in the space structure of the human skeleton for motion recognition is the aim of the traditional manual feature design method. Literature [4] listed nine geometric features, including eight static features and one time feature. The static feature encodes the form of motion and posture and uses the time feature to represent the change in time. The study in [5] proposed the use of the rotation and displacement of human bones to represent the three-dimensional transformation relationship between various body parts. The research in [6] proposed an integral invariant used to represent the motion trajectory of bone points and matched the motion trajectory. A collection of geometric characteristics, such as the separation between joints and the distance between joints to the plane formed by joints, were taken from study [7] and used to characterize posture and movement. While designing features, it is impossible to account for every factor so that most experimental results could be improved. Deep learning and other data-driven methods have gained popularity recently. Among them, the most popular models are CNN, GCN, and RNN/LSTM.

The main advantage of RNN/LSTM is that context dependencies can be modelled in the time domain. In addition, in the RNN/LSTM-based approach, the bone sequence is modeled as a coordinate vector of a series of joints, each coordinate representing a human joint. The study in [8] proposed the STA-LSTM network, which applies an attention mechanism to choose discriminating patio-temporal features, key joints, and keyframe information, respectively. The research in [9] proposed a VA-LSTM network. In VA-LSTM, two sub-networks were used to return parameters of rotation and translational matrix for rotating and translational bone coordinates to appropriate observation directions. Then, the new observed bone was input into the three-layer LSTM main network for motion recognition. The study in [10] proposed a

GCA-LSTM network and introduced global context memory to generate attentional representations for optimizing global context information. The SR-TSL approach was first presented in study [11] in 2018. It uses a time stack learning network (TSLN) to gather comprehensive temporal dynamic information on the bone sequence and a spatial inference network to gather high-level spatial structure information. The study [12] converted the input skeleton into several possible visual observation values, which were respectively processed by the attention LSTM network and finally fused with the output to generate recognition results.

In contrast to RNN/LSTM, the CNN-based method can learn spatial and temporal features simultaneously. The method based on CNN is used to encode bone sequences as pseudo-images (RGB or grayscale images) and time series as rows of bone joints in the image as columns. The study in [13] proposed to encode five spatial skeletal features as pseudo images and further explore space-time information by using CNN. The study in [14] proposed a new bone sequence representation method, which transformed a bone sequence into three fragments corresponding to the joint coordinate channel, and each fragment was composed of several grayscale images. The generated fragments are then fed into a deep CNN model for motion recognition. The research in [15] converted the transformed bone sequence into an RGB image, regarding the coordinates of the bone sequence (X, Y, Z) as the coordinates of the color image (R, G, B), and designed an arrangement network for data rearrangement. The study in [16] proposed an HCN model that can learn global co-occurrence features from skeletal sequences. This network combines graph convolution with LSTM, replaces the internal LSTM operations with graph convolution operations, and uses an attention mechanism to strengthen key node information while weakening non-key node information, highlighting more discriminative spatial features.

Recently, the GCN-based graph convolution network has attracted extensive attention because of its more natural representation of bone structure than based on RNN and CNN. In 2018, the research in [17] first developed a new deep learning model, namely space-time graph convolutional network (ST-GCN), which directly modeled bone data as graph structure, in which natural connections of human bones constitute spatial edges and corresponding joints in adjacent frames constitute temporal edges. Based on ST-GCN, the study in [18] used a frame distillation network to select keyframes and then sent the selected keyframes into a graph convolution network for action recognition. However, the spatial diagram in ST-GCN is fixed, and only human joints with natural connections are considered at the spatial edges. Moreover, it also proposed a multi-flow adaptive graph convolutional network (MS-AAGCN), which introduced an attention module and multi-flow network into 2S-AGCN. The study in [19] used the residual attention module to identify key joints. In contrast, the attention module used the original RGB image as input to generate attention masks to emphasize the areas that are important for emotion recognition in a frame. The research in [20] proposed that context information in original RGB videos should be used to extract joints with not only richer information but also highly relevant context information. At the same time, it used a neural structure search (NAS) algorithm to construct a graph convolutional network based on bone action recognition.

B. *Behavior Recognition in Sports*

The integration of human behavior recognition and attitude estimation technologies into display application scenes led to the gradual introduction of these technologies into intelligent sports analysis systems. Hoop Tracker is a smart basketball analytics system that works with smart wear. The hoop tracker has a speed sensor that detects every shot. The shot detector is made into a patch, fixed inside the basket, through which the ball passes after each goal. Each time the shooter takes a shot, the watch and the shot detector communicate in real-time to see how far the shooter is from the basket and whether the ball hits. The system displays data on shots, three-pointers, and free throws, as well as field goal percentage and points. Shot Tracker’s smart system, called Shot Tracker Team, has smart sensors attached to basketballs and players' shoes. In addition, the basketball court and the top of the court are surrounded by sensors, so the players are in a space without dead space [21]. These sensors give real-time feedback on the position of the player and the ball. Through the intelligent equipment, real-time analysis is made according to the data of players and ball movement on the court. The comparative information on the advantages and disadvantages of each player in the game is displayed in the form of data, including the analysis of players' shooting times, mistakes, assists, steals, dunks, and other actions. This data not only shows the players on the court to the audience but also provides the on-court coach with a data-backed tactical plan. In addition, in daily training, players can also use this system to let them understand their strengths and weaknesses to help adjust their targeted training. Most of the above products rely on smart wearable devices to capture and analyze athletes' movements. However, in general competitions, smart wearable devices will have a certain influence on athletes' competitions, and the sensors of smart wearers will have various uncertainties of system accuracy. NBA, as the highest professional basketball game in the world, mainly uses computer vision as a single information capture method of the Sport-VU system. The system has six 3D high-definition cameras fixed to the ceiling of each arena. Each camera takes pictures at high speed and sends them to a computer for data analysis. These cameras work at 25FPS. The software records and analyzes the player's movement trajectory and other information to obtain all kinds of technical and tactical data such as scoring, steals, rebounds, assists, instant speed, and so on.

III. Behavior Recognition Model based on 3D Graph Convolution and Attentional Enhancement

A. *Three-Dimensional Convolution with Graph Convolution*

1) 3D-convolution: The basketball training action recognition method based on big data technology mainly relies on data collection, feature extraction, and action classification. Firstly, this article collects a large amount of basketball training video data, including various movements of athletes. Then, computer vision algorithms are used to preprocess these videos and extract key motion features. Finally, machine learning algorithms are used to classify and recognize these features.

Specifically, this method combines deep learning and computer vision techniques, utilizing convolutional neural networks (CNNs) to identify and extract key information from videos. In order to better understand and recognize various actions in basketball training, 3D Convolutional Neural Network (3D CNN) was adopted, which can better process spatial and temporal information in video sequences. In the action classification stage, attention mechanism is introduced. The attention mechanism allows the model to focus on key information regions when processing complex basketball training videos, thereby improving the accuracy of action recognition. By integrating 3D graph convolution and attention mechanism, the method proposed in this paper has higher efficiency and accuracy in handling basketball training action recognition tasks. Sample areas at the same location in several consecutive frames make up the 3D sampling space of 3D convolution [22], which contains two dimensions: time and space. Through the three-dimensional convolution kernel, stack and sum the data of the sampling area in multiple consecutive frames to generate multidimensional data, thus realizing the convolution operation of the three-dimensional sampling space, as shown in Fig. 1. Given that the convolution kernel size of the three-dimensional convolution kernel is $[P_i, Q_i, R_i]$; thus, the position response of the JTH feature graph in the layer I network can be expressed as Formula (1).

$$u_{ij}^{xyz} = \sigma(b_{ij} + \sum_{p=0}^{P_i-1}\sum_{q=0}^{Q_i-1}\sum_{r=0}^{R_i-1} w_{ij}^{pqr} u_{(i-1)j}^{(x+p)(y+q)(z+r)}) \tag{1}$$

where, P_i and Q_i are the two spatial dimensions of the three-dimensional convolution kernel, R_i is the time dimension of the three-dimensional convolution kernel, u_{ij}^{xyz} represents the sampling weight in the three-dimensional convolution kernel, and b_{ij} represents the bias value; The A function contains operations such as batch standardization and activation functions.

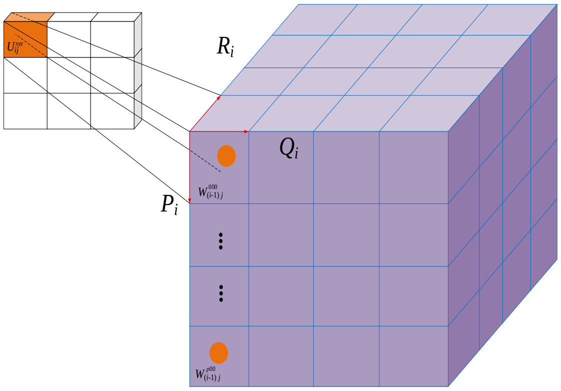

Fig. 1. Schematic diagram of the three-dimensional convolution operation.

3D sampling can not only collect spatial information but also build the connection between the current feature map and multiple consecutive frames in the output of the previous layer by weighted superposition of multiple consecutive frames in the output of the previous layer, realizing the capture of time information in the range of multiple frames. Therefore, 3D convolution can not only realize the collection of spatial and temporal information at the same time but also retain the correlation between the two. Therefore, the 3D convolution can be applied to the collection of spatial-temporal features of 3D sequential data in European space, such as continuous motion video frame sequence.

2) Graph convolution: Graph convolution is a general and effective way to learn graph structure data. Graph convolution aggregates information of neighbor nodes by weighted summation of hidden states of neighbor nodes through graph convolution kernel, which can process variable length neighbor nodes, realizes the convolution operation of graph structure data, and extracts information on a graph. Therefore, graph convolution can process graph structure data with generalized topological structure, so it is widely used in skeleton behavior recognition and attitude estimation.

Suppose there are m nodes in the output graph of layer *L* network, and the n-dimensional hidden state from the first node to the *m*-th node is represented $h_1^l, h_2^l, \ldots, h_m^l$, as shown in Fig. 2. The node states in the figure are denoted as $H^l[h_1^l, h_2^l, \ldots, h_m^l] \in R^{m\times n}$, and an adjacency matrix can represent the connection relationship $A \in R^{m\times n}$, so the first node in the output of the layer $l+1$ responds with 1, which is expressed as Formula (2).

$$h_1^{l+1} = \sigma(b + D^{-1/2} \otimes A \otimes D^{-1/2} \otimes H^l \otimes W) \tag{2}$$

where, D represents the degree matrix of A, a is the element of A to judge whether the node is A neighbor node with connection, W refers to the weight matrix of graph convolution, B is the bias value, $\sigma(\cdot)$ represents the activation function of nonlinear variation.

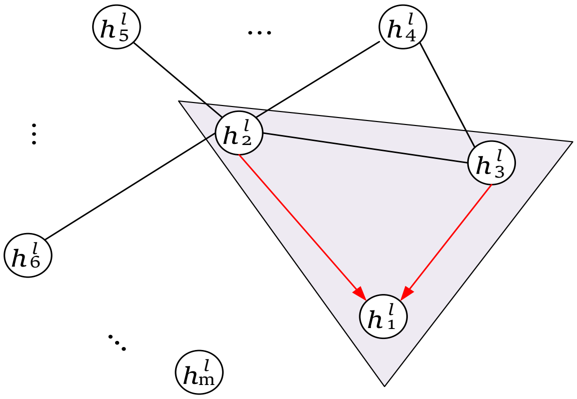

Fig. 2. Schematic diagram of the graph convolution operation.

3) 3D graph convolution: It is impossible to analyze the correlation between the spatial structure features and temporal features of skeleton sequences separately because they can describe all of the action information in the sequences together. Accordingly, the three-dimensional graph convolution method needs to be investigated to achieve the effective extraction of spatial-temporal information from the skeleton sequence.

In particular, the 3D sampling space in 3D convolution is rasterized sampling, which is only suitable for the feature collection of 3D sequential data in Euclidean space [23]. For 3D data in non-Euclidean space, the number of neighbor nodes in the sampling space is not fixed. Therefore, 3D convolution cannot extract spatial-temporal information from skeleton sequences with non-Euclidean three-dimensional data; Graph convolution can only extract spatial information on a graph through graph convolution kernel, which is capable of handling neighbor nodes with varying lengths. A three-dimensional graph convolution method is proposed in this paper to extract spatial and temporal information of three-dimensional skeleton sequences in non-Euclidean space. The technique is predicated on the graph convolution kernel, which is capable of managing neighbor nodes with varying lengths in graph convolution. Using the 3D sampling space in 3D convolution as an improvement idea, the 2D graph convolution kernel is improved to the graph convolution kernel with three-dimensional sampling space.

In the model process of the three-dimensional graph transformation based on the skeleton order, the adjacent nodes in the three-dimensional model space contain two adjacent nodes connected to the node in the skeleton stream and nodes close to the same point in several consecutive frames. Based on the three-dimensional graph convolution kernel, the three-dimensional graph convolution of the skeleton sequence is realized by weighted stack summation of neighbor node data in three-dimensional sampling space to generate multidimensional data, and the spatial-temporal information of the skeleton sequence is extracted effectively. As shown in Fig. 3, suppose L continuous skeleton frames in the three-dimensional sampling space. From frame 1 to frame L is denoted as $G^0, G^1, \ldots, G^{L-1}$ then the output result of three-dimensional graph convolution can be expressed as Formula (3).

$$x' = \sigma(b + \sum_{t=0}^{L-1}\sum_{c=0}^{C-1}\sum_{k=0}^{K-1} D^{-1/2} \otimes A \otimes D^{-1/2} \otimes G_{c,k}^{t} \otimes W_{c,k}^{t}) \tag{3}$$

where, A indicates the adjacency matrix of the connection relation, D denotes the degree matrix of A, $G_{c,k}^{t}$ is the characteristic value of channel C of the KTH neighbor node of frame T in the three-dimensional sampling space, $W_{c,k}^{t}$ refers to the weight matrix of three-dimensional graph convolution, b is the bias value; The $\sigma(\cdot)$ function contains operations such as batch standardization and activation functions.

B. Attentional Mechanism

1) Channel grouped attention: Channel grouping attention groups channel features and highlight salient features in each group by using the similarity between both local and global features. Fig. 4(a) presents the network layer structure of channel-grouped attention. Features are divided into G groups according to channels, and the input features of each group are fused with the feature map G containing a semantic vector after global average pooling to form a new feature map. After normalization and sigmoid activation function operation, the input features of each group are integrated with the original feature by the site. According to the definition of the dot product, $g \cdot x_i$ can be written as $\| g \| \| x_i \| cos\theta_i$, where θ_i is the Angle between g and x_i. Therefore, the feature of the modulus length and the feature that is close to the direction of the global feature vector will get a larger initial attention coefficient. At the same time, attention values of different samples vary greatly, so they need to be normalized to the same range to give accurate attention weight.

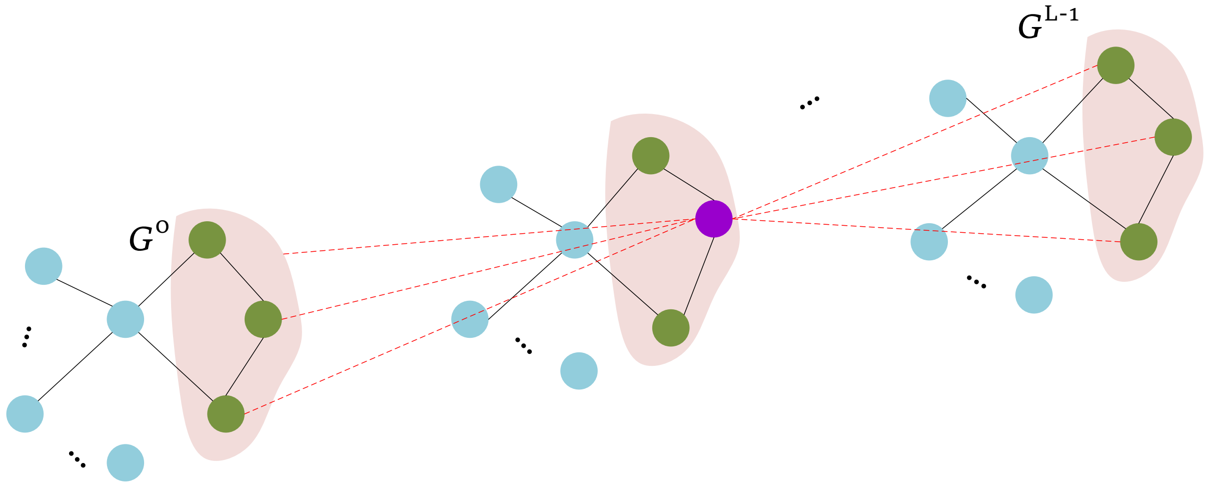

Fig. 3. Schematic diagram of 3D graph convolution operation in skeleton sequence.

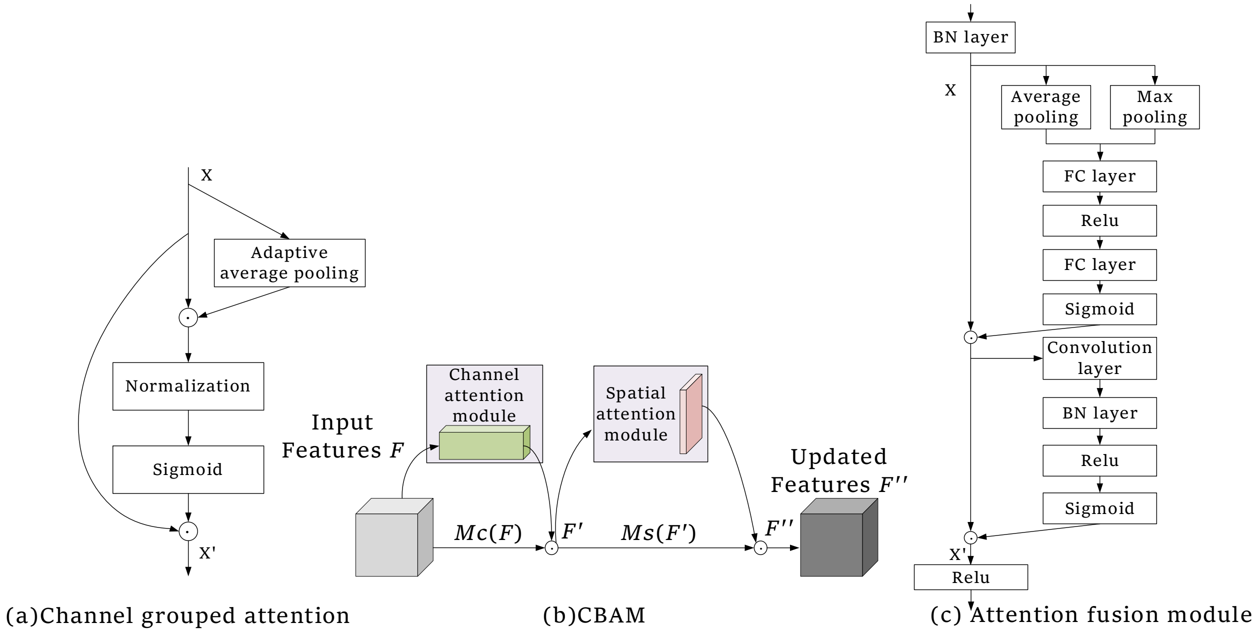

Fig. 4. Each attention mechanism module component.

2) Channel-spatial attention: CBAM attention network [24] is analogous to the human visual attention mechanism, which reconstructs the feature matrix through channels and Spaces. A self-learning method is adopted to recalibrate the weights of features. The overall network structure of CBAM is shown in Fig. 4(b). The feature F extracted from the input image was dotted with the feature $M_c(f)$ after the action of the channel attention module to obtain the feature F'. Similarly, the improved feature F'' was obtained through the action of the spatial attention module. The sequential connection of the channel attention module and spatial attention module is more effective than the parallel connection.

Unlike the channel attention module, which concentrates on the context in which the information is meaningful, the spatial attention module is location-specific. The channel attention module and the spatial attention module complement each other, focusing on location and content respectively and linking sequentially [25]. Similar to the channel attention module, for the H×W×C input feature F', the maximum pooling and average pooling of channel dimensions are firstly carried out to obtain two features of 1×1×C dimensions and then splice them according to channels. Then, the feature is convolved with a 7×7 convolution, and a spatial matrix with the same dimension as the sigmoid activation function obtains the original feature. The new feature after scaling can be obtained by multiplying the spatial attention matrix with the original feature.

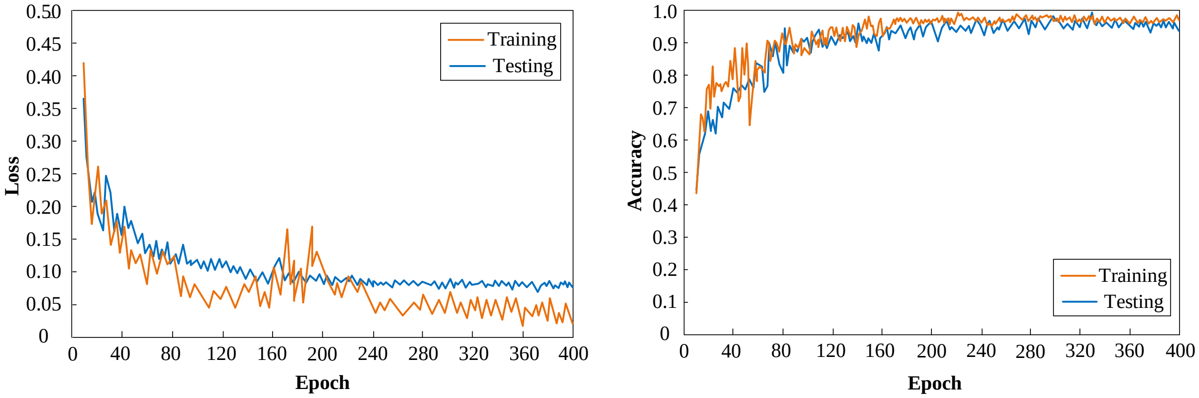
3) Attention fusion: Fig. 4(c) sows the attention fusion module, in which the CBAM module is added after the BN layer of the backbone network. In the training process, the fusion attention module divided the features into G groups according to the channels. After obtaining G from the global average pooling, the features of each group were integrated with the original group features by the site. After the normalization and activation function operation, the features were dotted with the original group features to obtain the activation of significant semantic regions based on the above operations [26]. The upper and lower parts in the figure respectively represent channel attention and spatial attention to features, and the feature W' of a channel or space with different weight distribution can be obtained through the action of the attention module.

IV. Experimental Design and Result Analysis

A. Experimental Environment and Evaluation Indicators

The experimental environment of this work is the Ubuntu 16.04 operating system. The experimental platform is Intel(R)Core I7-7800X processor, six-core 3.5ghz, and NVIDIA GTX1080Ti graphics card. The development language is Python 3.7. The testing platform is Pycharm, and the PyTorch deep learning framework is adopted. Set the initial learning rate as 0.0001, the weight attenuation term as 0.0005, and the random discard rate as 0.5. The batch size is set to 16.

The curves of training and testing performance and iteration times of the model in this paper are represented in Fig. 5. It is evident that as the number of iterations reaches 240, the training and test accuracy rate and Loss curve region are stable, and the model achieves stable convergence.



(a) Loss curve

(b) Accuracy curve

Fig. 5. Curves of the training and testing phases.

Fig. 5 shows the curves during the training and testing stages. (a) Indicates the loss curve. (b) Represents an accuracy curve. Time Overhead (TO) of single image motion recognition, Accuracy, Precision, Recall, F1-score, and other mainstream evaluation indices were employed to assess the model performance in order to confirm the efficacy of the suggested algorithm. Formula (4) to Formula (7) displays the computation expressions. In Table I, the confusion matrix is displayed. In particular, the calculation of Precision and Recall is contradictory, so the precision-recall curve is used for comparison in the current paper. The model's classification performance improves with increasing area under the curve.

$$Accuracy = \frac{Tp + Tn}{Tp + Fp + Tn + Fn} \tag{4}$$

$$Precision = \frac{Tp}{Tp + Fp} \tag{5}$$

$$Recall = \frac{Tp}{Tp + Fn} \tag{6}$$

$$F1 = \frac{2Precision \times Recall}{Precision + Recall} \tag{7}$$

TABLE I. CONFUSION MATRIX CALCULATION

Actual	**Predicted**	
	Positive	***Negative***
Positive	TP	FP
Negative	FN	TN

B. Result Analysis

Fig. 6 shows the confusion matrix generated by this method in three groups of experiments, where the actual action sequence is represented by the rows of the matrix. In contrast, the columns show the action sequence recognized by the algorithm. The confusion matrix states that 307, 311, 301, 318, and 307 times of the six movements were successfully recognized in the three groups of experiments, and the recognition accuracy was 97.07%, 96.14%, 98.34%, 94.03%, and 97.39% respectively. In addition, Fig. 7 represents the average Accuracy, Precision, Recall, and F1 curves of the proposed model in multiple experiments. Also, the performance of the presented model tends to be stable on several experimental results, indicating the robustness of the model presented in the present study.

C. Ablation Experiment

To assess the effect of different components in the model on the overall recognition performance, three ablation experiments were designed, respectively. 1) The original recognition model using skeleton analysis only; 2) Replace original graph convolution with 3D graph convolution; 3) Introduce channel-spatial attention mechanism. Fig. 8 displays the experimental results, where Original represents the first group of experiments; 3D-GC represents that only a three-dimensional graph convolution network is used; ATT means only channel-spatial attention mechanism is used; 3DGC-ATT represents the final model of this paper. It can be seen that compared with experiment 1) of the original control group, the overall performance of the model is improved by 3.91% in recognition accuracy by using 3D graph convolution instead of original graph convolution. The main reason is that the spatial structure features and time features of the skeleton sequence are introduced to improve the expression ability of the action sequence in the skeleton sequence further. In addition, after the introduction of the channel-spatial attention mechanism, the recognition accuracy of the model is improved by 5.18%, which is 1.31% higher than that of the recognition model after the introduction of three-dimensional graph convolution. The reason is that the attention mechanism can focus on the weight distribution of strong features, further, increase the contribution of the largest feature to the overall recognition performance, and suppress the weight of edge features.

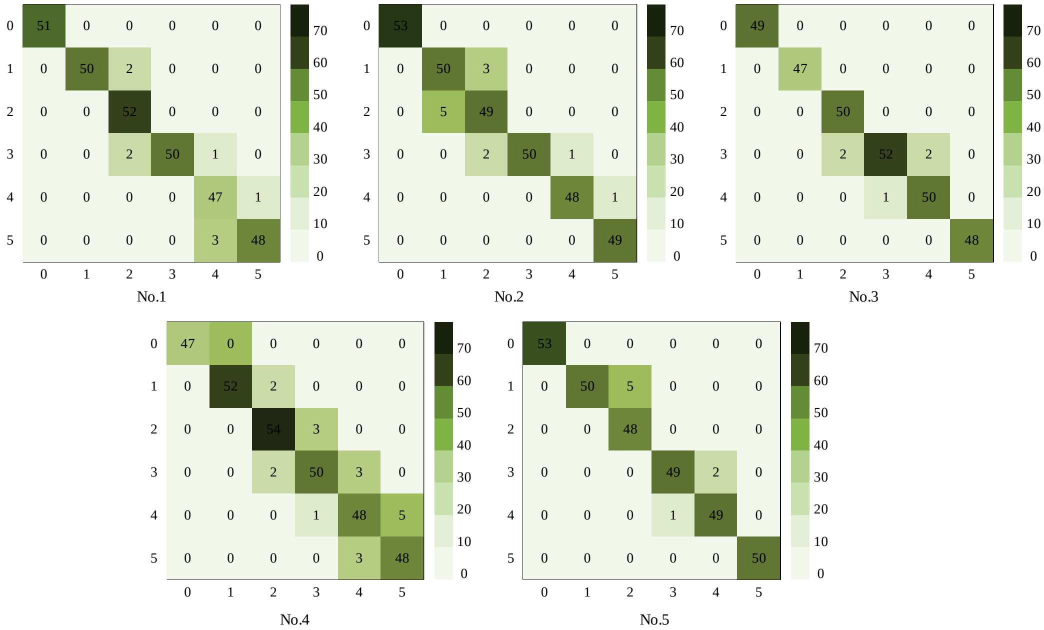


Fig. 6. Confusion matrix.

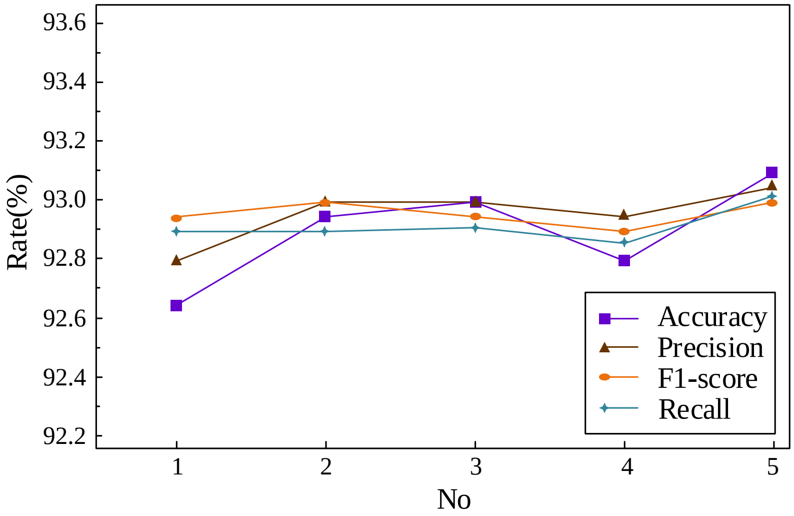

Fig. 7. Curves under different evaluation indexes.

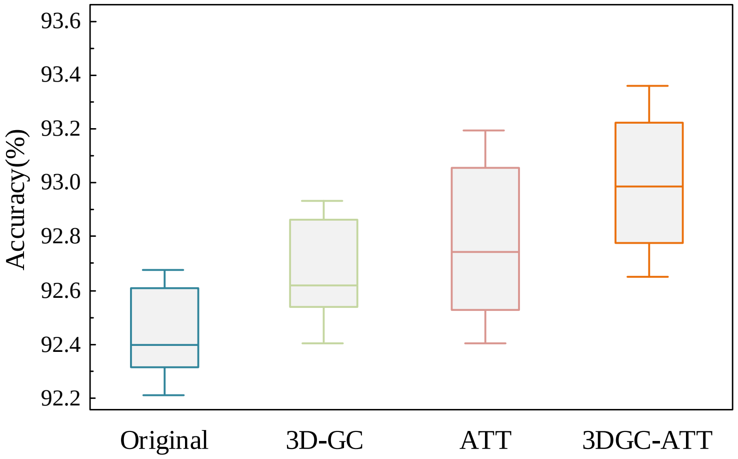

Fig. 8. Ablation experiment.

D. Comparison of Similar Related Works

To verify the effectiveness of the proposed model, the same data set, environment, and evaluation indicators were compared with the current mainstream model. Fig. 9 shows the curves of various models under Accuracy, Precision, Recall, and F1. Fig. 10 shows the comparison results of different models' running times. It can be seen that in Accuracy, Precision, Recall, F1, and other evaluation indicators, the model presented in the present work has obvious competitive advantages compared with mainstream models, and it is also competitive in identifying time costs. Although the time cost is improved compared with the model in literature [27], the comprehensive performance of this model is: The model in this paper performs well. In addition, to integrate the calculation contradiction between Precision and Recall, the precision-recall curve is adopted here for comparison. Fig. 11 shows the comparison results of P-R curves of different models. The model's classification performance improves with the increasing area under the curve.

The P-R curve of the model in this paper can all surround the P-R curve of the comparison model in the basketball action recognition results, which indicates that the performance of the overall action recognition of the model in the current study has been improved to varying degrees after the existing model is improved by using three-dimensional graph convolution and attention mechanism. The above data further verify the robustness of the proposed model.

The basketball training action recognition method based on big data 3D convolution technology is a very promising research direction. The accuracy and efficiency of this method have been validated in many cases, but there are still some areas that need improvement. Especially when dealing with large-scale data, how to improve computational efficiency and reduce the consumption of computing resources is an urgent problem that needs to be solved. In addition, how to improve the generalization ability of the model is also an important research direction. In practical applications, different basketball training scenarios and individual differences among athletes may lead to a decrease in model performance. Therefore, studying how to better adapt the model to these differences is a challenging task. I believe that with the continuous progress of technology and in-depth research, the basketball training action recognition method based on big data 3D convolution technology will be further optimized and improved, and will play a greater role in practical applications.

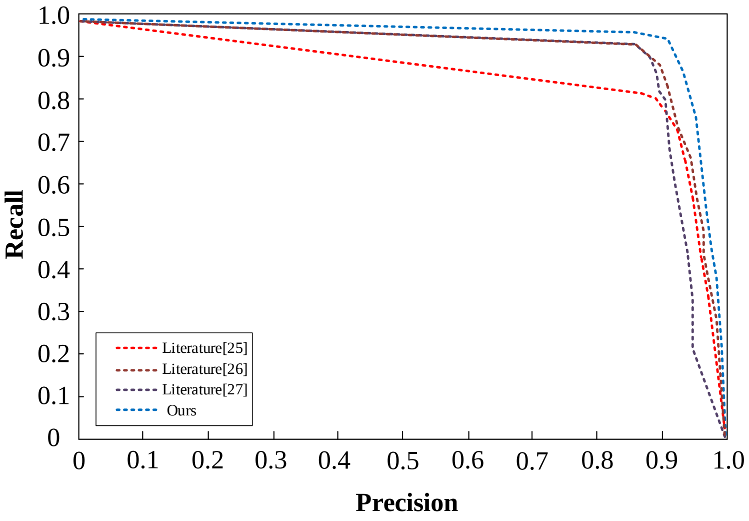

Fig. 11. Comparison of P-R curves of different models.

V. Conclusion

This paper explores the motion capture technology of computer vision and large data sets in advanced training technology application status in the field of motion gesture recognition. Using three-dimensional figure convolution and attention mechanism to improve the existing model, through the test in the practical data, this model is verified in recognition accuracy and time cost is increased. Thus, this model can be applied to the daily training of basketball players and provide a reference for the overall evaluation and decision-making of athletes and coaches.

However, the research has certain limitations. The method based on 3D CNN requires a large amount of computing resources, such as GPU memory and computing power, when processing large-scale basketball training video data. This may result in very time-consuming training and inference processes, which cannot meet the needs of real-time processing. Therefore, how to improve the efficiency of algorithms and the utilization of computing resources is also another challenge faced by current methods.

To address the issues of data scale and quality, future research can explore data augmentation techniques, such as using Generative Adversarial Networks (GANs) to generate high-quality simulated data or using transfer learning methods to acquire knowledge from other relevant datasets. In addition, adaptive learning algorithms can adaptively adjust model parameters based on individual characteristics of different athletes, improving adaptability to individual differences.

***Abstract*—Banking is a dynamic industry that places significant importance on risk management, requiring accurate and interpretable AI models to make transparent lending decisions. This study introduces a groundbreaking approach that combines a multistage ensemble technique with a 1D convolutional neural network (CNN) architecture. The algorithm not only delivers superior classification performance but also offers interpretable explanations for its decisions. The algorithm is designed with multiple strategic steps to enhance model performance without sacrificing explainability. Thorough experiments were conducted using datasets from private banks and non-banking financial companies (NBFCs) in India to evaluate the algorithm's performance. It was compared against various state-of-the-art models, demonstrating remarkable precision, recall, F1 score, and accuracy values of 0.994, 0.992, 0.993, and 0.991, respectively. This outperformed competing models like homogeneous deep ensembles, 1D CNN, and Artificial Neural Networks (ANN). Furthermore, individual borrower dataset evaluations confirmed the proposed algorithm's consistency and efficiency, achieving precision, recall, F1 score, and accuracy values of 0.960, 0.961, 0.952, and 0.964, respectively. The research emphasizes the effectiveness of the explanatory integration decision process, wherein the Explainable Multistage Ensemble 1D CNN not only provides enhanced credit risk prediction but also facilitates transparent and interpretable lending decisions. The algorithm's ability to offer understandable explanations empowers financial institutions to make well-informed lending decisions, reduce credit risk, and foster a more stable and inclusive financial ecosystem.**

Keywords*—Credit risk prediction; explainable AI; multistage ensemble; 1D convolutional neural network; interpretability; transparency; lending decisions; financial institutions

I. INTRODUCTION

In the realm of financial services, credit risk prediction plays a crucial role in enabling sound and responsible lending decisions [1], [2]. Accurate assessments of borrowers' creditworthiness are essential for financial institutions to mitigate risks, ensure fair lending practices, and maintain a stable financial ecosystem. With the advancements in Machine Learning (ML) and artificial intelligence (AI), there has been a surge in the development and adoption of advanced predictive models for credit risk assessment [3], [4]. These models, such as convolutional neural networks (CNNs) and artificial neural networks (ANNs), offer the ability to capture intricate patterns and dependencies within the data, leading to improved predictive accuracy. Despite their impressive performance, the use of complex AI models in the financial industry raises concerns about their inherent opacity and lack of interpretability. Often referred to as "black box" models, these approaches provide little insight into the factors that influence their decisions [5]. In highly regulated and sensitive domains like credit risk assessment, the lack of transparency can be a major obstacle, as stakeholders, including customers, regulators, and internal compliance teams, require explanations to trust and validate the model's decisions [6], [7].

To address these challenges and bridge the gap between predictive accuracy and interpretability, there has been a growing interest in explainable AI (XAI). XAI techniques aim to provide interpretable explanations for complex models, allowing stakeholders to understand how decisions are made and identify the key features driving predictions. In the context of credit risk prediction, XAI offers several advantages, including increased transparency, regulatory compliance, enhanced customer trust, and the ability to detect potential biases in decision-making [8], [9].

In this study, we introduce a technique aiming to incorporate explanations into the decision-making process. Our model utilizes multistage ensemble techniques, known for enhancing interpretability by offering explanations at various decision stages. By combining the strengths of multiple models, this ensemble approach improves predictive accuracy while retaining the capability to provide meaningful explanations for credit risk evaluations.

The proposed model’s objective is to achieve high predictive accuracy while ensuring that the underlying decision process is transparent and understandable. By providing interpretable explanations, financial institutions can gain valuable insights into the model's risk assessments, understand the relative importance of different features, and detect potential biases, ultimately leading to more informed lending decisions.

To proposed Explainable Multistage Ensemble 1D CNN model, is evaluated for the effectiveness on two different data sets. We conducted comprehensive experiments on enterprise credit risk dataset and individual borrower credit dataset. We compared the performance of proposed model with other state-of-the-art approaches, including Homogeneous deep Ensembles (ANN and CNN), as well as standalone ANN and 1D CNN classifiers. The results demonstrate the superior predictive accuracy and interpretability of our proposed model, reinforcing its potential value in the domain of credit risk prediction.

The rest of this paper is structured as follows: In Section II, covers a comprehensive review of related studies in the fields of credit risk prediction, explainable AI, and ensemble techniques. Section III presents the methodology and architecture of our innovative model. Following that, in Section IV, we present and analyze the experimental results, highlighting the strengths of our approach compared to other existing methods. Finally, in Section V, we conclude the paper and discuss potential avenues for future research.

II. Literature Review

Assessing credit risk is a crucial undertaking in the financial sector, as it involves evaluating borrowers' creditworthiness to make well-informed lending choices. To develop predictive models for credit risk assessment, researchers have explored various AI and machine learning approaches over time. Furthermore, the growing need for transparency and interpretability in models has given rise to explainable AI (XAI) techniques, which aim to provide insights into the decision-making process of intricate models. In this section, we present a thorough examination of pertinent literature concerning credit risk prediction, explainable AI, and ensemble techniques.

A. Credit Risk Prediction

The literature on credit risk prediction is vast and diverse, with numerous studies focusing on developing accurate and reliable models. Traditional credit scoring methods, such as logistic regression and decision trees, have long been used in the industry. However, with advancements in machine learning, more sophisticated models, including neural networks, support vector machines (SVM), and gradient boosting algorithms, have gained popularity due to their ability to capture complex patterns in credit data [4], [10], [11], [12].

B. Explainable AI for Credit Risk Prediction

The need for model transparency and interpretability in credit risk prediction has led to the exploration of explainable AI techniques. Several studies have proposed methods to generate explanations for credit risk models, enabling stakeholders to understand the rationale behind model decisions. Approaches such as LIME (Local Interpretable Model-agnostic Explanations) and SHAP (SHapley Additive exPlanations) have been applied to credit risk models to provide local and global interpretations [9], [13], [14]. Additionally, rule-based models and decision trees have been used as interpretable alternatives to black box models [15], [16].

C. Ensemble Techniques

Ensemble methods have demonstrated remarkable success in various machine learning tasks, including credit risk prediction. Ensemble approaches combine the predictions of multiple models to improve overall performance and robustness. Bagging and boosting techniques, such as Random Forest and Gradient Boosting Machines (GBM), have been widely employed in credit risk prediction [17]. Recent research has explored the benefits of using homogeneous and heterogeneous ensembles, where models from the same or different algorithm families are combined [8], [18], [19], [20], [21]. Researchers from various domains proved the effectiveness of ensemble techniques in their fields [22], [23], [24], [25], [26], [27], [28], [29], [30].

D. Multistage Ensemble Techniques

Multistage ensemble techniques offer a promising approach for improving both predictive accuracy and model interpretability. By combining multiple models at different stages of the decision-making process, these methods can provide valuable insights into the model's reasoning. Various studies have shown that multistage ensembles can outperform single model [22], [25], [30]. However, the application of multistage ensemble techniques in credit risk prediction remains relatively unexplored.

Credit risk prediction is a critical domain where model accuracy, transparency, and interpretability are of utmost importance. While various AI models have been employed for credit risk assessment, the emergence of explainable AI and ensemble techniques presents new opportunities to enhance predictive performance and provide interpretable explanations for model decisions. The proposed approach aims to leverage explainable multistage ensemble techniques to address the dual objectives of predictive accuracy and model transparency.

III. Proposed Methodology

A. Credit Risk Dataset used in the Experiments

The analysis focuses on two distinct borrower segments: individual borrowers and enterprise borrowers. Individual borrowers obtain loans in their personal capacity, while enterprise borrowers secure loans on behalf of their businesses. Data for both segments were collected under a Non-Disclosure Agreement (NDA). The individual borrower dataset was obtained from a private bank in India and comprises 105,163 records, with 100,497 records (95.6%) falling into the negative class (non-risky) and 4,665 records (4.4%) classified as positive class (risky). The enterprise dataset was collected from an NBFC (Enterprise) in India and consists of 97,451 records, with 92,900 classified (95.3%) as the negative class and 4,550 (4.7) as the positive class. The sample description is presented in Fig. 1. The target variable in this analysis is "risk," which is binary, and the other variables serve as independent variables. The dataset contains a mix of categorical and numerical variables. All data used in this analysis were collected following ethical guidelines and legal agreements to ensure confidentiality and privacy.

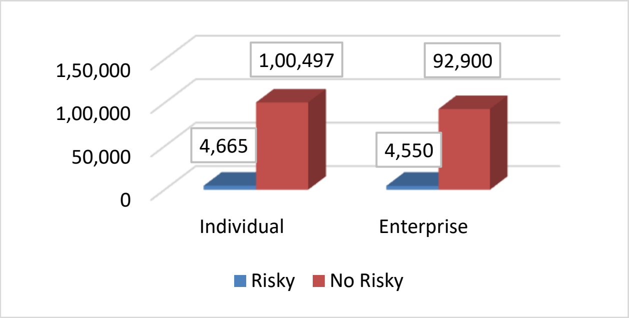

Fig. 1. Sample profile.

B. Multistage Ensemble Architecture Overview

The multistage ensemble classifier is designed to improve classification performance by employing a series of stages, each containing a 1D Convolutional Neural Network (CNN). Unlike a single CNN model, the ensemble classifier combines the outputs of all stages to make the final prediction. Each stage contributes its specialized knowledge to enhance the overall decision-making process. The choice of the number of stages will depend on the complexity of the classification task, the size of the dataset, and the available computational resources. Determining the appropriate number of stages for the ensemble classifier is crucial. Too few stages might limit the model's representational power, while too many stages could lead to excessive computational requirements and potential overfitting. The optimal number of stages is typically determined through experimentation and performance evaluation on the validation set. In the proposed setup five stages are used.

C. Stage-wise CNN Architecture

For each stage, design a 1D CNN architecture tailored to the specific characteristics of the dataset and classification problem. Each stage's CNN should consist of multiple convolutional layers, followed by activation functions and pooling layers. This design enables the CNN to learn hierarchical features from the 1D input data. Experimentation is done with different filter sizes, strides, and the number of filters in each layer to identify the configuration that yields the best results. Additionally, techniques like batch normalization are applied to accelerate training and improve convergence. To reduce overfitting, introduced dropout layers, which randomly deactivate neurons during training, preventing reliance on any single set of features. Table I represents the architecture of a 1D CNN-based ensemble classifier with multiple stages, where each stage consists of Conv1D layers, Batch Normalization, Max Pooling, LeakyReLU activation, and finally, an Average Pooling, Dropout, and Dense layer for classification.

D. Conv1D Layer

This layer performs 1-dimensional convolution on the input data. The "Filters" parameter is set to 128 for the first Conv1D layer, 256 for the second and third Conv1D layers, and 512 for the fourth Conv1D layer. The number of filters determines the number of features maps the layer will learn. Higher filter values allow the model to learn more complex patterns but also increase computational complexity.

E. Batch Normalization Layer

Batch normalization normalizes the input of the layer, helping to stabilize and accelerate the training process. It improves convergence and prevents internal covariate shift, which occurs when the distribution of inputs to a layer change during training.

F. Max Pooling 1D Layer

Spatial dimensions of the data can be reduced by using max pooling while retaining the most important features. The "Pool size" parameter is set to 4 for all Max Pooling layers. This means the layer will take the maximum value within a sliding window of size 4 along the temporal dimension.

TABLE I. ARCHITECTURE OF A 1D CNN-BASED ENSEMBLE CLASSIFIER WITH MULTIPLE STAGES

Type of Layer	Other Parameters
Conv1D **Batch Normalization** **Max Pooling 1D** **Activation**	Filters = 128 - Pool size = 4 LeakyReLU activation
Conv1D **Batch Normalization** **Max Pooling 1D** **Activation**	Filters = 256 - Pool size = 4 LeakyReLU activation
Conv1D **Batch Normalization** **Max Pooling 1D** **Activation**	Filters = 256 - Pool size = 4 LeakyReLU activation
Conv1D **Batch Normalization** **Max Pooling 1D** **Activation**	Filters = 512 - Pool size = 4 LeakyReLU activation
Average Pooling 1D **Flatten** **Dropout** **Dense**	Pool size = 2 - Rate 0.4 Regularizer L2 (0.001), Softmax activation

G. LeakyReLU Activation

Leaky ReLU (Rectified Linear Unit) is an activation function that introduces a small negative slope for negative input values, preventing the "dying ReLU" problem. The negative slope helps the model during backpropagation even for negative inputs, leading to improved gradient flow and avoiding potential dead neurons.

H. Average Pooling 1D Layer

After the last Conv1D layer, an Average Pooling layer is used instead of Max Pooling. Average pooling computes the average value of each feature map, reducing the data dimensionality and providing a global summary of the features.

I. Flatten Layer

The Flatten layer converts the 3-dimensional output from the previous layers into a 1-dimensional vector, preparing it for the fully connected layers.

J. Dropout Layer

Dropout is a technique that randomly drops out (sets to zero) a fraction of the neurons during training. The "Rate" parameter is set to 0.4, meaning 40% of the neurons will be dropped out during training. This helps prevent overfitting and encourages the model to learn more robust representations.

K. Dense Layer

The Dense layer is a fully connected layer, linking each neuron from the preceding layer to every neuron in this current layer. With a "Pool size" parameter of 2, this layer comprises 2 output neurons. To prevent overfitting, the layer employs L2 regularization with a coefficient of 0.001, penalizing large weights. By using the Softmax activation function, the final output values are transformed into probability scores for each class, making it suitable for multi-class classification.

L. Training the Stage-wise CNNs and Ensemble Combination

In the proposed approach, we utilize a multi-stage Convolutional Neural Network (CNN) architecture, where each stage's CNN is trained independently on the training set. Throughout the training process, we closely monitor the model's performance on the validation set to prevent overfitting. To achieve optimal results, we tune hyperparameters like learning rate, batch size, and the number of epochs. After training all stages' CNNs, we proceed to combine their outputs to create the final prediction. To evaluate the effectiveness of our ensemble classifier, we employ the test set and calculate various standard metrics, including accuracy, precision, recall, F1-score, and confusion matrices. Subsequently, we conduct a comparative analysis to assess how our proposed ensemble classifier performs in comparison to other state-of-the-art techniques. By doing so, we aim to demonstrate the superiority of our approach in making accurate predictions.

M. Explanation Generation

Adaptive Relevance Scaling for Layer-wise Relevance Propagation (ARSLRP) based explanations are employed to interpret the decision-making process of the multistage 1D CNN based ensemble classifier. Its primary objective is to attribute the model's prediction to the input features, offering a human-understandable explanation for the decision outcomes. ARSLRP operates on the principle of redistributing the model's output back to its input features, layer by layer, to identify the most influential features contributing to the final prediction.

The ARSLRP process starts from the final layer of the network, where the relevance is initialized based on the model's output (e.g., for a classification problem, relevance is initialized for the predicted class). Then, the relevance is propagated backward through the network layers using the Alpha-Beta rule until it reaches the input layer. The relevance scores obtained after the ARSLRP process indicate the importance of each input feature in influencing the model's decision.

IV. Results and Discussion

Multi Stage Heterogeneous Ensemble 1D CNN The proposed multistage ensemble 1D CNN model is evaluated based on various performance matrices namely precision, recall, f1-score and accuracy on two datasets namely enterprise data set and individual dataset. Table II illustrates the results for various performance matrices on enterprise dataset.

TABLE II. Explainable Ensemble 1 D CNN Performance on NBFC Data

Algorithm	Precision	Recall	F1-score	Accuracy
Proposed Algorithm (Multistage 1 D CNN)	0.994	0.992	0.993	0.991
Homogeneous deep Ensemble (ANN)	0.910	0.950	0.930	0.950
Homogeneous deep Ensemble (CNN)	0.900	0.950	0.930	0.950
ANN	0.891	0.893	0.892	0.894
1 D CNN	0.893	0.891	0.894	0.892

1) Precision: Multistage 1D CNN model achieves a precision of 0.994. This means that when the model predicts a customer as being at risk of defaulting on their credit, it is correct 99.4% of the time. A high precision value indicates that the model is effective in minimizing false positives, i.e., it rarely misclassifies customers who are not likely to default as high-risk, which is essential for banks to avoid unnecessary precautionary measures for low-risk customers.

2) Recall: The Multistage 1D CNN model achieves a recall of 0.992, meaning it successfully captures 99.2% of the customers who are genuinely at risk of defaulting on their credit. A high recall value indicates that the model has a low false negative rate, meaning it rarely misses identifying customers who are actually high-risk. This is crucial for banks to ensure that they do not overlook customers who pose a real credit risk.

3) F1-score: For the Multistage 1D CNN model, the F1-score is 0.993, which indicates an excellent balance between precision and recall. It demonstrates that the model is effective in achieving both accurate positive predictions and comprehensive identification of high-risk customers. A high F1-score suggests that the model is well-suited for credit risk prediction tasks where precision and recall need to be balanced.

4) Accuracy: The Multistage 1D CNN model achieves an accuracy of 0.991, which means it correctly predicts approximately 99.1% of all instances in the dataset. This high accuracy indicates that the model performs exceptionally well in making overall accurate predictions, regardless of the class distribution. A high accuracy value shows the reliability and effectiveness of the model in capturing credit risk patterns and making informed decisions.

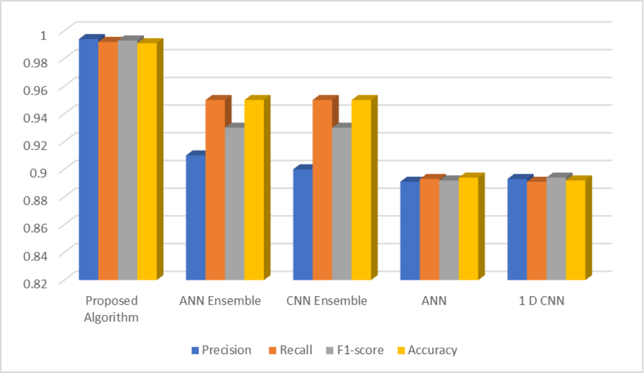

Fig. 2. Performance of proposed algorithm on NBFC dataset.

In summary, the results for the Multistage 1D CNN model in credit risk prediction are highly impressive. The model achieves exceptional precision, recall, F1-score, and accuracy values, demonstrating its ability to identify high-risk customers accurately while minimizing false predictions. This performance surpasses that of other algorithms tested in the study, making the Multistage 1D CNN model a promising choice for credit risk assessment tasks, and suggesting its potential for real-world implementation in financial institutions to enhance credit risk management and decision-making processes. Pictorial illustration for the same is shown in Fig. 2.

Similarly, Table III presents the performance metrics of various algorithms for individual borrower credit risk prediction dataset, with each row corresponding to a specific model. Among the algorithms tested, the "Proposed Algorithm" based on the Multistage 1D CNN stands out as the top-performing model across multiple evaluation metrics.

The Proposed Algorithm achieves a precision of 0.960, indicating that 96% of the predicted high-risk customers are genuinely at risk of defaulting on their credit. This demonstrates the model's effectiveness in minimizing false positives, ensuring that it correctly identifies most customers who pose an actual credit risk. Furthermore, the Recall for the Proposed Algorithm is 0.961, signifying that the model captures 96.1% of the actual high-risk customers present in the dataset. A high recall score suggests that the model has a low false negative rate, meaning it rarely misses identifying customers who are truly at risk of defaulting on their credit. This capability is crucial for financial institutions to avoid overlooking potential credit risks. The F1-score of 0.952 for the Proposed Algorithm reflects a balance between precision and recall, indicating a good overall performance. The F1-score is particularly valuable when there is an uneven distribution of classes in the dataset, making it a reliable measure for credit risk prediction tasks.

Lastly, the Proposed Algorithm achieves an accuracy of 0.964, implying that it makes accurate predictions for approximately 96.4% of all instances in the dataset. A high accuracy value indicates that the model's overall performance is strong, making it a reliable tool for credit risk assessment. In comparison, the other algorithms, including Homogeneous deep Ensemble (ANN), Homogeneous deep Ensemble (CNN), ANN, and 1D CNN, also show respectable results, but the Proposed Algorithm based on the Multistage 1D CNN consistently outperforms them across all metrics. In conclusion, the results demonstrate that the Multistage 1D CNN model proposed in the study is highly effective for credit risk prediction. Its balanced precision, recall, and F1-score, combined with its impressive accuracy, make it a promising approach for financial institutions seeking accurate and reliable credit risk assessment models. Pictorial illustration for the same is shown in Fig. 3.

B. Explanations / Interpretations

In this study, we explored the ARSLRP as an explainability technique for credit risk prediction models. The goal was to gain insights into how the model makes predictions and to provide transparent explanations to stakeholders, such as regulators, auditors, and customers, who need to understand the factors contributing to credit risk assessments. Fig. 4 and Fig. 5 illustrate the results generated by the model to provide explanations on enterprise and individual borrower dataset respectively.

TABLE III. EXPLAINABLE ENSEMBLE 1 D CNN ON INDIVIDUAL BORROWER DATASET

Algorithm	**Precision**	**Recall**	**F1-score**	**Accuracy**
Proposed Algorithm (Multistage 1 D CNN)	0.960	0.961	0.952	0.964
Homogeneous deep Ensemble(ANN)	0.918	0.952	0.939	0.958
Homogeneous deep Ensemble(CNN)	0.950	0.958	0.940	0.959
ANN	0.881	0.883	0.882	0.884
1 D CNN	0.883	0.881	0.884	0.882

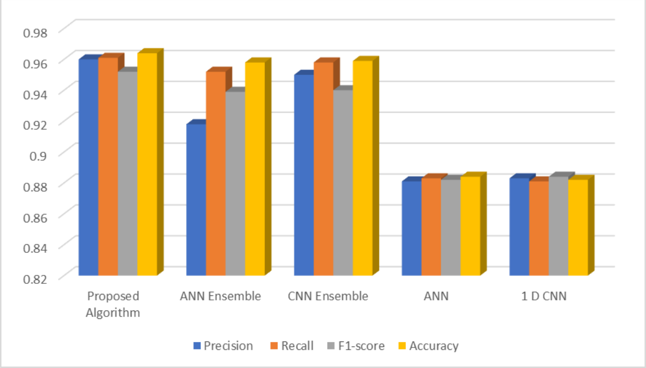

Fig. 3. Performance of proposed algorithm on individual borrower dataset.

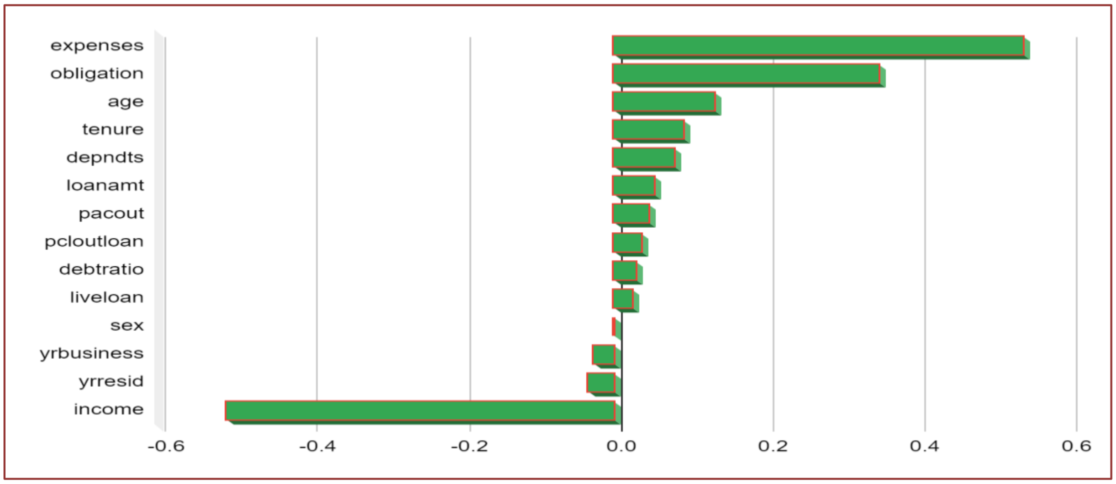

Fig. 4. Explanations / Interpretations on NBFC dataset.

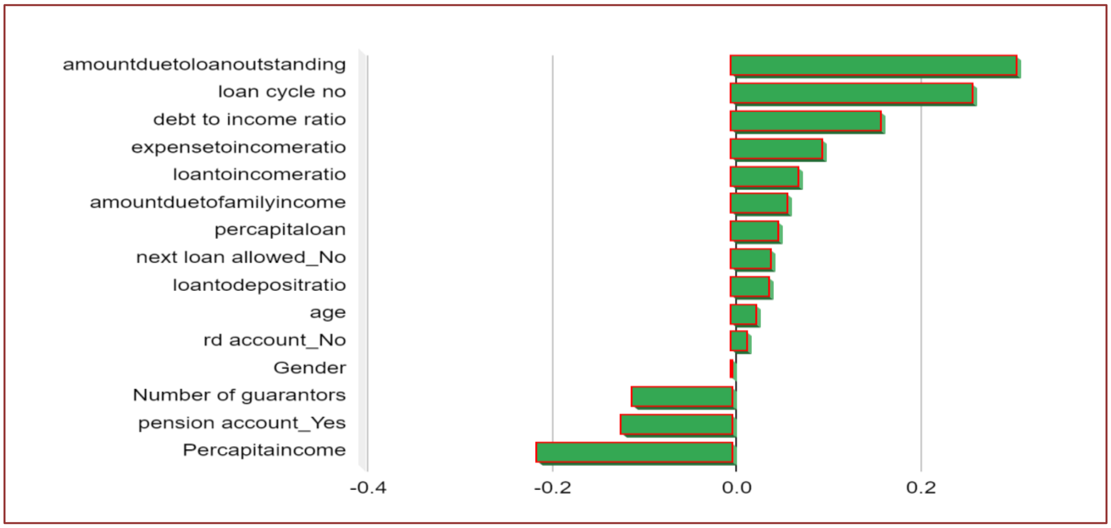

Fig. 5. Explanations / Interpretations on individual borrower dataset.

Fig. 4 illustrates the results generated by the model to provide explanations on enterprise (NBFC) dataset. The ARSLRP values for the NBFC dataset reveal key insights into the factors influencing the model's risk predictions. Notably, "Expenses" stands out as the most impactful variable with a substantial positive ARSLRP value of +0.5397. This implies that clients with higher reported family expenses are deemed riskier by the model. It suggests a correlation between increased spending and elevated risk in the context of the NBFC dataset. Similarly, "Obligation" contributes positively with an ARSLRP value of +0.3480, suggesting that clients with higher financial obligations are also considered riskier. These findings underscore the model's sensitivity to financial commitments and their association with increased risk. The positive contributions of demographic factors come into play with variables such as "Age" (+0.1320) and "Tenure" (+0.0915). The positive ARSLRP values indicate that older clients are perceived as riskier. Entrepreneurs with increased age may have higher family and social commitments as well as more expenses towards business and family. This could suggest that the model associates increased age and tenure with a higher likelihood of risk in the context of the dataset. The presence of dependents ("Dependents" with +0.0778) and certain loan-related variables, such as "Loan Amount" (+0.0521) and "Payout" (+0.0443), also contribute positively, indicating that clients with larger loan amounts, more dependents, and higher payouts are associated with increased risk according to the model. These associations in general reflect the model's perception of increased financial commitments and complexities contributing to higher default risk.

The variable "Sex" has a neutral impact with an ARSLRP value of 0.0000, suggesting that gender does not significantly contribute to the model's risk predictions. This implies that the model does not distinguish between male and female clients when assessing risk. On the negative side, variables such as "Year in Business" (-0.0258), "Year at Residency" (-0.0350), and "Income" (-0.5101) exert a negative influence on risk predictions. Longer durations in business and residency are associated with decreased risk, suggesting that recent businesses and residents are considered riskier by the model. The most impactful negative contributor, "Income," indicates that clients with higher incomes are perceived as less risky.

Fig. 5 illustrates the results generated by the model to provide explanations on individual borrower dataset. The ARSLRP values offer a comprehensive understanding of the factors influencing risk predictions in the individual borrower dataset. Starting with positive contributors, "Amount Due to Loan Outstanding" is the most influential variable with a positive ARSLRP value of +0.3076. This suggests that borrowers with higher number of dues of the loan outstanding are perceived as riskier by the model. Similarly, "Loan Cycle Number" and "Debt to Income Ratio" contribute positively, indicating that borrowers with higher loan cycles and those with elevated debt relative to income are associated with increased risk. These findings emphasize the model's sensitivity to the financial positions and credit history of the borrowers.

Additionally, various financial ratios such as "Expense to Income Ratio," "Loan to Income Ratio," and "Loan to Deposit Ratio" contribute positively, indicating that borrowers with higher expense and loan-to-deposit ratios are perceived as riskier. The model seems to prioritize a cautious approach towards borrowers with higher financial commitments and dependency on loans. The positive contribution of "Age" suggests that older borrowers are associated with increased risk, possibly indicating that the model considers factors related to the borrower's life stage in its risk assessment. The middle age borrowers may have higher family commitments towards children education, health and housing requirements which pushes them to higher level of debt.

Conversely, the neutral contribution of "Gender" suggests that gender does not significantly influence the model's risk predictions. The model does not differentiate between male and female borrowers in terms of perceived risk. Moving to negative contributors, "Number of Guarantors" negatively influences risk predictions, implying that borrowers with more guarantors are considered less risky. This suggests that having additional guarantors provides a sense of security in the model's assessment. The negative impact of "Pension Account (Yes)" as a contributor indicates that borrowers with pension

accounts are considered less risky. This aligns with the notion that individuals with stable sources of income, such as a pension, may be perceived as more reliable borrowers. However, the most impactful negative contributor is "Per Capita Income" with a negative ARSLRP value of -0.2108. This implies that borrowers with increasing per capita income are seen as less risky by the model. It suggests that higher individual income levels play a significant role in mitigating perceived risk of defaults.

ARSLRP values in individual borrower dataset reveal that the model relies on a combination of financial ratios, historical borrowing patterns, and demographic factors to assess default risk. Positive contributors highlight the risk associated with higher outstanding amounts, specific financial ratios, and certain borrower characteristics. Negative contributors point to factors such as having more guarantors, possessing a pension account, and higher per capita income as indicators of lower perceived risk. These insights provide valuable guidance for refining risk assessment strategies and making informed decisions tailored to the nuances of individual borrower datasets.

The ARSLRP -based explanations can shed light on the model's decision-making process and highlight the features that are most influential in determining credit risk. Our findings indicate that ARSLRP provides meaningful and interpretable explanations for credit risk predictions. By propagating relevance through each layer of the model, we identified the features that contribute the most to the final prediction. This feature importance helps users comprehend the risk factors considered by the model, leading to enhanced transparency and trust in the credit risk assessment process. Moreover, ARSLRP enables us to analyze how the model handles both positive and negative instances. We observed that high-risk customers received higher relevance on features associated with past credit history, debt-to-income ratio, and payment delinquencies. On the other hand, low-risk customers obtained higher relevance on features like steady income, low credit utilization, and a history of timely payments. These findings align with domain knowledge and provide valuable insights for risk managers in understanding the decision-making process of the model.

Furthermore, the ARSLRP -based explanations revealed cases where the model's predictions deviated from conventional wisdom. In such instances, stakeholders can closely investigate the underlying factors and potentially identify areas for model improvement or data validation. For instance, if the model assigns high relevance to a seemingly irrelevant feature, such as a customer's occupation, it may raise concerns about data quality or the model's sensitivity to certain attributes. One of the strengths of ARSLRP is its ability to handle complex models, including deep learning architectures. Traditional linear models or decision trees often lack the capacity to capture intricate patterns in credit risk prediction, whereas deep learning models like CNNs and LSTMs can capture nonlinear relationships in the data. ARSLRP can handle such complex architectures, providing detailed explanations for individual predictions and overall model behavior. In conclusion, ARSLRP -based explanations offer a valuable tool for interpreting credit risk prediction models. The insights provided by ARSLRP facilitate understanding model predictions, identifying influential features, and assessing the model's performance.

V. Conclusion

Credit risk prediction is a vital aspect of the financial industry, where accurate assessments of borrowers' creditworthiness are crucial for making responsible lending decisions. This research explored the integration of explainable AI (XAI) techniques and ensemble methods to address the dual objectives of predictive accuracy and model interpretability in credit risk prediction. Specifically, the proposed approach leverages multistage ensemble techniques with a 1D CNN architecture to achieve both high performance and transparent decision-making. Our proposed approach aims to enhance credit risk prediction by integrating multistage ensemble techniques with a 1D CNN architecture. The model operates through multiple stages, providing interpretable explanations for its decisions, while maintaining high predictive performance. By offering transparency into the decision-making process, our proposed approach empowers financial institutions to understand and validate the model's risk assessments, ensuring fair lending practices and regulatory compliance. In conclusion, the proposed approach presents a novel contribution to the field of credit risk prediction. By combining the advantages of multistage ensemble techniques and XAI, our proposed model offers a balance between predictive accuracy and model interpretability, making it a valuable tool for credit risk assessment in the financial industry. Transferability of the trained model across two credit risk domains or financial institutions is investigated, assessing the model's generalizability and ability to provide meaningful explanations in diverse settings. As a future enhancement extend the model to handle time-series or sequential data that often appear in credit risk scenarios. Incorporating temporal dependencies and sequential patterns could enhance the model's predictive performance and provide more meaningful explanations.

***Abstract*—The development of a software project is frequently influenced by various risk factors that can lead to project failure. Predicting potential software project failures early can aid organizations in making decisions regarding possible solutions and improvements. This paper proposes a software project failure prediction model based on a weighted ensemble learning approach. The proposed model aims to determine the failure probability as well as the expected project outcome (Success/Failure). Various ensemble approaches, such as simple majority voting, can be employed in predicting software project failure. However, in majority voting algorithms, all base models have the same weights, resulting in an equal effect on the final prediction result, regardless of their predictive abilities. Our proposed algorithm assigns higher weights to base models that demonstrate a greater ability to correctly predict more challenging data instances. The proposed model is developed based on a dataset gathered from real previous software project reports, comprising both successful and failed projects, to provide evidence supporting the predictive model's capabilities and to obtain high-confidence results. The performance of the developed model is comprehensively assessed through various measures, revealing its superiority in predicting software project failures compared to both simple majority voting and individual models. This research suggests that the proposed model can be integrated into the software system development process, spanning requirement analysis, planning, design, and implementation phases, to evaluate the project's status and identify potential risks.**

Keywords*—Ensemble learning; failure prediction; base models; project outcome

I. Introduction

Assessing the probable software project failure early during development process can mitigate the effect of the undesirable events that could lead to project failure [10]. The paper aims to develop new weighted ensemble predictive model which use historical failure data gathered from several past software projects to accurately predicting possible failures in future software projects. The developed model can be used early in the system software engineering process at inception and planning phase when decisions are being made to specify the projects to be embarked upon in the project portfolio. Furthermore, this model can be used during any phase of software development process to avoid project failure and improve reliability.

Ensemble learning is selected because it has been observed that this method achieves better results in terms of diversity and accuracy [1]. Using ensemble methods improve prediction results by combining abilities of different single predictors into one prediction model [7]. As these single predictors differ in the approach used, parameters, and dealing with training data, combining prediction abilities of these predictors enable the ensemble algorithms to capture different characteristics of the training data and produce more reliable and accurate prediction [7].

Ensemble learning is a machine learning technique where multiple base models are combined to produce one optimal model ([3]; [4]). The ensemble model constructs a set of base models on training data and then combines them or selects the best one to use [11]. The objective of this technique is to improve the model predictive accuracy over traditional single component models [18]. In many cases, the ensemble predictors show higher performance than other individual prediction models [1], [7]. According to [7], there are three reasons why this technique can improve the prediction accuracy:

1) The single component models learn from training data to perform prediction of the new examples. However, it can be hard to perform accurate prediction when the amount of training data is small. This problem can be solved by constructing a set of base models (combined to one ensemble model) and find the optimal prediction result.

2) Several prediction techniques use local search approaches such as gradient decent to find the optimal class. Even if the available training data is enough, these searches can stick to a local optimum. Since finding the global optimum can be computationally expensive, ensemble classifiers perform multiple local searches started at different data points to find the optimal class.

3) In such situations, it can be hard to find the optimal solution in the search space of the single classifiers. A combination of multiple classifiers could approximate the optimal solutions than the separated single classifiers. An example of a two-class classification problem is shown in Fig.1. In this example, none of the three classifiers A, B, and C can separate the two classes (+ and −) perfectly. The ensemble classifier as illustrated by a bold line in Fig. 1, that

*Corresponding Author.

combines the three single classifiers is capable of classifying the two classes accurately.

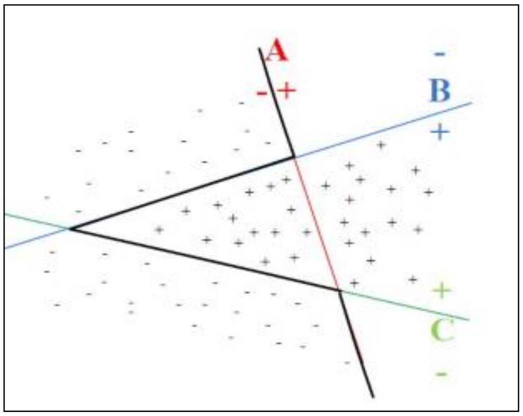

Fig. 1. Example of the three classifiers.

Although these reasons show that the ensemble classifiers could perform better than single classifiers, ensemble learning needs enough diversity to obtain accurate results [13]. This means that the classifiers should produce different errors in order to be able to learn from each other. When the classifiers make nearly the same errors, they will behave like a single classifier.

In this paper, a new weighted ensemble prediction model is proposed to predict the software project failure. This model combines ensemble-learning prediction with the predictor selection approach. The proposed algorithm incorporates six base models, namely, neural networks (NNs), logistic regression (LR), support vector machine (SVM), naïve Bayes (NB), adaptive neurofuzzy inference system (ANFIS), and decision trees (DT). These methods are selected because they show adequate prediction performance according to the study conducted by Ibraigheeth and Eid [9]. We suggest that the different prediction abilities of these six methods enable the proposed algorithm to capture different characteristics of the training data and produce more reliable and accurate prediction.

The proposed algorithm assigns a unique “ranking number” to each base model according to its ability to predict the most difficult-to-predict data. A higher performance model on the difficult-to-predict data will be assigned higher ranking numbers. A normalize weighted vector is constructed based on these ranking numbers, and the final probability of failure result is obtained based on the weight assigned for each base model.

In the proposed method, when the base models are constructed, a unique “ranking number” is assigned to each one according to its performance result over the data subset with lower average performance result, which was the most difficult subset to predict. The algorithm constructs a performance vector for each base model over all data subsets. In addition, the approach constructs a vector that represents the average performance results over each data subset for all base models. Furthermore, a ranking vector for base models is constructed as well as a normalized weight vector, which represents the weights of the base models.

II. RELATED WORKS

Over the past years, many ensemble approaches have been proposed. According to [5], ensemble methods can be categorized into two types: homogeneous and heterogeneous ensembles. In the homogeneous ensemble, the same learning algorithm using different training subsets trains a set of individual models. The final decision is taken by combining the outputs of these models. Examples of such ensemble methods in the literature include bagging [15], AdaBoost [37], and Random Forest [16]. In the heterogeneous ensemble, different learning algorithms using the same training set generate different models. The heterogeneous ensemble learning emphasizes more on meta-data combination techniques ([17]; [26-30]) to achieve a higher performance than an individual model. Wang and Zhong [33] applied the information granularity approach to develop an ensemble system combining multiple classifiers. First, the weighted distances between granularity prototypes and the base classifiers outputs are observed. Then, the shortest distance prototype is selected to predict the class label. Wu [35] proposed a new weighted ensemble method that considers the performance information for the base models in previous literature to obtain their optimal weights. Blaser and Fryzlewicz [22] developed a new ensemble system that generates the base models after generating matrices to rotate the features space. Moreover, different learning methods were applied for many ensemble systems, such as supervised learning [39], incremental learning ([2], [14], [36]) and multilabel classifiers ([12], [21]). Several researches focused on enhancing the performance of the existing ensemble approaches. Several methods were applied for this purpose, e.g., clustering approach [24], dynamic classifiers selection [23], and hybrid methods used in a random subspace to assign weights for the base classifiers [40]. Hybrid ensemble, which combines sample and feature space-based learning was proposed in [38]. Several techniques have been proposed to enhance AdaBoost performance, for example, by applying linear programming to maximize the margin between different classes and training instances [20].

Even though there are many researches concentrate on addressing software project failures [8], [31], [32], [41], most of these researches don’t perform project failure prediction. Ewusi-Mensah [8] was aimed to identify the impact of different failure factors on the SDLC stages. The empirically based study defines the reasons behind these factors and how they can prevented. Takagi et al. [31] performed a questionnaire based approach in order to determine core risk factors. A logistic regression model is used to characterize the confused projects, and to predict if the software project is risky or not risky. However, the developed model does not predict failures. Verner et al. [32] investigated number of failed projects to determine the factors behind project failing. This research aimed only to identify failure factors, and it did not predict the project failures. Rayes et al. [25] also propose an effective project resources allocation to maximize the probability of the project success. The authors suggest a strategy for effective resources allocation to get high success rate with minimum cost. The developed model was to identify and control the risks that affect the project success. However, the failure prediction is not observed also in this research.

Wang et al. [34] developed a predictive model based on Bayesian Network in order to predict the software projects outcome through prediction and controlling the variance in estimated project schedule. This research aimed to maximize the opportunity to complete the project on time through project re-planning, resource re-allocation, and schedule variance factors identification. Therefore, no software failure prediction is performed in this research. Lehtinen et al. [19] performed analysis in corporation with four software organizations to recognize the reasons behind failures and the relations among them. Their research developed diagrams that describe causal relationships among failure causes, and they recommended performing specific analysis for each cause, and managing these causes outside the development area to prevent the software project failure. However, a limitation of this research is the limited number of failure analyzed cases.

Most of previously developed methods were applied on certain case studies. Consequently, those methods might not be applicable for other software projects. Furthermore, many of these methods were implemented to assess the failure through specific phase of software development process. In this context, one of main contributions of our research is developing a new prediction model that can be applied on any software project during any phase of software development process.

III. Methodology

In the initial phase of this study, careful consideration is given to the selection of model inputs, also known as predictors, and the acquisition of a suitable dataset. This process involves identifying key factors that may influence the outcome of software projects, such as project size, complexity, development methodologies, and team composition. Subsequently, the dataset is divided into two distinct sets: the training set and the testing set. The training data serves as the foundation for model development, where algorithms are trained and fine-tuned to learn patterns and relationships within the data. Meanwhile, the testing data is reserved for evaluating the performance of the trained models, providing an independent measure of their predictive accuracy and generalization capabilities. Upon successful development and validation, the deployed model becomes a valuable asset in the software project development lifecycle. By leveraging historical project data and learned patterns, the model can effectively forecast the future outcomes of ongoing or upcoming projects. This predictive capability empowers project stakeholders with valuable insights, enabling informed decision-making and proactive risk management throughout the software development process.

For building the model, the list of failure factors identified by Ibraigheeth and Fadzli [10] is selected to be the model input. This list of identified factors is presented in Table I. The dataset constructed in their research is also selected to fit and verify the developed models. This dataset was gathered from 236 (n = 236) failed and successful software projects and used in our research to fit and verify the developed models.

TABLE I. List of Failure Factors

ID	Failure Factor
X1	Unrealistic project objectives
X2	Team technical problems
X3	Lack of users involvement
X4	Requirements instability
X5	Problematic technology
X6	Problems in project management
X1	Unrealistic project objectives

Table II presents the sample of collected data, which identifies the six failure factors results in 10 software projects. This table illustrates the actual projects outcome (0: Success and 1: Failed).

TABLE II. Data Sample of Actual Outcome for 10 Software Projects

Project ID	Failure factors						Actual outcome
	X1	X2	X3	X4	X5	X6

IV. Developing the Model

In this section, the ensemble-weighted algorithm, which combines six base prediction models, is developed.

The algorithm begins with randomly splitting the training dataset into n subsets, and then each base model is trained over all subsets. The average prediction performance for all base models over each subset is measured. Then, we identify the subset on which the base models achieved the worst average performance. The lowest performance rate indicates that this subset was the most difficult to predict. A unique “ranking number” is assigned to each base model according to its performance result over this subset.

The approach constructs four types of vectors:

1) A performance vector for each base model over all data subsets,

2) A vector represents the average performance results over each data subset for all base models,

3) A ranking vector represents the ranks of base models, and

4) A normalized weight vector represents the base models weights.

The proposed algorithm is described as follows:

a) Select the optimal predictor subset.

b) Randomly split the training dataset into n subsets.

c) Fit base models using all training data subsets.

d) Set the vector for each base model that represents the average performance for this model over each data subset. For i = 1 to k, calculate Pi,

$$\mathrm{P_i} = \frac{\mathbf{AC_i+F_i+K_i+AUC_i}}{\mathbf{4}} \quad (1)$$

where, AC is the accuracy, F is the F-measure, k is the kappa coefficient, and AUC is the area under the receiver operating characteristic curve.

e) A vector that represents the average of performance results (of all base models) is set over each data subset.

$$\mathrm{AvP_j} = \frac{\sum_{i=1}^{n} \mathrm{P_j}}{\mathrm{n}} \quad (2)$$

where, $\mathrm{AvP_j}$ is the average performance value for all base models over subset j. The subset with lowest AvP is the most difficult subset to predict.

f) A ranking vector that represents the ranks of base models according to their performance over the most difficult-to-predict data subset is set. Each base model gets a ranking number from 1 to k (k is the number of base models). The higher performance model (over the most difficult data subset) gets a higher ranking number.

g) Set a vector that represents the base model weights.

The weight of model m can be estimated by:

$$w_m = \frac{R_m P_m}{\sum_{i=1}^{k} R_i P_i} \quad (3)$$

where, k is the number of base models, and R is the base model rank (from 1 to k) over the most difficult dataset.

In the proposed algorithm, the weight assigned to each base model mm is determined by Eq. (3). This equation calculates the weight wmwm based on the rank and performance of the model mm relative to other base models in the ensemble. Here's a detailed explanation:

i) Base Model Rank R_m: The rank of a base model mm represents its performance relative to other models in the ensemble on the most challenging dataset instances. Models that exhibit better predictive capabilities or accuracy are assigned lower ranks, indicating higher effectiveness in handling difficult data instances.

ii) Base Model Performance P_m: The performance of each base model *m* is measured by its predictive ability or accuracy. Higher performance models, which accurately predict the outcomes of software project instances, are assigned higher values for P_m.

iii) Normalization Factor $\sum_{i=1}^{k} R_i P_i$: This term represents the sum of the ranks multiplied by the corresponding performance measures for all base models in the ensemble. It acts as a normalization factor to ensure that the weights w_m sum up to 1, thereby maintaining the integrity of the weighted ensemble.

h) The final predicted value Pr (probability of failure) is obtained according to each base model weight:

$$\mathrm{Pr} = \sum_{i=1}^{k} w_i D_i, \quad (4)$$

where, Di is the predicted value of base model i.

Eq. (4) calculates the final predicted value of the probability of failure (Pr) based on the weighted contributions of each base model in the ensemble. Here's a detailed explanation:

i) Base model weight w_i: Each base model ii in the ensemble is assigned a weight wiwi determined by its effectiveness in predicting software project failures. The weight reflects the relative importance or influence of the corresponding model in the ensemble. Models with higher weights contribute more significantly to the final prediction.

ii) Predicted value D_i: D_i represents the predicted value of failure probability by the base model ii. Each base model generates its own prediction based on its internal algorithms and training data. These predicted values represent the likelihood of failure for individual software project instances.

iii) Weighted summation: The final predicted value of failure probability (Pr) is obtained by summing the weighted contributions of all base models in the ensemble. Each predicted value D_i is multiplied by its corresponding weight wiwi, and these weighted values are summed up for all k base models in the ensemble.

By aggregating the predictions from multiple base models according to their respective weights, Eq. (4) produces a composite prediction of failure probability that leverages the strengths of individual models while mitigating the impact of potential weaknesses. This weighted ensemble approach enhances the overall accuracy and reliability of the prediction, providing a more robust assessment of the likelihood of failure for software project instances.

To illustrate the algorithm, a simple example of ensemble with three base models and three data subsets is considered. We define P = (P1| P2 |P3) and let P1 = (0.77, 0.66, 0.84), P2 = (0.78, 0.90, 0.81) and P3 = (0.97, 0.60, 0.78), where Pi represents the performance vector of base model i over the three data subset. We obtain AvP = (0.84, 0.72, 0.81), which indicates the average performance of the three base models over the three data subset. According to AvP values, the second data subset was the most difficult subset to predict as it gets the lowest average performance score (0.72). Therefore, we rank the base models according to their performance results over the most difficult subset to predict. The second base model will get the higher rank number = 3 as it achieved a higher performance (0.90) result over the most difficult subset. The rank number = 2 is given to first base model, and rank number = 1 is given to the third base model. The normalized weight vector W=(0.286,0.584,0.13) is obtained by:

$$W = \left(\frac{\mathbf{0.66 \times 2}}{(\mathbf{0.66 * 2})+(\mathbf{0.90 \times 3})+(\mathbf{0.60 \times 1})}, \frac{\mathbf{0.90 \times 3}}{(\mathbf{0.66 \times 2})+(\mathbf{0.90 \times 3})+(\mathbf{0.60 \times 1})}, \frac{\mathbf{0.60 \times 1}}{(\mathbf{0.66 * 2})+(\mathbf{0.90 \times 3})+(\mathbf{0.60 \times 1})}\right)$$

$$W = (0.286, 0.584, 0.13)$$

The highest weight is given for the second base model as it obtained a higher rank according to its performance in predicting the most difficult data subset to predict.

Finally, the prediction value for each data instant is obtained based on the above base model weights. Suppose that the three base models generate probabilities of failure: 0.66, 0.35, and 0.74; therefore, the final failure probability Pr generated by the model based on the estimated weight is 0.49.

$$Pr=(0.286 \times 0.66)+(0.584 \times 0.35)+(0.13 \times 0.74)= 0.49$$

The failure probability result is used to classify the expected project outcome (failed/success). The default probability value 0.5 is selected to be the classification threshold, with failure expected for any result higher than 0.5. Future research can be conducted to determine the optimal threshold for determining project failure.

V. Experimental Results

For comparison purpose, in addition to building the proposed model, the experiments included running the model using four methods. Initially, the model is implemented using three of the existing individual prediction techniques: LR, SVM, and ANFIS. These methods were chosen because they showed a high efficiency in failure prediction compared with other methods in a study conducted by Ibraigheeth and Eid [6]. These three models were combined to create a simple majority voting model. To run the simple majority voting model, the training dataset is used to build the three base models (LR, SVM, and ANFIS), and then the final prediction decision for any test instance is generated by majority voting. The new weighted ensemble model is implemented and tested in terms of its ability to predict software project failures. The experiments included calculating eight performance measures: sensitivity or recall, specificity, precision, negative predictive value, accuracy, F-measure, kappa coefficient, and AUC value.

Several statistical tests were applied on the proposed model to evaluate its performance. Confusion matrix that includes information about actual and predicted model outputs is shown in Fig. 2. For the project failure prediction problem, the confusion matrix is used to evaluate the model performance. The column of the confusion matrix represents the actual result (class), while the row represents the predicted result. TP (True Positive) and TN (True Negative) denote how many instances are classified correctly, while FP (False Positive) and FN (False Negative) denote how many instants are classified incorrectly.

		Predicted output	
		+	−
Actual Output	+	T P = 12	F N = 1
	−	F P = 1	T N = 10

Fig. 2. Confusion matrix.

TABLE III. Performance Measures

Measure	Value
Sensitivity (Recall)	0.923
Specificity	0.909
Precision	0.923
Negative predictive value	0.909
Accuracy	0.916
F-measure	0.923
Kappa	0.914
AUC	0.96
Average	0.92

Several performance evaluation metrics can be generated from the confusion matrix. Table III shows performance measures of the proposed model over testing dataset.

A comparative evaluation for the proposed weighted ensemble prediction model is performed. In this paper, the ensemble model was run to predict the software project failure. Table IV shows a summary of the performance measure for the proposed ensemble model versus the simple majority voting model as well as the other three individual models: LR, SVM, and ANFIS.

Table IV shows that the proposed weighted ensemble model has the highest values for most of performance measures; it has an average performance of 92% compared with 89% for the proposed majority voting model, 81% for LR model, 82% for SVM model, and 83% for ANFIS. Experiments also prove that the simple majority-voting model performs better than individual models.

TABLE IV. Proposed Weighted Ensemble Predictive Model Performance Measures

Measure	Proposed weighted ensemble model	Simple majority voting model	LR	SVM	ANFIS
Sensitivity (Recall)	0.92	0.92	0.85	0.77	0.81
Specificity	0.90	0.84	0.77	0.91	0.96
Negative predictive value	0.92	0.87	0.89	0.90	0.96
Accuracy	0.90	0.90	0.71	0.83	0.82
Precision	0.91	0.89	0.83	0.84	0.88
F-measure	0.92	0.90	0.87	0.83	0.88
Kappa	0.91	0.86	0.79	0.69	0.77
AUC	0.96	0.94	0.94	0.84	0.62
Average	0.92	0.89	0.81	0.82	0.83

Table V illustrates a sample of the data of 10 software projects and their corresponding actual outcome, the proposed weighted ensemble model predicted outcome. The table illustrates that all projects except P16 were labeled correctly. Projects P11, P13, P17, P19, and P20 were correctly labeled as failed projects with actual outcome = 1, and Projects P12, P14, P15, and P18 were correctly labeled as success projects with actual outcome =0. Project P16 was inaccurately labeled as success (Predicted outcome = 0) when the projects were failed (Actual outcome = 1).

In the comparative evaluation of the proposed weighted ensemble prediction model, the analysis delves into its performance in relation to alternative methodologies. By subjecting the ensemble model to prediction tasks for software project failure, a comprehensive understanding of its efficacy is garnered. Table IV elucidates the performance metrics, showcasing the superiority of the proposed weighted ensemble model over the simple majority voting model and individual models such as LR, SVM, and ANFIS. Notably, the ensemble model consistently achieves higher performance across various metrics, with an average accuracy of 92%, outperforming its counterparts. Moreover, insights gleaned from experimentation highlight the advantageous nature of employing a simple majority-voting model over relying solely on individual models. As the software industry navigates complex project landscapes, such evaluations play a pivotal role in informing decision-making processes and shaping future research directions

TABLE V. SAMPLE OF ACTUAL AND PREDICTED OUTCOMES

Project ID	Actual outcome	Predicted outcome
P 1 1	1	1
P 1 2	0	0
P 1 3	1	1
P 1 4	0	0
P 1 5	0	0
P 1 6	0	1
P 1 7	1	1
P 1 8	0	0
P 1 9	1	1
P 20	1	1

VI. CONCLUSION

In this paper, a new ensemble weighted model is proposed for predicting software project failures. The proposed algorithm incorporates six base models to provide the final decision of the software project outcome. These models are: NNs, LR, SVM, NB, ANFIS, and DT. We suggest that the different prediction abilities of these six methods enable the proposed algorithm to capture different characteristics of the training data and produce more reliable and accurate prediction. The proposed algorithm assigns a unique “ranking number” to each base model according to its ability to predict the most difficult data. Higher performance base models over the most difficult-to-predict data will be assigned higher ranking numbers. A normalized weighted vector is constructed based on these ranking numbers, and the final predicted value is obtained based on the weight assigned for each base model.

In the empirical analysis, eight performance measures are used to evaluate the proposed model performance. The research proves that the weighted ensemble model outperforms the simple majority voting and the individual prediction models. The experiments have also shown that the simple majority-voting model outperforms the other three individual models.

As this paper introduces a novel ensemble weighted model for predicting software project failures, future work could explore several avenues to enhance and extend the proposed approach. Firstly, further investigation could be conducted into the selection and incorporation of additional base models beyond the six currently utilized (NNs, LR, SVM, NB, ANFIS, and DT). This exploration may involve considering emerging machine learning techniques or domain-specific models tailored to software project prediction tasks. Additionally, research efforts could focus on refining the methodology for assigning ranking numbers to base models based on their predictive capabilities across different data instances. Fine-tuning this ranking system could potentially lead to more accurate and nuanced weighting of base models, thereby improving the overall performance of the ensemble model. Furthermore, the evaluation framework utilized in this study could be expanded to include additional performance metrics or consider alternative evaluation methodologies to provide a more comprehensive assessment of the proposed model's efficacy. Lastly, real-world deployment and validation of the model within software development environments could offer valuable insights into its practical utility and effectiveness in mitigating project failure risks. By addressing these future research directions, advancements can be made towards developing more robust and reliable predictive models for software project management.

Detection of Personal Protective Equipment (PPE) using an Anchor Free-Convolutional Neural Network

Honggang WANG[1]
School of Electronic Information Engineering, Xi'an Siyuan University, Xi'an 710038, Shaanxi, China

***Abstract*—In industrial environments, the utilization of Personal Protective Equipment (PPE) is paramount for safeguarding workers from potential hazards. While various PPE detection methods have been explored in the literature, deep learning approaches have consistently demonstrated superior accuracy in comparison to other methodologies. However, addressing the pressing research challenge in deep learning-based PPE detection, which pertains to achieving high accuracy rates, non-destructive monitoring, and real-time capabilities, remains a critical need. To address this challenge, this study proposes a deep learning model based on the Yolov8 architecture. This model is specifically designed to meet the rigorous demands of PPE detection, ensuring accurate results. The methodology involves the creation of a custom dataset and encompasses rigorous training, validation, and testing processes. Experimental results and performance evaluations validate the proposed method, illustrating its ability to achieve highly accurate results consistently. This research contributes to the field by offering an effective and robust solution for PPE detection in industrial environments, emphasizing the paramount importance of accuracy, non-destructiveness, and real-time capabilities in ensuring workplace safety.**

Keywords—PPE detection; deep learning; YOLOv8; industrial environments; real-time detection

I. INTRODUCTION

Personal Protective Equipment (PPE) plays a pivotal role in ensuring the safety of workers in industrial environments [1], [2]. The first line of defense against potential hazards, PPE includes various gear such as aprons, gloves, helmets, masks, and shoes designed to protect workers from physical, chemical, and biological risks [3]. Proper detection and monitoring of PPE utilization in industrial settings are of paramount importance to guarantee workplace safety [4]. This paper delves into the realm of PPE detection, highlighting its significance and examining the latest advancements in technology for this purpose [5].

The accurate detection of PPE, including aprons, gloves, helmets, masks, and shoes, in industrial environments is crucial for safeguarding workers from potential hazards. PPE detection ensures that employees are equipped with the necessary gear, minimizing the risk of injuries and health issues. The ability to monitor PPE utilization is instrumental in maintaining a safe work environment, not only for individuals but also for the overall efficiency of industrial operations [6]. To address the need for effective PPE detection, a range of technologies has been developed over the years. In this paper, we review existing methods and explore the latest advances in PPE detection techniques. These advancements in technology are essential for real-time monitoring of PPE usage and ensuring the utmost safety in industrial workplaces [8].

Deep learning-based approaches have gained significant attention in recent years for PPE detection [7]. These methods have become a focal point of research due to their exceptional ability to handle complex visual data and patterns. In comparison to traditional methods, deep learning offers superior accuracy and robustness in detecting PPE items. This paper provides insights into why deep learning-based approaches have garnered immense interest among researchers and have become a promising avenue for addressing PPE detection challenges [9].

Despite the potential of deep learning-based approaches, there exist certain limitations and research challenges. These include the demand for high accuracy and real-time requirements. In this paper, we emphasize the need for further exploration and research to overcome these challenges, underscoring the importance of striving for methods that can fulfill the rigorous demands of PPE detection in industrial settings.

In response to these challenges, this study proposes a deep learning method based on Convolutional Neural Networks (CNN) to address the complexities of PPE detection [10]–[12]. We provide a justification for adopting this deep learning approach and demonstrate how it can effectively resolve the research challenges and provide high-accuracy real-time PPE detection. The study involves the creation of a custom dataset and encompasses training, validation, and testing processes to ensure the robustness of the proposed method.

This research contributes to the field of PPE detection in several ways. First, it generates a custom dataset specifically designed for PPE detection challenges, enriching the available resources for future research in this domain. Second, it introduces an efficient deep-learning method tailored to the unique requirements of PPE detection. Lastly, extensive experiments and performance evaluations are conducted to validate the effectiveness of the proposed method, offering a comprehensive assessment of its capabilities and practical applications.

II. PREVIOUS STUDY

The realm of agriculture has seen remarkable progress, primarily propelled by the substantial contributions of machine learning and deep learning techniques. These state-of-the-art technologies have been instrumental in reshaping the prediction, classification, and identification of Personal Protective Equipment (PPE). Their integration offers a multitude of benefits, including non-invasiveness, cost-effectiveness, speed, and reliable PPE detection. This transformative potential has sparked numerous research endeavors dedicated to enhancing PPE diagnosis and detection.

This paper in [13] presented a Convolutional Neural Network (CNN) method for identifying Personal Protective Equipment (PPE) usage compliance in manufacturing laboratory settings. The CNN model is trained on a custom dataset and demonstrates remarkable accuracy in recognizing various PPE items, including aprons, gloves, helmets, masks, and shoes. However, a limitation of the approach is its sensitivity to variations in lighting conditions, which can affect detection accuracy. Future work could involve the integration of advanced lighting normalization techniques to address this limitation and further enhance the model's robustness for real-time PPE compliance monitoring in dynamic industrial environments.

The authors in study [1] introduced a deep learning-based framework for monitoring the wearing of Personal Protective Equipment (PPE) on construction sites. The method employs convolutional neural networks (CNNs) to detect and identify PPE items, ensuring compliance. However, a limitation is the challenge of real-time monitoring due to computational demands, which may impact its practical applicability. Future research could focus on optimizing the model for real-time performance to enhance its effectiveness in the dynamic and time-sensitive construction site environment.

This paper in [2] presented a Substation Safety Awareness intelligence model employing a Graph Neural Network (GNN) approach for rapid detection of Personal Protective Equipment (PPE). The GNN model effectively identifies PPE items, ensuring safety in substation environments. However, one limitation is the need for high-quality data, which may not always be readily available for model training, potentially limiting its practical implementation. Future research should explore techniques for mitigating data scarcity and enhancing model generalization to diverse substation settings.

The authors in [14] introduced a video-based smart safety monitoring system to prevent industrial work accidents. The method utilizes computer vision and machine learning algorithms to analyze video footage, detecting potential safety hazards. A limitation is that it may require substantial computational resources for real-time monitoring across extensive industrial settings. Future work should focus on optimizing computational efficiency to enhance its practicality and scalability.

This paper in [15] presented an enhanced detection network model based on YOLOv5 for safety warnings in construction sites. The method employs YOLOv5, a state-of-the-art object detection architecture, to identify potential safety hazards. However, a limitation lies in the sensitivity of the model to variations in lighting and environmental conditions, which can affect detection accuracy. Future research could focus on refining the model's robustness to lighting and environmental changes, improving its performance as a safety warning tool in dynamic construction site environments.

The five papers discussed focus on improving safety by monitoring the compliance of the PPE in various industrial contexts. They primarily employ deep learning and computer vision technologies for this purpose. While they all share the goal of enhancing workplace safety, each paper addresses a different industrial setting and applies distinct methodologies. The [13] emphasizes PPE compliance in manufacturing labs, using CNNs for detection. Its limitation is sensitivity to lighting variations. The study in [1] targets construction sites but doesn't explicitly mention limitations, hinting at potential real-time computational challenges. The study in [2] uses GNNs for rapid PPE detection in substation environments, highlighting data availability as a limitation. The study in [14] focuses on video-based safety across various industrial settings, with computational resource requirements as the main limitation. The research in [15] refines a YOLOv5-based model for construction site safety, noting sensitivity to lighting and environmental conditions. In summary, these papers contribute to safety monitoring by adapting their approaches to different industrial contexts, each with its own set of challenges and limitations. Despite common concerns, such as sensitivity to lighting and real-time computational demands, each paper offers unique insights to enhance workplace safety.

III. Methodology

A. Data Collection

We constructed our dataset by gathering PPE images from both publicly available internet resources and the Roboflow platform, aiming to create a comprehensive and diverse collection of images for training and testing. The original dataset is a collection of 3897 images of workers wearing safety vests in various industrial settings [1]. The images are annotated with bounding boxes that indicate the location and category of the safety vests. The dataset is intended for training computer vision models that can detect whether workers are wearing the PPE or not. The dataset is part of the Roboflow Universe Projects, which are open-source datasets for various computer vision tasks.

B. Data Augmentation

To ensure the dataset's richness and diversity, we employed data augmentation techniques. Data augmentation is a critical step in deep learning, especially in the context of the PPE detection, as it allows us to generate a more extensive and varied set of images, enhancing the model's ability to handle real-world scenarios. To augment our PPE dataset, we utilized common techniques such as rotation, translation, and scaling. These techniques simulate variations in object positions and orientations, which are essential for addressing real-world challenges like workers wearing PPE at different angles or in varying positions. We also applied techniques like horizontal and vertical flipping, which helps the model generalize better to PPE instances appearing both on the left and right sides of the frame.

Additionally, we used color adjustments, including brightness and contrast modifications, to account for varying

[1] https://universe.roboflow.com/roboflow-universe-projects/safety-vests

lighting conditions in industrial settings. Finally, noise injection and blurring were employed to replicate scenarios where the PPE items might be partially obscured or subject to environmental interference. These data augmentation techniques collectively enhance the dataset's diversity, making it more robust and suitable for training models capable of handling a wide range of real-world PPE detection scenarios. After the data augmentation process the size of dataset is tripled and the new size of the dataset in this study is 11691.

C. PPE Model Object Detection

There are several compelling reasons to consider utilizing YOLOv8 in our computer vision project:

1) Enhanced accuracy: YOLOv8 boasts improved accuracy compared to its predecessors, making it an attractive choice for various computer vision tasks.

2) Feature-rich implementation: The latest YOLOv8 implementation introduces a wealth of new features, with a particularly user-friendly Command Line Interface (CLI) and a dedicated GitHub repository. These additions streamline development and project management.

3) Versatility: YOLOv8 supports multiple computer vision tasks, including object detection, instance segmentation, and image classification, providing a comprehensive solution for various applications.

4) Efficient training: YOLOv8 offers faster training times in comparison to some other two-stage object detection models, making it a more time-efficient option for our computer vision projects.

The layout created by [16] offers an excellent visualization of the architecture, providing a clear and structured representation of the system. This visual aid can significantly enhance understanding and communication of complex concepts or technical architectures within the context of software development or any other field. In this study, a Yolov8 based method is proposed for PPE object detection. Fig. 1 shows the proposed system architecture.

Anchor-free detection refers to a method where an object detection model directly predicts the center of an object, eliminating the need to calculate the offset from a predefined anchor box.

In contrast, anchor boxes are predetermined bounding boxes with specific height and width characteristics. These boxes are strategically chosen based on the size and aspect ratio of objects present in the training dataset. During the detection process, these anchor boxes are systematically arranged and tiled across the image.

The network's output includes probabilities and attributes for each of these tiled boxes, encompassing information like background, Intersection over Union (IoU), and offset values. These attributes are instrumental in adjusting the anchor boxes. Multiple anchor boxes can be created to accommodate objects of various sizes, functioning as fixed reference points for predicting bounding boxes. An illustration depicting bounding box predictions based on anchor boxes is depicted in Fig. 2.

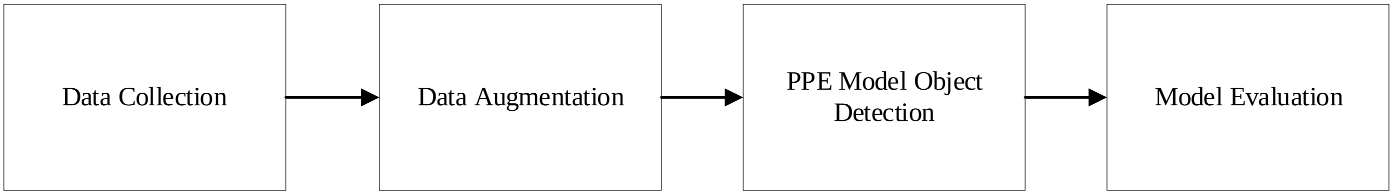

Fig. 1. The proposed system architecture.

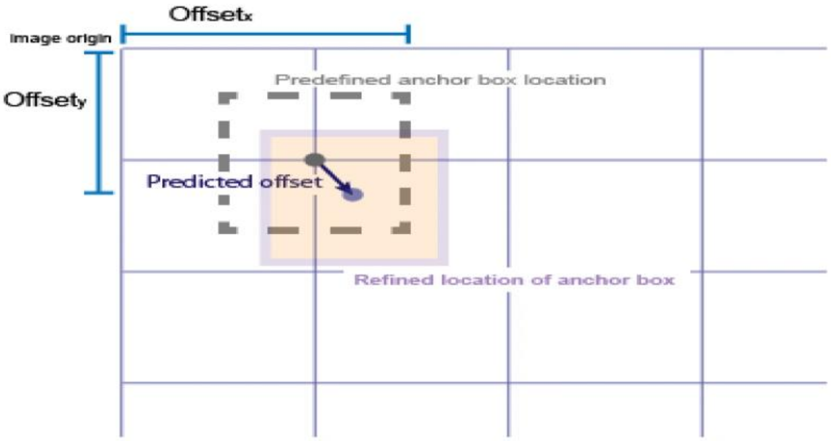

Offsetx
Image origin
Offsety
Predefined anchor box location
Predicted offset
Refined location of anchor box

Fig. 2. An illustration depicting bounding box predictions based on anchor boxes.

Anchor-free detection offers notable advantages due to its flexibility and efficiency. Unlike methods that rely on predefined anchor boxes, anchor-free detection eliminates the need for manually specifying these anchors. In previous YOLO models like v1 and v2, selecting anchor boxes was a challenge and could result in suboptimal outcomes. Anchor-free detection simplifies this aspect, allowing for more adaptability in object detection tasks.

D. Model Evaluation

To evaluate the performance of a YOLOv8 model for PPE detection using precision, recall, and mean Average Precision (mAP) metrics, we'll assess the model's ability to detect and localize PPE items in images correctly. Here's how we calculate these metrics and their formulas:

Precision measures the accuracy of positive predictions made by the model.

Precision = True Positives (TP) / (True Positives + False Positives)

True Positives (TP) are the number of correct PPE detections.

False Positives (FP) are the number of instances where the model incorrectly predicts PPE when there is none.

Recall, also known as sensitivity or true positive rate, measures the model's ability to identify all relevant PPE instances.

Recall = True Positives (TP) / (True Positives + False Negatives)

True Negatives (TN) are the number of instances where the model correctly predicts the absence of PPE.

False Negatives (FN) are the number of actual PPE instances that the model misses.

(mAP) is a comprehensive metric used in object detection tasks to assess the model's performance. It calculates the average precision at various confidence thresholds and is often visualized as a precision-recall curve. The mAP formula involves the following steps:

- Calculate precision and recall for different confidence thresholds.
- Calculate the area under the precision-recall curve.
- Average the areas under the curve for different classes, resulting in the mAP.

mAP provides a holistic view of the model's performance across various levels of confidence in detecting PPE items. A higher mAP indicates a more reliable and accurate model.

These metrics collectively provides a quantitative assessment of the YOLOv8 model's ability to detect PPE items in terms of accuracy, completeness, and overall performance. Evaluating precision, recall, and mAP helps we understand the model's strengths and weaknesses, enabling us to fine-tune it for improved PPE detection accuracy.

In this study, a YOLOv8 model was generated for the purpose of PPE detection on a custom dataset. The dataset was initially divided into three sets: 70% for training, 20% for validation, and 10% for testing. This division ensures a robust evaluation of the model's performance while preventing overfitting and enabling efficient training. For training the YOLOv8 model, the dataset was utilized to teach the model to recognize PPE items. The training process involved passing the dataset through the model multiple times iteratively adjusting the model's parameters to improve accuracy. In the context of improving PPE detection accuracy, it is advisable to consider a few key details. Firstly, an optimal learning rate should be selected, typically through experimentation, to ensure the model converges effectively. It's recommended to start with a lower learning rate and gradually increase it as necessary. Batch size is another crucial factor; larger batches can accelerate training but may require more memory. Striking the right balance is essential. Augmentation techniques such as rotation, translation, and color adjustment can further improve accuracy by diversifying the training data.

Furthermore, the dataset should be balanced, meaning that it should contain an equal distribution of PPE and non-PPE examples. This avoids bias and helps the model achieve better accuracy in detection. The validation module is pivotal in monitoring the model's performance. It assesses the model's generalization capability and helps identify any potential overfitting. In the context of PPE detection accuracy improvement, the validation set should be representative of real-world scenarios. Hyperparameter tuning is typically performed here, experimenting with various learning rates, batch sizes, and data augmentation techniques. The aim is to find the configuration that optimizes PPE detection accuracy without compromising the model's ability to generalize to unseen data. The testing module evaluates the YOLOv8 model's performance on an independent dataset, ensuring that it can accurately detect PPE items in real-world situations. To enhance PPE detection accuracy, the testing set should be diverse and representative of the environments in which the model will be deployed. This module is instrumental in quantifying the model's accuracy and assessing its readiness for real-world applications. The model's performance can be measured using metrics like precision, recall, and F1-score, which should be optimized to achieve the desired PPE detection accuracy.

In conclusion, to generate a YOLOv8 model for PPE detection, it is crucial to carefully consider training details such as learning rate, batch size, and data augmentation techniques. Balancing the dataset and ensuring diversity in the validation and testing sets are essential for accurate model evaluation. These suggestions should be tailored to the specific requirements of improving the accuracy of PPE detection, ensuring the model performs effectively in real-world scenarios

The Precision-Confidence Curve is a critical evaluation tool for assessing the performance and efficiency of a PPE detection model, such as YOLOv8s. It provides valuable insights into how the model's confidence in its predictions relates to the precision it achieves for various object classes. This curve helps in understanding the model's effectiveness and its ability to make accurate predictions while maintaining high precision. In this case, where we are detecting PPE items, including classes like aprons, gloves, helmets, masks, and shoes, achieving a high precision rate of approximately 0.95 for all classes is an exceptional accomplishment. It means that when the model makes a prediction for any of these classes, there is a very high likelihood that the prediction is correct, with very few false positives. This is particularly important in PPE detection, where ensuring the safety and compliance of individuals in industrial or medical settings is of utmost importance. The precision confidence curve of the model is depicted in Fig. 3.

The high precision values, nearly 0.95, across all classes in the Precision-Confidence Curve indicate the model's effectiveness in recognizing PPE items. It demonstrates the model's ability to confidently identify and localize these items, contributing significantly to safety and compliance. With such high precision, the model can be relied upon to provide accurate PPE detection, which is crucial for preventing accidents, maintaining safety standards, and ensuring that individuals are adequately protected. These values instill confidence in the model's performance and highlight its efficiency in recognizing PPE classes, underlining its practical utility in real-world applications.

The Recall-Confidence Curve is a crucial tool for evaluating the efficiency of a YOLOv8s model in PPE detection. Fig. 4 illustrates how the model's confidence in its predictions correlates with the recall it achieves for various PPE classes. The model's exceptional performance is evident, with an approximate 0.84 recall rate at the maximum confidence level across all classes. This means that the model effectively captures the majority of actual PPE instances, reducing the risk of missing important items and enhancing safety compliance in industrial and medical settings. The YOLOv8s model, as demonstrated by the Recall-Confidence Curve, proves to be highly efficient in recognizing PPE classes. These high recall values emphasize its effectiveness in minimizing the risk of overlooking critical PPE items and contribute significantly to maintaining safety standards and preventing accidents in real-world applications.

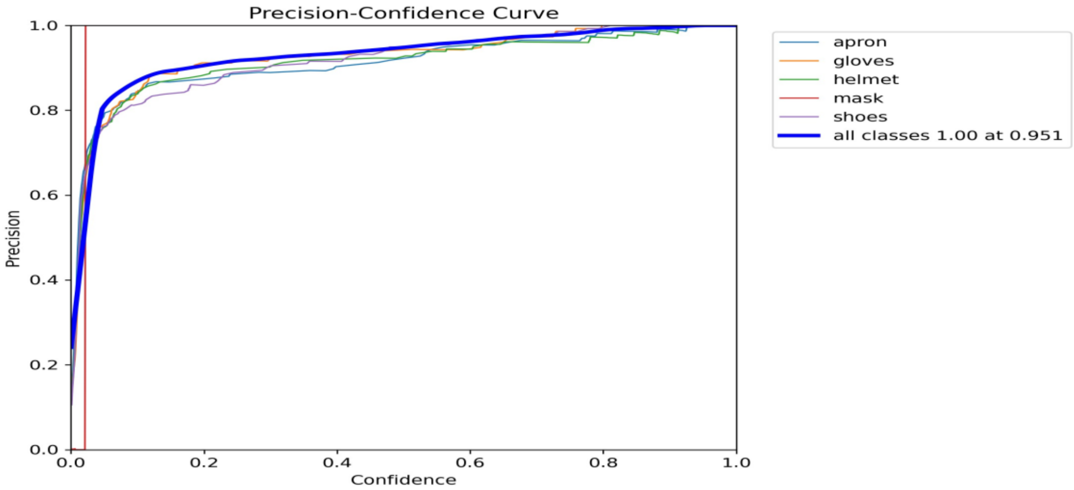

Fig. 3. Precision confidence curve of the model.

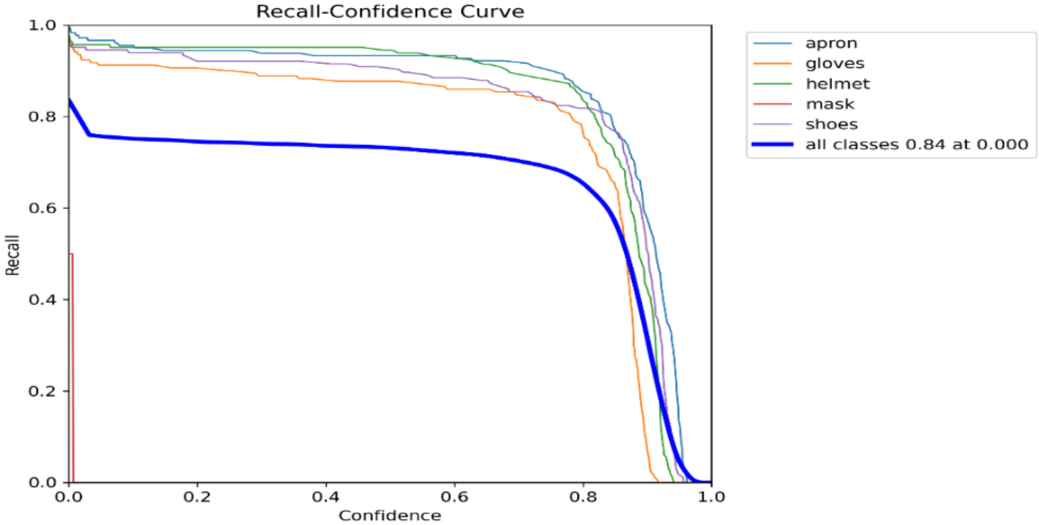

Fig. 4. Recall the confidence curve of the model.

The Precision-Recall curve is a crucial tool for evaluating the efficiency of a YOLOv8s model in PPE detection. Fig. 5 illustrates the trade-off between precision and recall, offering insights into the model's performance. The model's performance is notable, with an approximate 0.75 recall rate at the maximum confidence level across all PPE classes. This high recall rate indicates the model's effectiveness in recognizing these crucial PPE items, reducing the risk of overlooking important safety gear and enhancing safety compliance in industrial and medical settings. The YOLOv8s model, as shown by the Precision-Recall curve, is efficient and reliable in PPE detection, making it a valuable asset for maintaining safety standards and preventing accidents in real-world applications. These high recall values emphasize the model's effectiveness in minimizing the risk of missing important PPE items and contribute significantly to overall safety measures

The F1 Confidence Curve is a vital tool for evaluating the efficiency of a YOLOv8s model in PPE detection. Fig. 6 provides insights into the model's confidence in its predictions and the resulting F1-score, which balances precision and recall. The model's performance is impressive, with an approximate 0.74 F1 score at the maximum confidence level across all PPE classes. This high F1-score indicates the model's effectiveness in accurately recognizing these essential PPE items, striking a balance between precision and recall. This balance is crucial for minimizing false alarms and missed detections, contributing significantly to safety compliance in various industrial and medical settings.

In conclusion, the YOLOv8s model, as demonstrated by the F1 Confidence Curve, is a robust and reliable solution for PPE detection. It excels in minimizing false alarms and ensuring that important PPE items are accurately identified, enhancing overall safety measures in real-world applications. The results of the model are depicted in Fig. 7.

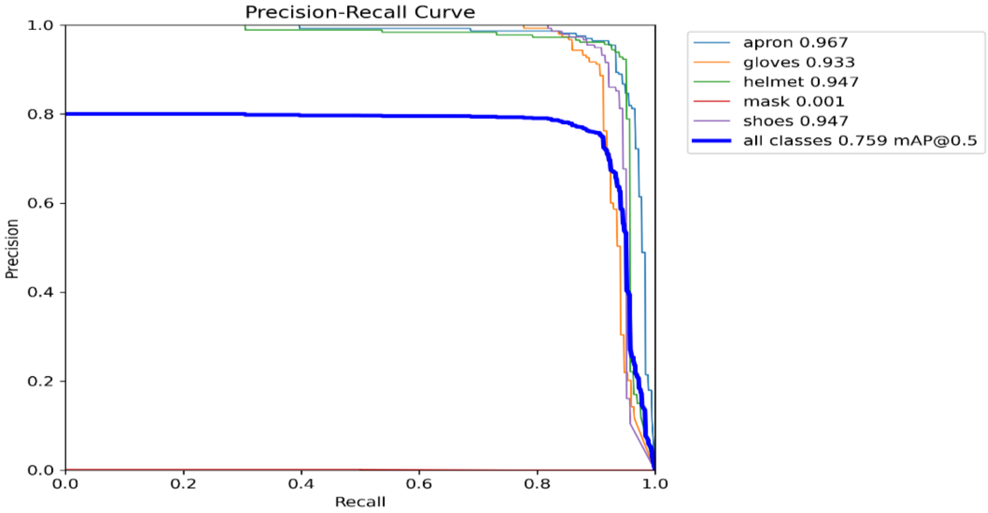

Fig. 5. Precision-Recall curve of the model.

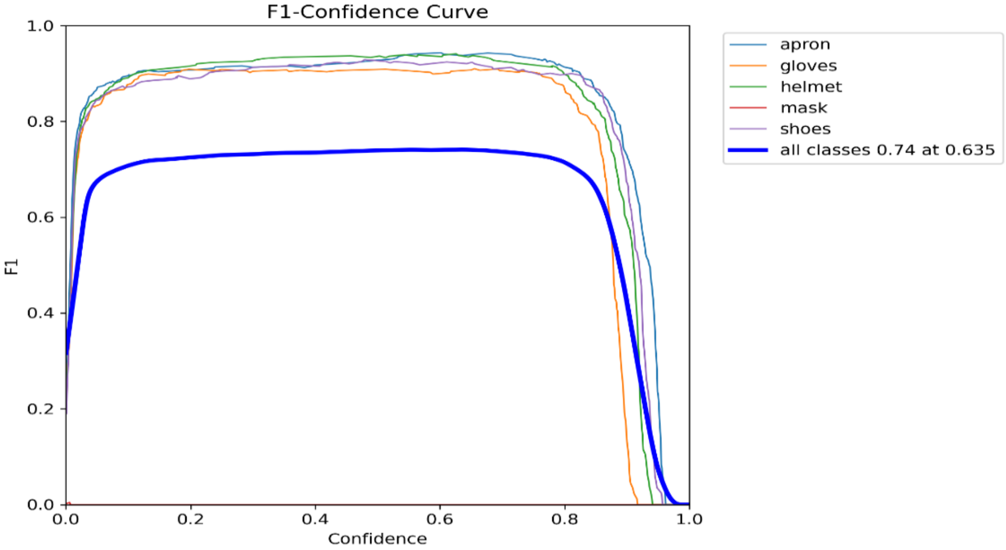

Fig. 6. F1-confidence curve of the model.

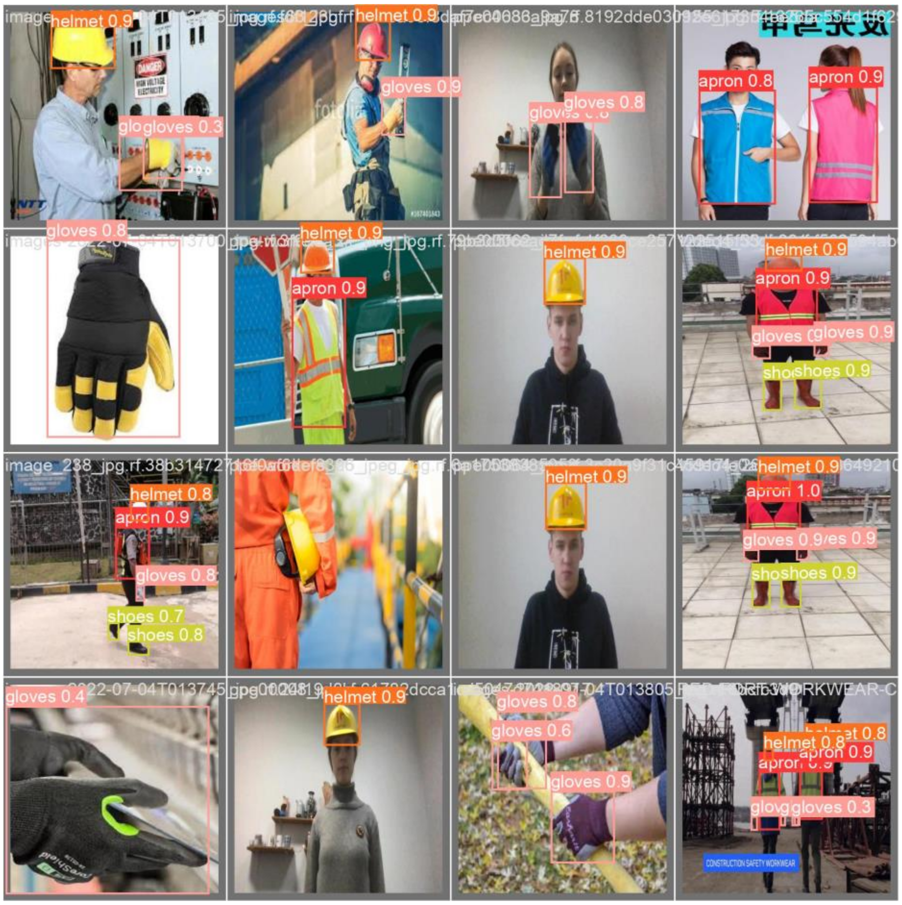

Fig. 7. The result of the model.

IV. Results And Discussion

We have performance metrics for two object detection models, YOLOv5s and YOLOv8s, both applied to Personal Protective Equipment (PPE) detection. The metrics include Precision, Recall, mAP (mean Average Precision at a confidence threshold of 0.5), and F1-score. The table shows the comparison of the results of YOLOv8s and YOLOv5s. YOLOv8s has a higher precision (0.95) compared to YOLOv5s (0.88). This means YOLOv8s makes fewer false-positive predictions, resulting in more accurate detection of PPE items. High precision is essential to minimize false alarms, ensuring accurate PPE identification.YOLOv8s has a higher recall (0.84) compared to YOLOv5s (0.78). This suggests that YOLOv8s successfully identifies a higher proportion of actual PPE items within the dataset, indicating improved completeness in detection. A higher recall means fewer missed PPE items, enhancing safety. Both YOLOv8s and YOLOv5s have good mAP values at a confidence threshold of 0.5, with YOLOv5s slightly outperforming YOLOv8s (0.76 vs. 0.75). This indicates that both models perform well in terms of precision and recall, with YOLOv5s being slightly more consistent in precision and recall trade-offs. The F1-score for both models is the same (0.74). This score represents the balance between precision and recall. YOLOv5s achieves a better balance between these two metrics, whereas YOLOv8s has a higher precision but a slightly lower recall.

In summary, YOLOv8s exhibits higher precision and slightly lower recall compared to YOLOv5s. The choice between these models depends on specific requirements. YOLOv8s is more accurate in identifying PPE and reducing false positives, but it may miss some items. YOLOv5s provides a good balance between precision and recall, which might be preferable in scenarios where minimizing false alarms is crucial. Ultimately, the choice depends on the trade-off between precision and recall that aligns with the specific PPE detection objectives. A graph of the comparison result for the different algorithms is depicted in Table I and Fig. 8.

TABLE I. The Comparison of the Results for the Different Algorithms

Model	Precision	Recall	mAP0.5
YOLOv5s	0.88	0.78	0.76
YOLOv8s	0.95	0.84	0.75
Faster R-CNN	0.92	0.82	0.78
SSD	0.89	0.80	0.73
RetinaNet	0.93	0.82	0.74

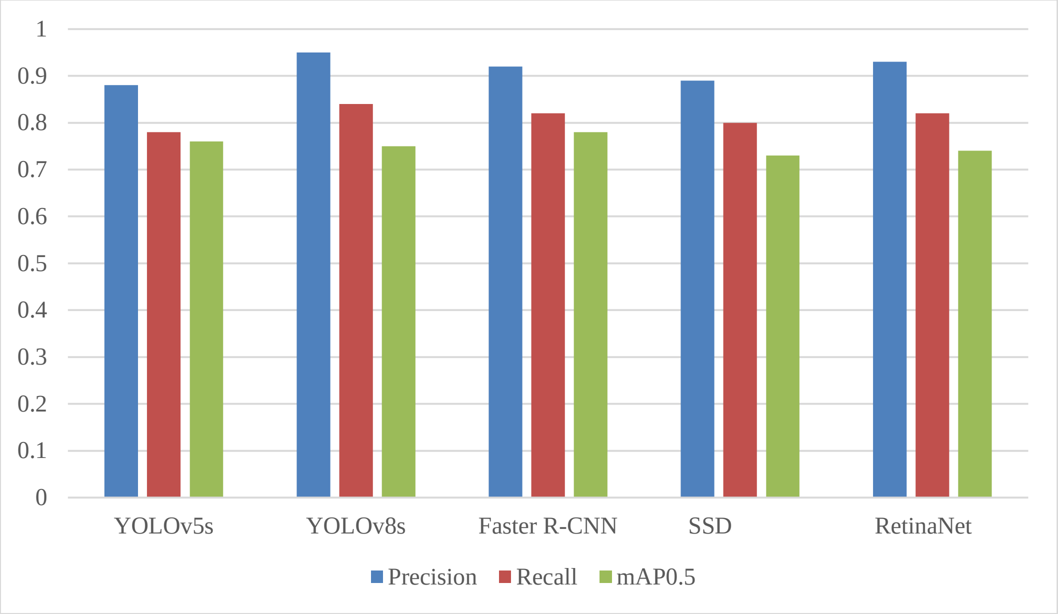

Fig. 8. Graph of the comparison result for the different algorithms.

The Table I and Fig. 9 present the performance metrics of various object detection algorithms, namely YOLOv5s, YOLOv8s, Faster R-CNN [17], RetinaNet [18], and SSD [19] in the context of PPE detection. YOLOv8s stands out with the highest precision of 0.95, indicating its ability to correctly identify PPE items with minimal false positives. This precision score suggests that YOLOv8s is adept at distinguishing between positive and negative predictions, crucial for applications where false alarms can have significant consequences. Additionally, YOLOv8s achieves a recall of 0.84, demonstrating its effectiveness in capturing a substantial portion of PPE instances present in the images. This balance between precision and recall is indicative of YOLOv8s' robust performance in detecting PPE across various scenarios.

Faster R-CNN also performs admirably with a precision of 0.92 and a recall of 0.82, closely trailing behind YOLOv8s. This indicates that Faster R-CNN is capable of achieving high accuracy in PPE detection, albeit with a slightly lower recall compared to YOLOv8s. Meanwhile, RetinaNet showcases competitive performance with a precision of 0.93 and a recall of 0.82, indicating its effectiveness in accurately identifying PPE items. However, SSD lags behind slightly with a precision of 0.89 and a recall of 0.80, suggesting that it may struggle with certain aspects of PPE detection compared to the other algorithms.

As result, YOLOv8s emerges as the algorithm with the overall best performance for PPE detection based on the provided metrics. Its combination of high precision and recall, along with a competitive mAP0.5 score, demonstrates its superiority over other models in accurately identifying PPE items. While Faster R-CNN and RetinaNet also exhibit strong performance, YOLOv8s' consistently high precision and recall make it the preferred choice for PPE detection tasks where both accuracy and reliability are paramount.

V. Conclusion and Future Work

In industrial environments, the importance of Personal Protective Equipment (PPE) cannot be overstated, as it serves as a critical safeguard against potential hazards. While various methods for PPE detection have been explored in the literature, deep learning approaches have emerged as frontrunners, consistently delivering superior accuracy. However, a pressing research challenge persists in deep learning-based PPE detection, revolving around the need for even higher accuracy, non-destructiveness, and real-time capabilities, as evidenced by previous studies. In response to this challenge, this study proposes a deep learning model utilizing the YOLOv8 architecture, specifically designed to address the demanding accuracy, non-destructive, and real-time requirements. The model is trained on a custom dataset and validated to ensure robust performance, and extensive experiments and performance evaluations are conducted to demonstrate its effectiveness. In this study, a dataset is generated with extensive diversity of images, aiming to cover a wide array of scenarios relevant to PPE detection. From varying environments to different lighting conditions and types of the PPE), the dataset ensures robustness and adaptability in algorithm training. Its scalability enables extensive training and testing, enhancing the algorithm's accuracy and generalization capabilities. By including images from diverse settings and featuring different types of PPE, the dataset enriches the learning process, equipping algorithms to detect PPE across a range of real-world situations. Ultimately, this dataset serves as a valuable resource for developing accurate and reliable PPE detection algorithms, vital for workplace safety and compliance. The experimental results and performance evaluation underscore the proposed method's ability to achieve remarkable accuracy, making it a promising solution for PPE detection in industrial environments, satisfying the stringent demands of accuracy, non-destructiveness, and real-time functionality. Two limitations in PPE detection methods are, first, the potential difficulty in differentiating between visually similar PPE items, such as gloves and protective sleeves, which could lead to misclassifications and compromise safety. Second, current PPE detection models may struggle in highly dynamic industrial environments, where the rapid movement of workers and changing scenes can hinder real-time tracking and detection accuracy. To address these limitations, two potential future research directions could be: Exploring advanced computer vision techniques, such as fine-grained object recognition and fusion with other sensor data, to improve the discrimination between visually similar PPE items, enhancing the model's precision. Investigating the integration of state-of-the-art real-time tracking algorithms and more sophisticated motion analysis to enhance PPE detection in dynamic industrial settings, ensuring accurate and reliable monitoring in high-speed, constantly changing work environments. Moreover, evaluation of different dataset is suggested to investigate the performance of the method on others scenarios.

***Abstract*—Understanding the deoxyribonucleic acid (DNA) sequence is a major component of bioinformatics research. The amount of biological data increases tremendously. Hence, there is a need for effective approaches to handle the critical problem in the general computational framework of DNA sequence prediction and classification. Numerous deep learning languages can be used to complete these tasks compared to manual techniques that have been followed for ages. The aim of this project is to employ effective approaches for pre-processing DNA sequences and using deep learning languages to train the sequences for making judgments, predictions, and classifications of DNA sequences into known categories. In this study, the pre-processing methods include k-mers and tokenization. We employ a novel hybrid deep learning algorithm that combines convolutional neural networks and is followed by bidirectional gated recurrent networks. This combination can capture dependencies within the genome sequence, even in large datasets with a lot of noise. The proposed model is compared with existing widely used models and classifiers. The results show that the proposed model achieves a good result with an accuracy of 82.90%. The dataset consists of 44,391 labeled DNA sequences obtained from the Encode project.**

Keywords*—DNA sequencing; deep learning; convolutional neural networks; bidirectional gated recurrent; k-mer; tokenizing

I. Introduction

Deoxyribonucleic acid (DNA) is unique. It contains a list of genetic codes which look likes no order random letters of adenine (A), cytosine (C), guanine (G), and thymine (T). Eventually, it is organised into little chunks that carry a set of meaning instructions for how to build and maintain body. The little chunks in known as genes. Most genes are alike to each other, only a small number of genes are slightly different between people, that resulted the uniqueness physical features. Genes instruct cells how to make proteins. As we need protein to repair cells and make a new ones for growth and maintenance of tissues. Our body proteins suppose is a constant state of turnover. Nevertheless, errors happen during the journey from genes to protein, it can develop into unhealthy genes and cause cells abnormal in growing.

To discovery these abnormal ChIP-seq is relying on experimental analysis the structures of DNA binding sequences [3], [4], [5]. These experimental analysis usually is time consuming [6], [7]. With quick expansion in the amount of genomic DNA, there is a need for efficient methods in predicting ChIP-seq allows the binding sites of transcription factors (TF). Hence, deep learning and machine learning are widely applied in predicting the DNA sequence binding specificities.

Deep learning techniques have accomplished exceptional outcomes in computer vision [8], [9], natural language processing [10], [11], bioinformatics [12], [13] and image analysis [14], [15]. Methods based on convolutional neural networks (CNN) [16] and recurrent neural networks (RNN) [17], [18] like gated recurrent unit (GRU), long short-term memory networks (LSTM) have been proposed to analyse and predict genome DNA. These techniques have been improved to generate autonomous prediction at learning process that spot specific trends and patterns to make better decisions based on the given data.

DeepBind [19] is pioneer CNN with single convolution layer, pooling operation and fully connected network. The design demonstrates a promising result to predict the sequence specification of DNA and ribonucleic acid (RNA) binding. This has inspired the following research like DeepSHR [20], DeepSEA [21] and Dilated [22]. KEGRU [23] uses a bidirectional gated recurrent (BiGRU) unit with k-mer sequences to find RNA protein binding sites. This method allows mining long dependencies of the sequences and thus achieves good performance in binding sites. DanQ [24] is a hybrid CNN + bidirectional LSTM (BiLSTM) model that applies the capabilities of CNN in extracting DNA features and BiLSTM in handling long range dependencies in order to obtain good performance.

Despite all these studies, there is a gap in finding a fair comparison which deep learning architectures perform well in detecting DNA sequences. As some methods use one-hot to code the DNA sequences, some use k-mer. One-hot is mutual orthoganal, it ignores the DNA sequence dependencies. k-mer overcomes the issue of one-hot by adjoining DNA sequences. Hence, this paper considering k-mer for data pre-processing in finding the dependency between the genome patterns and possibility independence for the underlying genome. Next, tokenize the k sequences to prepare a bag of vocabulary for deep learning process. This research, we aim to propose hybrid deep learning with CNN and BiGRU (DeepBiG) to classify Chromatin Immunoprecipitation Sequencing (ChIP-seq) data from lymphoblastoid cells (GM12878) and K562 chronic myelogenous leukemia (CML) obtained from the Encyclopedia of DNA Elements (ENCODE). CNN consists of extraction and representation capabilities. BiGRU allows capture long-range dependencies and thus obtains good performance. Next, DeepBiG is compared with different deep learning architectures with the same parameters and same dataset. Noted that, the ability in identifying the specific ChIP-seq can significantly improve our understanding on the epigenetic mechanism of the disease, thus promoting precision in drug discovery [1], [2].

The rest of this paper is organized as follows: Section II provides the experimental processes which include data pre-processing, deep learning algorithms. Section III presents the proposed model - DeepBiG. Evaluation matrices is shown in Section IV. Section V shows the experiment results and discusses the finding. Finally, Section VI concludes the paper.

II. Materials and Methods

The dataset includes 22832 labelled ChIP-seq data GM12878 lymphoblastoid cell and 21559 labelled ChIP-seq K562 chronic myelogenous leukemia (CML) cell. GM12878 is generated by Epstein–Barr virus which may cause infectious mononucleosis. K562 is one of the immortalized myelogenous leukemia cell that may cause for cancers of the blood cells. The TF of GM12878 consists ELK1 (5084 ChIP-seq) and SP1(17748 ChIP-seq). The TF of K562 consists ARID3A (9526 ChIP-seq) and CTCFL (12033 ChIP-seq). The dataset are obtained from Encode which has been processed and been provided in [19]. There are 44391 DNA cells in total and with no missing labelled. All the DNA sequences are labelled as 0 or 1. GM12878 sequences are labelled as 0 while K562 sequences are labelled as 1. Noted that the rational to choose the number of ChiP-seq is almost balance is to ensure model may perform the unbiased prediction. Saying that if given the ChIP-seq, the probability to perform the prediction manually towards the given ChIP-seq either is either GM12878 cell or K562 is about 50%.

A. Data Pre-processing

The data pre-processing steps are to transform the dataset into a uniform format that can be understood by the learning algorithms include k-mers and text tokenizer. k-mers is the common method for tokenizing the genome that splitting the long DNA sequence into k length biological sub-sequences [25], [26]. As shown in Table I, there are five k-mers where we can tokenize the sequence "AGGTCCGGGTCT". The five different k-mers will result different tokens and hence affect the performance of the language models. The k-mers range is between two until six are chosen as 1-mer will not provide any useful DNA sequence relation and accuracy prediction after 6-mers is decreased.

TABLE I. Example Biological Sub-sequences Generated by k-mers and the Number Sequence Index

v

k-mers	Biological k-mers sub-sequences	Distinct Sequence
2	AG GG GT TC CC CG GG GG GT TC CT	16
3	AGG GGT GGC TCC CCG CGG GGG GGT	64
4	AGGT GGGC GTCC TCCG CCGG CGGG GGGT	256
5	AGGTC GGTCC GTCCG TCCGG CCGGG CGGGT	1024
6	AGGTCC GGTCCG GTCCGG TCCGGT CCGGTC	4096

Tokenizer is essential to boost the performance of the natural language processing model. Firstly, creates a bag of "vocabulary" of ChiP-seq by transforming the splitting block of sequence based on k-mers into integer. For example, the bag of "vocabulary" for 2-mers ChIP-seq with 16 number of distinct sequence is 'gg'-1, 'cc'-2, 'gc'-3, 'ct'-4, 'ag'-5, 'tg'-6, 'ca'-7, 'tc'-8, 'ga'-9, 'tt'-10, 'aa'-11, 'cg'-12, 'gt'-13, 'ac'-14, 'at'-15, 'ta'-16. Next, converts the long ChIP-seq into integer based on the bag of "vocabulary", such that given the sequence "AGGTCCGGGTCT", the tokenizing output based on 2-mers is (5, 1, 13, 8, 2, 12, 1, 1, 13, 8, 4).

B. Convolutional Neural Networks (CNN)

Convolutional neural networks is deep neural networks that widely applied at the artificial intelligence research fields such that bioinformatics [27], [28], visual imagery [29] and natural language processing [30]. The design of CNN is composed of three layers, there are convolutional, pooling and fully connected layers. The layers of convolutional and pooling are designed to adaptive learn local information of original features, then extract and represent the spatial hierarchies features from low to high patterns through several feature maps and kernels. The layer of fully connected performs classification that maps the extracted features into final output. More specifically, a convolutional layer and pooling layer computes [31],

$$\begin{aligned} convolutional(X)_{i,k} &= Relu(\sum_{m=0}^{M-1}\sum_{n=0}^{N-1} W^{k}_{mn} X_{i+m,n}) \\ pooling(Y)_{ik} &= max(Y_{iP,k}, Y_{iP+1,k}, ..., Y_{iP+P-1,k}) \end{aligned} \quad (1)$$

where X is the input matrix, i is index of output position, k is the filter index, W^k is an MxN matrix. Y is the output of convolutional layer. P is the pooling.

C. Gated Recurrent Unit (GRU)

Gated recurrent unit network [32] is a deep learning machine learning that to process and to uncover the underlying relationship for a given sequences of data. The data can be text, speech, video and images. Human brain activates the process of acquiring information, forgetting and memory. The memory can be long or short. The long-term memory is applied if the matters are important. Otherwise, we tend to forget, which called short-term memory. GRU is modeled like a human brain which consists the process of reset and update. The reset process help captures short-term dependencies in sequence. The update process help captures long-term dependencies in sequence. The inputs are h_{t-1} and x_t. The reset and update processes consist of two gates to manage the cell state's information. The two gates we denoted it as z_t and r_t, where z_t is the reset gate and r_t is update gate. W_z and W_r are two weight matrices as well as $b_z and b_r$ are two bias value corresponding to these two gates. The two gates are composed by a sigmoid neural net layer (σ) and a pointwise multiplication operation. The candidate hidden state we denoted it as $\hat{C}_t$. Here, $tanh$ function is activated. The t_t is the hidden state. The value of z_t is either close one or close zero. Old state is retained, if value of z_t is closed to one. Otherwise, new latent state t_t.

Noted that, these layers are repeating and form a chain. The gate structures and cell states are calculated as follows [32]:

$$\begin{aligned} z_t &= \sigma(W_z x_t + V_z h_{h-1} + b_z) \\ r_t &= \sigma(W_r x_t + V_r h_{h-1} + b_r) \\ \hat{C}_t &= tanh(W_C x_t + V_C(r_t.h_{t-1}, x_t)) \\ t_t &= z_t.h_{t-1} + (1 - z_t).\hat{C}_t \end{aligned} \tag{2}$$

D. Bidirectional GRU (BiGRU)

Bidirectional GRU [33] accomplishes the training without the limitation of using input information just up to a present future frame. It predicts the sequence for each class using finite sequence based on the context of elements of past and future. One can see the two GRUs are executed parallel, one is forward and another one is backward. Eq. 3 and 4 shows the calculation of BiGRU that takes L inputs and H number of hidden units. The final output of BiGRU is based on the hidden BiGRU forward and backward values [33].

$$a_h^t = \sum_{l=1}^{L} x_l^t.w_{lh} + \sum_{h',t>0}^{H} b_{h'}^{t-1}.w_{h'h} \tag{3}$$

$$a_t^h = \theta_h(a_t^h) \tag{4}$$

III. The Proposed Model (DeepBiG)

CNN architecture consists of convolutional layer, pooling layer and fully connected layer. The proposed model is composed with the modified CNN architecture by replacing the fully connected layer with bidirectional GRU (BiGRU), the first two layers are remained, which is shown in Fig. 1. The rational of this design that remains the CNN first two layers to shorten the training time while maintains the accuracy during data processing by generalizing ChIP-seq patterns. Next, replacing fully connected layer with the BiGRU is to deal with the past and present order dependency information in the ChIP-seq which may efficiently characterize the highly complex order of ChIP-seq.

The first layer is a convolutional layer which is constructed with 32 filters, five kernels with rectified linear units (relu) as the activation function. During the training phase, the filters and kernels read the input matrices with same weights, produces different strengths of signals and extracts the correlation ChIP-seq patterns.

The second layer is a max pooling layer to improve the reliability and performance in term of time for the proposed model. It summarizes the feature maps so that the model will not need to be trained by maximizing the output signals of each kernel along the entire sequence.

The third layer is BiGRU to process the filtered correlated ChIP-seq with its own interpretation by considering the context of elements of past and future into its hidden state. The interpretation is further propagated to the next GRU block. Once the nucleotide is remarked, the last block of GRU makes the final decision for the goodness of the probe.

The last layer is a non-linear transformation with sigmoid activation. The sigmoid activation will produce a value between 0 and 1. This value represents the probability of a binding preference of each probe. In this case, 0 is GM12878 ChIP-seq, 1 is K562 ChIP-seq.

The proposed model is implemented based on Keras library. The experiment is undergo three phases: training, validation and testing. For the training phase, the experiment will randomly train 50% of the dataset and 25% dataset is validated at validation phase. Then, remaining 25% dataset is tested at testing phase. Early stopping is applied for overfitting. Lastly, the performance for the models are evaluated. The model is simulated on on graphical processing units (GPU) with Intel(R) Core (TM) i9-10980XE CPU@ 3.00GHz, 128GB random access memory and 1T hard disk.

IV. Performance Metrics

A confusion metric is used to assess the performance of the models on the data as shown in Table II. True positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) are four assessment elements formulated in the confusion matrix table. TN is both predict and actual events fall on GM12878 ChIP-seq. The sequence is not K562 ChIP-seq. FP is prediction is the model incorrectly classified GM12878 ChIP-seq as K562 ChIP-seq. FN is the prediction is GM12878 ChIP-seq but the actual is K562 ChIP-seq. TP is both predict and actual events fall on K562 ChIP-seq that are correctly classified by the model.

TABLE II. Confusion Matrix

	GM12878 seq	K562 seq
GM12878 seq	True Negative (TN)	False Positive (FP)
K562 seq	False Negative (FN)	True Positive (TP)

With this matrix, one may evaluate the performance of the design model based on accuracy, precision, recall, and F1-score are as follows.

1) Accuracy: Accuracy refers to how close a measurement is to the accepted value. As shown in Eq. 5 [34], the accuracy is the proportion of correct predictions for both true positive and true negative. High accuracy requires high precision and high trueness.

$$Accuracy(A) = \frac{TP + TN}{TP + FP + FN + TN} \tag{5}$$

2) Precision: Precision refers to positive predictive value. As shown in Eq. 6 [34], the precision is the fraction of correct predictions among the true and false positive (such as correct predict the DNA sequence is K562 ChIP-seq). High precision requires high trueness.

$$Precision(P) = \frac{TP}{TP + FP} \tag{6}$$

3) Recall: Recall refers to sensitivity of the model in capturing true positive value. As shown in Eq. 7 [34], the recall value is the fraction of correct predictions among the actual positive value.

$$Recall(R) = \frac{TP}{TP + FN} \tag{7}$$

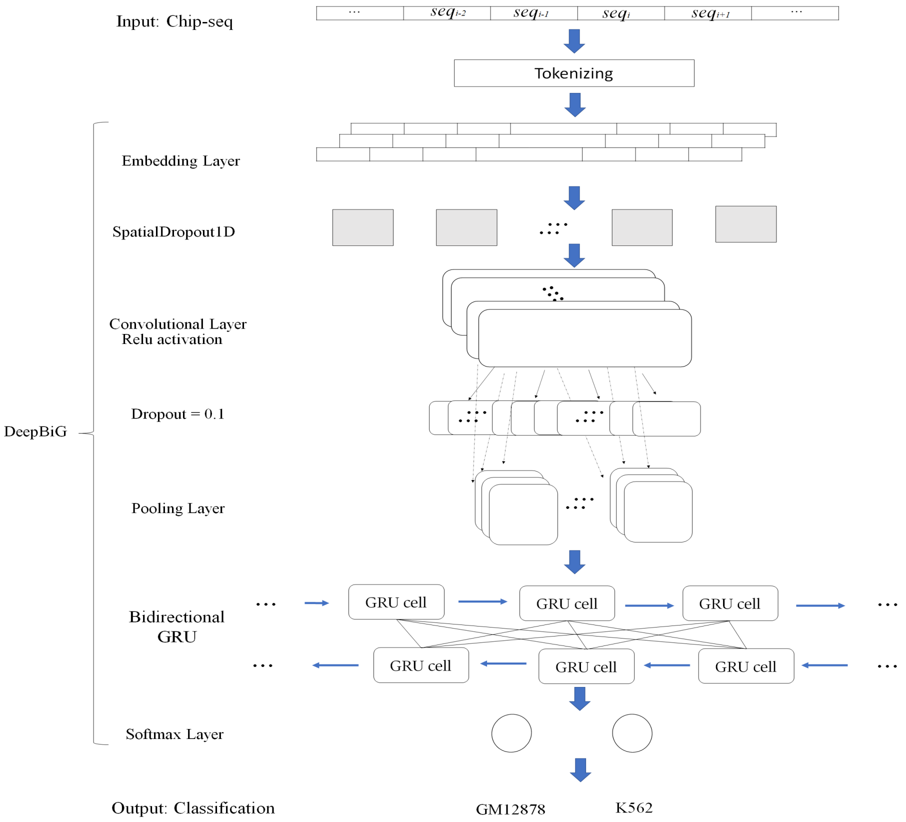

Fig. 1. Proposed Model - DeepBiG.

4) F1-Score: F1-score refers to seek for balance of the precision and recall. As shown in Eq. 8 [34], F1-score measures is there any uneven class distribution.

$$F1 - Score(F1) = \frac{2 * P * R}{P + R} \tag{8}$$

V. Result and Discussion

The results and discussion consist tables of performance metric in percentage that include accuracy, precision, recall and F1-score as well as model training time in minutes. There are four types of performance metrics comparison: 1) The comparison k-mers spectra with each being tokenized before being trained based on DeepBiG. 2) The comparison performance metric with difference combination of activation functions. 3) The comparison performance metric with different types of models and classifiers. 4) The comparison performance metric with different datasets.

A. Performance Comparison with Different k-mers

Table III shows the performance metric for k-mers spectra to evaluate genome assemblies. Noted that Class 0 is GM12878 and Class 1 is K562. Time is model training time in minutes. There are 2-mers, 3-mers, 4-mers, 5-mers and 6-mers. The accuracy increases from 2-mers to 4-mers and decreases after 4-mers. The simulations show 4-mers outperforms compare with others k-mer spectra with only 63 minutes in model training and 82.90% accuracy in predicting the ChIP-seq either belong to GM12878 or K562. However, the F1-score, the weighted average of precision and recall for 3-mers is better with only 1% different between class 0 and class 1 compare with 4-mers with 2% difference. But, the training time for 3-mers is double compare with 4-mers.

TABLE III. Performance Results in Term of Accuracy, Precision, Recall and F1-score for DeepBiG Model

k-mers	Time	A (%)	Class	P(%)	R(%)	$F1$(%)
2	99	81.70	0	78	90	84
			1	87	73	79
3	133	82.70	0	85	81	83
			1	81	84	82
4	63	82.90	0	82	86	84
			1	84	80	82
5	91	79.60	0	82	78	80
			1	78	81	79
6	67	77.30	0	84	70	76
			1	72	86	78

Fig. 2 displays the accuracy and loss for 4-mers during the training and validation phases with the highest accuracy is 88.17% and 82.80%, respectively. Early stopping at epochs 8 as overfitting occurred. This is one of the limitation of the design but it provides better accuracy compare with other models or classifiers as shown in Table V. Therefore, 4-mers encoding DeepBiG is chosen for the remaining experiments.

B. Performance Comparison with Different Activation Functions

Table IV shows the simulation results for different combination activation functions like relu, softmax and tanh. These

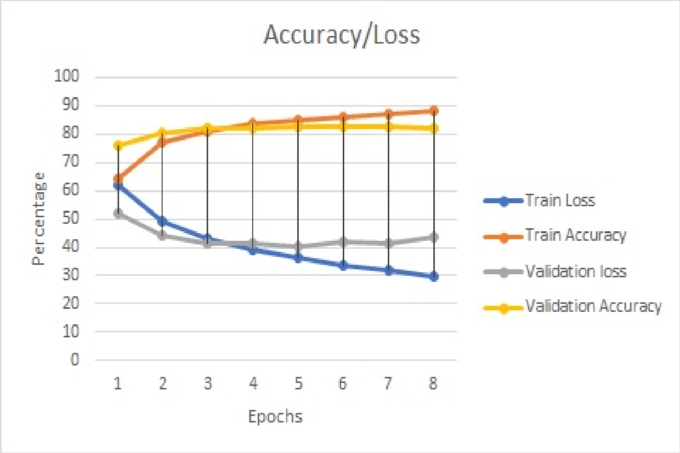

Fig. 2. DeepBiG using 4-mers, the training / validation's accuracy and loss.

activation functions are generally applied in deep learning models. The result shows that activation softmax for the last layer is preferable as it compatible with the adam optimizer and categorical cross-entropy loss. The accuracy for models where last layer is softmax activation is more than 80%. Relu and tanh are not suitable to be placed at last layer as vanishing gradient problem, in this simulation, class 0 is on higher side as the number of dataset is larger compares with class 1, then the gradient will be near zero. This has resulted no learning during backpropagation for class 1 as weights is updated with really small values. Noted that the simulation dataset for Class 0 is GM12878 and Class 1 is K562. Time is model training time in minutes.

DeepBiG is using relu activation at CNN layer and softmax activation at last layer. The performance in term of accuracy is higher almost 2% compares with relu and tanh activation in CNN layer. DeepBiG training time is double faster compares to softmax activation and 6 minutes quicker compares to tanh activation.

TABLE IV. Comparison Performance Results in Term of Accuracy, Precision, Recall and F1-score for Different Types of Models

Models	Time	A (%)	Class	P(%)	R(%)	$F1$(%)
Relu* - Softmax$^+$	63	82.90	0 1	82 84	86 80	84 82
Softmax* - Softmax$^+$	134	81.00	0 1	86 77	76 86	81 81
Tanh* - Softmax$^+$	76	80.60	0 1	81 80	81 80	81 80
Softmax* - Tahn$^+$	34	51.40	0 1	51 0	100 0	68 0
Softmax* - Relu$^+$	39	51.40	0 1	51 0	100 0	68 0
Relu* - Relu$^+$	34	51.40	0 1	51 0	100 0	68 0

C. Performance Comparison with Different Existing Predictors

Table V compares the performance in term of accuracy, precision, recall and F1-score between the deep learning models and machine learning classifiers. The dataset for Class 0 is GM12878 and Class 1 is K562. Time for these simulation is recorded in minutes. The deep learning models are bidirectional GRU (BiGRU), bidirectional long short-term memory (BiLSTM), CNN and the combination models. The machine learning classifiers are Naïve Bayes (NB), K-Nearest Neighbors Algorithm (KNN) and Random Forest (RF). Each method is simulated using the same dataset as stated and the dataset undergoes the pre-processing process as shown in Section II. The parameters for deep learning models are similar with DeepBiG which using dropout ratio of 0.1, kernel number is 5, cell number is 10, epochs is 15 and batch size is 64. The parameters for machine learning classifiers are varied for each others. NB smoothing parameter is set between the range of 0.1, 1, 10, 100 and 1000. In the KNN classification, the number of neighbors to be used in this simulation is in the range of 2, 5, 8, 10 and 15. For RF, the number of trees in the forest is set in the range of 10, 25, 30, 50, 100 and 200. The maximum depth of the tree is in the range of 2, 3, 5, 10 and 20. The minimum number of samples require to be at a leaf node is in the range of 5, 10, 20, 50, 100 and 200.

Deep learning models outperform compare to machine learning classifiers in term of accuracy, average is 80%. Machine learning classifiers' accuracy in average 55%. The result demonstrates the performance in term of accuracy of the proposed DeepBiG model is the highest (82.90%) by comparing with other models and classifiers on the same dataset. It follows by CNN + BiLSTM model with 81% accuracy. The training time for CNN is the only requires only 6 minutes but the accuracy below 80%. The weakest performance is NB classifier with best parameter 1000 achieves only 54.10% accuracy.

We noted overfitting with the symbol of *. The simulation dataset is long sequence with combination of nucleobases, A,C,G, and T. For each long ChiP-seq, it might contains some irrelevant DNA information related with the TF. We named it as noisy data. The models like DeepBiG, BiGRU, BiLSTM, CNN and CNN+BiLSTM learn the noisy within the training data. This has caused the overfitting. Hence, two solutions are provided to overcome the overfitting by adding dropout in the model and early stopping during training phase.

D. Performance Comparison with Different Size of Datasets

To further assess the performance of DeepBiG, we conduct experiments on four different combination TF datasets using DeepBiG and CNN+BiLISTM as shown in Table VI. The dataset include GM12878-ELK1, GM12878-SP1, K562-ARID3A and K562-CTCFL. Class 0 is GM12878 and Class 1 is K562. Simulation time is recorded in minutes.

Based on the results, we find that when the dataset size is smaller, the accuracy rate for DeepBiG is above 82.9%. If the dataset is smaller, the noisy decreases, this has resulted the increase of accuracy rate. Hence, this has proven there are noisy for the simulation dataset in Table V indirectly.

From Table VI, one may find that the DeepBiG predicts well when the dataset is larger compares to CNN+BiLSTM model. DeepBiG predictions accuracy for dataset EC, SA and SC are 87.90%, 84.10% and 89.40% respectively. CNN+BiLSTM model predictions accuracy for dataset EC, SA

TABLE V. COMPARISON PERFORMANCE RESULTS IN TERM OF ACCURACY, PRECISION, RECALL AND F1-SCORE FOR DIFFERENT TYPES OF MODELS AND CLASSIFIERS

Models/Classifiers	Time	A (%)	Class	P(%)	R(%)	$F1$(%)
*DeepBiG	63	82.90	0	82	86	84

EA - GM12878-ELK1 and K562-ARID3A with total dataset 14610.[1] . EC - GM12878-ELK1 and K562-CTCFL with total dataset 17117.[2] . SA - GM12878-SP1 and K562-ARID3A with total dataset 27274.[3] . SC - GM12878-SP1 and K562-CTCFL with total dataset 29781.[4]

VI. CONCLUSION AND FUTURE WORK

In this paper, the combination of k-mers encoding with tokenizing have been introduced for the data pre-processing phase. In the experiments, the DNA sequences are sized from 2-mers up to 6-mers are considered. The hybrid deep learning algorithms, we named it as DeepBiG is proposed with combination of CNN and BiGRU. DeepBiG is simulated and is analysed in terms of training time, accuracy, precision, recall and F1-score. The results reveal that the proposed 4-mers encoding DeepBiG gives better accuracy with 82.90% when compares with other deep learning models and machine learning classifiers. Although our model achieves better result, there is a limitation of DeepBiG is overfitting. Therefore, dropout and early stopping is adding into the model. There are open researches for improving this model which may still preserve the accuracy during learning, validation and prediction phases. For example, noise deduction during data pre-processing and reduces overfitting at model training phase.

***Abstract*—In recent times, large applications that need near real-time processing are increasingly being used on devices with limited resources. Multi access edge computing is a computing paradigm that provides a solution to this problem by placing servers as close to resource constrained devices as possible. However, the edge device must consider multiple conflicting objectives, viz., energy consumption, latency, task drop rate and quality of experience. Many previous approaches optimize on only one objective or a fixed linear combination of multiple objectives. These approaches don't ensure best performance for applications that run on edge servers, as there is no guarantee that the solution obtained by these approaches lies on the pareto-front. In this work, Multi Objective Reinforcement Learning with Actor-Critic model is proposed to optimize the drop rate, latency and energy consumption parameters during offloading decision. The model is compared with MORL-Tabular, MORL-Deep Q Network and MORL-Double Deep Q Network models. The proposed model outperforms all the other models in terms of drop rate and latency.**

Keywords—Edge computing; reinforcement learning; multi objective optimization; neural networks; deep learning

I. Introduction

In the modern day, mobile devices handle more computationally demanding activities, including data processing, artificial intelligence, and virtual reality. Despite advancements in mobile technology, these devices lack sufficient computational capacity to complete all of their duties locally with low latency and reasonable energy consumption. Mobile apps for online gaming, signal or image processing (such as facial recognition), augmented reality, and real-time translation services are some examples of computational domains whose use has grown drastically that places a substantial computing demand on mobile devices (MDs) which have a limited amount of resources.

Mobile edge computing (MEC), also known as fog computing and multi-access edge computing, is a technology that enables effective job processing. [1] It is a new computing paradigm in which computing, network, storage, capabilities are migrated to edge nodes, which is closer to end-users to meet real-time needs of fast changing IT industries. The demand for on-demand computation close to mobile devices is only expected to grow. Additionally, as 5G networks become more and more popular, the three main services - massive machine communication, enhanced mobile broadband and ultra-reliable low-latency communication pose network, computing, storage, and application core capabilities. As a result, their applications can be run on the edge server, enabling faster network service response and satisfying the real-time processing, intelligent application, security, and other requirements. Despite edge computing's enormous potential, there are many obstacles. Mobile real-time apps are extremely sensitive to latency and power usage. However, the prolonged time of execution of these applications can result in excessive energy consumption owing to the randomness and volatility of mobile edge networks.

Single objective reinforcement learning algorithms perform considerably well in environments where there is only one objective to optimize, which is often not the case in real world scenarios. The offloading requirement in the case of multi-access edge computing needs to satisfy many conflicting requirements like latency, energy, drop rate, QoS, and cost, among others. Optimization of just one objective can provide neither a guarantee of pareto optimality nor a control over the order of preference of the multiple objectives to suit the specific use-case, albeit at the cost of pareto optimality. Multi objective reinforcement learning (MORL) approaches can be leveraged to overcome the above shortcomings whilst maintaining adaptability to work in dynamic environments.

The research contribution of this work is the application of the actor critic method in multi objective reinforcement learning algorithms for the task offloading problem as opposed to previous literature that have used the actor critic method for single objective reinforcement learning.

II. Related Work

The decision to offload a task or not is a complex one, with multiple factors about the problem itself and the solution to be considered. Firstly, tasks can be considered to either be dependent or independent of one another. Literatures choosing to work on dependent tasks usually consider a directed acyclic graph to represent task dependencies. Secondly, the decision to offload or not can be made either centrally or by each mobile device, in a decentralized fashion. We have considered the papers that have used reinforcement learning to make the decision to offload or not. The network architecture of mobile devices and servers must be considered. The parameters for making the decision to offload or not are the task size, algorithmic complexity, the time by which the task needs to be completed, task interdependencies, and bandwidth. Authors choose a subset of these parameters for their system. The RL system can either be based on table or on function approximation. The reward for the RL agent can be based on latency, energy, cost, drop rate, QoS considerations.

Tang et al. [2] propose a cost optimized reinforcement learning algorithm, where every mobile device makes an independent decision to offload or not, while also being aware of edge load dynamics. T Alfaikh et al. [3] propose using SARSA for making the decision to offload or not to the closest server or adjacent server or to compute it locally. J Wang et al. [4] propose using meta RL for faster adaptability and use a sequence2sequence network for making the decision to offload or not. J Wang et al. [5] combine their approach with a specific off-policy policy gradient algorithm with a clipped surrogate objective. Liang Huang et al. [6] propose using deep q learning while optimizing on energy with constraints on bandwidth. Peizhi Yan et al. [7] propose using deep q learning with both node and edge level offloading. Xiaowei Liu et al. [8] propose using a parameterized, indexed-value function for value estimation for achieving faster convergence.

Zhenjiang Zhang et al. have proposed a multi-agent load balancing distribution deep reinforcement learning algorithm [9]. It minimizes the latency, load factor and the algorithm complexity as compared to a centralized algorithm. It uses a genetic algorithm to identify the decision to offload or not while still meeting the QoS requirements of all the tasks. Yu Dai et al. propose a federated reinforcement learning algorithm to address the issue of weak generalization of the model and privacy leakage caused by sharing user sensitive information to the central server [10]. Attention is used to aggregate the parameter weights resulting in the reduction of the processing time of the task. Yuanchao Xu et al. [11] explore decentralized multi-agent reinforcement learning algorithms to solve the problem of task offloading accounting for reward uncertainty. They try different approaches like Multi-Agent Deep-Deterministic Policy-Gradient (MADDPG), Robust MADDPG and Decentralized Partially-Observable Markov Decision Process (Dec-POMDP). Baris Yamansavascilar et al. [12] propose a task orchestrator based on deep reinforcement learning which learns to satisfy different task requirements without any human interaction. The problem is modeled as a Markov decision process and the Double Deep Q-Network algorithm is used to minimize the task drop rate. Xiangjun Zhang et al.[13] propose a task offloading algorithm for Reconfigurable Intelligent Surface (RIS) empowered Mobile Edge Computing networks. The problem is formulated as a Markov Decision Process (MDP) where latency, energy consumption and operating costs are minimized. DDPG is used to jointly optimize the phase shift and amplitude of RIS, task allocation strategy and offloading decision. Tu et al. [14] design a predictive offloading algorithm that makes use of deep RL and long short-term memory (LSTM) networks. The MEC server's load is monitored and the next task is predicted using the LSTM network. The amount of latency, energy used, and work abandonment is decreased. Liang Huang et al [15] propose an online, deep RL based algorithm to adapt task offloading and resource allocation decisions to the time varying wireless channel conditions. They aim to minimize the latency. Mingjie Feng et al. [16] explore offloading of tasks between MEC servers and cloud servers using DRL. They aim to minimize average latency and achieve optimization in task partitioning ratio and cloud selection.

Yi Ouyang et al. propose a task offloading algorithm for a vehicle edge computing environment based on Dueling-DQN [17]. The proposed approach considers the mobility of the vehicles and the changing network conditions make a better decision to offload or not. The results of the experiment demonstrate the effectiveness and superiority of the proposed algorithm with respect to existing approaches. Fuhong Song et al. have proposed an approach which uses multi-objective reinforcement learning for optimizing the UAV's trajectory and offloading decisions in real-time [18]. The algorithm considers multiple objectives, including minimizing energy consumption, maximizing data processing efficiency while maintaining a stable network connection. Xianfu Chen et al. propose a new approach based on deep reinforcement learning which optimizes performance of offloading algorithms in virtual edge computing systems [19]. Unlike other approaches which use traditional heuristics or machine learning algorithms, the proposed approach uses a deep-neural network to learn the optimal offloading policy in a data-driven manner. Junyao Yang et al. [20] propose an inverse order based optimization technique for resource allocation and task offloading in multi-access edge computing systems. It makes the offloading decision and resource allocation and optimizes them jointly using an inverse order optimization strategy unlike other approaches which consider them separately. Ting Wang et al. [21] propose an approach based on deep reinforcement learning (DRL) for improving the performance of task offloading in the Internet of Vehicles (IoV) scenario. The proposed approach uses a deep neural network to learn the optimal offloading policy based on IoV's dynamic and uncertain environment. Hongxia Zhang et al. [22] propose an ultra-low latency multi-task offloading approach for making task offloading decisions in mobile edge computing that considers multiple tasks with different requirements, such as computation, communication, and storage. The proposed approach uses a multi-agent reinforcement learning algorithm to make the decision to offload or not while satisfying the different task requirements. X Zhang et al. [23] propose an approach based on deep reinforcement learning for energy-efficient task offloading in secondary mobile edge systems. The proposed approach uses a deep-neural network to learn the optimal offloading policy in accordance with the dynamic and uncertain environment of the edge system. Mushu Li et al. [24] propose creating a cooperative edge computing framework to lower latency and increase dependability for vehicular networks. In order to determine the best option that reduces the cost of the service, a DDPG algorithm is used.

Juan Chen et al. [25] propose a multi-agent DRL solution to minimize total cost in terms of energy requirement of IOT device and long term renting cloud costs. They have explored centralized training and decentralized execution, hence, each IOT device will be a decision making agent. Xing Chen et al. [26] explore a federated DDPG solution for combined optimization of energy consumption and reduction in latency. The federated learning procedure ensures privacy of user data because only parameters of locally trained models are sent to central servers. Hao Meng et al. [27] constructs a DRL model with a new reward function design for optimizing the battery power of mobile devices. The reward function simulates the tradeoff between latency and battery consumption. Kun Wang et al. [28] formulated a Double DQN model to apply the task offloading concept to the Internet of Vehicles. This proposed algorithm solves real-time changes in the network due to user movement. Fuhong Song et al. propose a MORL algorithm to make the decisions with respect to task offloading when subject to multiple dependent tasks to optimize on three objectives, energy consumption, latency and user costs, simultaneously and using independent rewards for each [29]. They use tournament selection schemes to maintain previously learnt policies. Yu Chen et al. [30] investigated multi-user edge video analytics task offloading problems. The authors design two algorithms, one based on Game Theory and another based on the Actor-Critic method. The proposed A2C is observed to be more flexible, users can adjust accuracy decisions and achieve the converged reward.

III. MEC ARCHITECTURE

The considered architecture shown in Fig. 1 is similar to [2] where there is a set of resource constrained mobile devices M = {1, 2, 3, …. , m} and a single edge server in the MEC environment. We measure time using discrete timesteps where each timestep is equal to 100 milliseconds. All mobile devices are polled at the start of each timestep to check if any tasks have been generated. The following section explains the device and server models.

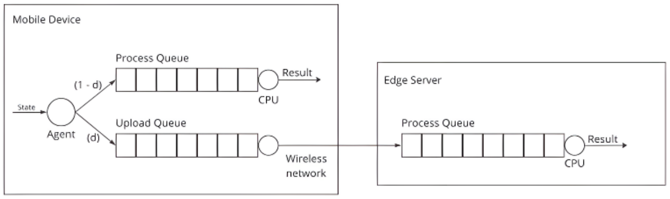

Fig. 1. MEC architecture

A. Device Model

The test environment consists of multiple mobile devices which generate non-divisible tasks with no interdependency which can either be computed locally on the device or on an edge server. Tasks can only be generated at the start of each timestep. The decision d as to whether a task has to be computed locally on the resource constrained mobile device or offloaded to an edge server is taken by a reinforcement learning (RL) agent. If the task has to be computed locally, it is first pushed into the local process queue of the device. The process queue follows a first-in first-out (FIFO) principle and once the task is computed, its result is returned. If the task is supposed to be offloaded, it is pushed into the upload queue of the device and subsequently uploaded to the edge server. Similar to the process queue, the upload queue follows a FIFO principle. It is assumed that once a task is computed or uploaded, the computation or upload process of the next task in the respective queue will be started only in the next timestep.

1) Task model: It is assumed that new tasks are only generated at the start of each timestep. Tasks are generated in all mobile devices with a probability of 0.3. For each task the parameters considered are, the task size (in bits), task timeout (in timesteps), algorithmic complexity and start time of the task. The task start time is the timestep at which the task was generated. In case a task is computed locally, the total execution time is equal to the sum of the duration of time spent in the process queue of the device and the actual computation time. Otherwise, if it is offloaded, the total execution is equal to the sum of the duration of time spent in the upload queue of the device, the time necessary to upload the task to the edge server, the duration of time spent in the process queue of the edge server and the time necessary to execute the task on the edge server. Each task has an associated timeout and if the task is not executed within the timeout, it is considered to be dropped.

2) Offloading decision: The Agent A makes the decision to offload or not d, depending on the state which contains the task timeout, task size, the time required to upload the task, time required to execute the task on the server and the local execution time of the task. d is a binary variable d {0, 1} where d is 1 if the task is to be offloaded or 0 if it is to be processed locally. As seen in Fig. 1, if d is 1 it is pushed into the upload queue of the device, else it is pushed into the local process queue of the device.

B. Edge Server Model

A single edge server is considered in our MEC environment. Tasks which are uploaded to the edge server are pushed into the process queue of the server only at the start of a time step. Before a task is pushed into the process queue of the server, we check if the task is going to be dropped, i.e, it is checked if the task has no possibility of getting executed within its timeout and if so, the task is considered to be dropped and the task will not be pushed into the process queue of the server. The tasks in the queue are computed in a First-In First-Out order. Instead of having one process queue for each mobile device, we maintain a single process queue for all devices. This has the same effect as having a process queue for each device and a First-In First-Out scheduler to pick tasks from all the queues.

C. Reinforcement Learning Environment

We consider a single edge server connected to multiple resource constrained mobile devices via a wireless network.

1) State space: State space is essentially the input to the RL agent to make the task offloading decision. It is a vector of task size, algorithmic complexity and the time before which the task must be processed.

2) Action space: Action space is the set of values that can be returned by the agent. The agent makes a binary decision (0 or 1) i.e. to offload or not.

IV. MULTI OBJECTIVE REINFORCEMENT LEARNING

Multi objective reinforcement learning is a type of reinforcement learning that aims to optimize multiple potentially conflicting objectives simultaneously to achieve ideal performance in real world scenarios. The architecture explained in the previous section is used to compare four multi-objective reinforcement learning algorithms in a simulated environment containing ten resource constrained mobile devices connected to a single edge server.

A. Actor Critic Method

The actor-critic method is a popular temporal difference (TD) learning approach that consists of two main components, the actor and the critic. The actor suggests actions that can be taken based on a particular state and the critic evaluates the actions taken after being suggested by the actor. Four neural networks are considered namely, actor, critic, actor-target and critic-target. The actor network outputs the expected Q value for each action and the action which has the highest expected Q value is chosen as the next action to be taken. The critic network is used to evaluate how good the action suggested by the actor network is. In addition to the state, the critic network also takes the action taken and the reward obtained as the input. Then, the loss is computed for both the actor and the critic networks and update them.

The actor-target and critic-target networks are used to stabilize the training of the actor and critic networks. At the end of each timestep the network parameters are partially copied from the main networks to the target networks via soft updates. Experience replay is used every 25 timesteps to effectively train the model. This algorithm outperforms all the previous algorithms with respect to drop rate and latency.

Algorithm 1: Actor-Critic method for task offloading

```
Params: Learning rate $\alpha \in [0, 1)$, small epsilon $\varepsilon$, $0 < \varepsilon < 1$, convergence parameter $\gamma$ close to 1
Initialize networks $Q_a$ , $Q_a$`, $Q_c$ and $Q_c$`
foreach timestep with task do
    select action a from the set of possible actions A
    using policy derived from $Q_a$`($\varepsilon$-greedy);
    if a is offload:
        add task to upload_queue at mobile device
    elseif a is local_computation:
        add task to process_queue of the respective mobile device
    observe reward R, next state s`;
    store the experience (s, a, R, s`) in replay-buffer
    $Q^*(s, a) = R + \gamma \max Q_c`(s, a)$
    compute mean squared error between $Q_c(s, a)$ and $Q^*(s, a)$, update critic network
    update actor network using loss$\leftarrow \frac{1}{N} \boldsymbol{\Sigma}_i Q_c (s_i , \max Q_a(s_i, a))$
    update target networks
        $\theta_a` \leftarrow \tau \theta_a + (1 - \tau) \theta_a`$
        $\theta_c` \leftarrow \tau \theta_c + (1 - \tau) \theta_c`$
    $s \leftarrow s`$
    use experience replay to train the actor and critic networks every 25 timesteps
end foreach
```

B. Objectives

The multi objective reinforcement learning model aims to optimize three objectives namely, the task drop rate, latency and the energy consumed by the device.

Task drop rate: The task drop rate is the number of tasks dropped until the current timestep divided by the total number of tasks that were generated until the current timestep.

Latency: Latency is the duration of time between task generation and task completion.

latency = d * (upload_latency + process_latency_server) + (1 - d) * (process_latency_device)

where,

d is the decision to offload or not which takes a binary value (0 or 1)

upload_latency is the total timesteps required to upload the task

process_latency_server is the total timesteps which the server takes to execute the task taking into account the server load (time spent by the task in the process queue of the server)

process_latency_device is the total timesteps taken by the mobile device to execute the task considering the time spent by the task in the process queue of the device.

Energy: It is the energy utilized by the mobile device from the moment the task is generated on it, to the moment the task is completely processed. Naturally, offloaded tasks use a lot less energy than the tasks that are processed locally.

energy = d * (latency * idle_energy_rate) + (1 - d) * (latency * active_energy_rate)

where,

idle_energy_rate is the energy utilized by the device in its idle state

active_energy_rate is the energy utilized by the device during execution

Single objective optimization usually comes at the expense of other objectives which might make the solution not feasible for a lot of real-world applications where we often need to jointly optimize multiple objectives. Multi objective reinforcement algorithms are handy in such scenarios.

C. Reward Engineering

The reinforcement learning agent is given some reward as a result of every action it takes. It gets a positive reward if it takes an action that contributes towards optimization of the objective, otherwise it is punished with a negative reward.

When it comes to multi-objective reinforcement learning where the model optimizes the task drop rate, energy and latency, three rewards need to be considered.

1) A reward of +1 is given to the agent if the task gets executed successfully within its timeout, else it is given a reward of -1. A task is considered to be dropped if it cannot be executed within the timeout specified for that particular task.

2) With regard to energy, we consider a threshold of 0.5 mJ if the task is offloaded and 160 mJ if the task is computed locally. This difference is due to the fact that when a task is offloaded, the mobile device consumes energy only to offload the task and not execute it. The agent gets a reward of +1 if the energy consumed for the given task is below the threshold, otherwise it gets -1 as the reward.

3) Similarly, if the latency for the given task is below 2000 ms, the agent gets a reward of +1, else -1.

The establishment of these thresholds was the outcome of experimentation. It was observed that the average amount of energy consumed per task and the average latency over a period of time for the given task parameters were 0.5 mJ / 160 mJ and 2000 ms respectively in our simulation environment. The three rewards are combined using a set of weights that add up to 1 to obtain a single total reward that is utilized to train the multi-objective reinforcement learning agent. The weights can be changed accordingly if a particular objective is required to have a higher priority than other objectives.

V. Experiments

The experiment was run with different models with tasks generated at the mobile devices with a probability of 0.3 at each timestep. The model under training makes the decision as to either offload the task or to process it locally. The task is appended to the respective mobile devices' upload queue if it is to be offloaded. If the task is to be computed locally, the task is appended to the local computation queue of the mobile device. The experiment is run with ten mobile devices and one edge server for 10,000 tasks. The latency, energy and drop rate is monitored and recorded during the experiment.

VI. Experimental Results

The MEC environment is simulated with ten resource constrained mobile devices and one edge server. We implemented and compared four multi objective optimization algorithms in the same environment with uniform random policy, which is a standard benchmark for any RL model. All the multi objective reinforcement learning models aim to optimize the task drop rate, energy and latency.

We compare the performance of the MORL Actor-Critic model with three other MORL models.

1) MORL-Tabular: We apply the Tabular Q learning algorithm to make the task offloading decision in our MEC system. We consider the four parameters task size, algorithmic complexity, timeout in timesteps and store the action-value pair in a table. In each iteration, the Q-learning model refers to the previous action-value pairs from the table and based on the bellman equation for each update the new action-value pair. Tabular Q Learning can be used for solving problems where the number of states is not large as the storage is limited. Once the problem size increases, we cannot scale Tabular Q Learning, especially in environments where the state space has continuous values.

2) MORL-DQN: We implemented the Deep Q Learning algorithm where, instead of a table we make use of a neural network to map a particular state to an action value, i.e the neural network takes the current state as the input and we get the expected Q value as the output. The action which has the highest Q value stands as the most optimal choice for the present state. We consider the task size, task timeout, time taken to upload the task, time taken to compute the task on the server and time taken to complete the task on the mobile device to make the decision as to whether the particular task at hand should be offloaded to the MEC server.

3) MORL-DDQN: Although Deep Q Learning algorithms perform well, there exists a maximization bias. If at any point in time the Q value is overestimated, the error gets compounded overtime and leads to suboptimal policies and poor exploration. To overcome this issue, in Double Deep Q Learning, two neural networks are used instead of one. We assume one network as the target Q network which is updated less frequently and is used to calculate the target Q values for the Q value update of the other neural network called the online network. The online network is used to determine the best known action in a particular state. The weights of the online network are copied to the target network intermittently.

B. Cumulative Reward

In MORL, a positive reward is given to the model for not just executing the task successfully but also if the task is executed within a limited latency and limited battery utilization of the edge device. A negative reward is given if the task is dropped or if the task is not executed within the thresholds of energy or latency. Fig. 2 shows the plot of cumulative reward vs. timesteps. Although, an analysis is necessary, it is unreasonable to infer the comparison of agent performance from this plot alone.

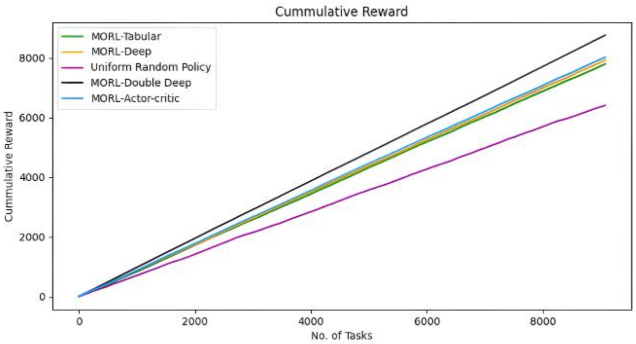

Fig. 2. Cumulative reward of different models.

C. Drop Rate

The crucial factor to adjudicate the performance is the total tasks dropped as a result of the decision made by the models. Each task has a timeout within which the task must be executed, otherwise, it is considered to be dropped. At each timestep we calculate the number of dropped tasks. This factor can be used to consider the task offloading problem as a minimization problem. Fig. 3 shows that uniform random policy drops a significant number of tasks. Deep MORL models, on the other hand, have the running task drop rate close to zero. The MORL actor critic model not only decreases the drop rate but also improves the stability of its output compared to both DQN models.

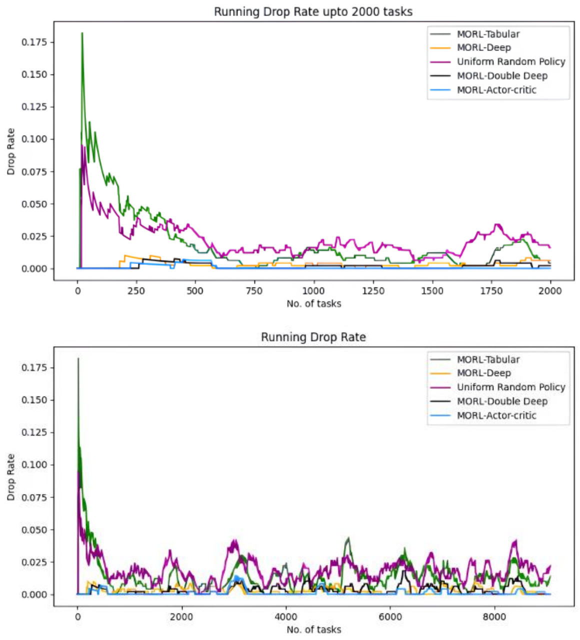

Fig. 3. Running drop rate of tasks.

D. Latency

The second most important factor to adjudicate the performance of our models is how quickly we are able to execute all the tasks. The agent gets a positive reward if a task is executed within the latency threshold or else it gets a negative reward. From Fig. 4, it can be seen that the MORL-DQN model performs considerably well compared to the tabular MORL model and uniform random policy. The MORL actor critic model estimates and optimizes the latency significantly compared to the other approaches.

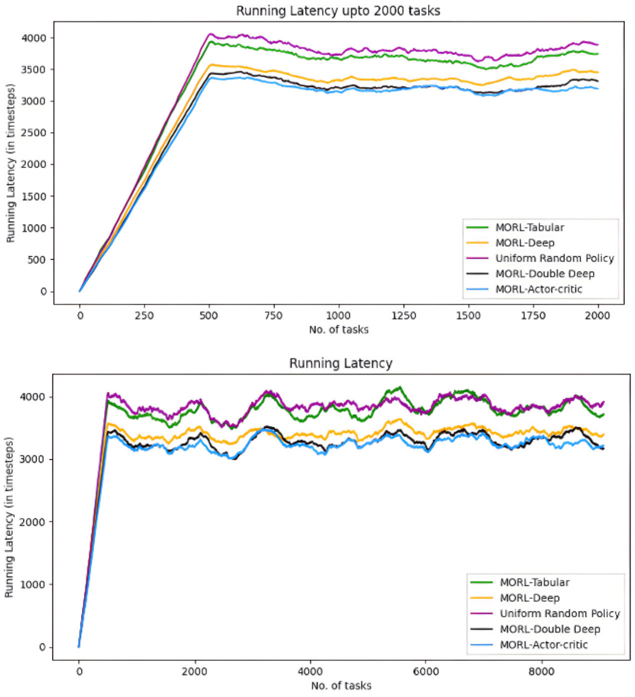

Fig. 4. Running latency of execution of tasks.

E. Energy

Another important factor to consider is the battery consumption to process the tasks at the edge device. This factor allows the model to take into consideration that we intend to minimize the battery utilization of the edge device. Hence the decision made by MORL is not just influenced by latency or drop rate but also by battery consumption. We have set a threshold for each device and if a task is going to get executed locally, we want those tasks to be executed within this threshold. In such cases, we provide the agent with a positive reward and if any task's execution crosses the threshold, we provide the agent with a negative reward.

From Fig. 5, it is observed that the Deep MORL model does considerably well compared to all the other models. The tabular MORL model performs quite well but doesn't provide the same stability that the deep MORL model gives. It is true that MORL actor-critic leads to a greater amount of energy consumption on average than other approaches, but it is due to the fact that more tasks are executed on the mobile device as compared to other algorithms to achieve better drop rate and latency. It shows a greater degree of stability compared and better overall performance on all objectives.

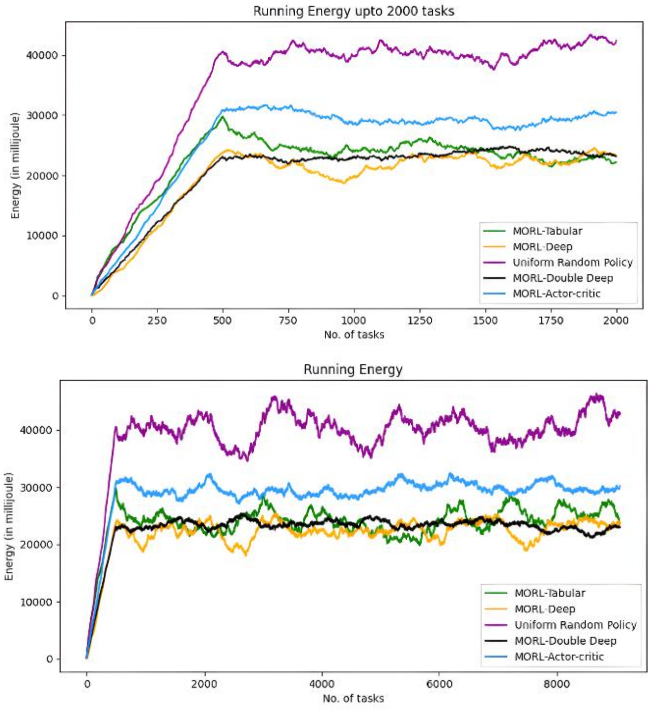

Fig. 5. Running energy consumed by the edge device.

F. Comparison

Table I provides a comparison of the results obtained when all algorithms were applied to 3000 episodes using 10 edge devices connected to a single MEC server. All edge devices generated a total of 9073 tasks.

G. Benefits of Multi-objective Optimization over Single-objective Optimization

Single objective approaches seem to outperform the multi objective ones on the objective which they have been trained to optimize. However, a closer look into the performance of all objectives will reveal the obvious superiority of multi-objective reinforcement learning approaches. To better understand the aforementioned claim, we compare a SORL model [31] which optimizes energy consumption and the MORL actor-critic model.

TABLE I. RESULT EVALUATION TABLE

	Objectives			**Decisions**	
Model	Net Drop Rate	Mean Latency (in timesteps)	Mean Energy consumerd (in mJ)	Offload	Local
MORL-Tabular	0.0406	22.963	147.5110	5891	3182
MORL-DQN	0.0083	20.690	**136.1579**	6304	2769
MORL-DDQN	0.0081	19.853	140.6437	5187	3886
MORL-Actor Critic	**0.0034**	**19.62**	179.6439	4861	4212
Uniform Random Policy	0.0590	23.521	248.1667	4515	4558

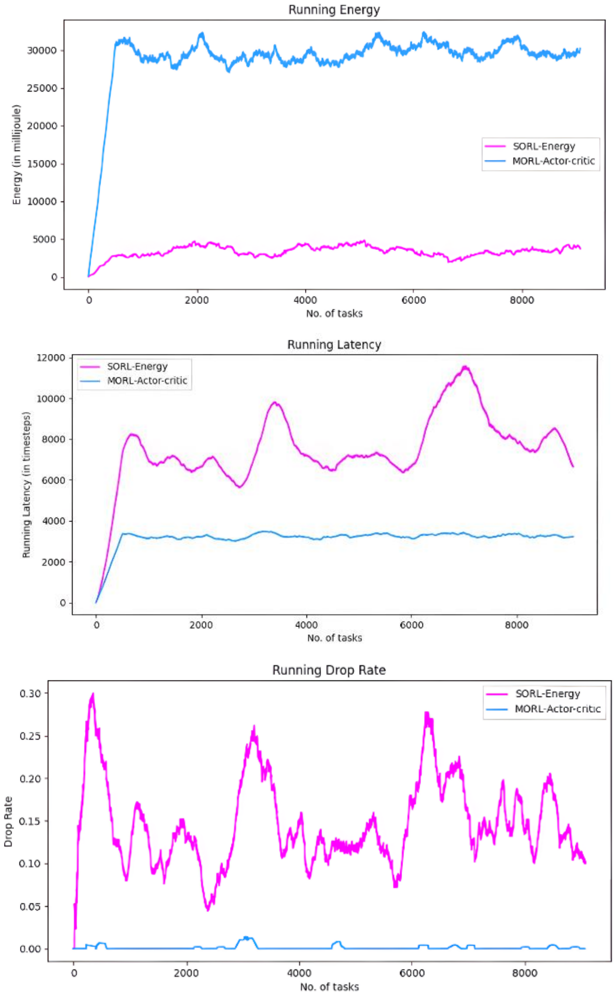

Fig. 6. Comparison of objectives' performance using single-objective and multi-objective optimization techniques.

Fig. 6 shows that the SORL model performs exceptionally well in terms of the objective that it optimizes, i.e, energy consumed. It offloads most of the tasks to the edge server to cut down on the energy consumption. However, this comes at a cost of drop rate and latency. The drop rate and latency achieved by the SORL model is unacceptable in real world applications, whereas the MORL actor-critic model optimizes all three objectives reasonably well which makes it more practical.

We conclude with the observation that the agent trained using the MORL actor critic method exhibited the best overall performance.

VII. CONCLUSION

Multi-access Edge Computing (MEC) tries to improve user experience and reduce energy consumption. It is a popular and emerging paradigm that takes the cloud closer to resource constrained mobile devices. A general scenario depicting the interaction between a few mobile devices and a MEC Server is simulated in which four multi-objective reinforcement learning algorithms are compared. From the results observed, we can conclude that multi-objective reinforcement learning based actor critic model outperforms other models in terms of both latency as well as task drop rate.

A Review on Applications of Electroencephalogram: Includes Imagined Speech

S. Santhakumari, Kamalakannan.J
School of Computer Science Engineering and Information Systems, Vellore Institute of Technology, Vellore, India

***Abstract*—In the last two decades, the Brain-Computer Interface system with EEG signals has assisted people in various ways. In particular, to patients with paralysis, epilepsy, and Alzheimer's disease, not only to the patient but also to physically, visually challenged people and Hard-of-Hearing people. One of the non-invasive methods that can read human brain activities is Electroencephalogram (EEG). The EEG has been used in many applications, especially in medicine. The applications of the EEG are not limited to the medical domain; it keeps extending to many areas. This review includes the various application of EEG; and more in imagined speech. The main objective of this survey is to know about imagined speech, and perhaps to some extent, will be useful future direction in decoding imagined speech. Imagined speech classifications have used different models; the models are discussed, the significance of choosing the number of electrodes, and the main challenges in EEG.**

Keywords—Electroencephalogram; brain signals; invasive; non-invasive; imagined speech; electrodes; epilepsy

I. Introduction

Speaking, hearing, seeing, and moving are all necessary to humans. However, few people are having issues with that, either by birth or due to illness. They could not lead an everyday life. However, technology and science can provide some alternatives for them. Artificial Intelligence (AI) and Brain-computer Interface (BCI) [1] are considerable gifts to them to lead a better life. The Brain-Computer interface system introduced during the year 1973 by Jacques Vidal. It converts the human brain signals into instructions for the computer [2].

In the last two decades, Brain-Computer Interface had a vital role in the field of the medical domain. In particular, for those who have paralyzed, have a seizure problem, have a brain disorder, have speech problems, have hard of hearing, and so on., it has given confidence to them in assisting in many ways. Specifically, they are not necessary to depend on others. A fully paralyzed person has motor issues, eyeballs that will not move, and articulation problems. They cannot communicate in any other technique except brain wave with the BCI system [3] because, cognitively, they are normal. Invasive and non-invasive methods are available to read brain signals. Many researchers have used these methods, but for the practical approach, non-invasive is more suitable rather than invasive. Complete details were in the other sections of this systematic review. Imagined speech, covert speech, inner speech, and intended speech are new paradigms for researchers. No phonetic sounds, but tongue and jaw movements will be present are refers as silent speech. Imagined speech is akin to silent speech, but tongue and jaw movements will not be present; a person should be in verbal thinking [4].

As per Proix et al., non-invasive methods have not given convincing results and have limited success due to brain signals taken on the scalp by either EEG or MEG technique during the imagined speech; brain signals are weak and vary with overt speech [5]. Instead of non-invasive, Proix et al. used invasive techniques. Many researchers have applied Machine learning or Deep learning algorithm to decode imagined speech using non-invasive.

The deep learning method required massive data to train the model for good accuracy [6]. This systematic review includes details of the few machines learning algorithm and the deep learning algorithm applied in decoding EEG signals by the researchers. Reddy et al. proposed Hamilton-Jacobi-Bellman (HJB) equation to get an optimal update rule for training Feed Forward Neural Network (FFNN); in this, the author achieved faster convergence and better performance [7].

In any BCI application, the brain signal controls the system. BCI system is composed of four different phases. Signal Acquisition, Feature extraction, classification, and device output [8]. Reading electrical activity of the brain is called signal acquisition. Different modalities are available to acquire the signals in the brain; EEG is one of the modalities. The details have given in the following section. Feature extraction is a method of analyzing the signal as per the application. Assign a label to the extracted feature in the classification result; this will enable specific control commands like cursor control, robotic arm movement, and user feedback. Thus, it closes the loop [8, 9]. Before performing all these, people must know about the human brain.

II. Brain Anatomy

The human brain has divided into two different portions: the cerebellum, a smaller portion, and the cerebral/cortex, a large portion of the brain. The brain's cortex area has divided into four different lobes: frontal lobe, parietal lobe, temporal lobe, and occipital lobe, respectively. Each lobe has its function. The frontal lobe is associated with cognitive function, speech, and short-term memory.

The responsibility of the parietal lobe is to have senses like smell, taste, and touch. The temporal lobe is associated with the hearing and memory process. The occipital lobe recognizes color and visual processes. Broca's and Wernicke's are associated with speech and language [10].

A. Brain Signals

The brain generates the electrical activity of the brain signals. During the electrical activity, electrochemical signals pass through the entire brain region with oscillation; they are called brain signals [11]. Delta (δ), Theta (θ), Alpha (α), Beta (β), and Gamma (γ) are the five different brain signals generated in the human brain [12]. Details of brain signal's frequency and its associated characteristics are provided in Table I.

TABLE I. CHARACTERISTICS OF THE BRAIN WAVE

Frequency Band	Frequency in Hz	Brain states	Originating place
Delta (δ)	0.5 - 4	Sleep	Frontal lobe
Theta(θ)	4 -8	Deeply relaxed	Temporal lobe
Alpha(α)	8 - 12	Very relaxed, eyes are closed	Frontal lobe & Occipital lobe
Beta(β)	12 - 35	Active, high awareness, and eyes open	Frontal lobe & central
Gamma(γ)	Above 35	Full concentration	Frontal, Temporal, and Parietal Lobes

B. Brain Signals Acquisition

There are two methods in the signal acquisition, namely Invasive and non-invasive methods. The first method required surgery to implant the electrodes in the brain's cortical area. The second one does not require implanting. Moreover, for research and practical purpose, it uses the non-invasive method. Its ease of use, cost-effectiveness, better accuracy, and reliability with the advancement of technology is why it prefers the non-invasive method [13]. Invasive type of electrode requires surgery to implant. Electroencephalography (ECoG) should place on the brain surface under the skull. ECoG provides electrical potential measured directly on the brain surface at a high spatial and temporal resolution without filtering the signals through the skull or scalp [14]. Intracortical electrodes are inserted in the cerebral cortex to record electrical signals. Any invasive electrodes have high spatial and temporal resolutions with the drawback of neuronal damage [15, 16]. Electroencephalography (EEG) Hans Berger recorded his first EEG in 1924. It is a non-invasive type [17]. Traditionally EEG is considered low spatial resolution but good at a temporal resolution [18]. A few researchers proved that the EEG is good at spatial resolution using surface Laplacian computation [19] and Tripolar Concentric Ring Electrodes [20] and combining EEG and fMRI to encode visual stimuli [21]. Magnetoencephalography (MEG) measures brain activity by the magnetic field generated by the electrical activity of the neurons. It provides high spatial and temporal resolution than the EEG [22, 23].

Functional Magnetic Imaging (fMRI) Clinical laboratories use Functional Magnetic Resonance Imaging (fMRI). When a particular brain area is active, that area will have more blood flow. fMRI finds the activity of the brain during changes in blood flow. The fMRI is good at spatial resolution and poor at a temporal resolution [24, 25]. Functional Near-infrared Spectroscopy (fNIRS) is a non-invasive brain signal acquisition device. Which is used widely in clinical applications like Parkinson's, Alzheimer's diseases, and childhood disorders could be diagnosed, and also it could be used in the Brain-computer interface. It emits less radiation, is user-friendly, has less cost, and is portable [26].

Among all non-invasive methods, EEG is the better option for researchers. Because of these reasons, easy to use, cost-effective, portable, and good at temporal resolution. In general, spatial resolution is low. However, it could enhance with Surface Laplacian computation [19] and Tripolar Concentric Ring electrodes [20] and more use of practical applications. 1 to 256 channels are available.

C. International Standard 10-20 EEG System

EEG signals are non-linear and highly non-static. The numbers 10 and 20 are the distance between adjacent electrodes. 10% and 20% of the total distance of the skull from the front to the back or left to right [26, 27]. Reference points of the measurements are Nasion (which is between nose and forehead), Inion (which is the lower point of the skull), vertex (which is the center point on the top of the skull), and pre-auricular points anterior to the ear. Moreover, F, T, O, and P denote the Frontal Lobe, Temporal Lobe, Occipital Lobe, and Parietal Lobe of the brain area. Sub-indexes indicate even or odd numbers for the right and left hemispheres [28].

Researchers are using three kinds of evoked potential to measure the electrical activity of the brain. Three kinds of evoked potentials are used to measure the human brain's neuron activity during a stimulus and response. They are:

Auditory Evoked Potential [29], Visual Evoked Potential [30], and Somatosensory Evoked Potential [31], respectively. In his 2017 study, Spüler wrote that Visual Evoked Potential (VEP) has significant communication speed in non-invasive EEG. To read an electrical signal from the brain gel-based electrode or dry electrode could be used. The application of gel-based electrodes takes more time to capture the signal. In order to create a more user-friendly BCI system, we can use dry EEG electrodes with a VEP-based system. However, it gives high variability between the subjects. Introduces averaging and dynamic stopping methods to mitigate the performance variability and deal with the lower signal-to-noise ratio of dry electrodes [32].

III. PREVIOUS WORKS IN EEG

Though the invasive method is sound in SNR and spatial resolution and apt to the BCI application, the risk factor is possible after the surgery [33]. Therefore, researchers are choosing the non-invasive method. The medical domain uses EEG for early identification of Alzheimer's, Parkinson, Paralyzing, and Epilepsy, and monitoring Anesthesia drug levels during surgery. Few researchers are also showing more interest in the non-medical domain, like decoding covert speech; this will be useful to impaired people, even brain-id for authentication purposes, Emotion detections, and in-home appliances.

The EEG signals have been used in many applications related to brain wave analysis, like the presence of epilepsy, to classify the covert word, brain-computer interface to activate external devices, and Emotion detection.

A. EEG Applications in Diagnosing Brain Disorders

1) Epilepsy: Conventionally neurologists go for a direct visual method to predict the epileptic abnormality. However, it takes more time to predict, may produce a variable result, and abnormality has limitations. Nowadays, to predict the above abnormality, a Computer-Aided Diagnosis is used [34]. In their work no separate steps for feature extraction and feature selection because they used the deep CNN model; this is one of the models in the deep learning technique [35]. The model will help predict Seizure disease. However, the data set was not enough for excellent performance, and the data should increase or apply data augmentation method [36] to achieve optimal performance of the result.

In another research, the author compared various Ensemble methods like bagging, boosting, Ada boosting, Multi boosting, random subspace, and rotation forest to discriminate the non-epileptogenic region of the brain with the epileptogenic location of the brain. They concluded that the rotation forest classifier had high performance [37].

2) Parkinson's disease: Many Parkinson's patients have a problem with locomotion. They will get stuck in forwarding movement while walking due to the Freezing of Gait (FOG) issue. One study revealed that it is possible to predict the FOG of Parkinson's disease (PD) before happening through EEG visual or auditory cues. The author investigated the specific EEG feature to implement real-time FOG prediction [38]. They used three layers-back propagation neural network model. They achieved 85.86% of sensitivity and a specificity of 80.25%.

B. EEG Applications in Emotions Detection

Emotions are the real feelings of humans, and the human brain controls them. Every human can have positive and negative emotions [39]. Positive emotions are love, happiness, surprise, joy, etc., as negative emotions are guilt, sadness, and annoyance. In various situations, they generate these emotions. If the emotions are within a limit, no problem for humans, or it may affect their health. Early identification of these problematic emotions makes it possible to reduce the many problems. Initially, the researchers detected these emotions using facial expressions, Text, or gestures [40]. They developed a model to recognize their facial expression or their gestures. However, nowadays, researchers are interested in using the human brain with the help of EEG. Much research has been available to classify emotions in the last decade. One study concluded that the neurons in the left hemisphere are active during positive emotions, and those in the right hemisphere are active during negative emotions [41].

C. EEG Application in BCI

One of the main aims of the BCI is to assist the paralyzed person in communicating with the outside world by controlling assistive devices through their brain signals without moving their legs or hands so that the dysfunctional motor system can bypass them. Some neuronal disorders cause patients to suffer significantly from impaired communication, including amyotrophic lateral sclerosis (ALS). As per the study by Chaudhary and his team in 2001, paralyzed patients could communicate with the aid of multiple brain-computer interfaces (BCI), including those that use electroencephalography [42].

P300 speller is one of the most popular BCI applications. There is a possibility to increase the performance of the P300 in practical usage. The author has examined the correlation between the P300 speller's versions with Rapid Serial Visual Presentation (RSVP) task features in this paper. In this study, the author identified the features of the correlation between the ERP (Event Relation Potential) and its behavior in offline binary classification accuracy. Using these features, the author proposed a simple multi-feature predictor. Their study revealed that a multi-feature predictor model could achieve higher predictability than the single-feature predictor model [43].

A recent study shows that a new system dimension controls the categories of people with speech problems and with ordinary people to assist them in everyday life by humming [44]. This article revealed the feasibility of EEG in BCI with vocal Imagery and vocal Intention. Four types of tasks were instructed to the subjects to perform, non-task specific (NTS), motor task (MT), vocal Imagery task (Vim), and vocal Intention task (VInt). The author concluded that the Vim task was highly classifiable in the EEG paradigm with BCI systems.

In their 2019 study, Kim et al. believe that the application of Brain-Computer Interface has been reaching out to non-medical applications too. That controls home appliances like a TV, digital door-lock, and electric light [45]. In another research, the author developed an assistive BCI system, which is helpful to differently-abled people. It will generate synthesized speech while the eye is blinking. During EEG recording, when the subjects notice the desired option on the display, they will wink their eyes; the system generates the synthesized speech per the options display. This system will be helpful to a patient who has a locomotive disorder like "locked-in syndrome"; this patient can communicate with their caretaker. This model could be used only for patients who have neurology disorders. Here the author suggested that instead of eyeblink EEG signals better to identify imagined movements through EEG signals [46].

D. EEG in Authentication

In information security, authentication is essential for in-person identification. Many techniques exist, like hand signature, password, fingerprint, iris, face, and voice recognition. However, all these have vulnerabilities. There is an alternative technique for every authentication technique, like forgery in the hand signature; the password can hack, film for fingerprint, contact lenses for the iris, face masks, and a voice vocoder [47]. Brain signature is the best solution because it is unique and cannot steal or hack. In one study, the author used only Alpha and Beta waves captured through EEG while subjects read 4-digit numbers when they saw numbers. A linear Discriminant algorithm (LDA) have used in the classifier. The training model has taken Common Spatial Analysis (CSA) values. Before authenticating, the trained model should have all the user's details. Finally trained model is used to authenticate the user [48]. In the later study, the author found that the delta wave has more specific information in user identification among all the five brain waves [47].

This research used biometric authentication to identify the individual using the brain signal system. The author captures EEG signals while performing three mental tasks with the participants. The author adapted a novel protocol and algorithm using NN and used mu and beta waves with a single trial analysis to test the novel algorithm. The Levenberg Marquardt back propagation algorithm trained NN. This research shows that the reading task is more suitable for biometric verification [49].

E. EEG in Imagined Speech

In the world, approximately nine billion people have problems speaking and hearing either by birth or accidentally last their speaking and hearing capability. It is tough for them to speak with ordinary people. With the same community, they can communicate with their sign language. (Communication between visually challenged and ordinary people is acceptable since they can speak well). Many researchers have developed an assistive tool that helps hard-of-hearing people communicate with ordinary people by converting sign language images into audible speech.

Recently researchers are showing interest in decoding the intended speech using brain waves invasively or non-invasively. In the last year, a few scientists have proven that imaged speech can interpret by implanting electrodes invasively using AI in the medical domain.

Imagined speech or covert speech, or inner speech, is a new paradigm used in the Brain-Computer interface to assist impaired people in communicating with the outside world for those who cannot produce the speech either partially or entirely or due to any health issues. Imagined or covert speech means thinking of a word without having articulation sound or tongue movement. An Imagined word could capture in EEG.

Since the last decade, researchers have been involved in imagined speech using EEG brain signals. Decoding silent speech will be helpful in many aspects like locked-in syndrome people, cognitive biometrics, and entertainment [50]. All the researchers used a complete band frequency with the different channels and subjects. However, Valuable information may not be present in the EEG signal during the analysis period <100ms. Better decoding accuracy in the classification, especially in the phase pattern in Theta and Delta waves [21].

This systematic review contains the classification performance result of the model. The researchers used the subjects to imagine the different vowels, consonants, words, both the vowel and words, and directions in symbols or words and objects. They used different classification algorithms. Most researchers applied benchmark algorithms like SVM, Random Forest, and LDA.

Methodologies used in imagined speech classification: Support Vector Machine (SVM) has been used in EEG classification for the diagnosis of neurological disorders [51]. This model was used effectively in many applications for disease prediction analysis, particularly in the medical domain. The linear SVM is an efficient technique for high-dimensional data application. Nowadays, researchers have used EEG brain signals to decode imagined speech. Support Vector Machine (SVM) is used in imagined speech analysis using EEG signals. The following article has evidence of the application of SVM to classify vowels and consonants [21, 52, 53]. To classify the Imagined word [50]. In one more repeated study, SVM as a benchmark algorithm is used to classify the vowels [54].

Extreme Learning Machine (ELM) is another effective classifier. Many real-time applications use the ELM technique. It is for binary as well as multi-class classification. It has a high learning speed, so researchers have used this model in robotic applications [55]. Since its fast-learning capability and no iteration, the reason is that a single hidden layer connects the output layer; it is used in EEG applications to classify the imagined vowels and words [53, 56]. The performance of ELM in sparse high-dimensional applications which are currently under investigation [57].

In Decision Tree (DT), only training data is sufficient because once the decision tree is present with the help of training data, it can support new samples. While classification, new data was inserted without disturbing the entire tree. Moreover, it is very flexible to include the sample [58].

The importance of channel selections and reducing electrodes are in the next section. For these, the decision tree algorithm is suitable because EEG signals may contaminate with noises or contain irrelevant information, which will reduce the classification's performance. One study revealed that a decision tree could improve performance.

Furthermore, the authors proved that the decision tree is better than the following algorithms: Mutual information, SVM, CSP coefficient, and Fisher's criterion, respectively [59]. It is easy to interpret the brain signal by a decision tree. However, if the data set is large, then it is challenging. For smaller data decision tree is more suitable for decoding silent speech [50, 60].

Random Forest (RF) is another classifier. Recent study proved that sufficient electrodes could reduce the time and effort in analysis during EEG signal classification by the time Random Forest model [61]. The random forest model is an improved version of the decision tree, widely used in EEG signals classification. The Random Forest model is used as a benchmark classifier to classify vowels and words [54] and in the imagined word classification[50].

Linear discriminant analysis (LDA) is a familiar feature reduction technique to project the features in higher dimension space into lower dimension space. Moreover, as a classifier, it is used. It creates a new axis from the features, reducing the variance and increasing the two variables' class distance. The main drawback of LDA in feature reduction is required all the features as the input signal. The new feature is calculated based on all the observations. This situation will not occur in real-time BCI applications [62].

K-Nearest Neighbor (KNN) is a multi-class classifier. It does not take training duration; the reason is that the data itself is a model. Implementation is straightforward when compared with another classification algorithm. The reason is that it just calculates the distance between the different features using either Euclidian or Manhattan**.** Moreover, it has only one hyper-parameter k and several clusters. However, it has a few drawbacks also.

For small datasets, it works well, but not in large datasets and high dimensional data sets. It also takes more cost to calculate the distance. Noise and missing data can affect this model. In the imagined word classification, Naïve Bayesian and MLP models are used [50, 63].

Classifying the EEG signal with a few layers in CNN is impossible. For better classification accuracy Deep Neural Network could be the best for the EEG imagined data [64]. CNN[54, 64, 65] RNN and DBN[66], DNN[67]. The DBN was introduced in 2006 and, in the next year, was analyzed by Bengio [68]. The table shows the pros and cons of the various classifier.

1) Subject focused on imagine vowel and consonant: Table II depicts various studies involved in classifying imagined speech with vowel and consonant using different model. One study shows the discrimination between the vowel sound of /a/, /u/, and rest as control states for the imagined. The vowel /a/ and /u/ was the following muscles involved while uttering these vowels. They are digastric and Orbicularis Oris muscles [52]. They used a linear classifier and SVM to give the excellent performance result in the table.

TABLE II. IMAGINE VOWELS AND CONSONANTS

Reference	Vowels/ Consonant	Classifier	Performance
[21]	/a/, /e/, /i/, /o/, /t/	SVM	δ, θ has better classification accuracy in the phase pattern
[52]	/a/, /u/, rest	Linear, SVM	87.5 – 100% 78.33 – 96.67
[53]	/a/,/e/,/i/, /o/, /u/	ELM	68.5%
[65]	/a/,/e/,/i/, /o/, /u	CNNeeg1-1 Compared with DL Shallow CNN	65.62% in BD1 and 85.66% in BD2

In another study, the vowels /a/, /u/, / i/, /o/, and /u/ were used. They aimed to classify the imagined speech of EEG using a single trial [53].

In the Feed-Forwarded Neural Network [6], all the weights and biases are necessary to tune each layer. It slows down the process. Therefore, the author used the ELM method. G. Huang invented ELM [53, 57], which uses random weight to calculate output weight analytically. Hence learning speed is significantly high compared with other conventional neural network algorithms.

Normally classifying EEG data gives poor generalization overfitting due to limited samples. However, the generalization was good in this research and achieved minimum squared training error. The result shows that the ELM and its variants have better classification results than other algorithms [53].

One more research conducted used all the vowels /a/, /u/, /i/, /o/, /u/ and created a new dataset with 50 subjects. In this, they proposed a new algorithm named CNNeeg1-1 in deep learning to classify imagined vowels in EEG signals and compared the performance of CNNeeg1-1 with DL Shallow CNN and EEGNet benchmark algorithm by an open-access dataset (BD1) and a new dataset (BD2). CNNeeg1-1 performs better than the other mentioned algorithm, with 65.62% in BD1 and 85.66% in BD2 [65].

Another study used English alphabets /a/, /e/, /i/, /and /t/ they identified that the EEG phase signals have more information than the other frequency band of the EEG signal during auditory and visual stimuli. So decoding accuracy is more in EEG phase signals than the power information.

Also, it is possible to get good accuracy in decoding during the time between 180ms and 300ms after the appearance of the stimulus [21].

Subject focused on imagine words: Table III shows that some of the researchers used specific words instead of using either vowels or consonants. So that the model will be helpful to persons who are not able to speak or not able to move their bodies; they could get help from the caretaker.

TABLE III. IMAGINED WORDS

Reference	Words	Classifier	Performance
[10]	Go, back, left, right, stop	ELM	40.30% and 87.90% in multi-class and binary class
[50]	Sos, medicine, stop	RF, DT, KNN, SVM	76.4% in theta wave.
[63]	Yes, no, the rest state	MLP	Yes vs. rest 73.73% No vs. rest 75.38% Ternary classification 53.91%
[66]	10 CVC	RNN, DBN	72% & 80%
[67]	In, Cooperate	DNN	71.8 %
[69]	Forward, backward, up, down, help, take, stop, release	ResNet18+2GRU	85%
[70	Ambulance, hello, light, stop, toilet, water, clock, help me, pain, thank you, TV, and Yes.	RF, SVM	39.73±5.64% in imagined speech. 40.14±4.17% in visual imagery.

It is possible to develop more intuitive BCIs for communication-based on BCI activation tasks involving covert speech. The author used 'Yes' and 'no' as imagined words [63]. In the same year, Quresh et al. conducted more research to classify the five words: go, back, left, right, and stop. They used a sigmoid activation function-based linear ELM classifier and all the frequency bands. The author suggested that δ and α can be used instead of all the frequencies. Because more activation processes were present in that frequency band [10], they achieved good classification results in both the multi-class and binary classification.

In another research, the author suggested that acquiring EEG signals from more channels will increase the training data size. It improves the classification accuracy in the deep learning technique [67]. Furthermore, channel selection also has a vital role [18]. It is easier to train a DNN if the selected channels correspond to individual imagined words and are considered independent data vectors [67]. This author has taken two words to decode one short word, 'in' and one long word, Cooperate, and the DNN model gave a 71.8% performance result. A large data set is required to build a neural network classifier for good accuracy. In another paper, Vorontsova confirmed that a small data set is enough to construct a more accurate neural network classifier on EEG in a single participant subject rather than a group of subjects with an extensive data set. In addition, they concluded that limited sample EEG data could apply to the general population [69]. In silent EEG, speech recognition with Russian words: Forward, backward, up, down, help, take, stop, release, and pseudo-word. The research conduct result shows that RNN yields good accuracy than CNN.

To identify the vowel from Consonant-Vowel-Consonant words were used RNN and DBN models. From the brain connectivity estimator result, the author identified that more electrons are activated during speech and imagery speech in the left frontal and left temporal portions. Deep Belief Network has given a better classification result than the RNN [66].

A recent study by Agarwal & Kumar (2021) analyzed all the brain waves of the three words of silent speech sos, medicine, and stop. The research result was 76.4% accuracy in the theta wave. This research identified that more details would be available in theta and high gamma waves during a silent speech [50]. Moreover, some words share a similar pattern in brain activity [69]. Decoding EEG signals with more classes is also not advisable. In multi-class classification, the author found that the decoding performance may reduce moderately due to the more feature in imagined and visual imagery speech while decoding imagined words [70].

TABLE IV. IMAGINE VOWELS AND WORDS

Reference	Vowels/Words	Classifier	Performance
[54]	/a/, /e/, /i/, /o/, /u/ up, down, left, right, backward, forward	CNN	Word accuracy 24.97% Vowel accuracy 30%
[64]	/a/, /e/, /i/, /o/, /u/ up, down, left, right, backward, forward	CNN, TL	CNN-23.98% and 24.77%, 24.12%, 23.22%

2) Subject focused on imagine vowels and words-repeated study: Table IV depicts two research conducts have done the repeated study with the same open-access data set created by Coretto but used a different method to classify the word [54, 64]. The article's main objective was to enhance the classification result by decoding imagined speech in EEG using DL with Hyper-parameter optimization [54,71] on classifier performance. They tried both overt and covert speech. From this, the author concluded that CNN has significantly better accuracy than SVM, RF, and rLDA classifiers. All the classifiers used the nCV method for HP optimization. The result shows that the robust selection of HP in CNN for decoding was critical. The effect of the model determines by the number of epochs, activation function, and learning rate. So, the selection of optimal HP depends on the other hyper-parameters [54]. The author proposed a new CNN for the classification in the subsequent repetition study. The idea was to reduce the complexity, retaining the same accuracy, but the result has shown considerably less accuracy. The author recommended more data and powerful machine learning algorithms to increase accuracy. The effectiveness of the neural network improved through transfer learning [72].

The research revealed that the brain signal is unique for the same imagined action in a different subject [64]. Subject focused on imagine directions: Feature extraction and classification have a vital role in any BCI system. Researchers have used classical approaches like pattern recognition in feature extraction and classification for decades. Now many researchers are applying a deep learning approach in many areas. Few researchers have introduced the deep learning method into the study of biomedical signals, especially EEG signals. Table V shows that the subjects were imagined the directions instead of vowel, consonant, or words.

TABLE V. IMAGINE DIRECTIONS

Reference	Direction	Classifier	Performance
[56]	Left, right, up, and down	ELM multi & binary	49.77%
[73]	+, ← or → Both feet and tongue	CNN	92.7%

In their research, input has been taken based on wavelet transform; the time-frequency input images acquired in the C4, C3, and Cz channels; resize technique is applied to the input image to minimize the training duration in 2D CNN. The research result shows that the proposed method is more efficient in the 1D kernel with fewer parameters. However, it has challenges in performance due to the quality of the signals and limited samples [73]. Another research proposed by Pawar & Dhage (2020) in multi-class covert speech classification using an extreme learning machine (ELM). The ELM provides the generalized and optimal solution in multi-class covert speech recognition. It has the advantage of training and testing the model will take less cost because it is a single hidden layer feed-forward neural network. It is not required to tune the weights. Moreover, the author has shown that the EEG signals taken from a particular region in the brain will be sufficient instead of acquiring signals from the entire brain. Their future challenge is to develop an intelligent algorithm to classify many words in real-time [56]. The authors have taken three different brain areas; Brain Area 1 was the Prefrontal cortex, right inferior frontal gyrus, and Wernicke's and Broca's areas. Brain Area 2 is the same as Brain Area 1, and Brain Area 3 is the entire brain area.

3) Subject focused on imagined object: Table VI shows that the objects were used instead of imagine vowel, consonant and word.

TABLE VI. IMAGINED OBJECT

Reference	Objects	Classifier	Performance
[60]	Cube, Rectangular prism, Pyramid	Decision tree	43%

The author used two visually challenged subjects and two sighted subjects to recognize the objects. The author achieved 43% classification accuracy, which was less. Still, it could be 90% accurate for an enormous decision tree, but if it is too large, it is not easy to analyze. The author revealed that sighted people could identify the object through their vision signal though blindfolded. It means the occipital lobe was significantly active. However, visually impaired people identified the same things by sensing only. Neurons in the parietal lobe were active [60].

However, this decoding of covert speech is in the NP-Hard problem only; we hope it will soon be NP-Complete. If researchers achieved 100% success in decoding covert speech and deploying it successfully, many impaired people could lead better life in society.

IV. SIGNIFICANCE OF THE NUMBER OF CHANNELS AND SUBJECTS, KEY CHALLENGES

It is essential to select the proper electrodes and their locations. If fewer electrodes are selected correctly, they may retain critical information. If too many electrodes are selected, then it may produce redundant information. Similarly, the number of subjects is essential to acquire the EEG signals for better classification results. Training a model with significantly fewer data will be an issue with underfitting. Sometimes an over-fit problem may occur after training a model with sufficient data. So, it is necessary to have more subjects and attention to place sufficient electrodes in the scalp location as per the researchers' application. In one research, the authors stated that increasing the number of electrodes in the front temporal of the brain's left hemisphere could improve the imagined speech signal reorganization [65].

Many researchers showed more interest in decoding imagined speech using the non-invasive method. Various techniques were used to increase the accuracy of the classifications; however, it is hard to implement in a real-world scenario. Because of an insufficient EEG data set, takes long calibration time, Poor SNR and non-static signal. These are all significant challenges to the researchers.

V. CONCLUSION

In this systematic review, number of studies reviewed, which reveals a promising result for decoding imagined speech using vowels, consonants, words, directions and objects from EEG signals. However more work required to be conducted to interface with the machine and human. And also, we have observed that very few imagined data sets are available for BCI applications but still need to be adequately deployed in BCI applications due to a lack of data. Furthermore, all the available EEG data sets pertain to normal and healthy subjects only, particularly in decoding imagined speech. Any BCI model developed using the available data set will be helpful to people who have brain disorders while they are growing up or who are injured accidentally or due to illness. But may not be helpful to disabled people by birth itself.

***Abstract*—Ultrasound imaging is a unique medical imaging modality due to its clinical versatility, manageable biological effects, and low cost. However, a significant limitation of ultrasound imaging is the noisy appearance of its images due to speckle noise, which reduces image quality and hence makes diagnosis more challenging. Consequently, this problem received interest from many research groups and many methods have been proposed for speckle suppression using various filtering techniques. The common problem with such methods is that they tend to distort the edge detail content within the image and blurring is commonly encountered. In this work, we propose a new method that could be combined with previous speckle suppression techniques to preserve edge detail content of the image. The original image is first processed to extract the edge detail content. Rather than presenting the original method to the speckle suppression filtering technique, the edge detail content is subtracted from the original image before it is filtered. Then, such edge detail content is added to the output of filtering to form the final image. The new method is practically verified using 26 imaging experiments as well as ultrasound images from publicly available databases in combination with four widely used speckle reduction filters. The results are evaluated qualitatively and quantitatively using standard image quality metrics.**

***Keywords*—Edge detail preservation; image quality metrics; speckle reduction; ultrasound imaging**

I. Introduction

Ultrasound imaging stands out as a widely embraced clinical imaging technique, lauded for its safety, cost-effectiveness, and diverse soft tissue imaging applications encompassing abdominal imaging, echocardiography, and obstetrics and gynecology [1]. The mechanism involves emitting low-intensity acoustic wave pulses into the body, capturing the reflected and scattered echoes from internal structures to construct a cross-sectional anatomical image. With its inherent safety and an impeccable track record in clinical applications, ultrasound imaging stakes its claim as the safest imaging modality to date. Its prevalence in critical applications, such as monitoring fetal growth and assessing biophysical profiles during pregnancy, attests to its reliability. The technology spans a spectrum, ranging from basic handheld units costing a few thousand dollars to sophisticated systems tailored for specialized applications like echocardiography, commanding prices in the hundreds of thousands. This versatility ensures accessibility in rural and low-income communities and integration into large, specialized hospitals, poised to become as indispensable to medical practice as the stethoscope.

Despite the myriad advantages of ultrasound imaging, a glaring issue persists in the quality of its images compared to other modalities. The visual noise and the requisite training to correlate anatomy with ultrasound images stem from speckle, a persistent problem since the inception of ultrasound imaging. Research efforts, both academic and industrial, have focused on mitigating speckle noise in ultrasound images due to its undeniable impact on the technology [2].

Speckle noise emerges inevitably as a direct consequence of the underlying physics in ultrasound imaging. The process involves transmitting an ultrasonic pulse through the body using a 1D or 2D array-formatted ultrasonic transducer. This pulse propagates through tissues, engaging with their various components, resulting in reflected waves from specular reflectors and scattering from point reflectors [1]. The distinguishing factor between specular and point reflectors lies mainly in size; specular reflectors surpass the ultrasound wavelength, while scatterers are notably smaller than this wavelength, typically a fraction of a millimeter within the 2-15 MHz range of ultrasound imaging frequencies. Consequently, tissue interfaces and major blood vessels mimic specular reflectors, while blood capillaries and cells within the extracellular space act as scatterers [3][4]. In tissues like the liver, hepatocytes independently scatter ultrasound waves, with the backscattered part received by the ultrasound transducer. Given the dependence on ultrasound transducer frequency, orientation, and the intricate 3D tissue structure, the received scattered waves from myriad cells interfere, creating a pattern of partial constructive and destructive interference points that manifest as random noise in the image. The crucial disparity between speckle noise and true random noise lies in the former's persistence under unaltered imaging conditions, resisting improvement through averaging or conventional methods [5][6].

Numerous approaches have been proposed to tackle the challenge of speckle reduction, broadly categorized as either acquisition or post-processing methods. Acquisition methods aim to diminish speckle by acquiring multiple versions of the same slice with varying beamforming parameters, such as steering, focal point, and frequency [7] [8]. Although this approach appears straightforward, its practical implementation demands the reprogramming of acquisition protocols for different applications, incurring substantial costs and posing challenges in applications requiring high frame rates or specific acquisition sequences, such as in 3D and 4D imaging [8]. Alternatively, the second approach, centered on postprocessing, has garnered attention from research groups since the 1980s. The fundamental premise involves commencing with the acquired image and applying diverse filtering strategies to suppress speckle noise. This approach mandates only a digital processing platform and access to the ultrasound imaging system's frame buffer. It can also operate on an external computer with a frame grabber or other means to collect ultrasound images without altering the existing system. Given the advancements in modern computing platforms, including parallel processing and GPUs, this approach emerges as the pragmatic starting point for practical purposes with existing ultrasound imaging systems. Technically, most classical post-processing methods fall into four main categories, with hybrids across them—linear, nonlinear, diffusion-based, and wavelet-based filtering methods [2]. Linear filters encompass techniques like first-order statistics filtering, local statistics filtering with higher moments, and homogeneous mask area filtering [9], [10], [11]. Nonlinear filtering methods include median filtering, linear scaling filter, geometric filtering, and homomorphic filtering [12], [13], [14], [15]. Diffusion-based methods include various variants of anisotropic diffusion filtering [16], [17], [18], [19], [20]. Wavelet-based methods primarily operate using wavelet shrinkage with different wavelet families and levels of composition [21], [22], [23], [24]. Hybrids incorporating elements from these methods have also been introduced [25], [26], [34], [35]. Other approaches include methods that use a human visual system model to reduce the appearance of noise in ultrasound images [36], and methods involving deep learning using convolutional neural networks to build despeckling models from training custom-designed networks [37], [38].

Despite the strides made in speckle reduction methods, challenges persist in bridging the gap between the perceived quality of processed images by researchers and clinicians. The apparent smoothness achieved by these methods may compromise crucial edge details, significant to clinical sonographers. To harness the full potential of existing techniques, there is an imperative to enhance their performance and align them more accurately with the clinical perspective on image quality [27]. Recognizing the substantial contributions of current techniques is vital, but addressing their common shortcomings is crucial to maximizing their efficacy in routine clinical ultrasound applications.

In this work, we propose a new method that could be combined with previous speckle suppression techniques to preserve edge detail content of the image. The original image is first processed to extract the edge detail content. Rather than presenting the original method to the speckle suppression filtering technique, the edge detail content is subtracted from the original image before it is filtered. Then, such edge detail content is added to the output of filtering to form the final image. The new method is experimentally verified using 26 imaging experiments as well as ultrasound images from publicly available databases with four widely used speckle reduction filters. The results are evaluated qualitatively and quantitatively using image quality metrics.

II. Methodology

Ultrasound image acquisition involves gathering a series of lines (or sticks) extending across the scanned area, arranged either linearly or in a sector pattern, contingent upon the employed imaging probe. The acquired data, referred to as stick data, serves as the foundation for generating a properly formatted output image through image reconstruction techniques, leveraging the provided geometry information. The new method starts from estimating the edge detail content from the original stick data. It works by applying edge detection techniques such as Canny edge detection to the original stick data to generate a map of the locations of salient edge detail features [27]. To better include the complete edge detail features and take into account having a smooth transition to their surroundings in the subsequent steps, the generated edge map is blurred using a simple spatial domain filtering with a Gaussian kernel. The normalized version of the outcome is used as a mask that is multiplied by the original stick data to extract the edge detail content. A version of the original stick data that contains only the edge detail-free parts of the data is computed by subtracting such edge detail content from the original stick data. The detail-free data is used as the input to the speckle reduction filtering method. The restoration of edge detail content to the filtering output is done by adding them. The basic block diagram of the new edge detail preservation method is shown in Fig. 1. In order to visually illustrate the steps of the process, example stick data for all steps of the process are presented in Fig. 2 with comparison to the stick data output from the original speckle filtering alone.

The implementation and testing of the novel edge detail preservation method involved four widely adopted speckle reduction filtering techniques, serving as representative examples from each of the four primary post-processing categories, without sacrificing generality. These techniques were wavelet denoising [21], [23], relaxed median (RMedian) denoising [14], [15], speckle reducing anisotropic diffusion (SRAD) [17], [16], [18], and local statistics based filtering (Lee) [9], [10]. In each of these techniques, the original technique is implemented with the implementation details suggested in the most recent variant. In order to quantitatively assess the image quality improvement, eleven image quality metrics are compared between the original filtering technique alone and its combination with the new edge detail preservation method. The image quality metrics used are geometric absolute error (GAE) [2], mean-squared error (MSE) [2], Laplacian mean-squared error (LMSE) [28], normalized absolute error (NAE) [28], Minkowski error metric (for β=1, 3, 4) [29], universal quality index (Q) [30], structural similarity index (SSIN) [29], signal-to-noise ratio (SNR) [31], and peak signal-to-noise ratio (PSNR) [31].

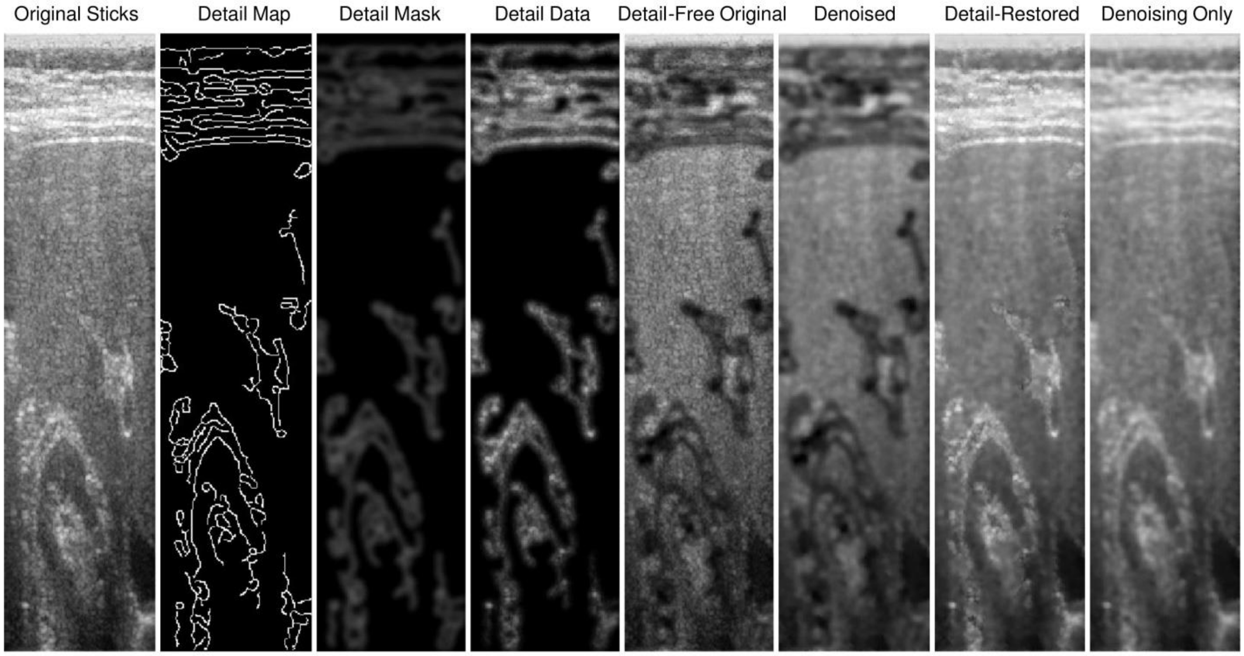

Fig. 1. Illustration of outputs at each block of the proposed edge detail preservation method. The last image to the right illustrates the output of the speckle suppression filter without the new method for comparison.

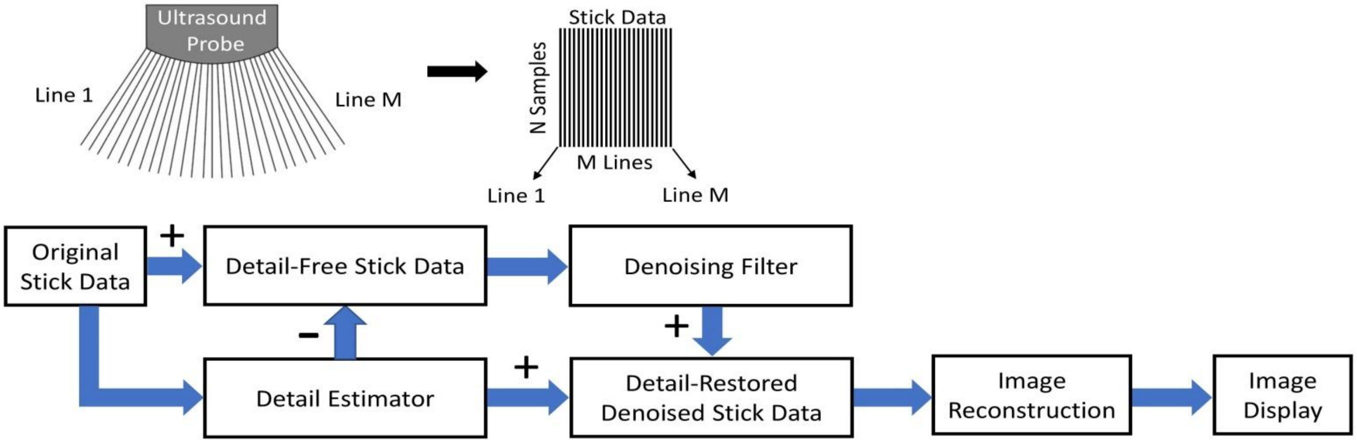

Fig. 2. Block diagram of the proposed edge detail preservation method applied to experimental stick data. The same block diagram applies to images from public databases without need for image reconstruction block.

III. Experimental Verification

The proposed method was verified using collected experimental ultrasound imaging data as well as ultrasound imaging data from publicly available resources. While the latter come in the form of image files encoded using 8-bit image formats such as Joint Photographic Experts Group (JPEG) or Portable Network Graphics (PNG) formats, the collected experimental data come in the form of raw data at a higher quantization rate of 16 bits.

The acquisition of ultrasound imaging data employed the Digison Digital Ultrasound Research system from Mashreq, Egypt. This system, featuring a customized research interface, facilitated image acquisition control with the capability to access and store raw radiofrequency sampled data for each image line. To ensure a representative spectrum of applications, ultrasound array probes, including convex array abdominal probes, small parts linear probes, and tight convex array endo-cavity probes, were utilized. Imaging experiments spanned various clinical applications, conducted on human volunteers and a quality control tissue-mimicking phantom (Multi-Tissue Ultrasound Phantom CIRS Model 040GSE, CIRS Inc., U.S.A.). Each imaging experiment focused on a specific region, employing a designated imaging probe, and entailed collecting 10 images for each application to derive an average, minimizing interference from random noise in speckle reduction filtering. The total number of conducted imaging experiments was 26, yielding a total of 260 images. Fig. 3 illustrates the diversity of images from these 26 experiments. The research interface facilitated raw image data collection at a sampling rate of 50 M samples/s with 16 bits of quantization. Signal processing involved filter-based Hilbert transformation for peak detection, followed by resampling to yield 512 data samples per line (or stick). The resultant stick data formed a 512×128 array that could subsequently use to reconstruct the final image using scan conversion and interpolation.

The ultrasound imaging data from publicly available resources were obtained from the Breast Ultrasound Imaging (BUSI) database [32] and the B-mode ultrasound imaging cases from Ultrasound Cases training web site [33]. The BUSI database comprises breast sonography images collected from women aged 25 to 75 years in 2018. The dataset encompasses 600 female patients, containing a total of 780 images with an average size of 500 by 500 pixels, provided in PNG format. On the other hand, the data from Ultrasound Cases website are put together through a collaboration between SonoSkills (a provider of ultrasound training in Europe) and FUJIFILM Healthcare Europe. (a manufacturer of medical imaging products, encompassing ultrasound, MRI, and X-ray). The database comprises information gathered from 7678 cases, covering a diverse range of applications, including liver, urinary tract, male reproductive system, gynecology, breast and axilla, as well as musculoskeletal joints and tendons. From this database, a total of 2428 images of size 225 by 300, specifically representing B-mode images, were utilized. Therefore, the total number of images from combining both databases is 3208 images.

The stick data (experimental data) or image (public database data) underwent detection of edge detail mapping using Canny edge detection with thresholds of 0.1 and 0.4 for strong and weak edges, respectively, in both vertical and horizontal directions [27]. Subsequently, a 2D Gaussian spatial filter with a kernel size of three created a mask, which was then multiplied by the original stick data to extract the edge detail content. This content served two purposes: first, subtracted from the original stick data to form detail-free stick data, serving as input for speckle reduction filtering; second, restored to the filtering output to create the final image. The processing steps for experimental stick data are visualized in Fig. 1, with illustrations of the data at each step in Fig. 2. It should be noted that the same diagram applied to public database data with no need for the image reconstruction step. The image quality assessment involved eleven quantitative metrics, comparing output from the speckle suppression filter with and without the edge detail preservation technique. Averaging metrics from the 26 experiments provided reliable comparisons, and standard deviations were computed. Percentage improvement facilitated observation of relative changes across metrics with different numerical ranges. The statistical significance between the two sets of results across experiments was evaluated using the p-value of a two-sample t-test to test the null hypothesis that the observed differences in image quality metrics come from the same distribution where such hypothesis is rejected at a significance level of 0.05.

The final image reconstruction utilized scan conversion and/or interpolation, aligning with array geometry and dimensions to present the image in the correct spatial format. All processing occurred on Matlab 2023a (Mathworks, Inc.) with an educational license from King Abdulaziz University. The computing platform featured an HP Omen 25L personal computer with an 11th generation Intel® Core™ i7-11700F running at 2.50 GHz, using a 64-bit Windows 11 Home Edition, and equipped with 32 GB of RAM.

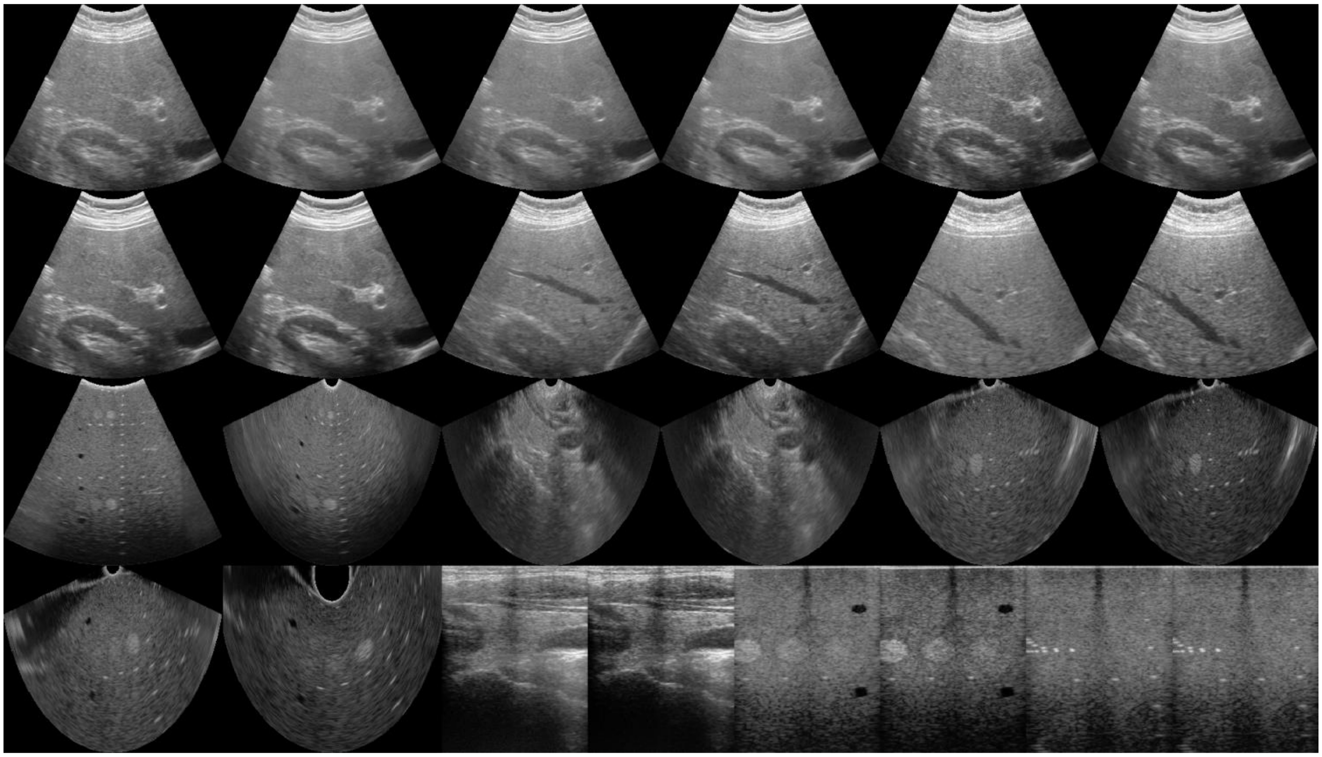

Fig. 3. Visualization of diverse imaging experiments conducted in this investigation.

IV. Results and Discussion

For the experimental data, Fig. 4 presents the output image results stemming from the implementation of the novel edge detail preservation technique, coupled with four illustrative techniques representing the prevailing approaches in speckle reduction for sample applications. Also, Fig. 5 presents magnified versions of parts of the output image results in Fig. 4 to better demonstrate the effect of the new edge preservation method. The considered previous techniques encompass the widely used methods of wavelet denoising [21], [23], relaxed median (RMedian) denoising [14], [15], speckle-reducing anisotropic diffusion (SRAD) [17], [16], [18], and local statistics-based filtering (Lee) [9], [10]. The original images are provided in the left column with the outputs of the four techniques on the first row and their combination with edge detail preservation technique on the second row in each application. As can be observed, the details are sharper with the new method for all techniques and across different applications.

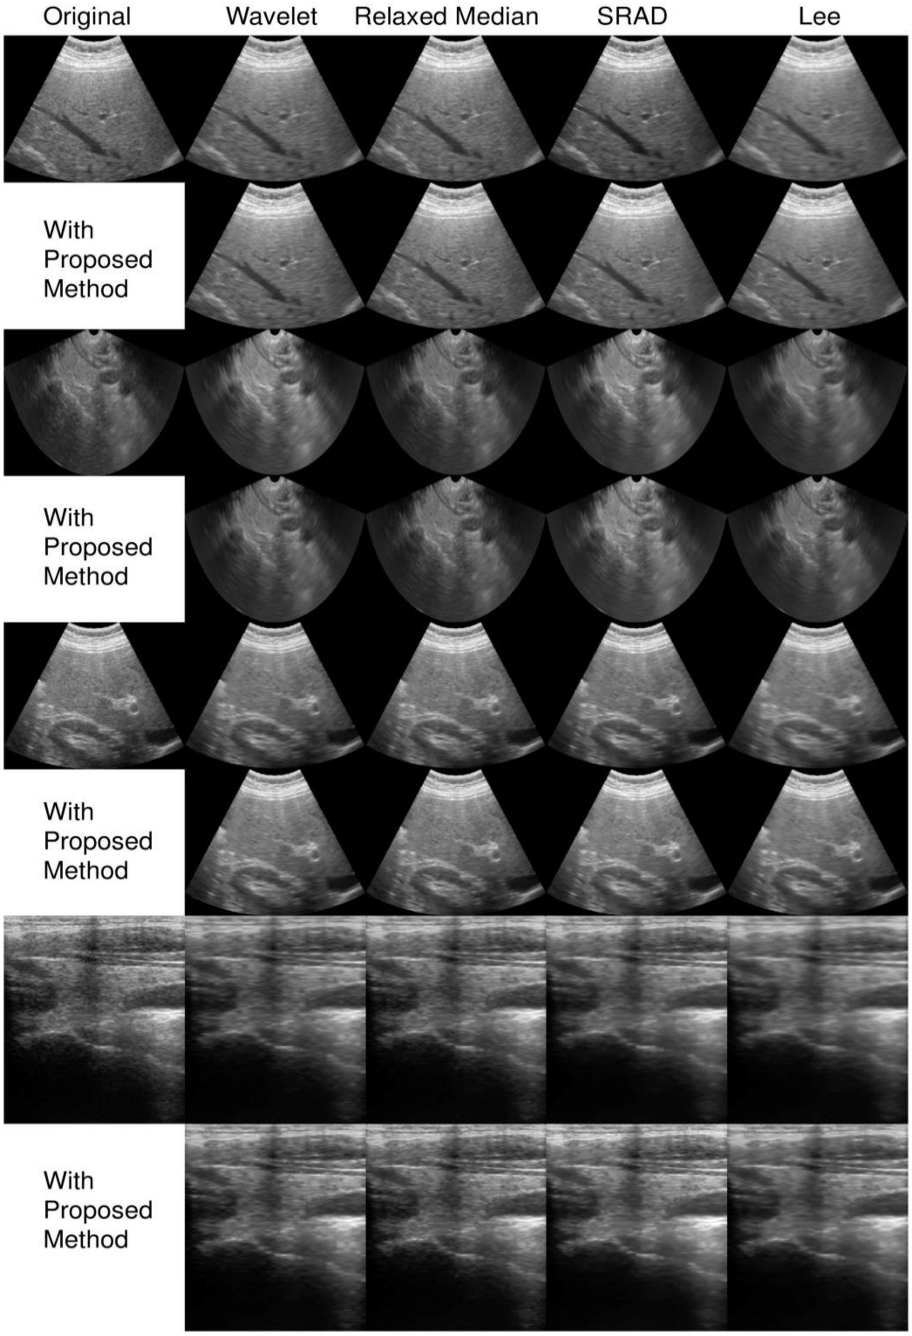

Fig. 4. Diagram showing the output image results from the original speckle suppression techniques (first row of each experiment) and combined with new edge detail preservation method (second row of each experiment) for four example experiments with original image in the left column.

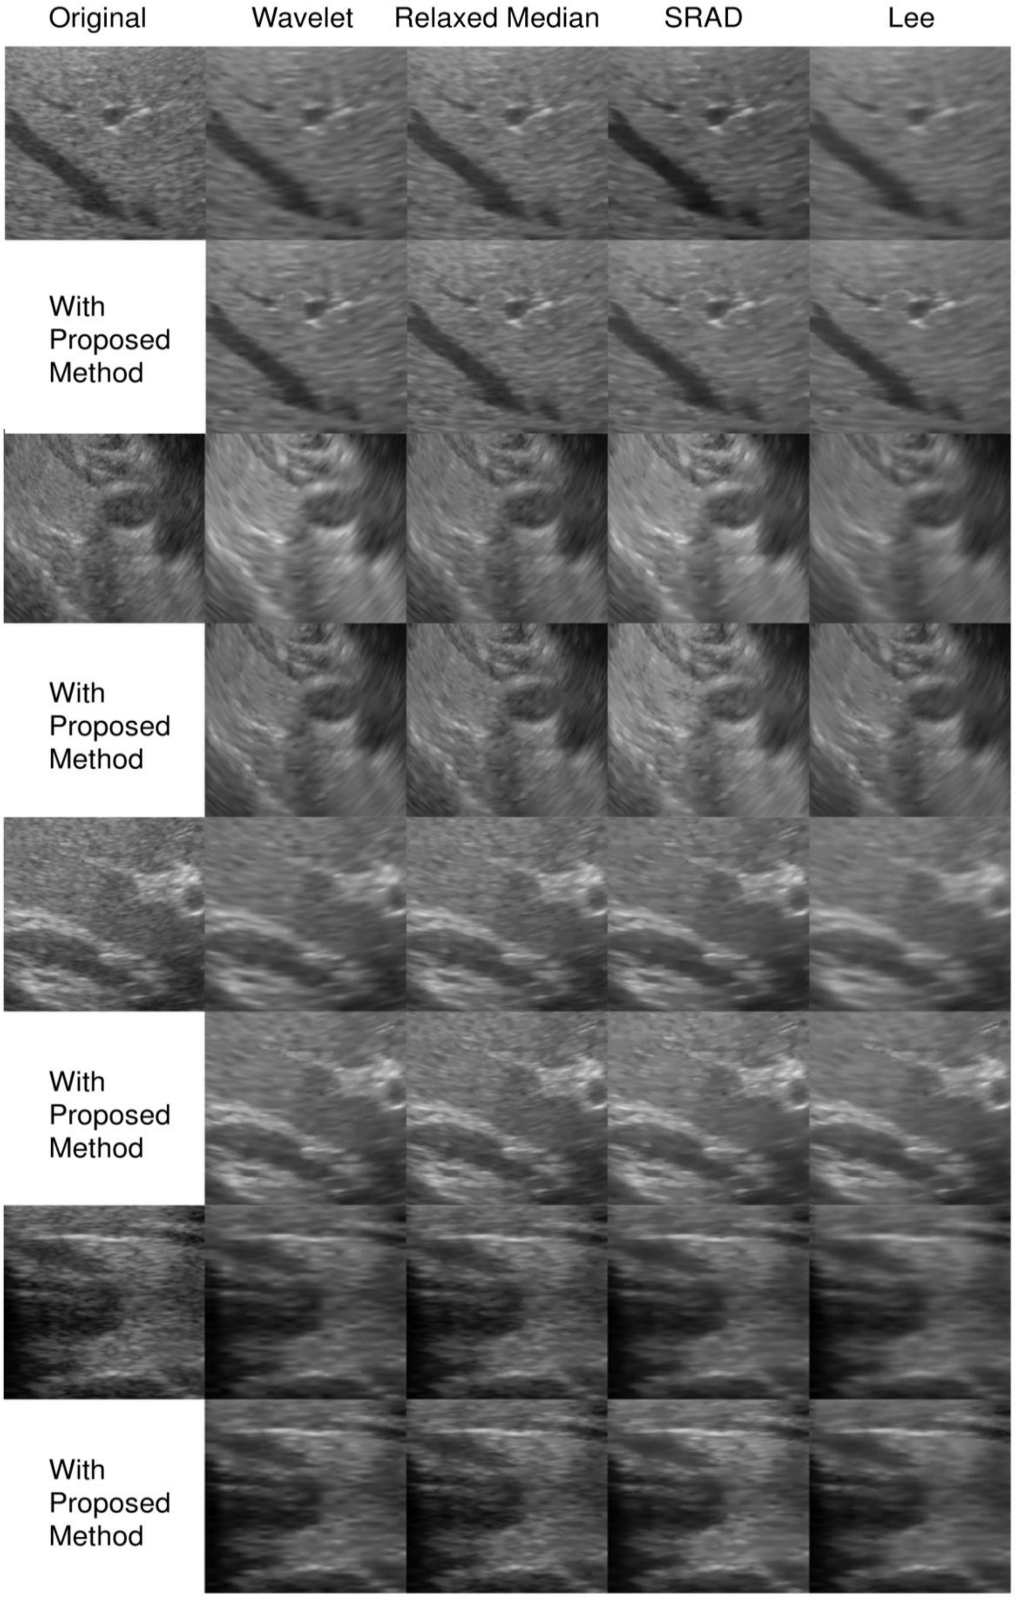

Fig. 5. Magnified parts of the output image of Fig. 4 showing results from the original speckle suppression techniques (first row of each experiment) and combined with new edge detail preservation method (second row of each experiment) for four example experiments with original image in the left column.

TABLE I. IMAGE QUALITY METRICS BEFORE AND AFTER APPLICATION OF PROPOSED EDGE PRESERVATION TO ORIGINAL SPECKLE REDUCTION METHOD, AND ITS STANDARD DEVIATION CALCULATED ACROSS THE SET OF 26 EXPERIMENTS

In order to assess the results from the experimental data quantitatively, Table I presents the image quality metrics before and after applying the proposed edge detail preservation method to the original speckle reduction methods and their standard deviations. Table II presents the percentage mean change in image quality metrics after applying the proposed edge detail preservation method to the original speckle reduction methods and their percentage standard deviations. The p-values of statistical significance testing for the two sets of results over the 26 experiments were all significant at the 0.05 level, which supports the hypothesis that the reported changes in image quality metrics are statistically significant. The results indicate that the new edge detail preservation method significantly improves image quality metrics for all speckle reduction methods where error metrics (GAE, MSE, LMSE, NAE, and Minkowski error metrics) become lower and quality metrics (SNR, PSNR, Q, and SSIN) become higher. To illustrate the actual image quality metric values across different imaging experiments, Fig. 6 shows plots of three example metrics of LMSE, SSIN and Quality, where the metric values from the original speckle suppression alone were plotted as a colored solid line and the combination with the new edge detail preservation method were shown as 'x' marks with the same color. It can be noted that the different applications affect the outcome of speckle suppression techniques in general and that different techniques vary in their performance. The addition of the new edge detail preservation method still resulted in marked improvement across applications and techniques. This suggests its robustness and potential to meet the rigorous demands in real clinical use.

In order to further qualitatively demonstrate the advantage of using the new edge detail preservation method, a zoomed version of the outcomes from using the tissue-mimicking resolution phantom is presented in Fig. 7 where the resolution pins are compared between the outputs from the Lee method with and without the new method. The blurring in the original technique is evident and significant visual improvement is observed after using the new method.

For the ultrasound imaging data from public databases, Table III presents the image quality metrics before and after applying the proposed edge detail preservation method to the original speckle reduction methods and their standard deviations across all 3208 images. Also, Table IV presents the percentage mean change in image quality metrics after applying the proposed edge detail preservation method to the original speckle reduction methods and their percentage standard deviations. The results indicate that the new edge detail preservation method generally improves image quality metrics for all speckle reduction methods where most error metrics (GAE, MSE, LMSE, NAE, and Minkowski error metrics) become lower and quality metrics (SNR, PSNR, Q, and SSIN) become higher. However, the percentage mean change rates of image equality metrics improvement are lower than those in the experimental data particularly for quality metrics (SNR, PSNR, Q, and SSIN). This is most obvious with SRAD technique. This can be explained by the quantization effects on the calculations of the proposed method where edge detection accuracy can be significantly affected, especially for weak edges encountered inside tissues such as edges of blood vessels within the liver. Whereas the experimental data have a quantization level of 16 bits per pixel, the images from public databases come with only 8 bits per pixel, which is substantially lower. This indicates that the proposed method may be better suited to process the raw data rather than the formed, limited quantization ultrasound images.

The advantage of the new edge detail preservation method is that it recognizes the significant body of research already presents in the field of speckle reduction filtering and works to boost the performance of existing methods. This study demonstrated the effectiveness of combing the new method with four existing speckle reduction filters, but its generality and applicability with any other technique are readily evident from its block diagram. The improvement results presented should encourage broader adoption in this area.

Even though the proposed method is meant to be applied as a tool to complement speckle reduction methods rather than compete with them, it is important to demonstrate that its performance enhancement with classical methods compare well with recent techniques to show its potential. Comparing the presented results to those of [34] using real ultrasound data, the best reported values of PSNR and SSIM are 31.47 and 0.8026 respectively, whereas these same metrics reach 33.25 and 0.87 in the proposed method for experimental data and 34.02 and 0.95 for data from publicly available databases. This particular study shares the utilization of raw ultrasound imaging data as the input to the technique like the proposed method, but the number of images used in that study was reported to be only 20 images out of 366 images that were available in their data source [34], which is much lower than the number of experimental images used in this study of 260 images. Furthermore, simulated speckle noise was added artificially to such real images, which makes such testing data artificial. On the other hand, the study in [37] reported best PSNR and SSIM values of 38.1952 and 0.9770 respectively, which are significantly higher than this work. However, close inspection of the methodology used in that study reveals that such high values were obtained using simulated low variance speckle patterns superimposed on publicly available ultrasound images with very high SNR (small depth of penetration for neural ultrasound images and low attenuation from blood within cardiac images). The reported best results for PSNR and SSIM in that same study from higher speckle variance were 31.3849 and 0.9046 respectively, which are outperformed by the proposed method when applied to publicly available ultrasound images. Furthermore, in [38] the reported best values for PSNR and SSIM were 34.89 and 0.89 respectively, which are again outperformed by the proposed method for publicly available ultrasound images. Hence, the comparison with recent techniques indicates that the proposed method has potential to enhance classical, explainable speckle reduction methods to perform well against more recent deep learning-based methods while maintaining lower complexity.

Given that the new method adds more steps to existing speckle reduction filtering, a concern arises about whether this will affect the real-time performance that is considered very important in ultrasound imaging. In order to estimate the computational complexity of the added blocks in the new method, we need to consider the blocks used to do Canny edge detection (dominated by convolutions), 2D Gaussian filtering (convolution), and final edge detail restoration (addition). For an ultrasound image acquisition M sticks and N samples per line, the combined computational complexity of efficient implementations of these blocks will be $\boldsymbol{O}(MN\log_2(MN))$. This is close to the same order of computations as the image reconstruction process involving scan conversion and interpolation of raw data but with M being the second dimension of the image rather than the smaller number of sticks. Hence, adding the proposed method to the processing chain is not expected to pose any burden for real-time performance especially with current high processing capabilities available in modern digital ultrasound imaging systems. The added complexity of different speckle reduction techniques to be used in combination with the proposed method varies widely across different techniques. To investigate this issue further, we conducted several experiments on Matlab to measure the computation time for the four speckle reduction techniques used in this work along with that of the added processing to implement the proposed method and also the image reconstruction from experimental data for different images sizes. The computational time results are shown in Fig. 8. As can be observed, the computational time of the proposed method scales fairly adheres to the theoretical estimate where it is close to the reconstruction time for smaller image sizes and becomes significantly lower for the commonly used image size of 512. The image reconstruction time increases at a much higher rate at this size because of the much larger number of points in the sector format image that need to be interpolated compared to those at smaller sizes. Furthermore, the proposed method has a significantly lower computational time compared to all speckle reduction methods except the Lee method at this size. Even with the techniques having the largest computation time (Wavelet method), the total computational time needed of 19 ms (Wavelet method) + 11 ms (image reconstruction) + 3 ms (proposed method) = 33 ms at image size of 512×512, offers real-time performance of 30 frames/s on Matlab under Windows operating system without parallel processing or GPU computation. This indicates that real-time performance requirements will be met or exceeded with the dedicated high performance processing platforms used in modern ultrasound imaging systems.

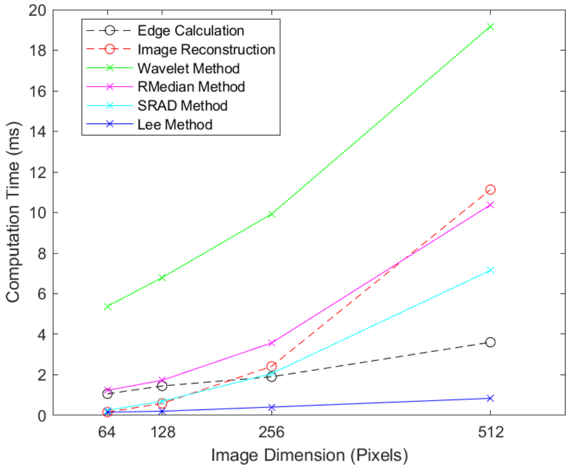

Fig. 8. Computational time for different speckle reduction techniques compared to additional processing for proposed method and image reconstruction for different image sizes.

V. Conclusion

This work introduces a novel method designed to augment existing speckle suppression techniques by preserving the edge detail content of images. The process initiates by extracting the edge detail content from the original image. Instead of directly applying the traditional method to the speckle suppression filtering technique, the edge detail content is subtracted from the original image before undergoing the filtering process. Subsequently, this edge detail content is incorporated into the output of the filtering, culminating in the generation of the final image. Experimental validation of this new method was conducted through 26 imaging experiments as well as 3208 ultrasound images from publicly available databases, employing four representative speckle reduction filters. Real ultrasound imaging data were used to assess the method's performance. Evaluation involved both qualitative comparisons of image appearances and quantitative analyses using eleven image quality metrics. The results affirm the effectiveness of the proposed method and underscore its potential to enhance diagnostic accuracy. Future work includes use for other imaging modalities such as low field MRI or nuclear medicine and combination with other despeckling methods.
